ABSTRACT SYMPOSIUM ATHEROTHROMBOSIS & STROKE

ASY 13.1 | Impact of Venous Thromboembolism on Formation and Progression of Carotid Atherosclerosis - The Tromsø Study

C. Lind[1,2]; B. Småbrekke[1]; L. Balteskard Rinde[1]; K. Hindberg[1]; E. B. Mathiesen[1,3,4]; S.H. Johnsen[3,4]; K.A. Arntzen[4]; I. Njølstad[1,5]; W. Lijfering[6]; S. Brækkan[1]; J.-B. Hansen[1,2]

[1]K. G. Jebsen TREC - Thrombosis Research and Expertise Center, Department of Clinical Medicine, UiT - The Arctic University of Norway, Tromsø, Norway, [2]Division of Internal Medicine, University Hospital of North Norway, Tromsø, Norway, [3]Brain and Circulation Research Group, Department of Clinical Medicine, UiT - The Arctic University of Norway, Tromsø, Norway, [4]University Hospital of North Norway, Department of Neurology and Clinical Neurophysiology, Tromsø, Norway, [5]Epidemiology of Chronic Diseases Research Group, Department of Community Medicine, UiT - The Arctic University of Norway, Tromsø, Norway, [6]Leiden University Medical Center, Department of Clinical Epidemiology, Leiden, The Netherlands

Background: Venous thromboembolism (VTE) is associated with increased risk of arterial cardiovascular diseases (CVD). The mechanism behind this relationship remains unsettled, but atherosclerosis may play a key role, as atherosclerosis is a major risk factor for arterial CVD. No previous study has examined the association between incident VTE and risk of future formation and progression of carotid atherosclerosis. We hypothesized that inflammatory processes secondary to VTE could promote formation and progression of carotid atherosclerosis.

Aims: To investigate whether incident VTE was associated with subsequent carotid atherosclerosis formation and progression in a population-based observational study.

Methods: Subjects attending ≥2 ultrasound examinations of the right carotid artery, including measurement of total plaque area (TPA), in the Tromsø Study in 1994-95, 2001-02 and/or 2007-08 were eligible for the study. We identified 150 subjects diagnosed with first-lifetime VTE between the initial and follow-up visit, and randomly selected 600 age- and sex-matched subjects without VTE between the visits.

Results: Subjects with VTE and presence of carotid plaque(s) at the first visit had 4.1 mm^2 (β 4.13, 95% CI -1.72 to 9.98) larger change in TPA between the first and second visit compared to subjects without VTE after adjustment for change in high-sensitivity C-reactive protein (hs-CRP) and traditional atherosclerotic risk factors. This association remained after restricting the analyses to VTE events diagnosed in the initial time-interval between the carotid ultrasounds, but was not statistically significant due to low study power. No association was found between incident VTE and novel carotid plaque formation.

Conclusions: Incident VTE was associated with atherosclerosis progression in those with already established plaques, but not with novel plaque formation. The association between VTE and carotid plaque progression was not mediated by low-grade inflammation assessed by hs-CRP.

ASY 13.2 | Carotid Atherosclerotic Plaque Matrix Metalloproteinase-2 Content Predicts Adverse Outcome in Patients Undergoing Endarterectomy

G. Gubbiotti[1]; G. Isernia[2]; E. Falcinelli[1]; G. Guglielmini[1]; M. Lenti[2]; P. Gresele[1]

[1]University of Perugia, Perugia, Italy, [2]Hospital S.M. Misericordia, Perugia, Italy

Background: Matrix metalloproteinases (MMPs), participate in the vascular remodeling associated with atherosclerotic plaque development and rupture, responsible for ischemic cardiovascular events.

Aims: To investigate the association between plaque MMP-2 levels with the occurrence of clinical adverse events in a large cohort of patients undergoing endoarterectomy (CEA).

Methods: A biobank was created (Athero-Matrix Biobank) by collecting carotid plaque specimens from all patients undergoing CEA between 2009 and 2015. Carotid plaque tissue was removed, cleaned in sterile saline, extracted and analysed for MMP-2 content by SDS-PAGE zymography (total, pro and active forms) and TIMP-2 by ELISA. Relevant previous clinical history, risk factors and treatments were systematically collected. Cardio-cerebrovascular events occurring during follow-up were registered. Patients were followed up for a median 3 years (1-11 years).

Results: 690 atherosclerotic plaque specimens were collected. A total of 150 cardio-cerebrovascular events occurred during follow-up (1.6% myocardial infarction, 0.3% TIA, 2.4% stroke, 6.2% vascular death, 5.8% restenosis, 8.1% new carotid revascularization, 4.9% stenosis of the contralateral carotid). Significantly higher carotid plaque active MMP-2 levels, active MMP-2/pro-MMP-2 and active MMP-2/TIMP-2 ratios were found in patients who developed an event at follow-up (23.4 ± 4.5 vs 8.7 ± 1.0 ng/μg protein, 0.9 ± 0.2 vs 0.3 ± 0.05, 0.6 ± 0.1 vs 0.3 ± 0.04, respectively). Higher carotid plaque active MMP-2 was also predictive of vascular death, new

carotid revascularization, and stenosis of the contralateral carotid (30 ± 9.3 vs 11 ± 1.3 ng/μg protein, 16.3 ± 4.0 vs 9.0 ± 1.1, 34 ± 17.4 vs 9.2 ± 1.0, respectively). MMP-2 levels in plaques were significantly lower in statin-treated subjects.

Conclusions: Active MMP-2 in plaques predicts adverse cardiovascular outcome in patients undergoing CEA. MMP-2 may represent a biomarker for atherosclerosis progression and drugs reducing active MMP-2 in plaques may be of special interest.

ASY 13.3 | Vascular Matrix Metalloproteinase-9 Enhances Blood Brain Barrier Breakdown and Ischemic Brain Injury in Experimental Thromboembolic Stroke

S. Singh; T. Zhao; A. Houng; S. Saleem; G. Reed

University of Tennessee Health Science Center, Medicine, Memphis, United States

Background: Thromboembolic ischemic stroke causes blood brain barrier (BBB) breakdown, fibrin deposition, brain swelling, hemorrhage and ischemic cell death. Elevated levels of matrix metalloproteinase-9 (MMP-9) correlate positively with ischemic brain injury in human stroke and animal models. Still, the effects of intravascular vs brain MMP-9 on stroke outcomes are poorly understood.

Aims: We examined the effects of MMP-9 deficiency and MMP-9 supplementation on outcomes following thromboembolic stroke in mice.

Methods: Thromboembolic stroke was induced by injecting autologous clots into the proximal middle cerebral artery in mice. After 24 h, brain swelling, hemorrhage and cerebral infarction were quantitated. MMP-9 expression, BBB breakdown, fibrin deposition (immunostaining) and cell death (TUNEL staining) were quantitatively determined. The data were analyzed by Student's t-test or one way ANOVA.

Results: After 24 h stroke, MMP-9 expression was specifically upregulated in the ischemic hemisphere and co-localized with neutrophils and the endothelium. In comparison to MMP-$9^{+/+}$ mice, MMP-$9^{-/-}$ mice showed a significant decrease in cerebral infarction ($p < 0.05$), swelling ($p < 0.01$) and a nonsignificant decrease in brain hemorrhage. BBB breakdown ($p < 0.05$), fibrin deposition ($p < 0.01$) and cell death ($p < 0.01$) were also significantly decreased in MMP-$9^{-/-}$ mice. Intravenous MMP-9 supplementation (45 min before stroke) to MMP-$9^{-/-}$ mice reversed the beneficial effects of MMP-9 deficiency. Cerebral infarct and swelling were restored in MMP-9 supplemented MMP-$9^{-/-}$ mice to levels equivalent to MMP-$9^{+/+}$ mice demonstrating the role of intravascular MMP-9 in ischemic stroke injury.

Conclusions: Intravascular MMP-9 has profound deleterious effects on BBB breakdown, brain swelling, hemorrhage and cell death in ischemic stroke. Targeted inhibition of vascular MMP-9 may prove beneficial for reducing ischemic brain injury.

Financial support: NIH (NINDS NS089707 & NHLBI HL092750) to G. Reed, AHA Postdoctoral fellowship to S Singh.

ASY 13.4 | High Risk of Ischemic Stroke in Patients with Acute Pulmonary Embolism and Patent Foramen Ovale: Paradoxical Embolism Confirmed as an Important Mechanism. The EPIC FOP Prospective Multicentre Study (Clinical Trials.gov Number NCT01216423)

E. Le Moigne[1]; Y. Jobic[2]; S. Timsit[3]; D. Ben Salem[4]; N. Paleiron[5]; C. Tromeur[1]; T. Joseph[6]; C. Hoffmann[7]; A. Dion[8]; G. Le Gal[9]; F. Couturaud[10]; D. Mottier[9]

Background: Cryptogenic stroke is more frequent among patients with patent foramen ovale (PFO) but the underlying mechanism of stroke in these patients remains unclear. We hypothesized that paradoxical embolism should be the main mechanism.

Aims: We aimed to compare the prevalence of recent ischemic stroke in patients with symptomatic pulmonary embolism (PE) according to whether PFO is detected or not.

Methods: In a prospective study of 374 patients with symptomatic documented PE, a cerebral magnetic resonance imaging (MRI) was systematically performed within 15 days of onset of PE symptoms. Recent ischemic stroke was diagnosed by hypersignal on diffusion-weighted imaging and restricted apparent diffusion coefficient on cerebral MRI. PFO was assessed by contrast trans-thoracic echocardiography. The prevalence of ischemic stroke was compared between PE patients with PFO and those without PFO.

Results: Contrast trans-thoracic echocardiography was conclusive in 324 patients and showed PFO in 43 patients and no PFO in 281. Median age was 66 years (IQR: 54-77), deep vein thrombosis was associated in 45% of PE and 55% of patients had a modified severity score (s-PESI) of 0 (no difference between PFO and non-PFO group). One patient in the PFO group and 8 in the non-PFO group were excluded because of absence of MRI or > 15 days delay in MRI. The prevalence of ischemic stroke was significantly higher in the PFO group than in the non-PFO group (9/42 (21.4%) and 15/273 (5.5%), respectively, Fisher test $p = 0.0016$).

Conclusions: We found that among patients with acute PE, those with a PFO have a higher risk of ischemic stroke than PE patients without a PFO. This finding supports the hypothesis of paradoxical embolism being an important mechanism of ischemic stroke. The implications of this finding on duration of anticoagulation remain to be determined.

ASY 16.1 | bApolipoprotein C-III is a Predictor of Activated Factor VII-antithrombin Complex Levels: A New Link between Plasma Lipids and Coagulation Pathway

N. Martinelli[1]; F. Tosi[1]; M. Baroni[2]; A. Castagna[1]; F. Stefanoni[1]; F. Pizzolo[1]; A. Bassi[3]; P. Pattini[1]; B. Lunghi[2]; D. Girelli[1]; B. Woodhams[4]; F. Bernardi[2]; O. Olivieri[1]

[1]University of Verona, Department of Medicine, Verona, Italy, [2]University of Ferrara, Department of Life Sciences and Biotechnology, Ferrara, Italy, [3]University Hospital of Verona, Institute of Clinical Chemistry, Verona, Italy, [4]Haemacon Ltd, Bromley, Kent, United Kingdom

Background: Activated factor VII-antithrombin (FVIIa-AT) complex is a potential biomarker of prothrombotic diathesis, reflecting tissue factor (TF) exposure, and has been associated with mortality in patients with coronary artery disease (CAD). Previous works indicated plasma lipids as predictors of FVIIa-AT variability.

Aims: To evaluate the relationships between FVIIa-AT plasma concentration and lipid/apolipoprotein profile.

Methods: Within the framework of the Verona Heart Study we selected 460 subjects (120 CAD-free and 340 CAD, 68.9% males, mean age 59.9 ± 10.3 years) not taking anticoagulant drugs and for whom plasma samples were available for FVIIa-AT assay and for a complete lipid profile, including apolipoprotein (Apo) A-I, B, C-III, and E. FVIIa-AT plasma levels were measured by ELISA.

Results: There were significant direct correlations of FVIIa-AT levels with total and HDL cholesterol, triglyceride, Apo A-I and Apo C-III. Apo A-I ($R = 0.164$, $P = 4 \times 10^{-4}$) and Apo C-III ($R = 0.236$, $P = 3 \times 10^{-7}$) showed the strongest correlations. Including all the lipid parameters in an adjusted regression model only Apo A-I and Apo C-III remained significant predictors of FVIIa-AT levels, with Apo C-III explaining 5.6% of FVIIa-AT variability. Such results were confirmed after adjustment for sex, age, CAD diagnosis, and renal function.

The rs964184 polymorphism (tagging also APOC3 gene locus), which has been linked with cardiovascular risk and plasma lipids by genome-wide association studies, was associated not only with Apo C-III levels but also with FVIIa-AT plasma concentration, being higher in the carriers of the risk allele G (CC 81.6 [77.9-85.5], CG 90.0 [83.2-97.4], and GG 98.5 [77.8-124.6] pM, P = 0.015).

Conclusions: Our results indicate a strong association between Apo C-III and FVIIa-AT levels, thereby supporting the hypothesis that Apo C-III, one of the most important actor in lipid metabolism, may influence TF-FVIIa pathway with prothrombotic effects.

ASY 16.2 | Markers of Vascular Function Are Associated with Procoagulation Factors in the General Population

I. Dekkers; R. de Mutsert; A. de Vries; F. Rosendaal; S. Cannegieter; T. Rabelink; H. Lamb; W. Lijfering

Leiden University Medical Center, Leiden, The Netherlands

Background: The strength and direction of the associations between vascular function and procoagulant factors remain unclear, especially in the general population.

Aims: We investigated whether three measures of vascular function (i.e. estimated glomerular filtration rate (eGFR), urinary albumin creatinine ratio (UACR), and arterial stiffness measured by pulse wave velocity (PWV)) are associated with an increased procoagulant state.

Methods: In this cross-sectional analysis of baseline measurements of the NEO Study eGFR, UACR, serum fibrinogen, and coagulation factors (F)VIII, FIX, and FXI were determined in all participants (n = 6,536). PWV was assessed by MRI in a random subset (n = 2433). eGFR, UACR and PWV were analysed on a continuous scale and per percentile based categories. eGFR and UACR were grouped into 6 categories (>50th [reference] to < 1st percentile for eGFR and < 50th [reference], to >99th percentile for UACR), and PWV was grouped in 4 categories (< 50th [reference] to >95th percentile). We performed linear regression analysis and adjusted for age, sex, total body fat, smoking, education, ethnicity, total cholesterol, CRP, and use of vitamin K antagonists (FIX).

Results: Mean age was 56 years, mean eGFR 86.2 (12SD) ml/1.73 m² and UACR 0.45 mg/mmol (IQR 0.30; 0.71). All coagulation factors showed a procoagulant shift with vascular function, for example FVIII concentration was 22 IU/dL (95% CI: 13-32) higher in the < 1st percentile. Compared with the UACR< 50th percentile, FVIII was 12 IU/dL (3-22) higher in the >99th percentile. PWV was only associated with procoagulant factors FIX an FXI in continuous analysis: to illustrate, for every m/s difference in PWV, FIX concentrations were 1.96 IU/dL (95% CI 0.70-3.2) higher.

Conclusions: All tested measures of vascular function were associated with increased levels of procoagulant factors, supporting the hypothesis that vascular function plays a role in the etiology of venous thrombosis.

TABLE 1 Association between PWV, eGFR, UACR and coagulant factors

Procoagulant Factor	eGFR per 10 ml/min/1.73 m² lower difference (n = 6,536)	UACR (mg/mmol) per 2-fold higher difference (n = 6,536)	PWV per m/s higher difference (n = 2,433)
Fibrinogen (mg/dL), crude	1.06 (0.6 to 2.7)	5.44 (3.7 to 7.2)	2.25 (0.5 to 4.0)
Fibrinogen (mg/dL), adjusted	0.46 (1.0 to 1.9)	1.96 (0.6 to 3.3)	0.60 (−1.9 to 3.1)
Factor VIII (IU/dL), crude	3.15 (2.2 to 4.1)	0.36 (−0.6 to 1.3)	1.39 (0.3 to 2.4)
Factor VIII (IU/dL), adjusted	2.34 (1.3 to 3.3)	−0.93 (−1.9 to 0.1)	0.38 (−1.2 to 1.9)
Factor IX (IU/dL), crude	1.09 (0.5 to 1.7)	0.79 (0.2 to 1.4)	1.89 (1.3 to 2,5)
Factor IX (IU/dL), adjusted	1.01 (0.4, to 1.6)	0.32 (−0.2 to 0.8)	1.96 (0.7 to 3.2)
Factor XI (IU/dL), crude	0.77 (0.13 to 1.4)	1.02 (0.5 to 1.6)	0.68 (0.06 to 1.3)
Factor XI (IU/dL), adjusted	0.49 (0.1 to 1.1)	−0.05 (−0.6 to 0.5)	1.05 (0.1 to 2.0)

ASY 16.3 | TFPI in Human Atherosclerotic Plaques

B. Stavik[1,2]; S. Espada[1,2,3]; S. Holm[2,4]; V. Bjerkeli[2,5]; P.M. Sandset[1,2,5]; T. Børresdatter Dahl[2]; M. Skjelland[6]; T. Espevik[7]; N. Iversen[8]; G. Skretting[1,2]; B. Halvorsen[2,5]

[1]Oslo University Hospital, Dept. of Haematology, Oslo, Norway, [2]Oslo University Hospital, Research Institute of Internal Medicine, Oslo, Norway, [3]Oslo University Hospital, Dept of Basic Medical Sciences, Oslo, Norway, [4]Hospital for Rheumatic Diseases, Lillehammer, Norway, [5]University of Oslo, Institute of Clinical Medicine, Oslo, Norway, [6]Oslo University Hospital, Department of Neurology, Oslo, Norway, [7]Norwegian University of Science and Technology, Centre of Molecular Inflammation Research, Department of Cancer Research and Molecular Medicine, Trondheim, Norway, [8]Oslo University Hospital, Dept. of Medical Genetics, Oslo, Norway

Background: The coagulation inhibitor tissue factor pathway inhibitor (TFPI) is present in human atherosclerotic plaques and the levels are elevated compared to in healthy arteries. TFPI induces a protective effect in atherosclerotic mice models, but it is not known which isoform of TFPI is important and what regulates TFPI levels in the atherosclerotic plaque.

Aims: To uncover the expression pattern and regulation of TFPI and its isoforms (α and β) in relation to atherosclerotic disease in humans.

Methods: Human carotid endarterectomies were collected and processed, while human monocyte-derived macrophages were isolated from buffy coats of blood donors, differentiated into M1 and M2 subtypes with GM-/M-CSF and LPS + INFg/IL-4, respectively, and subsequently stimulated with cholesterol crystals (CCs). mRNA and protein levels of TFPI isoforms were quantified using qRT-PCR and ELISA, respectively, while protein detection in the plaques were performed with IHC.

Results: TFPI mRNA levels were significantly increased in human atherosclerotic plaques compared to healthy vessels, and both isoforms were elevated. However, Ct values indicated that TFPIα was the prominent isoform in the plaques. TFPI mRNA levels correlated significantly with the macrophage markers CD68, CCR7, CD163, and ADRP, but not with the B cell markers CD45 or CD3 g. TFPI protein co-localized with CD68, CD80 and CD163 in plaque sections. Interestingly, TFPI mRNA levels were elevated in M2 macrophages compared to the M1 phenotype and further increased when the M2 macrophages were incubated with the atherogenic agent CCs. This increase in TFPI mRNA levels was dependent on ER stress induction in the M2 macrophages.

Conclusions: Both isoforms of TFPI were increased in human plaques with TFPIα as the major isoform. Alternatively activated M2 macrophages may contribute to the elevated levels of TFPI observed in atherosclerotic plaques, indicating a novel protective mechanism of these cells in atherosclerosis.

ASY 16.4 | Protease-activated Receptor 2 Deficiency Attenuates the Formation of Atherosclerosis

S. Jones[1]; N. Robbins[1]; K. Saum[1]; J. Thompson[2]; N. Mackman[3]; P. Owens[1]

[1]University of Cincinnati, Internal Medicine, Cincinnati, United States, [2]University of Kentucky, Internal Medicine, Lexington, United States, [3]University of North Carolina at Chapel Hill, Medicine, Chapel Hill, United States

Background: Protease-activated receptor 2 (PAR-2)-dependent signaling results in augmented inflammation and has been implicated in the pathogenesis of several autoimmune conditions. While PAR-2 protein is present in coronary atherosclerotic lesions, the relevance of this finding has not been investigated in experimental models.

Aims: The objective of this study was to determine the effects of PAR-2 on the development of atherosclerosis.

Methods: Male low density lipoprotein receptor deficient (*Ldlr*$^{-/-}$) mice (8-12 weeks old) that were on a *Par-2*$^{+/+}$ or *Par-2*$^{-/-}$ background were fed a fat and cholesterol-enriched diet for 12 (n = 10 each group) or 24 weeks (n = 5 each group). Bone marrow transplantations were utilized to examine non-marrow or marrow-derived effects (n = 15 for each of 4 chimeric groups). For mechanistic considerations, PAR-2 agonist peptide or scrambled peptide were utilized in oxidized LDL (oxLDL) loaded peritoneal macrophages or water-soluble cholesterol treated vascular smooth muscle cells (VSMCs).

Results: Expression of PAR-2 is increased in human coronary artery (21 fold) and mouse aortic arch (16 fold) atheroma versus control coronary and aortic arch arteries, respectively (P = 0.001). PAR-2 deficiency attenuated atherosclerosis in the aortic sinus and aortic root with no effects on total plasma cholesterol concentrations or lipoprotein distributions after 12 (P < 0.05) or 24 (P < 0.05) weeks.

These reductions were attributable to both hematopoietic and non-hematopoietic-derived PAR-2. Activation of PAR-2 augmented oxLDL-induced foam cell formation and apoptosis in conjunction with decreased expression of cholesterol transporters. Further, PAR-2 activation of VSMCs augments the transition to a macrophage-like state. **Conclusions**: Our results that indicate PAR-2 deficiency significantly attenuates the initiation (12 weeks) and reduces the progression (24 weeks) of atherosclerosis potentially via regulation of both lipid efflux from macrophages and the phenotypic modulation of VSMCs.

ASY 31.1 | Targeted Termination of Plasminogen Activation after Tissue Plasminogen Activator Therapy Reduces Ischemic Brain Injury and Hemorrhage in Experimental Ischemic Stroke

T. Zhao; S. Lane; Y. Zhang; A. Houng; G. Reed

University of Tennessee Health Science Center, Medicine, Memphis, United States

Background: In ischemic stroke, early treatment with recombinant tissue plasminogen activator (r-tPA) is beneficial. However, r-tPA blood levels remain high for hours and studies indicate that after prolonged ischemia, r-tPA increases brain hemorrhage, early mortality and neurotoxicity.
Aims: To determine whether termination of prolonged r-tPA action is beneficial in experimental ischemic stroke.
Methods: Experimental ischemic stroke was induced by a middle cerebral artery embolus in anesthetized mice by a blinded investigator. After 2.5 hours of ischemia, mice were treated by r-tPA followed, in a randomized manner, by placebo or a monoclonal antibody antidote of r-tPA. Ischemic brain injury was assessed in a blinded fashion after 6 h.
Results: The r-tPA antidote bound specifically with sub-nanomolar affinity to r-tPA. The r-tPA antidote inhibited plasminogen activation and human clot dissolution in a dose-related fashion with greater specificity and potency than plasminogen activator inhibitor-1. In experimental ischemic stroke, when given immediately after the r-tPA bolus, during the r-tPA infusion, the r-tPA antidote caused a 4-fold reduction in hemorrhage ($p < 0.05$) and a 2.9-fold reduction in brain infarction ($p < 0.01$) compared with placebo. Treatment with the r-tPA antidote 30 min. after the r-tPA bolus also significantly reduced brain bleeding >4-fold ($p < 0.05$) and brain infarction 2.2-fold ($p < 0.01$) by comparison to placebo.
Conclusions: A specific monoclonal antibody antidote specifically blocks r-tPA plasminogen activation and clot dissolution in vitro. When administered at various times after r-tPA bolus therapy, the antidote markedly reduces ischemic brain infarction and hemorrhage. This suggests that early termination of r-tPA activity may reduce ischemic brain injury and hemorrhage in patients given r-tPA after prolonged brain ischemia.

ASY 31.2 | A Novel and Effective Fibrinolytic Approach in a Murine Model of Diabetes-associated Ischemic Stroke

M. Navarro-Oviedo[1]; C. Roncal[1,2]; B. Zandio[3]; J.A. Rodríguez[1,2]; J.A. Páramo[2,4]; R. Muñoz[3]; J. Orbe[1,2]

[1]CIMA-University of Navarra, Program of Cardiovascular Diseases, Pamplona, Spain, [2]CIBER Cardiovascular (CIBERCV), Instituto de Salud Carlos III, Pamplona, Spain, [3]Neurosciences Service, Complejo Hospitalario de Navarra, Pamplona, Spain, [4]Hematology Service, Clínica Universidad de Navarra, University of Navarra, Pamplona, Spain

Background: Stroke is clinically characterized by a rapid loss of brain function due to the disruption of the blood flow to the brain. Diabetes influences the prognosis of stroke patients. The thrombolytic agent tissue-type plasminogen activator (tPA) is the only approved pharmacological treatment for ischemic stroke (IS). Nevertheless, tPA has been associated with adverse effects, such as cerebral haemorrhage and neurotoxicity.
Aims: We previously showed the fibrinolytic effects of matrix metalloproteinase-10 (MMP10) in an IS animal model (Orbe et al., Circulation 2011). Considering comorbidity factors, we wanted to study whether MMP10 treatment would reduce brain damage after IS in a murine diabetes model, thus avoiding the adverse effects of tPA.
Methods: Type I diabetes mellitus was induced in mice by a single dose of streptozotocin (180 mg/Kg). Two weeks later, IS was performed by injection of thrombin into the middle cerebral artery and the effect of recombinant MMP10 (6.5 μg/Kg), tPA (10 mg/Kg) or tPA/MMP10 on brain damage and functional outcome were analysed. Motor activity was assessed before and after stroke using the open field test.
Results: Our results showed that MMP10 treatment alone or combined with tPA significantly reduced the lesion volume 24 h after stroke ($p < 0.05$). At day 3 all treatments reduced infarct volume when compared to saline ($p < 0.05$), although maximal reduction was obtained with t-PA/MMP10 combination ($p < 0.05$, when compared to tPA). Moreover, the combination therapy demonstrated a decrease of neuronal degeneration 24 h after stroke ($p < 0.05$). Analysis of motor activity showed a deteriorated function associated with blood glucose levels at 24 h. None of the treatments significantly improved the impaired motor activity induced by diabetes-IS.
Conclusions: Our data suggest that MMP10 or MMP10/tPA treatment reduces brain damage more effectively than tPA after diabetes-associated IS, identifying MMP10 as a novel and effective thrombolytic agent for IS.

ASY 31.3 | Late Administration of a new Antifibrinolytic Strategy (CM352) Reduces Lesion Size and Improves Functional Outcome in a Collagenase-Induced Rat Model of Intracerebral Hemorrhage

M. Navarro-Oviedo[1]; T. Sobrino[2]; J.A. Rodriguez[1,3]; F. Campos[2]; J. Oyarzabal[4]; J. Castillo[2]; J.A. Páramo[1,3,5]; J. Orbe[1,3]

[1]CIMA-University of Navarra, Program of Cardiovascular Diseases, Pamplona, Spain, [2]Clinical Neurosciences Research Laboratory, Health Research Institute of Santiago de Compostela (IDIS), Santiago de Compostela, Spain, [3]CIBER Cardiovascular (CIBERCV), Instituto de Salud Carlos III, Pamplona, Spain, [4]Small Molecule Discovery Platform, Center for Applied Medical Research (CIMA), Pamplona, Spain, [5]Hematology Service, Clínica Universidad de Navarra, University of Navarra, Pamplona, Spain

Background: Intracerebral hemorrhage (ICH) is an acute neurological disorder, comprising approximately 10-20% of all stroke cases, with high mortality and no proven treatment. We have previously demonstrated the efficiency of CM352, a short half-life (1.4 h) antifibrinolytic agent and matrix metalloproteinase (MMP) inhibitor, to reduce early (1 h) hematoma expansion and improve functional outcome in a rat model of collagenase-induced ICH (ISTH 2015, OR116).

Aims: To study in a collagenase-induced ICH model whether late (3 h) CM352 administration still has a beneficial effect on lesion size and functional outcome.

Methods: ICH was induced by striatal injection of collagenase. 3 h later, rats received an intravenous injection of saline (n = 6) or CM352 (1 mg/kg, n = 6). Hematoma (1 h, 3 h, 5 h and 24 h) and lesion (14d) volumes were quantified on T2-weighted magnetic resonance images (MRI). Neurologic deficit was analyzed by Bederson and Wahl scales (24 h and 14d). Motor impairment was assessed using the cylinder test and quantified by laterality index. Prothrombin time (PT) and activated partial thromboplastin time (aPTT) were measured to assess the effect of CM352 on hemostasis.

Results: Intracerebral hematoma was similar in all animals at 1 h (mm^3: 15.3 ± 5.2 vs 16.0 ± 1.9) and 3 h (mm^3: 38.8 ± 9.9 vs 39.8 ± 6.7) post-ICH. Late (3 h) CM352 administration reduced hematoma at 5 h (mm^3: 59.3 ± 14.2 vs 34.4 ± 4.5; $p < 0.01$) and 24 h (mm^3: 54.9 ± 14.2 vs 34.5 ± 9.5; $p < 0.05$), and lesion size up to day 14 (mm^3: 9.4 ± 2.3 vs 5.1 ± 2.4; $p < 0.05$). CM352 drastically reduced sensorimotor impairment after ICH in rats at 24 h ($p < 0.01$) and 14d ($p < 0.01$). Interestingly, it also attenuated neurological deficit at 24 h ($p < 0.01$) and 14d ($p < 0.05$). No differences were found in PT or aPTT at any time point.

Conclusions: Late CM-352 administration reduces lesion size, associated to better functional and neurological recovery, in a rat model of collagenase-induced ICH, without interfering normal hemostatic function.

ASY 31.4 | Restoring Cardiac Function after Myocardial Infarction by Targeting CD39 to Activated Platelets

M. Ziegler[1]; J.D. Hohmann[1]; A.K. Searle[1]; M.-K. Abraham[1]; H. Nandurkar[2]; X. Wang[1]; K. Peter[1]

[1]Baker Heart and Diabetes Institute, Melbourne, Australia, [2]Australian Centre for Blood Diseases, Monash University, Melbourne, Australia

Background: CD39 is a cell membrane NTPase with anti-inflammatory and anti-platelet effects. However, its clinical use is limited by its bleeding side effect.

Aims: We aimed to harness CD39's therapeutic potential while avoiding hemostatic problems. We designed a fusion protein (Targ-CD39) consisting of the extracellular domain of CD39 and a single-chain antibody that specifically binds to the activated platelet receptor GPIIb/IIIa. Through this enrichment at activated platelets, the required systemic dose is below the dose impairing hemostasis.

Methods: Using an ischemia/reperfusion (IR) mouse model (LAD ligation for 1 hour) we achieved remarkable protection of the reperfused tissue with Targ-CD39 (0.4 µg/g, i.v. post reperfusion) compared to Non-targ-CD39 (mutated, non-binding version of Targ-CD39) and PBS. This was measured using ultrasound, histological analysis and cytokine assays.

Results: Targ-CD39 restored ejection fraction as well as fractional shortening at week 4 to a non-significant difference to pre IR injury (62.6 ± 3.8 baseline vs. 54.5 ± 5.3% EF for week 4 Targ-CD39) but significant differences to PBS and Non-Targ CD39 at week 4 (54.5 ± 5.3 Targ-CD39 vs. 38.5 ± 11.5 PBS and 40.9 ± 10.5% EF Non-Targ CD39, $p < 0.01$).

Employing advanced, clinically relevant methods of ultrasound analysis, we observed that strain showed infarct-typical changes of myocardial deformation in controls, but not in Targ-CD39 treated mice (Targ-CD39 of 22.1 ± 4.1 vs. PBS of 3.4 ± 2.5 and Non-Targ-CD39 of 7.9 ± 6.8% $p < 0.05$). Histological assessment confirmed strong reduction of infarct size ($p < 0.01$) and increase in neovascularization ($p < 0.001$). Furthermore, attenuation of post-ischemic inflammation was seen in cytokine profiling. 32 inflammatory cytokines and receptors were down-regulated more than twofold in the Targ-CD39 group, as compared to the Non-targ-CD39 control group. No marker was up-regulated.

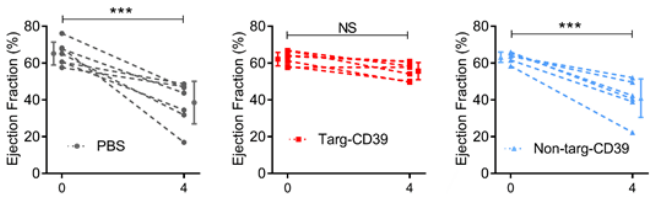

FIGURE 1 Treatment with Targ-CD39 restores ejection fraction 4 weeks post myocardial infarction

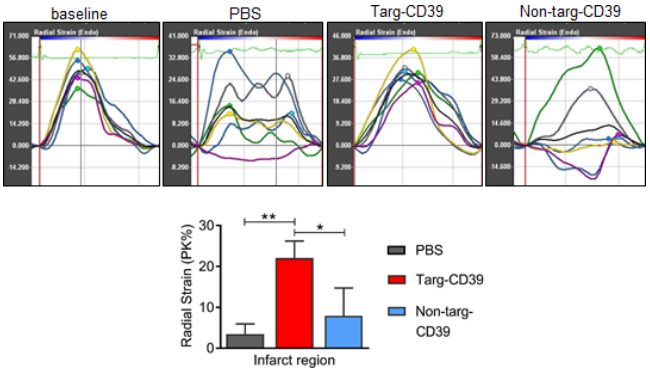

FIGURE 2 Radial strain curves showed infarct-typical changes of myocardial deformation in controls, but not in Targ-CD39 treated mice

Conclusions: In conclusion, we demonstrate that Targ-CD39 holds promise for the prevention of IR injury in reperfused myocardial infarction.

COAGULANT & ANTICOAGULANT MECHANISMS

ASY 02.1 | Human-snake Chimeras of Cofactor V Reveal Allostery between the A- and C-domains

D. Verhoef[1]; G.A.F. Nicolaes[2]; R. Schrijver[2]; R.M. Camire[3]; P.H. Reitsma[1]; M.H.A. Bos[1]

[1]Leiden University Medical Center, Division of Thrombosis and Hemostasis, Einthoven Laboratory for Vascular and Regenerative Medicine, Leiden, The Netherlands, [2]Maastricht University, Department of Biochemistry, Maastricht, The Netherlands, [3]The Children's Hospital of Philadelphia, Pediatrics/Hematology, Philadelphia, United States

Background: The venom of the snake Pseudonaja textilis contains a highly stable homolog of cofactor V, ptFV. The ptFV C-domains share ~60% sequence identity with those of human FV, but have lost the ability to bind anionic membranes despite retaining a number of conserved lipid-binding motives.

Aims: Investigate whether loss of lipid association by the ptFV C-domains relates to enhanced ptFV cofactor stability.

Methods: The C-domains of constitutively active B-domainless human FV (hFV) and ptFV were exchanged and the chimeric variants hFV-ptC and ptFV-hC were expressed, purified and characterized.

Results: Thermal analysis of the FV variants employing differential scanning calorimetry (DSC) revealed a single denaturation event for hFV at 54°C. In contrast, ptFV displayed distinct denaturation events at 60°C and 70°C. Swapping of the C-domains resulted in a more stable human cofactor as hFV-ptC exhibited a denaturation peak at 58°C. No DSC profile could be obtained for ptFV-hC. Thermal FV cofactor activity decay rate constants assessed at 52°C confirmed the high stability of ptFV ($k < 0.001$) relative to hFV (k 0.39 ± 0.04). The C-domain exchange adversely affected the ptFV stability (ptFV-hC, k 0.73 ± 0.25), yet improved that of hFV (hFV-ptC, k 0.13 ± 0.04). Examination of phospholipid binding on a Biacore L1-chip coated with vesicles containing 25-5% PS anionic content showed no binding of ptFV (>1M) compared to hFV (0.5 μM). Weak binding constants were observed for hFV-ptC (≥11 μM) and ptFV-hC (≥3 μM). A purified prothrombinase assay confirmed the weak lipid-binding by the C-domains of ptFV as full cofactor activity of hFV-ptC required 10-100-fold higher concentrations of 25-5% PS vesicles compared to hFV.

Conclusions: Collectively, our results implicate allosteric crosstalk between the C- and A-domains of FV, since when linked to the hFV A-domains, the ptFV C-domains were able to bind PS-containing phospholipids and, in part, improved cofactor stability.

ASY 02.2 | Uncovering the Unique Functional APC-resistant Modifications of Snake Venom FV

M. Schreuder[1]; D. Verhoef[2]; K.L. Cheung[2]; P.H. Reitsma[2]; M.H.A. Bos[2]

[1]Leiden University Medical Center - Department of Thrombosis and Hemostasis, Einthoven Laboratory for Vascular and Regenerative Medicine, Leiden, The Netherlands, [2]Leiden University Medical Center – Division of Thrombosis and Hemostasis, Einthoven Laboratory for Vascular and Regenerative Medicine, Leiden, The Netherlands

Background: Coagulation factor Va (FVa) is proteolytically inactivated by activated protein C (APC), which is key to downregulate the procoagulant response. APC cleaves FVa at several positions throughout the A2-domain, with Arg306 and Arg506 as major cleavage sites. We previously reported the functional resistance of snake venom *P.textilis* factor V (ptFV) to human APC, despite proteolysis within the A2-domain. Sequence analysis revealed the absence of the 306 site and surrounding residues in ptFV.

Aims: Assess the role of the ptFV sequence that replaces the region surrounding cleavage site Arg306.

Methods: The non-conserved ptFV region (GNPDTLT) was exchanged for the human Arg306 region (PKKTRNL), thereby generating ptFV-h306 and hFV-pt306.

Results: While human APC did not proteolyze ptFV at the 306 position, introduction of the human 306 region resulted in 306 cleavage of ptFV-h306. Conversely, this cleavage was absent in hFV-pt306. Full proteolysis of human FV (500 nM) was achieved following treatment with 10 nM APC, while a 75-fold higher APC concentration (750 nM) was required to obtain fully proteolyzed ptFV-h306, similar to ptFV. Functional analysis in a purified prothrombinase system revealed no significant differences in APC-induced inactivation, with both human FV molecules being fully inactivated following a 5 min incubation with APC. Surprisingly, both ptFV and ptFV-h306 maintained full activity for at least 15 min, despite extensive APC-mediated proteolysis.

Conclusions: These findings indicate that, conversely to human FV, APC-dependent cleavage of ptFV at Arg306 does not abrogate FVa cofactor function. This may suggest that even following APC cleavage at the positions homologous to human 306 and 506, the functional integrity of the ptFV A2-domain is stabilized such that it is able to form productive interactions. As such, ptFV provides a biological model to further study structure-function requirements that may ultimately contribute to a FV molecule with enhanced procoagulant cofactor activity.

ASY 02.3 | X-ray Crystallographic Studies of the Factor VIII C2 Domain in Complex with O-phospho-L-serine Indicate that Arg 2320 Contributes to the Phospholipid Membrane Binding Site

P.C. Spiegel; S. Wo

Western Washington University, Chemistry, Bellingham, United States

Background: Factor VIII is a glycoprotein cofactor that is essential for proper regulation of blood coagulation. Genetic deficiencies in factor VIII cause hemophilia A, which affects 1 in 5,000 males worldwide. The C-terminal "C2" domain of factor VIII is essential for proper interactions with the membrane surface of activated platelets and is a major epitope that is recognized by inhibitory antibodies. Previous X-ray crystallographic studies of the factor VIII C2 domain in complex with classical anti-C2 antibodies suggested that the face of the C2 domain harboring Arg 2320 contributes to phospholipid membrane binding.
Aims: In this study, we aim to test our working model of factor VIII membrane association that involves Arg 2320. Understanding the structural mechanism by which factor VIII associates with activated platelet surfaces to form the intrinsic tenase complex with blood coagulation factor IXa will further illustrate their roles in hemostasis.
Methods: Using a combination of X-ray crystallography, site-directed mutagenesis and phospholipid binding assays, we have soaked crystals of the factor VIII C2 domain with the soluble headgroup of phosphatidylserine, o-phospho-L-serine (OPS). Hemophilia A-associated point mutants at Arg 2320 were also generated for membrane binding analysis.
Results: A 1.4 Å X-ray crystal structure of the porcine factor VIII C2 domain soaked with OPS was determined. Continuous positive density features were observed that were not attributed to the model within a binding cleft centered on Arg 2320. Subsequent to these structural findings, mutations to Arg 2320 (R2320S/T) indicate a dramatic loss in activity while the R2320M mutant is insoluble upon overexpression.
Conclusions: Taken together, these results strongly suggest that blood coagulation factor VIII binds to activated platelet surfaces through phospholipid membrane interactions with the binding site containing Arg 2320, which is in contrast to previously suggested hypotheses.

ASY 02.4 | Full Length Activated Plasma Prekallikrein Crystal Structure reveals Autoactivation Model Involving the Apple Domains

C. Li; J. Emsley

University of Nottingham, Centre for Biomolecular Sciences, School of Pharmacy, Nottingham, United Kingdom

Background: Plasma Prekallikrein (PPK) is a serine protease zymogen that circulates in plasma bound to high molecular weight kininogen (HK). It is an important component both in kallikrein-kinin system composed of PPK, plasma kallikrein (PK), HK; and in the contact system consisting of PPK, Factor XII (FXII) and HK. PPK is activated by Factor XIIa to become PK that cleaves HK to liberate bradykinin (BK), an inflammatory peptide. PK reciprocally activates the FXII zymogen to amplify generation of FXIIa which then leads to activation of FXI, which initiates the intrinsic pathway of coagulation. Animal models have shown that deficiencies of PPK had a defect in thrombus formation while maintaining hemostasis which raises the possibility that targeting PK may serve as a strategy to treat pathological thrombosis with less risk of side effects than currently used anti-coagulants.
Aims: To solve plasma kallikrein full length crystal structure and compare these with previously determined FXI.
Methods: SPR was used to obtain affinity binding constants for protein interactions; and protein crystallography was used to determine PK structures.
Results: We here report the first crystal structure of full-length plasma kallikrein revealing the 3D arrangement of the four apple domains at the N terminus and the catalytic light chain. A comparison with the previously determined FXI zymogen structure reveals the activated PK protease shifts significantly and we speculate this exposes a substrate exosite. We also solved a series of crystal structures of the heavy chain of PK in complexes with peptides derived from the cofactor HK revealing the binding on the apple domains. The binding constants for PPK bound to HK peptides were in the low nM range, our data showed that HK is a dimer bound to a PPK monomer.
Conclusions: The plasma kallikrein structure reveals the first model for autoactivation of this protease and provides a scaffold on developing new inhibitors for kallikren-kinin system and Contact activation.

ASY 21.1 | Functional Characterization of Three Novel Activated Protein C (APC) Binding Aptamers

N. Shahidi Hamedani; S. Gasper; J. Oldenburg; J. Müller; B. Pötzsch

Institute of Exp. Haematology and Transfusion Medicine,University of Bonn Medical Center, Bonn, Germany

Background: Activated protein C (APC) is a multifunctional serine protease that controls blood coagulation and exhibits anti-inflammatory and cytoprotective functions involving different exosite structures. We have selected three aptamers (NB1, NB2 and NB3) against APC using systematic evolution of ligands by exponential enrichment (SELEX).
Aims: To characterize the binding site of NB1-3 within the APC molecule and to assess the impact of the NB1-3 aptamers on APC-substrate interactions.
Methods: The functional properties of the APC aptamers were investigated through analysis of their impact on (I) the amidolytic activity of APC using different peptide substrates, (II) APC-catalyzed FVa/FVIIIa inactivation in purified enzyme systems, (III) the anticoagulant effects of APC in the plasma matrix using calibrated automated thrombogram

(CAT), and (IV) plasma protein C-inhibitor (PCI)-mediated APC inactivation using an enzyme-capture assay.

Results: All 3 aptamers inhibit the anticoagulant functions of APC with IC50-values of 5.9 and 8.3 nM for FVa and FVIIIa inactivation, respectively, while hydrolysis rates of APC peptide substrates were only marginally influenced. Within the plasma matrix, NB3 proved to be the most effective inhibitor of anticoagulant functions of APC (IC50 = 46 nM). Most interestingly, binding of NB1 and NB2 enhanced the inactivation of APC by PCI while NB3 protected APC from PCI-induced inactivation.

Conclusions: The newly selected APC-binding aptamers share a common binding site within the basic exosite of APC but differentially influence the functional properties of APC. While all three aptamers selectively block the anticoagulant functions of APC, NB-3 only protects APC from early inactivation by PCI. This fetures qualifies NB-3 to an interesting drug candidate in clinical situations such as septicemia where selective inhibition of the anticoagulant functions without inhibiting the cytoprotective functions of APC is of particular interest.

ASY 21.2 | Inhibition of Activated Protein C Aspartyl Beta-hydroxylation Restricts Anticoagulant Function but Enhances Cytoprotective Signaling Activity

O. Willis Fox; E. Gleeson; H. Rushe; A. Rehill; R. Preston

Royal College of Surgeons in Ireland, Molecular and Cellular Therapeutics, Dublin, Ireland

Background: The anticoagulant enzyme activated protein C (APC) also triggers cytoprotective cell signaling via protease-activated receptor 1 (PAR1) proteolysis. These properties have prompted the development of non-anticoagulant APC mutants for clinical use, and new strategies to selectively boost APC cytoprotective signaling activity would be therapeutically advantageous.

Aims: APC is subject to post-translational aspartyl β-hydroxylation, but the functional role of this modification is poorly understood. To evaluate this, an APC mutant resistant to β-hydroxylation (D71E) was generated and characterised.

Methods: APC-D71E anticoagulant activity was measured using calibrated automated thrombography and activated factor V (FVa) degradation assays. APC-D71E cell signaling activity was assessed using reporter assays of PAR1 proteolysis and endothelial cell (EC) barrier integrity.

Results: APC-D71E was unable to restrict plasma thrombin generation or mediate protein S-independent FVa degradation, implying a new role for aspartyl β-hydroxylation in enabling APC anticoagulant substrate recognition and degradation. In contrast, APC-D71E exhibited significantly enhanced PAR1 proteolysis, and triggered downstream cytoprotective signaling on ECs 5-fold more effectively than wild type APC. Combining defective aspartyl β-hydroxylation with an amino acid substitution (N329Q) previously shown to enhance PAR1 proteolysis yielded an APC mutant (APC-D71E/N329Q) with even greater signaling potency. Remarkably, APC-D71E/N329Q exhibited no anticoagulant activity, but mediated rapid PAR1 proteolysis and reduced thrombin-induced EC barrier disruption ~100-fold more effectively than wild type APC.

Conclusions: Collectively, these data describe novel gain-of-function APC mutants with selectively amplified cytoprotective properties, and identify an intriguing new role for aspartyl β-hydroxylation ablation in preventing APC anticoagulant function, whilst simultaneously boosting cytoprotective signaling activity.

ASY 21.3 | TFPIα Protects FV-short from Rapid Inactivation by Activated Protein C

F. Ayombil[1]; T. Petrillo[1]; R.M. Camire[1,2]

[1]Childrens Hospital of Philadelphia, Pediatrics - Hematology Division, Philadelphia, United States, [2]University of Pennsylvania Perelman School of Medicine, Philadelphia, United States

Background: Factor V (FV)-short, an alternatively spliced B-domainless variant (missing residues 756-1458) of the coagulation *FV gene* is the molecular defect in the FV East Texas bleeding disorder. In this case, reduced thrombin generation potential is partly explained by increased levels of TFPIα and its tight association via its C-terminal basic region (BR) to the available acidic region 2 (AR2) on FV-short.

Aims: The present study investigates the mechanism by which the TFPIα-FV-short complex regulates the susceptibility of this cofactor-like molecule to proteolytic inactivation by the anticoagulant, activated protein C (APC).

Methods: Using a 56-amino acid C-terminal TFPIα BR fragment or full length TFPIα, we monitored the discontinuous proteolysis and inactivation of FV-short in the presence of APC and membranes. Cleavage products were visualized using monoclonal antibodies against the heavy chain of FV.

Results: APC cleaves both FVa and FV-short with similar profiles. However, densitometric analyses showed that both TFPIα and the BR fragment significantly inhibited proteolysis of FV-short with >80% of the starting material remaining after 15 min of incubation with APC compared to the controls. Using FV-short and other B-domainless variants (FV-DT-R306Q, and R506Q) we found that TFPIα and the BR fragment blocked cleavage at R506 suggesting the BR somehow obscures the ability of APC to engage FV-short at this site. TFPIα and the BR fragment had no effect at R306 or R679. Consistent with data showing a high affinity interaction between TFPIα-BR and AR2 of FV-short, TFPIα or the BR has no impact on FVa (lacks AR2) inactivation by APC. Together these data show the FV-short-TFPIα complex is resistant to APC proteolysis.

Conclusions: The findings are consistent with data from our laboratory showing that the internal BR of FV has a major impact on APC inactivation of the procoafactor. Thus, not only does TFPIα block the procoagulant function of FV-short it also protects it from the protein C pathway.

ASY 21.4 | Factor V-Short and Protein S as Synergistic TFPIα-cofactors

B. Dahlbäck[1]; L.J. Guo[1]; R. Livaja-Koshiar[1]; S. Tran[1]; R. Camire[2]

[1]*Lund University - Centre for Thrombosis and Haemostasis - Skåne University Hospital, Malmö, Sweden,* [2]*University of Pennsylvania Perelman School of Medicine, Philadelphia, United States*

Background: In the East Texas bleeding disorder a *F5* gene mutation activates a splice donor site resulting in the in frame deletion of 702 residues. The truncated B domain of FV-Short exposes a high affinity TFPIα binding site - FV-Short and TFPIα forming a circulating complex. Due to the increase in FV-Short in affected individuals, the TFPIα concentration increases 10-fold, which results in a bleeding phenotype. FV-Short is also present in normal plasma at low levels and circulates in complex with TFPIα.

Aims: To elucidate whether the complex formation between FV-Short and TFPIα affects the function of TFPIα as FXa inhibitor and to test whether the TFPIα-cofactor activity of protein S is affected by the presence of FV-Short.

Methods: Using purified components (FXa, TFPIα, FV-Short, protein S and negatively charged phospholipid vesicles), the TFPIα mediated inhibition of FXa was monitored with S2765.

Results: FV-Short has intrinsically weak TFPIα-cofactor activity but the presence of a low protein S concentration, which in itself is insufficient to stimulate TFPIα, results in rapid inactivation of the FXa. In the absence of FV-Short, relatively high concentrations of protein S (>25 nM) are required to achieve full TFPIα-mediated inactivation of FXa. In contrast, in the presence of FV-Short full inhibition of FXa is observed at 10-fold lower protein S. Activation of FV-Short by thrombin results in the loss of the TFPIα-cofactor activity.

Conclusions: We demonstrate that FV-Short and protein S are synergistic cofactors to TFPIα in the regulation of FXa activity. Our results suggest the formation of an efficient FXa-inhibitory complex between FV-Short, TFPIα and protein S on the surface of negatively charged phospholipids, which presumably is important for the inhibition of initially generated FXa. This is the second reported anticoagulant activity associated with FV, which emphasizes the central importance of FV as a regulator of blood coagulation.

COAGULATION SIGNALING & IMMUNITY

ASY 03.1 | Platelet Necrosis Induces Neutrophil Macro-aggregation and Pulmonary Thrombosis Following Gut Ischemia

Y. Yuan[1]; I. Alwise[1]; M. Wu[1]; Z. Kaplan[2]; K. Ashworth[2]; A. Pham[3]; J. Mcfadyen[2]; S. Schoenwaelder[1]; E. Josefsson[4]; B. Kile[4]; S. Jackson[1]

[1]*Heart Research Institute, Sydney University, Charles Perkins Centre, Sydney, Australia,* [2]*Monash University, Australian Centre for Blood Diseases, Melbourne, Australia,* [3]*The Alfred Hospital, Pathology, Melbourne, Australia,* [4]*Walter Eliza Hall Institute, Melbourne, Australia*

Background: Gut ischemia is common in critically ill patients, promoting thrombosis and inflammation in distant organs, especially the lung, leading to the development of acute respiratory distress syndrome (ARDS). The mechanisms linking gut ischemia to pulmonary thrombosis remain ill defined.

Aims: Investigate how gut ischemia leads to pulmonary thrombosis.

Methods: A murine model of gut ischemia reperfusion (IR) injury and intravital microscopies were used to monitor the interactions between platelets and neutrophils in the gut and lung vasculature.

Results: We have demonstrated that gut ischemia in the mouse induces a distinct pulmonary thrombotic mechanism triggered by dying platelets and neutrophil macro-aggregates. These neutrophil macro-aggregates lead to occlusion of pulmonary arteries and veins. Similar pulmonary neutrophil macro-aggregates were also identified in lung specimens from ARDS patients, with 20-66% of the vessels containing aggregates, but not in the lungs from patients with acute pulmonary oedema or emphysema. Intravital microscopy during gut IR injury and in vitro neutrophil perfusion studies revealed fragmentation of dying platelet membranes by rolling neutrophils, with the extracted platelet fragments bridging adjacent neutrophils to facilitate neutrophil macro-aggregation. This process is not inhibited by conventional antiplatelet agents, however, platelet specific-deletion of cyclophilin D, a mitochondrial mediator of platelet necrosis, maintained platelet membrane stability, prevented neutrophil macro-aggregation and pulmonary thrombosis, and improved respiratory function and survival post gut IR injury.

Conclusions: We have identified a distinct neutrophil-rich thrombosis mechanism following gut IR injury. This unique thrombotic response is triggered by membrane fragmentation of dying platelets by rolling neutrophils, and links gut ischemia to pulmonary thrombosis. Targeting platelet necrosis may represent a new approach to reduce pulmonary thrombosis in critically ill patients.

ASY 03.2 | Going against the Flow: How Staphylococcus Aureus and Staphylococcus Lugdunensis Adhere to the Heart Valves and Initiate Endocarditis by Binding to von Willebrand Factor

L. Liesenborghs[1]; J. Claes[1]; M. Peetermans[1]; R.T. Veloso[1]; M. Criel[1]; M. Lox[1]; G. Vande Velde[2]; T. Vanassche[1]; M. Hoylaerts[1]; P. Verhamme[1]

[1]*KU Leuven, Center For Molecular and Vascular Biology, Leuven, Belgium,* [2]*KU Leuven, Biomedical MRI/Mosaic, Leuven, Belgium*

Background: Both *S. aureus* and *S. lugdunensis* are feared and frequent causes of endocarditis, but the real reason why remains elusive. Before infecting the hearth valves, bacteria must first adhere to the valve endothelium. However, their adhesion is hampered by the high shear stress of blood flowing though the valves.

Aims: Investigate how these bacteria adhere under shear stress and if similarly to platelets they achieve this by binding to von Willebrand factor (VWF).

Methods: We studied the adhesion of *S. aureus* and *S. lugdunensis* to VWF and endothelial cells in a flow chamber. With a mesenteric microvascular perfusion mouse model we examined the interaction of fluorescent bacteria with the vessel wall in real time in vivo. To measure bacterial adhesion to the heart valves we developed a new unique endocarditis mouse model. For this we intravenously injected fluorescent bacteria and activated the valve endothelium by locally infusing histamine through a catheter placed in the carotid artery. With confocal microscopy we measured the adhesion of bacteria to the valves. We used VWF knockout mice to evaluate the role of VWF.

Results: Both *S. aureus* and *S. lugdunensis* bind to VWF under shear stress, in contrast to other staphylococci that seldom cause endocarditis. This enabled the bacteria to adhere to activated endothelial cells in vitro and to the vessel wall in vivo. In our new endocarditis mouse model we could show that *S. aureus* and *S. lugdunensis* hardly adhered to resting valve endothelium. However, by locally infusing histamine and inducing endothelial activation we could make the valves more prone to bacterial adhesion and induce endocarditis. In addition, binding of both *S. aureus* and *S. lugdunensis* to heart valves of VWF knockout mice was greatly reduced compared to wild type mice.

Conclusions: Binding to VWF allows *S. aureus* and *S. lugdunensis* to overcome shear stress and infect the hearth valves. This explains why they are so effective in causing endocarditis compared to other staphylococci.

ASY 03.3 | Soluble Short Fractions of β-1,3 Glucans Derived from Candida albicans Act as a Shield for Pathogenic Yeasts and Modulate the Activation of Platelets

H. Vancraeyneste[1]; R. Charlet[1]; Y. Guerardel[2]; L. Choteau[1]; A. Bauters[3]; M. Tardivel[4]; N. Francois[5]; L. Dubuquoy[6]; D. Soloviev[7]; D. Poulain[1]; B. Sendid[1]; S. Jawhara[1]

[1]University Lille 2, Inserm U 995 Team 2, Lille, France, [2]CNRS, UMR 8576, Villeneuve d'Ascq, France, [3]Laboratoire d'Hémostase, Pôle de Pathologie Génétique, Lille, France, [4]Plateforme d'Interaction Moléculaire, IMPRT-IFR 114, Faculté de Médecine de Lille, Lille, France, [5]Service de Parasitologie Mycologie, Pole de Biologie Pathologie Génétique, Lille, France, [6]University Lille 2, Inserm U 995, Lille, France, [7]Joseph J. Jacobs Center for Thrombosis and Vascular Biology, Cleveland Clinic, Department of Molecular Cardiology, Cleveland, United States

Background: Platelets play a crucial role in hemostasis, thrombosis, and pathogen clearance. Many pathogenic fungi can interact with platelets in circulating blood. The pathogenic fungus *Candida albicans* is the predominant cause of invasive forms of candidiasis. Its cell wall contains β-1,3 glucans that are known to trigger a wide range of host cell activities.

Aims: Clinically, β-glucans are released in the circulation during infection and their detection allows the early diagnosis of an invasive fungal infection, but the role of β-glucans in the modulation of platelet activities and platelet-neutrophil interactions is unknown.

Methods: Platelets pretreated with β-glucan fractions were analyzed in terms of activation, receptor expression, aggregation and adhesion to neutrophils and to *C. albicans*.

Results: Our study shows that β-glucan fractions decrease platelet aggregation, and modulate the coagulation process. The biological activities of these oligoglucosides depend on their degree of polymerization and their concentration. They also affect the regulation of platelet receptors (P-selectin and $\alpha_{IIb}\beta_3$). Interestingly, these oligoglucosides at a low concentration reduce platelet activation, and both platelet-*C. albicans* and platelet-neutrophil interactions, which allow *C. albicans* to be protected from leukocyte activation. Mechanistically, these oligoglucosides block protein kinase-C activation in platelets that affect the regulation of platelet receptors. Bedsides, the pentaglucosides reduced platelet activities through TLR4 mediated TGF-β1 production

and ATP release, and blocking this receptor by an anti-TLR4 antibody abolished the effect of the pentaglucosides on platelets suggesting that TLR4 is involved in the immuno-modulatory effects induced by β-glucans.

Conclusions: Our study offers new insights, showing that these fungal-derived oligoglucosides are not involved exclusively in the protection of *C. albicans* during infection but also in the modulation of platelet activation mediated via TLR4 stimulation.

ASY 03.4 | VWF and ADAMTS-13 Modulate the Outcome of Staphylococcus aureus Sepsis

M. Peetermans[1]; L. Liesenborghs[1]; J. Claes[1]; M. Jacquemin[1]; K. Vanhoorelbeke[2]; M.F. Hoylaerts[1]; S. De Meyer[2]; T. Vanassche[1]; P. Verhamme[1]

[1]KU Leuven, Center for Molecular and Vascular Biology - Department of Cardiovascular Sciences, Leuven, Belgium, [2]KU Leuven Campus Kulak Kortrijk, Laboratory for Thrombosis Research, Kortrijk, Belgium

Background: The size and functionality of the multimeric von Willebrand factor (VWF) is regulated by its cleaving protease ADAMTS-13. Despite the correlation of VWF and ADAMTS-13 levels with disease severity and outcome in the heterogenous population of sepsis patients, animal models on this topic have yielded conflicting results and have focused mainly on gram-negative or polymicrobial abdominal sepsis.

Aims: To study the role of VWF and ADAMTS-13 in gram-positive monomicrobial *Staphylococcus aureus* (*S. aureus*) sepsis.

Methods: Analysis of blood samples of *S. aureus* bacteremia patients. Animal model for *S. aureus* sepsis, in wildtype, *Adamts13* -/- or *Vwf* -/- mice.

Results: In patients with *S. aureus* bloodstream infection, high VWF levels correlated with inflammatory parameters and inversely with kidney function. Low ADAMTS-13 levels associated with parameters of disease severity and DIC.

In an animal model for severe sepsis, mice deficient in VWF had improved survival. In contrast, *Adamts13* -/- mice showed increased mortality. Immediate clearance of bacteria was enhanced in VWF-deficient mice. The differences in mortality for the studied genotypes were associated with differential loads of organ microthrombi in liver and kidneys.

Conclusions: This is the first study that consistently shows the relation of VWF, ADAMTS-13 and their ratio to disease severity in patients and mice with *S. aureus* sepsis. VWF and its cleaving protease are not only involved in the primary adhesion of *S. aureus* to the vasculature, but also in the development of organ microthrombi containing platelets, neutrophils and bacteria, and thus potentially in end organ failure. Further research investigates whether substitution of the relative ADAMTS-13 deficiency that occurs in sepsis will reduce organ microthrombi and improve outcome in mice with *S. aureus* sepsis.

ASY 25.2 | Inflammatory Activities of rRNA-containing Microparticles from Mast Cells

A.-K. Elsemüller; V.Y. Tomalla; K.T. Preissner; S. Fischer

Justus Liebig University Giessen, Biochemistry, Giessen, Germany

Background: Mast cells (MC) are resident tissue cells and well known effectors of allergic or anti-parasitic responses but also first line players in inflammation and innate immunity. Following activation of MC with the rapid release of pre-stored mediators through regulated exocytosis (degranulation), rapid anaphylactic reactions, allergic responses and inflammatory activities are induced, including the recruitment of leukocytes. Likewise, extracellular RNA was found to promote inflammatory and procoagulant activities *in vitro* and *in vivo*.

Aims: Studies were performed to investigate whether MC may release RNA as an additional early inflammatory agonist and self-DAMP.

Methods: Bone marrow-derived MC or the MC-line HMC-1 were stimulated to induce degranulation, which was followed by the release of histamine and b-hexosaminidase activity. Microparticles were isolated by the centrifugation method and assessed by Annexin staining and FACS analysis. Membrane components of microparticles and RNA were stained by fluorescent dyes.

Results: Stimulation of MC by various agonists like ionomycin, compound 48/80, complement anaphylatoxins, or Toll-like receptor agonists induced the release of RNA (predominantly ribosomal RNA), which was largely associated with the microparticle fraction. The liberation of RNA from degranulating MC correlated well with the release of histamine and b-hexosaminidase activity and was abolished by inhibiting the degranulation process. Staining of microparticles with the antibody against rRNA and analysis by immuncytochemistry and electronmicroscopy demonstrated that rRNA was localized inside the microparticles. Following uptake of MC-released microparticles by human umbilical vein endothelial cells, the expression of cytokines like monocyte chemoattractant protein or interleukin-6 increased in a concentration-dependent manner.

Conclusions: Results indicate that MC-derived RNA-containing microparticles play a role in amplifying the initial cytokine storm during the inflammatory response.

ASY 32.1 | Platelets Modulate the Proinflammatory Phenotype of Macrophages via the Interaction of CLEC-2 and Podoplanin

J. Rayes; S. Lax; M. Zuidscherwoude; S. Wichaiyo; B. Grygielska; S. Watson; S.P. Watson; Birmingham platelet group

University of Birmingham, Institute of Cardiovascular Sciences, Birmingham, United Kingdom

Background: Platelets interact with macrophages to regulate thrombo-inflammatory and infectious disease. Depletion of platelets

or macrophages reduces survival during mouse models of sepsis. Furthermore, podoplanin-expressing, inflammatory macrophages induce platelet activation through CLEC-2. However the effect of CLEC-2 binding to podoplanin on macrophages is not known.

Aims: In this study, we investigate the role of the platelet ITAM receptor CLEC-2 in modulating macrophage function during sepsis.

Methods: Platelet-specific CLEC-2 deficient mice (*Clec2*$^{fl/fl}$PF4cre), hematopoietic-specific podoplanin-deficient mice (PDPN$^{fl/fl}$VAV1cre) or wild type (WT) mice were subjected to caecal ligation and puncture (CLP). A systemic clinical score, kidney and liver function, cytokine levels and bacterial load were assessed 24h post CLP. Spreading, migration and cytokine secretion were also assessed in bone marrow-derived macrophages (BMDM) using recombinant CLEC-2 or an anti-podoplanin antibody *in vitro*.

Results: We show that CLEC-2 deletion from platelets increases the clinical score and bacterial load in the peritoneum and the kidney, and exacerbates the inflammatory response. This was associated with an increase in the proinflammatory cytokines TNF-α and IL-6 and the anti-inflammatory cytokine IL-10 with increased sepsis-mediated acute kidney injury. A similar increase in bacterial load and sepsis-mediated acute kidney injury was observed in PDPN$^{fl/fl}$VAV1cre mice. *In vitro*, anti-podoplanin antibody induces a switch from an M1 proinflammatory phenotype to an M2 tissue-repair phenotype as measured by the expression of iNOS, CD206 and Egr2 on macrophages.

Conclusions: These results demonstrate that platelet CLEC-2 protects from septic shock possibly via interaction with podoplanin on macrophages and modulating their function. This interaction reprograms the macrophages toward a tissue repair phenotype M2 which is required to limit the inflammatory response.

ASY 32.2 | Activation of Circulating Platelets Leads to Innate-like Delivery of Potent Antiviral Antibodies

W.C. Schrottmaier[1]; A.-L. Luik[2]; M. Salzmann[3]; S. Badrnya[3]; S. Morava[3]; J.B. Kral-Pointner[3]; M. Karlsson[2]; A. Assinger[3]; M. Forsell[1]

[1]Umeå University, Clinical Microbiology, Umeå, Sweden, [2]Karolinska Institutet, Department of Microbiology, Tumor and Cell Biology, Stockholm, Sweden, [3]Medical University of Vienna, Center of Physiology and Pharmacology, Vienna, Austria

Background: Platelet activation and subsequent thrombus formation is a well-defined process to maintain vascular integrity upon tissue damage. However, platelets are also activated by an array of inflammatory stimuli, including microbial infection. Further, circulating platelets contain intracellular IgG that are released upon activation.

Aims: We aimed to elucidate the physiologic function of platelet-derived IgGs and their effect on viral infections *in vitro* and *in vivo*.

Methods: IgG levels, subclass and light chain distributions in human plasma and shear-induced platelet releasate were quantified by ELISA. For *in vitro* neutralization assays, CMV-infected HUVECs were incubated or perfused with platelets or plasma of anti-CMV IgG seropositive or -negative donors before quantification of CMV titer by IF or qPCR. IgG content of neonatal Fc-receptor (FcRn)-deficient or wildtype murine megakaryocytes (MK) was measured by flow cytometry.

Results: Human platelets can store and release anti-Influenza type A and anti-CMV IgG. Under both static conditions and microvascular shear stress, platelets from anti-CMV IgG seropositive but not seronegative donors potently neutralized *in vitro* CMV-infection. In spite of containing approximately 100-fold less IgG, platelets were equally efficient at neutralization as plasma from the same donor. While platelets are not enriched for a specific subclass of IgG, nor have a specific kappa or lambda light chain preference, anti-CMV antibodies were enriched as compared with the total amount of IgG in platelets. As MKs contain FcRn, sequestration of IgG might occur in the shared microenvironment of MKs and Ig-producing plasma cells. Indeed, MK FcRn is partially responsible for IgG uptake and may thus rescue IgG from degradation after endocytosis.

Conclusions: Our data show that platelets mediate potent IgG-mediated antiviral effects directly at foci of infection, indicating that platelet activation may represent a novel mechanism for focused serological immunity.

ASY 32.3 | Platelets Orchestrate Bleomycin-induced Lung Fibrosis in Circuitry with NETs

M. Bosmann[1]; D.R. Riehl[1]; J. Roewe[1]; S. Klebow[2]; N.L. Esmon[3]; S. Eming[4]; G. Colucci[5]; M. Gunzer[6]; A. Waisman[2]; K. Schäfer[7]; C.T. Esmon[3]; W. Ruf[1]

[1]University Medical Center Mainz, Center for Thrombosis and Hemostasis, Mainz, Germany, [2]University Medical Center Mainz, Institute for Molecular Medicine, Mainz, Germany, [3]Oklahoma Medical Research Foundation, Coagulation Biology Laboratory, Oklahoma City, United States, [4]University of Cologne, Department of Dermatology, Cologne, Germany, [5]Clinica Luganese Moncucco, Department of Hematology, Lugano, Switzerland, [6]University Hospital, University Duisburg-Essen, Institute for Experimental Immunology and Imaging, Essen, Germany, [7]University Medical Center Mainz, Center for Cardiology, Cardiology I, Mainz, Germany

Background: Platelets have been demonstrated to interact with immune cells in the context of neutrophil extracellular trap (NETs) formation. NETs are released during inflammation as an innate immune defense mechanism. NETs not only exert bactericidal activities but are toxic for host cells and thus promote tissue injury. In recent years, several reports have uncovered the important roles of platelet-neutrophil interactions for NET formation not only during thrombosis but also during acute inflammatory diseases. On the other hand, our current knowledge on the contribution of NETs during chronic inflammation, namely fibrotic disorders, remains incomplete.

Aims: The aim of this study was to characterize the immunologic networks involving platelets, neutrophils and NETs during lung fibrosis.

Methods: Transgenic mice (C57BL/6 background) were studied in a model of intra-tracheal bleomycin administration for the induction of lung fibrosis.

Results: Transient depletion of Ly6G+ neutrophils (Ly6G-Cre/iDTR mice) was sufficient to decrease the build-up of extracellular matrix (collagen I,V) and cytokines such as TGFβ1 in lungs. We hypothesized

that platelets may be the major source of TGFβ1 in lung fibrosis. We used platelet-specific genetic deletion (PF4-Cre/TGFb1flox/flox mice) in our subsequent studies: These mice displayed a ≥70% reduction of TGFβ1 in plasma. TGFβ1 was reduced in broncho-alveolar lavage fluids during the acute phase of lung injury. The accumulation of collagen and the severity of lung fibrosis was significantly ameliorated in PF4-Cre/TGFb1flox/flox mice. Furthermore, the release of TGFβ1 by platelets was directly triggered by extracellular histones, which are a major component of NETs. The blockade of extracellular histones by antibodies reduced the release of TGFβ1 and other endpoints during lung fibrosis.
Conclusions: Our data suggest that platelet-neutrophil interactions including NET formation are an important pathologic mechanism during lung fibrosis.

ASY 32.4 | Platelets Interact with Neutrophils and Promote Intravascular Neutrophil Activation in Acute Glomerulonephritis

M. Finsterbusch; M.J. Hickey

Monash University, Department of Medicine, Melbourne, Australia

Background: Leukocyte recruitment is central to the pathology of several forms of glomerulonephritis. We previously observed that in acute glomerulonephritis, platelets accumulate in glomerular capillaries and facilitate neutrophil recruitment and neutrophil-dependent injury. However, the nature of the platelet/neutrophil interaction and whether platelets contribute to neutrophil activation in glomeruli is unclear.
Aims: Here, we aimed to characterise platelet-neutrophil interactions in the glomerulus and investigate their role in neutrophil recruitment and activation in acute glomerular inflammation.
Methods: Spinning disc confocal intravital microscopy was used to analyse neutrophil and platelet behaviour in the mouse kidney under resting conditions and in an in situ immune complex model of glomerulonephritis.
Results: Under steady-state conditions, circulating platelets constitutively interacted with glomerular endothelial cells and neutrophils in glomerular capillaries. During inflammation, platelets that interacted with neutrophils, but not other intraglomerular cells, were retained in the glomerulus for longer durations, a response that required P-selectin. Removal of platelets or inhibition of P-selectin diminished neutrophil retention in the glomerulus and reduced neutrophil oxidant generation. To address the role of platelet activation in promoting these neutrophil responses, we inhibited the ADP/P2Y12 and thromboxane/TP receptor pathways demonstrating that neutrophil ROS production, but not recruitment, was dependent on signalling via these pathways. In contrast, inhibition of platelet activating factor only inhibited neutrophil recruitment.
Conclusions: These findings demonstrate that circulating platelets constitutively interact with neutrophils in glomerular capillaries. During inflammation, these interactions are associated with neutrophil retention and activation. Together, these data show a previously undescribed role for platelets in neutrophil activation in the acutely-inflamed glomerulus.

ASY 34.1 | Tissue Factor-PAR2 Signaling Promotes Cutaneous Inflammation in Mice

M.I. Schmidgen[1,2,3]; T. Schmidt[1,3]; N. Lorenz[1,3]; V. Raker[1,3]; J. Haub[1,3]; G. Carlino[2]; S. Reyda[2]; W. Ruf[2]; K. Steinbrink[1,2,3]

[1]University Medical Center Mainz, Dermatology, Mainz, Germany, [2]University Medical Center Mainz, Center for Thrombosis and Hemostasis, Mainz, Germany, [3]University Medical Center Mainz, Institute for Immunotherapy (FZI), Mainz, Germany

Background: Tissue factor plays a crucial role in hemostasis and thrombosis, but its distinct function in supporting protease-activated receptor-2 (PAR2) signaling in the innate and adaptive immune system is poorly understood. PAR2 is activated by a broad array of serine proteases including the TF ligands activated coagulation factors VII (FVIIa) and X (FXa).
Aims: We here focus on TF-PAR2 signaling in cutaneous inflammation of relevance for allergic contact dermatitis in humans.
Methods: We studied contact hypersensitivity (CHS) in a murine model by inhibiting TF with an anti-TF antibody in C57BL/6 wildtype mice, preventing proteolytic activation through PAR2 mutation to abolish all (R38E) or specifically FXa (G37I) signaling, and conditionally deleting PAR2 in $CD11c^{+}$ dendritic cells (DC) and myeloid cells ($CD11c\text{-}cre^{+/-}/PAR2^{flox/flox}$ and $LysMcre^{+/-}/PAR2^{flox/flox}$, respectively). The cutaneous inflammatory reaction was assessed by the ear swelling and analysis of the cutaneous immune cell infiltrate with histology and flow cytometry. The hapten-specific Tc1-mediated T cell response was measured after hapten-specific restimulation *in vitro*, as shown by T cell proliferation and Tc1 cytokine production.
Results: TF inhibition and PAR2 mutation significantly reduce the 2,4,6-trinitrochlorobenzene (TNCB)-induced CHS reaction. In particular, complete insensitivity to proteolytic PAR2 activation (R38E) results in a stronger CHS reduction than the exclusive resistance to the proteolytic effect of FXa (G37I). Interestingly, $CD11c^{+}$ DC derived PAR2 does not influence the allergic inflammatory reaction, whereas PAR2 signaling in myeloid cells enhances the early effector phase of CHS.
Conclusions: TF-PAR2 signaling is a key mediator of inflammation in CHS and may provide novel targets in the topical and systemic treatment of cutaneous inflammatory diseases.

ASY 34.2 | Protease Activated Receptor 2 Cleavage by Coagulation Factor VIIa Contributes to Lung Inflammation

M. Zelaya[1]; C. Graf[1]; W. Ruf[1,2]

[1]Center for Thrombosis and Hemostasis, Johannes Gutenberg University Medical Center, Mainz, Germany, [2]The Scripps Research Institute, Department of Immunology and Microbial Science, La Jolla, United States

Background: Coagulation activation is frequently observed during respiratory viral infections generating double-stranded RNA intermediates that act as toll-like receptor (TLR) 3 ligands. In addition to their roles in coagulation, proteases induce intracellular signaling by

cleavage of cell surface protease-activated receptors (PAR). PAR2 can be activated by both tissue factor (TF)-FVIIa and the ternary TF-FVIIa-FXa complex. To better understand roles of coagulation proteases in infection, we have generated PAR2 mutant mice with selective resistance to activation by coagulation proteases.

Aims: To define the role of PAR2 activating coagulation factors in the recruitment of inflammatory cells to the lung after challenge with the TLR3 agonist poly(I:C).

Methods: Adult mice received three doses of nasal administration of poly(I:C) with 24 h rest period between each administration. The inflammatory response after nasal administration of poly(I:C) was determined by measuring broncho-alveolar lavage (BAL) counts of leukocytes in wild-type and (PAR2 R38E) or FXa (PAR2 G37I) cleavage-resistant PAR2 mutant mice, as well as mice with macrophage-specific coagulation factor deficiency.

Results: Poly(I:C) stimulation of WT and FXa cleavage-insensitive PAR2 G37I mice caused a marked increase in BAL total leukocyte counts and specifically a significant increase in myeloid cell counts (neutrophils, monocytes and macrophages). In contrast, the completely cleavage insensitive PAR2 R38E strain was protected from the increase in inflammatory cell recruitment to the alveolar space. Since we had previously shown that FVII and FX can be expressed by macrophages, we studied mice with myeloid cell deficiency of coagulation factors in this model. Loss of FVIIa expression by macrophages similarly protected mice from lung inflammatory cell recruitment.

Conclusions: These new transgenic animals provide evidence that lung recruitment of inflammatory cells in response to viral challenge depends on TF-FVIIa-PAR2 signaling in myeloid cells.

ASY 34.3 | Effector-memory T cells Attenuate Thrombus Resolution

F. Shahneh[1,2]; N. Luther[2]; B. Kleis-Fischer[2]; C. Reinhardt[1]; H.C. Probst[3]; P. Wenzel[1,4]; K. Schäfer[1,4]; C. Becker[1,2]

[1]Center for Thrombosis and Hemostasis (CTH), University Medical Center Mainz, Johannes Gutenberg-University, Mainz, Germany, [2]University Medical Center Mainz, Johannes Gutenberg-University, Department of Dermatology, Mainz, Germany, [3]Institute for Immunology, University Medical Center Mainz, Johannes Gutenberg-University, Mainz, Germany, [4]Cardiology, University Medical Center Mainz, Johannes Gutenberg-University, Mainz, Germany

Background: Innate immune cells are key effectors in venous thrombus formation and resolution but the participation and role of adaptive immune cells remains largely unexplored.

Aims: Investigating the functional role of T cells in venous thrombosis we observed that DVT recruits effector-memory T cell (T_{EM}) cells into the vein wall and thrombus.

Methods: Deep vein thrombosis (DVT) was induced by 80% flow reduction in the inferior vena cava (IVC) of mice. T cell recruitment and inflammatory activity was followed by flow cytometry, histology and intrathrombotic gene expression in reporter strains and upon depletion of T cells over various time points after DVT.

Results: Using reporter mice we show that DVT-recruited intravenous T_{EM} receive an immediate antigen-independent activation and produce IFN-g *in situ*. We further identify a set of DVT up-regulated cytokines and chemokines that synergize to induce antigen-independent IFN-g-production in $CD4^+$ and $CD8^+$ T_{EM} cells and demonstrate that intravenous T_{EM} activation and IFN-g-production determines neutrophil and monocyte recruitment into the vein wall and attenuates thrombus revascularization and resolution.

Conclusions: Our findings identify innate T cell activation in the vein wall as a key event in post-thrombotic inflammation and suggest T cells as a valid target for therapeutic intervention with the post-thrombotic inflammatory process.

ASY 34.4 | Caveolin-1 is a Novel Key Player in the Crosstalk between Tissue Factor and the IGF-1R

M. Åberg; A. Siegbahn

Uppsala University, Department of Medical Sciences, Clinical Chemistry and Science for Life Laboratory, Uppsala, Sweden

Background: The IGF-1 receptor promotes survival and has also been implicated in the pathogenesis of e.g. cardiovascular disorders and cancer. We recently showed that binding of coagulation factor VIIa (FVIIa) to its receptor tissue factor (TF) induces a transactivation of the IGF-1R in several different cell types. This leads to increased resistance to apoptosis and nuclear translocation of the intact IGF-1R.

Aims: Lipid rafts/caveolae are known modulators of TF/VIIa- and IGF-1R signaling. To clarify the TF/FVIIa transactivation mechanism of the IGF-1R further, we investigated the interplay between TF/FVIIa, IGF-1R, and the caveolae protein caveolin-1 (Cav1).

Methods: The levels, interactions and phosphorylations of proteins were assessed by the Duolink *in situ* proximity ligation assay in intact cells and by and western blot on whole- and fractionated cell lysates. PC3 prostate or MDA-MB-231 breast cancer cells were used as model systems.

Results: Treatment with 10 nM FVIIa, but not PAR1 or PAR2 agonists, resulted in a Src-family dependent phosphorylation of Tyr14 of Cav1 in both PC3 and MDA-MB-231 cells. Cav1 downregulation singlehandedly increased the IGF-1R tyrosine phosphorylation, whereas treatment with a peptide corresponding to amino acids 82-101 of Cav1, i.e. the Cav1 scaffolding domain, blocked the phosphorylation of the IGF-1R by TF/FVIIa. The presence of the Cav1 scaffolding domain peptide consequently broke the TF/FVIIa/IGF-1R signaling pathway, which intact leads to increased resistance to death receptor-induced apoptosis, and blocked the nuclear translocation of the IGF-1R after FVIIa treatment.

Conclusions: Our data shows that Cav1 prevents IGF-1R activation in resting cells via its scaffolding domain, and that this inhibition is terminated by TF/FVIIa-induced phosphorylations of Src and Cav1. We thereby propose Cav1 to be a novel key player in TF/FVIIa signaling by its crucial role in the intra-cellular crosstalk between TF/FVIIa and the IGF-1R.

ASY 38.3 | Septic Conditions Modulate the Level of miRNAs in Platelets and Megakaryocytes that May Contribute to Abnormal Platelet Reactivity

Z. Fejes[1]; T. Orosz[1]; S. Póliska[2]; Z. Czimmerer[2]; G. Nagy[3]; B. Fülesdi[3]; J. Kappelmayer[1]; B. Nagy Jr[1]

[1]*University of Debrecen, Faculty of Medicine, Department of Laboratory Medicine, Debrecen, Hungary,* [2]*University of Debrecen, Faculty of Medicine, Department of Biochemistry and Molecular Biology, Genomic Medicine and Bioinformatics Core Facility, Debrecen, Hungary,* [3]*University of Debrecen, Faculty of Medicine, Department of Anesthesiology and Intensive Care, Debrecen, Hungary*

Background: Bone marrow may be affected in sepsis causing platelet activation, which can lead to thrombotic complications. The molecular mechanisms regulating elevated platelet activation are still not fully known.

Aims: In this study, we examined the expression of platelet miRNAs in patients with sepsis, and miRNAs in megakaryocytes (MKs) were also investigated among *in vitro* septic circumstances.

Methods: MiRNAs were investigated in leukocyte-depleted platelet samples obtained from 20 individuals suffering from sepsis and 24 age- and sex-matched healthy controls. We randomly selected 3 RNA samples from each group, and we first analyzed miRNAs using TaqMan Open Array (ABI). We further quantified miR-223 and miR-26b in all samples by UPL-probe based RT-qPCR (Roche), and target P2RY12 and SELP (P-selectin) mRNAs, respectively, were also analyzed. Platelet activation was studied through measuring surface P-selectin by flow cytometry. To prove the effect of altered miRNA profile of MKs in sepsis, miRNA analysis in MEG-01 and K562 cells (Sigma-Aldrich) was performed after the treatment with recombinant TNF-α (100 ng/mL) and/or LPS (O55:B5, 100 ng/mL) for 4-24 hours at 37°C.

Results: There was augmented platelet activation as P-selectin expression was increased in septic patients (P< 0.001). Sixty-six platelet miRNAs indicated more than two-fold decrease (e.g. miR-223, miR-26b), while 37 (e.g. miR-155) were increased at the same degree in sepsis. Consequently, P2RY12 and SELP mRNA levels were significantly upregulated (P< 0.01) in platelets. Mature MKs from K562 cells by PMA and MEG-01 cells showed enhanced miR-146a and miR-155 levels by TNF-α and/or LPS with significantly lower miR-223 and miR-26b expression after 4 and 24 hours, respectively. In addition, we could also detect their elevated target MK mRNA levels by 24 hours in response to these inflammatory triggers.

Conclusions: Decreased level of platelet miRNAs with elevated target mRNAs may result in enhanced activation of platelets in sepsis.

DIAGNOSTICS AND OMICS

ASY 04.1 | A Microfluidic Model of Hemostasis Sensitive to Platelet Function and Coagulation

R.M. Schoeman; N. Danes; K. Leiderman; K.B. Neeves

Colorado School of Mines, Golden, United States

Background: Most in vitro flow chambers simulate intravascular thrombus formation, which is relevant to thrombotic events. However, relatively few simulate extravascular thrombus formation, which is more pertinent to bleeding diatheses.

Aims: To develop an in vitro model of extravascular thrombus formation whereby a hemostatic thrombus forms under physiological pressure gradients that is sensitive to platelet function and coagulation.

Methods: A microfluidic device was fabricated with an 'H' geometry that includes vascular, injury, and extravascular channels (Fig. 1A). Type I collagen, tissue factor (TF) or collagen-TF were adsorbed on the walls of the injury channel. Citrated whole blood was recalcified in a continuous mixer upstream of the vascular channel. A pressure-based flow controller enabled user-defined control of the pressure gradient across the injury channel. The velocity field and shear stresses were calculated by computational fluid dynamics (Fig. 1B). Thrombus formation was visualized with DiOC6 labeled platelets and Alexa-555 labeled fibrinogen (Fig. 1C). Blood was treated with anti-FVIII or anti-TFPI antibodies, the P2Y12 antagonist 2-MeSAMP, or vehicle prior to the assay.

Results: Collagen and TF acted synergistically to yield a stable thrombus that stops blood loss into the extravascular compartment in 7.5 ± 1.6 min. Platelets first formed a plug that stop blood flow, followed by fibrin polymerization that stabilized the thrombus. Anti-FVIII treatment resulted in an unstable thrombus that did not close the injury. Treatment with a P2Y12 antagonist prolonged the closure time two-fold. Anti-TFPI treatment resulted in a reduced closure time of 3.5 ± 0.5 min.

Conclusions: These data demonstrate a hemostatic model that is sensitive to both coagulation and platelet function that recreates the dynamics of primary and secondary hemostasis. This model can be used to study the biophysical phenomena that regulate coagulopathies and platelet dysfunction that cause bleeding.

ASY 04.2 | Introduction of a National Protocol for Light Transmission Aggregometry in The Netherlands: Results of More than 80 Healthy Volunteers Before and after Standardisation

Y. Henskens[1]; F. van derGraaf[2]; H. Hopman-Kerkhoff[3]; C. Hudig[4]; M. de Maat[5]; M. Schoorl[6]; J. Slomp[7]; A. Stroobants[8]

[1]Maastricht University Medical Centre+, Maastricht, The Netherlands, [2]Maxima Medisch Centrum, Veldhoven, The Netherlands, [3]VUMC, Amsterdam, The Netherlands, [4]Lab West, The Hague, The Netherlands, [5]Erasmus MC, Rotterdam, The Netherlands, [6]Noordwest Ziekenhuisgroep, Alkmaar, The Netherlands, [7]Medlon, Location Medisch Spectrum Twente, Enschede, The Netherlands, [8]Academic Medical Center, University of Amsterdam, Amsterdam, The Netherlands

Background: Light Transmission Aggregometry (LTA) is considered the gold standard method for evaluation of platelet function. The SSC Platelet Physiology published a guideline in order to standardize LTA. The Society of Hematological Laboratories in The Netherlands (VHL) has set a goal for 2017, namely to reduce variability in LTA results by stimulating all laboratories to uniform their methods.

Aims: To establish a national LTA procedure, based on the SCC 2013 guideline, and to compare LTA results of more than 80 healthy volunteers from 8 hospital laboratories, before (2013) and after (2016) standardisation.

Methods: The SSC guideline was adapted to a national procedure. Almost all advices of the SSC were followed up e.g.: no adjustment of PRP, citrate concentration 109 mM, 21 needle gauge, fasting, resting time for whole blood and PRP, centrifugation time and speed and agonist concentrations. Results of healthy volunteers were collected in 2013 (before standardisation) and in 2016 (after standardisation) in respectively 9 and 8 hospital laboratories including more than 80 results of healthy volunteers per year (maximal aggregation %) on 4 different analysers (Chronolog, PAP-8, APACT and AggRam) using their own choice reagent brand.

Results: Before standardisation a large diversity in pre-analytical procedures and agonist concentrations were used. After standardisation all participants used the same agonist concentrations (Table 1) and (pre)analytical procedure. Median (IQR) for maximal aggregation per agonist is shown in Table 1.

Strikingly, variation increased after standardisation for ADP but decreased for collagen low and ristocetin low. Analyser specific differences were detected e.g. for ADP low Figure 1.

Conclusions: A standardised Dutch procedure for LTA, based on the SSC guideline, does not result in a smaller variability in healthy volunteers for all agonists.

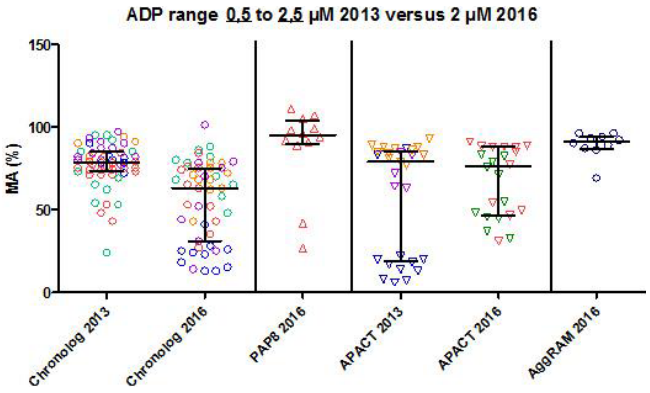

FIGURE 1 Comparison of ADP maximal aggregation of healthy volunteers between 2013 and 2016

ASY 04.4 | Novel Integrin αIIbβ3 and GPIbα Coatings that Feature Anti-fouling Properties for Platelet Research and Clinical Diagnostics

M.A.D. Neves[1,2]; Y. Wang[1,2]; G. Zhu[1,2]; R.C. Gallant[1,2]; T.W. Stratton[1,2]; M. Thompson[2]; H. Ni[1,2,3]

[1]St. Michael's Hospital, Toronto, Canada, [2]University of Toronto, Toronto, Canada, [3]Canadian Blood Services, Toronto, Canada

Background: Platelets play key roles in thrombosis and hemostasis. Fibrinogen (Fg) binding to integrin αIIbβ3 (GPIIbIIIa) has been considered to be required for platelet aggregation. However, we found platelet aggregation persists even in the absence of Fg and VWF, suggesting unidentified αIIbβ3 ligands are involved in thrombosis. Additionally, ligands for GPIbα have not been fully explored.

TABLE 1 Median and IQR of maximal aggregation in 2013 and 2016 in healthy volunteers

Agonist	2013 concentrations	2013 n	2013 median (IQR)	2016 concentration	2016 n	2016 median (IQR)
ADP low (µM)	0.5;1;2;2.5	85	79 (70-85)	2	96	72 (45-88)
ADP intermediate (µM)	4;5	43	86 (82-90)	5	98	84 (72-87)
Ristocetin low (mg/mL)	0.25;0,5;0.6	86	9 (4-14)	0.5-0.7	55	7 (3-12)
Ristocetin high (mg/mL)	1;1.2; 1.25	138	92 (88-94)	1.2	86	92 (88-98)
Collagen low (µg/mL)	1;1.25; 2	102	85 (79-89)	2	86	89 (83-92)
Collagen high (µg/mL)	4, 5, 10	95	87 (84-91)	5	66	88 (80-93)
Epinephrine µM	5	47	80 (75-85)	5	53	87 (73-91)
Arachidonic acid (mM)	0.5; 1; 1.5; 1.6	70	84 (79-86)	1	64	89 (80-92)

Aims: Development of αIIbβ3- and GPIbα-bound monolayer coatings that can be applied to any hydroxyl (-OH) terminated surface (e.g. glass, metals and plastics).

Methods: Surface- and bio-chemistry synthesis.

Results: Both coatings are based on a trimethoxysilyl diethylenetriamine (DETA) monolayer which forms covalent bonds to the underlying -OH surface, facilitates covalent linkage of either αIIbβ3 or GPIbα, and is anti-fouling (resistance to non-specific protein adsorption). These two coatings were synthesized on planer (glass slide) and spherical (3 μm silica bead) surfaces. GPIbα surfaces bound both conformational and linear epitope specific anti-GPIbα mAbs. αIIbβ3 coated surfaces bound Fg as well as conformational and linear epitope specific mAbs. Furthermore, αIIbβ3 coated beads were incorporated into murine wild type platelet aggregates and VWF/Fg $^{-/-}$ platelet aggregates, demonstrating the interaction with the yet unidentified "x-ligand" responsible for VWF/Fg independent aggregation.

Conclusions: These data indicate αIIbβ3 and GPIbα adopt ligand binding conformations when immobilized on DETA. Moreover, DETA remarkably resists non-specific interactions and maintains a very low background signal regardless of detection method, even without employing a blocking agent (e.g. BSA). This work presents the first use of anti-fouling organic-monolayer attached platelet surface receptors and demonstrates the enormous potential that these synthetic coatings possess in platelet research. Identification of novel αIIbβ3 and GPIbα ligands and evaluation of these coatings for auto- and allo-antiplatelet antibody detection remains ongoing.

ASY 25.1 | Microparticles as a Biomarker to Detect Thrombosis in Patients with Implanted Ventricular Assist Devices

T. Torres[1]; J. Walenga[1]; B. Menapace[1]; E. Coglianese[2]; W. Jeske[1]; E. Kumar[3]; V. Escalante[1]; J. Schwartz[1]; M. Bakhos[1]

[1]Loyola University Medical Center, Thoracic and Cardiovascular Surgery, Maywood, United States, [2]Loyola University Medical Center, Heart Failure Section of Cardiology, Maywood, United States, [3]Loyola University Medical Center, Pathology, Maywood, United States

Background: Left ventricular assist devices (LVADs), increasingly common for heart failure management, have associated thrombosis as a major cause of mortality. LVAD thrombosis is detected by elevated plasma lactate dehydrogenase levels (LDH); however, this method has limited sensitivity. Sub-micron cellular microparticles (MPs) are derived by outward blebbing of the plasma membrane in response to hemostatic activation, inflammation, altered rheology or infection.

Aims: To determine whether MPs are more sensitive than clinical parameters to predict thrombotic events in LVAD implanted patients.

Methods: Citrated blood samples were collected periodically from 26 consented patients implanted with a Thoratec HeartMate II LVAD and once from 12 healthy controls. Plasmas were processed by ultracentrifugation to pellet MPs which were quantitated by flow cytometry using polystyrene beads < 1μm, PKH67 (biological membrane dye), and monoclonal antibodies CD41-PE (platelets), CD45-PE [leukocytes (WBCs]), CD146-PE [endothelium (ECs)], CD235-PE [erythrocytes (RBCs)]. Documented thrombosis, LDH, platelet count, aPTT, D-dimer, fibrinogen, INR were recorded.

Results: MP levels in patients without thrombosis remained below the 500 MP normal count threshold. Patients with thrombotic events had elevated levels (2000-9000 MPs) a median 50 days (35-391 days) prior to LDH elevation. MP levels reverted to normal with resolution of thrombosis. Platelet and RBC MPs were elevated earlier and greater than WBC and EC MPs, and occasionally only RBC MPs were elevated when thrombosis was present. There was no obvious association with thrombosis for platelet count, D-dimer, INR time out of therapeutic range or any other clinical parameter.

Conclusions: Blood cell-derived MP levels rise above the normal threshold weeks prior to when common clinical parameters indicate an LVAD-associated thrombotic event, suggesting a role for this predictive biomarker.

ASY 25.3 | Analysis of Platelet Polyphosphate

Z. Pons Vila[1]; L. Labberton[1]; T. Renné[1,2]

[1]Karolinska Institutet, Molecular Medicine and Surgery, Stockholm, Sweden, [2]Institute of Clinical Chemistry and Laboratory Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Background: Platelet polyphosphate is an inorganic procoagulant polymer of orthophosphate units that is stored in dense granules and is released upon platelet activation. Polyphosphate has been shown to have a critical function for thrombosis making the polymer an attractive biomarker.

Aims: Here, we describe an assay to measure polyphosphate on human platelets and show that procoagulant platelets expose long chain polyphosphates on their surfaces.

Methods: Recombinant Escherichia coli-expressed exopolyphosphatase deletion mutant PPX_Δ12 that lacks the enzymatic domain was labeled with fluorescent Alexa488 dye and was used as a polyphosphate probe in flow cytometry.

Results: PPX_Δ12-Alexa488-signal dose-dependently increased with synthetic long-chain polyphosphate binding to platelets. Both exopolyphosphatase treatment and polyphosphate pre-incubation abolished PPX_Δ12-Alexa488 binding to polyphosphate on platelets. In contrast, short-chain polyphosphate that was found in the supernatant of activated platelets, did not bind to platelet surfaces. Ion exchange chromatography revealed that platelets contain two pools of polyphosphate of 60-100 and >500 phosphate units chain length, respectively. Stimulation of platelets with thrombin receptor agonist Trap6, and P2Y12 receptor activator ADP increased polyphosphate accumulation on platelet surfaces and PPX_Δ12-Alexa488 signal in a dose-dependent manner indicating that long chain polyphosphates are retained on activated platelet surfaces.

Conclusions: This study indicates that long-chain polyphosphate is exposed on platelet plasma membranes while short chain molecules are released into the supernatant. Our assay presents a promising

diagnostic assay to measure polyphosphates on human platelets and in platelet-rich plasma. Future investigations will aim to determine if polyphosphate can be used as a novel biomarker of thrombosis.

validation of these results in a larger population would open the possibility of implementing such a marker in clinical practice.

ISCIII y FEDER (P14/00253), Fundación Séneca 19873/GERM/15

ASY 25.4 | NETosis Markers Predict Adverse Events in Anticoagulated Patients with Atrial Fibrillation

A.B. Arroyo Rodríguez[1]; J.M. Rivera Caravaca[1]; A.M. De los Reyes García[1]; P. Valledor[1]; R. Teruel Montoya[1]; V. Vicente[2]; C. Martínez[1]; R. González Conejero[1]; V. Roldán[1]

[1]Servicio de Hematología y Oncología Médica, Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, Murcia, Spain, [2]Servicio de Hematología y Oncología Médica, Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, CB15/00055-CIBERER, Murcia, Spain

Background: Thrombogenesis in atrial fibrillation (AF) is multifactorial. Adverse cardiovascular events (ACEs) occur in ~4% of AF patients undergoing oral anticoagulation therapy. Recently, the relationship between neutrophil extracellular trap (NET) formation and thrombogenesis has been described.

Aims: To investigate plasma cell free DNA levels (cfDNA) and neutrophil elastase (NE) as prognostic biomarkers of ACE in anticoagulated patients with AF.

Methods: We included 248 healthy volunteers (59% male, median age 46, range 18-95) and 485 AF patients (53% male, median age 76, range 71-81) with stable anticoagulation for 6 months and a follow-up of 8 years. ACEs were stroke (ischaemic/embolic), ACS, acute HF and global or vascular death. cfDNA was measured with Sytox Green. NE activity was determined by ELISA. Data were analyzed using Cox regression.

Results: In controls, cfDNA was uniform up to 75 years, increasing significantly above that age [< 75 (n =221): 50ng/mL±0.02 vs. ≥75 (n =26): 80ng/mL±0.01, p< 0.001]. Therefore, we selected patients < 75 years [n=336, 62% males, age 69(63-72)]. cfDNA was higher in patients than in controls: 70 ng/mL±0.05 (p< 0.05). During follow-up, 50 patients suffered from thrombosis/vascular events; 27 stoke/embolism; 73 global death. cfDNA levels were not associated with ACEs. NE activity, which showed a significant correlation with cfDNA in patients (rho=0.261; p< 0.001), was also higher in patients than in controls (median 37.8 *vs.* 27.4 ng/ml; p< 0.001). Morever, NE activity was significantly associated with: combined ACE [2.2 (1.24-3.99), p=0.007], stroke [2.6 (1.21-5.56), p=0.01], global death [2.2 (1.35-3.61), p=0.001] and vascular death [5.3(1.26-22.33), p=0.02].

Conclusions: Besides providing prognostic information in AF patients, NE plasma activity might also influence the occurrence of ACE. Thus,

ASY 38.1 | Plasma miRNA Expression as Risk Marker of Stroke in Patients with Atrial Fibrillation

R. Teruel-Montoya[1,2]; A.B. Arroyo[1]; P. Valledor[1]; M.A. de los Reyes-García[1]; N. García-Barbera[1]; V. Vicente[1,2]; F. Marin[3]; V. Roldán[1]; R. González-Conejero[1]; C. Martínez[1]

[1]Servicio de Hematología y Oncología Médica, Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, Murcia, Spain, [2]CB15/00055-CIBERER, Murcia, Spain, [3]Hospital Virgen de la Arrixaca, IMIB-Arrixaca, Murcia, Spain

Background: Atrial fibrillation (AF) is a highly prevalent disorder that contributes to increased mortality and morbidity. The use of oral anticoagulation (OAC) reduces stroke risk, even using risk stratification scales such as CHA2DS2-VASc score, AF patients with OAC suffer from stroke. Thus, searching new biomarkers is needed to improve the clinical management of these patients. In recent years miRNAs, have become important players in cardiovascular biology.

Aims: To evaluate the expression of plasma miRNAs in AF patients with OAC and to investigate their prognostic value for the risk of stroke.

Methods: From 789 AF patients with stable OAC for 6 months (INR=2-3) with a median follow-up of 2888 days, we randomly selected 10 patients, who had suffered from stroke and 10 age and sex-matched patients who did not developed stroke during the same follow-up. Samples were obtained when AF was diagnosed. MiRNAs were purified using Nucleo Spin miRNA Plasma Kit (Macherey-Nagel). *Plasma focus miRNAs PCR panel V4* (Exiqon) was used to evaluate miRNA expression and GraphPad Prism 5 was employed to analyze data.

Results: Using *t*-test Sidak-Bonferroni, we observed that miR-328 and miR-22-3p, had up-regulated levels in stroke patients compared to the no-stroke group (*p*-value< 0.1; fold>1.5). Confirmation of the arrays in the same cohort was performed with individual qRT-PCRs. Only miR-22-3p remained statistically elevated in stroke patients (*p*-value=0.017; fold=2.13).

Conclusions: AF patients who suffered from stroke, showed high levels of miR-22-3p. This miRNA has been associated with hypertrophy and cardiac remodeling. These data suggest that miR-22-3p could be a potential prognostic marker of stroke and could provide additional information to current risk stratification schemes (such as CHA2DS2-VASc) to improve the clinical management of AF patients.

FIBRINOLYSIS & PROTEOLYSIS

ASY 07.1 | Deriving the Full Atom Structure for the Coagulation Factor XIII A_2B_2 Hetero-tetrameric Complex by Molecular Modeling Using Guiding Constraints Based on Mass Spectrometric Analysis of the Complex

S. Singh[1]; A. Nazabal[2]; V. Ivaskevicius[1]; J. Dodt[3]; H. Philippou[4]; J. Oldenburg[1]; A. Biswas[1]

[1]*Institute of Experimental Haematology and Transfusion Medicine, University Clinic Bonn, Bonn, Germany,* [2]*CovalX, Zurich, Switzerland,* [3]*Paul Ehlrich Institute, Langen, Germany,* [4]*Leeds Institute of Cardiovascular and Metabolic Medicine LIGHT Laboratories, University of Leeds, Leeds, United Kingdom*

Background: The coagulation Factor XIII (FXIII) is a heterotetramer composed of two catalytic A and two protective/regulatory B subunits. The structure of this heterotetramer complex is not known.

Aims: To use cross-linking chemistry in conjunction with High-Mass MALDI mass spectrometry and nLC Orbitrap MS/MS analysis to determine inter and intra-subunit interface residues within the $FXIIIA_2B_2$ heterotetramer complex and then to use these residues as guiding constraints to generate an accurate all atom model of the complex.

Methods: The $FXIIIA_2B_2$ complex was purified from the plasma concentrate Fibrogammin by size exclusion chromatography. The intact purified complex was subjected to chemical cross-linking and High-Mass MALDI MS analysis to determine the stoichiometry and molecular weight of the intact protein complex. The cross-linked protein complex was subjected to proteolysis using five different enzymes (Trypsin, Chymotrypsin, Elastase, Thermolyse and ASP-N). The peptides generated were injected in an nLC chromatographic system coupled with an Orbitrap mass spectrometer. After MS/MS analysis, XQuest and Stavrox softwares were used to identified the interlink peptides of the complex. The residues identified were used as guiding constraints to dock a threaded model of the $FXIIIB_2$ subunit on the repaired (gaps and loops filled) crystal structure of the $FXIIIA_2$ subunit. The resulting model was subjected to classical MD simulation to check for stability.

Results: The High-Mass MALDI MS analysis allowed the detection of the intact cross-linked protein complex, its molecular weight and its stoichiometry. Post proteolysis more than 85% of the sequence of $FXIIIA_2B_2$ complex is covered by the peptide mass fingerprint. The model generated from the interface residues detected in the MS coverage is very stable as observed from a long MD simulation.

Conclusions: We have been able to generate an accurate all atom model of the $FXIIIA_2B_2$ heterotetramer based on experimental data.

ASY 07.2 | Reciprocal Inter-tissue Regulation of Factor XIII-A and -B Subunits Determines Factor XIII Levels in Plasma

J.R. Byrnes; A.S. Wolberg

University of North Carolina at Chapel Hill, Department of Pathology and Laboratory Medicine, Chapel Hill, United States

Background: Plasma coagulation factor XIII (FXIII) is composed of two zymogen FXIII-A subunits and two carrier FXIII-B subunits ($FXIII\text{-}A_2B_2$). FXIII-A is produced in bone marrow-derived cells, whereas FXIII-B is synthesized by hepatocytes. FXIII-B stabilizes FXIII-A; consequently, deficiency in either subunit is associated with bleeding. Interestingly, FXIII-A-deficient mice and humans have decreased levels of FXIII-B. In humans, therapeutic infusion of recombinant $FXIII\text{-}A_2$ ($rFXIII\text{-}A_2$) increases FXIII-B levels. The mechanism mediating this inter-tissue reciprocal regulation has not been defined.

Aims: Determine how FXIII-A regulates FXIII-B levels.

Methods: FXIII-B protein and mRNA were measured using Western blotting and RT-qPCR, respectively. Liver proteomes were compared using label-free quantitative mass spectrometry and KEGG pathway analysis.

Results: $rFXIII\text{-}A_2$ treatment increased FXIII-B production in two human hepatocellular carcinoma lines (HepG2 and Huh7), but did not promote cell growth or increase FXIII-B stability. *F13a*$^{-/-}$ mice infused with $rFXIII\text{-}A_2$ showed increased FXIII-B levels within 3-6 hours, and by 24 hours, FXIII-B levels were similar to levels in *F13a*$^{+/+}$ mice. *F13b* mRNA isolated from treated cell cultures and livers of infused mice was not elevated relative to untreated controls, suggesting FXIII-A did not enhance *F13b* gene expression. Proteomic profiling of liver lysates from *F13a*$^{+/+}$, *F13a*$^{-/-}$, and $rFXIII\text{-}A_2$-infused *F13a*$^{-/-}$ mice identified unique proteins that were significantly upregulated in both *F13a*$^{+/+}$ and $rFXIII\text{-}A_2$-infused *F13a*$^{-/-}$ mice relative to *F13a*$^{-/-}$ mice. Pathway analysis reveals several of these proteins regulate RNA processing.

Conclusions: FXIII-A and FXIII-B subunits show reciprocal regulation in mice and humans. FXIII-B promotes FXIII-A stability in circulation, while FXIII-A enhances FXIII-B production, likely via post-transcriptional processing. Identification of this unique regulatory mechanism exposes newly-recognized inter-tissue crosstalk critical for hemostasis.

ASY 07.3 | Plasma-, but Not Platelet-factor XIII Promotes Red Blood Cell Retention in Contracted Clots and Mediates Clot Size during Venous Thrombosis

S. Kattula[1]; J.R. Byrnes[1]; S.M. Martin[2]; B.C. Cooley[1]; M.J. Flick[3]; A.S. Wolberg[1]

[1]*University of North Carolina at Chapel Hill, Department of Pathology and Laboratory Medicine, Chapel Hill, United States,* [2]*College of New Jersey, Department of Chemistry, Ewing Township, United States,* [3]*Cincinnati Children's Hospital Medical Center, Division of Experimental Hematology and Cancer Biology, Cincinnati, United States*

Background: The transglutaminase factor XIII (FXIII) plays a seminal role in venous thrombosis by crosslinking fibrin α-chains and promoting

red blood cell (RBC) retention in contracted clots. However, the contributions of plasma ($FXIII_{plasma}$)- vs. platelet ($FXIII_{plt}$)-derived FXIII to clot composition, thrombosis, and hemostasis remain undefined.

Aims: Determine the role of $FXIII_{plasma}$ and $FXIII_{plt}$ in clot contraction, composition, and size. Identify the level of FXIII deficiency that reduces thrombus weight without increasing bleeding.

Methods: Thrombin generation, FXIII activation, and fibrin crosslinking were measured in whole blood, platelet-rich plasma (PRP) and reconstituted whole blood and PRP from *F13a*$^{+/+}$, *F13a*$^{+/-}$, and *F13a*$^{-/-}$ mice by calibrated automated thrombography and western blotting. Mice were subjected to inferior vena cava thrombosis, as well as tail transection and saphenous vein bleeding assays.

Results: FXIII activation and fibrin crosslinking were delayed in *F13a*$^{+/-}$ PRP relative to *F13a*$^{+/+}$ PRP, but thrombin generation and clot contraction were similar in PRP across genotypes. In reconstituted assays, PRP containing $FXIII_{plasma}$, but not $FXIII_{plt}$, formed fibrin α-chain crosslinks. Similarly, the absence of $FXIII_{plasma}$, but not $FXIII_{plt}$, decreased RBC retention in reconstituted whole blood contracted clots, resulting in smaller clots. In vitro and in vivo, FXIII deficiency reduced thrombus weight in a gene dose-dependent manner. In hemostatic challenges, *F13a*$^{-/-}$, but not *F13a*$^{+/-}$, mice had prolonged tail bleeding times, whereas no genotype-dependent difference was observed following saphenous vein puncture.

Conclusions: FXIII deficiency results in a gene dose-dependent decrease in thrombus weight without altering thrombin generation or platelet contraction. $FXIII_{plasma}$, but not $FXIII_{plt}$, mediates fibrin crosslinking, promoting RBC retention and increased thrombus weight. Imposition of mild-to-moderate FXIII deficiency may reduce venous thrombosis without simultaneously increasing bleeding risk.

ASY 07.4 | FXIII on Cold-stored Platelet Surface Enhance Clot Contraction and Anti-fibrinolysis

P.M. Nair[1,2]; X. Wu[2]; A. Wells[3]; J.D. Keesee[2]; L. Bin[2]; C. Lafleur[2]; A.P. Cap[2]; A.K. Ramasubramanian[4]

[1]*University of Texas at San Antonio, Department of Biomedical Engineering, San Antonio, United States,* [2]*U.S. Army Institute of Surgical Research, Coagulation and Blood Research, Ft. Sam Houston, United States,* [3]*U.S. Army Institute of Surgical Research, Dental and Craniofacial Trauma Research, Ft. Sam Houston, United States,* [4]*San José State University, Department of Biomedical, Chemical and Materials Engineering, San José, United States*

Background: Currently, platelets (PLT) for transfusion are stored at room temperature (22°C, RT) for up to 5 days, although recently FDA clarified that PLT stored in cold (4°C) for up to 72 h may be used for active hemorrhage. We have previously demonstrated that 4C-stored PLT have significantly better metabolic reserves, hemostatic responses to agonists and inhibitors, and clot strength, compared to RT-stored PLT. Recently, we discovered a novel mechanism of fibrinogen-mediated plasma-FXIII binding to 4C-stored PLT surface as the principal contributor to enhanced clot strength.

Aims: To test the hypothesis that increased FXIII activity on 4C-stored PLT surface will increase fibrin cross-linking, clot contraction, and anti-fibrinolytic activity.

Methods: Clinical clot retraction assay in normal, FXIII-deficient plasma or with FXIII inhibitor was employed along with immunohistochemistry, electron microscopy and serum analysis to investigate structure and composition of retracted clots. Image analysis was used to quantify porosity, morphological parameters, and PLT-fibrin interaction from clot histology. Lytic properties in tPa were measured by ROTEM. (n=4,*P=0.05).

Results: Clots formed by 4C-stored PLTs were heavier than those from RT-stored PLTs, (Fig. 1A) with a highly organized structure compared to a disintegrated structure in RT PLT clots (Fig. 1B). 4C-stored PLT, but not RT-stored PLT, actively interacted with fibrinogen and formed nucleating centers for fibrin formation and cross-linking yielding clots with denser, thinner and unswerving fibrin network which offer lytic resistance to tPa (Fig. 1C). Results with FXIII-deficient plasma and FXIII inhibitor corroborate that plasma FXIII binding to 4C-stored PLT surface is a key regulator of these processes.

Conclusions: We have shown that FXIII-mediated fibrin crosslinking on 4C-stored PLT surface improve contraction and mitigate fibrinolysis forming strong and stable clots necessary to combat traumatic hemorrhage.

ASY 15.1 | The Antithrombotic Protein C Activator E-WE Thrombin Supports Fibrinolysis by Inhibiting TAFI Activation

B. Markway[1]; M. Wallisch[1,2]; N. Verbout[1,2]; C. Lorentz[1,2]; M. Carris[1]; O. McCarty[2]; A. Gruber[1,2]; E. Tucker[1,2]

[1]*Aronora, Inc., Portland, United States,* [2]*Oregon Health & Science University, Portland, United States*

Background: Thrombin contributes to clot stabilization by activating thrombin-activatable fibrinolysis inhibitor (TAFI). The thrombin

mutant, E-WE thrombin, has diminished activity toward procoagulant substrates but can still activate protein C when bound to thrombomodulin (TM), making it a potent antithrombotic enzyme. Activation of TAFI by thrombin also requires TM but the specificity of E-WE thrombin for TAFI is unknown.

Aims: The aim of this study was to investigate whether E-WE thrombin activates TAFI and to determine whether E-WE thrombin can act as a profibrinolytic agent through competitive inhibition of thrombin-mediated TAFI activation.

Methods: The ability of E-WE thrombin to activate TAFI was evaluated using Western blot and quantitative colorimetric assays to measure hippuric acid generation by activated TAFI. For both experiments, purified TAFI was incubated with wild-type (WT) thrombin and/or E-WE thrombin with or without rabbit TM for increasing times before downstream analysis. Lysis of a formed plasma clot was measured by recording the time until plasma liquefied again.

Results: Western blotting and quantitative assays showed that E-WE thrombin was a poor activator of TAFI compared to WT thrombin in the presence of TM. Whereas WT thrombin activated TAFI within minutes, we found no evidence of equimolar E-WE thrombin-mediated activation until nearly 1 hr. Furthermore, E-WE thrombin concentration-dependently inhibited thrombin-mediated activation of TAFI. Finally, when both E-WE thrombin and tPA were incorporated within plasma clots, lysis was accelerated by up to 74% compared with the addition of tPA alone.

Conclusions: Our data suggest that the human thrombin analog, E-WE thrombin, which is a selective protein C activator under development for treating acute thrombotic emergencies, also may act as a profibrinolytic agent through inhibition of TAFI activation. These data suggest that co-administration of E-WE thrombin with tPA may improve the efficacy of thrombolysis.

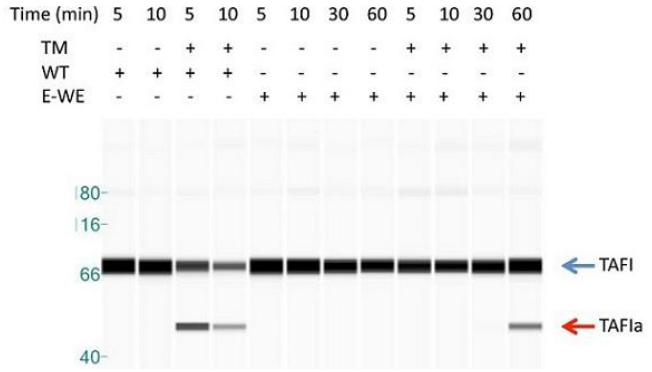

FIGURE 1 E-WE thrombin is a poor activator of TAFI compared to WT thrombin

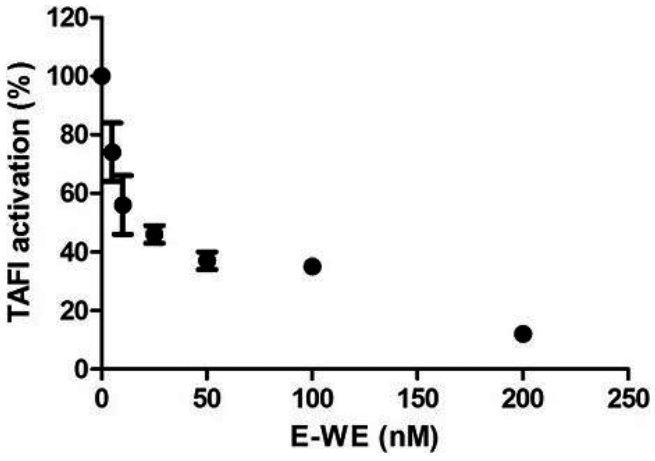

FIGURE 2 E-WE thrombin dose-dependently inhibits thrombin-mediated activation of TAFI

ASY 15.2 | Plasminogen Activator Inhibitor 1 is Retained on the Surface of Activated Platelets in a $\alpha IIb\beta_3$ and Fibrin Dependant Manner

G.B. Morrow; N.J. Mutch; C.S. Whyte

University of Aberdeen, Institute of Medical Sciences, Aberdeen, United Kingdom

Background: Plasminogen activator inhibitor 1 (PAI-1) is the principal physiological inhibitor of tissue-type plasminogen activator and urokinase. Platelet a-granules harbour the primary pool of PAI-1, which is secreted upon activation.

Aims: To analyse the retention of platelet-derived PAI-1 on the activated platelet membrane.

Methods: Platelets activated with collagen ± thrombin receptor activator peptide 6 (TRAP-6) or thrombin were analysed for PAI-1 by ELISA and activity assay. Tirofiban was included to inhibit $\alpha IIb\beta_3$ or fibrin polymerisation blocked with Gly-Pro-Arg-Pro (GPRP). Flow cytometry and confocal microscopy were performed using fluorescently-labelled antibodies to PAI-1, fibrin(ogen), $\alpha IIb\beta_3$ and the α-granule marker, P-selectin. Chandler model thrombi lysis and Hemacore analysis was performed with platelet-rich plasma ± a neutralising antibody to PAI-1 and lysed with tPA.

Results: Real-time lysis of platelet-rich clots revealed a significant increase upon inhibition of PAI-1 (20 ± 13 min vs. >60 min), which was mirrored by a 3-fold increase in the lysis rate of Chandler model thrombi. The majority of PAI-1 antigen was detected in the platelet releasate, however ~20% was associated with the membrane fraction. Flow cytometry revealed an increase in membrane PAI-1 with TRAP-6 stimulation, however maximum exposure was observed with thrombin; suggesting a role for fibrin in PAI-1 retention. Tirofiban and GPRP attenuated membrane-bound PAI-1 on activated platelets. Similarly, PAI-1 antigen was reduced in the membrane fraction by tirofiban (73 ± 7%) and GPRP (64 ± 3%), as quantified by ELISA. PAI-1 was observed as a "cap" on phosphatidylserine positive platelets, co-localizing with fibrin(ogen), $\alpha IIb\beta_3$ and P-selectin. Blocking $\alpha IIb\beta_3$ and fibrin polymerisation completely abrogated PAI-1 activity associated with the membrane fraction.

Conclusions: Our data reveals a striking dependence for $\alpha IIb\beta_3$ and fibrin in modulating the retention of active, platelet-derived PAI-1 on the surface of activated platelets.

ASY 15.3 | The Signaling Lipid Sphingosine-1-Phosphate (S1P) Regulates Expression and Secretion of the Plasminogen Activator Inhibitor-1 (PAI-1) in Differentiated Fat Cells

V. Witschel; A. Böhm; C. Joseph; E. Moritz; B.H. Rauch

Universitätsmedizin Greifswald, Institut für Pharmakologie, Greifswald, Germany

Background: The versatile lipid signaling molecule sphingosine-1-phosphate (S1P) is a regulator of immune functions such as utilization of immune cells and local inflammatory responses. It has also been suggested as a link between inflammation and coagulation as platelets generate and release large amounts of S1P upon activation. S1P regulates expression of the protease-activated receptors (PARs) to enhance cellular responses to thrombin in monocytes and has been implicated in mechanisms of platelet activation.

Aims: Since hyperlipidemia and obesity are typical risk factors for thrombosis, this study investigates possible effects of S1P on prothrombotic gene expression in adipocytes in vitro.

Methods: Murine 3T3-L1 fibroblasts were differentiated with MDI (methylisobutylxanthine, dexamethasone, insulin) induction medium. Gene expression of adiponectin, PAR1-4, the S1P receptors S1PR1-5 and the anti-fibrinolytic factor plasminogen activator inhibitor-1 (PAI-1) were determined by RT-PCR. PAI-1 protein was measured by Western blotting and ELISA.

Results: MDI-induced differentiation resulted in characteristic phenotypical changes as well as a 600-fold increase in adiponectin expression. Cell viability was maintained and apoptosis not significantly elevated. Expression of the PARs and S1PRs was reduced in differentiated adipocytes which fitted with cellular senescence. Incubation of adipocytes with S1P (0.3 to 10 μM) resulted in a significant upregulation of PAR-1 (2.7-fold) and PAI-1 (8-fold) mRNA. Conversely, thrombin (0.1 to 3.0 units/mL) induced expression of S1PR3, but not of the other S1P receptors. S1P also highly significantly induced PAI-1 protein expression and secretion to the culture media (about 4-fold). This was attenuated by pharmacological inhibition of S1PR2 and -3, but not by a S1PR1 inhibitor.

Conclusions: S1P regulates expression and secretion of PAI-1 in adipocytes in vitro. This mechanism may modulate the pathogenesis of thrombosis in individuals at risk such as in obesity or metabolic syndrome.

ASY 15.4 | CPU Inhibition with AZD9684: Effects on Fibrinolytic Rate in Different in vitro Models

D. Leenaerts[1]; S. Loyau[2]; J.C. Mertens[1]; M. Jandrot-Perrus[2]; D. Hendriks[1]

[1]University of Antwerp, Department of Pharmaceutical Sciences, Laboratory of Medical Biochemistry, Antwerp, Belgium, [2]University Paris Diderot, UMRS-1148 INSERM, Laboratory for Vascular Translational Science, Paris, France

Background: Carboxypeptidase U (CPU, CPB2, TAFIa) is a basic carboxypeptidase able to downregulate fibrinolysis.

Aims: At this moment, little is known about the contribution of the CPU system to clot resistance in more advanced hemostatic models that include components such as blood cells and shear stress. The aim of this study is to evaluate the effect of AZD9684, a small molecule CPU inhibitor, in different *in vitro* systems with an increasing grade of complexity.

Methods: The contribution of the CPU system was evaluated in the following systems: I) standard plasma clot lysis; II) front lysis with confocal microscopy in platelet free and platelet rich plasma; III) thromboelastometry in whole blood (ROTEM); IV) microfluidic system with whole blood under arterial shear stress. All experiments were carried out in the absence or presence of AZD9684 (5 μM) in at least 5 healthy volunteers. In the experiments without inhibitor, samples were collected in order to assess proCPU (TAFI, proCPB2) consumption. Data are presented as mean ± SEM.

Results: During standard *in vitro* clot lysis in plasma, addition of AZD9684 resulted in a 22.1 ± 4.2% faster lysis. In ROTEM experiments we also found a clear acceleration of fibrinolysis. Lysis onset time decreased by 41.6 ± 3.9% in the presence of the inhibitor. Additionally, for both clot lysis and ROTEM a dose-dependent response of AZD9684 was observed and a clear consumption of proCPU was detected. Front lysis experiments in PFP resulted in a 33.6 ± 2.6% faster lysis in the presence of AZD9684. In PRP however only a tendency towards faster lysis was observed. Finally, fibrinolytic rate was accelerated by 15% in the microfluidic system when AZD9684 was added. No effect on platelet binding and DNA-content were observed.

Conclusions: Overall these experiments provide evidence that the CPU system is able to modulate fibrinolysis in complex biological systems. What the clinical significance of this observation is, requires more research.

ASY 28.1 | Fibrin Protofibril Structure at the Atomic Level

V. Barsegov[1,2]; A. Zhmurov[2]; A.D. Protopopova[3]; R.I. Litvinov[3,4]; P. Zhukov[2]; A.R. Mukhitov[3]; J.W. Weisel[3]

[1]University of Massachusetts at Lowell, Department of Chemistry, Lowell, United States, [2]Moscow Institute of Physics and Technology, Dolgoprudny, Russian Federation, [3]University of Pennsylvania, Perelman School of Medicine, Department of Cell & Developmental Biology, Philadelphia, United States, [4]Institute of Fundamental Medicine and Biology, Kazan Federal University, Kazan, Russian Federation

Background: Fibrin polymerization starts when fibrinopeptides A are cleaved from the central nodule of the fibrinogen molecule. The exposed knobs 'A' then bind to the holes 'a' of the neighboring fibrin molecule, thus forming double stranded half-staggered fibrin oligomers. These oligomers elongate, spanning 10-15 monomers, thereby forming fibrin protofibrils, an important intermediate structure of fibrin polymer. Although a considerable amount of experimental effort has been expended to gather structural information about fibrin protofibrils, the atomic-level details remain elusive.

Aims: To construct the atomic structure of fibrin protofibrils and to characterize atomic-level interactions that stabilize the double-stranded half-staggered arrangement in fibrin protofibrils.

Methods: Multiscale computational modeling, which combines the full-atom MD simulations (both explicit and implicit water schemes), coarse-grained Langevin simulations. Experimental validation was performed using high-resolution atomic force microscopy imaging.

Results: The full atomic three-dimensional model of a fibrin protofibril that consists of 19 fibrin monomers was reconstructed computationally. The amino-acid residues that were not resolved by X-ray crystallography were incorporated into the structures, including the αC chain. In excellent agreement with experimental data, the structure of the protofibril shows a twist, with one strand wrapping around the other. The knobs 'A' participate in the intra-molecular interactions within each protofibril, whereas the knobs 'B' are capable of forming in both intra- and inter-protofibril non-covalent bonds with holes 'b'.

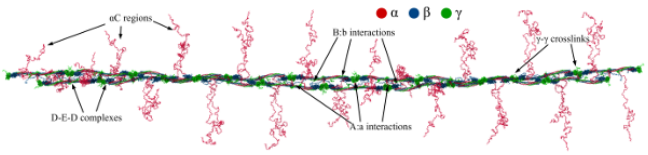

FIGURE 1 Structure of fibrin protofibril, reconstructed computationally, with the A-a and B-b knob-hole bonds, γ-γ crosslinks, and αC chains.

Conclusions: By employing our multiscale modeling approach, we have resolved and characterized in atomic detail the complete structure of fibrin protofibrils.The structures are availible for downloading in the PDB format at http://faculty.uml.edu/vbarsegov/research/fibrin.html

ASY 28.2 | Extended D-E Interaction Sites Near the Classical Knob-hole Binding Site Play an Important Role in Fibrin Polymerisation and Clot Formation

N. Asquith[1]; C. Duval[1]; M. Domingues[2]; H. McPherson[1]; F. Macrae[1]; S. Connell[3]; V. Barsegov[4]; R. Ariens[1]

[1]University of Leeds, Leeds Inst. of Cardiovascular & Metabolic Medicine, Leeds, United Kingdom, [2]University of Lisbon, Institute of Molecular Medicine, Lisbon, Portugal, [3]University of Leeds, Molecular and Nanoscale Physics Group, Leeds, United Kingdom, [4]University of Massachusetts, Department of Chemistry, Lowell, United States

Background: Molecular simulations indicate the presence of an extended binding interface beyond the traditional knob-hole interactions that occur when thrombin converts fibrinogen to fibrin (Kononova, JBC 2013). Within this extended binding interface, γAsp297, γGlu323 and γLys356 in the D-region of one fibrin molecule interact with βLys58, βAsp61 and βHis67 in the E-region of another, respectively. The effects of these novel electrostatic interactions on fibrin polymerisation and clot structure are unknown.

Aims: To study the role of the extended knob-hole interface in polymerisation kinetics, clot structure and clot mechanics.

Methods: Recombinant human fibrinogen γDEK variant (γD297N/E323Q/K356Q) and wild-type (WT) were produced in CHO cells and purified by affinity chromatography. Clot polymerisation kinetics were studied by turbidity. Clot visco-elastic properties were determined by magnetic tweezers. Confocal microscopy was used to study clot formation, clot structure and clot lysis.

Results: γDEK showed extended lag phase (+30%), slower clotting rate (-45%) and lower maximum OD (-41%) compared to WT. This variant produced a denser clot network (+41%) in hydrated conditions compared to WT, which resulted in slower lysis rates (-37%). Frequency dependent moduli were calculated and G' (elastic modulus), was similar at 0.1Hz but higher at 1 and 10Hz, compared to WT. G" (energy loss modulus) was increased at 0.1Hz 1Hz and 10Hz, compared to WT. The loss tangent (tanδ, visco-elasticity) was increased at 0.1Hz and 1Hz but similar at 10Hz.

Conclusions: The abolition of electrostatic interactions responsible for the extended binding interface results in altered polymerisation kinetics (prolonged protofibril formation), clot structure and viscoelastic properties. Our findings support previous molecular simulations and demonstrate that the D-E binding interface extends beyond the classical knob-hole interaction to reinforce fibrin polymerisation.

ASY 28.3 | The Factor VII Activating Protease (FSAP) Accelerates Fibrinolysis by Altering Fibrin Clot Structure

M. Etscheid[1]; S. Subramaniam[2]; G. Lochnit[3]; M. Zabczyk[4]; K.-M. Hanschmann[5]; A. Undas[4]; S. Kanse[6]

[1]Paul Ehrlich Institute, Haematology/Transfusion Medicine, Langen, Germany, [2]University of North Carolina, Division of Hematology/Oncology, Chapel Hill, United States, [3]Justus Liebig University, Department of Biochemistry, Faculty of Medicine, Giessen, Germany, [4]Jagiellonian University Medical College, Institute of Cardiology, Krakow, Poland, [5]Paul Ehrlich Institute, Section Biostatistics, Langen, Germany, [6]University of Oslo and Oslo University Hospital, Oslo, Norway

Background: The plasma Factor VII activating protease (FSAP) affects both coagulation and fibrinolysis, although a physiologic role in haemostasis is still unclear. A pro-fibrinolytic activity is attributed to FSAP due to its ability to activate plasminogen activators. Cleavage of fibrinogen by FSAP in plasma has been reported, but the consequences for fibrinolysis are not known. Here we re-investigated the pro-fibrinolytic potential of FSAP with a particular emphasis on its interaction with fibrinogen.

Aims: To systematically investigate the influence of FSAP on clot structure and fibrinolysis.

Methods: Processing of fibrinogen by FSAP was analyzed by SDS-PAGE, Western blotting, RP-HPLC and N-terminal sequencing. Clot formation and lysis were studied by clot lysis time assay or by thrombelastometry. The clot structure was visualized by laser scanning microscopy and scanning electron microscopy. The functional characterization of fibrin clots included clot permeability and resistance to lysis by tPA.

Results: FSAP accelerated fibrinolysis independently of the activation of plasminogen activators by cleaving fibrinogen at multiple sites in the Bβ chains and within the αC-region of the Aα chains, generating a unique fibrinogen isoform. Clots of FSAP-treated plasma had a less

coarse fibrin network with thinner fibers and lower pore size, but still were less resistant to lysis by exogenous tPA. Similar observations were made in plasma after activation of endogenous FSAP. The effects of FSAP on clot structure and permeability were less pronounced in FXIII-depleted plasma, suggesting that in the αC-region important donor-and acceptor sites for FXIII cross-linking are involved.

Conclusions: Altering the fibrin clot structure in a unique way is a novel function of FSAP and is the main mechanism of its pro-fibrinolytic activity in plasma. Once activated in plasma, FSAP assumes a protective function in the vasculature by rendering fibrin clots more susceptible to lysis and reducing the risk of thrombosis.

ASY 28.4 | Relevance of Fibrinogen α-chain Cross-linking in Clot Formation, Structure, and Stability

C. Duval[1]; M. Gold[1]; H. McPherson[1]; N. Asquith[1]; S. Baker[1]; M. Domingues[2]; R. Ajjan[1]; V. Ridger[3]; S. Connell[4]; H. Philippou[1]; R. Ariens[1]

[1]University of Leeds, Leeds Inst. of Cardiovascular & Metabolic Medicine, Leeds, United Kingdom, [2]University of Lisbon, Institute of Molecular Medicine, Lisbon, Portugal, [3]University of Sheffield, Dpt of Infection, Immunity & Cardiovascular Science, Sheffield, United Kingdom, [4]University of Leeds, Molecular and Nanoscale Physics Group, Leeds, United Kingdom

Background: FXIII plays a major role in stabilising clots by cross-linking fibrin γ- and α-chains. Previous studies using a fibrinogen (FGN) mutant (γ3X), unable to cross-link γ-chains, indirectly revealed that α-chain cross-linking may play a role in increasing clot stiffness and decreasing clot lysis rate. We have now produced a FGN mutant (α4X) where all 4 glutamine residues previously identified as substrate for α-chain cross-linking by FXIII have been mutated.

Aims: The aims of this study were to directly investigate the relevance of fibrin α-chain cross-linking in fibrin clot formation, structure and stability.

Methods: FGN wild-type (WT), γ3X (γQ398N/Q399N/K406R) and α4X (αQ221N/Q237N/Q328N/Q366N) were produced in CHO cells and purified by affinity chromatography. Cross-linking of α- and γ-chains was analysed by SDS-PAGE. Fibrin formation and lysis were studied by turbidity. Microscale fibrin viscoelasticity was analysed by magnetic tweezers. ANOVA was used to analyse the data.

Results: SDS-PAGE showed that whilst α- and γ-chains were cross-linked within 15 and 5 minutes (respectively) for WT, α-chain cross-linking was largely delayed (120min) for α4X whilst γ-chain cross-linking was abolished for γ3X. Preliminary data showed that the addition of FXIII increased the time to half lysis for WT and γ3X, but not for α4X. Magnetic tweezers showed that in the absence of FXIII, clot stiffness (G', storage modulus) was decreased for both α4X and γ3X, compared to WT. When FXIII was added, G' was significantly increased for WT and γ3X, but unchanged for α4X.

Conclusions: Our data show that fibrin α-chain cross-linking is a key player in reducing lysis and increasing clot stiffness. This novel FGN variant provides a welcome tool for the study of (patho)physiological role of fibrin α-chain cross-linking by FXIII *in vitro* and *in vivo*.

HEMORRHAGIC DISORDERS, HEMOPHILIA

ASY 01.2 | Fitusiran, an Investigational RNAi Therapeutic Targeting Antithrombin for the Treatment of Hemophilia: Interim Results from a Phase 2 Extension Study in Patients with Hemophilia A or B with and without Inhibitors

K.J. Pasi[1]; P. Georgiev[2]; T. Mant[3]; M.D. Creagh[4]; T. Lissitchkov[5]; D. Bevan[6]; S. Austin[7]; C. Hay[8]; I. Hegemann[9]; R. Kazmi[10]; P. Chowdary[11]; S. Rangarajan[12]; C.-H. Soh[13]; A. Monpara[13]; H.V. Nguyen[13]; K. Madigan[13]; M.V. Ragni[14]

[1]Barts and the London School of Medicine and Dentistry, London, United Kingdom, [2]University Multiprofile Hospital for Active Treatment "Sveti Georgi', Plovdiv, Bulgaria, [3]Quintiles IMS, Reading, United Kingdom, [4]Royal Cornwall Hospitals NHS Trust, Truro, United Kingdom, [5]Clinical Hematology Clinic Specialized Hospital for Active Treatment of 'Joan Pavel' Sofia, Sofia, Bulgaria, [6]Guy's and St Thomas' Hospital NHS Trust, London, United Kingdom, [7]St. George's Healthcare NHS Trust Haemophilia Centre, London, United Kingdom, [8]Manchester Royal Infirmary, Manchester, United Kingdom, [9]University Hospital Ghent, Zurich, Switzerland, [10]University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom, [11]Royal Free Hospital, London, United Kingdom, [12]Haemophilia, Haemostasis & Thrombosis Centre, Hampshire Hospitals NHS Foundation Trust, Basingstoke, United Kingdom, [13]Alnylam Pharmaceuticals, Cambridge, United States, [14]University of Pittsburgh and Hemophilia Center of Western Pennsylvania, Pittsburgh, United States

Background: Hemophilia is a bleeding disorder characterized by a defect in the ability to generate sufficient thrombin for effective hemostasis. Fitusiran is a subcutaneously (SC) administered investigational RNA interference (RNAi) therapeutic targeting antithrombin (AT) as a means to improve thrombin generation (TG) and promote hemostasis in patients with hemophilia A or B with and without inhibitors. Interim data from the Phase 1 study showed fitusiran was generally well tolerated and administration of monthly fitusiran led to dose-dependent AT lowering, TG increase, and decrease in bleeding frequency (Pasi KJ, et al. *Haemophilia*. 2016, 22(Suppl 4). Pasi KJ et al. *Blood*. 2016, 128: 1397. Ragni MV et al. *Blood*. 2016, 128: 2562.).

Aims: To report interim safety, pharmacodynamics (PD), and clinical activity of fitusiran from the Phase 2 extension study.

Methods: The Phase 2 open label extension study (NCT02554773) included patients with hemophilia A or B with and without inhibitors, previously dosed in the Phase 1 study. Patients received monthly, fixed SC doses of fitusiran, 50 mg or 80 mg.

Results: As of Oct 2016, 23 patients were enrolled in the study. Previously reported data showed that fitusiran was generally well tolerated, with no serious adverse events related to study drug and no thromboembolic events. Once-monthly subcutaneous dosing achieved dose-dependent AT lowering of ~80% and TG levels approaching the lower end of normal range. Exploratory post-hoc analysis of bleed events showed median ABR=1 in patients without inhibitors and median ABR=0 in patients with inhibitors. Bleed events

were successfully managed with either replacement factors (patients without inhibitors) or bypassing agents (patients with inhibitors). Updated safety, tolerability and clinical activity, including the management of bleed events, will be presented.

Conclusions: Emerging clinical data suggest that fitusiran-mediated lowering of AT may be a promising investigational approach for promoting hemostasis in hemophilia.

ASY 01.3 | Musculoskeletal Ultrasound for Intra-articular Bleed Detection: A Highly Sensitive Imaging Modality Compared to Conventional Magnet Resonance Imaging

S. Nguyen[1]; X. Lu[2,3]; Y. Ma[2,3]; J. Du[2,3]; E.Y. Chang[2,3]; A. von Drygalski[4,5]

[1]Michigan State University, College of Human Medicine, Grand Rapids, United States, [2]VA San Diego Healthcare System, Radiology, San Diego, United States, [3]University of California San Diego, Radiology, San Diego, United States, [4]University of California San Diego, Medicine, San Diego, United States, [5]The Scripps Research Institute, Molecular Medicine, La Jolla, United States

Background: There is an increasing demand for musculoskeletal ultrasound (MSKUS) to detect hemophilic joint bleeding, but there is uncertainty regarding the blood detection concentration threshold, and if magnetic resonance imaging (MRI) would be more accurate.

Aims: We studied intra-articular blood detection by MSKUS in comparison to MRI.

Methods: Blood concentrations of 0, 5, 10, 25, 50, 75 and 100% in plasma or saline (enriched with 2 mg/mL hyaluronic acid to mimic joint fluid) were imaged at room temperature after 0-2 hrs, 5 hrs, 1 day, 3 days, and 1 week after transfer into 3-5 cc syringes, and also after injection of 3-5 cc into metatarsophalangeal joints of cadaveric pig feet. MSKUS was performed using a 9-18 MHz linear transducer, and MRI was performed at 3T using T1-weighted and T2-weighted fat-suppressed sequences. Images were reviewed by both a hematologist formally trained in MSKUS and a musculoskeletal radiologist.

Results: MSKUS permitted the detection of blood in syringes and pig joint spaces at concentrations as low as 5%, demonstrated by the presence of echogenic signals that were absent with plasma or saline only. However, there was no visual difference in echogenicity in relation to blood concentrations. As blood clot and degradation products formed over time, echogenicity patterns of the fluid changed dynamically during the 1 week time course. In contrast, no discernible differences between fluids were visible on the T1-weighted or T2-weighted fat-suppressed MRI images.

Conclusions: MSKUS is extremely sensitive to detect low concentrations of intra-articular blood at low volumes, and to discriminate between bloody and non-bloody fluid, whereas conventional MRI is not. These observations are the first of their kind, demonstrate the advantages of MSKUS over MRI to detect intra-articular blood, and should enable MSKUS for rapid bleed detection in hemophilia clinics.

ASY 01.4 | The Thunder Study: Haemophilia Epidemiology Treatment, Outcome and Unmet Needs in the UK: An Analysis from the UK National Haemophilia Database

C.R. Hay[1]; B.P. Palmer[2]; M. Scott[2]; H. Xiang[2]; C. Sima[3]; D.P. Hart[4]; P.W. Collins[5]

[1]University of Manchester, University Dept of Haematology, Manchester, United Kingdom, [2]UK National Haemophilia Database, Manchester, United Kingdom, [3]Genentech Inc., San Francisco, United States, [4]Barts and the London School of Medicine and Dentistry, London, United Kingdom, [5]Cardiff and Vale University Hospital, Cardiff, United Kingdom

Background: The Thunder study is an analysis of UK National Haemophilia Database data sponsored by Roche.

Aims: It aims to determine the current Haemophilia A (HA) and inhibitor epidemiology, treatment patterns and outcomes and to quantify unmet needs for this patient group.

Methods: All 5732 patients (pts) registered with HA in 2015 were analysed. 1428 pts with severe (1155) or moderate (273) HA using the HAEMTRACK electronic pts diary were analysed for treatment patterns and bleeding outcomes.

Results: We reported 1831, 884 and 3017 pts with severe, moderate and mild HA, respectively, of whom 96%, 71% and 25% were treated in 2015. Regular prophylaxis was used in 95% of children < 12 years (yrs), falling to 74% of pts age ≥40 yrs. A med. (IQR) of 3,591 IU/Kg/year (2,194-5,247) and 1,321 IU/kg/year (250-3,642) in 2015 were used for severe and moderate HA, respectively. Annual usage has increased by 21% (severe) and 25% (moderate) in 5 years through a 13% (severe) and 4% (moderate) increase in pts and 8% (severe) and 21% (moderate) increase in treatment intensity. Factor VIII inhibitors were reported at some time in 406/1831 (22%) of severe HA, 94/884 (11%) of moderate HA and 62/3017 (2%) with mild HA. Inhibitors were present during 2015 in 161 (9%); 35 (4%) and 61 (2%) pts with severe/moderate/mild HA, respectively. The age-incidence of inhibitors was bimodal for both severe and moderate HA. In inhibitor-free severe HA managed with prophylaxis, median annualized bleed rate increased with age from 1.0 (IQR 0 - 4.75) (< 12 yrs) to 3.0 (1.0 - 8.0) (≥40 yrs). In severe inhibitor pts treated with prophylaxis, median ABR was 2.0 (0.25 - 8.75) (≤18yrs) and 3.0 (0.75 - 17.50) (>18yrs); Inhibitor pts on bypass therapy prophylaxis had a median ABR of 11.0 (5.0 - 20.0).

Conclusions: The increase in ABR with age in inhibitor-free patients was only partially corrected by prophylaxis. Inhibitors have a progressive adverse effect on ABR. ABR is much higher in inhibitor than non-inhibitor patients, despite prophylaxis.

ASY 12.1 | Next Generation Sequencing in Patients with No Apparent Laboratory Platelet Defect Despite Having an Extensive Bleeding History

A. Maclachlan; S.P. Watson; N.V. Morgan

University of Birmingham, Institute of Cardiovascular Sciences, Birmingham, United Kingdom

Background: Inherited bleeding disorders comprise a heterogeneous group of diseases that reflect abnormalities of blood vessels, coagulation proteins and platelets. Next-generation sequencing (NGS) technologies have been used previously for the rapid analysis of genes implicated in bleeding disorders and genes known to have a key role in haemostasis.

Aims: To determine the genetic aetiology of disease in a UK-wide cohort of patients with no apparent laboratory platelet defect despite having an extensive bleeding history leading to a clinical diagnosis of a platelet disorder.

Methods: Patient blood was obtained and analysed using a unique approach combining platelet phenotyping by lumi-aggregometry and genotyping by whole exome sequencing (WES), as outlined by the UK-Genotyping and Phenotyping of Platelets (GAPP) study.

Results: In the last 10 years, over 900 patients have been recruited to the UK-GAPP study. Approximately 60% have no platelet defect despite significant bleeding consistent with platelet dysfunction. To date, patients with more than one affected family member in the 'no defect' group have undergone WES (n=17). We have identified and confirmed the genetic basis of disease in two related patients; a heterozygous genetic variant (c.1611 C>A) was found in *THBD* which encodes the protein thrombomodulin and results in a stop codon and truncation of the protein (p.Cys537Stop) showing proof-of-principle of the workflow employed. In addition, novel variants in genes not previously associated with haemostasis have been discovered through our custom developed bioinformatic pipeline. The function of these genes and their encoded proteins is under investigation.

Conclusions: WES combined with platelet phenotyping is an efficient method of determining the genetic cause of disease in patients with inherited bleeding disorders. In addition, it aids in the discovery of novel genetic variants and genes not previously implicated in haemostasis helping further our knowledge of haemostasis.

ASY 12.2 | An International Prospective Cohort Study of Patients with Fibrinogen Deficiency (PRO-RBDD Study)

R. Palla[1]; M. Menegatti[1]; M. Boscarino[1]; J. Blatny[2]; O. Zapletal[2]; J.F. Schved[3]; M. Giansily-Blaizot[3]; S. Halimeh[4]; M.A. Daoud[4]; H. Platokouki[5]; H. Pergantou[5]; S.M. Peyvandi[1]

[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Fondazione Luigi Villa, Milan, Italy, [2]Children's University Hospital, Department of Pediatric Hematology, Brno, Czech Republic, [3]Hospital Saint Eloi, Laboratoire d'Hematologie, Montpellier, France, [4]Coagulation Center Rhine-Ruhr area, Thrombosis and Hemophilia Treatment Center, Duisburg, Germany, [5]Agia Sofia Children's Hospital, Haemophilia Centre/Haemostasis Unit, Athens, Greece, [6]Radboud University Medical Centre, Department of Paediatric Haematology, Nijmegen, The Netherlands, [7]Radboud University Medical Center, Department of Hematology, Nijmegen, The Netherlands, [8]Universitair Medisch Centrum, Van Creveldkliniek, Utrecht, The Netherlands, [9]National Institute of Blood Disease & Bone Marrow Transplantation, Karachi, Pakistan, [10]Blood Transfusion Institute of Serbia, Haemostasis Department, Belgrade, Serbia, [11]University Hospitals of Geneva, Division of Angiology and Haemostasis, Geneva, Switzerland, [12]Cerrahpasa Medical Faculty of Istanbul University, Department of Pediatric Hematology, Istanbul, Turkey, [13]Dr. Behcet Uz Children's Hospital, Izmir, Turkey, [14]St. George's University Hospitals NHS Foundation Trust, St. George's Haemophilia Centre, London, United Kingdom, [15]Royal Hallamshire Hospital, Sheffield Haemophilia and Thrombosis Centre, Sheffield, United Kingdom, [16]Indiana Hemophilia and Thrombosis Center, Indianapolis, United States, [17]Weill Cornell Medicine, NewYork Presbyterian Hospital, Comprehensive Center for Hemophilia and Coagulation Disorders, New York, United States

Background: Management of patients with fibrinogen deficiency is challenging because the minimum amount of fibrinogen to prevent bleeding is unknown and thromboembolism may occur during substitution therapy.

Aims: To evaluate the incidence of bleeding episodes in patients with fibrinogen deficiency in a 3-year observational prospective study.

Methods: Data on 151 patients were collected in a web-based database at baseline and every 6 months by 17 HTCs worldwide.

Bleeding incidence of any type of bleeding episode and cumulative incidence of the first bleeding requiring replacement therapy were calculated in patients with available data on both antigen and activity levels.

Results: Activity and antigen levels were available on 98 patients (55 females/43 males), of whom 83 are currently on follow up. Twenty-one (25%) patients were afibrinogenemic, 17 (20%) hypofibrinogenemic, 38 (46%) dysfibrinogenemic and 7 (9%) hypodysfibrinogenemic. Patients were followed up for a median of 992 days (IQR:898-1098, min-max:298-1397).

Prophylaxis regimen with fibrinogen concentrate was used in one third of afibrinogenemic patients (7/21) with dosages range of 50-666 mg/Kg/month. Prophylactic treatment reduced the median number of bleeding events per year [from 1 (min-max: 1-3) to 0.4 (min-max: 0-1.25)]. Two allergic reactions and no thrombotic events were reported. Two deliveries (1 vaginal, 1 cesarean) and 15 surgeries (3 major, 10 minor, 2 dental) were performed successfully with no bleeding or thrombotic events, using fibrinogen concentrate or antifibrinolytics.

Conclusions: This observational study showed that the bleeding incidence decreased accordingly to plasmatic fibrinogen levels with the highest in afibrinogenemia and the lowest in dysfibrinogenemia. Preliminary data on prophylaxis in afibrinogenemia showed a reduction of bleeding episodes. A larger group of patients and a longer follow up period are required to find the optimal target level to prevent spontaneous major bleeding.

TABLE 1 Shows results in patients on on-demand therapy. [Bleeding incidence in patients on on-demand therapy]

	Afibrinogenemia	Hypofibrinogenemia	Dysfibrinogenemia	Hypodysfibrinogenemia
Bleeding incidence (patient-year-1)	0.73 (95% CI 0.48-0.97)	0.25 (95% CI 0.12-0.42)	0.12 (95% CI 0.06-0.21)	0.05 (95% CI 0. -0.22)
Bleeding cumulative incidence of the first bleeding treated with replacement therapy at 1400 days of follow up	0.43 (95%C I 0.11-0.64)	0.30 (95% CI 0.05-0.48)	0.06 (95% CI 0.0-0.13)	0.14 (95% CI 0.0-0.37)

ASY 12.3 | Studying Adaptor Protein 3 Dependent Trafficking to Weibel-Palade Bodies Using Hermansky-Pudlak Syndrome Type 2 Blood Outgrowth Endothelial Cells

E. Karampini[1]; M. Hofman[1]; F.P.J. van Alphen[1]; T. Kuijpers[2,3]; S. Meijer[1,4]; J. Voorberg[1]; R. Bierings[1]

[1]*Sanquin Research, Plasma Proteins, Amsterdam, The Netherlands,* [2]*Sanquin Research, Blood Cell Research, Amsterdam, The Netherlands,* [3]*Academic Medical Center, University of Amsterdam, Pediatric Hematology, Immunology and Infectious Diseases, Amsterdam, The Netherlands,* [4]*Utrecht Institute for Pharmaceutical Sciences, Utrecht University, Pharmaceutical Sciences, Utrecht, The Netherlands*

Background: Weibel-Palade bodies (WPBs) are endothelial secretory organelles that contain Von Willebrand factor (VWF), P-selectin and CD63 and play a crucial role in hemostasis. WPBs belong to the lysosome-related organelles (LROs), which also includes platelet dense granules, melanosomes and lytic granules. Trafficking of CD63 to WPBs is dependent on the Adaptor Protein 3 complex (AP3). Mutations in the *AP3B1* gene, which encodes for the AP3β3 subunit of the AP3 complex, result in Hermansky-Pudlak syndrome 2 (HPS2). HPS2 is a rare genetic disorder that leads to a bleeding diathesis as a result of abnormal platelet dense granule formation, but secretory organelle defects in HPS2 are not restricted to platelets.

Aims: The objective is to investigate the role of AP3-dependent mechanisms in trafficking of proteins to WPBs.

Methods: Blood outgrowth endothelial cells (BOECs) were isolated from an HPS2 patient with compound heterozygous mutations in *AP3B1*. We used mass spectrometry and subsequent analysis using Maxquant and Perseus to perform whole proteome analysis of HPS2 BOECs versus healthy control BOECs. We generated clonal AP3B1 knockout BOEC lines using CRISPR/Cas9 genome editing of cord blood BOECs. Morphology of WPBs in AP3B1$^{-/-}$ and HPS2 BOECs was studied using confocal microscopy.

Results: HPS2 BOECs contain elongated WPBs that are entirely devoid of CD63, but still contain P-selectin. Whole proteome analysis revealed that apart from AP3β3 also the AP3μ1 subunit of the AP3 complex was depleted from HPS2 BOECs, while AP3δ1 and AP3σ1 subunits were unaffected. Interestingly, several other proteins involved in trafficking and exocytosis were also downregulated in HPS2 BOECs, including the WPB SNARE vesicle associated membrane protein 8 (VAMP8).

Conclusions: *Ex vivo* HPS2 patient-derived BOECs and CRISPR/Cas9-engineered AP3B1$^{-/-}$ BOECs have provided new insights in AP3-dependent trafficking mechanisms in endothelial cells.

ASY 12.4 | Involvement of OCRL, a Phosphoinositide 5-phosphatase, in Cytoskeleton Reorganization and Megakaryocyte Maturation

S. Poirault-Chassac[1]; E. Dreano[1]; M. Egot[1]; D. Pidard[1]; R. Salomon[2]; G. Baujat[3]; D. Lasne[4]; P. Gaussem[1,5]; C. Bachelot-Loza[1]

[1]*UMRS-1140, Faculté de Pharmacie - Université Paris Descartes, Paris, France,* [2]*AP-HP Hôpital Necker-Enfants Malades, Service de Néphrologie Pédiatrique, Paris, France,* [3]*AP-HP Hôpital Necker-Enfants Malades, Service de Génétique, Institut Imagine, Paris, France,* [4]*AP-HP Hôpital Necker-Enfants Malades, Laboratoire d'Hématologie, Paris, France,* [5]*AP-HP Hôpital Européen G. Pompidou, Service d'Hématologie Biologique, Paris, France*

Background: Lowe syndrome (LS) is a rare genetic disorder that results from loss-of-function mutations in *OCRL1*. The protein OCRL, a phosphatidylinositol-4,5-bisphosphate 5-phosphatase that contains also a RhoGAP homology domain, is involved in reorganization of the actin cytoskeleton. We previously reported an increased bleeding risk in LS patients that was associated with abnormalities in primary haemostasis. Despite a moderate thrombocytopenia in LS patients, no data however exist regarding the role of OCRL in megakaryocyte (MK) maturation and platelet formation.

Aims: To get further insights into the mechanisms underlying the thrombocytopenia present in Lowe patients by studying MK maturation.

Methods: CD34+ haematopoietic progenitor cells, isolated from blood of 6 controls and 6 patients, were differentiated into MK. CD41+/CD42b+ MK were quantified by FACS. MK morphology was monitored using transmission or immunofluorescence microscopy. Similar experiments were made with normal MK transfected with siRNA to silence OCRL expression.

Results: At D10 of MK differentiation, no difference in CD41+/CD42b+ cell numbers was noted between patients and controls. Control MK formed large proplatelet extensions on D12, and isolated platelets were observed from D14. In LS patients, the number of MK bearing proplatelets was about half the control value. Control MK showed the typical structure of proplatelets with

numerous actin filaments and microtubule extensions with buds. Despite an increase level of F-actin, these structures were less developed for LS patients, and an increased basal phosphorylation of myosin light chain (P-MLC) was noted with abnormal punctuated labelling. Similar results were obtained with MK silenced for OCRL with siRNA.

Conclusions: These results support a role of OCRL in MLC phosphorylation and actin organization accompanying MK maturation and proplatelet formation. Thus, OCRL deficiency in LS causes alterations in cytoskeleton organization that may participate to the defect of platelet production.

ASY 23.1 | Product Type and the Risk of Inhibitor Development in Nonsevere Hemophilia A Patients

Background: Inhibitor development is a major complication of treatment with factor VIII concentrates in nonsevere hemophilia. It has been suggested that plasma-derived factor VIII concentrates elicit fewer inhibitors than recombinant factor VIII concentrates, however recent studies in severe hemophilia A patients have shown conflicting results. We designed a case-control study that aims to investigate the clinical risk factors and genetic risk factors for inhibitor development in nonsevere hemophilia A patients.

Aims: We investigated whether the type of factor VIII concentrate was associated with inhibitor development in nonsevere hemophilia A patients.

Methods: This nested case-control study includes 75 inhibitor patients (cases) and 223 controls, selected from a source population of the INSIGHT study, including all nonsevere hemophilia A patients (FVIII:c 2-40%) that have been treated with FVIII concentrates in 33 European and 1 Australian center. Cases and controls were matched for date of birth and cumulative number of exposure days (CED) to FVIII products. A conditional logistic regression model was used to calculate both unadjusted and adjusted odds ratios; the latter adjusted for the following a-priori specified confounders.

Results: We did not find an increased risk for inhibitor development for any type of FVIII concentrate; either when comparing recombinant FVIII concentrates to plasma-derived FVIII concentrates (adjusted odds ratio 1.1, 95% confidence interval 0.4-2.8) or for specific types of FVIII concentrates.

Conclusions: In this nested case-control study including nonsevere hemophilia A patients, the type of FVIII concentrate was not associated with the development with inhibiting anti-FVIII antibodies.

Background: Inhibitors mainly develop in children with severe hemophilia A during the first 50 exposure days and are classified in low- and high-titer according to the peak titer ever reached with a cut off of 5 BU/ml. At the first positive titer, the real nature of the antibody may be unclear, since some low-titers progress to high-titers afterwards.

Aims: The aim of this study was to investigate potential risk factors of the progression towards high-titers in children with severe hemophilia A and newly diagnosed inhibitors.

Methods: This study was a follow-up study of the PedNet Registry and included 260 children with severe hemophilia A and inhibitors, born between 1990 and 2009 and consecutively recruited from 31 hemophilia centers. Clinical and laboratory data were collected from the date of first positive inhibitor test for at least a 3-years follow-up. Immune tolerance induction (ITI) was defined as any regular FVIII replacement regimen of at least 45 IU/kg FVIII given for at least 3 times/week. ITI regimens were defined as daily or non-daily based on injection frequency. High-dose ITI was defined by a FVIII dose given ≥ 100 IU/kg.

Results: At first positive inhibitor test, 49% (n=127) had low-titer inhibitors, however, 50% of them progressed to high-titers following FVIII re-exposure, so only 25% maintained low-titers. Factor VIII gene (*F8*) mutation type was known in 247 patients (95%), including 202 (82%) null mutations. The progression to high-titer inhibitors was associated with null *F8* mutations (OR 2.6, 95%CI 1.0-6.5), family history of inhibitors (OR 7.2, 95%CI 1.8-28.4) and the use of high-dose ITI (OR 3.9, 95%CI 1.5-10.0).

Conclusions: These results suggest that high-dose ITI should be avoided as initial strategy in patients who develop low-titer inhibitors.

ASY 23.3 | Antigen-specific Regulatory T Cells Generated by Factor VIII-CAR Retrovirus Ttransduction Suppress Anti-factor VIII Immune Responses

R.Y. Fu; M.J. Lyle; X. Cai; I. Khan; X. Wang; D.J. Rawlings; C.H. Miao

Seattle Children's Research Institute, Immunity and Immunotherapies, Seattle, United States

Background: The antibody formation to factor VIII (FVIII; F8 in constructs) is a major challenge for effective treatment for hemophilia A (HemA). In our previous studies, the small number of expanded FVIII-specific regulatory T cells (Tregs) from polyclonal $CD4^+$ splenocyte exerted better suppressive function compared with non-specific Tregs.

Aims: In order to obtain the stable source of antigen-specific T cells, we adopted chimeric antigen receptor (CAR) approach to generate antigen-specific Tregs and examined their suppressive function.

Methods: The CAR construct included high-binding anti-FVIII variable region (scFV) linked to signaling and costimulatory moieties of immune receptors and murine Foxp3 (F8CAR-mFoxp3). Murine $CD4^+$ T cells were transduced with retrovirus carrying F8CAR-mFoxp3 transgene to generate engineered Tregs. *In vitro* suppressive assay was performed using engineered Tregs and FVIII-specific effector T cells (Teffs) from FVIII-primed HemA mice. In addition, FVIII-specific CFSE was performed using F8CAR-Tregs and F8CAR retrovirus transduced $CD4^+$ T cells (F8CAR-Teffs). Subsequently, we adoptively transferred $1x10^6$ F8CAR-Tregs into HemA mice to examine their suppressive function *in vivo*.

Results: The engineered F8CAR-mFoxp3 Tregs showed F8CAR and Foxp3 expression by flow cytometry analysis. In both *in vitro* tests, the engineered Tregs exerted FVIII-specific suppressive function towards Teffs from two different sources. One day after adoptive cell transfer, the treated mice were injected with FVIII plasmid hydrodynamically. F8CAR-Foxp3-Tregs more significantly decrease the production of anti-FVIII antibodies overtime compared to control untransduced T cells and polyclonally expanded FVIII-specific Tregs.

Conclusions: F8CAR-mFoxp3 Tregs exerted superior suppressive activities towards FVIII-specific immune responses in both in vitro and in vivo tests, indicating the potential of F8CAR-mFoxp3 engineered cells to modulate anti-FVIII immune responses.

ASY 23.4 | Stabilin-2 Deficiency or Competitive Inhibition Reduces Human FVIII Immunogenicity in a VWF-dependent Manner

J.D. Lai[1]; L.L. Swystun[1]; I. Georgescu[1]; K. Nesbitt[1]; K. Schledzewski[2]; C. Géraud[2]; S. Goerdt[2]; D. Lillicrap[1]

[1]*Queen's University, Pathology & Molecular Medicine, Kingston, Canada,* [2]*University of Heidelberg, Department of Dematology, Venereology and Allergology, University Medical Center and Medical Faculty, Mannheim, Germany*

Background: Inhibitory antibodies against factor VIII (FVIII) remain the most significant complication in hemophilia A (HA). To date, no receptor has been described to influence FVIII immunogenicity *in vivo*. The scavenger receptor stabilin-2 (Stab-2) contributes to the clearance of human von Willebrand factor (VWF) and FVIII.

Aims: To assess the role of Stab-2 on FVIII immunogenicity.

Methods: Association of VWF with Stab-2 in the spleen was assessed using immunofluorescent staining of human pdVWF-infused VWF KO mice. Wild-type (WT) and Stab-2 knockout (KO) C57Bl/6 mice were infused weekly with 2 IU (~50 IU/kg) of human plasma-derived FVIII/VWF (pdFVIII; VWF:FVIII ratio of 2.4:1) or human recombinant FVIII (rFVIII). FVIII antibodies and inhibitors were assessed by ELISA and one-stage Bethesda assay at day 28.

Results: Infused pdVWF was found to associate with CD31 and Stab-2-expressing cells in the spleen.

Compared to WT mice, Stab-2 KO mice treated with pdFVIII showed a lower incidence of αFVIII IgG (30% vs 90%; p=0.02; n=10) and lower aFVIII antibody titres (p=0.003). Stab-2 KO mice also displayed a decreased incidence of inhibitors (≥0.6 BU) compared to WT KO mice (10% vs 50%; p=0.14) and higher inhibitor titres (p=0.051). All mice developed αhuman VWF IgG, but titres were lower in Stab-2 KO mice (p=0.003). Stab-2 KO mice exposed to rFVIII exhibited a less pronounced decline in the incidence of αFVIII IgG (40% vs 80% respectively; p=0.17; n=10) and inhibitors (20% vs 50%; p=0.35) compared to WT mice.

Concurrent infusion of pdFVIII with 100 μg of hyaluronic acid (a major Stab-2 ligand) in WT mice decreased the incidence (10% vs 90%; p=0.001; n=10) and titre of αFVIII IgG (p=0.0008). No significant differences were observed in the titre of αVWF IgG.

Conclusions: Stab-2 plays a role in the immunogenicity of human FVIII in a VWF-dependent manner. Inhibiting Stab-2-VWF/FVIII interaction may be an effective method to prevent inhibitors in hemophilia A patients.

ASY 27.1 | A Sparse Sampling Method for FVIII Population Pharmacokinetic (PK) Analyses in Males with Severe Hemophilia A (SHA)

V. Blanchette[1,2]; S. Jackson[3]; L. Tiseo[4]; V. Bouskill[1]; S. Ito[5]; D. Lillicrap[6]; M. Morfini[7]; M. Rand[8]; D. Stephens[9]; K. Usuba[4,10]; C. Wakefield[1]; E. Zapotocka[1]; M. Carcao[1]

[1]The Hospital for Sick Children, Division of Haematology/Oncology, Toronto, Canada, [2]University of Toronto, Department of Paediatrics, Toronto, Canada, [3]St. Paul's Hospital, Department of Hematology, Vancouver, Canada, [4]The Hospital for Sick Children, Child Health Evaluative Sciences, Research Institute, Toronto, Canada, [5]The Hospital for Sick Children, Division of Clinical Pharmacology and Toxicology, Toronto, Canada, [6]Queen's University, Department of Pathology and Molecular Medicine, Kingston, Canada, [7]Italian Association of Haemophilia Centres, Florence, Italy, [8]The Hospital for Sick Children, Department of Physiology & Experimental Medicine, Research Institute, Toronto, Canada, [9]The Hospital for Sick Children, Department of Clinical Research Services, Toronto, Canada, [10]Laurentian University, Evaluating Children's Health Outcomes Research Centre, Sudbury, Canada

Background: Standard PK assessments are demanding for patients with SHA, requiring a 72 hr washout and minimum of 5 timed blood samples at baseline and following FVIII infusion (ISTH Guidelines, 2001). A sparse sampling method is an attractive alternative.

Aims: The aim of this study was to identify a practical sparse sampling method using a population PK program (myPKFiT™) built from pre-licensure PK data of a recombinant FVIII (rFVIII) concentrate.

Methods: 27 inhibitor negative males with SHA (FVIII< 1%) receiving a standard half-life rFVIII were pooled from 2 studies (median age 12 yrs, range 5-34). Subjects were consented and studies approved by the research ethics boards. 50 IU/kg rFVIII was infused after a 72 hr washout. FVIII activity levels were measured pre-infusion and at 1, 9, 24 and 48 hrs post-infusion (5-point PK, study 1). Study 2 (6-point PK) had an added 3 hr post-infusion sample. Study 2 also included a 2-point PK taken 1 week later (no washout): a sample was taken at the start of a clinic visit 24 hrs after self-infusion at home (15-50 IU/kg), followed by an in-clinic infusion of 25 IU/kg and 3 hr post-infusion sample. PK parameters clearance (Cl), volume of distribution at steady state (Vss), terminal half-life (t1/2) and time to 1% (tt1%) were calculated using the PK program. Intra-class correlations (ICCs) were used to compare the sparse sampling methods to the full 5 or 6 point PK.

Results: Table 1 shows an overview of PK parameters derived from the 5 sampling time points. It was noted, in males < 18 yrs (n=23), Cl was strongly negatively (r=−0.73, p< 0.01) and t1/2 strongly positively (r=0.78, p< 0.01) correlated with age. Table 2 shows the agreement between full sampling PKs and sparse sampling methods.

Conclusions: There is substantial/almost perfect agreement for all PK parameters between the sparse sampling methods and full 5 or 6 point PKs. In an outpatient setting, the 24 and 3 hr sampling method is the most practical option for obtaining a PK profile estimate in a single clinic visit.

TABLE 1 Overview of PK parameters derived from the 5 sampling time points

PK parameters	median (range), n=27
Cl (dL/hr/kg)	0.03 (0.02-0.05)
Vss (dL/kg)	0.5 (0.3-0.6)
t1/2 (hrs)	12.4 (8.2-16.1)
tt1% (hrs)	79.0 (52.0-110.0)

ASY 27.2 | Factor VIII Concentration and the Risk of Spontaneous Bleeding Following Treatment with rFVIII (Turoctocog Alfa) in Patients with Severe Haemophilia A

recently completed guardian™2 trial is a large extension of the guardian™1 and guardian™3 phase 3 trials.

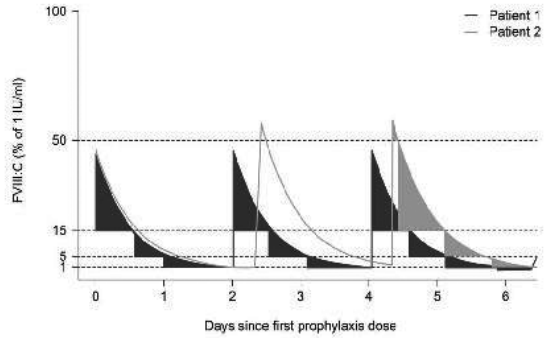
Aims: To investigate the relationship between FVIII concentration (FVIII:C) and annualised bleeding rate (ABR) for spontaneous bleeds.

Methods: A population pharmacokinetic (PK) model derived from the guardian™ trials was combined with patients' diary-recorded dosing data. Each patient's time on prophylaxis was categorised into five clinically meaningful groups of predicted FVIII:C (Figure, 0-1%, >1-5%, >5-15%, >15-50% and >50%) calculating exposure time, mean FVIII:C and number of bleeds. Bleeding data were used to estimate ABRs for each category using negative binomial regression and predictions of a parametric model. Relationships between ABR and mean FVIII:C were evaluated for the overall dataset by trial phase (guardian™1 and 3 [main phase] + guardian™2 [extension phase]) and age (adults/adolescents [≥12 years] versus children [0-< 12 years]).

Results: Patient numbers and patient years of exposure (PYE) in the populations analysed were: main (n=170; PYE=84.78) versus extension phase (n=185; PYE=665.61), adults/adolescents (n=133; PYE=504.88) versus children (n=54; PYE=245.51), and overall (n=187; PYE=750.40). Patients were predicted to reach FVIII:C levels associated with non-severe haemophilia for 86.6% of the time. Spontaneous bleed ABR decreased as FVIII:C increased (Table) evident in both the main and extension phases, with lower ABRs in the extension phase. The FVIII:C-response relationship was apparent for adults and children, although children had lower ABRs than adults.

Conclusions: Bleed risk data offer insight into tailoring prophylactic regimens. Clinicians should consider the association between PK, age, and bleed risk when designing prophylaxis strategies.

Figure: Patients' time spent in different FVIII:C activity ranges predicted from dosing diaries



The first week of prophylaxis is illustrated for two representative patients on thrice weekly turoctocog alfa dosing. Predicted profiles of FVIII:C activity were calculated from the patients' diary information on doses and timing of doses. Both patients exhibited a dosing interval pattern in their first week of 2-2-3 days, although the last two doses were delayed and higher for Patient 2 compared to Patient 1.

Triangles represents the area under the curve (AUC) of FVIII:C contributing to the mean FVIII:C value for each range. The horizontal span of each triangle defines the time spent in the relevant FVIII:C range. Both the AUC and time spans were calculated across dosing intervals and patient years.

FIGURE 1

TABLE 1

Table: FVIII concentration ranges and spontaneous ABR

FVIII concentration range (mean)	Patient years	Total number of spontaneous bleeds	Mean spontaneous ABR (negative binomial estimate, 95% CI)				
			Analyses population				
			Overall	Main	Extension	Adults / Adolescent	Children
0–1% (0.4%)	101	324	4.19 (3.28–5.39)	5.79 (4.02–8.41)	3.25 (2.40–4.48)	5.53 (4.18–7.36)	2.03 (1.29–3.26)
>1–5% (2.7%)	203	374	2.80 (2.18–3.62)	4.54 (3.20–6.56)	1.70 (1.27–2.33)	3.44 (2.66–4.49)	1.28 (0.64–2.77)
>5–15% (9.2%)	180	361	2.48 (1.92–3.24)	3.74 (2.49–5.76)	1.72 (1.28–2.34)	3.15 (2.38–4.22)	0.85 (0.48–1.54)
>15–50% (29.0%)	205	200	1.06 (0.80–1.41)	1.48 (0.91–2.43)	0.86 (0.63–1.19)	1.33 (0.99–1.82)	0.37 (0.19–0.76)
>50% (71.0%)	62	14	0.24 (0.12–0.46)	0.63 (0.14–1.92)	0.19 (0.09–0.37)	0.40 (0.20–0.74)	0.03 (0.00–0.15)

ABR, annualised bleeding rate; CI, confidence interval; FVIII, Factor VIII.

ASY 27.3 | Current PK Tools Differ in Prophylactic Dosing Advice of Factor VIII Concentrate in Hemophilia A Patients

I. van Moort[1]; T. Preijers[2]; K. Fijnvandraat[3]; F.W.G. Leebeek[4]; R.A.A. Mathot[2]; M.H. Cnossen[1]; OPTI-CLOT' Study Group

[1]Erasmus University Medical Center - Sophia Children's Hospital, Pediatric Hematology, Rotterdam, The Netherlands, [2]Academic Medical Center, Hospital Pharmacy - Clinical Pharmacology, Amsterdam, The Netherlands, [3]Academic Medical Center, Pediatric Hematology, Amsterdam, The Netherlands, [4]Erasmus University Medical Center, Hematology, Rotterdam, The Netherlands

Background: Patients with severe and moderate hemophilia A (HA) are often treated prophylactically with factor VIII (FVIII) concentrate. Individualization of prophylaxis can be achieved by pharmacokinetic (PK)-guided dosing. Currently three PK tools are available for calculating the FVIII dose to ensure the FVIII concentrations above the target FVIII trough level.

Aims: To compare the estimated PK parameters and FVIII doses generated by the current PK tools.

Methods: Twenty-seven patients with HA (FVIII< 0.05 IU/ml) underwent individual PK profiling after a FVIII bolus of 50 IU/kg (Advate®) followed by three FVIII measurements at 4, 24 and 48 hours. The PK was analyzed by application of (1) Bayesian analysis in NONMEM®-software using population model reported by Bjorkman et al. 2012, (2) myPKFiT PK tool, and (3) WAPPS-Hemo portal. For each patient individual PK parameters clearance (CL) and volume of distribution at steady-state (Vss) were estimated by (1) and (2). The terminal half-life was produced by all methods, whereas FVIII dosing advices were calculated by (1) and (2) aiming for trough levels >0.01 IU/ml.

Results: Age (mean±SD) of the patients was 40.8±20.6 year with a body weight of 80.4±17.0 kg. Method (2) did not produce individual PK parameters for five patients. V_{ss} estimated by (2) was significantly higher than by (1) and CL estimated by (2) was lower than by (1) (Table 1). The three methods produced different estimates for terminal half-life; values were 10.6±2.1h (1), 12.5±1.9h (2) and 11.4±1.9h (3) (p< 0.001). Due to the shorter half-life (1) produced significantly higher doses for severe HA patients while dosing every 48 hours (mean difference: 721 IU, p=0.01).

Conclusions: Currently available PK tools show significant variation in individual PK parameters estimates and consequently a significant difference in the advised prophylactic dose. Prospective validation of

TABLE 1 Individual PK parameters and FVIII doses generated by the current PK tools

	(1) Bayesian analysis using NONMEM		(2) MyPKFiT		(3) WAPPS-Hemo portal

PK tools is crucial to attain a uniformed approach towards PK-guided dosing of FVIII prophylaxis.

ASY 27.4 | Preoperative Screening for Bleeding Disorders: A Comprehensive Laboratory Assessment of Clinical Practice

M.J.A. Vries[1]; P.E.J. van derMeijden[1]; G.J.A.J.M. Kuiper[2]; P.J. Nelemans[3]; R.J.H. Wetzels[4]; R.G.M. van Oerle[1,4]; M.D. Lance[2,5]; H. ten Cate[1,6]; Y.M.C. Henskens[1,4]

[1]Maastricht University, Biochemistry, Maastricht, The Netherlands, [2]Maastricht University Medical Centre +, Anaesthesiology, Maastricht, The Netherlands, [3]Maastricht University Medical Centre +, Epidemiology, Maastricht, The Netherlands, [4]Maastricht University Medical Centre +, Central Diagnostic Laboratory, Maastricht, The Netherlands, [5]Hamad Medical Centre, Anaesthesiology, Qatar, United Arab Emirates, [6]Maastricht University Medical Centre +, Internal Medicine, Maastricht, The Netherlands

Background: Patients with mild bleeding disorders (MBDs) are at risk of perioperative bleeding, but preoperative screening for MBDs remains challenging.

Aims: We aimed to 1) assess and compare the prevalence of haemostatic deficiencies in patients with and without reported bleeding symptoms on a preoperative questionnaire, consisting of guideline-proposed bleeding questions, and 2) appraise the diagnostic value of the ISTH-Bleeding Assessment Tool (BAT), and laboratory screening tests for the identification of patients with haemostatic deficiencies.

Methods: Patients without known bleeding disorders were included. All patients completed the ISTH-BAT and underwent haemostatic testing (Table 1). Haemostatic deficiencies were defined as coagulation, von Willebrand Factor (vWF) or fibrinolysis factor levels below reference range (usually < 50-60%) or ≥2 abnormal LTA curves. Informed consent was obtained and the medical ethics committee approved the study.

Results: In 21 of 240 (8.8%) patients reporting bleeding symptoms, mild haemostatic deficiencies were found, including 7 coagulation factor deficiencies, 10 platelet function abnormalities and 4 low vWF levels. In comparison, 10 of 95 (10.5%) patients not reporting bleeding symptoms had a deficiency. The prevalence of deficiencies was not different between the groups after adjustment for age, gender, blood type (p=0.48). The ISTH-BAT could not identify patients with haemostatic deficiencies (ROC-curves: women AUC 0.51 (95%CI 0.34-0.67), p=0.94. Men AUC 0.55 (95%CI 0.39-0.72), p=0.51), while the aPTT, PT and PFA had high specificity but low sensitivity to detect haemostatic deficiencies (Table 2).

Conclusions: The prevalence of haemostatic deficiencies in both patients with and without reported bleeding symptoms was 9-10%. This indicates

Andrea Hospital, La Spezia, Italy, [4]Ferrara Hospital, Ferrara, Italy, [5]Careggi University Hospital, Firenze, Italy, [6]University of Siena, Siena, Italy, [7]Cremona Hospital, Cremona, Italy, [8]Vibo Valentia Hospital, Vibo Valentia, Italy, [9]Ospedale Civico di Palermo, Palermo, Italy, [10]Lodi Hospital, Lodi, Italy, [11]Ospedali Riuniti di Ancona, Ancona, Italy, [12]Ospedale Maggiore della Carità, Novara, Italy, [13]Avezzano Hospital, L'Aquila, Italy, [14]University Hospital 'Carl Gustav Carus', Technische Universität Dresden, Dresden, Germany, [15]Cattinara Hospital, Trieste, Italy, [16]Santa Croce Hospital, Cuneo, Italy, [17]University of Pisa, Pisa, Italy, [18]San Giovanni Battista Hospital, Foligno, Italy

Background: Whether mortality is increased in patients with intracerebral hemorrhage (ICH) associated with vitamin K antagonists (VKAs), direct oral anticoagulants (DOACs), or antiplatelets (APs) remains unclear.

Aims: To assess the risk for death in patients with ICH associated with VKAs, DOACs, or APs or no antithrombotic treatment.

Methods: This is a multicenter cohort study in consecutive patients admitted for ICH while on treatment with VKAs, DOACs, APs or no antithrombotic. Cerebral CTs were centrally evaluated by a panel unaware of antithrombotic treatment. Primary outcome was death at 30 days.

Results: 481 patients with ICH associated with VKA (163 patients), DOAC (54 patients), AP (97 patients) or no antithrombotic treatment (167 patients) were included in the study (Table 1).

At multivariate analysis, age (HR 1.04 per year; 95% CI 1.02-1.07), GCS ≤8 at admission (HR 5.47; 95% CI 3.58-8.35) and previous stroke (HR 1.96; 95% CI 1.21-3.18) were independent predictors of death. No association was found between antithrombotic therapy and death (HR 1.07, 95% CI 0.57-2.01 for VKAs; HR 1.18, 95% CI 0.58-2.44 for DOACs; HR 1.06, 95% CI 0.53-2.10 for APs) after adjusting for differences among the study groups.

Baseline cerebral CT was available for central reading in 339 patients (83 VKA, 35 DOAC, 80 AP and 141 no antithrombotic patients). In these patients, ICH volume at admission ≥30 mL (HR 2.78; 95% CI 1.54-5.02) was an independent predictors of death.

TABLE 1 Clinical features of patients, according with treatment

	No Antithrombotics=167	APs=97	VKAs=163	DOACs=54
Age,mean±SD	68±14	76±10	79±9	80±9
Hypertension, n (%)	128 (77)	86 (89)	126 (77)	36 (67)
Renal failure, n (%)	6 (4)	14 (14)	29 (18)	7 (13)
Diabetes, n (%)	25 (15)	24 (25)	36 (22)	15 (28)
Previous stroke, n (%)	3 (2)	18 (19)	50 (31)	16 (30)
Heart failure, n (%)	4 (5)	11 (11)	34 (21)	5 (7)
Vascular disease, n (%)	2 (1)	25 (26)	47 (29)	7 (13)

Trauma, n (%)	11 (7)	11 (11)	52 (32)	11 (20)

TABLE 2 Death at 30 days occurred in 90 patients (19%). [Death at 30 days and radiological features, according with treatment]

	No antithrombotics	APs	VKAs	DOACs
Death at 30 days, n (%)	18/167 (11)	16/97 (16)	39/163 (24)	17/54 (31)
DEEP, n (%)	82/161 (38)	45/89 (50)	39/88 (44)	14/37 (38)
LOBAR, n (%)	65/161 (40)	37/89 (41)	38/88 (43)	20/37 (54)
POSTERIOR FOSSA, n (%)	14/161 (9)	7/89 (8)	11/88 (12)	3/37 (8)
Volume at admission >30 mL, n (%)	38/141 (27)	26/80 (32)	27/83 (32)	15/35 (43)
Volume at admission, mean±SD; median; IQR	24.85±33; 11.6; 29.1	30.02±40; 12.4; 32.3	34.48±47; 12.8; 38.7	42.26±52; 18.3; 51.1
Intraventricular extension, n (%)	38/141 (27)	32/80 (40)	26/83 (31)	11/35 (31)
Volume expansion ≥6 mL or 33%, n (%)	28/134 (21)	17/74 (23)	22/73 (30)	8/29 (27)

Baseline and 48-hours CTs were available for central reading in 310 patients (73 VKA, 29 DOAC, 74 AP or 134 no antithrombotic patients). In these patients, volume expansion (>6 mL or 33%) (HR 2.31; 95% CI 1.20-4.45) was independent predictor of death.

Conclusions: GCS, ICH volume at admission and volume expansion were predictors of death in ICH patients regardless of the associated antithrombotic therapy.

ASY 10.2 | Rates, Management and Outcome of Bleeding Complications during Apixaban and Edoxaban Therapy in Daily Care - Results from the Dresden NOAC Registry (NCT01588119)

S. Marten; S. Helmert; I. Beyer-Westendorf; M. Göbelt; L. Tittl; J. Beyer-Westendorf

Universitätsklinikum Carl Gustav Carus, Dresden, Germany

Background: Apixaban and edoxaban (A/E) are approved for treatment and prevention of thromboembolic diseases but, in contrast to rivaroxaban and dabigatran, detailed data on the rates, management and outcome of bleeding complications in daily care are scarce.

Aims: To evaluate rates, management and outcome of bleeding complications during A/E therapy.

Methods: Bleeding events during A/E therapy were evaluated using data from a prospective, non-interventional oral anticoagulation registry of daily care patients. All A/E patients enrolled in the *Dresden NOAC registry* were assessed and bleeding events which occurred during A/E exposure (during or within 3 days after last intake) were evaluated.

Results: Between December 1st 2012 and November 30th 2016, 3419 patients were enrolled into the registry. Of these, 677 patients (19.8%) received apixaban and 292 patients (8.5%) received edoxaban. The mean duration of follow-up was 521.7±355.9 days (median 512 days; IQR 184/822 days). The mean duration of A/E exposure was 451.8±360.7 days (median 275 days; IQR 135/791 days). During follow-up 405 patients (41.8%) reported 672 bleeding events during or within 3 days after last intake of A/E (69.9% minor, 48.9% clinically relevant non-major (CRNM) and 7.4% major according to ISTH definition).

The main driver for classification as "ISTH major bleeding" was "transfusion of ≥ 2 units of red blood cells" (16/33), followed by "drop of haemoglobin > 2g/dl" (15/33), "critical organ bleeding" (13/33) and "fatal bleeding" (3/33). Most cases of major bleeding (66.7%) could be treated conservatively but in 11 cases (33.3%) surgical or interventional treatment was needed.

Following bleeding, all-cause mortality at 90 days were 1.7% (7/405) for all bleeding and 2.5% (5/198) for CRNM and 20% (6/30) for major bleeding, respectively.

Conclusions: In daily care, bleeding complications are frequent also with apixaban/edoxaban treatment. However, bleeding rarely manifests as major bleeding and such cases can mostly be managed by transfusion only.

ASY 10.3 | Prevention of Exsanguination under Apixaban Anticoagulation Using Andexanet Alfa in a Polytrauma Model

O. Grottke[1]; T. Braunschweig[2]; N. Akman[1]; R. Rossaint[1]; P.B. Conley[3]; J.M. Leeds[3]; M. Honickel[1]

[1]RWTH Aachen University Hospital, Department of Anesthesiology, Aachen, Germany, [2]RWTH Aachen University Hospital, Institute of Pathology, Aachen, Germany, [3]Portola Pharmaceuticals, Inc., San Francisco, United States

Background: Life-threatening bleeding requires prompt reversal of factor Xa inhibitors. Andexanet alfa is being investigated for reversal of their anticoagulation effects.

Aims: The ability of andexanet to reverse bleeding in an apixaban anticoagulated porcine trauma model was investigated.

Methods: After ethical approval, male pigs (n=15) were given apixaban for 3 days (20 mg daily), the sham group (n=5) received placebo. A standardized polytrauma by blunt liver injury and bilateral femur

TABLE 1 Severity and management strategies of apixaban-/edoxaban-related bleeding complications

672 bleeding events in 405 patients	Conservative (no treatment or compression / tamponade / transfusion)	Surgery or intervention	Red blood cell transfusion	Vitamin K supplementation	Fresh frozen plasma transfusion	Prothrombin complex concentrate	Recombinant Factor VII
Minor 375/672 (55.8%)	375/375 (100.0)	0	0	0	0	0	0
NMCR 264/672 (39.3%)	225/264 (85.2)	39/264 (14.8)	2/264 (0.8)	0	0	0	0
Major 33/672 (4.9%)	22/33 (66.7)	11/33 (33.3)	16/33 (48.5)	0	4/33 (12.1)	3/33 (9.1)	0
TOTAL	622/672 (92.6)	50/672 (7.4)	18/672 (2.7)	0	4/672 (0.6)	3/672 (0.4)	0

fractures was inflicted. 12 min post trauma animals were randomized (n=5 group) to a single andexanet bolus (1000 mg), a bolus (1000 mg) + infusion (1200 mg over 2 h) regimen, or vehicle (control). Blood loss (BL) and hemodynamics were monitored over 5 h or until time of death and analyzed by ANOVA (mean±SEM).

Results: Apixaban anti-fXa levels were 183±26 ng/mL with no differences between anticoagulated groups prior to injury. BL in the sham animals was 494±24 mL 12 min after injury (Total BL 651±39 mL at 5 h, 100% survival). Anticoagulation with apixaban significantly increased BL 12 min after injury (873±25 mL, p< 0.01). Controls exhibited a total BL of 3913±235 mL with 100% mortality (mean survival time 165 min). Treatment with a bolus or bolus + infusion of andexanet was associated with a significant reduction in BL and 100% survival (Fig. 1a). 2 h after injury, apixaban anti-fXa levels in bolus animals were 99±45 ng/mL, while the levels were 17±6 ng/mL in the bolus + infusion animals (Fig. 1b). Hemodynamic parameters (e.g., cardiac output) and markers of shock (e.g., lactate) recovered to pre-trauma levels in andexanet treated groups. Clinically and macroscopically no adverse events were observed.

Conclusions: In this study, andexanet safely reversed anticoagulation effects of apixaban, reduced BL, and decreased mortality induced by severe trauma under anticoagulation. The bolus alone had a similar impact as the bolus + infusion regimen in this lethal porcine model.

ASY 10.4 | Reduction of Hepatic Factor XII Expression in Mice by ALN-F12 Inhibits Thrombosis without Increasing Bleeding Risk

J. Liu[1]; J. Qin[1]; B. Cooley[2]; J. Butler[1]

[1]*Alnylam Pharmaceuticals, Cambridge, United States,* [2]*University of North Carolina at Chapel Hill, UNC McAllister Heart Institute, Chapel Hill, United States*

Background: Plasma coagulation Factor XII (FXII) plays a crucial role in contact activation, ultimately regulating both the kallikrein-kinin system and the intrinsic pathway of coagulation. A growing body of evidence suggests that inhibition of FXII, and its proximal substrate Factor XI (FXI), can prevent thrombosis. Given FXII does not appear to modulate hemostasis, targeting FXII appears to be a promising strategy for the prevention of pathological thrombus formation without the hemostatic risks typically associated with anticoagulants. To this end, a subcutaneously administered investigational RNAi therapeutic targeting F12 mRNA (ALN-F12) was developed.

Aims: To investigate the thromboprotective and hemostatic effects of FXII reduction by ALN-F12 in rodent thrombosis and hemostasis models.

Methods: A single dose of ALN-F12 was subcutaneously administered to C57Bl/6 mice. After reaching steady state FXII reduction, the impact on hemostasis (saphenous vein and tail tip transection bleeding models) and thrombosis (ferric chloride and laser injury induced thrombosis models) was evaluated. A siRNA targeting Factor XI (FXI-siRNA) was included for comparison.

Results: Administration of ALN-F12 resulted in dose-dependent reductions of F12 mRNA and plasma FXII protein. Further, ALN-F12 led to dose dependent reductions in platelet and fibrin accumulation in the thrombosis models evaluated in this study. At 10 mg/kg ALN-F12, the top dose level evaluated, this resulted in >95% reduction of plasma FXII and ~10 fold reduction in fibrin deposition. Similarly, administration of FXI-siRNA also led to dose dependent reductions in FXI as well as platelet and fibrin accumulation; >95% FXI reduction resulted in ~5 fold reduction in fibrin deposition. Finally, hemostasis models showed that >95% reduction of plasma FXII or FXI had no impact on bleeding time or blood loss.

Conclusions: Reduction of plasma Factor XII by ALN-F12 provided thromboprotective effects with no increased bleeding risk in rodent models of thrombosis and hemostasis.

ASY 14.1 | Two Years versus Six Months of Oral Anticoagulation after a First Episode of Unprovoked Proximal Depp Vein Thrombosis: the PADIS DVT Multicenter, Double-blind, Randomized Trial (Clinical Trials. Gov Number NCT00740493)

Background: Patients with unprovoked deep vein thrombosis (DVT) have a high risk of recurrent venous thromboembolism (VTE) after stopping anticoagulation; however, the optimal duration of anticoagulation remains uncertain.

Aims: To assess the benefits and risks of extended anticoagulation after a first episode of unprovoked DVT initially treated during 6 months.

Methods: In a multicenter, randomized, double-blind, controlled trial, we compared an additional 18 months of warfarin with placebo in patients with a first episode of unprovoked proximal DVT initially treated during 6 months. After stopping study treatment, all patients were followed up for an additional period of 2 years. Primary outcome was the composite of recurrent VTE or major bleeding during the 18-month treatment period. Secondary outcomes included the composite outcome during the entire study period, deaths not caused by VTE or major bleeding and the components of the composite outcome. All outcomes were centrally adjudicated.

Results: A total of 104 patients were included and analyzed on an intention-to-treat basis. During the treatment period, the composite outcome occurred in 0 of 50 patients in the warfarin group and in 16 of 54 patients (29.6%) in the placebo group (hazard ratio [HR], 0.03; 95% confidence interval [CI], 0.01-0.09; p< 0.001). During the entire study period of 42 months, the composite outcome occurred in 14 (36.8%) patients in the warfarin group and in 17 (31.5%) in the placebo group (HR, 0.72; 95%CI, 0.35-1.46; p=0.36) (Figure). There were 1 major bleeding in the warfarin group and 3 deaths unrelated to study outcome (1 in the warfarin group and 2 in the placebo group). Of the 31 episodes of recurrent VTE, 27 (87.1%) were DVT and 28 (90.3%) were unprovoked.

Conclusions: After 6 months of anticoagulation for a first episode of unprovoked proximal DVT, extending anticoagulation for an additional 18 months was not associated with a long-term reduction in the risk of recurrent VTE or major bleeding after stopping anticoagulation.

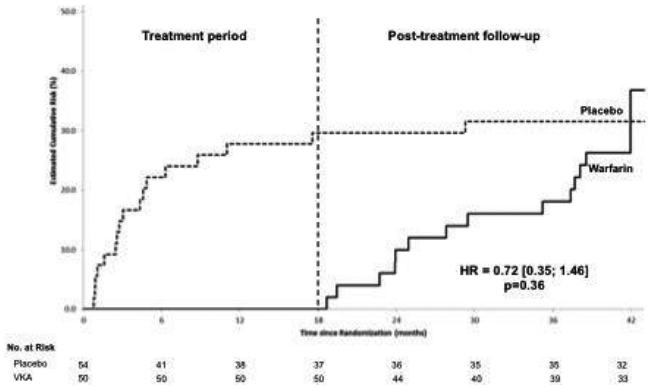

FIGURE 1 Cumulative risk of the composite outcome (recurrent VTE or major bleeding) over the entire study period

ASY 14.2 | Odds of Pharmacologic Prophylaxis by Venous Thromboembolism and Bleeding Risk Groups

S. Kaatz[1]; D. Paje[2]; A. Conlon[3]; S. Bernstein[3,4]; B. Almasri[5]; P. Patel[1]; G. Salem[6]; M. Hettiarachchi[7]; V. Hereford[8]; M. Cerasale[1]

[1]Henry Ford Hospital, Hospital Medicine, Detroit, United States, [2]University of Michigan, Hospital Medicine, Ann Arbor, United States, [3]University of Michigan, Internal Medicine, Ann Arbor, United States, [4]Ann Arbor VA, HSR&D Center of Innovation, Ann Arbor, United States, [5]Beaumont Hospital, Hospital Medicine, Royal Oak, United States, [6]Mclaren, Hospital Medicine, Lapeer, United States, [7]Detroit Medical Center Wayne State University / Detroit Medical Center - Sinai Grace Hospital, Internal Medicine, Detroit, United States, [8]St.Joseph Mercy Hospital, Family Medicine, Brighton, United States

Background: Guidelines for venous thromboembolism (VTE) prevention recommend risk assessment for both VTE and bleeding.

Aims: To evaluate the current practice of pharmacologic prophylaxis by VTE and bleeding risk groups.

Methods: Trained abstractors from 51 hospitals participating in the Michigan Hospital Medicine Safety collaborative collected elements of the Padua VTE risk and IMPROVE bleeding risk scores of hospitalized medical patients. Those admitted to intensive care, on therapeutic anticoagulation or admitted with VTE were excluded. A Padua score of ≥ 4 and an IMPROVE score of ≥7 were classified as high risk. Rates of pharmacologic prophylaxis during the admission by VTE and bleeding risk groups were compared. VTE and major bleeding event rates were also assessed. Major bleeding was defined using ISTH

TABLE 1 Prophylaxis, Major Bleed and VTE Rates by Risk Group

VTE risk	Bleed risk	Total Subjects	Prophylaxis	Major Bleed	VTE	Major Bleed or VTE
High	High	2678 (3.4%)	1111 (41.5%)	215 (8.0%)	13 (0.5%)	225 (8.4%)
High	Low	14156 (17.9%)	10588 (74.8%)	194 (1.4%)	48 (0.3%)	236 (1.7%)
Low	High	4137 (5.2%)	1473 (35.6%)	401 (9.7%)	7 (0.2%)	405 (9.8%)
Low	Low	58093 (73.5%)	37404 (64.4%)	919 (1.6%)	70 (0.1%)	979 (1.7%)

TABLE 2 Odds of Receiving Pharmacologic Prophylaxis by Risk Group

Comparison	OR (95% CI)	P-value
High risk bleed vs. Low risk bleed	0.28 (0.27, 0.30)	<.0001
High risk VTE, low risk bleed vs. All others	2.09 (2.01, 2.19)	<.0001

criteria. All hospitals used VTE risk assessment tools; however none formally assessed bleeding risk.

Results: Of 79,064 patients, 50,576 (64%) received pharmacologic prophylaxis. Major bleeding events were more common than VTE (Table 1). Patients at high risk of bleeding were less likely to receive pharmacologic prophylaxis, regardless of VTE risk, OR 0.28 (Table 2). Odds of receiving pharmacologic prophylaxis was highest (OR 2.09) in patients with high VTE and low bleeding risk, representing 17.9% of the cohort. Of those receiving pharmacologic prophylaxis, 39,988 (79.1%) were either low risk for VTE or high risk for bleeding. Odds of Receiving Pharmacologic Prophylaxis was calculated from logistic mixed effects models with hospital level random intercepts.

Conclusions: Despite the lack of hospital-supported formal bleeding risk assessment tools, providers tend to use less pharmacologic prophylaxis in patients at increased risk of bleeding. In congruence with guidelines, patients at high risk for VTE and low risk of bleeding were twice as likely to receive pharmacologic prophylaxis. However, four out of five patients received anticoagulant prophylaxis despite having low VTE risk or high bleeding risk.

ASY 14.3 | VTE in Acute Leukemia: Improved Survival with Anticoagulation

T. Cox[1,2]; M. Khan[3]; W. Qiao[4]; M. Nassif[3]; M. Alzubaidi[3]; N. Garg[5]; T. Oo[6]; C. Rojas-Hernandez[6]

[1]*University of Texas Health Science Center at Houston, Internal Medicine, Houston, United States,* [2]*University of Texas MD Anderson Cancer Center, Houston, United States,* [3]*University of Texas MD Anderson Cancer Center, Leukemia, Houston, United States,* [4]*University of Texas MD Anderson Cancer Center, Biostatistics, Houston, United States,* [5]*University of Texas MD Anderson Cancer Center, Diagnostic Radiology, Houston, United States,* [6]*University of Texas MD Anderson Cancer Center, Benign Hematology, Houston, United States*

Background: Venous thromboembolism (VTE) has long been regarded as the second leading cause of death in cancer patients. Treatment with anticoagulation (AC) can be complicated in cancer patients owing to therapeutic side effects and thrombocytopenia (TCP). Contraindications to VTE treatment are prominent in acute leukemia (AL) patients, where antineoplastic treatment expectedly causes significant myeloid and end-organ toxicity. Due in part to its lethality and rarity, therapeutic outcomes of VTE in patients with AL and severe TCP have not been looked at in detail.

Aims: Delineate the differences in VTE treatment outcomes in patients with AL+TCP.

Methods: Approved by the Institutional Review Board with consent waiver, we retrospectively identified 74 AL+TCP patients from 2002 to 2016 with acute pulmonary embolism (PE;21), lower extremity proximal deep venous thrombosis (DVT;44), or both (9) treated with only AC (23), only inferior vena cava filter (IVCF) (21), or observation (OB) (30). We excluded those with both IVCF and AC from analysis. χ^2 or Kruskal-Wallis tests were used to examine associations between groups. Cox regression model was used to evaluate the effect on overall survival (OS; VTE to death or last follow-up).

Results: There were no significant differences in age, sex, performance status, VTE recurrence, clinically relevant bleeding (CRB), or cause of demise, and no IVCF complications. A statistical difference between index event and treatment modalities was found, with predominant use of IVCF in patients with DVT (16) or both (3) vs PE (2) (p=0.02). AC had a strikingly significant improvement in OS, while IVCF was nearly indistinguishable from OB (Figure 1). On multivariate analysis, AC was associated with a 71% lower hazard of death compared to OB (Table 1).

Conclusions: Treating AL-associated VTE with AC was associated with increased survival, without increased CRB. IVCFs did not lead to

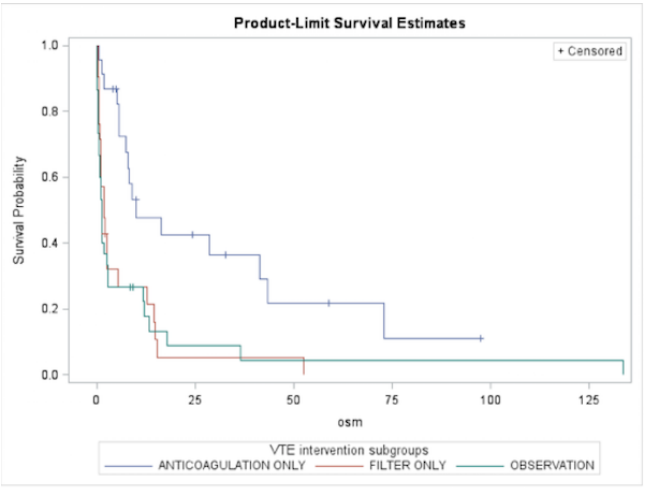

FIGURE 1 Kaplan-Meier Estimates Stratified by Intervention

TABLE 1 Multivariate Cox model for OS

Parameter		Hazard Ratio	95% Confidence Limits		p-value
Intervention	Anticoagulation vs. observation	0.29	0.14	0.58	0.0004
	Filter vs. observation	0.66	0.36	1.22	0.19
History of VTE	Yes vs. no	1.77	1.01	3.09	0.05
Index event	PE vs. Both	0.26	0.1	0.72	0.009
	DVT vs. Both	0.55	0.22	1.35	0.19

complications or an increased rate of death by sepsis, or provided no statistical benefit compared to observation.

ASY 14.4 | Incidence of Fatal Thromboembolic and Bleeding Events in over Ninety Year-old Patients on Treatment with Oral Anticoagulants for Non-valvular Atrial Fibrillation

M. Giustozzi[1]; M.C. Vedovati[1]; M. Verso[1]; P. Verdecchia[2]; G. Bogliari[1]; S. Conti[3]; L. Pierpaoli[4]; E. Marchesini[1]; G. Agnelli[1]; C. Becattini[1]

Matteo degli Infermi Hospital, Division of Cardiology, Spoleto, Italy, [4]Santa Maria della Croci Hospital, Emergency Medicine, Ravenna, Italy

Background: The net clinical benefit of oral anticoagulants (OAC) in very elderly patients with non-valvular atrial fibrillation (AF) remains to be defined.

Aims: To evaluate the clinical features associated with type of OAC treatment and the clinical outcome in patients with AF and more than 90 year of age.

Methods: Consecutive patients with age ≥ 90 years treated with either direct oral anticoagulants (DOACs) or vitamin K antagonists (VKAs) for non-valvular AF were included in the study.

Results: Overall, 235 patients were analyzed: mean age was 91.8±1.8, female gender 63%. Previous ischemic stroke or TIA, chronic heart failure and renal creatinine clearance lower than 50 ml/min were reported in 27.2, 35.3, 15.3% respectively.

168 (72.5%) patients were treated with DOACs (dabigatran 19%, rivaroxaban 46% and apixaban 35%) and 67 (28.5%) with VKAs. Twenty-three out of 168 (13.7%) were prescribed with the standard dose of DOACs. The mean CHA_2DS_2-VASc score was 5.07±1.3 and 4.37±1.3 (p=0.001) and the mean HAS-BLED score was 2.64±1.2 and 2.27±1.1 (p=0.026) in patients receiving DOACs and VKAs, respectively. Previous stroke (OR 3.7 95% CI 1.6-8.2), female gender (OR 2.4 95% CI 1.4-4.4) and previous bleeding (OR 4.2 95% CI 1.8-9.8) were independently associated with DOAC prescription. Mean $CHADS_2$, CHA_2DS_2-VASc and HAS-BLED were similar in patients prescribed with standard and reduced doses of DOACs. In patients receiving VKAs mean TTR was 68.8±22.8%.

After a mean follow-up of 483±375 days, 46 patients died (21%). Fatal bleedings occurred in 4 patients, fatal myocardial infarction in 2 and fatal ischemic stroke in one (8.9, 4.3 and 2.2% of all deaths). Fatal thrombotic and bleeding events occurred in 4 and in 2% of patients receiving DOACs and VKAs (p=ns).

Conclusions: A considerable proportion of very elderly patients treated with DOACs receive a standard dose. DOAC patients have a higher thrombotic and bleeding risk compared to VKA patients. No differences were found in terms of fatal events between DOAC and VKA patients.

ASY 22.1 | Sex-specific Incidence Rates of Deep Vein Thrombosis and Pulmonary Embolism in The Netherlands

L.J.J. Scheres[1,2]; D. Kort[1]; N. van Rein[3]; N. Wiersma[4]; H.W. Vermaas[5]; F.J.M. van derMeer[3]; W.M. Lijfering[1,3]; S.C. Cannegieter[1,3]

[1]Leiden University Medical Center, Department of Clinical Epidemiology, Leiden, The Netherlands, [2]Academic Medical Center, Department of Vascular Medicine, Amsterdam, The Netherlands, [3]Leiden University Medical Center, Department of Internal Medicine, Section of Thrombosis and Hemostasis, Leiden, The Netherlands, [4]Thrombosis Center Saltro, Utrecht, The Netherlands, [5]Thrombosis Center Lab West, The Hague, The Netherlands

Background: The incidence of venous thrombosis (VT) differs between men and women but its distribution over the ages is uncertain, as well as whether the presenting location (deep vein thrombosis, DVT or pulmonary embolism [PE]) differs between the sexes.

Aims: To study sex-specific incidence rates stratified by VT location in a large population.

Methods: Data on all VT patients who were treated with vitamin K antagonists between 2008-2013 were collected at 3 anticoagulation clinics in 2 Dutch provinces serving 1.5 million people. The Dutch Statistics Netherlands provided total numbers of inhabitants by age and sex per postal code. Person-years (py) were calculated based on these numbers corresponding with the geographical service areas of the anticoagulation clinics. Incidence rates (IR) were estimated with 95% confidence intervals (CI) for DVT, PE (with or without DVT) and total VT events. Incidence rate ratios (IRR) in men and women were adjusted for age by Mantel-Haenszel methods.

Results: 7373 VT (3707 DVT [50.2%] and 3666 PE [49.8%]) events occurred in 7 472 400 py at a rate of 9.9 per 10 000 py (95%CI 9.6-10.1), IR 10.5 per 10 000 py (95%CI 10.0-10.9) for women and 9.2 per 10 000 py (95%CI 8.9-9.5) for men. VT incidence was higher in women than in men until the age of 50. At ages 50-70 VT incidence

TABLE 1 Incidence rates (IR) and incidence rate ratios (IRR) with 95%CI for DVT and PE in men and women per age group

Age group and sex		Events (n), PE/DVT	Person years (n)	IR (95%CI), DVT/PE	IRR (95%CI), DVT/PE
Men 15-50 yrs	DVT/PE	462/421	2254325	2.1 (1.9-2.2)/ 1.9 (1.7-2.1)	1.1 (1.0-1.2)
Men 50-70 yrs	DVT/PE	831/696	1018525	8.2 (7.6-8.7)/ 6.8 (6.3-7.4)	1.2 (1.1-1.3)
Men >70 yrs	DVT/PE	413/502	352550	11.7 (10.6-12.9) / 14.2 (13.0-15.5)	0.8 (0.7-0.9)
Women 15-50 yrs	DVT/PE	738/636	2283025	3.2 (3.0-3.5)/ 2.8 (2.6-3.0)	1.2 (1.1-1.3)
Women 50-70 yrs	DVT/PE	517/593	1031875	5.0 (4.6-5.5)/ 5.8 (5.3-6.2)	0.9 (0.8-1.0)
Women >70 yrs	DVT/PE	746/816	531250	14.0 (13.1-15.1) / 15.4 (14.3-16.4)	0.9 (0.8-1.0)

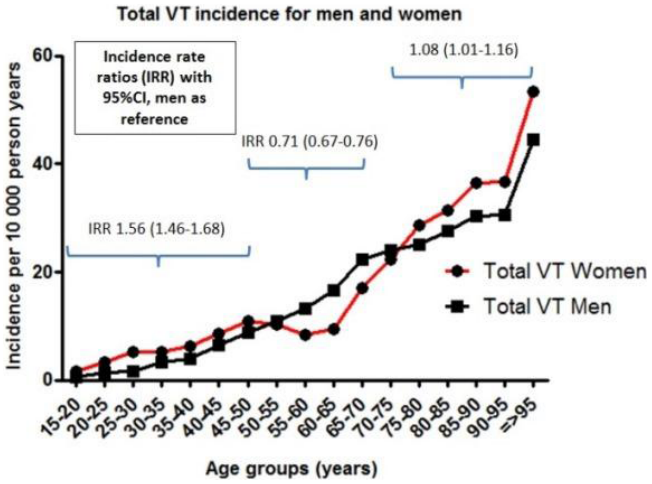

FIGURE 1 Total venous thromboembolism (VT) incidence for men and women separately

was higher in men. From 70 years onwards VT incidence was again higher in women (Figure 1). In women, DVT incidence was higher than PE incidence for ages 15-50, IRR 1.2 (95%CI 1.1-1.3) (Table 1), while for ages 50-70 and >70, DVT incidence was lower than PE, IRR 0.9 (95%CI 0.8-1.0) and 0.9 (0.8-1.0), respectively. In men DVT incidence was higher than PE incidence for both age groups 15-50 and 50-70, IRR 1.1 (95%CI 1.0-1.13) and 1.2 (95%CI 1.1-1.3), respectively, and was lower at 0.8 (95%CI 0.7-0.9) >70 years.

Conclusions: The incidence and presenting VT location differ between men and women among age groups for which the explanation is yet unknown.

ASY 22.2 | Incidence Rate and Factors Influencing Occurrence of Unprovoked Venous Thrombosis during Long Term Period of Follow-up in Women with Previous Pregnancy Related Thromboembolism

J. Bodrozic[1]; P. Miljic[1,2]; D. Lekovic[1,2]; M. Mitrovic[1,2]; M. Gojnic Dugalic[2,3]

[1]*Clinical Centre of Serbia, Clinic of Haematology, Belgrade, Serbia,* [2]*University of Belgrade, Faculty of Medicine, Belgrade, Serbia,* [3]*Clinical Centre of Serbia, Clinic for Gynecology and Obstetrics, Belgrade, Serbia*

Background: Venous thromboembolism (VTE) complicates 0.5-2.2 per 1000 deliveries. Women with pregnancy related thrombosis are at increased risk of venous thromboembolism in next pregnancies. However, little is known about long term risk of unprovoked venous thrombosis in women with previous pregnancy related thrombosis.

Aims: Determine the incidence rate and try to identify risk factors for occurrence of unprovoked VTE in women with pregnancy related index VTE

Methods: We conducted a retrospective analysis of 223 consecutive women that developed VTE during pregnancy or puerperium (6 weeks after the delivery) from January 1985 to January 2015, and who were referred to our institution. We evaluated age, gestational age at time of thrombosis, localization and massiveness of VTE, history of spontaneous pregnancy loss, presence of congenital thrombophilia and family history as risk factors for development of unprovoked VTE after pregnancy related thrombosis. Time to event analysis was done with Kaplan-Meier estimates and Cox proportional hazards modeling.

Results: After the median follow-up of 9 years, in 223 consecutive woman with pregnancy related thrombosis, 22 recurrent unprovoked VTE episodes were documented with incidence rate of 10,3 cases per 1000 person-years. Two women (9,1%) developed recurrent VTE during 2 year follow up, 4 (18,2%) during 5 years and 16 (72,7%) during more than 5 years of follow up. Cox regression model didn't identify any of the investigated factors as unfavorable in terms of occurrence of unprovoked thrombosis. Only positive thrombophilia testing was close to reaching statistical significance (X^2 = 3.486, p=0,062).

Conclusions: After initial pregnancy related thrombosis the rate of spontaneous VTE during long term period is about 1% per year. Carriers of hereditary thrombophilia who experienced pregnancy related thrombosis may be at slightly increased risk than non-carriers to develop unprovoked thrombosis during long term period.

ASY 22.3 | Aspirin, Heparin or Both to Improve Live Birth in Women with Antiphospholipid Syndrome and Recurrent Pregnancy Loss

M.C. Marijnen[1]; L.J.J. Scheres[1,2]; S. Middeldorp[1]

[1]*Academic Medical Center, Department of Vascular Medicine, Amsterdam, The Netherlands,* [2]*Leiden University Medical Center –, Department of Clinical Epidemiology, Leiden, The Netherlands*

Background: Aspirin and heparin are widely used to prevent pregnancy complications in women with antiphospholipid syndrome

(APS), although the evidence underlying this approach is limited. We are currently updating a previous systematic review (Empson et al, 2005, Cochrane Database of Systematic Reviews). Here, we report the evidence on the outcome live birth. We will report other predefined outcomes on the congress.

Aims: To systematically review the evidence from randomized controlled trials that compared aspirin, heparin, or both on the effect of live birth in women with APS and recurrent pregnancy loss.

Methods: A systematic literature search updating the previous search (Empson 2005) was done in Embase and PubMed on the 29th of March 2016. Randomized controlled trials in women with APS and recurrent pregnancy loss (2 or more) assessing the effect of aspirin, heparin (low-molecular-weight heparin [LMWH] or unfractionated heparin [UFH]) or both versus aspirin or placebo with live birth as outcome were included. Studies in which the laboratory criteria of APS were not met were excluded. Studies underwent critical appraisal and effects were pooled in a random effects model.

Results: We found 939 articles of which 27 remained after title and abstract screening. Full text review yielded 9 studies. Five studies with a total of 398 women were included. We compared aspirin plus heparin (LMWH or UFH) versus aspirin alone. The pooled odds ratio (OR) for live birth was 2.28 (95%CI: 1.24-4.18) in favour of aspirin plus heparin compared to aspirin (Figure 1). There was significant heterogeneity between the subgroups of LMWH and UFH (OR for aspirin plus LWMH versus aspirin 1.16, 95%CI: 0.58-2.29; OR for aspirin plus UFH versus aspirin 3.75, 95%CI: 2.04-6.09; test for subgroup differences: I^2 84.2%, p 0.01;).

Conclusions: Heparin plus aspirin compared with aspirin improves live birth in women with APS and recurrent pregnancy loss. This effect is driven by studies that investigated UFH and not LMWH.

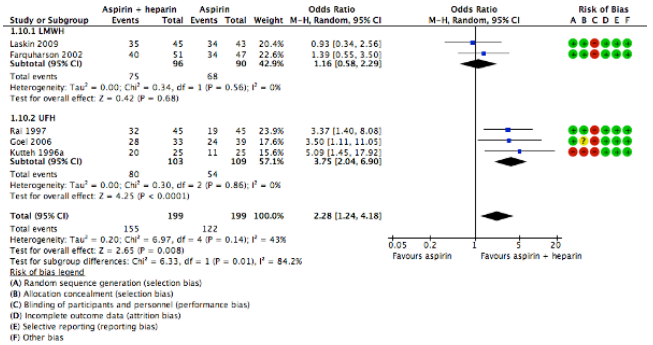

FIGURE 1 Aspirin plus heparin (LMWH or UFH) versus low-dose aspirin for live birth as outcome

ASY 22.4 | Induced Delivery and Neuraxial Anesthesia in Pregnant Women Using Thromboprophylaxis: Data from the Highlow Study

I. Bistervels[1]; A. Buchmüller[2]; S. Bleker[1]; C. Chauleur[3]; F. Ní Aínle[4]; J. Donnelly[4]; P. Verhamme[5]; A.F. Jacobsen[6]; H. Décousus[2]; S. Middeldorp[1]; for the Highlow Investigators

[1]Academic Medical Center Amsterdam, Vascular Medicine, Amsterdam, The Netherlands, [2]CHU Saint-Etienne, Hôpital Nord, Service Médecine Vasculaire et Thérapeutique, Saint-Etienne, France, [3]CHU Saint-Etienne, Hôpital Nord, Service de Gynéco-Obstétrique, St Etienne, France, [4]Rotunda Hospital, Dublin, Ireland, [5]University Hospital Leuven, Center for Molecular and Vascular Biology, Leuven, Belgium, [6]Oslo University Hospital, Oslo, Norway

Background: Antepartum and postpartum thromboprophylaxis with low-molecular-weight heparin (LWMH) is indicated in most women with a personal history of venous thromboembolism (VTE) to prevent recurrence. The optimal dose of LMWH is unknown and both low and intermediate doses are suggested. A higher dose may be more efficacious but may increase the risk of (peripartum) bleeding and affect the possibility to receive neuraxial anesthesia (NA). NA is contraindicated when time since last injection is less than 12 hours for low or less than 24 hours for intermediate dose LMWH. Delivery may be induced to assure the possibility of NA.

Aims: To explore the practices regarding inducing delivery and applying NA in women using antepartum LMWH.

Methods: The ongoing Highlow study (NCT **01828697**) is a multicenter, multinational randomized controlled trial comparing efficacy and safety of two doses of LMWH. We compared the type of delivery

TABLE 1 Distribution of type of delivery and NA by dose LMWH

Variable	Low dose LMWH	Intermediate dose LMWH	OR (CI 95%)
Total, n	78	83	
Spontaneous delivery, n (%)	34 (43.6)	43 (51.8)	1.18 (0.69-2.06)
Induced delivery, n (%)	43 (55.1)	35 (42.2)	
Time between last injection and delivery in hours, median (range)	29.3(4.7- 312.1)	35.0 (0.8-149.7)	
Type of anesthetic			
None, n (%)	30 (38.5)	32 (38.6)	
Neuraxial anesthesia, n (%)	32 (41.0)	31 (37.3)	
• Netherlands n (% of delivery per country) • France, n (% of delivery per country) • Ireland, Norway and Belgium n (% of delivery per country)	16/49 (33), 13/19 (68), 3/10 (30)	16/55 (29), 10/15 (66), 5/12 (42)	
Other, n (%): • Due to time interval • Due to preference for other type of anesthesia	16 (20.5), 1 (1.3) 15 (19.2)	19 (22.9) 6 (7.2), 13 (15.6)	5.64 (0.66-47.90)

TABLE 2 Distribution of type of anesthetic by type of delivery

Variable	Spontaneous delivery	Induced delivery	OR (CI 95%)
Total, n	77	79	
Time between last injection and delivery in hours, median (range)	27.4 (0.8-222.1)	38.4 (7.5-312.1)	
Type of anesthetic			
None, n (%)	36 (46.28)	24 (30.4)	
Neuraxial anesthesia, n (%)	22 (28.6)	40 (50.6)	1.77 (0.97-3.25)
Other, n (%)	19 (24.7)	15 (19.0)	
Due to time interval	4 (5.2)	3 (3.8)	

and type of anesthesia between the two doses of LMWH and between countries. Data from 161 patients who have delivered were used for this analysis; updated results will be presented at the Congress.

Results: There was no difference in spontaneous and induced delivery between LMWH doses. NA was applied in 41.0% of women on low dose and 37.3% of women on intermediate dose (Table 1). In women who used another type of anesthesia, this was more often due to a short time interval since last injection in the low than the intermediate dose (1.3% versus 7.2%, OR 5.64, 95% CI 0.66-47.90). In induced deliveries, NA was applied more often than in spontaneous deliveries (Table 2). Use of NA varied substantially between countries (Table 1).

Conclusions: Both spontaneous and induced delivery is applied regardless of LMWH dose. Women using intermediate dose LMWH seem more likely to not receive NA due to a short time interval since last dose. There is substantial variation in NA practice between countries.

ASY 35.1 | No Further Reduction in the Number of Required CT Pulmonary Angiograms When Implementing the ADJUST (Age Adjusted) D-dimer Cut-off Level in the YEARS Algorithm

L.M. van derPol[1,2]; T. van derHulle[1]; Y.W. Cheung[3]; T. van Bemmel[4]; J. van Es[5]; L.M. Faber[6]; M. ten Wolde[7]; H. Hofstee[8]; M.M.C. Hovens[9]; M. Nijkeuter[10]; R.C.J. van Klink[11]; M.J.H.A. Kruip[12]; A.T.A. Mairuhu[2]; S. Middeldorp[3]; M.V. Huisman[1]; F.A. Klok[1]

[1]*Leiden University Medical Center, Department of Medicine - Thrombosis and Hemostasis, Leiden, The Netherlands,* [2]*HagaHospital, Department of Internal Medicine, The Hague, The Netherlands,* [3]*Amsterdam Medical Center, Department of Vascular Medicine, Amsterdam, The Netherlands,* [4]*Gelre Hospital, Department of Medicine, Apeldoorn, The Netherlands,* [5]*OLVG Hospital, Department of Pulmonology, Amsterdam, The Netherlands,* [6]*Red Cross Hospital, Department of Medicine, Beverwijk, The Netherlands,* [7]*Flevo Hospital, Department of Medicine, Almere, The Netherlands,* [8]*The Hague Medical Center, Department of Medicine, The Hague, The Netherlands,* [9]*Rijnstate Hospital, Department of Medicine, Arnhem, The Netherlands,* [10]*Univeristy Medical Center Utrecht, Department of Medicine, Utrecht, The Netherlands,* [11]*Alrijne Hospital, Department of Pulmonology, Leiderdorp, The Netherlands,* [12]*Erasmus MC, Department of Hematology, Rotterdam, The Netherlands*

Background: The YEARS algorithm was designed to simplify the diagnostic work-up of pulmonary embolism (PE) and to reduce the number of necessary computer tomography pulmonary angiography (CTPA) scans (*Figure 1*). A recent outcome study confirmed the safety and efficacy of YEARS (*2016 ESC abstract 5727*). Another strategy to reduce the number of CTPAs is the age-adjusted D-dimer cut-off in patients aged 50 or older. A combination of both diagnostic strategies might save additional CTPAs.

Aims: To investigate whether the age adjusted cut-off for D-dimer in patients aged 50 or older provides incremental diagnostic value to YEARS in patients with suspected PE, i.e. whether the number of required CTPAs will diminish further after implementation of this D-dimer cut-off without jeopardizing safety.

Methods: We performed a post hoc analysis of the YEARS study to compare the number of required CTPAs for the two D-dimer cut-off scenarios.

Results: Using YEARS, 1651 patients (48%) were managed without CTPA; PE was diagnosed in 456 (13%) patients at baseline and 18 (0.52%) venous thrombo-embolism (VTE) during 3-month follow-up in patients with initial normal testing (*Figure 1*). When applying the age adjusted D-dimer cut-off, 1497 patients (43%) would have been managed without CTPA for an absolute difference of 4.4% (95%CI 2.1-6.8) (*Table 1*). However, 4 PE would have been missed at baseline in patients with ≥ 1 YEARS item (*see arrow in figure 1*).

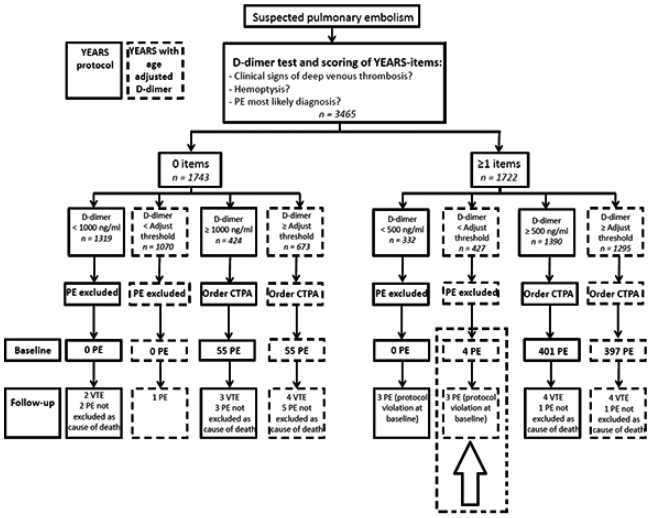

FIGURE 1 Flowchart of YEARS algorithm for both strategies

TABLE 1 Overview of patients managed without CTPA and failure rate

	Number of patients managed without CTPA	Failure rate
YEARS protocol	1651/3465 (48%)	18/3465 (0.52%)
Years combined with age adjusted D-dimer	1497/3465 (43%)	22/3465 (0.64%)
Total difference between both protocols	+ 154 CTPAs	+ 4 failures

Conclusions: In our cohort, there was no added value of implementing the ADJUST (age adjusted) D-dimer cut-off level into the YEARS algorithm due to both an increased required number of CTPAs for excluding PE and an increased 3-month VTE failure rate.

ASY 35.2 | Mean Bilateral Proximal Extension of the Clot - A New Score for Risk Stratification of Pulmonary Embolism

J.P. Ghanima[1]; F. Bremptum[2]; M. Schnitzkewitz[2]; M. Tavoly[1]; J. Gleditich[3]; W. Ghanima[2]

[1]Østfold Hospital, Medicine, Grålum, Norway, [2]Østfold Hospital, Gålum, Norway, [3]Østfold Hospital, Radiology, Grålum, Norway

Background: Risk stratification is routinely performed to decide the management of patients with pulmonary embolism (PE). Various tools have been proposed and validated for risk stratification oF PE including clinical, biochemical, radiological and echocardiographic parameters. Mean bilateral proximal extension of the clot (MBPEC) is a simple CT radiological score that was derived and validated in a small cohort of PE patients (Ghanima et al. J Inter Med 2007; 261).

Aims: To validate the score by investigating in a larger cohort of patients the association between MBPEC and the severity of PE as determined by various clinical (Pulse rate (PR), Systolic Blood pressure (SBP), PESI score), biochemical (troponin), management associated (ICU admission and thrombolysis) and CT radiological (right/Left ventricular ratio (RV/LV)) parameters.

Methods: MBPEC score is estimated by calculating the mean value of the largest affected vessel [subsegmental= 1, segmental= 2, lobar= 3, main pulmonary artery= 4] in each lung. Patients were identified from Østfold Thrombosis Registry, Norway. Only patients who were alive and provided written consent were included in this study. The study was approved by the ethics committee. ANOVA or Kruskal Wallis test were used for continuous variables and Chi square test for categorical variables.

TABLE 1 Level or the distribution of various pe severity markers according to the mbpec score

MPEC score	1 n=25 n=25	2 n=67	3 n=65	4 n=98	P-value
PR /min	80	85	85	91	0.017
SBP mmHg (mean)	134	141	142	140	0.497
SaO2% (mean)	95	96	96	94	0.004
PESI score (mean)	66	66	67	75	0.050
Troponin T/I (n +/-)	2	2	4	37	0.000
D-dimer mg/l (mean)	2	2.6	5.3	9	0.000
RV/LV ratio (mean)	1	1	1.1	1.3	0.000
ICU admission (N)	2	6	8	35	0.000
ICU admission (N) Thrombolysis (N)	0	0	2	8	0.006

Results: 255 patients with PE were identified; 152 (59%) were males. Mean age was 59 years. MBPEC score was 1 in 25 (10%), 2 in 67 (26%), 3 in 65 (25%) and 4 in 98 (38%). Table shows the level or the distribution of various PE severity markers according to the MBPEC score. Troponin T or I were available in 153 patients only (16, 38, 31, 68 in score 1-4).

Conclusions: Higher MBPEC score was associated with increased severity of PE in most studied parameters including PESI score, ICU admission and thrombolysis. The score can be a potentially valuable tool for risk stratification of PE. Prospective outcome studies are needed to evaluate its prognostic value in clinical practice.

ASY 35.3 | Disease Prevalence Dependent Failure Rate in Diagnostic Management Studies in Suspected Deep Vein Thrombosis

C.E.A. Dronkers[1]; Y.M. Ende-Verhaar[1]; P.A. Kyrle[2]; M. Righini[3]; S.C. Cannegieter[1,4]; M.V. Huisman[1]; F.A. Klok[1]

[1]Leiden University Medical Center, Department of Thrombosis and Hemostasis, Leiden, The Netherlands, [2]General Hospital Vienna, Department of Medicine I, Vienna, Austria, [3]Geneva University Hospitals and Faculty of Medicine, Department of Angiology and Hemostasis, Geneva, Switzerland, [4]Leiden University Medical Center, Department of Clinical Epidemiology, Leiden, The Netherlands

Background: Current guidelines state that the standard against which deep vein thrombosis (DVT) diagnostic management studies should be evaluated is a failure rate of < 1.3% (upper limit 95%CI 4.4%), i.e. the percentage of patients with a VTE during 3 months of follow-up despite a normal venogram. However, the disease prevalence in DVT studies has decreased over the past decade. Bayes' theorem states that disease prevalence and failure rate are connected, implying that the diagnostic standard of future diagnostic management studies should be changed accordingly.

Aims: To evaluate the association of DVT prevalence and diagnostic failure rate in published studies on diagnosis of DVT.

Methods: Systematic review and meta-analysis selecting all high-quality diagnostic studies in suspected acute DVT from 1990 on, including ≥ 100 consecutive patients with a follow-up period of ≥ 3 months, using an appropriate diagnostic standard, i.e. (an algorithm consisting of) a validated clinical decision rule combined with a highly sensitive D-dimer test, venography, compression ultrasound (CUS) (whole leg or 2 point CUS) or duplex ultrasound.

Results: Fifty-one studies including 31.511 patients were selected, with a mean baseline DVT prevalence of 20% (95%CI 19.6-20.5, range 1.2-47%) and a failure rate of 0.83% (95%CI 0.73-0.93, range 0-2.8%). Disease prevalence decreased over the years with 2.55% per 5 year (R^2 0.066, p< 0.001; Fig. 1). The mean failure rate decreased with lower disease prevalence in individual studies (R^2 0.121, p< 0.001; Fig. 2), with an absolute 1.0% lower DVT prevalence leading to a mean 0.020 percentage points decrease in failure rate.

Conclusions: We have confirmed the trend of decreasing DVT prevalence and diagnostic failure rates in DVT diagnostic studies. A DVT prevalence-dependent diagnostic safety threshold for future

diagnostic studies should be considered to prevent validation and implementation of new diagnostic strategies with insufficient sensitivity to safely rule-out DVT.

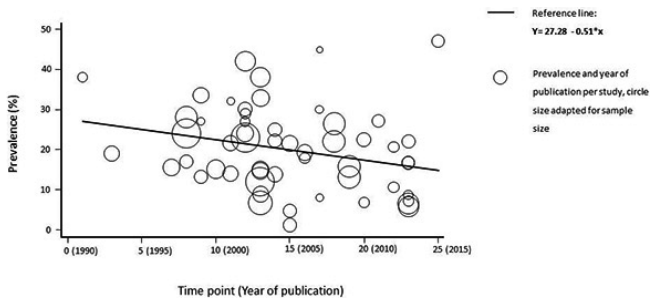

FIGURE 1 Decrease of disease prevalence over the last years

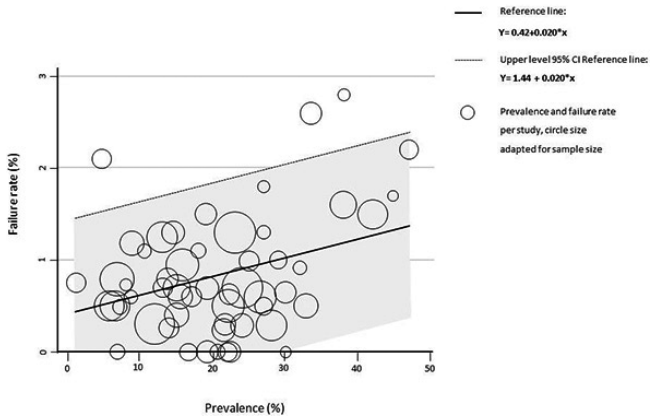

FIGURE 2 Prevalence versus failure rate in high quality deep vein thrombosis diagnostic management studies

ASY 35.4 | Clinical characteristics and management of 10,329 patients with a confirmed diagnosis of venous thromboembolism: the GARFIELD-VTE registry

W. Ageno[1]; P. McCallum[2]; S. Haas[3]; J.I. Weitz[4]; P. Angchaisuksiri[5]; H. Bounameaux[6]; S.Z. Goldhaber[7]; S. Goto[8]; G. Kayani[9]; J. Dalsgaard Nielsen[10]; L.G. Mantovani[11]; S. Schellong[12]; A.G.G. Turpie[13]; P. Prandoni[14]; A.K. Kakkar[9,15]

[1]University of Insubria, Department of Clinical and Experimental Medicine, Varese, Italy, [2]Queen Mary University of London, Barts and The London School of Medicine and Dentistry, London, United Kingdom, [3]Technical University of Munich, Formerly Department of Medicine, Munich, Germany, [4]McMaster University and Thrombosis and Atherosclerosis Research Institute, Hamilton, Canada, [5]Ramathibodi Hospital, Mahidol University, Department of Medicine, Bangkok, Thailand, [6]University Hospitals of Geneva, Faculty of medicine, Geneva, Switzerland, [7]Harvard Medical School, Boston, United States, [8]Tokai University School of Medicine, Kanazawa, Japan, [9]Thrombosis Research Institute, London, United Kingdom, [10]Copenhagen University Hospital, Copenhagen, Denmark, [11]University of Milano- Bicocca, Milan, Italy, [12]Krankenhaus Dresden Friedrichstadt, Dresden, Germany, [13]McMaster University, Hamilton, Canada, [14]University of Padua, Padua, Italy, [15]University College London, London, United Kingdom

Background: The aim of venous thromboembolism (VTE) treatment is prevention of the acute and chronic complications of deep vein thrombosis (DVT) and pulmonary embolism (PE). The treatment of VTE has evolved with the introduction of direct oral anticoagulants (DOACs). GARFIELD-VTE is a global prospective registry designed to characterize the epidemiology and to observe management and outcomes of VTE patients.

Aims: To describe the baseline characteristics of patients enrolled from 2014 to 2016.

Methods: Interim data on patient demographics, risk factors, and diagnostic and treatment strategies were collected at 410 sites in 28 countries.

Results: Of the 10,329 patients eligible for analysis, 61.7% had DVT and 38.3% had PE. Mean (SD) age was 58.4 y (16.9), and 49.7% were female. Provoking factors included: surgery (12.3%), hospitalization (11.8%), trauma (7.7%), acute illness (5.6%), known thrombophilia (2.8%) and in women, oral contraceptives (10.0%), pregnancy (3.6%) and hormone replacement therapy (2.8%). A total of 2057 patients had either a history of cancer (10.8%) or active cancer (9.1%), and 3.7% had renal insufficiency. DVT was diagnosed using compression ultrasonography in 95.4% and PE by CT scan in 91.5%. DVT commonly involved the lower limb (89.9%), on the left side (53.6%) and 6.6% were bilateral. Upper limb involvement occurred in 8.4%. The most proximal artery involvement in PE patients was: main (29.5%), lobar (29.5%), segmental (31.3%) or sub-segmental (9.7%). Anticoagulant (AC) treatment within ±2 wks of diagnosis included: parenteral AC only (17.6%), parenteral AC followed by vitamin K antagonists (VKA) (28.3%), VKA only (3.7%), and DOACs (50.5%). In addition, 4.4% received thrombolytic therapy; 2.1% underwent surgical/mechanical interventions; and 34.8% of patients received graduated compression stockings.

Conclusions: Our data indicate that there is wide heterogeneity among VTE patients necessitating an individualized approach to therapy.

ASY 36.1 | Direct Oral Anticoagulants for Pulmonary Embolism: Importance of Anatomical Extent

M.P.A. Brekelmans[1]; H.R. Buller[1]; M.F. Mercuri[2]; W. Ageno[3]; C.Z. Chen[4]; A.T. Cohen[5]; N. van Es[1]; M.A. Grosso[2]; A.P. Medina[6]; G. Raskob[6]; A. Segers[7]; T. Vanassche[8]; P. Verhamme[8]; P.S. Wells[9]; G. Zhang[2]; J.I. Weitz[10]

[1]Academic Medical Center, Vascular Medicine, Amsterdam, The Netherlands, [2]Daiichi Sankyo Pharma Development, Clinical Development, Edison, United States, [3]University of Insubria, Department of Clinical and Experimental Medicine, Varese, Italy, [4]Daiichi Sankyo Inc., Global Medical Affairs, Parsippany, United States, [5]Guy's and St Thomas' Hospitals, King's College, Department of Haematological Medicine, London, United Kingdom, [6]University of Oklahoma Health Sciences Center, College of Public Health, Oklahoma, United States, [7]Itreas BV, Amsterdam, The Netherlands, [8]University of Leuven, Vascular Medicine and Haemostasis, Leuven, Belgium, [9]University of Ottawa, Ottawa Hospital Research Institute, Department of Medicine, Ottawa, Canada, [10]Thrombosis & Atherosclerosis Research Institute and McMaster University, Hamilton, Canada

Background: Studies in pulmonary embolism (PE) have used direct oral anticoagulants (DOACs) with or without a heparin lead-in. In

practice, the anatomical extent of PE is often considered when deciding whether to use a heparin lead-in.

Aims: To

1). evaluate if PE patients benefit from initial heparin;
2). describe patient characteristics in the phase III DOAC studies;
3). investigate whether the anatomical extent of PE correlates with N-terminal pro-brain natriuretic peptide (NT-proBNP) levels, cause of PE, and recurrence rate.

Methods:

1). We performed an indirect meta-analysis comparing the risk of recurrence in DOAC-treated patients with or without a heparin lead-in relative to that in patients given heparin with vitamin K antagonists (VKAs).
2). To compare the PE studies, we extracted available information on the characteristics including anatomical extent and causes of PE.
3). We used the Hokusai-VTE study to correlate the anatomical extent of PE at baseline with NT-proBNP levels, causes of PE and recurrent venous thromboembolism (VTE). Hokusai-VTE was approved by the institutional review boards; informed consent was obtained.

Results: The meta-analysis included 11,539 PE patients. The relative risk of recurrent VTE with DOAC treatment versus VKA was 0.76 (95% confidence interval [CI] 0.6-1.1) with heparin lead-in and 1.05 (95%CI 0.8-1.5) without heparin. In the DOAC studies the proportion of patients with extensive PE varied from 24% to 47%. In Hokusai-VTE, NT-proBNP was elevated in 4% of patients with limited disease and in over 60% with extensive PE. Cause of PE and anatomical extent were not related. Recurrence rates increased from 1.6% with limited extent to 3.2% with extensive disease in the edoxaban group, and from 2.4% to 3.9% in the warfarin recipients.

Conclusions: Indirect evidence suggests that heparin lead-in before DOACs may be advantageous in PE. Anatomical extent was related to elevated NT-proBNP and outcome, but not to PE cause.

ASY 36.2 | Validation of the IMPROVE Bleeding Risk Assessment Model in Hospitalized Medical Patients: A Multi-center Study

S. Kaatz[1]; D. Paje[2]; S. Bernstein[3,4]; B. Almasri[5]; M. Hettiarachchi[6]; P. Patel[7]; G. Salem[8]; V. Hereford[9]; M. Cerasale[1]

[1]Henry Ford Hospital, Hospital Medicine, Detroit, United States, [2]University of Michigan, Hospital Medicine, Ann Arbor, United States, [3]University of Michigan, Internal Medicine, Ann Arbor, United States, [4]Ann Arbor VA, HSR&D Center of Innovation, Ann Arbor, United States, [5]Beaumont Hospital, Hospital Medicine, Royal Oak, United States, [6]Detroit Medical CenterWayne State University / Detroit Medical Center - Sinai Grace Hospital, Internal Medicine, Detroit, United States, [7]Henry Ford Hospital, Internal Medicine, Detroit, United States, [8]Mclaren, Hospital Medicine, Lapeer, United States, [9]St. Joseph Mercy Hospital, Family Medicine, Brighton, United States

Background: Guidelines recommend against venous thromboembolic (VTE) pharmacologic prophylaxis for hospitalized medical patients at high risk for bleeding. The IMPROVE risk assessment model was developed to predict bleeding up to 14 days from admission.

Aims: To validate the IMPROVE bleeding score using clinical data from a large population of hospitalized medical patients at multiple sites.

Methods: Trained abstractors from 51 hospitals participating in the Michigan Hospital Medicine Safety collaborative collected elements of the IMPROVE score and receipt of pharmacologic prophylaxis from patient records, and contacted patients 90 days after discharge to capture VTE and bleeding events. Patients admitted to intensive care, on therapeutic anticoagulation or admitted with VTE were excluded. An IMPROVE score ≥7 was considered high risk for bleeding. Outcomes of interest were clinically overt bleeding within 14 days of admission and ISTH defined major bleeding during hospitalization. Receiver operator characteristic (ROC) curve was generated for overt bleeding with continuous scores.

Results: Of 50,408 patients, 4,779 (9.5%) were classified as high risk for bleeding. Overt bleeding occurred in 11.4% (95% CI, 10.5-12.3%) of high risk and 2.6% (95%CI, 2.4-2.7%) of low risk patients. Major bleeding occurred in 8.5% (95%CI, 7.8-9.4%) high and 1.5% (95%CI, 1.4-1.7%) low risk patients. Test characteristics are shown in Table 1

TABLE 1 Test Characteristics of the IMPROVE Bleeding Risk Assessment Model

	All patients	95% CI	With pharmacologic prophylaxis	95% CI	Without pharmacologic prophylaxis	95% CI
Sensitivity any overt bleed	31.8%	29.6% to 34.1%	21.4%	18.4% to 24.3%	40.7%	37.5% to 43.9%
Specificity any overt bleed	91.3%	91.0% to 91.6%	94.8%	94.5% to 95.0%	85.0%	84.4% to 85.5%
Positive predictive value any overt bleed	11.3%	10.6% to 12.1%	9.0%	7.9% to 10.3%	12.7%	11.7% to 13.6%
Negative predictive value any overt bleed	97.5%	97.4% to 97.6%	98.0%	97.9% to 98.1%	96.4%	96.2% to 96.6%
Sensitivity major bleed	36.7%	33.9% to 39.7%	25.6%	21.3% to 30.3%	42.5%	38.8% to 46.1%
Specificity major bleed	91.1%	90.9% to 91.4%	94.6%	94.4% to 94.9%	84.8%	84.2% to 85.3%
Positive predictive value major bleed	8.5%	7.9% to 9.2%	5.3%	4.5% to 6.3%	10.5%	9.7% to 11.4%
Negative predictive value major bleed	98.5%	98.4% to 98.5%	99.1%	99.0% to 99.1%	97.2%	97.0% to 97.4%

and the area under the ROC curve was 0.75 for overt bleeding (Figure 1). Among patients who received pharmacologic prophylaxis, the negative predictive values were 98% (95%CI, 97.1-98.1) for overt bleeding and 99.1% (95%CI, 99.0-99.1) for major bleeding.

Conclusions: The IMPROVE score reliably predicts the risk of overt or major bleeding. It appears to be most useful in identifying patients who are less likely to bleed when given pharmacologic prophylaxis.

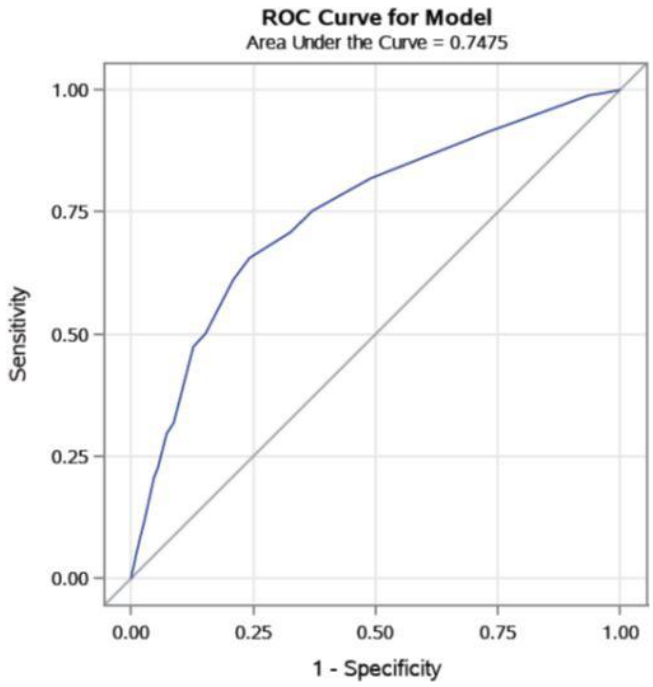

FIGURE 1 Overt Bleeding 14 Days after Admission Receiver Operator Characteristic Curve for the IMPROVE Risk Assessment Model Using a Continuous Score

ASY 36.3 | Tinzaparin for Treatment of Fetal Growth Retardation: A Randomized Multicenter-trial

A.T. Hansen[1]; P. Sandager[2]; M. Ramsing[3]; O.B. Pedersen[2]; J.D. Salvig[2]; N. Uldbjerg[2]; A.-M. Hvas[1]

[1]Aarhus University Hospital, Center For Hemophilia and Thrombosis, Department of Clinical Biochemistry, Aarhus, Denmark, [2]Aarhus University Hospital, Department of Obstetrics and Gynecology, Aarhus, Denmark, [3]Randers Regional Hospital, Denmark, Department of Pathology,, Randers, Denmark

Background: Fetal growth retardation (FGR) is a leading cause of perinatal death. Placental thromboses are pivotal for developing FGR. In lack of randomized trials, there has been no evidence of low-molecular weight heparins (LMWH) for FGR treatment.

Aims: We conducted a randomized trial testing the hypothesis that LMWH (tinzaparin) increases birth weight in FGR pregnancies.

Methods: The trial was undertaken in 3 obstetric centers in Denmark during 2011 to 2016. Pregnant women with FGR (estimated fetal weight < 2.3 percentile, ≤-22%) and no chronic disease, substance abuse, no fetal malformations, or fetal chromosome anomalies were included. Informed consent was obtained upon inclusion, and the regional ethics committee approved the study. Participants were randomly allocated to Tinzaparin (Innohep®, 4500 international units daily until 37 gestational weeks) or no Tinzaparin. We used an intention to treat analysis approach including all randomized women in our statistical analyses. The trial was registered in ClinicalTrials.gov (EudraCT number: 2011-000818-20).

Funding: The Danish Council for independent Research (Grant no: 0602-02173B FSS), Aarhus University, Health, Denmark, and Central Region of Denmark. The trial drug was donated by Leo Pharma. The funders had no role in the design or conduct of the study; in the collection, analysis and interpretation of the data.

Results: In total, fifty three women consented to participate. Baseline characteristics were balanced across the groups. The Tinzaparin group (N=27) had a higher mean birth weight than the untreated women (N=26), an absolute difference 354 grams (p=0.05). The Tinzaparin group had significantly less placental infarctions (p=0.03) and gestational age at delivery tended to be higher (p=0.06).

Conclusions: Preliminary results suggest that Tinzaparin improves birth weight in FGR pregnancies probably mediated through diminished placental infarction enabling later delivery.

ASY 36.4 | Puerperium But Not Pregnancy Is a Risk Factor for Cerebral Venous Thrombosis

S.M. Silvis[1]; L.J.J. Scheres[2,3]; S. Hiltunen[4]; E. Lindgren[5]; K. Jood[5]; S.M. Zuurbier[1]; S. Middeldorp[3]; D. Mandell[6]; J. Putaala[4]; S.C. Cannegieter[2]; T. Tatlisumak[4,5]; J.M. Coutinho[1]

[1]Academic Medical Center Amsterdam, Neurology, Amsterdam, The Netherlands, [2]Leiden University Medical Center, Clinical Epidemiology, Leiden, The Netherlands, [3]Academic Medical Center Amsterdam, Vascular Medicine, Amsterdam, The Netherlands, [4]Helsinki University Central Hospital, Neurology, Helsinki, Finland, [5]Sahlgrenska University Hospital, Neurology, Gothenburg, Sweden, [6]University Health Network, Division of Neuroradiology, Toronto, Canada

Background: Pregnancy and puerperium are generally considered to be risk factors for cerebral venous thrombosis (CVT), but this has not been assessed in a controlled study.

Aims: We aimed to assess whether pregnancy or puerperium are risk factors for CVT.

Methods: We performed an unmatched case-control study. Cases were consecutive adult patients with CVT admitted to four academic hospitals between 1987 and 2015. Controls were subjects from the control population of the Dutch MEGA study (Multiple Environmental and Genetic Assessment of risk factors for venous thrombosis). We excluded men, subjects older than 50, and women who used oral contraceptives. Puerperium was defined as the first 12 weeks after delivery. We adjusted for age and history of cancer. We stratified for pregnancy vs. puerperium, and 0-6 vs. 7-12 weeks postpartum.

Results: We included 145/714 cases and 1231/6296 controls in the analysis. Cases were younger (median 38 vs. 41 years) and more often had cancer (14% vs. 4%) than controls. A total of 38/145 (27%) cases and 82/1231 (7%) controls were pregnant or postpartum. Pregnancy

TABLE 1 Effect of pregnancy or postpartum period on the risk of cerebral venous thrombosis

	CVT cases (n=145)	Controls (n=1231)	Unadjusted OR (95% CI)	Adjusted OR (95% CI)
Pregnancy or postpartum	38/145 (26%)	82/1231 (7%)	5.0 (3.2-7.7)	3.8 (2.4-6.0)
Pregnant	12/145 (8%)	64/1231 (5%)	1.7 (0.9-3.1)	1.2 (0.6-2.3)
Postpartum	26/145 (18%)	18/1231 (2%)	15.5 (11.6-56.6)	19.3 (8.5-43.7)
Postpartum 0-6 weeks	23/145 (16%)	9/1231 (1%)	25.6 (11.6-56.6)	19.3 (8.5-43.7)
Postpartum 7-12 weeks	3/145 (2%)	9/1231 (1%)	2.9 (0.8-10.7)	1.7 (0.4-6.6)

or puerperium was associated with an increased risk of CVT (adjusted odds ratio 3.8; 95% confidence interval 2.4-6.0). This association was fully attributable to an increased risk during puerperium (10.7; 5.5-20.6). There was no association between pregnancy and CVT (1.2; 0.6-2.3). Women had the highest risk of CVT during the first 6 weeks after delivery (0 to 6 weeks: 19.3; 8.5-43.7 and 7 to 12 weeks: 1.7;0.4-6.6)).

Conclusions: Puerperium is a strong risk factor for CVT, in particular during the first 6 weeks. We did not find an association between pregnancy and CVT.

PATHOGENESIS OF THROMBOEMBOLISM

ASY 06.1 | IgM Antibodies against Oxidation-specific Epitopes Identify Patients with a Lupus Anticoagulant at Risk for Thrombotic Complications: The Vienna Lupus Anticoagulant and Thrombosis Study

F. Posch[1]; L. Alic[2,3,4]; S. Koder[1]; J. Gebhart[1]; C. Ay[1]; C.J. Binder[2,3]; I. Pabinger[1]

[1]Medical University of Vienna, Clinical Division of Haematology & Haemostaseology, Department of Medicine I, Vienna, Austria, [2]Medical University of Vienna, Department of Laboratory Medicine, Vienna, Austria, [3]Research Center for Molecular Medicine (CeMM) of the Austrian Academy of Sciences, Vienna, Austria, [4]University of Sarajevo, Department of Medical Biochemistry, Sarajevo, Bosnia and Herzegovina

Background: The pathomechanisms leading to an increased risk of arterial and venous thrombotic complications in patients (pts) with the lupus anticoagulant (LA) are incompletely understood. Low levels of IgM antibodies against oxidation-specific epitopes (IgM-OSE-Abs) have recently been identified as risk factors for coronary events and stroke in several human populations.

Aims: To quantify the relationship between IgM-OSE-Abs, LA laboratory phenotype, and thrombotic outcomes in pts with the LA.

Methods: In this prospective cohort study, we examined clinical and laboratory characteristics of 171 pts with persistent LA (Table 1), and 37 healthy controls. 141 of the 171 LA-positive pts were followed-up for symptomatic arterial (n=16 events) and/or venous thrombosis (n=15 events; median follow-up: 9.5 years; 10-year risk of arterial+venous thrombosis: 24.6% (95%CI: 17.0-33.0)). IgM-OSE-Abs were determined with a chemiluminescent ELISA, and normalized for total serum IgM. Specifically, we investigated IgM antibodies against MDA-LDL and CuOx-LDL.

Results: LA-positive patients had lower levels of MDA-LDL abs than healthy controls (p=0.008, Table 1). MDA-LDL abs were inversely correlated with LA-specific autoantibodies, such as IgM aCL (rho=-0.32, p=0.0002), and IgM aβ2GPI (rho=-0.32, p=0.0003). Ten-year thrombotic risk was 48.6% in the 14 patients that had CuOx-LDL < the 10th percentile of the CuOx-LDL distribution, and 22.4% in the 130 pts ≥ this cut off (48.6% vs 22.4%, Gray's test p=0.018, Figure **1**). This association was more pronounced for arterial (Hazard ratio (HR)=3.9, 95%CI: 1.2-12.3, p=0.021) than for venous events (HR=1.6, 0.4-6.8, p=0.554).

Conclusions: We demonstrate a critical link between IgM-OSE-Abs and prospective thrombotic risk in LA-positive patients, which suggests that OSE-specific immune responses are protective modulators of thrombotic burden and potential biomarkers for thrombotic risk stratification in patients with the LA.

TABLE 1 Baseline characteristics of the study population - Cross-sectional analysis (n=208)]

Variable	LA-positive (n=171) Median [25th-75th percentile], or Absolute count (percent)	Healthy controls (n=37) Median [25th-75th percentile], or Absolute count (percent)	p for difference
Age (years)	42.1 [32.3-60.1]	44.9 [39.4-55.3]	0.486
Female gender	137 (80.1%)	28 (75.7%)	0.545
Prior history of thrombosis	110 (64.3%)	0 (0.0%)	<0.0001
Established Anti-Phospholipid-Syndrome (APS)	124 (72.5%)	0 (0.0%)	<0.0001
aβ2GPI IgM (MPL)	6.6 [3.1-15.6]	3.0 [2.3-4.2]	<.0001
aCL IgM (MPL)	9.0 [3.7-23.9]	3.9 [3.1-6.5]	0.0001
"Triple positivity"	57 (45.2%)	0 (0.0%)	<0.0001
MDA-LDL	325 [254-434]	388 [323-463]	0.008
CuOx-LDL	407 [300-539]	396 [333-469]	0.732

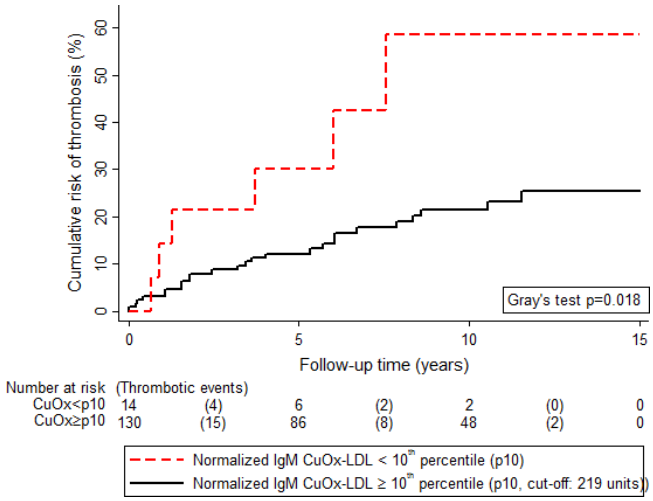

FIGURE 1 Cumulative risk of thrombosis in patients with a Lupus Anticoagulant according to baseline levels of IgM-OSE-Abs against CuOx-LDL

ASY 06.2 | Differences in the Platelet Proteome Between Lupus Anticoagulant Positive Individuals with or without Thrombotic Manifestations and Healthy Controls

L. Hell[1]; K. Lurger[1]; J. Gebhart[1]; S. Koder[1]; C. Ay[1]; I. Pabinger[1]; M. Zellner[2]

[1]*Medical University of Vienna, Department of Internal Medicine I, Vienna, Austria,* [2]*Medical University of Vienna/ Institute of Physiology, Centre for Physiology and Pharmacology, Vienna, Austria*

Background: Patients with lupus anticoagulants (LA) are at high risk to develop thromboembolism (TE), however, not all individuals with LA experience TE. Whether platelets play a role for the development of thrombosis in patients with LA is still not clear. Several studies have shown that LA/antiphospholipid antibodies interact with platelets, leading to platelet activation and aggregation.

Aims: We investigated whether there is a difference in the platelet proteome between LA-positive individuals with TE (LA+TE+), LA-positive individuals without TE (LA+TE-) and healthy controls. Identification of thrombotic biomarkers provide new mechanistic insights into the role of platelets in diseases with a high thrombotic risk.

Methods: Platelets from 30 LA+TE+ patients, 17 LA+TE- patients and 47 matched healthy controls were isolated and analyzed for differences in the platelet proteome with two-dimensional differential in-gel electrophoresis (2D-DIGE). Differentially expressed proteins were identified by mass spectrometry.

Results: Significant differences in the expression of eight proteins (Fig 1) were observed between LA+TE+ individuals, LA+TE- individuals and healthy controls, whereas no differences between LA+TE- patients and healthy controls could be detected. Most of the changed proteins correspond to platelet activation and degranulation, including protein disulfide isomerase (Fold change 1.1, p=0.00013) and proteasome activator PA28 (Fold change 1.14, p=0.0037). In addition, leukocyte elastase inhibitor, involved in the cross talk with neutrophils, was downregulated by 10% (p=0.014) in LA+TE+ patients compared to healthy controls (Fig 2).

Conclusions: Our findings correspond to platelet activation and degranulation in LA-patients with thrombosis, suggesting an indirect and direct involvement of platelets in thrombotic complications of this pathology. The reduced abundance of leukocyte elastase inhibitor expression might ease increased formation of neutrophil extracellular traps and thus add to the thrombotic risk.

ASY 06.3 | Antiphospholipid Antibody Induced Cellular Signal Transduction Depends on Antigen Specificity

A. Hollerbach[1]; N. Müller-Calleja[2]; K. Lackner[2]

[1]*University Medical Center Mainz, CTH, Mainz, Germany,* [2]*University Medical Center Mainz, Institute of Clinical Chemistry and Laboratory Medicine, Mainz, Germany*

Background: The antiphospholipid syndrome (APS) is characterized by venous and/or arterial thrombosis and severe pregnancy morbidity associated with persistently elevated titers of antiphospholipid antibodies (aPL).

Aims: In the present study we analyzed cellular effects of three human monoclonal aPL with different antigen specificity and compared them with IgG isolated form APS patients.

Methods: Mouse monocytes or human platelets were stimulated with three human monoclonal aPL IgG: HL5B (anticardiolipin - aCL), rJGG9 (anti-b2-glycoprotein-1 - anti-b2GPI) and HL7G (aCL+anti-b2GPI). Gene expression in mouse monocytes was measured by qRT-PCR, platelet aggregometry was performed on an APACT 4004 aggregometer.

Results: Using monocytes from different knock-out mice we could show that two distinct signaling pathways were activated by HL5B and rJGG9. HL5B was dependent on the previously described signaling pathway via endosomal NADPH-oxidase (NOX) 2. rJGG9 signaling was fully dependent on the presence of LDL-receptor related protein 8 (LRP8). HL7G activated both signaling pathways. Deficiency of TLR2 or TLR4 had no effect on HL5B but reduced cellular activation by rJGG9. While HL5B had no effect on platelets, rJGG9 and HL7G strongly induced platelet aggregation. IgG-fractions from APS patients most often activated cells like HL7G (aCL + anti-b2GPI). Some patient IgG were restricted to either the aCL or the anti-b2GPI-pattern of cellular responses.

Conclusions: We show for the first time that aCL and anti-b2GPI aPL induce completely different cellular signal transduction pathways. This is also reflected in platelet reactivity to different aPL. All patient IgG fractions tested follow one or the other pattern observed with the three monoclonal aPL.

ASY 06.4 | Complement-dependent Monocyte TF Activation Triggers Antiphospholipid Antibody Internalization and ROS Signaling

N. Müller-Calleja[1,2]; K. Lackner[1]; W. Ruf[2]

[1]University Medical Center of the Johannes Gutenberg University Mainz, Institute of Clinical Chemistry and Laboratory Medicine, Mainz, Germany, [2]University Medical Center of the Johannes Gutenberg University Mainz, CTH, Mainz, Germany

Background: Pathogenic effects of antiphospholipid antibodies (aPL) are linked to complement activation. β2-glycoprotein-independent aPL amplify inflammation and coagulation by inducing NADPH oxidase2 (NOX2) translocation into endosomes and reactive oxidant species (ROS) production required for TNF and tissue factor (TF) upregulation. Although complement is known to convert monocyte TF to a procoagulant molecule, the underlying mechanisms remain incompletely understood.

Aims: We tested the hypothesis that aPL cause complement-dependent signaling through TF and coagulation activation on monocytes.

Methods: We studied human and mouse monocytic cell activation by aPL by single stage clotting assay, induction of genes and ROS, and molecule tracking by confocal microscopy.

Results: Quiescent monocytes were found to express low levels of cryptic cell surface TF that was rapidly activated by aPL dependent on complement C3 and protein disulfide isomerase(PDI). Blockade of this pathway or of subsequently generated thrombin and thrombin-dependent protease activated receptor 1 cleavage prevented aPL internalization, ROS production and TNFα induction in mouse and human monocytic cells. In addition, blockade of TF and thrombin prevented NOX2 internalization into $EEA1^{+}$ endosomes. Mice lacking the TF cytoplasmic domain ($TF^{\Delta CT}$ mice) are protected from ROS production and pregnancy loss induced by aPL. Although aPL induced TF procoagulant activity normally in $TF^{\Delta CT}$ monocytes, NOX2 internalization, ROS production and inflammatory cytokine production was completely absent. Although ROS production can contribute to TF procoagulant conversion e.g. in the context of inflammasome activation, inhibition of endosomal ROS production did not prevent aPL-induced TF procoagulant activity.

Conclusions: Our results demonstrate an unexpected pathway that connects complement and PDI generation of procoagulant monocyte TF to aPL ROS and pro-inflammatory signaling of cofactor-independent aPL.

ASY 18.1 | Citrullinated Histone H3, a Biomarker of Neutrophil Extracellular Trap Formation, is Associated with Increased Risk of Venous Thromboembolism in Patients with Cancer

L.-M. Mauracher[1]; J. Thaler[1]; F. Posch[1,2]; K. Martinod[3]; E. Grilz[1]; T. Däullary[1]; L. Hell[1]; S. Koder[1]; C. Brostjan[4]; C. Zielinski[1]; C. Ay[1,5]; D.D. Wagner[3]; I. Pabinger[1]

[1]Medical University of Vienna, Department of Medicine I, Vienna, Austria, [2]Medical University of Graz, Department of Medicine, Graz, Austria, [3]Harvard Medical School, Department of Pediatrics, Boston, United States, [4]Medical University of Vienna, Department of Surgery, Vienna, Austria, [5]University of North Carolina at Chapel Hill, Department of Medicine, Chapel Hill, United States

Background: Neutrophil extracellular traps (NETs) are decondensed chromatin fibers which might play a role in the prothrombotic state of patients with cancer. Cancer mouse models showed that NETs were associated with venous thrombus formation and it is well known that patients with cancer have a high risk to develop venous thromboembolism (VTE).

Aims: The aim of this project was to investigate if NET markers (citrullinated histone H3 (H3Cit), cell free DNA (cfDNA), and nucleosomes could be used to predict the risk of VTE in patients with cancer.

Methods: In 946 patients with newly-diagnosed cancer or progression after remission H3Cit, cfDNA, and nucleosomes were determined from blood samples drawn at study inclusion. Patients were followed prospectively for 2 years until occurrence of symptomatic VTE or death.

Results: VTE occurred in 89 patients, and 352 patients died during follow-up. Patients with elevated H3Cit (i.e. $>75^{th}$ percentile of its

distribution, n=236) experienced a higher cumulative incidence of VTE (2-year risk=15.6%) as compared to patients below this cut-off (2-year risk=8.2%, n=710, Gray's test p=0.002, Figure 1). In a competing risk regression analysis, a 100ng/mL increase in H3Cit was associated with a 13% relative increase in the risk of VTE (subdistribution hazard ratio (SHR) =1.13, 95%CI: 1.04-1.23, p=0.005). This association prevailed after adjustment for high- and very-high-VTE risk tumor sites, D-dimer, and soluble P-selectin. The association between elevated nucleosomes and cfDNA with risk of VTE was time-dependent with associations with higher risk of VTE only during the first 3-6 months (Figure 2).

Conclusions: Biomarkers of NETs predict the occurrence of VTE in patients with cancer, indicating an important role of NET-formation in the pathogenesis of cancer-associated thrombosis.

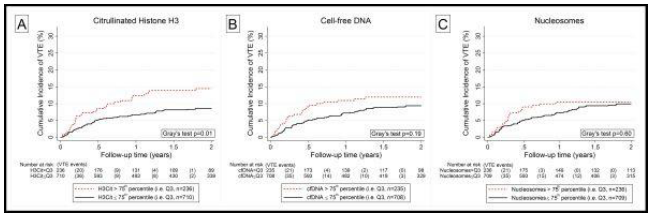

FIGURE 1 Cumulative incidence of VTE according to baseline H3Cit, cfDNA and nucleosome levels

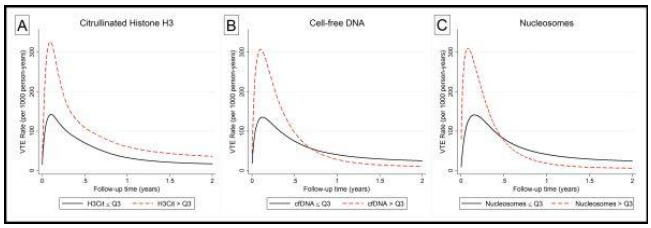

FIGURE 2 Predicted time-dependent VTE rates over 2 years of follow-up according to baseline levels of H3Cit, cfDNA and nucleosomes

ASY 18.2 | Elucidation of the Role of Neutrophils in Human Pancreatic Cancer-associated Thrombosis Using a Humanized NSG Mouse Model

M.-N. Fan[1]; C.-T. Yen[1]; T.-Y. Cheng[2,3]; S.-F. Yang[1]; Y.-L. Yang[2]; S.-C. Chou[2]; C.-Y. Chang[4]; S.-W. Lin[1]

[1]*College of Medicine, National Taiwan University, Clinical Laboratory Science and Medical Biotechnology, Taipei, Taiwan, Republic of China,* [2]*National Taiwan University Hospital, Laboratory Medicine, Taipei, Taiwan, Republic of China,* [3]*National Taiwan University Hospital, Internal Medicine, Taipei, Taiwan, Republic of China,* [4]*College of Medicine, National Taiwan University, Laboratory Animal Center, Taipei, Taiwan, Republic of China*

Background: Patients with pancreatic cancer have a high incidence to develop deep vein thrombosis (DVT). NETs (Neutrophil extracellular traps) that are formed by neutrophils enhance DVT. The white counts, however, are not necessarily elevated in the pancreatic cancer patients who develop DVT as compared to those without DVT.

Aims: To investigate whether neutrophils contribute to cancer-associated thrombosis in a humanized mouse model.

Methods: NSG (NOD.Cg-Prkdc^{scid} Il2rg^{tm1Wjl}/SzJ) mice with functionally defective neutrophils were used as neutropenia models and SCID mice were used representing neutrophil-rich controls. A moderately differentiated human pancreatic cancer cell line, AsPC-1, established from the ascites of a metastatic cancer patient, was orthotopically inoculated into NSG and SCID mice. At 3 weeks after inoculation, mice were sacrificed and analyzed.

Results: We found that the tumor volumes in the SCID and NSG mice were comparable (502.3±157.8 and 478.1±365.5 mm^3; mean ± SD, n=7 in each group). The levels of thrombin-antithrombin (TAT) complex and cell-free DNA (cfDNA) were significantly elevated in tumor-bearing SCID mice (TAT complex: 5.18±4.67 ng/mL; cfDNA: 4.18±1.25 ng/mL) but not in tumor-bearing NSG mice (TAT complex: 1.77±0.51 ng/mL; cfDNA: 1.66±0.15 ng/mL) as compared with non-tumor bearing controlled mice respectively.

Conclusions: We have demonstrated that the levels of the TAT complex and cfDNA in tumor-bearing NSG mice did not increase as those observed in the SCID mice. The difference may be due to the lack of functionally competent neutrophils in NSG mice. Functional competence of neutrophils was associated with the TAT and cfDNA levels in our human pancreatic cancer mouse models. Whether neutrophils play a major role in TAT complex formation and/or cfDNA elevation through the formation of NETs in human pancreatic cancer mouse models will be further addressed.

ASY 18.3 | Neutrophils Prothrombotic Characteristics during Myeloproliferative Neoplasms

A. Guy[1,2]; L. Deloison[1,2]; V. Gourdou-Latyszenok[1,2]; C. James[1,2,3]

[1]*University of Bordeaux, Bordeaux, France,* [2]*INSERM, UMR 1034, Pessac, France,* [3]*Laboratory of Hematology, University Hospital Center of Bordeaux, Pessac, France*

Background: Thrombosis is the most frequent complication during evolution of myeloproliferative neoplasms (MPN) but the events causing these clotting abnormalities remain unclear. Recently, clinical studies have identified leukocytosis as a risk factor for thrombosis and neutrophils are now recognized as important actors of thrombosis, especially by their capacity to emit neutrophil extracellular traps (NET) when activated.

Aims: To assess if JAK2V617F neutrophils are more activated than JAK2WT neutrophils, emit more NET, thus promoting thrombosis.

Methods: We first studied MPN patients and quantified: 1) neutrophils activation markers, 2) plasma levels of free DNA and MPO-DNA complex. In a second part, we used *PF4-iCreERT2;JAK2$^{V617/WT}$* mice with expression of JAK2V617F in hematopoietic cells. We quantified: 1) NET emission after neutrophils activation, 2) plasma levels of circulating DNA and matrix metallopeptidase 9 (MMP9), 3) pulmonary thrombus formation.

Results: In MPN patients, we found: 1) increased neutrophils CD11b expression, 2) increased neutrophils TF expression in patients with history of thrombosis, 3) increased plasma levels of free DNA in all patients and increased plasma levels of MPO-DNA complex in patients with history of thrombosis. In *PF4-iCreERT2;JAK2*$^{V617F/WT}$ mice, we observed: 1) proliferation of all hematopoietic lineage, secondary to presence of JAK2V617F in neutrophils, platelets and red blood cells, 2) increased NET formation after neutrophils activation, 3) increased plasma level of free DNA and MMP9, 4) increased pulmonary thrombus formation.

Conclusions: Our results show that neutrophils are hyperactivated during MPN, in a patient cohort, and in a mouse model with JAK2V617F expression in neutrophils. Increased NET formation in PF*4-iCreERT2;JAK2*$^{V617F/WT}$ model, associated with increased thrombus formation suggests an important role of neutrophils in thrombus formation during JAK2V617F positive MPN.

ASY 18.4 | Mice Lacking the Novel Venous Thromboembolism Susceptibility Gene Slc44a2 Have Normal Hemostasis, but Reduced Fibrin Accumulation upon Vascular Injury

J. Tilburg[1]; R. Adili[2]; T.S. Nair[3]; M.E. Hawley[2]; B.J.M. van Vlijmen[1]; D.C. Tuk[1]; H.M. Spronk[4]; M. Holinstat[2]; T.E. Carey[3]; C.X. Maracle[1]

[1]Leiden University Medical Center, Einthoven Laboratory for Experimental Vascular Medicine, Department of Internal Medicine, Division of Thrombosis and Hemostasis, Leiden, The Netherlands, [2]University of Michigan, Department of Pharmacology and Department of Internal Medicine, Division of Cardiovascular Medicine, Ann Arbor, United States, [3]University of Michigan, Kresge Hearing Research Institute, Department of Otolaryngology/Head and Neck Surgery, Ann Arbor, United States, [4]Maastricht University Medical Center, Laboratory for Clinical Thrombosis and Hemostasis, Department of Internal Medicine and Biochemistry, Cardiovascular Research Institute Maastricht, Maastricht, The Netherlands

Background: Recently SNPs located within the *SLC44A2* gene were identified to be susceptibility loci for venous thromboembolism (VTE) by two independent GWAS studies. *SLC44A2* encodes the Solute Carrier-Like Family 44 Member 2 (SLC44A2) protein which has not been previously linked to VTE and therefore is of interest to study in order to identify novel mechanisms of VTE pathogenesis.

Aims: Characterize *Slc44a2* knockout (KO) mice from a hemostasis perspective.

Methods: Lung and liver isolated from *Slc44a2* wild type or KO mice were used to determine expression of several coagulation genes by qPCR in addition to measuring changes in fibrin deposition by immunoblot (n=7). Differences in thrombin generation by plasma (n=7) and *ex-vivo* analysis of platelet aggregation and activation were also evaluated (n=10). Finally, we used intravital microscopy cremaster arteriole thrombosis model to distinguish variations in platelet and fibrin recruitment upon vascular damage induced by laser injury.(3 mice/group; 8-10 independent injuries per mouse).

Results: In KO mice, a significant increase in lung *Plat* transcript levels was observed (p=0.018) with no differences found in *F3*, *Vwf*, *F2r*, *F8*, *Thbd*, *Tfpi* or *Serpine1*. In the liver, expression of *Fga*, *F2*, *F5*, *F11* and *Proc* was not altered by the loss of *Slc44a2*. No differences in fibrin deposition and tissue factor triggered thrombin generation were found. Interestingly, platelet analysis revealed an increased induction of P-selectin upon thrombin stimulation in KO mice, however no other sizeable changes in activation were recorded. Upon laser injury, KO mice had reductions in fibrin accumulation ($p < 0.001$) whereas platelet recruitment remained unaffected.

Conclusions: In general *Slc44a2* KO mice without a thrombotic stimuli do not present obvious defects in hemostasis however, our initial characterization has uncovered a deviant response upon vascular injury, possibly due to an effect of *Slc44a2* on thrombus fibrin turnover.

ASY 29.1 | Variety of Activators and Intracellular Sources Determine the Structural Diversity of Platelet-derived Microparticles

R.I. Litvinov[1]; A.A. Ponomareva[2,3]; T.A. Nevzorova[2]; E.R. Mordakhanova[2]; I.A. Andrianova[2]; L. Rauova[1,4]; J.W. Weisel[1]

[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, United States, [2]Kazan Federal University, Kazan, Russian Federation, [3]Kazan Institute of Biochemistry and Biophysics, Kazan, Russian Federation, [4]The Children's Hospital of Philadelphia, Philadelphia, United States

Background: Platelet-derived microparticles (MPs) comprise the major population of circulating blood MPs that play an important role in hemostasis and thrombosis. Despite numerous studies on the (patho)physiological roles of platelet MPs, their structural composition and the basis for heterogeneity remain largely unknown.

Aims: To study the intracellular origin and structural diversity of MPs derived from human platelets activated by various stimuli.

Methods: MPs released by isolated quiescent human platelets or platelets stimulated with arachidonic acid, ADP, collagen, thrombin, or calcium ionophore A23187 were studied with flow cytometry, scanning and transmission electron microscopy.

Results: The structure, dimensions, and intracellular origin of MPs depend on the cell-activating stimulus. The most common structural groups include a vesicle surrounded by a membrane or multivesicular structures. Thrombin, unlike other stimuli, induced formation of MPs not only from the outer plasma membrane but also from intracellular membranous structures comprising the endomembrane system, including the open canalicular system. Some vesicular particles contained organelles, such as mitochondria, glycogen granules, and vacuoles, indicating their cytoplasmic origin. The size of platelet MPs varied from 30 nm to 500 nm, but the size distributions depended on the nature of the cell-activating stimulus with the smallest MPs formed by thrombin, a strong platelet activator.

Conclusions: The study has shown that the structure of platelet MPs depends on whether they originate from the plasma membrane or the endomembrane system. Based on their detailed structure, platelet microvesicles are classified as homogenous rounded particles surrounded by one single membrane, multivesicular structures, and vesicles containing cellular organelles. The results obtained show that the structural diversity of platelet-derived MPs is based on the nature and strength of cell-activating stimulus and their intracellular origin.

ASY 29.2 | Tissue Factor-Positive Microvesicles from a Human Pancreatic Tumor Grown Orthotopically Enhance Venous Thrombosis in Mice

Y. Hisada[1,2]; C. Ay[3]; A. Auriemma[1]; B. Cooley[4]; N. Mackman[1,2]

[1]University of North Carolina at Chapel Hill, Department of Medicine, Chapel Hill, United States, [2]University of Tromso, K.G. Jebsen Thrombosis Research and Expertise Center, Tromso, Norway, [3]Medical University of Vienna, Department of Medicine I, Vienna, Austria, [4]University of North Carolina at Chapel Hill, Department of Pathology and Laboratory Medicine, Chapel Hill, United States

Background: Patients with pancreatic cancer have elevated levels of circulating microvesicle (MV) tissue factor (TF) activity, and there is an association between MV TF activity and venous thromboembolism. We showed that injection of exogenous TF-positive MVs (TF+ MVs) derived from a human pancreatic cancer cell line (BxPc-3) increased thrombosis in an inferior vena cava (IVC) stenosis mouse model.

Aims: Determine if endogenous human TF+ MVs derived from a human pancreatic tumor grown orthotopically enhance thrombosis in an IVC stasis mouse model.

Methods: We used the human pancreatic cancer cell line BxPc-3 because it expresses a high level of TF. Tumors were growth subcutaneously or orthotopically in nude mice. Tumor-bearing mice and controls were subjected to IVC ligation and thrombi harvested after 48 hours. Thrombus formation was also assessed using ultrasound at 3, 6, 24 and 48 hours after surgery. In a second experiment, mice with orthotopic tumors were treated with either an inhibitory anti-human TF antibody (HTF-1) or control IgG (2.86 mg/kg i.v.) just before surgery and 24 hours after surgery.

Results: Mice with subcutaneous BxPC-3 tumors (0.50 - 1.08 g) had a non-significant increase in the thrombus compared with sham controls (20.81±7.12 mg, n=8 vs 18.53±4.09 mg, n=13, *P*=0.4249). In contrast, mice with orthotopic BxPC-3 tumors (1.13 - 3.14 g) had significantly larger thrombi compared with sham controls (30.74±3.80 mg, n=8 vs 19.23±3.71 mg, n=9, *P*=0.0006). Importantly, administration of HTF-1 significantly reduced thrombosis in mice with orthotopic tumors compared with IgG (*P*=0.0152).

Conclusions: Our studies show mice containing orthotopic BxPc-3 tumors have increased thrombosis compared with control mice. The enhanced thrombosis was abolished with an antibody against human TF, which suggests that TF+ MVs released from the tumor increase venous thrombosis in this mouse model.

ASY 29.3 | SerpinE2 Deficiency Accentuates Coagulation and Inflammation and Promotes Pulmonary Fibrosis

L. Venisse[1]; D. François[1]; Y. Boulaftali[1]; K. Aymonnier[1]; M. Jandrot-Perrus[1]; E. Camerer[2]; V. Arocas[1]; M.-C. Bouton[1]

[1]INSERM U 1148, Paris, France, [2]INSERM U 970, Paris, France

Background: Idiopathic pulmonary fibrosis (IPF) is a devastating form of interstitial lung disease associated with extracellular matrix deposition. SerpinE2/protease nexin-1 (PN-1) is a tissue serpin with both anticoagulant and antifibrinolytic properties and has been shown to be overexpressed in lungs during IPF.

Aims: To determine the role of PN-1 in the development of pulmonary fibrosis.

Methods: We compared bleomycin-induced pulmonary fibrosis on the survival of Wild-Type (WT) and PN-1-deficient mice (PN-$1^{-/-}$), and of irradiated mice reconstituted with bone marrow cells from *PN-1*$^{-/-}$ or *Par4*$^{-/-}$ or *PN-1*$^{-/-}$/*Par4*$^{-/-}$ or WT mice. Bronchoalveolar lavages (BAL) of the mice were analysed by counting platelets and leucocytes at the hemocytometer, by measuring thrombin activity using a specific chromogenic substrate and by quantification of TGFβ_1, platelet factor 4, myeloperoxidase and D-Dimers using ELISA.

Results: PN-1 deficiency in mice was associated with a significant increase in mortality resulting from more severe fibrosis after bleomycin challenge. Active TGFβ_1, a profibrotic growth factor, was detectable only in BAL from bleomycin-treated *PN-1*$^{-/-}$ mice. These data indicate a protective role of PN-1 in lungs. When the direct thrombin inhibitor argatroban was administered to the mice, a significant improvement of the survival of PN-$1^{-/-}$ mice treated with bleomycin was observed. PN-1 deficiency was also associated with a marked increase in active thrombin, and an accumulation of platelets and neutrophils in BAL. Bone marrow transplantation experiments showed that protective PN-1 was derived from the hematopoietic cell compartment. Compound deficiency of PN-1 and the thrombin receptor PAR-4, in hematopoietic cells, abolished the mortality associated with PN-1 deficiency.

Conclusions: Prevention of thrombin signalling by PN-1 present in hematopoietic cells, constitutes an important endogenous mechanism of protection against lung fibrosis and associated mortality in mice.

ASY 29.4 | Von Willebrand Factor Regulates Deep Vein Thrombosis in a Mouse Model of Diet-induced Obesity

A. Michels; C. Dwyer; L.L. Swystun; D. Lillicrap

Queen's University, Kingston, Canada

Background: Obesity is associated with increased von Willebrand factor antigen (VWF:Ag), factor VIII activity (FVIII:C) and risk of deep vein thrombosis (DVT). VWF may regulate thrombosis by localizing FVIII, platelets and leukocytes to the site of thrombus formation.

Aims: To evaluate the role of VWF in DVT in a diet-induced obese (DIO) mouse model.

Methods: DVT was induced by inferior vena cava (IVC) ligation in DIO C57BL/6 mice and lean littermates. Thrombi were weighed and longitudinal sections were analyzed by IHC 24 hours post stenosis.

Results: DIO mice had increased VWF:Ag (1.3-fold, p=0.003), FVIII:C (1.4-fold, p=0.006), circulating granulocytes (1.15-fold, p=0.006) and erythrocytes (1.05-fold, p=0.0002) after 2 weeks on a high-fat diet compared to controls. DIO mice had larger thrombi after 2 weeks (1.75-fold, n=32, p=0.0497) and 10 weeks (1.28-fold, n=39, p=0.24)

on diet than controls. DVTs from DIO mice were comprised of more red thrombus (71.6% vs. 61% in controls, p=0.01) that correlated with DVT size (r^2=0.8, p=0.006). High-intensity VWF staining co-localized with white thrombus (leukocytes and platelets) and low-intensity VWF staining with red thrombus. Quantitative IHC showed that DVTs from DIO mice had increased VWF (1.4-fold, p=0.03) and total leukocytes (1.5-fold, p=0.098) but not fibrin or platelets. In DIO mice and controls, DVT size correlated with VWF (r^2=0.43, p=0.002), leukocytes (r^2=0.41, p=0.003), fibrin (r^2=0.69, p=0.0002) and platelets (r^2=0.48, p=0.006). ADAMTS13 KO DIO mice did not have increased DVT size. VWF KO DIO mice were protected from developing DVT (55% decreased incidence) with DVT size decreased by 89% (p=0.003). Treatment of DIO mice with a polyclonal anti-VWF antibody decreased DVT incidence by 35% and size by 73% (p=0.005).

Conclusions: DIO mice exhibit increased venous thrombogenicity that may be related to the role of VWF in platelet/leukocyte recruitment and FVIII binding. VWF is integral to DVT formation in this model and may be a novel therapeutic target.

ASY 37.1 | Adverse Pregnancy Outcomes in Women with Persistent Lupus Anticoagulant - Experiences from the Prospective Vienna Lupus Anticoagulant and Thrombosis Study (LATS)

S. Koder[1]; J. Gebhart[1]; F. Posch[1]; P. Quehenberger[2]; C. Ay[1]; I. Pabinger[1]

[1]*Medical University of Vienna, Department of Medicine I, Clinical Division of Hematology and Hemostaseology, Vienna, Austria,* [2]*Medical University Vienna, Department of Laboratory Medicine, Vienna, Austria*

Background: Lupus anticoagulant (LA) positivity is a known risk factor for pregnancy complications.

Aims: To prospectively analyze pregnancy complications in women with persistently positive LA.

Methods: In the ongoing prospective Vienna Lupus Anticoagulant and Thrombosis Study (LATS) we followed 165 (female=136, 82%) patients over a median follow-up (FU) period of 9.2 years. Eighty-two women (60%) were of child-bearing age (≤45 years) at study inclusion.

Results: During FU, we observed 34 singleton pregnancies in 21 women (Table 1).

One induced abortion and one tubular pregnancy, each, were not included in further analysis. Pregnancy complications occurred in 16 women during 22 pregnancies (65%), including 17 spontaneous abortions (< 10^{th} week of gestation (WOG): n=11, 10^{th}-24^{th} WOG: n=6) and 5 deliveries ≤34^{th} WOG (4 due to preeclampsia/HELLP syndrome). Ten pregnancies were uneventful with live births ≥36^{th} WOG. Neither a prior history of pregnancy complications (Odds ratio (OR)=5.3, 95%CI: 0.3-82.8, p=0.23) nor a prior history of thrombosis (OR=2.0, 95%CI: 0.2-16.6, p=0.52) were significantly associated with pregnancy complications during FU. Women with pregnancy complications had higher baseline levels of anti-β2-GPI IgG antibodies than those without pregnancy complications (median: 53.5 vs. 23.7 GPL, p=0.06). Pregnancy complications according to treatment are listed in Table 2. The combination of low molecular weight heparin (LMWH) with low dose aspirin (100 mg qd) led to the most favorable pregnancy outcome.

Conclusions: The risk for pregnancy complications is extremely high in women with persistent LA. This finding urges a more precise identification of patients at risk for pregnancy complications and improved treatment options.

TABLE 1 Baseline characteristics of the 21 women with at least one pregnancy during follow up

Variable	Median [25th-75th percentile], or absolute count (percent)
Age at entry (years)	28 [24-29]
Diagnosis of APS	18 (86%)
Prior history of arterial or venous thrombosis	16 (76%)
Prior history of pregnancy complications	11 (52%)
aPTT-LA (seconds)	99 [86-118]
aβ2GPI IgM (MPL)	7.7 [3.0-15.8]
aβ2GPI IgG (GPL)	50.0 [8.2-84.2]
aCL IgM (MPL)	6.4 [3.8-16.7]
aCL IgG (GPL)	40.8 [16.4-104.3]

TABLE 2 Treatment modalities and pregnancy outcomes of 32 pregnancies

	LMWH	LMWH+ low dose aspirin	VKA or Rivaroxaban	No therapy
Total number of pregnancies	11	13	4	4
Early abortion (<10th WOG)	5	1	3	1
Late abortion (10th-24th WOG)	3	2	1	1
Live birth ≤34th WOG	2	3	0	0
Live birth >34th WOG	1	7	0	2
Live birth vs total	3/11	10/13	0/4	2/4

ASY 37.2 | Identification of Gene-environment Interactions in Pregnancy-related Venous Thromboembolism

M. deAndrade[1]; S.M. Armasu[1]; B.M. McCauley[1]; T.M. Petterson[1]; H.G. de Haan[2]; J.A. Heit[1,3]

[1]*Mayo Clinic, Health Sciences Research, Rochester, United States,* [2]*Leiden University Medical Center –, Clinical Epidemiology, Leiden, The Netherlands,* [3]*Mayo Clinic, Cardiovascular Diseases, Rochester, United States*

Background: Pregnancy and the postpartum period are major risk factors for venous thromboembolism (VTE), with 4-fold increased odds of VTE and a VTE incidence of 200 per 100,000 women-years. Pregnancy-related VTE accounts for approximately 10% of all maternal deaths.

Aims: Our aim is to identify genetic variants associated with VTE in pregnancy using the Mayo Clinic VTE study.

Methods: Of 758 female VTE cases in the study (all of non-Hispanic European ancestry), 318 had a VTE event during the considered procreative age interval of 18 to 45 years; 634 of these women had genome-wide 1000G imputed genotype data. We used this data to perform a genome wide association (GWA) analysis to identify genetic variants associated with pregnancy-related VTE (gene-environment interaction) using Cox proportional hazards modeling, adjusted for age, stroke/MI and state of residence.

Results: None of the common genetic variants known to be associated with VTE (i.e., *F5* rs6025 [Factor V Leiden], *ABO* rs8176719 [ABO non-O blood type], and *F2* rs1799963 [prothrombin G20201A]) reached genome-wide significance in this analysis, indicating that there is a different genetic mechanism for pregnancy-related VTE. Only two intragenic single nucleotide polymorphisms (SNPs) reached genome-wide significance: *PURB* chr7.44909852.D (HR=0.41; p=3.34E-08) and rs10215876 (HR=0.40; p=1.15E-08); two additional intragenic SNPs, *LINGO2* rs4878679 (HR=0.63; p=3.31E-07), and *RDXP2* chrX.rs2191549 (HR=0.52; p=4.91E-07) reached borderline genome-wide significance. All four SNPs were validated using internal cross-validation. We are in the process of validating our results using pregnant females with VTE from the MEGA study.

Conclusions: We observed that the main genetic risk genes involved in VTE, F5, ABO and F2, are not genome-wide significant for pregnancy-related VTE, indicating that the genes, PURB, LINGO2 and RDXP2, are potential candidate genes for provoked VTE in pregnant women.

ASY 37.3 | Cancer and Venous Thromboembolism in Pregnancy

V. Barros; E. Hase; A.M. Igai; R. Francisco; M. Zugaib

University of Sao Paulo, Department of Obstetrics and Gynecology, Sao Paulo, Brazil

Background: Hospitalized patients with cancer are at high risk of developing venous thromboembolism (VTE), and this risk increases with pregnancy. No studies have assessed the risks of VTE in women with cancer during pregnancy and hospitalization.

Aims: The goal of this study was to apply a thromboprophylaxis protocol with a VTE risk score for hospitalized pregnant women with cancer and to evaluate the effect on maternal morbidity and mortality.

Methods: This was a longitudinal, interventional and prospective study of hospitalized pregnant women diagnosed with cancer. Patients were classified as low risk or high risk according to a VTE risk score. The high-risk group received thromboprophylaxis with low-molecular-weight heparin (LMWH) unless the patient had a contraindication for anticoagulation, such as active bleeding or a high bleeding risk. The collected data were descriptively analysed to identify the profile of pregnant women and type of cancer using percentages and absolute values. One patient could have undergone more than one evaluation.

Results: The data of 87 cases (61 patients) were descriptively analysed: 64 (73.5%) were classified as high-risk and 55 (86%) received enoxaparin; 46 (52.8%) had breast cancer, 10(11.49%) cervical cancer of the uterus and 14 (21.9%) had metastatic cancer. The main risk factors for VTE were chemotherapy (within 6 months) - 39/64 (61%) and age ≥ 35 years (24 - 37%). No patient exhibited VTE, adverse effects of anticoagulation or death up to three months after hospitalization.

Conclusionss: Most pregnant women with cancer had a high risk for VTE at the time of hospitalization. Breast cancer was the most prevalent and recent chemotherapy was the main risk factor for anticoagulation. The application of a thromboprophylaxis protocol and determination of a VTE risk score for these patients was effective for the prevention of maternal morbidity and mortality due to VTE.

ASY 37.4 | Type of Combined Contraceptives, Factor V Leiden Mutation and Risk of Venous Thromboembolism: A Case-Only Study

J. Hugon-Rodin[1]; M.H. Horellou[2]; J. Conard[3]; A. Gompel[1]; G. Plu-Bureau[4]; COREVE Investigators

[1]Hopital Port Royal, University Paris 5, Gynecology Endocrinology, Paris, France, [2]Hopital Cochin, Hematology Biology, Paris, France, [3]Hopital Cochin-University Paris 5, Hematology Biology, Paris, France, [4]Hopital Port-Royal, University Paris 5, Gynecology Endocrinology, Hematology Biology, Paris, France

Background: Combined hormonal contraceptives (CHC) and Factor V Leiden mutation (FVL) increase the risk of venous thromboembolism event (VTE). Whether the risk level of VTE differs with the progestin-type of CHC in women with FVL as compared to non-carriers remains to be determined.

Aims: Using Data from Contraception and Recurrent Venous Event (COREVE) study, we estimated the interaction between types of CHC and FVL on VTE risk.

Methods: We conducted a case-only study (a tool for testing gene-environment interactions) in women with first documented VTE who were referred to our hemostasis Unit between 2000 and 2009. FVL screening was performed in all women. Under the assumption of independence between genotype and exposure, this methodology is equivalent to comparing the risk of VTE associated with CHC use in FVL carriers with the risk of VTE associated with CHC use in non-carriers.

Results: Among 2613 women, 415 had a FVL (15.9%). At the time of the VTE, 803 (30.7%) were non-users and 1810 (69.3%) used CHC. The interaction between CHC use and presence of FVL on VTE risk was statistically significant (1.37; 1.06-1.77 95% CI).

The comparison between the progestin types of CHC showed that CHC containing drospirenone (n=98) or cyproterone acetate (n=326) had a higher interaction in FVL carriers than in non-carriers (2.09 (1.23-3.53) and 1.79 (1.26-2.56) respectively). In addition, interactions

were higher in drospirenone or cyproterone acetate group as compared with 1st (norethisterone), 2nd (lévonorgestrel) or norgestimate CHC users (p=0.02 and p=0.03 respectively). The results were similar when we restricted the population to women without familial history of VTE or women with idiopathic VTE.

Conclusions: Our results suggest that CHC containing drospirenone or cyproterone acetate may increase risk of VTE more in FVL carriers that in non-carriers, even among women without familial history of VTE.

ASY 38.2 | Identification of a microRNA Profile for Predicting the Thrombotic Risk of Biliopancreatic Cancer Patients

J. Oto[1]; A.C. Larsen[2]; E. Plana[1,3]; D. Hervás[4]; L. Martos[1]; L.A. Ramón[1]; M.J. Solmoirago[1]; Á. Fernández-Pardo[1]; F. España[1,5]; S. Navarro[1]; S.R. Kristensen[6,7]; O. Thorlacius-Ussing[2,7]; P. Medina[1]

[1]La Fe Sanitary Research Institute, Haemostasis, Thrombosis, Atherosclerosis and Vascular Biology Research Group, Valencia, Spain, [2]Aalborg University Hospital, Department of Gastrointestinal Surgery and Center of Clinical Cancer Research, Aalborg, Denmark, [3]La Fe University and Polytechnic Hospital, Angiology and Vascular Surgery Service, Valencia, Spain, [4]La Fe Sanitary Research Institute, Biostatistics Unit, Valencia, Spain, [5]La Fe University and Polytechnic Hospital, Valencia, Spain, [6]Aalborg University Hospital, Department of Clinical Biochemistry, Aalborg, Denmark, [7]Aalborg University, Department of Clinical Medicine, Aalborg, Denmark

Background: Venous thromboembolism (VTE) is a common complication of cancer increasing mortality and morbidity, and new biomarkers to identify cancer patients with high VTE risk are needed. microRNAs (miRs) are small non-coding RNAs that regulate protein expression. miRs seem to regulate cancer progression and VTE.

Aims: To find a miR profile to identify biliopancreatic cancer patients with high VTE risk.

Methods: 125 biliopancreatic cancer patients were prospectively recruited and followed for two years. Blood was drawn at diagnosis and every three months. The miR expression level was studied in plasma of 5 selected patients who developed VTE and in 5 who did not, at inclusion and right before the VTE event, with the Serum/plasma Focus microRNA PCR Panel V4 (Exiqon). Statistical analysis was performed using R (v3.2.3). Next, we validated the VTE predictive model in a different subset of 32 biliopancreatic cancer patients.

Results: We adjusted an elastic net logistic regression model for VTE risk using the miR expression levels at inclusion. This predictive model included 7 miRs with fold-changes ranging from 1.51 to 4.28 and achieved an *AUC* of 0.95 in the validation cohort (95% CI: 0.87-1.00; p < 0.001). Moreover, comparing the miR expression level at inclusion and right before the VTE event with the Paired T-test, we identified a profile of 7 dysregulated miRs that might prompt the VTE. We have identified the cancer- and VTE-related target proteins of these miRs.

Conclusions: A profile of 7 miRs may allow us to estimate the risk of VTE in biliopancreatic cancer patients at diagnosis. This could promote a closer follow-up and a personalized thromboprophylaxis in high-risk patients. We have also identified 7 dysregulated miRs right before the VTE that could shed light on the mechanism triggering a VTE in biliopancreatic cancer patients. ISCIII-FEDER (PI12/00027, RIC RD12/0042/0029, PIE13/00046, PI14/00079, PI14/00512, FI14/00269, CPII15/00002), GVA (PrometeoII/2015/017), SETH, OBEL Family Foundation (26145).

PEDIATRICS

ASY 26.1 | Unravelling Pediatric Pulmonary Embolism: Outcomes and Severity Predictors

M.-C. Pelland-Marcotte; L.M. Avila; A. Amid; S. Williams; L.R. Brandao

The Hospital for Sick Children, Division of Haematology/Oncology, Department of Pediatrics, Toronto, Canada

Background: Pulmonary embolism (PE) is increasingly recognized in children, Little is known about pediatric massive and submassive PE in children (M/SMPE).

Aims: Main: To describe pediatric PE-related outcomes according to PE severity [M/SMPE vs non-MPE (NPE)].

Secondary: To explore the role of PE severity scores in children as outcome predictors.

Methods: Patients aged 0-18 years with objectively confirmed PE diagnosed between 2003-2016 were included. Hypotension/shock/death within 24h of presentation defined MPE, whereas right ventricular dysfunction defined SMPE. Main outcomes were death and combined unfavourable outcomes (pulmonary hypertension, recurrence and progression). Pulmonary Embolism Severity Index (PESI) and simplified PESI (sPESI) were calculated using age-adjusted parameters. Group comparisons used Wilcoxon rank sum, Chi-square or Fisher exact tests, as appropriate. Associations between outcomes and predictors were tested with logistic regression. The institutional review board approved the study.

Results: 95 cases of PE were reviewed; 26/95 (27%) were classified as M/SMPE.

M/SMPE patients were younger [median age, years (25th-75th percentile) 12 (0.8-15) vs NPE 15 (10-16), p=0.04].

TABLE 1 Patients characteristics divided by PE groups

Characteristics	NPE n=69	M/SMPE n=26	*P value*
Age, years [median, (25th-75th percentile)]	15 (10-16)	12 (0.8-16)	0.04
Male:female ratio	1.09	1.17	0.88
Underlying conditions			0.03
Cancer	19 (27%)	3 (11%)	
Heart disease	9 (13%)	9 (34%)	
Inflammatory/infectious conditions	15 (22%)	2 (8%)	
No underlying condition	4 (6%)	0 (0%)	
Central venous catheter	29 (42%)	13 (50%)	0.49

Treatment modalities included observation [M/SMPE 4%, NPE 10%], anticoagulation [M/SMPE: 35%, NPE 81%] or invasive treatment [embolectomy/local-/systemic-thrombolysis (M/SMPE 61%, NPE 9%; p< 0.001]. M/SMPE was associated with PE-related death (12% vs 0%, p=0.02) and unfavourable outcomes (31% vs 10%, p=0.01).

Cardiac disease and M/SMPE were associated with unfavourable outcomes in univariable logistic regression. In a multivariable analysis, only M/SMPE associated with unfavourable outcomes (OR 4.2 (95% CI 1.2-14.4)).

Finally, PESI was not associated with death or unfavourable outcomes, but sPESI was associated with death (p=0.02).

Conclusions: Despite more aggressive therapy, M/SMPE led to a higher morbidity and mortality than NPE in children. However, PESI and sPESI may not be applicable to predict pediatric PE outcomes.

ASY 26.2 | Congenital Antithrombin Deficiency Increases 43-fold the Risk of Pediatric Thrombosis and 200-fold the Risk of Neonatal Thrombosis. Results from 468 Patients with Antithrombin Deficiency from 176 Unrelated Families

Background: Pediatric thrombosis is rare: 0.14/10,000 children and 5.1/100,000 births. Deficiency of endogenous anticoagulants increases the risk of pediatric thrombosis, but the low number of cases limits the conclusions on clinical characteristics of these patients. Antithrombin (AT) deficiency is the strongest thrombophilia, but there are few studies in small cohorts evaluating the role of AT deficiency on pediatric thrombosis.

Aims: To define the prevalence of pediatric thrombosis in carriers of congenital AT deficiency and to describe their clinical features.

Methods: We performed an observational retrospective multicentric study of 468 subjects (0-85 years, y) with congenital AT deficiency from 176 unrelated families. Genetic, functional and biochemical analysis were done.

Results: 28 cases had pediatric thrombosis, 6% of our cohort. Two periods with high risk of thrombosis were identified: adolescence (16-18y, N=13) in whom localizations and risk factors are common in adults (deep venous thrombosis or pulmonary embolism, and contraceptives, surgery or pregnancy); and newborns (< 30 days, N=5) with idiopathic thrombosis in unusual localizations.

Cerebral sinovenous thrombosis was frequent (N=5, 2 neonates & patients with 2, 5 and 18y).

Thrombosis was very severe, with fatal consequences (N=5, including a neonate homozygous for p.Leu131Phe); serious sequelae (psychomotor delay or amputation, N=5); and recurrence overtime (N=5).

Type I deficiency was predominant (75%).

AT levels in available neonates were very low (11-20%).

Conclusions: Our data support the high risk of pediatric (43-fold) and particularly neonatal thrombosis (200-fold) associated to congenital AT deficiency. The low levels of AT in neonates probably exacerbates the reduced anticoagulant capacity associated with the deficiency, making this moment of high thrombotic risk. Our results support the screening of AT deficiency (mainly if it is type I) in children of affected families.

ASY 26.3 | A Polymorphism in the Transcriptional Repressor Growth Factor Independence-1 Gene GFI1^{36N} is Associated with DVT Risk in Pediatric Oncology Patients: Results from a Genome-wide Association Analysis

F. Ruehle[1]; M. Stoll[1]; L. Brandão[2]; J. Halton[3]; S. Israels[4]; K. Dietrich[5]; M. Spavor[5]; L.G. Mitchell[5]; ABLE Study Investigators

[1]University of Muenster, Muenster, Germany, [2]Hospital for Sick Children, Toronto, Canada, [3]Children's Hospital of Eastern Ontario, Ottawa, Canada, [4]Winnipeg Children's Hospital, Winnipeg, Canada, [5]University of Alberta, Edmonton, Canada

Background: Pediatric cancer patients are at increased risk for deep vein thrombosis (DVT). Investigation of genomic loci contributing to DVT risk may help to identify novel mechanisms for risk and to manage affected patients. Genome-wide association studies (GWAS) are a valuable tool in an unbiased approach to identifying unique genetic factors.

Aims: Identification of susceptibility loci for DVT in pediatric oncology patients using GWAS.

Methods: A population based nested case control study was conducted in 7 Canadian centers. A total of 411 survivors of pediatric cancer were recruited, 127 with DVT (cases) and 284 without DVT (controls) during treatment for cancer in childhood. DNA isolates from probands were hybridized to Illumina marker Infinium PsychArrays and 308496 markers remain for analysis. Genomic inflation factor lambda is 1.035 indicating no serious inflation. Association analysis was performed using logistic regression assuming an additive model adjusted for age, blood group, cancer type, chemotherapy.

Results: The SNP rs34631763 was significantly associated with DVT (p = 3.32 E-7). The SNP rs34631763 on chromosome 1 is an exonic

missense variant within the transcriptional repressor Growth Factor Independence 1 (GFI1) gene which generates a protein with asparagine ($GFI1^{36N}$) in place of a serine ($GFI1^{36S}$) at position 36. GFI1 is primarily important in hematopoietic stem cells lymphoid and myeloid differentiation and has been shown to be involved with development of acute lymphoblastic leukemia. $GFI1^{36N}$ variant is associated with risk for developing acute myeloid leukemia in adults.

Conclusions: The increased incidence of the $GFI1^{36N}$ variant in pediatric solid tumor and leukemia patients who developed DVT during cancer treatment suggests a novel role for GFI1 in regulation of genes involved with development of DVT. Future directions include replicating these results in an independent patient cohort and assessing pathways for GFI1 mediated transcriptional repression of genes involved with DVT.

ASY 26.4 | Haemostatic Monitoring and Thresholds for Blood Product Replacement Therapy during Treatment of Acute Lymphoblastic Leukaemia in Children and Young People Vary between Centres in the UK

T.T. Biss[1]; K.R. Sibson[2]; J.D. Grainger[3]; C. Macartney[4]; J.H. Payne[5]; R.E. Hough[6]; E.A. Chalmers[7]

[1]Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom, [2]Great Ormond Hospital for Children NHS Foundation Trust, London, United Kingdom, [3]Royal Manchester Children's Hospital, Manchester, United Kingdom, [4]Royal Belfast Children's Hospital, Belfast, United Kingdom, [5]Sheffield Childrens Hospital, Sheffield, United Kingdom, [6]University College Hospital, London, United Kingdom, [7]Royal Hospital for Children, Glasgow, United Kingdom

Background: Bleeding is a frequent cause of morbidity and can contribute to mortality in children and young people treated for acute lymphoblastic leukaemia (ALL). Recommendations vary in terms of frequency of coagulation testing and thresholds for blood product replacement therapy.

Aims: This study aimed to determine current UK practice in relation to coagulation testing and blood product replacement therapy during treatment of ALL in young people.

Methods: A survey was sent using a web-based tool, SurveyMonkey.com, to the 28 centres participating in the Medical Research Council UKALL 2011 trial for individuals aged 1-24 years.

Results: The survey was completed by investigators at 23 centres. 96% have a local protocol for blood product replacement therapy in young people with ALL. 21/23 centres (91%) routinely perform coagulation screening at the time of ALL diagnosis. 6/23 centres (26%) routinely monitor coagulation tests during induction chemotherapy. During the period of asparaginase activity, fibrinogen is supplemented in 9 centres (39%) prior to insertion of a CVAD and 6 centres (26%) prior to lumbar puncture. Threshold for supplementation of fibrinogen is < 1.0 g/L in all cases. The replacement product chosen is cryoprecipitate in 7, plasma in 1 and fibrinogen concentrate in 2. Threshold for platelet transfusion varies, particularly prior to lumbar puncture, insertion of a central venous access device (CVAD) and in the patient with bleeding.

During therapeutic anticoagulant therapy, interruption of anticoagulation or transfusion of platelet concentrate is considered necessary when platelet count is < 20 x 10^9/L in 1 centre (4%), < 30 x 10^9/L in 6 (26%) and < 50 x 10^9/L in 16 (70%).

Conclusions: This survey has identified significant variation in practice in relation to the frequency of coagulation testing and thresholds for blood product replacement therapy in children and young people with ALL highlighting the need for future research and evidence-based guidance.

PLATELETS – BASIC

ASY 04.3 | Three-Dimensional Fluorescence Emission Computed Tomography (FLECT) with a Newly Generated Activated Platelet-specific Fluoroprobe: A Unique Technology for the Diagnosis of Thrombotic Diseases

Background: Effective preclinical testing involving small animal studies is fundamental to the development of new pharmaceutical products.

TABLE 1 Thresholds for the transfusion of platelet concentrate in children and young people with acute lymphoblastic leukaemia

	Threshold for the transfusion of platelet concentrate, Number of centres (%)						
	<10 x 10^9/L	<20 x 10^9/L	<30 x 10^9/L	<50 x 10^9/L	<70-80 x 10^9/L	<100 x 10^9/L	No response
Well patient	20 (87%)	2 (9%)	0	0	0	0	1 (4%)
Febrile patient	3 (13%)	20 (87%)	0	0	0	0	0
Patient with active bleeding	0	0	4 (17%)	14 (61%)	3 (13%)	1 (4%)	1 (4%)
Prior to lumbar puncture	1 (4%)	3 (13%)	5 (22%)	13 (57%)	1 (4%)	0	0
Prior to insertion of CVAD	0	0	0	12 (52%)	9 (39%)	2 (9%)	0

Targeted molecular imaging that characterizes biological processes in living animals is important to determine the clinical translation of novel drug candidates. Especially for detection of thromboembolism, there is a strong need for sensitive preclinical imaging technologies.

Aims: We aim to demonstrate the use of a world-first three-dimensional near-infrared (NIR)-fluorescence whole-animal bioimager called FLuorescence Emission Computed Tomography (FLECT) to diagnose thromboembolism using a novel probe that is safe, easily prepared in large scale and stably stored.

Methods: We generated a novel NIR-fluoroprobe comprising a single-chain antibody ($scFv_{GPIIb/IIIa}$), which exclusively binds activated-platelets, conjugated via the combination of biological (Sortase A) and chemical (Click-Chemistry) coupling to Cy7 dye for *in vivo* detection. The ability of the FLECT scanner to detect this probe in thrombotic sites of mice was then ascertained.

Results: Upon carotid artery injury, the injected fluoroprobe bound platelet-rich thrombi and was detected by FLECT-imaging of mice. The analyzed FLECT image quantified the NIR signal and clearly localized it to the injured artery. The FLECT-detected fluorescence was verified on the excised arteries using a 2-dimensional IVIS® scanner. Next, longitudinal FLECT-imaging to monitor thrombolysis over time demonstrated a loss of detected signal in successfully thrombolyzed mice. Besides intravascular thrombosis, we have also successfully employed FLECT imaging for the diagnosis of *in vivo* pulmonary embolism, with the detection of the affected lung lobes.

Conclusions: This report showcases a novel preclinical imaging technology using a newly generated, radioactivity-free fluoroprobe in a three-dimensional *in vivo* fluorescence scanner that allows sensitive thromboembolism detection and monitoring the efficacy of antithrombotic/thrombolytic drugs.

ASY 08.1 | CLEC-2 Contributes to Hemostasis Independently of Classical HemiTAM Signaling in Mice

E.J. Haining[1,2]; D. Stegner[1]; D. Cherpokova[1,3]; K. Wolf[1]; S.P. Watson[2]; B. Nieswandt[1,4]

[1]*University Hospital Würzburg, Institute of Experimental Biomedicine, Würzburg, Germany,* [2]*University of Birmingham, Institute of Cardiovascular Sciences, College of Medical and Dental Sciences, Birmingham, United Kingdom,* [3]*Harvard Medical School, Program in Cellular and Molecular Medicine, Boston Children's Hospital, Boston, United States,* [4]*University of Würzburg, Rudolf Virchow Center, Würzburg, Germany*

Background: C-type lectin-like receptor 2 (CLEC-2) is a platelet receptor that is critical during development and implicated in thrombus stability in thrombosis and hemostasis. It is the only known platelet receptor to signal through a hemi-immunoreceptor tyrosine-based activation motif (hemITAM). Current investigations into the function of CLEC-2 *in vivo* have focused on knock-out studies; however these are unable to explore the possible signaling independent functions of the receptor indicated by its only known physiological ligand, podoplanin, being an integral membrane protein.

Aims: To investigate possible signaling independent functions of CLEC-2 in development and hemostasis and thrombosis.

Methods: We generated a knock-in mouse in which the critical tyrosine in the CLEC-2 hemITAM is replaced by an alanine (Y7A KI). This is the first approach to specifically target the hemITAM of CLEC-2 *in vivo*.

Results: Constitutive and chimeric Y7A KI mice showed signs of blood-lymphatic mixing defects despite normal CLEC-2 surface expression levels on Y7A KI platelets. In ex vivo activation studies the Y7A KI mutation abolished platelet activation responses to CLEC-2 agonists in a dominant-negative fashion. Blocking the CLEC-2 ectodomain with Fab′ fragments of the antibody INU1 destabilized Y7A KI platelet aggregate formation under flow but the presence of the Y7A KI mutation alone had no effect. This contribution of the CLEC-2 ectodomain, but not hemITAM signaling, to thrombus stability was also seen in *in vivo* hemostasis and thrombosis assays.

Conclusions: We present a novel knock-in mouse that expresses a signaling-dead CLEC-2 receptor. This work identified an as yet undescribed signaling-independent function of CLEC-2. Further studies will be required to identify the blood-borne ligand/counter receptor through which CLEC-2 mediates its adhesive role in thrombosis and hemostasis.

ASY 08.2 | Desialylation of O-glycans on GPIbα Drives Receptor Signaling and Platelet Clearance

Y. Wang[1]; W. Chen[1]; C. Casari[2]; S.A. Druzak[1]; W. Bergmeier[2]; J. Ware[3]; R. Li[1]

[1]*Emory University School of Medicine, Aflac Cancer and Blood Disorders Center, Department of Pediatrics, Atlanta, United States,* [2]*University of North Carolina, Department of Biochemistry and Biophysics, Chapel Hill, United States,* [3]*University of Arkansas for Medical Sciences, Department of Physiology and Biophysics, Little Rock, United States*

Background: Sialidase is involved in platelet clearance under pathological and/or physiological circumstances. While the involvement of the Ashwell-Morell receptor (AMR) in clearing desialylated platelets is established, the underlying mechanism remains unclear. It was thought that AMR mediates platelet clearance by binding the exposed galactoses in the N-glycans of platelet GPIbα. However, sialidases can induce platelet clearance in mice, and yet unlike its human ortholog murine GPIbα contains no N-glycosylation sites (NxS/T). GPIbα is highly O-glycosylated. We recently showed that ligand binding to GPIbα under physiological shear could induce unfolding of its mechanosensory domain (MSD) and subsequently GPIb-IX signaling that leads to platelet clearance. The MSD contains O-glycosylation sites.

Aims: To test whether desialylation of O-glycans in GPIbα induces MSD unfolding and platelet clearance.

Methods: Bacterial sialidase was injected into wild type (WT), $Vwf^{-/-}$, $Adam17^{\Delta Zn/\Delta Zn}$, IL4R-IbαTg (transgenic mice expressing only the IL4R-GPIbα chimera), and hTg mice (transgenic mice expressing only human GPIbα), and the effects on counts and glycans of platelets and erythrocytes measured. Sialidase-induced effects on GPIb-IX dynamics and signaling in the platelet were analyzed by flow cytometry and fluorescence microscopy.

Results: Injection of bacterial sialidase or α-2,3-sialidase significantly reduced the platelet count in WT, Vwf$^{-/-}$, Adam17$^{\Delta Zn/\Delta Zn}$, and hTg mice, but not in IL4R-IbαTg mice. Changes in PNA binding, but neither ECL nor SNA binding, correlated inversely with the change in platelet count. In vitro treatment of hTg and human platelets with sialidase induced MSD unfolding, indicated by the increased binding of an anti-MSD antibody 5G6, and GPIb-IX-mediated intracellular signaling, indicated by the filopodia formation.

Conclusions: Desialylation of O-glycans of platelet GPIbα results in unfolding of the MSD in GPIbα, which leads to GPIb-IX signaling and platelet clearance.

ASY 08.3 | Impaired GlycoproteinVI-mediated Signaling and Platelet Functional Responses in CD45 Knockout Mice

V. Inamdar; J. Kostyak; R. Badolia; C. Dangelmaier; B.K. Manne; A. Patel; S. Kim; S. Kunapuli

Temple University, Physiology, Philadelphia, United States

Background: CD45 is a Receptor Protein Tyrosine Phosphatase C (PTPRC) which regulates Src Family Kinase (SFKs) activation in Lymphocytes. Although CD45 is absent from the platelet surface, proteomics studies showed that the CD45 c-terminal catalytic domain is present in platelets.

Aims: The aim of this study is to identify the presence of the CD45 c-terminal domain in platelets and characterize the functional implications of CD45 deficiency in platelets.

Methods: All experiments were performed using CD45 WT and KO mice.In order to establish the presence of CD45 in platelets, we used an established primary antibody that recognizes the c-terminal domain of CD45 for western blot analysis. Isolated murine platelets were used to perform platelet functional tests such as aggregation, secretion, and flow-cytometry. Activation of SFK, Syk, and PLCγ2 were evaluated using western blotting and the in vivo platelet functions were tested using techniques such as tail bleeding and pulmonary embolism.

Results: We observed that CD45 c-terminal domain antibody recognizes a protein of approximately 65 kDa, which is the expected size of the c-terminal 1 and 2 domains of CD45, in platelets from wild-type mice (WT), but not from CD45 Knockout (KO) mice. Platelets from CD45 KO mice displayed a selective impairment of aggregation and dense granule secretion mediated by the collagen receptor, glycoprotein VI (GPVI). CD45 KO mice show increased bleeding times, indicating an important role for CD45 in hemostasis. Using a model of pulmonary embolism, we observed prolonged time to cessation of respiration in CD45 KO mice as compared to WT mice, which is indicative of a defect in thrombus formation in CD45 KO mice. Signaling downstream of the GPVI receptor, indicated by SFK, Syk, and PLCγ2 tyrosine phosphorylation was also impaired in CD45 KO murine platelets compared to WT murine platelets.

Conclusions: We conclude that CD45 is expressed in platelets as a truncated form and regulates GPVI signaling through regulation of SFK activation.

ASY 08.4 | Visualizing Cooperative Mechanosensing of GPIb and GPIIb-IIIa on a Single Aspirated Platelet

L. Ju[1,2,3]; Y. Chen[4,5]; S. Jackson[2,6]; C. Zhu[3,4,5]

[1]The University of Sydney, Charles Perkins Centre, Camperdown, Australia, [2]Heart Research Institute, Newtown, Australia, [3]Georgia Institute of Technology, Coulter Department of Biomedical Engineering, Atlanta, United States, [4]Georgia Institute of Technology, Woodruff School of Mechanical Engineering, Atlanta, United States, [5]Georgia Institute of Technology, Petit Institute for Bioengineering and Biosciences, Atlanta, United States, [6]The University of Sydney, Charles Perkins Centre, Willoughby, Australia

Background: Unlike the classic model of agonist driven platelet thrombus formation, under disturbed blood flow conditions with atherosclerotic plaques, medical device intervention or pre-existing thrombi, thrombus formation is driven by shear-dependent discoid platelet aggregation. This "biomechanical thrombosis" model features a two-step cascade: rapid tethering of platelets via receptor GPIb followed by stable adhesion via GPIIb-IIIa. How these interactions are orchestrated and how they crosstalk are unclear.

Aims: To elucidate how GPIb cooperates with GPIIb-IIIa to mediate platelet adhesion and signaling under force.

Methods: We developed a novel nanotool: dual biomembrane force probe (dBFP) with concurrent force spectroscopy and Ca^{2+} imaging to control signal initiation, visualize signal transduction and interrogate signal outcome, which temporally dissects GPIb and GPIIb-IIIa behaviors (Fig. 1). A micropipette aspirated platelet first repeatedly engages a GPIb ligand (VWF-A1) under controlled force to trigger Ca^{2+}, then quickly switch (< 1min) to engage a GPIIb-IIIa ligand (FN), which allows us to visualize the activation of GPIIb-IIIa triggered by GPIb in real time. GPIIb-IIIa conformational dynamics is observed using conformation reporter antibodies.

Results: A 25pN force lasting >2s is sufficient to trigger Ca^{2+} flux by unfolding a GPIb juxamembrane domain, which activates GPIIb-IIIa to an intermediate affinity 7-fold higher than the affinity of the resting

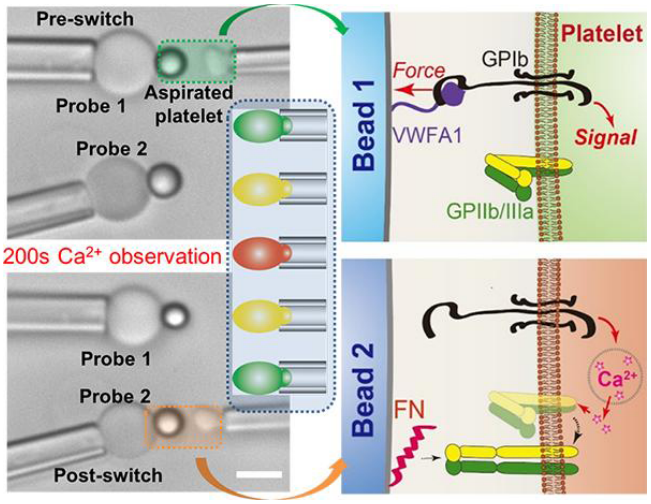

FIGURE 1 Micrograph and illustration of the dual biomembrane force probe to visualize GPIb and GPIIb-IIIa crosstalk on an aspirated platelet

state and 3.5-fold lower than that of the ADP-activated state (Fig. 2). The intermediate integrin adopts an extended-close conformation. Replacing the VWF-A1 with its 2B and 2M VWD mutants abrogates the GPIIb-IIIa intermediate activation.

Conclusions: The dBFP allows us to observe signal crosstalk between GPIb and GPIIb-IIIa on a single platelet in real-time. Force transmitted through GPIb upregulates GPIIb-IIIa to an intermediate affinity state. Our study explains how discoid platelets form aggregation independent of agonists under highly dynamic shear.

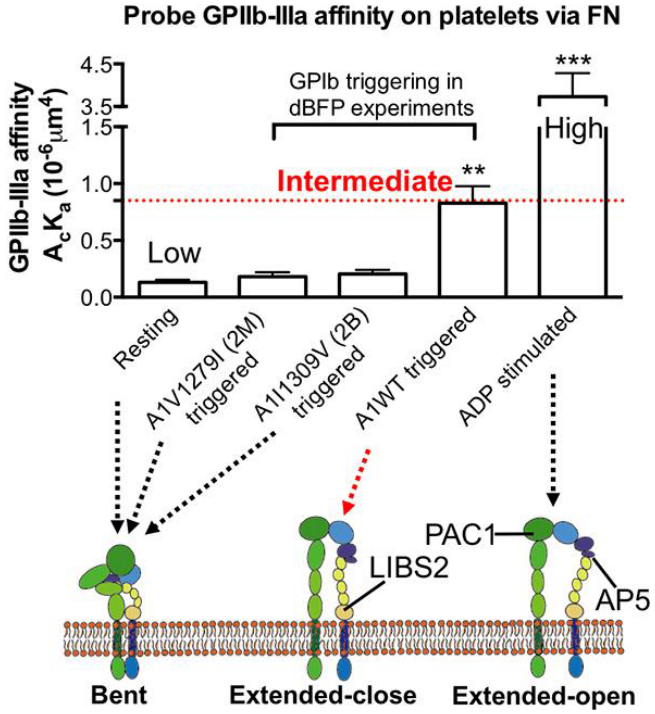

FIGURE 2 Probe GPIIb-IIIa affinity and conformation states on single aspirated platelets of different conditions

ASY 20.1 | Mutations in Tropomyosin 4 Underlie a Rare Form of Human Macrothrombocytopenia

Background: Platelets are produced by large polyploid precursor cells called megakaryocytes. Previous genome-wide association studies (GWAS) indicated that single nucleotide variants in the gene encoding the actin cytoskeletal regulator Tropomyosin (TPM) 4 exert an effect on platelet count and volume. The function of tropomyosins in haematopoiesis has not been investigated.

Aims: We studied the role of TPM4 for platelet biogenesis and function in humans and mice.

Methods: A lookup study of *TPM4* in the BRIDGE Bleeding and Platelet Disorders (BPD) collection was performed. In parallel, a mouse line with an *N*-ethyl-*N*-nitrosourea (ENU)-induced missense mutation in *Tpm4*, as well as *Tpm4* knock-out (KO) mice were generated. Platelet function in mutant mice and in individuals carrying *TPM4* missense variants was analysed by flow cytometry, and static and flow adhesion assays. MK morphology and proplatelet formation were investigated using confocal immunofluorescence microscopy.

Results: We describe two unrelated families identified in the BPD collection that carry a variant which causes truncation of the TPM4 protein, and segregates with macrothrombocytopenia. *Tpm4* mutant and KO mice likewise exhibited dose-dependent macrothrombocytopenia. Insufficient TPM4 expression did not affect MK maturation but resulted in defective proplatelet formation in vitro. Platelet function was mildly affected, as demonstrated by the variable bleeding phenotype observed in *TPM4* patients, as well as delayed platelet spreading on fibrinogen and reduced thrombus formation on collagen under flow in vitro. Decreased TPM4 expression impacted on different cytoskeletal regulators of known importance in MKs and platelets, including Myosin IIa, Actinin 1, Filamin A and Cofilin.

Conclusions: Our findings demonstrate a non-redundant role for *TPM4* in platelet biogenesis in humans and mice, and reveal that truncating variants in *TPM4* cause a rare, dominant, Mendelian platelet disorder.

ASY 20.2 | A Human Germ Line Mutation in the Ephrin Receptor B2 Gene Associated with a Bleeding Syndrome, Affects Platelet Functions and GPVI Signaling

E. Berrou[1]; C. Soukaseum[1]; R. Favier[2]; A. Kauskot[1]; F. Adam[1]; Z. Elaib[1]; K. Dias[2]; J.-C. Bordet[3]; W.H. Ouwehand[4]; J.-P. Rosa[1]; P. Nurden[5]; M. Bryckaert[1]

[1]INSERM, UMR_S 1176, Kremlin Bicêtre, France, [2]Assistance Publique Hôpitaux de Paris, Armand Trousseau Children Hospital, Paris, France, [3]Université Claude Bernard Lyon 1, Lyon, France, [4]University of Cambridge, Cambridge, United Kingdom, [5]Institut Hospitalo-Universitaire LIRYC PTIB, Pessac, France

Background: The ephrin (Eph) transmembrane receptor family of tyrosine kinases is involved in platelet functions but their contribution to inherited platelet disorders has never been reported.

Aims: To understand how an *EPHB2* variant impairs platelet functions, platelet signaling and proplatelet formation in two children P1 and P2 of a consanguineous family with a recurrent bleeding syndrome.

Methods: Whole exome sequencing identified a c.2233C>T mutation (missense p.R745C) of the *EPHB2* gene. Gene sequencing demonstrated that P1 and P2 were homozygous for this variant while their parents were heterozygous. Platelet functions (aggregation, secretion, adhesion), signaling (protein phosphorylation) and morphology (electron microscopy (EM)) were studied. Proplatelet formation in vitro by immunofluorescence microscopy of $CD34^+$-culture megakaryocytes (MKs) was examined.

Results: P1 and P2 exhibited a severe platelet functional defect including platelet aggregation, Ca^{++} mobilization, $\alpha_{IIb}\beta_3$ integrin activation and granule secretion induced by ADP, convulxin and thrombin, and thrombus formation on collagen under blood flow conditions. Most importantly, the phosphorylation of Syk, FcRγ and Akt, the initial steps in GPVI platelet signaling were drastically impaired. In contrast, clot retraction and platelet adhesion on fibrinogen under blood flow, were only mildly defective indicating limited effects on $\alpha_{IIb}\beta_3$ outside-in signaling. Initially normal for P1 and P2 platelet counts decreased moderately (120 $x10^9$ platelets/L) for P1 as he aged. EM showed abnormal elongated platelets with membrane extensions, while MK proplatelets, appeared moderately enlarged.

Conclusions: We conclude that EphB2 is involved in the first steps of GPVI signaling, thereby controlling platelet activation and is required for thrombus formation. Furthermore, EphB2 is involved in regulating platelet morphology and fragmentation.

ASY 20.3 | Cytokine Receptor-like Factor 3 (CRLF3): A Novel Regulator of Platelet Biogenesis and Potential Drug Target for Thrombocythaemia

C. Bennett[1]; J. Guerrero[1]; S. Stritt[2]; Y. Yan[1]; R. Mifsud[1]; D. Adams[3]; A. Baig[2]; W. Erber[4]; B. Nieswandt[2]; R. Read[1]; C. Ghevaert[1]

[1]University of Cambridge, Haematology, Cambridge, United Kingdom, [2]University of Würzburg, Würzburg, Germany, [3]Wellcome Trust Sanger Institue, Cambridge, United Kingdom, [4]University of Western Australia, Perth, Australia

Background: Essential thrombocythaemia (ET) is characterised by a sustained circulating platelet count above 450$x10^9$/L causing an increased risk of cardiovascular events. Current therapies have unwanted side effects.

Aims: We aim to show CRLF3's role in platelet biogenesis and how it could be used as a novel therapeutic target to treat ET.

Methods: *Crlf3* knockout mice (*Crlf3*$^{-/-}$) were used in a range of *in vitro* and *in vivo* assays focusing on platelets and megakaryocytes (MKs). They were also crossbred with JAK2 V617F mice to create an ET mouse deficient of *Crlf3*.

Results: *Crlf3*$^{-/-}$ mice have an isolated and sustained 30-40% decrease in platelet count compared to wildtype (WT) controls. They have increased bone marrow MKs compare to WT controls but MK morphology and their ability to form proplatelets is preserved. *Crlf3*$^{-/-}$ platelet survival is normal and no gross functional abnormalities of platelets were demonstrated in a range of assays (response to agonists in flow cytometry, platelet spreading and *in vitro* thrombus formation). However, pre/pro-platelet structures are abnormally present in the circulation of elderly *Crlf3*$^{-/-}$ mice (see figs.). Immunohistochemistry showed increased microtubule stability of *Crlf3*$^{-/-}$ platelets compared to WT controls, especially in the pre/pro-platelet forms. Splenectomy of *Crlf3*$^{-/-}$ animals restored platelet counts to WT values.

JAK2V617F ET mice crossbred with *Crlf3*$^{-/-}$ mice showed restoration of platelet counts to WT values without affecting other blood lineages.

Conclusions: We identified a mechanism by which *Crlf3* controls platelet biogenesis. Slowed maturation of *Crlf3*$^{-/-}$ pre/pro-platelets in the peripheral circulation due to increased structural stability leads to rapid removal of these immature forms by the spleen and therefore a decrease in platelet count. The isolated effect on platelet numbers and normalisation of platelet count in ET mice deficient of *Crlf3* provides the rational for further study on CRLF3 drug targeting as a novel therapeutic strategy for ET.

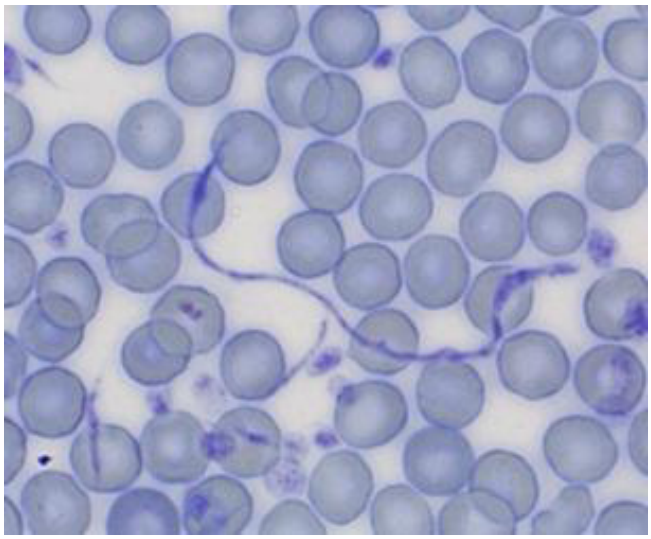

FIGURE 1 Blood smear of an elderly (>1 year) Crlf3-/- mouse stained with rapid Romanowsky. Abnormal platelets resembling pre/pro-platelets can be seen

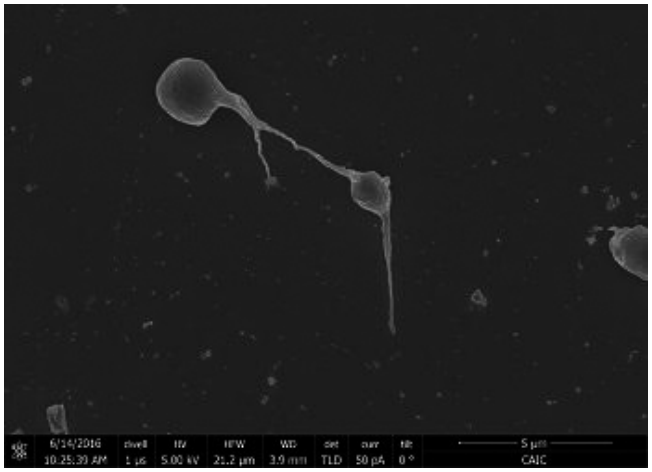

FIGURE 2 Washed platelets from elderly (>1 year) Crlf3-/- mice were imaged by scanning electron microscopy. Pre/pro-platelets were readily seen

ASY 20.4 | RNA Sequencing of Roifman Syndrome Megakaryocytes Reveals a Role for a Small Nuclear RNA in Platelet and Granule Biology

J. Heremans[1]; E. Turro[2,3,4]; C. Thys[1]; C. Wouters[5]; C. Van Geet[1]; I. Meyts[6]; K. Freson[1]; BRIDGE-BPD Consortium

[1]*KU Leuven, Center for Molecular and Vascular Biology, Department of Cardiovascular Sciences, Leuven, Belgium,* [2]*Cambridge Biomedical Campus, Department of Hematology and National Health Service Blood and Transplant, Cambridge, United Kingdom,* [3]*Cambridge Biomedical Campus, Medical Research Council Biostatistics Unit, Cambridge Institute of Public Health, Cambridge, United Kingdom,* [4]*Cambridge Biomedical Campus, National Institute for Health Research BioResource-Rare Diseases, Cambridge, United Kingdom,* [5]*KU Leuven, Laboratory of Immunobiology (Rega Institute), Department of Microbiology and Immunology, Leuven, Belgium,* [6]*KU Leuven, Laboratory of Pediatric Immunology, Department of Microbiology and Immunology, Leuven, Belgium*

Background: Roifman syndrome is a rare inherited multisystem disorder characterized by spondyloepiphyseal dysplasia, growth retardation, cognitive delay and antibody deficiency. In some cases, immune thrombocytopenia has been reported. Compound heterozygous variants in *RNU4ATAC*, a nuclear RNA essential for minor intron splicing, were recently identified to cause Roifman. Pathological RNA processing has previously been described in TAR syndrome due to variants in *RBM8A*.
Aims: Investigate platelet defects in 3 patients with Roifman phenotypes from 2 unrelated pedigrees. All cases had low platelet counts with abnormal alpha- and dense-granules but no bleeding. The patients underwent whole genome sequencing in the BRIDGE-BPD study.
Methods: Phenotype similarity regression identified a significant association between two rare alleles in *RNU4ATAC* and a Roifman-like phenotype. CD34+ hematopoietic stem cells of 2 patients and controls were differentiated to megakaryocytes (MKs) for RNA sequencing. Minor intron retention was assessed by DEXseq, adapted for differential intron usage. Immunostaining and Western blot were done on MKs and platelets to study cytoskeleton and granules.
Results: We found novel pathogenic variants in *RNU4ATAC*. Relative to controls, Roifman MKs reach similar ploidy levels, but are smaller and generate less proplatelets with abnormal cytoskeletal organization. Roifman platelets are also larger, show elevated tubulin and actin levels and an increase in granule markers CD63 and vWF. RNA-seq of Roifman MKs revealed minor intron retention in 354 genes of which the top 50 were mainly involved in vesicular transport, cytoskeleton organization or cognitive function. One of the most disrupted genes (P=1.49x10^{-127}) was *DIAPH1*, which is linked to cytoskeleton and macrothrombocytopenia.
Conclusions: Roifman syndrome is the second disorder after TAR syndrome implicating RNA processing in megakaryopoiesis, but the first in which variants in a non-coding RNA are pathogenic.

ASY 33.1 | Differential Signaling through Platelet Collagen Receptors Investigated Using Metabolomics

A. Bussey[1]; Z. Ament[2]; J.-D. Malcor[1]; J. Griffin[1]; R.W. Farndale[1]

[1]*University of Cambridge, Biochemistry, Cambridge, United Kingdom,* [2]*MRC Human Nutrition Research, Fulbourn Road, Cambridge, United Kingdom*

Background: Platelet lipids provide multiple para- and autocrine signaling molecules. Collagens elicit aspirin-sensitive platelet thromboxane (Tx) synthesis that amplifies their activation. Glycoprotein (GP) VI is the main signalling receptor, whilst integrin alpha2beta1 supports platelet adhesion and less prominent signals.
Aims: We sought to discriminate GPVI from alpha2beta1 signaling by investigating lipid metabolism in activated platelets.
Methods: We used open-profiling of the platelet lipidome, by Folch extraction and liquid chromatography-mass spectrometry (LC-MS), to identify classes of lipid mobilised by triple-helical peptides specific for GPVI and alpha2beta1, CRP-XL and GFOGER-XL, respectively. Specific stimuli were resolved by principal component analysis, followed by targeted analysis of eicosanoids by tandem LC/MS.
Results: GPVI stimulated both the cyclooxygenase (COX) and cytochrome P_{450} (CYP450) pathways, generating abundant TxA_2, measured as the stable metabolite, TxB_2. Alpha2beta1 promoted little flux through these pathways, but caused marked production of lipoxygenase (LOX) metabolites, notably LTB_4, 15-HEPE and 15-HETE. These eicosanoids, established mediators of inflammation that may be relevant to atherothrombosis, tended to inhibit thrombus deposition from flowing blood, and to modulate platelet aggregation. Inhibition of the COX pathway by aspirin enhanced the activity of the CYP450 and LOX pathways.
Conclusions: The platelet lipidome is a sensitive indicator of platelet signals from collagen, including those arising through the adhesive receptor alpha2beta1, for which little detailed functional activity has been described.
The LOX pathway is very responsive to alpha2beta1 ligation, whereas the COX and CYP450 pathways are the primary route for GPVI signaling to the lipidome.
The LOX metabolites tend to exert a moderating effect on platelet thrombus formation, but their known action on leukocytes suggest that alpha2beta1 may also contribute to inflammatory processes in the vessel wall.

ASY 33.2 | Characterization of the Gp1ba-Cre Transgenic Mouse: A Novel Approach for Generating Megakaryocyte/Platelet-specific Knockout Mice

Z. Nagy[1]; T. Vögtle[1]; G. Di Nunzio[1]; J. Mori[1]; M. Geer[1]; S. Heising[1]; R. Gareus[2]; A. Mazharian[1]; Y.A. Senis[1]

[1]*University of Birmingham, Institute of Cardiovascular Sciences, Birmingham, United Kingdom,* [2]*The Jackson Laboratory, Bar Harbor, United States*

Background: The *Pf4-Cre* transgenic mouse developed by Skoda and co-workers has been used extensively to generate megakaryocyte/platelet (MK/plt)-specific knockout (KO) mouse models. Although highly efficient at deleting *floxed* genes in the MK lineage, several studies have emerged challenging the specificity of this transgene,

and raising the possibility that some of the phenotypes associated with this model may be due to non-specific deletion of *floxed* genes in other cell types.

Aims: To develop an alternative approach to produce MK/plt-specific KO mice. In this study, we investigate the specificity and efficiency of deletion of *floxed* genes by this deleter strain.

Methods: *Gp1ba-Cre* mice were generated by knocking-in a transgene coding for *Cre recombinase* downstream of the endogenous *Gp1ba* locus by homologous recombination. Potential effects of the transgene on platelet parameters and function were assessed by standard assays. Expression pattern of the transgene *in vivo* was investigated by crossing deleter mice with *mT/mG* double-fluorescent Cre reporter mice and quantifying GFP^+ haematopoietic cells by flow cytometry.

Results: *Gp1ba-Cre* heterozygous mice are born at normal Mendelian frequency, have normal platelet count, a 17% increase in platelet volume and marginally reduced GPIb-IX levels; however, platelets from these mice function normally *in vitro* and *in vivo*. Virtually all platelets and nearly half of αIIb^{high} bone marrow (BM) cells from *mT/mG*;*Gp1ba-Cre* reporter mice were GFP^+, demonstrating highly efficient Cre-mediated gene excision in the MK lineage. Notably, no significant GFP expression was detected in erythrocytes, leukocytes, splenocytes or $CD45^+$ BM cells from these mice.

Conclusions: We demonstrate that the *Gp1ba-Cre* transgene is expressed specifically in the MK lineage. This mouse model will be an invaluable tool for generating MK/plt-specific KO mice, for validating conclusions from *Pf4-Cre* generated KO mice and for studying the spatiotemporal expression pattern of GPIbα during development.

ASY 33.3 | Real-time Platelet Production from Human iPS-derived Megakaryocytes in a Micropillar-textured Microfluidic Chip

G. Sicot[1]; K. Khelloufi[1]; A. Magniez[1]; A. Legoff[2]; S. Corbineau[3]; A. Nivau[1]; F.S. Hamdi[1]; B. Teste[2]; N. Debili[3]; M. Reyssat[2]; D. Baruch[1,4]

[1]*PLATOD, Paris, France,* [2]*ESPCI, CNRS UMR 7083, Paris, France,* [3]*INSERM U 1170, Villejuif, France,* [4]*Paris Descartes University, INSERM UMR_S 1140, Paris, France*

Background: Bioreactors that recapitulate some features of the bone marrow microenvironment and cell reprogramming techniques to produce megakaryocytes (MKs) represent major improvements towards ex vivo platelet generation for therapeutic applications to treat or prevent bleeding in severe thrombocytopenic patients.

Aims: In this study, we provide evidence of efficient production of platelets from MK of different sources, based on a new microfluidic chip that upregulates and synchronizes platelet production by exposure of MKs to von Willebrand Factor (VWF) at a high shear rate.

Methods: Mature MKs are directly injected into microchannels comprising arrays of VWF-coated pillars acting as anchors. Time-lapse observation allows measuring single MK elongation velocity, as well as number of releasable platelets per MK, calculated as ratio of released bead volume / smallest volume of released element defined as a platelet.

Results: Captured MKs adopt a beads-on-a-thread conformation before being fragmented into proplatelets and releasing platelets in the flow of the perfusion. MKs derived from hUES cells and iPS cells, as well as from primary HSC, underwent similar sequences of fragmentation into proplatelets and platelets, indicating an efficient and robust process. In each of the 4 experiments, mean elongation velocities of MKs obtained from hUES cells and iPS cells were calculated and varied between 23. 7 and 48. 1 μm/min and 30. 0 and 57. 3 μm/min, respectively. The number of releasable platelets per MK varied between 20 and 800, and 39 and 833, for MK derived from hUES cells and iPS cells, respectively.

Conclusions: In conclusion, these data indicate that high numbers of platelets are releasable from iPS cell-derived MK anchored onto VWF-coated micropillars at high shear rates and provide an innovative way to overcome the limitations of low platelet shedding from iPS cell-derived MKs in static conditions.

ASY 33.4 | Quantification of Platelet Contractile Movements during Thrombus Formation

K. Claesson[1]; N. Boknäs[1,2]; T. Lindahl[1]; L. Faxälv[1]

[1]*Linköping University, Department of Clinical and Experimental Medicine, Linköping, Sweden,* [2]*Linköping University Hospital, Department of Hematology, Linköping, Sweden*

Background: During thrombus formation platelet contractile forces can redefine the overall geometry of the thrombus as well as the distribution of aggregatory and procoagulant platelets within the thrombus. Thrombus formation, contraction and individual platelet movements can be monitored and evaluated through different approaches. However, none of the existing methods can generate information about both single platelet movements and thrombus contraction at the same time. Such information would be valuable to better understand the details and dynamics of thrombus development and contraction.

Aims: To characterize platelet movement and thrombus contraction by tracking a large number of platelets during in-vitro thrombus formation experiments.

Methods: Time-lapse and z-stack fluorescence microscopy were used to capture thrombus formation in hirudinised blood in a flow chamber. 5% of the platelets were labelled using CD42a (AF647) and Annexin V (AF488) was present in the blood during experiments. Thrombus formation was studied both in the presence of inhibitors; ASA, cangrelor, abciximab, 6B4 (antibody inhibiting VWF binding), and without inhibition at different shear rates. The thrombus development was quantified as described previously (Claesson et al., 2016, Thromb. Hemost).

Results: Platelet movements within the thrombus were tracked and quantified in x, y and z-axis. The movement patterns of the annexin V and CD42a labelled platelets was distinctively different (Fig 1 and 2, showing the same thrombus) and the movement was affected by the shear rate. The contractile movements were reduced during inhibition.

Conclusions: By tracking individual platelets during thrombus formation, we have the possibility to get new insights into the platelet driven contraction process of the thrombus.

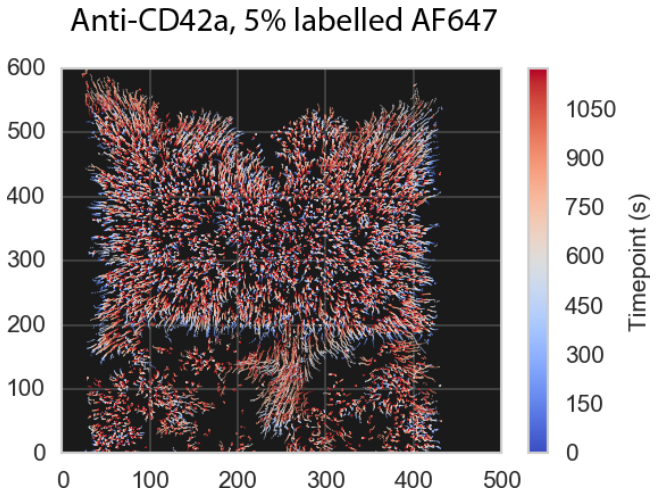

FIGURE 1 Platelet tracks at 400s-1 (without inhibition) for CD42a labelled platelets. The platelet positions were tracked throughout the whole experiment

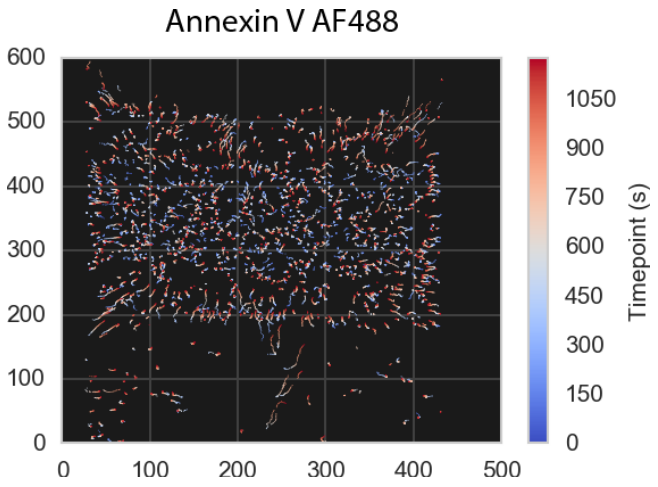

FIGURE 2 Platelet tracks at 400s-1 (without inhibition) for A-V labelled platelets. The platelet positions were tracked throughout the whole experiment

ASY 38.4 | miR-125a-5p Regulates Megakaryocyte Differentiation and Proplatelet Formation

S. Bhatlekar[1]; S. Nagalla[2]; C. Lindsey[3]; L. Ma[3]; X. Kong[3]; I. Basak[1]; R. Pellegrino da silva[4]; L. Yichuan[4]; M. Rondina[1]; A. Weyrich[1]; L. Edelstein[3]; P. Bray[1,5]

[1]University of Utah, Program in Molecular Medicine, Salt Lake City, United States, [2]University of Texas Southwestern Medical Center, Division of Hematology/Oncology, Dallas, United States, [3]Thomas Jefferson University, Cardeza Foundation for Hematologic Research, Philadelphia, United States, [4]The Children's Hospital of Philadelphia, Center for Applied Genomics, Philadelphia, United States, [5]University of Utah, Division of Hematology and Hematologic Malignancies, Department of Medicine, Salt Lake City, United States

Background: Numerous reports indicate microRNAs (miRs) regulate or are associated with megakaryocyte (MK) differentiation (MKpoiesis), but none have been correlated with human peripheral blood platelet number *in vivo*.

Aims: To use an unbiased approach to identify miRs regulating MK progenitor differentiation and proplatelet formation (PPF).

Methods: Umbilical cord blood (CB) derived $CD34^+$ stem cells were grown in MK favoring cultures and $CD61^+$ MKs were isolated on day 6, 9 and 13 (Fig 1A). Primary MKs were isolated from human bone marrow (BM) aspirates by laser capture micro-dissection (Fig 1B). All cell types were profiled for miRs (Exiqon) and mRNA (RNA sequencing) expression (Fig 1C).

Results: To identify miRs regulating MKpoiesis and PPF, we considered only miRs expressed in both primary BM MKs and cultured MKs (107 miRs) (Fig 1D), whose expression either increased (33 miRs) or decreased (18 miRs) during MK differentiation (Fig 1E), and significantly associated with platelet number (Fig 1F). This stringent filtering left only 3 miRs. Of these, we focused on miR-125a-5p, because it is known to positively regulate stem cells in mice, but its effects on MKpoiesis is unknown. We found miR-125a-5p was positively correlated with platelet count (p=0.02). Knock down of miR-125a-5p caused a 70% reduction in MK PPF ($p=9.58x10^{-5}$) and 35% reduction in MK CD41 expression. Overexpression of miR-125a-5p increased PPF by ~15%. We also identified 5 putative targets of miR-125a-5p (*LCP1*, *JAZF1*, *PRKCH*, *AHNAK*, *RPL32A*) that decreased expression during MKpoiesis and were negatively associated with platelet number ($p< 0.05$).

Conclusions: miR-125a-5p positively regulates MKpoiesis and PPF. As miRs are increasingly becoming clinical therapeutic targets, miR-125a-5p over expression has potential for improving the in vitro manufacture of platelets or treating thrombocytopenia, whereas its inhibition could be effective in myeloproliferative disorders.

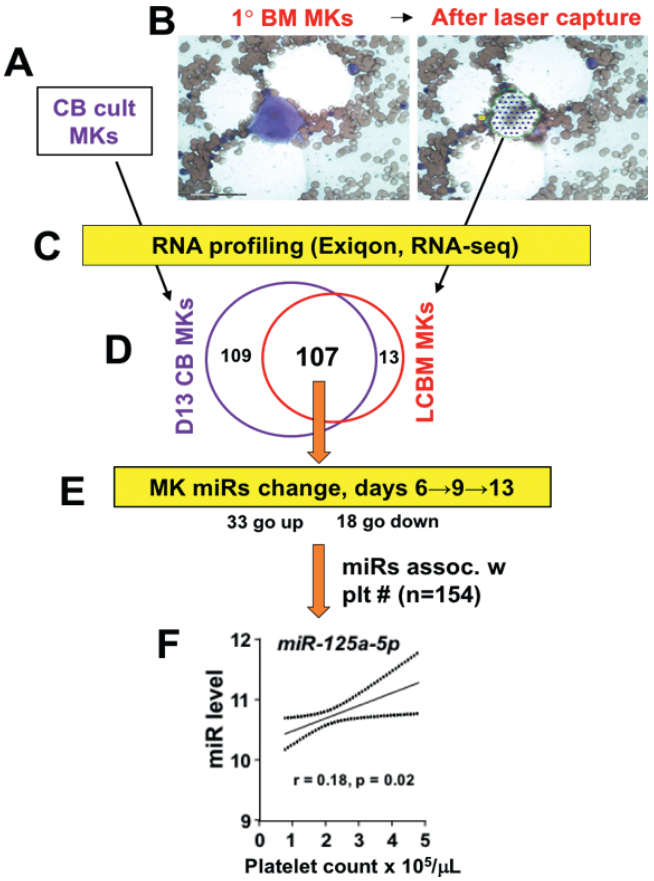

FIGURE 1 Identification of miRs that regulate proplatelet formation

PLATELETS – CLINICAL

ASY 05.1 | Enhancing Autophagy Protects Platelets in Immune Thrombocytopenia Patients

S. Ma[1]; C. Wang[1]; J. Miao[2]; M. Hou[1]; J. Peng[1]

[1]Qilu Hospital, Shandong University, Department of Hematology, Jinan, China, [2]Shandong Provincial Key Laboratory of Animal Cells and Developmental Biology, School of Life Science, Shandong University, Jinan, China

Background: Immune thrombocytopenia (ITP) is an autoimmune bleeding disorder, in which platelets show increased apoptosis. Autophagy is an essential pathway for platelets to maintain their life and physiological functions. However, the role of autophagy in ITP platelets was previously unclear.

Aims: The objectives of this study were to estimate the level of platelet autophagy in ITP patients, and to investigate the effects of autophagy regulation on platelet protection and life extension.

Methods: Peripheral blood was collected from ITP patients and healthy donors for further cultivation with RAPA, 3-MA and ABO. Previously we have first identified that ABO (6-amino-2,3-dihydro-3-hydroxymethyl-1,4-benzoxazine) could stimulate autophagy in an mTOR-independent but Annexin A7-dependent manner. LC3 level, platelet viability and apoptosis were measured. Statistical data were expressed as mean ± standard error of the mean (SEM). $P < 0.05$ was considered statistically significant.

Results: Immunofluorescence revealed that accumulation of LC3-positive puncta was reduced in ITP patient platelets and was increased upon RAPA or ABO treatment (Fig. 1A). Western blotting demonstrated that the LC3-II/I ratios in RAPA- or ABO-treated ITP platelets were significantly higher than in ITP platelets. No significant difference was found between the ABO-treated ITP platelets and the RAPA-treated ITP platelets or healthy platelets (Fig. 1B, 1C). Platelet apoptosis in ITP decreased and that platelet viability improved significantly after treatment with either RAPA or ABO, with no difference from that in healthy controls (Fig. 2A, 2B, 2C).

Conclusions: Platelet autophagy in ITP patients was diminished, whose increase could alleviate platelet destruction by inhibiting apoptosis and improving platelet viability. These results suggest a role for autophagy regulation in the pathogenesis of ITP and offer a novel treatment.

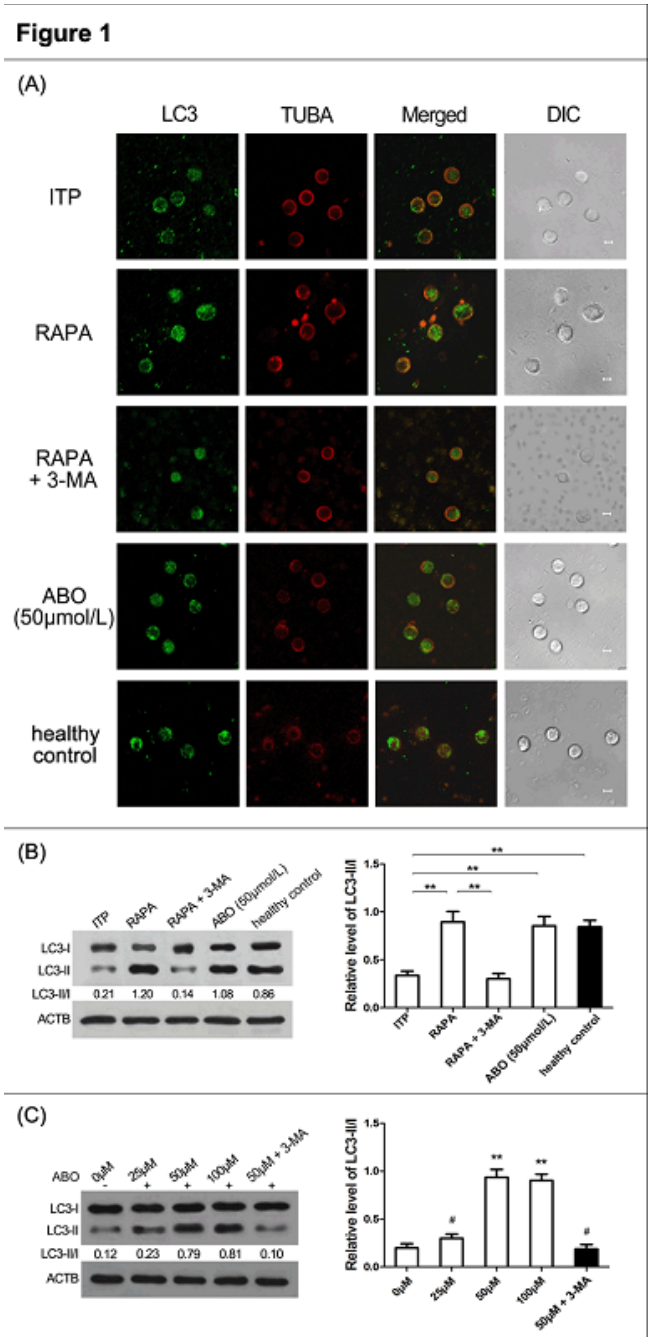

FIGURE 1 Platelet autophagy in ITP patients and healthy controls

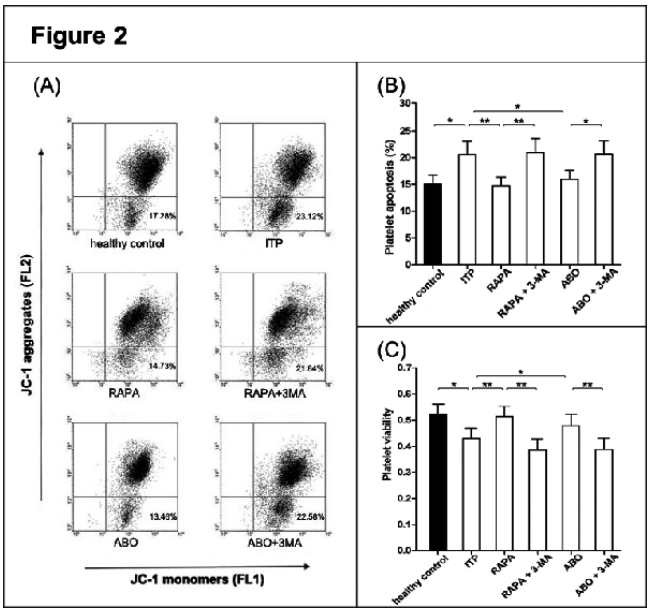

FIGURE 2 Inducing autophagy alleviated destruction of ITP platelets

ASY 05.2 | Antibody Mediated Glycan Modification: A Potential Role in Platelet Destruction in Autoimmune Thrombocytopenia

R. Jouni[1]; I. Marini[1]; J. Alex[2]; L. Janzen[2]; A. Greinacher[2]; T. Bakchoul[1,2]

[1]University Hospital Tübingen, Transfusion Medicine, Tübingen, Germany, [2]Universitätsmedizin Greifswald, Transfusionsmedizin, Greifswald, Germany

Background: Immune thrombocytopenia (ITP) is a bleeding disorder caused by autoantibodies (AAbs) directed against platelet (PLT) glycoproteins (GP). Recently, Fc-independent PLT clearance via Ashwell-Morell receptors, that recognize glycan changes on PLT surface, was proposed as a new way of Ab-mediated PLT destruction in mice.

Aims: In our study we analyzed the impact of AAbs from ITP patients on the glycan pattern of human PLTs and its effect on their survival *in vivo*.

Methods: Sera from ITP patients and healthy donors were analyzed using monoclonal platelet antigen capture assay (MAIPA) and lectin binding assay (LBA). In LBA, after incubation of sera with PLTs from healthy donors the change of glycan pattern (flow cytometry) and its impact in NOD/SCID mice were analyzed.

Results: 37 sera (ITP patients) and 25 sera (healthy donors) were analyzed and different patterns of glycan modification were observed after incubation with AAbs (LBA). 17/37 sera induced a significant increase in Peanut agglutinin binding compared to heathy donors (median fold increase (FI): 1.21, range 1.08-1.40). 9/37 sera caused higher Erythrina cristagalli lectin binding (median FI: 1.02, range: 1.08-1.15). While, 8/37 sera showed strong decrease in Ricinus communis agglutinin binding (median FI: 0.52, range: 0.50-0.59). Interestingly, not only GP-Ib/IX AAbs but also GPIIb/IIIa AAbs were able to modify glycan pattern. No significant change was induced by sera from healthy donors. The injection of AAbs resulted in accelerated clearance of human PLTs in NOD/SCID mice. The destruction of human PLTs by ITP-AAbs was reduced but not completely inhibited by a specific neuraminidase inhibitor that prevents glycan changes on PLT surface (survival of human PLTs after 5h: 29%, range 22-40% vs. 48%, range 41-53%, respectively).

Conclusions: Our data indicate that AAbs from ITP patients can induce modifications of glycan pattern on PLT surface which seem to contribute to PLT destruction in vivo.

ASY 05.3 | Fc-independent Immune Thrombocytopenia via Mechanomolecular Signaling in Platelets

M. Quach[1]; M. Dragovich[2]; W. Chen[1]; A. Syed[1]; X. Liang[1]; W. Deng[1]; H. Ni[3]; S. De Meyer[4]; J. Ware[5]; H. Deckmyn[4]; F. Zhang[2]; R. Li[1]

[1]Emory University, Pediatrics, Atlanta, United States, [2]Lehigh University, Department of Mechanical Engineering and Mechanics, Bethlehem, United States, [3]University of Toronto, Toronto, Canada, [4]Laboratory for Thrombosis Research of KU Leuven Kulak, Kortrijk, Belgium, [5]University of Arkansas for Medical Sciences, Little Rock, United States

Background: Immune thrombocytopenia (ITP) is an autoimmune disease in which anti-platelet autoantibodies induce thrombocytopenia. First-line treatments are intravenous immunoglobulin (IVIG) or corticosteroids. Unfortunately, 20-25% of patients are refractory to this type of treatment. ITP mediated by anti-GPIb-IX antibodies (Abs) is not ameliorated by IVIG. Although most Abs targeting the ligand-binding domain (LBD) of GPIba clear platelets in an Fc-independent manner, there are some exceptions. Further, many Abs targeting the mechanosensory domain (MSD) of GPIbα, GPIbβ, or GPIX do not cause platelet clearance. We have showed that VWF binding to GPIbα under physiological shear induces unfolding of the MSD and subsequent GPIb-IX signaling leading to platelet clearance.

Aims: To elucidate the mechanism of anti-LBD Ab-induced platelet clearance.

Methods:

(1). Shear was applied to human and murine platelet-rich plasma mixed with anti-LBD Abs. Platelets were analyzed via flow cytometry for GPIb-IX signaling and crosslinking.

(2). Transgenic mice expressing human GPIba (hTg) were treated with IVIG and injected with anti-LBD Abs. Platelet count was assayed.

(3). Single-molecule force spectroscopy was performed to pull anti-LBD Abs bound to an anchored GPIb-IX complex.

Results: Clearance-inducing anti-LBD Abs, such as 6B4, induce GPIb-IX signaling in human and murine platelets in a shear-dependent manner. 6B4 Fab or anti-LBD Ab AK2 does not induce platelet signaling under the same conditions. Pulling with 6B4 and other Abs, but not AK2, on GPIb-IX causes MSD unfolding. Similarly, 6B4 and other Abs, but not 6B4 Fab or AK2, induce ~20% aggregation or agglutination of platelets in the aggregometer and IVIG-resistant platelet clearance in hTg mice.

Conclusions: Anti-LBD Abs induce GPIb-IX signaling and platelet clearance via unfolding the MSD on the platelet. AK2 is not able to because its unbinding force (force required to cause AK2 to unbind from the LBD) is not sufficiently large to allow unfolding of the MSD.

ASY 05.4 | Induction of Immune Thrombocytopenia in Mice Expressing Human Fcy Receptors: An Improved Experimental Model that Better Reflects the Inflammatory State Associated with ITP

M. Davila; T. Meyer; L. Robles-Carrillo; H. Desai; M. Rivera-Amaya; J. Francis; A. Amirkhosravi

Florida Hospital, Center for Thrombosis Research, Winter Park, United States

Background: Fcγ receptors (FcγRs, e.g. FcγRIIa) contribute to the pathophysiology of immune thrombocytopenia (ITP). Mouse models are often used to study the biology of ITP. In these,

thrombocytopenia is achieved by passive administration of anti-platelet antibodies. However, they fail to reflect the inflammatory state associated with human ITP. Differences in the types and expression patterns of FcγRs between humans and mice may contribute to this discrepancy.

Aims: Here, using mice transgenic for human FcγRs, we assessed ITP induced by native or chimeric anti-mouse platelet antibodies.

Methods: Mice transgenic for either the entire human Fcγ-receptor family (huFcγR) or only FcγRIIa (hFc), and wild type (WT) mice, were injected i.v with anti-mouse platelet antibodies: MWReg30, 6A6 or chimeric 6A6 (c6A6), containing rat, mouse or human Fc domains, respectively. Core temperature and platelet counts were measured before and 30 min after injection. Alternatively, MWReg30 and c6A6 were injected i.p and platelets counted daily for 7 days. Plasma IFN-γ, TNF-α, IL-2, IL-6 and IL-10 were measured 30 min after i.v, and on days 0, 3, 5 and 7 after i.p injections.

Results: MWReg30 injected i.v induced severe thrombocytopenia (>90% platelet loss), hypothermia, and shock in huFcγR and hFc but not WT mice. 6A6 caused severe thrombocytopenia in huFcγR and hFc but hypothermia and shock only in huFcγR. In contrast, c6A6 caused mild thrombocytopenia (30% platelet loss) without hypothermia or shock in all strains. Severe sustained thrombocytopenia was achieved in all strains injected i.p. Significant elevation of IFN-γ, TNF-α, IL-6 and IL-10 levels was observed in huFcγR mice injected i.v or i.p with MWReg30, and in both huFcγR and hFc mice with c6A6, but not in WT mice.

Conclusions: The use of anti-platelet antibodies having a human effector region in mice expressing human FcγRs is an improved model that more closely reflects the pathophysiology of human ITP and reveals its inflammatory nature.

ASY 19.1 | The Platelet COX-1 Knockout Mouse as a Model to Study the Effects of Aspirin in the Cardiovascular System

M. Crescente[1]; P.C. Armstrong[1]; M.V. Chan[1]; J. Jiao[2]; C. Gaston-Massuet[1]; G.S. Cottrell[3]; N.S. Kirkby[4]; J.A. Mitchell[4]; H.R. Herschman[2]; T.D. Warner[5]

[1]Queen Mary University of London/William Harvard Research Institute, London, United Kingdom, [2]UCLA, Los Angeles, United States, [3]University of Reading, Reading School of Pharmacy, Reading, United Kingdom, [4]Imperial College London, London, United Kingdom, [5]Queen Mary University of London/William Harvard Research Institute, London, United States

Background: The anti-thrombotic effect of low dose aspirin is due to its inhibition of platelet cyclooxygenase-1 (COX-1) and blockade of the production of thromboxane A_2. Aspirin also has off-platelet actions that may limit its effectiveness. Since mice have very marked differences in aspirin pharmacokinetics they cannot be used to explore the effects of low dose aspirin in humans.

Aims: To address these questions, we developed platelet COX-1 knockout mice (*platelet-COX-1*$^{-/-}$) to recapitulate the effect of low-dose aspirin in humans.

Methods: *Platelet-COX-1*$^{-/-}$ mice were generated by pairing *Cox-1*$^{fl/fl}$ mice with *Pf4-Cre* mice. The presence of COX-1 in washed platelets was investigated by western blot analysis and confocal immunofluorescence microscopy. Platelet function and eicosanoid production was investigated by aggregometry and ELISA, respectively.

Results: Western blot analysis and confocal microscopy confirmed the absence of COX-1 in platelets. The production of thromboxane B_2, but not 12-HETE induced by arachidonic acid, collagen, A23187 and the PAR-4 activating peptide in platelet rich plasma and whole blood was significantly decreased in *platelet-COX-1*$^{-/-}$ mice. This effect was not further reduced by the addition of aspirin in vitro. *Platelet-COX-1*$^{-/-}$ mice also displayed decreased arachidonic acid-induced platelet aggregation.

Conclusions: We have produced the first *platelet-COX-1*$^{-/-}$ mouse. We envisage that this mouse will allow mechanistic dissection of the platelet and non-platelet effects of aspirin, identification of the range of eicosanoids whose production is affected by aspirin at different sites, and better modelling of the effects of clinically important anti-thrombotic therapy.

ASY 19.2 | Low Platelet Count is an Independent Risk Factor for Infection in Patients with Primary Immune Thrombocytopenia

A.J.G. Jansen[1,2]; M. Qu[3,4]; Q. Liu[3,4]; H.-G. Zhao[5]; J. Peng[3,4]; H. Ni[6,7,8]; M. Hou[3,4]

[1]Erasmus MC, Hematology, Rotterdam, The Netherlands, [2]Sanquin-AMC Landsteiner Laboratory, Plasma Proteins, Amsterdam, The Netherlands, [3]Qilu Hospital, Shandong University, Jinan, China, [4]Chinese Ministry of Education and Chinese Ministry of Health, Key Laboratory of Cardiovascular Remodeling and Function Research, Jinan, China, [5]The Affiliated Hospital of Qingdao University Medical College, Hematology, Qingdao, China, [6]Toronto Platelet Immunobiology Group, Toronto, Canada, [7]Keenan Research Centre for Biomedical Science of St. Michael's Hospital, Toronto, Canada, [8]Canadian Blood Services, Toronto, Canada

Background: Thrombocytopenia is a common and severe complication after infection. Recent *in vitro* evidence suggests a potential role of platelets in the inflammation process.

Aims: In this study we further investigated the role of thrombocytopenia on infections in patients with primary immune thrombocytopenia (ITP).

Methods: Data of a recently published large randomized clinical trial in patients with primary ITP, who were randomized for prednisone or high dose dexamethasone, were used. From 195 patients who were analyzed in this study we could use data on platelet count, infections and clinical characteristics from 158 patients.

Results: Twenty four percent of the patients with primary ITP had an infection in the first month of treatment with prednisone or high dose dexamethasone. Patients who had an infection had significantly lower platelet counts during the first month of treatment (Figure 1) leading to a significantly lower response rate at 1 month ($P < 0.05$) and a significantly longer hospital stay (9.8 vs. 14.0 days, $P < 0.01$). Additionally Cox regression analysis showed that an increase in platelet count of $20x10^9$/L led to a risk reduction of 52% for infections in the next week

(P< 0.01). Although not significant, platelet transfusion led to a large increase in platelet count in ITP patients without infection, but not in patients with infection.

Conclusions: Infections are common in patients with primary ITP leading to significantly worse response rate and longer hospital stays. Additionally low platelet count was independently associated with an increased risk of infection. The role of platelet transfusion as therapeutic tool however remains unclear.

ASY 19.3 | Increased Circulating T Follicular Helper Cells in Patients with Chronic Immune Thrombocytopenia

L. Dai[1,2]; M. Zhu[1,2]; X. Bai[1,2]; Z. Wang[1,2]; C. Ruan[1,2]

[1]The First Affiliated Hospital of Soochow University, Suzhou, China, [2]Key Laboratory of Thrombosis and Hemostasis, Jiangsu Institute of Hematology, Suzhou, China

Background: Immune thrombocytopenia (ITP) is a common hematologic disorder characterized by isolated thrombocytopenia. T follicular helper(TFH) cells are a subset of CD4+ T-helper cells and can activate B cells.

Aims: This study aims to investigate the role of T follicular helper (TFH) cells in the immunopathogenesis of chronic immune thrombocytopenia (CITP),and its chang before and after treatment.

Methods: Fifty-four patients with CITP and 30 age-matched healthy controls were enrolled into this study.The frequencies of circulating TFH cells were characterized using flow cytometry in patients with CITP and in healthy controls. The levels of IL-2, IL-4, IL-10 and IL-21 associated with TFH cells were measured using ELISA. The expression of transcription factors and regulatory factors of Bcl-6, c-Maf, Blimp-1 and PD-1 mRNA in CD4+ T cells were detected by real-time PCR .All these indicators were analyzed before and after treatment.

Results: The proportion of TFH cells were significantly higher (P< 0.05) in CITP compared with controls and decreased percentage of TFH cells were present in CITP responders after treatment (p< 0.05); correlation analysis showed that the TFH cells were positively correlated with the levels of PAIgG and negatively with the platelet counts in peripheral blood. Transcription levels of Bcl-6 and c-Maf mRNA in CD4+ T lymphocyte cells were significantly elevated, the Blimp-1 and PD-1 mRNA in CD4+ lymphocyte cells were lower in CITP patients in comparison with healthy controls. The higher plasma concentration of IL-21, and lower concentration of IL-2, IL-10 were found in CITP patients. After treatment these abnormal indicators were improved in CITP responders.

Conclusions: These data demonstrate that circulating TFH cells and CD4+ TFH lineage-associated cytokines may play a role in CITP. The overactivation of TFH cells may contribute to the immunopathogenesis of CITP, blocking the pathway of TFH cells may be reasonable cellular targets for therapeutic intervention.

ASY 19.4 | Anti-ADAMTS13 Autoantibodies against Cryptic Epitopes in Acquired TTP Patients

E. Roose[1]; G. Vidarsson[2]; O. Verhagen[2]; R. Visser[2]; M. Berkowska[2]; J. Caron[1]; I. Mancini[3]; L. Desender[1]; I. Pareyn[1]; N. Vandeputte[1]; A. Vandenbulcke[1]; M.-A. Azerad[4]; H. Deckmyn[1]; S.F. De Meyer[1]; F. Peyvandi[3]; K. Vanhoorelbeke[1]

[1]KU Leuven Campus Kulak Kortrijk, Laboratory for Thrombosis Research, Kortrijk, Belgium, [2]Sanquin Research, Department of Experimental Immunohematology, Amsterdam, The Netherlands, [3]Università degli Studi di Milano, and Fondazione Luigi Villa, Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Fondaione IRCCS Ca' Granda Ospedale Maggiiore Policlinico, Department of Pathophysiology and Transplantation, Milan, Italy, [4]CHU Brugmann, Jules Bordet, Hematology, Brussels, Belgium

Background: Acquired thrombotic thrombocytopenic purpura (aTTP) is characterized by the presence of anti-ADAMTS13 autoantibodies (autoAbs). ADAMTS13 can adopt different conformations which can be induced by its substrate VWF or an activating Ab that disrupts the spacer-CUB interaction. In other pathologies, like heparin induced thrombocytopenia, autoAbs recognize cryptic epitopes which become exposed after a conformational change in the antigen.

Aims: To clone anti-ADAMTS13 autoAbs from aTTP patients to identify autoAbs with cryptic epitopes.

Methods: Peripheral blood mononuclear cells (PBMCs) from aTTP patients were single cell sorted using FITC and RPE labelled ADAMTS13 and CD19-APC. Anti-ADAMTS13 specific B cells were identified via ELISA. Variable sequences of the Ab heavy and light chains were determined and cloned onto an IgG_1 or kappa constant backbone respectively. Cloned Abs were expressed, purified and tested in ELISA to determine their specificity for ADAMTS13, their epitope and their capacity to recognize MDTCS, T2C2 or full length ADAMTS13.

Results: After sorting PBMCs from two aTTP patients seven anti-ADAMTS13 positive B cell clones were identified: 2 IgG's (TTP73-1 and TTP1a) and 5 IgM's. The IgG's were cloned and expressed. Both IgG's detected coated ADAMTS13, which shows that they are indeed ADAMTS13 specific. Epitope mapping revealed that Ab TTP73-1 is directed against the cysteine/spacer domain, while Ab TTP1a recognizes the TSP1-2/3 domain of ADAMTS13. Remarkably, the Abs were not able to capture ADAMTS13, MDTCS or T2C2, implying that their epitopes are cryptic. Indeed, direct coating of ADAMTS13, MDTCS or T2C2, which induces a conformational change and exposes cryptic epitopes, did result in binding of both Abs TTP73-1 and TTP1a.

Conclusions: We cloned two anti-ADAMTS13 autoAbs from aTTP patients which recognize cryptic epitopes in ADAMTS13. Identifying which factors induce conformational changes in ADAMTS13 in aTTP patients will allow to elucidate autoAb formation in these patients.

ASY 39.1 | Elevated Plasma Soluble GPVI (sGPVI) Can Aid Detection of Platelet-activating Autoantibodies in Heparin-induced Thrombocytopenia (HIT)

C. Lee[1]; M. Al-Tamimi[2]; M. Berndt[3]; R. Baker[4,5]; R. Andrews[6]; P. Choi[1,7]; A. Cuker[8]; E. Gardiner[1]

[1]John Curtin School of Medical Research, Australian National University, ACRF Department of Cancer Biology and Therapeutics, Canberra, Australia, [2]Hashemite University, Department of Basic Medical Sciences, Zarqa, Jordan, [3]Curtin University, Perth, Australia, [4]Royal Perth Hospital, Department of Haematology, Perth, Australia, [5]Murdoch University, Centre for Thrombosis and Haemophilia, Perth, Australia, [6]Australian Centre for Blood Diseases, Monash University, Melbourne, Australia, [7]The Canberra Hospital, Department of Clinical Haematology, Canberra, Australia, [8]Perelman School of Medicine, University of Pennsylvania, Departments of Medicine and Pathology & Laboratory Medicine, Philadelphia, United States

Background: HIT is caused by platelet-activating antibodies binding an antigenic complex of heparin and platelet factor-4 (PF4). This immune complex engages platelet FcγRIIa, causing platelet activation, aggregation and clearance. Identifying activating (pathological) HIT antibodies is challenging because not all patients with detectable HIT antibody develop HIT. Engagement of FcγRIIa induces metalloproteolytic shedding of the platelet-specific collagen receptor, GPVI, to release soluble GPVI (sGPVI).

Aims: To characterise GPVI shedding upon engagement of FcγRIIa by activating HIT antibodies and assess the utility of sGPVI to identify pathological heparin-PF4 antibodies by prospectively evaluating sGPVI in samples from 310 query HIT patients.

Methods: Donor washed platelets were mixed with plasma from healthy donors, or thrombocytopenic patients and therapeutic or saturating heparin doses. Levels of sGPVI were assessed by enzyme-linked immunosorbent assay (ELISA).

Results: HIT patient plasma induced heparin-dependent metalloproteolytic shedding of GPVI and was blocked by saturating heparin dose or 10 mM EDTA or 10 μg/mL FcγRIIa-blocking antibody, IV.3. Of the 310 query HIT patients, 32 had clinically confirmed HIT. In the prospective cohort, sGPVI levels positively correlated with antibody levels (r=0.131; p=0.021) and sGPVI was significantly elevated (p=0.044) in HIT-positive (heparin-PF4 ELISA and serotonin release assay positive) patients with 4Ts score ≥4. Using a sGPVI level ≥59 ng/mL together with 4Ts ≥4 and positive heparin-PF4 ELISA improved HIT diagnostic specificity from 87% (using only 4Ts and heparin-PF4 ELISA) to 96%, and the overall positive predictive value from 0.48 to 0.76.

Conclusions: Engagement of platelet FcγRIIa by HIT patient plasma releases sGPVI. Considering sGPVI levels in addition to 4Ts score and heparin-PF4 antibody levels improved specificity and overall accuracy of HIT diagnosis. Patient sGPVI levels may help identify a platelet-activating HIT antibody.

ASY 39.2 | Pathogenic Antibodies in Heparin-induced Thrombocytopenia (HIT) Activate Monocytes and Induce Profound Membrane Remodeling

I.A. Andrianova[1]; V. Hayes[2]; R.I. Litvinov[3]; D.B. Cines[4]; M. Poncz[2,5]; J.W. Weisel[3]; L. Rauova[2,5]

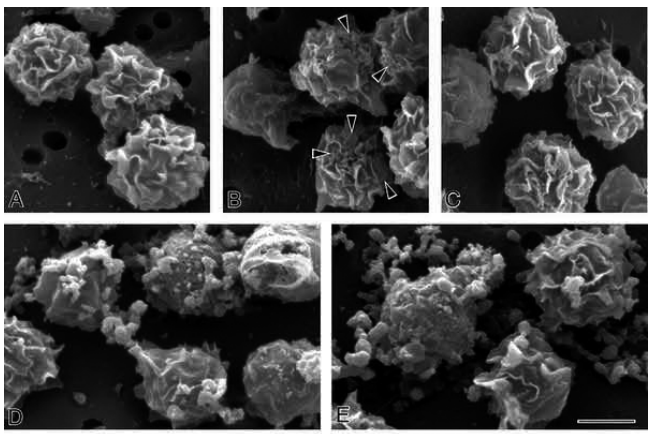
[1]Kazan Federal University, Institute of Fundamental Medicine and Biology, Kazan, Russian Federation, [2]The Children's Hospital of Philadelphia, Pediatrics, Philadelphia, United States, [3]University of Pennsylvania Perelman School of Medicine, Cell and Developmental Biology, Philadelphia, United States, [4]University of Pennsylvania Perelman School of Medicine, Pathology and Laboratory Medicine, Philadelphia, United States, [5]University of Pennsylvania Perelman School of Medicine, Pediatrics, Philadelphia, United States

Background: HIT is an antibody mediated thrombocytopenia and thrombosis. HIT antibodies react with a multimolecular complex of PF4 with cell membrane glycosaminoglycans (GAGs) initiating cell activation. We have shown that monocytes are preferentially targeted and contribute to the prothrombotic state, but the effect of HIT antibodies on cell structure has not been described.

Aims: To study changes in the structure of the monocytes caused by HIT antibodies.

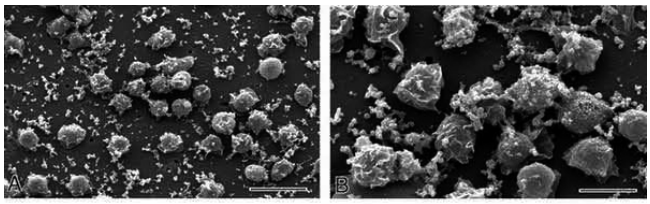
Methods: We studied isolated human and transgenic Fcγ receptor IIA positive (FcγRIIA+) and wild type (wt) (FcγRIIA-) mouse monocytes by scanning electron microscopy, confocal microscopy and flow cytometry to characterize their morphology, function and release of microparticles induced by HIT antibodies.

Results: PF4 binds to monocytes, inducing time-dependent "knobs" that project from the cell surface (average size 148 ± 27nm after 1 hr). Addition of the pathogenic HIT-like monoclonal antibody KKO caused expression of phosphatidylserine and profound remodeling of the cell



Monocyte membrane remodeling in the presence of PF4 and HIT antibodies.
A. Control monocytes - No PF4: few knobs on the cell surface.
B. Monocytes with PF4 - Addition of 100 μg/ml recombinant human PF4 initiates appearance of small knobs (black arrows; average size 148 ± 28 nm).
C. Monocytes with PF4 and RTO show similar morphology as control monocytes.
D, E. Monocytes with PF4 and KKO (50 μg/ml, 60min) dramatically enhanced clustering of PF4/GAGs complexes, forming much larger surface blebs (701 ± 208 nm).
Magnification bar = 5 μm

FIGURE 1 Monocyte membrane remodeling in the presence of PF4 and HIT antibodies



Microparticles released from monocytes.

B. Higher magnification. Magnification bar = 10 μm

FIGURE 2 Microparticles released from monocytes

membrane characterized by loss of membrane ruffles and clustering of PF4/GAG complexes into large surface "blebs" (Fig. 1). These blebs increased in number and size over time (701 ± 208nm, after 1 hr) and were shed as microparticles (average diameter 356 ± 307nm) (Fig. 2). Flow cytometry confirmed these microparticles contained cell membrane lipids and receptors. In contrast, RTO, a monoclonal antibody that blocks PF4 oligomerization and prevents thrombocytopenia/thrombosis in an animal model, inhibited PF4/KKO-induced modification of monocyte surfaces. Comparing monocytes isolated from FcgRIIA+ vs wt mice indicated that bleb formation results from clustering of knobs caused by bivalent HIT antibodies through crosslinking of FcγRIIA's.

Conclusions: Binding of pathogenic HIT antibodies to PF4 antigenic complexes assembled on the monocyte plasma membranes promotes large scale remodeling, activation through FcγRIIA and shedding of procoagulant microparticles, all of which may contribute to thrombosis.

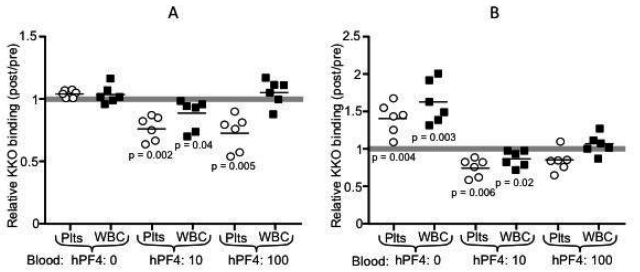
ASY 39.3 | Dynamic Redistribution of Platelet Factor 4 on Vascular and Intravascular Cell Surfaces: Implications for Heparin-induced Thrombocytopenia (HIT)

J. Dai[1,2], V. Hayes[1], I. Johnston[1], K. Golomp[1], G.M. Arepally[3], D.B. Cines[4], M. Poncz[5,6], L. Rauova[1,6]

[1]*The Children's Hospital of Philadelphia, Pediatrics, Philadelphia, United States,* [2]*Shanghai Jiao Tong University School of Medicine Ruijin Hospital, Shanghai Jiaotong University School of Medicine, Laboratory Medicine, Shangai, China,* [3]*Duke University Medical Center, Durham, United States,* [4]*University of Pennsylvania Perelman School of Medicine, Pathology and Laboratory Medicine, Philadelphia, United States,* [5]*The Children's Hospital of Philadelphia, Philadelphia, United States,* [6]*University of Pennsylvania Perelman School of Medicine, Pediatrics, Philadelphia, United States*

Background: HIT is an iatrogenic disorder involving antibodies (Abs) that recognize PF4/heparin complexes, leading to thrombocytopenia and thrombosis. We posit that PF4 released from platelets redistributes along the surface of leukocyte and endothelial glycosaminoglycans where it becomes a target for pathogenic Abs leading to a systemic hypercoagulable state.

Aims: To assess the redistribution of PF4 released from activated platelets among various vascular and intravascular cells.



Effect of endothelial cells on binding of PF4 to platelets and total WBCs.
Whole PF4^{null} murine blood was flowed through a channel coated with HUVECs either (A) previously unexposed to PF4 or (B) saturated with 100 μg/ml of recombinant hPF4. In both, relative surface-bound PF4 as estimated by KKO binding after traversing the channel was compared to the level prior to entering the channel. The cells in whole blood had been exposed to 0, 10 or 100 μg/ml of recombinant PF4 as indicated. The mean is shown for each study as a horizontal line. N = 6 separate studies per arm.

FIGURE 1 Effect of endothelial cells on binding of PF4 to platelets and total WBCs

Methods: Surface-bound PF4 was analyzed by flow cytometry using labeled HIT-like monoclonal Ab (MoAb) KKO, anti-PF4 MoAb RTO, and polyclonal anti-PF4 Ab. Intravital confocal imaging of the liver and a microfluidic model were used to evaluate PF4-binding to endothelial cells.

Results: PF4 released from platelets activated in whole blood formed HIT antigenic complexes predominantly on monocytes. After inducing HIT in transgenic mice overexpressing human PF4, there was a >80-fold increase in HIT Ab binding to monocytes compared with a < 4-fold increase on platelets ($p < 0.008$). This increase in HIT Ab targeting was associated with ~4 hrs of monocytopenia. Binding of PF4 to platelets correlated inversely with total WBCs added. Depletion of monocytes increased binding of PF4 to platelets 2-3 fold. Intravital confocal imaging showed PF4-mediated binding of KKO to hepatic sinusoid endothelium. When whole blood was perfused through endothelial-lined microfluidic channels, PF4 was displaced preferentially from platelets to the endothelium relative to loss of PF4 from WBCs (Fig. 1). Hematoporphyrin mediated endothelial injury enhanced this redistribution of platelet PF4.

Conclusions: Our studies support a model in which PF4 released from activated platelets binds to diverse intravascular and vascular cell surfaces that become targets of HIT antibody and potential sites of prothrombotic activity. Methods that shift PF4 binding away from monocytes and endothelium may reduce the risk of thrombosis in patients with HIT.

ASY 39.4 | Neutrophils and Released Neutrophil Extracellular Traps (NETs) Contribute to the Prothrombotic State in HIT

K. Gollomp[1], V. Hayes[1], I. Johnston[2], G. Zhao[1], L. Rauova[1], M. Poncz[1]

[1]*The Children's Hospital of Philadelphia, Hematology, Philadelphia, United States,* [2]*The University of Pennsylvania, Philadelphia, United States*

Background: HIT is a prothrombotic thrombocytopenic disorder that occurs in heparin-exposed patients due to antibodies (Abs) to PF4/

heparin complexes. Although the high risk of thrombosis in HIT has been attributed to platelet (Plt) activation, recent data suggests that other cells, including neutrophils (PMNs), may contribute to clot formation. We studied the role of PMNs and NETs, extruded PMN chromatin that promotes clot formation, in this disorder.

Aims: We used in vitro and in vivo methods to study if HIT Ab exposure leads to enhanced PMN adhesion to endothelial cells (EC) and increased PMN thrombi infiltration. We also explored if inhibition of NET formation can attenuate these effects.

Methods: PMN exposed to HIT Abs were flowed through human endothelial umbilical vein cell (HUVECs)-lined microfluidic channels and EC adhesion was quantified. Peptidyl arginine deiminase (PAD) 4, which citrullinates histones and is an essential NET mediator, was disrupted in human PF4/FcgRIIa mice that develop HIT after infusion of a HIT Ab. Clot formation following cremaster venule laser injury was studied in$PAD4^{+/+}$ and $PAD4^{-/-}$ HIT mice. Plt and PMN accumulation within thrombi was assessed.

Results: HIT Ab exposure led to increased PMN adhesion in HUVEC-lined microfluidic channels (Figs. 1A and B). Enhanced EC adhesion (Fig. 1C) and PMN thrombus infiltration in HIT mice was observed following HIT induction (Fig. 2A). Plt and PMN accumulation was decreased in $PAD4^{-/-}$ HIT mice relative to $PAD4^{+/+}$ HIT mice (Fig. 2B-D).

Conclusions: HIT Ab-exposed PMN are recruited to sites of vascular injury where they contribute to plt adhesion and thrombus growth. These findings are less pronounced in $PAD4^{-/-}$ mice demonstrating that NETs contribute to the prothrombotic state in HIT. We propose that inhibition of PMN recruitment and/or NET release should be explored as strategies in the treatment of HIT and may be relevant to other immune-based prothrombotic disorders.

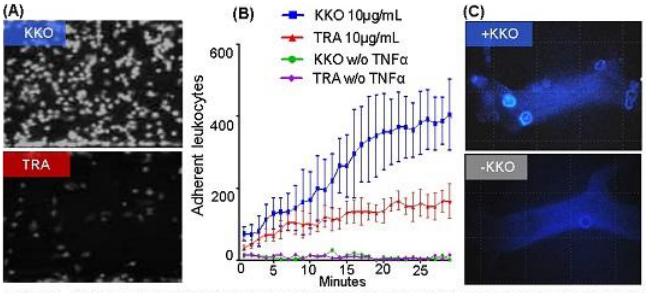


Figure 1. KKO promotes neutrophil adhesion to inflamed ECs. Microfluidic channels coated with 50µg/ml fibronectin. HUVECs infused through channels, grown to confluence, ± incubated with TNFα 1 ng/ml x 6 hrs. Whole blood labeled with calcein AM(34) flowed through channels after exposure to KKO or its isotype control, TRA. Leukocytes counted using imaging software FIJI, with particle-size exclusion. **(A)** Representative fields from studies showing adherent neutrophils. **(B)** Temporal profile of adherent neutrophils under conditions noted in graph. Mean ± 1 SEM is shown (N = 3 per arm). P = <0.0001 for KKO vs. TRA on TNFα-treated ECs using a two-tailed Student T test. **(C)** Representative image of neutrophil-EC adhesion in cremaster venule of HIT mouse before and 30 minutes after 1µg/g KKO injection.

FIGURE 1 KKO promotes neutrophil adhesion to inflamed endothelial cells

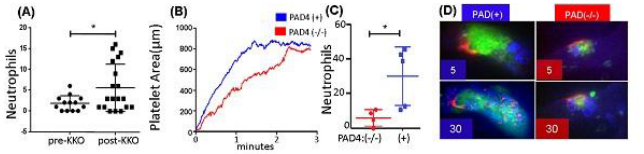

Figure 2. Cremaster injury studies in PAD4-/- HIT mice. Cremaster venule injuries were induced with a nitrogen laser. Platelets were detected using $Alexa^{488}$ anti-CD41 Ab and neutrophils using $Alexa^{647}$ anti-ly6G Fabs. Confocal videos were done. **(A)** Neutrophils incorporated in thrombi 5 minutes following laser injury were counted in injuries made before and after HIT induction. 13 venous injuries made prior to KKO injection were compared to 19 injures made after KKO injection. * P = 0.03 comparing the two arm by two-sided Student T test. **(B)** Platelet accumulation measured in 4 injuries made in 2 $PAD4^{-/-}$ mice compared to 6 injuries made in in 3 $PAD4^{+/+}$ mice. **(C).** After HIT induction, a significantly smaller number of neutrophils infiltrated venule thrombi 30 minutes following laser injury in $PAD4^{-/-}$ mice compared to $PAD4^{+/+}$ controls. ** P = 0.03 comparing the two arm by two-sided Student T test. **(D)** Representative images of injured cremaster venule in KKO-treated $PAD4^{+/+}$ mouse compared to $PAD4^{-/-}$ sibling 5 and 30 minutes following laser injury, demonstrating the typical extent of neutrophil accumulation. Red = KKO, green = platelets, blue = neutrophils.

FIGURE 2 Cremaster injury studies in PAD4-/- HIT mice

TRANSFUSION & BIOTHERAPEUTICS

ASY 11.1 | Synthesis of the First GMP Grade Biotin 3-sulfo N-Hydroxysuccimide Is now Available to Label Blood Cells Intended for Human Transfusion Studies, but not Exclusively

G. Kemperman[1], J. Basten[1], M.-C. Viaud-Massuard[2], C. Ravanat[3], P. Ohlmann[4]

[1]*ChemConnection BV, Oss, The Netherlands*, [2]*Universitersité de Tours, UFR des Sciences Pharmaceutiques, Tours, France*, [3]*EFS Grand Est, BPPS UMR-S 949, FMTS, Strasbourg, France*, [4]*Proteomic & Biochemistry Consulting, Centre d'Affaires Your Office, Lingolsheim, France*

Background: Platelet or red blood cell (RBC) survival and recovery is currently measured with radioactive reference tracers such as ^{111}In or ^{51}Cr. However due to regulatory obstacles such radiolabeling studies are only carried out in designated institutes. We propose an alternative tracer (Biotin-Sulfo-NHS) which could be used in human. A good comparison between the survival of RBC labeled with either a non GMP-biotin or ^{51}Cr was demonstrated in a clinical trial (Mock, 2014). The benefits are:

1) non-radioactive compound,
2) safe,
3) lower cost,
4) limited device for tracking labeled cells by flow cytometry (FC).

Aims: To develop a non-radioactive and safe cell tracker, Biotin-Sulfo-NHS, manufactured in accordance with Q7 GMP Guidance for API.

Methods: Synthesis of GMP-Biotin-Sulfo-NHS was performed by mixing *N*-hydoxysulfosuccinimid in anhydrous *DMF* and diclohexylcarbodiimide during 24h under argon. All chemical steps were performed according to the EudraLex guidelines: *The Rules Governing Medicinal Products in the European Union Volume 4; GMP; Medicinal Products for Human and Veterinary Use, Part II: Basic Requirements for API used as Starting Materials.*The labeling efficacy of RBC or platelets with this GMP-Biotin was compared to a non GMP-biotin, by FC.

Results: Mean Fluorescence Intensities (MFI) were obtained with washed RBC, labeled with 2 densities of either GMP- or non GMP-biotin, overlaid. Biotin (µg/mL): 0 (MFI 0.5 vs 0.5), 2 (MFI 3 vs 3), 20 (MFI 41 vs 32). Same results were obtained with washed platelets: 0 (MFI 0.4 vs 0.4), 4 (MFI 12 vs 11), 18 (MFI 48 vs 52). No microparticles were detected excluding cell damage.

Conclusions: The new GMP-Biotin was efficient to label RBC and platelets *ex vivo*. It will increase the safety and contribute to overcome the need for non-radioactive methods within the framework of studies in human. Its field of application is extended: transfusion, oncology -hematology, chronic disease (anemia, diabetes).

ASY 11.2 | French Lyophilized Plasma versus Fresh Frozen Plasma for the Initial Management of Trauma Induced Coagulopathy: A Randomized Open-label Trial

D. Garrigue-Huet[1], A. Godier[2,3], A. Glacet[1], J. Labreuche[4], E. Kipnis[1], E. Resch[5], P. Goldstein[6], A. Bauters[7], B. Tavernier[8], A. Sailliol[9], S. Susen[10,11]

[1]Lille University Hospital, Department of Anesthesiology and Trauma Center, Lille, France, [2]Inserm UMR_S 1140, Université Paris Descartes, Sorbonne Paris Cité, Paris, France, [3]Fondation Ophtalmologique Adolphe de Rothschild, Paris, France, [4]Lille University Hospital, Department of Biostatistics, Lille, France, [5]Etablissement Français du Sang (EFS) Hauts de France, Lille, France, [6]Lille University Hospital, Trauma Centre and Emergency, Lille, France, [7]Institut d'Hématologie, Hôpital Cardiologique, University of Lille, Lille, France, [8]Department of Anesthesiology and Intensive Care, Lille, France, [9]Centre de Transfusion Sanguine des Armées, Clamart, France, [10]Institut d'Hématologie, Hôpital Cardiologique, University of Lille, Haematology Department, Lille, France, [11]Inserm UMR 1011, Lille, France

Background: Hemorrhage is the major cause of preventable death in trauma patients. Guidelines recommend to begin haemostatic resuscitation immediately, including plasma transfusion.

Aims: We aimed to investigate if French Lyophilized Plasma (FLyP) was more effective than FFP for the initial management of the trauma-induced coagulopathy (TIC).

Methods: In an open-label, phase 3, randomised trial, we enrolled trauma patients aged 18 years or older needing an emergency pack of 4 plasma units within 6 hours of injury. We randomly assigned patients in a 1:1ratio to receive 4FLyP or 4FFP units. The primary endpoint was the fibrinogen concentration at 45 minutes after randomisation. Secondary outcomes included changes in hemostatic parameters, intervals transfusion, hemostatic product requirement and in-hospital mortality at 30 days. NCT0275015.

Results: 48 patients were randomised (24/group); one patient (FLyP group) discontinued intervention before any blood sampling and was excluded for primary efficacy analysis. FLyP reduced the time from randomisation to transfusion of first plasma unit ($p< 0.0001$). Compared to FFP, FLyP achieved a higher fibrinogen concentration 45 minutes after randomisation (baseline-adjusted mean difference, 0.29 g/L; 95% CI, 0.08-0.49). Similarly, a greater improvement in Prothrombin Time ratio, Factors V and II with FLyP were found at 45 minutes. The between-group differences in coagulations parameters remained significant at 6 hours but not after 12 and 24 hours. FLyP reduced the need of fibrinogen concentrates [J1] but not blood product requirement. 30-day in-hospital mortality rate was 22% in FLyP and 29% in FFP (ns).

Conclusions: FLyP was more effective than FFP for the initial management of trauma patients as increase in fibrinogen concentration and TIC improvement were faster and greater. FLyP represents an attractive option for trauma management, especially when facing logistical issues including combat casualty care and terrorism.

ASY 11.3 | The Neutralization of CD40/CD40L Complex Inhibits TRALI Development in a Mouse Model Induced through Lipopolysaccharide and Anti-MHC I mAb Injection

S. Tariket[1,2], C.-A. Arthaud[2], A. Meneveaux[2], H. Hamzeh-Cognasse[3], O. Garraud[3,4], F. Cognasse[2,3]

[1]University of Lyon, GIMAP-EA3064, GIMAP-EA3064, Saint-Etienne, France, [2]French Blood Establishment (EFS) Rhône - Alpes -Auvergne, Scientific Dpt, Saint-Etienne, France, [3]University of Lyon, GIMAP-EA3064, Saint-Etienne, France, GIMAP-EA3064, Saint-Etienne, France, [4]INTS - Institut National de la Transfusion Sanguine, International Affairs, Paris, France

Background: Even though used systematically with leukocyte reduction, platelet transfusions still cause adverse reactions in the recipient. They include TRALI (Transfusion-Related Acute Lung Injury), respiratory distress that occurs within 6 hours of the transfusion. The pathophysiology of this transfusion complication brings complex cellular communication into play which depends on a number of signalling channels. The role, particularly inflammatory, played by blood platelets in TRALI pathophysiology is evident but still under debate. Blood platelets play a major role in inflammation, particularly via the immunomodulator complex CD40/CD40L (sCD40L).

Aims: In this work, we studied the specific function of the CD40/CD40L (sCD40L) complex in regulating TRALI in an inflammatory context.

Methods: We developed a mouse model of immune TRALI, triggered by a double injection of LPS and an anti-MHC I antibody. A neutralizing anti-CD40L antibody was injected 30 minutes before inducing TRALI. The characteristics of TRALI we studied were a decrease in body temperature, pulmonary lesions, infiltration into the alveolar space and death. Blood counts of the target cells, and CD41 and Ly6G markers on lung sections enabled an evaluation of pulmonary infiltration. Cellular communication was measured from a cytometric study. Lastly, the inflammatory state of the mice and the cellular phenotype of the neutrophils were assessed.

Results: Inhibiting this immunomodulator complex significantly reduces the development of pulmonary oedema. The neutralizing antibody targets mainly the three-way cellular communication normally established during TRALI between the endothelial cells, the neutrophils and the platelets, and thus blocks the cell migration essential for the pathology to develop.

Conclusions: This target protein appears to play a major role in preventing the induction of TRALI. Improving the conditions in which the platelet concentrates are prepared and stored would thus help to control the risks of non-immune TRALI.

ASY 11.4 | Controlling Hydrophobicity to Minimize Thrombogenic Risk on Medical Devices in an Arterial Environment

D. Bark Jr.

Colorado State University, Mechanical Engineering, Fort Collins, United States

Background: Medical devices placed in the arterial circulation are at high risk for thrombosis associated with shear induced platelet activation and protein adsorption followed by platelet adhesion. Superhydrophobic surfaces and hydrophilic surface coatings have both been proposed for use on medical devices to prevent thrombosis from occurring by passivating the surface but none have been implemented commercially due to drawbacks.

Aims: To isolate the mechanism(s) in superhydrophobic surfaces that mitigates thrombus risk, while reproducing the characteristics on a hydrophilic surface to mitigate high affinity hydrophobic plasma protein binding.

Methods: We analyzed the potential for "slip" between the surface and blood through a computational physics model to determine the potential role in reducing shear stress experienced by blood, while also reducing the potential for cells to adhere to the surface. We further develop coatings in a polydimethylsiloxane (PDMS) microfluidic channel consisting of a sharp stenosis that exhibits characteristics of a high shear gradient, a region of high shear stress, and a region of flow stagnation, all of which are proposed to promote thrombosis. We evaluate slip in the channel and quantify thrombus growth on the surface relative to bare PDMS.

Results: Surface slip in the channel does reduce shear stress. Through computations and experiments, we further show that the coated surface significantly reduces the potential for platelet adhesion and activation. Surface feature size and "slipperiness" of the surface both played a significant role in the platelet response.

Conclusions: Hydrophobic surfaces are prone to protein and then cell adhesion, while hydrophilic are not. Counterintuitively, superhydrophobic surfaces are resistant to adhesion and thrombus formation. We show potential reasons why these surfaces can mitigate thrombus formation and propose new potential coatings for arterial-based medical devices.

ASY 24.1 | Sequential Mesenchymal Stromal Cell Treatment of Thrombocytopenia after Allogeneic Stem Cell Transplant: Results from a Multicenter Phase II Trial

A. Veiga[1], A. Redondo[1], E. Villarón[1], J.M. Bastida[1], M. López-Parra[1], O. López-Villar[1], N. Arratibel[1], M. Baile[1], F. López-Cadenas[1], E. Pérez[1], M. Cabrero[1], L. López-Corral[1], L. Vázquez[1], J.A. Pérez-Simón[2], F. Prósper[3], M.D. Caballero[1], M.C. Del Cañizo[1], J.R. González-Porras[1], F. Sánchez-Guijo[1]

[1]*IBSAL-Hospital Universidad de Salamanca, Hematology Department, Salamanca, Spain,* [2]*IBIS-Hospital Virgen del Rocio, Hematology Department, Sevilla, Spain,* [3]*Clínica Universidad de Navarra, Hematology Department, Pamplona, Spain*

Background: Post-transplant thrombocytopenia is a complex complication with remarkable morbidity and mortality for which there is no effective treatment in refractory cases. Mesenchymal stromal cells (MSC) are a potentially attractive therapeutic tool because of their immunomodulatory properties and regulation of the bone marrow (BM) niche.

Aims:

a) To analyze the safety and feasibility of the sequential MSC infusion.
b) To analyze the effectiveness in terms of platelet recovery and length of the response.

Methods: Eleven patients with platelets count (P)< $50x10^9$/L and complete BM chimerism were treated within a phase II clinical trial. MSC were isolated and expanded from 50 mL of BM from third-party healthy donors. Partial and complete response (PR and CR) at day 90, was defined by achieve P=$50\text{-}100x10^9$/L or >$100x10^9$/L, respectively; adverse effects (AE) and survival was analyzed after infusion 4 doses of $1x10^6$ MSC/kg on days 1, 4, 11 and 18.

Results: Baseline patients' characteristics are shown in Table 1. MSC infusion was performed after a median of 86 days from allo-transplant (range 35-633). There were no AE related to infusion. Within the first 90 days, 9 out of 11 patients (82%) responded to cellular therapy and 7 of them achieved CR. On day 90, six patients maintained CR and one PR, two patients had no response and two were non-evaluable. At the last follow-up, with a median of 202 days (range 76-820), 7 patients (CR=3, PR=3) maintained the response, 1 patient achieved CR with an alternative treatment and 4 patients deceased due to the progression of disease (n=1) or sepsis (n=3). Patients that achieve response to MSC therapy seemed to have an advantage in terms of long-term survival.

TABLE 1 Baseline patients characteristics

AGE	Median 49 years (Range, 20-66 years)
SEX	Male = 9; Female = 2
HEMATOLOGICAL DISEASE	Acute Myeloid Leukemia = 7; Non-Hodgkin Lymphoma = 3; Acute Lymphoblastic Leukemia = 1
DONOR	Unrelated = 3; Sibling = 3; Cord Blood = 1
CONDITIONING REGIMEN	Reduced intensity = 6; Myeloablative = 5
PRIOR TREATMENT	Median 1 line (Range, 1-3)
MEDIAN PLATELET COUNT BEFORE INFUSION MSC	22x103/mm3 (Range, 12-47x103/mm3)
MEDIAN PLATELET COUNT AT 90 DAY POST INFUSION MSC	106.000 Range (5-170x103/mm3)
CONCOMITANT GVHD	8 out of 11 patients (73%)

Conclusions: Treatment of peripheral thrombocytopenia with MSC is feasible, has no adverse effects and is potentially useful in most patients. Achieving either CR or PR to MSC therapy seems to favor long-term survival for those patients.

Funding: Clinical trial was funded by the EC11-389 grant from Ministerio de Sanidad, Spain.

ASY 24.2 | Optimization of in vitro Megakaryocyte and Platelet Production by Inducible Overexpression of Supporting Factors

K. Cullmann[1], K. Blokland[1], A. Mucci[2], F. Schenk[1], K. Boller[3], S. Kohlscheen[1], L. Latorre[1], T. Moritz[2], N. Heinz[1,4], U. Modlich[1]

[1]*Paul Ehlrich Institute, LOEWE Centre of Cell and Gene Therapy Frankfurt, LOEWE RG for Gene Modification in Stem Cells, Langen, Germany,* [2]*Hannover Medical School, Institute of Experimental Hematology, RG Reprogramming and Gene Therapy, Hannover, Germany,* [3]*Paul Ehlrich Institute, Div. Immunology, Dep. Morphology, Langen, Germany,* [4]*Eufets GmbH, Idar-Oberstein, Germany*

Background: Induced pluripotent stem cells (iPSC) are of great interest for generation of patient-specific megakaryocytes (MK) and platelets for cellular therapies.

Aims: Although differentiation of platelets from iPS cells is possible, the recovered numbers are low. To optimize the process we focus on the overexpression of supporting factors like transcription factors (TF) e.g. Gata-1 and Nfe2. To avoid off target effects in pluripotent cells and during differentiation TF expression must be time-controlled. We therefore established a tet-inducible system in murine iPSC based on retroviral vectors. To overcome problems caused by vector silencing during differentiation, the reverse tetracycline-controlled transactivator M2 (rtTA M2) is expressed from the ROSA26 safe harbor locus.

Methods: MKs and platelets were generated via embryoid body formation. After dissociation and co-cultivation on OP-9 feeder cells with thrombopoietin, cytomorphological analysis and cell surface phenotype identified culture-derived MK/ proplatelets.

Results: Overexpression of Gata-1 resulted in expandable megakaryocytes which were almost 20% double positive for CD41/ CD42d and maintained their phenotype for >6 weeks until termination. Similarly, Nfe2 overexpression supported in vitro MK development, however, the expansion capacity was lower. More than 70% of the platelets from Gata-1 overexpressing MK were positive for CD41, hereof almost 25% were double-positive for CD41/CD42d after 6 weeks. To modify human iPSC, Tet-inducible all-in-one retroviral vectors were developed containing different sized chromatin opening elements for prevention of vector silencing. Repeated induction/repression by doxycycline was most faithful when using a 670bp element of the CBX3 5‘ region/gene, which also showed the highest fold-induction and strongest expression in human iPSC.

Conclusions: Inducible Gata-1 and NFe2 expression by retroviral modification of iPSC improves in vitro MK and platelets production.

ASY 24.3 | Endothelial and Cancer Cell Gene Silencing by Platelet-vehiculated siRNAs

M. Malvestiti, G. Manni, A. Marturano, L. Bury, P. Gresele

University of Perugia, Department of Medicine - Section of Internal and Cardiovascular Medicine, Perugia, Italy

Background: Platelets interact actively with normal and pathologic cells in the circulation. In particular, platelets and platelet-derived-microparticles (PMP) release some of their miRNAs to endothelial cells. Short interfering RNAs (siRNAs) are a novel class of drugs that downregulate the expression of a target gene by degrading its relative mRNA. A major limitation of siRNAs therapy is their degradation in blood and insufficient achievement of target cells. We have developed a novel method to transfect therapeutically-designed siRNAs into platelets.

Aims: To assess whether coincubation with siRNA-transfected platelets can silence an endothelial-cell or cancer-cell specific gene.

Methods: Platelets were transfected with a fluorescent TYE563-labeled-siRNA and transfection efficiency was assessed by flow-cytometry and confocal microscopy. Fluorescent siRNA-transfected platelets were coincubated with human umbilical vein endothelial cells (HUVEC) or HeLa cells (cervical tumor) to assess transcellular siRNA transfer. Moreover siRNA-HPRT transfected platelets were coincubated with HUVEC and HeLa to assess gene silencing efficacy by measuring HPRT mRNA by Real-Time PCR and HPRT protein by Western Blotting.

Results: Around 90% of platelets were transfected with fluorescent siRNA. TYE563-labeled-siRNA was detected in HUVECs and in HeLa cells after co-incubation with siRNA-transfected platelets. Coincubation with platelets transfected with siRNA-HPRT determined a significant downregulation in target cells of HPRT mRNA (-57%±11% in HUVEC and -55%±4% in HeLa) and protein (-43%±18% in HUVEC and -55% in HeLa).

Conclusions: siRNA-transfected platelets deliver therapeutically-designed siRNA to HUVEC and HeLa silencing the target gene. The ability of platelets to deliver active siRNA to endothelial and tumor cells can be used to downregulate pathogenic gene expression in vivo. Using platelets as carriers is a potentially new original approach to RNAi therapy.

ASY 24.4 | Targeting Peripheral Blood Mononuclear Cells to Activated Platelets Preserves Cardiac Function after Ischemia-reperfusion Injury

M. Ziegler[1], X. Wang[1], B. Lim[1], E. Leitner[1], V. Ching[1], K. Alt[2], H. Kiriazis[1], C.E. Hagemeyer[2], I. Ahrens[1], K. Peter[1]

[1]*Baker Heart and Diabetes Institute, Melbourne, Australia,* [2]*Australian Centre for Blood Diseases, Monash University, Melbourne, Australia*

Background: One of the major hurdles and potential reason of failure of intravenous regenerative cell therapy is a low homing efficacy to the infarcted myocardium post MI.

Aims: Developing a highly specific anchor to guide cells to the ischemic myocardium and thus minimize cardiac remodeling/injury and restore cardiac function after ischemia and successful reperfusion.

Methods: A bispecific tandem single-chain antibody (scFv) that binds with high affinity and specificity to activated platelets via the GPIIb/IIIa receptor and to peripheral blood mononuclear cells (PBMC) via the Sca-1 receptor was engineered and characterized. The tandem-scFv was tested in a mouse model of ischemia-reperfusion (IR) injury by LAD ligation for 60 min. Fluorescence (IVIS) imaging, cell infiltration studies, echocardiographic and histological analyses were performed.

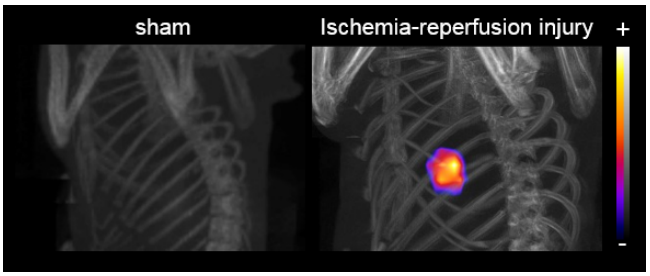

FIGURE 1 PET/CT images show accumulation of activated platelets post IR injury

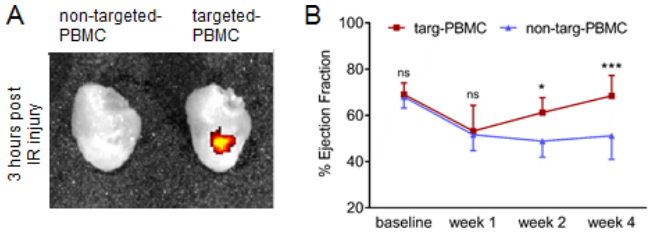

FIGURE 2 A) IVIS image shows enhanced delivery of targeted-PBMCs post IR injury. B) Treatment with Targ-PBMC preserves cardiac function post IR injury

Results: Dynamic flow assays applying physiological shear stress showed strong binding of tandem-scFv pre-incubated cells to activated platelets. After IR injury, a PET/CT scan using a platelet specific radiotracer showed abundant accumulation of activated platelets in the post-ischemic myocardium and thus activated platelets represent an ideal target to redirect cells.

Systemic delivery of tandem-scFv targeted-PBMCs led to successful cell delivery to the infarcted myocardium followed by a significant decrease in infiltrating inflammatory cells. Homing of targeted-PBMCs ultimately decreased necrosis (7.2±3.3 vs. 11.9±2.1%, $p< 0.01$), increased capillary density (929±148 vs. 544±103 capillaries, $p< 0.0001$), and most importantly nearly completely restored cardiac function 4 weeks post IR injury (68.3±5.3 baseline vs. 68.4±8.8 targ-PBMC vs. 51.1±10.2 %EF control, $p< 0.001$).

Conclusions: Targeting of Sca-1$^+$-PBMCs to activated platelets allows effective intravenous delivery of cells to the infarcted myocardium thereby preventing IR injury and loss of cardiac function. Overall, activated-platelet targeting of PBMCs represents a novel and promising approach for cell therapy after MI.

VASCULAR BIOLOGY & ANGIOGENESIS

ASY 09.1 | Thrombin-reduced miR-27b Attenuates Platelet Angiogenic Activities via Enhancing Platelet de Novo Synthesis of Anti-angiogenic Thrombospondin-1

X. Miao[1], M.F.-U. Rahman[1], L. Jiang[1,2], S. Tan[1], H. Xie[3,4], W.-O. Lui[3], N. Li[1]

[1]Karolinska Institutet, Department of Medicine-Solna, Clinical Pharmacology, Stockholm, Sweden, [2]Ningbo University School of Medicine, Department of Pathology, Zhejiang Provincial Key Laboratory of Pathophysiology, Ningbo, China, [3]Karolinska Institutet, Department of Oncology-Pathology, Cancer Center Karolinska, Stockholm, Sweden, [4]Tianjin Medical University, School of Basic Medical Sciences, Tianjing, China

Background: Platelets can synthesize proteins upon activation. Platelets contain microRNAs (miRNA) and a functional miRNA effector machinery. It is, however, unclear if platelet miRNAs can regulate protein synthesis of platelets.

Aims: To investigate if and how platelet miRNAs regulate de novo syntheses of angiogenic factors.

Methods: Platelet miRNA profiling was performed using an oligonucleotide microarray allowing detection of both mature and precursor miRNAs. Transfection of Meg-01 cells and platelets were carried out using specifically developed techniques for these transfection-resistant cells. Impact of miRNA intervention on platelet angiogenic activities was assessed by an endothelial tube formation assay.

Results: Microarray-based miRNA profiling showed that thrombin stimulation down- or up-regulated a number of platelet miRNAs, whilst thrombin consistently decreased Ago2-associated miRNAs. Among those altered miRNAs, miR-27b was down-regulated in both the total and Ago2-immunoprecipitated miRNA profiles of platelets. Using western blotting assays, we showed that thrombin stimulation induced platelet de novo synthesis of thrombospondin-1 (TSP-1), and that the level of TSP-1 content reached 3-fold higher than that before thrombin stimulation. With either platelet precursor megakaryocyte cell line MEG-01 cells or platelets, we showed that transfection of miR-27b mimic, but not the negative control of miRNA mimic, markedly reduced TSP-1 protein levels, implying that miR-27b inhibits, or reduced miR-27b can enhance TSP-1 synthesis. Notably, reduced TSP-1 synthesis by miR-27b overexpression potentiated platelet-enhanced endothelial tube formation.

Conclusions: Thrombin stimulation reduces platelet miR-27b levels, and evokes platelet de novo synthesis of TSP-1. Elevation of miR-27b by transfection inhibits platelet TSP-1 de novo synthesis, and enhances platelet angiogenic activities, indicating that platelet activation-reduced miR-27 is a novel regulatory mechanism of platelet angiogenic activity.

ASY 09.2 | Human Endothelial Cells Infected with Staphylococcus aureus Leads to an Up-regulation of miR-330, Resulting in Loss of Barrier Integrity in an ex vivo Model of Sepsis

R.L. Watkin[1], O. Piskereva[2], S. Das[2], S. Madden[3], R. Stallings[2], S.W. Kerrigan[1]

[1]Royal College of Surgeons in Ireland, Cardiovascular Research Group, Dublin, Ireland, [2]Royal College of Surgeons in Ireland, Cancer Genetics Research Group, Dublin, Ireland, [3]Royal College of Surgeons in Ireland, Dublin, Ireland

Background: Sepsis is one of the major causes of mortality in critically ill patients and is commonly caused by *Staphylococcus aureus*. Typical characteristics of sepsis are oedema and swelling due to excessive

vascular leakage, caused by endothelium degradation. However the nature of the signals leading to vascular leakage is currently unknown and is often difficult to control pharmacologically. MicroRNA are short non-coding RNA that control many cellular processes. Their dysregulation is often linked to disease.

Aims: This study aims to investigate if endothelial miRNA are dysregulated following infection and if this contributes to sustained and excessive responses in sepsis.

Methods: Human endothelial cells, sheared at physiological rates, were infected with *S. aureus* and resulting changes in miRNA expression analysed by TaqMan® Arrays (RQ=2-ΔΔCt). Whole genome sequencing and bioinformatics uncovered potential miRNA-mRNA interactions linked to infection with effects on endothelial function determined by mirmimetic transfections.

Results: Following *S. aureus* infection, 93 endothelial miRNA were significantly modified, of which 35 were up- and 58 were down-regulated ($p< 0.05$). miR330 was significantly up-regulated and using next generation sequencing and bioinformatics we identified 102 potential targets in the cells ($p< 0.0005$). Of particular interest were key genes responsible for ensuring barrier integrity of the cells. Therefore changes to permeability following infection were investigated. Results suggest that *S. aureus* significantly increases permeability ($p< 0.05$) by reducing expression of a key junctional protein, VE-Cadherin. Consistent with this, transfection of a miR330 mimetic to uninfected cells resulted in an increase in permeability.

Conclusions: We propose that following *S. aureus* infection of human endothelial cells, rapid dysregulation of miRNA occurs contributing to degradation of the endothelial permeable barrier through down-regulation of essential junction barrier proteins such as VE-Cadherin.

ASY 09.3 | Identification of Eight Oestrogen-sensitive miRNAs that Regulate Coagulation Factors, One of which (miR-365a-3p) Inhibits Tissue Factor Expression

J. Tian[1], J. Tay[1,2], Q. Hughes[1,2], J. Tiao[1,2], R. Baker[1,2]

[1]*Western Australian Centre for Thrombosis and Haemostasis, Murdoch University, Perth, Australia,* [2]*Perth Blood Institute, Perth, Australia*

Background: High oestrogen (E_2) levels during pregnancy are associated with an increased risk of venous thrombosis, however, the role of E_2-responsive miRNAs (miRs) binding to the 3'UTR regions of coagulation genes regulating function remains poorly understood. NanoString nCounter® miRNA array analyses identified a number of E_2-responsive miRs in HuH-7 cells that may be involved in regulating haemostasis.

Aims: This study sought to validate the E_2-responsiveness of the candidate miRs and investigate their direct effects on predicted coagulation gene targets.

Methods: Nine significantly E_2-responsive miRs ($p< 0.05$) detected by NanoString nCounter® miRNA array were selected and their putative coagulation gene targets were identified using *in silico* miRNA target prediction tools. E_2 effects on the expression of the candidate miRs and mRNA levels of predicted gene targets were determined by RT-qPCR in HuH-7 cells. The direct interaction between the miRs and the putative miRNA-binding sites in Tissue Factor (*F3*) and Factor VIII (*F8*) were measured via dual luciferase assays. Statistical significance was assessed by Student t-test.

Results: Out of the 9 potential miRs, we confirmed by RT-qPCR E_2 significantly downregulated ($p< 0.05$) 8 miRs, let-7f-5p, miR-26b-5p, miR-98-5p, miR-128-3p, miR-365a-3p, miR-423-5p, miR-455-3p and miR-548aa. We also found E_2 significantly increased ($p< 0.05$) *F3* and *F8* mRNA levels. One miRNA, miR-365a-3p showed a functional miR-365a-3p binding site in the *F3*-3'UTR, whereby deletion of the predicted miR-365a-3p binding site in the *F3*-3'UTR abolished the inhibitory activity, confirming miR-365a-3p direct regulation of *F3* mRNA expression.

Conclusions: We have confirmed 8 miRs that are downregulated by E_2, and that one, miR-365a-3p, inhibits *F3* mRNA expression which could lead to an increase in E_2-driven tissue factor expression. NanoString nCounter® miRNA array analysis is a useful screen for E_2-responsive miRs but positive findings need confirmation by RT-qPCR to determine their significance.

ASY 09.4 | Everolimus Eluting Coronary Stenting Elicits Less Cellular Activation via Altered miRNA Levels in Plasma and Endothelial Cells

Z. Fejes[1], T. Szük[2], Z. Czimmerer[3], S. Póliska[3], E. Balogh[4], V. Jeney[4], I. Édes[2], J. Kappelmayer[1], B. Nagy Jr.[1]

[1]*University of Debrecen, Faculty of Medicine, Department of Laboratory Medicine, Debrecen, Hungary,* [2]*University of Debrecen, Faculty of Medicine, Department of Cardiology, Debrecen, Hungary,* [3]*University of Debrecen, Faculty of Medicine, Department of Biochemistry and Molecular Biology, Genomic Medicine and Bioinformatics Core Facility, Debrecen, Hungary,* [4]*University of Debrecen, Faculty of Medicine, Department of Internal Medicine, Debrecen, Hungary*

Background: We have recently described higher levels of soluble E-selectin and VCAM-1 after bare-metal stenting (BMS, n=28) in contrast to drug-eluting stenting (DES, n=21) in stable angina patients. One fifth of BMS subjects displayed in-stent restenosis (ISR) in the first 6 months, while no individuals with DES suffered from such complication.

Aims: Here we compared plasma miRNA levels of these patients with or without ISR, and the background of some of these miRNA alterations was further analyzed via the evaluation of RNA content of endothelial cells *in vitro*.

Methods: Total RNA was extracted from plasma samples obtained after 1 month of intervention, and a global expression pattern of miRNAs was analyzed by using TaqMan Open Array (ABI) in 3 samples from each study group. UPL-probe based RT-qPCR assay (Roche) was used for validation of selected miRNAs showing at least 2-fold alteration. We investigated the effect of vascular inflammation and that of everolimus on endothelial miRNA and mRNA levels after

stenting using RT-qPCR. For this purpose, cultured human umbilical vein (HUVEC) and coronary artery (HCAEC) endothelial cells (Sigma-Aldrich) were challenged with recombinant TNF-α (100 ng/mL) for 4-24 hours in the presence or absence of externally added everolimus (0.5 μM).

Results: There were 36 significantly decreased (e.g. miR-126, miR-181b) and 21 upregulated

(e.g. miR-185) miRNAs in BMS with ISR (P< 0.01) vs. those BMS without complication and all DES patients. TNF-α enhanced miR-146a, miR-155 and miR-185 expression in endothelial cells indicating the development of inflammatory response and endothelial dysfunction. Decreased miR-424 and miR-181b were found with elevated E-selectin and VCAM-1 mRNA levels by 4 hours. In contrast, everolimus via raising these miRNAs caused significantly (P< 0.01) depressed mRNAs of these adhesion proteins.

Conclusions: Everolimus shows a substantial effect on endothelial cell activation in DES via altering the level of circulating and cellular miRNAs.

ASY 17.1 | Vascular Endothelial Cells Derived from Human PAI-1 Deficient iPS Cells Reveal Physiological Functions of PAI-1 in Angiogenesis

H. Sano[1], M. Otsu[2], Y. Suzuki[1], H. Tanaka[1], K. Nagahashi[3], T. Iwaki[4], N. Kanayama[3], T. Urano[1]

[1]Hamamatsu University School of Medicine, Medical Physiology, Hamamatsu, Japan, [2]University of Tokyo /The Institute of Medical Science, Stem Cell Bank, Tokyo, Japan, [3]Hamamatsu University School of Medicine, Gynecology, Hamamatsu, Japan, [4]Hamamatsu University School of Medicine, Pharmacology, Hamamatsu, Japan

Background: Plasminogen Activator inhibitor-1 (PAI-1), the principle inhibitor of plasminogen activators (PAs), play essential role not only in the regulation of fibrinolysis but other pathophysiological-events including angiogenesis. We have identified two distinct PAI-1 deficient patients having apparent phenotypes of severe bleeding and impaired wound healing.

Aims: In order to investigate the intrinsic function of human PAI-1 in endothelial cells, we have established iPS cells from the patients.

Methods: iPS cells from the patients were generated, and differentiated to endothelial cells. The endothelial cells were isolated by magnetic sorting with anti-VEGFR-2 antibody, and their functions and the related gene expressions were analyzed.

Results:

(1) Endothelial cells derived from PAI-1 iPS cells (PAI-1 iPS-ECs) detached from gelatin-coated dishes easier than control.

(2) PAI-1 iPS-ECs migrated faster in migration assay.

(3) The expression of Dll4 gene, known to be highly expressed in so-called tip cells existing at the angiogenic-edge, was enhanced, and the number of branching in tube formation assay was less in PAI-1 iPS-ECs.

(4) As these results suggested that PAI-1 iPS-ECs acted like mesenchymal cells, we checked the cell response to TGF-beta induced endothelial mesenchymal transition. TGF-beta induced alpha-smooth muscle actin expression more effectively in PAI-1 iPS-ECs.

(5) In in-vitro endothelial sprouting assay, tube-like vascular formation was less mature and tip-like cells were more dominant in PAI-1 iPS-ESs.

Conclusions: Immature vascular sprouting, due to dominance of tip-like cells, seems to be responsible for the impairment in both angiogenesis and wound healing in human PAI-1 deficiency.

ASY 17.2 | Perivascular Progenitor Cells Regulate the Balance between Regeneration vs. Fibrosis via PDGFRa Signalling

M. Reyes Gil[1], N. Ieronimakis[2], J. Duffield[3]

[1]Albert Einstein College of Medicine & Montefiore Medical Center, Pathology, New York, United States, [2]Madigan Army Medical Center, Tacoma, United States, [3]Biogen, Cambridge, United States

Background: PDGFRα is restricted to mesenchymal progenitors that reside in the perivascular tissue of multiple organs. Although the stem cell capacity of vascular and perivascular cells has been extensively studied in numerous models, the cellular and molecular mechanisms responsible for fibrosis are poorly understood.

Aims: Herein we aimed to study the molecular mechanism regulating fibrogenesis of perivascular cells and developed a new antifbrotic treatment to reduce cardiac and skeletal muscle fibrosis.

Methods: We utilized the *Collagen1a1-GFP* transgene and conditional Cre mouse lines to identify cells producing Collagen-I matrix in wild type mice exposed to acute injury or those mutated at the dystrophin gene locus (*mdx*) as a model of Duchenne Muscular Dystrophy (DMD), to study the mechanisms of cardiac and skeletal muscle injury/repair and fibrosis.

Results: Fate mapping experiments indicate that these perivascular progenitors contribute to regeneration whereas in injury they become collagen producing fibroblasts. While in acute injury/repair of muscle and heart, PDGFRα signalling is transiently upregulated during the regenerative phase, in the DMD model and in human DMD it is chronically over-activated. Conditional expression of the constitutively-active PDGFRα D842V mutation in perivascular cells, during injury/repair, hindered the repair phase and instead promoted fibrosis. In DMD, treatment of *mdx* mice with crenolanib, an investigational drug, highly selective PDGFRα tyrosine kinase inhibitor, reduced fibrosis, improved cardiac function, muscle strength and was associated with decreased activity of Src, a downstream effector of PDGFRα signalling.

Conclusions: Transient PDGFRα-activation of perivascular progenitors is required for repair of the injured heart and muscle, but persistent and excessive activation of this pathway directly drives fibrosis and hinders repair. The PDGFRα pathway is a potential new target for treatment of fibrosis in progressive skeletal muscle and cardiac diseases.

ASY 17.3 | Co-injection of Mesenchymal Stem Cells with Endothelial Progenitor Cells Accelerates Muscle Recovery in Hind Limb Ischemia by an Endoglin-dependent Mechanism

E. Rossi[1], C. Goyard[2], A. Cras[3], B. Dizier[1], N. Bacha[2], A. Lokajczyk[1], C.L. Guerin[4], B. Planquette[2], V. Mignon[5], C. Bernabeu[6], O. Sanchez[2], D.M. Smadja[2]

[1]Paris Descartes University - INSERM UMRS 1140, Paris, France, [2]Paris Descartes University - INSERM UMRS 1140, AP-HP Hôpital Européen Georges Pompidou, Paris, France, [3]Paris Descartes University - INSERM UMRS 1140, AP-HP Hôpital Saint Louis, Paris, France, [4]National Cytometry Platform, Department of Infection and Immunity, Luxembourg Institute of Health, Luxembourg, Luxembourg, France, [5]Paris Descartes University, Cellular and Molecular Imaging Facility, Inserm US 25, CNRS UMS 3612, Paris, France, [6]Centro de Investigaciones Biologicas (CIB) - CSIC, Madrid, Spain

Background: Endothelial colony-forming cells (ECFCs) are progenitor cells committed to endothelial lineages that have robust vasculogenic properties. Mesenchymal stem cells (MSCs) have been described to support ECFCs angiogenic process in different kind of matrices.

Aims: MSCs potential interaction with ECFCs in hind limb ischemia (HLI) remains largely unknown. Therefore, we assessed whether co-administration of ECFCs and MSCs can support vasculogenic properties in HLI of nude mice.

Methods: We previously described endoglin as a key adhesion molecule; we thus evaluated its implication in ECFCs/MSCs interaction. We examined the effect of ECFCs+MSCs injection after HLI in athymic nude mice. Immunohistochemistry for human and mouse CD31 and *in situ* hybridization (ISH) for ALU sequence were performed.

Results: Foot perfusion was increased after ECFCs injection in day 7 and was even better 14 days after injection. Co-administration of MSCs significantly increased vessel density and foot perfusion at day 7, although this difference was no longer significant at day 14. Capillary density was enhanced in ECFCs+MSCs mice by analysis of mouse CD31, human CD31 incorporation and ISH detecting human ALU sequence. We then examined injection of ECFCs silenced for endoglin + MSCs and found a decreased vessel density and foot perfusion at 7 and 14 days ($p < 0.001$). Silencing endoglin in ECFC did not block MSC differentiation potential in perivascular cells or other mesenchymal lineages. However, silencing endoglin in ECFC dramatically decreased their adhesive properties on MSCs.

Conclusions: We demonstrate that MSCs in combination with ECFCs accelerate muscle recovery by an endoglin-dependent mechanism. Our data suggest the systematic use of MSC as a means to improve ECFCs engraftment in hind limb ischemia.

ASY 17.4 | Thromboembolic Events in Patients with BCR-ABL1-negative Myeloproliferative Neoplasms Are Not Related to in vitro Endothelial Cells Adhesiveness Nor JAK2-V617F Expression

B.K.L. Duarte[1,2], S. Ospina[1], G.G. Yamaguti-Hayakawa[1], R.C. Saez[1], K.B.B. Pagnano[1], F.F. Costa[1], M.C. Ozelo[1,2]

[1]University of Campinas, INCT do Sangue Hemocentro UNICAMP, Campinas, Brazil, [2]University of Campinas, Department of Internal Medicine, Faculty of Medical Sciences, University of Campinas, FCM UNICAMP, Campinas, Brazil

Background: BCR-ABL1-negative myeloproliferative neoplasms (MPN) are a group of hematological malignancies characterized by the proliferation of mature myeloid cells, a tendency towards acute leukemia transformation and a high risk of venous and arterial thromboembolic events (TEE). They harbor several driving mutations, among which *JAK2*-V617F is the most frequent and is associated with TEE.

Aims: To better understand the role of endothelial cells in the pathogenesis of TEE in patients with *JAK2*-V617F-positive MPN, we analyzed the in vitro adhesive properties of these cells, isolated from these patients with and without a prior history of TEE, as well as from healthy individuals.

Methods: Endothelial colony-forming cells (ECFCs) were isolated from peripheral blood mononuclear cells and seeded on collagen with conditioned media. Red blood cells (RBCs) were obtained after centrifugation of whole blood. The presence of *JAK2*-V617F mutations on ECFCs was assessed by RT-PCR. Adhesion was evaluated after incubation of ECFCs with RBCs with or without TNF-α. Circulating endothelial cells (CEC) were quantified by flow cytometry.

Results: ECFCs were successfully cultured from 7/19 patients (3 with polycythemia vera; 1 with essential thrombocythemia and 3 with primary myelofibrosis), 3 of which have had a TEE. The number of CECs was not associated with the success in isolating ECFCs. However, we observed a difference in the median number of CECs in patients with (0.03 CECs/µl; n=7) and without (0.08 CECs/µl; n=8) a prior TEE ($p=0.09$). We also observed a higher median adhesion of RBCs from healthy individuals with ECFCs isolated from patients with MPN without TEE (31%; n=3) than those with TEE (7.2%; n=4) without TNF-α stimulus ($p=0.0023$). We could not detect a *JAK2*-V617F mutation in the ECFCs from any of the patients.

Conclusions: Our findings do not support an increased adhesive capacity of ECFCs nor the presence of JAK2-mutations in these cells as drivers of thromboembolic events in patients with JAK2-mutated MPN.

ASY 30.1 | Targeting the Angiopoietin-Tie2 Axis to Regulate Microvascular Thrombosis in Sepsis

K. De Ceunynck[1], S.J. Higgins[2], S.A. Chaudhry[1], S.M. Parikh[2], R. Flaumenhaft[1]

[1]*BIDMC/Harvard Medical School, Department of Medicine, Division of Hemostasis and Thrombosis, Boston, United States,* [2]*BIDMC/Harvard Medical School, Department of Medicine, Division of Nephrology and Center for Vascular Biology Research, Boston, United States*

Background: Treatment of disseminated intravascular coagulation (DIC) in the context of sepsis is a therapeutic challenge because patients can present concurrently with thrombosis and bleeding. Inflammation-induced changes in endothelium contribute to systemic activation of coagulation. We hypothesized that DIC is initiated largely by these endothelial changes and that targeting the endothelium could ameliorate thrombosis without causing bleeding.

Aims: To determine whether modulation of the Angiopoietin(Ang)-Tie2 axis can reduce microvascular thrombosis in endotoxemia.

Methods: We monitored laser-induced thrombus formation in cremaster arterioles of TIE2+/- mice and following IP injection of 10 mg/kg LPS in C57B6 mice, infused with an adenovirus expressing Tie2 receptor agonist Ang1 (Ang1Ad) or control adenovirus (CtlAd).

Results: LPS exposure (1-3 hrs) significantly increased platelet and fibrin formation at injury sites to 190% ($p< 0.05$) and 195% ($p< 0.001$) of control, respectively. Platelet function was unaffected in these experiments; however, phosphorylation of endothelial Tie2 was substantially reduced. Evaluation of thrombus formation in TIE2+/- mice (without LPS infusion) showed enhanced fibrin formation at injury sites to 197% ($p< 0.01$) of TIE2+/+ controls. Given that Tie2 deficiency and prothrombotic responses are linked, we assessed whether Tie2 activation could reduce the LPS-induced phenotype. Fibrin formation was significantly attenuated ($p< 0.05$) in endotoxemic mice injected with Ang1Ad compared to CtlAd. In contrast, elevated Ang1 levels did not prolong bleeding times in tail clip assays. Studies using cultured endothelium showed that Ang1 pre-treatment significantly blocked LPS-induced phosphatidylserine and tissue factor expression and inhibited thrombin and FXa generation.

Conclusions: These data suggest that the Ang-Tie2 axis controls clot formation in endotoxemia. Targeting this axis represents a novel approach for reducing thrombotic complications without increasing bleeding risk in sepsis.

ASY 30.2 | AMPK Promotes VEGF-induced Angiogenesis via GFAT1 Inhibition

D. Zibrova[1], F. Vandermoere[2], O. Göransson[3], M. Peggie[4], K.V. Mariño[5], A. Knierim[1], K. Spengler[1], C. Weigert[6,7,8], B. Viollet[9,10,11], N.A. Morrice[12], K. Sakamoto[13], R. Heller[1]

Background: Activation of AMP-activated protein kinase (AMPK) in endothelial cells regulates energy homeostasis, stress protection and angiogenesis, but the underlying mechanisms are incompletely understood. We identified glutamine:fructose-6-phosphate amidotransferase 1 (GFAT1) as an AMPK substrate. GFAT1 is the rate-limiting enzyme in the hexosamine biosynthesis pathway (HBP) and as such controls the modification of proteins by O-linked β-N-acetylglucosamine (O-GlcNAc).

Aims: The aim of this study was to check if AMPK controls O-GlcNAc levels and cellular function via GFAT1 phosphorylation.

Methods: Using phosphoproteomic and biochemical analyses, we identified GFAT1 as AMPK target and studied the functional significance of its regulation by AMPK in primary human endothelial cells with biochemical, pharmacological, genetic and in vitro angiogenesis techniques.

Results: Activation of AMPK in cells by 5-aminoimidazole-4-carboxamide riboside (AICAR) led to GFAT1 phosphorylation at serine 243 and inhibition of its activity. In parallel, reduced O-GlcNAc levels were observed. Vascular endothelial growth factor (VEGF), a major angiogenic stimulus, induced GFAT1 phosphorylation in an AMPK-dependent manner. Inhibition of GFAT1 potentiated VEGF-induced sprouting indicating that GFAT1 acts as negative regulator of angiogenesis. In cells expressing non-phosphorylatable S243A-GFAT1, VEGF-induced sprouting was reduced compared to cells expressing wild-type GFAT1. These data suggest that VEGF relieves the inhibitory action of GFAT1/HBP on angiogenesis via AMPK-mediated GFAT1 phosphorylation. Activation of GFAT1/HBP by high glucose impaired VEGF-induced sprouting, while GFAT1 inhibition improved sprouting even at high glucose.

Conclusions: Our findings provide novel mechanistic insights into the role of HBP in angiogenesis. They suggest that targeting AMPK in endothelium might help to ameliorate hyperglycaemia-induced vascular dysfunction associated with metabolic disorders.

ASY 30.3 | Endothelial Primary Cilia Coordinate Vascular Regression During Development

A.-C. Vion[1,2,3], A. Klaus[1,3], T. Zheng[1], T. Perovic[1], S. Alt[1], E. Bartels-Klein[1,3], I. Hollfinger[1], M. Bernabeu[4,5], H. Gerhardt[1,3,6]

[1]*Max Delbrück Center for Molecular Medicine, Berlin, Germany,* [2]*BIRAX (the Britain Israel Research and Academic Exchange Partnership), London, United Kingdom,* [3]*Berlin Institute of Health (BIH) and German Center for Cardiovascular Research (DZHK) Partnersite Berlin, Berlin, Germany,* [4]*Centre for Medical Informatics, Usher Institute, The University of Edinburgh, Edinburgh, United Kingdom,* [5]*Centre for Computational Science, Department of Chemistry, University College London, London, United Kingdom,* [6]*Vesalius Research Center, VIB, Vascular Patterning Laboratory, Leuven, Belgium*

Background: The primary cilium plays a major role during embryonic development as a sensor for chemical and mechanical morphogenetic signals. However, its role in endothelial cells during blood vessel formation is essentially unknown. During development, newly-formed blood vessels remodel into mature networks to ensure efficient perfusion of the tissue. This process is based on the divergent migration of endothelial cells to remove superfluous connections, and is driven by blood flow.

Aims: We evaluated the possible role of the primary cilium as a mechanosensor for blood flow during vessel regression.

Methods: We depleted endothelial cells of their primary cilium in vivo using endothelial-specific inducible gene knockout of IFT88 in mice. In vitro, we silenced IFT88 in endothelial cells exposed to different shear stress conditions.

Results: In vivo, knockdown of IFT88 promoted vascular remodeling in the retina, without affecting endothelial cell death or proliferation. Interestingly, we found that the proportion of endothelial cells carrying a primary cilium decreased with the level of shear stress. In vitro, silencing of ITF88 modified the response of endothelial cells to flow. Under low levels of shear stress, cilium-depleted cells polarized (front-rear polarity) better in the direction of flow compared to control cells, while at high levels of shear stress cells polarized better against the direction of flow. In addition, endothelial cells devoid of primary cilia migrated faster than control cells. Finally, BMP signaling is down-regulated in vitro following IFT88 knockdown, suggesting that the effect of the primary cilium on cell polarity could be mediated by BMPs.

Conclusions: In vitro, we found that endothelial cell polarization and migration are enhanced by the loss of the primary cilium. Together with the early vascular regression we observed in the absence of primary cilia in vivo, this could suggest that the primary cilium negatively regulates divergent migration of endothelial cells during vascular remodeling.

ASY 30.4 | Nterm-Phosphatase of Soluble Epoxide Hydrolase (sEH) in the Regulation of Vascular Endothelial Inflammation

E. Suzuki[1], H. Hirosaki[1], M. Tajima[1], M. Kaseda[1], J. Abe[1], N. Matsumoto[1], K. Hasumi[2]

[1]*Tokyo Noko University, Department of Applied Biological Science, Tokyo, Japan,* [2]*TMS Co., Ltd., Tokyo, Japan*

Background: Soluble epoxide hydrolase (sEH) is a homodimeric enzyme consisting of C-terminal epoxide hydrolase (Cterm-EH) and N-terminal lipid phosphate phosphatase (Nterm-phos) domains that allosterically interact with each other. Cterm-EH regulates the activity of bioactive epoxy-fatty acids through hydrolysis to corresponding diol-fatty acids, whereas information about the natural substrate of Nterm-phos is limited, leaving its physiological role unknown. The small molecule SMTP-7 inhibits both of the two activities of sEH and suppresses endothelial inflammation, while contribution of each inhibition remains unknown.

Aims: To investigate the role of Nterm-phos in SMTP-mediated suppression of endothelial inflammation and to identify endogenous substrate of Nterm-phos.

Methods: Gene expression was assessed by DNA microarray and qPCR. LPS was used to induce CAM expression in microvessel endothelial cells. Nterm-phos inhibitors were generated based on SAR of *N*-substituted amino acids.

Results: SMTP-7 inhibited LPS-induced cell adhesion molecule expression (CAM) in endothelial cells. There was a striking similarity in the gene expression pattern between SMTP-7-treated mice and sEH-KO mice (Fig. 1), exemplified by marked elevation *Saa* and *Lcn2* expression. Fmoc-Tyr, which selectively inhibits Nterm-phos, but not a Cterm-EH-specific inhibitor suppressed CAM expression and induced *Saa* or *Lcn2*. For the screening for endogenous substrate of Ntem-phos, total lipids isolated from mouse liver were treated with purified sEH (wild-type, EH-deficient D335S, or Phos-deficient D9A). Alcohols pre-existed or emerged after sEH reaction were analyzed by LC-MS after respectively derivatized with deuterated or unlabeled dansyl chloride, resulting in identification of candidate substrates.

Conclusions: sEH Nterm-phos is responsible for the regulation of endothelial inflammation. Nterm-phos substrate may control CAM expression and endothelial inflammation.

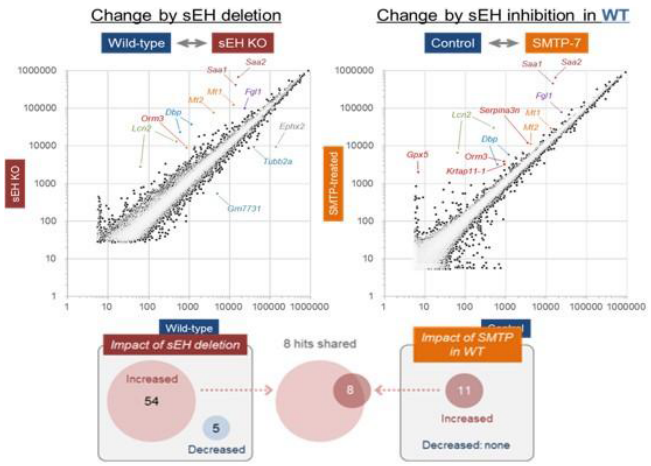

FIGURE 1 SMTP causes gene expression change similar to that observed in sEH deletion

ORAL COMMUNICATION ATHEROTHROMBOSIS & STROKE

OC 27.1 | Hypertension Upregulates Tissue Factor Expression in Bone Marrow Megakaryocytes and in Circulating Platelets

M. Brambilla[1], L. Rossetti[1], P. Gelosa[1], L. Castiglioni[2], P. Canzano[1], C. Zara[1], L. Sironi[1,2], E. Tremoli[1], M. Camera[1,2]

[1]*Centro Cardiologico Monzino, Milan, Italy,* [2]*Università degli Studi di Milano, Department of Pharmacological and Biomolecular Sciences, Milan, Italy*

Background: Hypertension is a predisposing factor to thrombotic complications of cardiovascular diseases. Indeed, increased levels of circulating tissue factor (TF) have been reported in hypertensive patients. Angiotensin II (Ang) has been shown to induce TF expression in monocytes. Also platelets (PLT) express TF but whether Ang affects PLT-TF expression is still unknown.

Aims: To investigate whether:

1) Ang modulates *in vitro* PLT-TF expression;

2) in an animal model of hypertension the number of TF^{pos} PLT and megakaryocytes (MK) is affected;

3) pharmacological control of hypertension with captopril restores PLT- and MK- TF expression.

Methods: TF^{pos} PLT from Wistar Kyoto rats were analyzed by flow cytometry (FC) after stimulation *ex vivo* with Val5Ang (1-100nM). *In vivo*, spontaneously-hypertensive stroke-prone rats (SHRSP) received standard diet (SD,) or high-sodium permissive diet (HSD) plus vehicle or plus captopril (50 mg/kg/die). PLT- and MK- TF expression was analyzed by whole blood FC. Thrombin generation was measured by CAT assay.

Results: *Ex vivo* stimulation of PLT with Ang resulted in a concentration dependent increase in the surface expression of TF, which was significantly inhibited by valsartan preincubation. *In vivo*, 4 week-HSD induced hypertension in SHRSP. The number of TF^{pos} PLT and MK increased compared to SD rats (PLT:64±6.7% vs 33.8±5%; p< 0.0001; MK: 47.8±6.8% vs 32.2±4%; p=0.007) and was reduced by captopril (PLT: 32.8±10.6%, p< 0.0001; MK: 36.7±5.2%; p=0.04). Similarly, PLT-TF activity was increased in hypertensive rats. Treatment with captopril reverted these effects.

Conclusions: Ang induces TF expression on the platelet surface, an effect mediated by AT1 receptor. *In vivo* hypertension upregulates MK TF expression leading to an increased number of PLT expressing a functionally active TF..In turn, the PLT prothrombotic potential is increased. Pharmacological treatment with captopril reverts TF up-regulation in MK and PLT.

OC 27.2 | Elevated Mean Platelet Volume is Associated with Lower Risk of Death in a General Population, but is a Predictive Marker of Death in Patients with History of Cardiovascular Disease

M. Bonaccio[1], A. Di Castelnuovo[1], S. Costanzo[1], A. De Curtis[1], M. Persichillo[1], C. Cerletti[1], M.B. Donati[1], G. de Gaetano[1], L. Iacoviello[1,2], Moli-Sani Study Investigators

[1]*IRCCS Neuromed, Department of Epidemiology and Prevention, Pozzilli, Italy,* [2]*University of Insubria, Department of Medicine and Surgery, Varese, Italy*

Background: Larger mean platelet volume (MPV) has been associated with adverse health outcomes. Yet, the majority of studies have addressed the role of MPV in high-risk populations or patients with cardiovascular disease (CVD).

Aims: To test the possible association of MPV with all-cause mortality in a large prospective population-based cohort study.

Methods: 17,402 adult subjects randomly recruited from a general population within the Moli-sani study (2005-2010), were analysed and subsequently subdivided in two subgroups (with or without CVD at baseline). MPV was measured within 3 hours from blood collection, that was performed in the same laboratory. The same operator used the same cell counter (Coulter HMX, Beckman Coulter, IL, Milan, Italy) for all subjects. Hazard ratios were calculated by multivariable Cox-proportional hazard models.

Results: Over a median follow up of 8 years (137,547 person-years), 925 all-cause deaths occurred. In a multivariable model controlled for platelet and leukocyte counts, platelet distribution width and C-reactive protein, the highest MPV quintile (mean MPV=10.0 fL) was associated with 21% reduced risk of death (HR=0.79; 95% CI 0.64-0.98) as compared to the lowest one (mean MPV=7.4 fL). The inverse association appeared even stronger in the subgroup without CVD at baseline (HR=0.64; 95% CI 0.50-0.81). In contrast, within 920 subjects reporting a previous CVD event, increased MPV was associated with higher risk of death (HR=1.69; 95% CI 1.05-2.72 for highest *vs* lowest quintile; p for interaction=0.048). Similar results were obtained when a sample (n= 4,777) of the Moli-sani population was enrolled in a different laboratory, where MPV was measured by a different counter and a different operator.

Conclusions: Elevated MPV is associated with lower risk of death in subjects free from CVD, but appears to be a predictive marker of death in CVD patients. History of CVD is an effect modifier of the inverse association between MPV and all-cause death.

OC 27.3 | Acute Phase Serotonin-mediated Neutrophil Trafficking is Independent of Endothelial Adhesion Molecules

C. Schönichen[1,2], F. Glatzki[1,2], M. Mauler[1,2,3], V. Ollivier[4,5], N. Herr[1,2], C. Starz[1,2], D. Stallmann[1,2], I. Ahrens[1,2], C. Bode[1,2], I. Hilgendorf[1,2], B. Ho-Tin-Noé[4,5], D. Duerschmied[1,2]

[1]University Heart Center Freiburg - Bad Krozingen, Cardiology and Angiology I, Freiburg, Germany, [2]University of Freiburg, Faculty of Medicine, Freiburg, Germany, [3]University of Freiburg, Faculty of Biology, Freiburg, Germany, [4]INSERM U 1148, Laboratory for Vascular Translational Science, Paris, France, [5]Université Paris Diderot, Sorbonne Paris Cité, Paris, France

Background: Acute phase neutrophil endothelial interactions are partly regulated by platelet-derived serotonin (5-HT), as mice deficient for tryptophan hydroxylase 1 (*Tph1*$^{-/-}$), the rate limiting enzyme for serotonin synthesis show attenuated neutrophil recruitment in inflammation.

Aims: Evaluation of serotonin mediated effects on endothelial cells (EC) and neutrophils *in vitro* and *in vivo* following endotoxic shock and myocardial ischemia reperfusion (I/R) injury.

Methods: HUVEC or isolated neutrophils were stimulated with 100µM 5-HT to assess cell adhesion under flow *in vitro*. Endotoxic shock in WT and *Tph1*$^{-/-}$ *mice* was induced by i.p. administration of LPS. 30 min LAD ligation was followed by 24 h of reperfusion. Endothelial adhesion molecule expression profile and neutrophil transmigration into the peritoneum and affected heart tissue was analyzed using flow cytometry and histology.

Results: 5-HT stimulation of HUVEC did not affect neutrophil adhesion, while pre-incubation of neutrophils with 5-HT increased neutrophil adhesion by 50% under flow. Neutrophil kinetics in blood of mice after endotoxic shock were similar in WT and *Tph1*$^{-/-}$ mice (2,4 vs. 2,7 x10^5 cells/mL; n.s.) whereas infiltrated peritoneal neutrophils were reduced by 40% in *Tph1*$^{-/-}$ mice. Flow cytometry revealed similar levels of ICAM, VCAM, E- and P-selectin expression on EC.

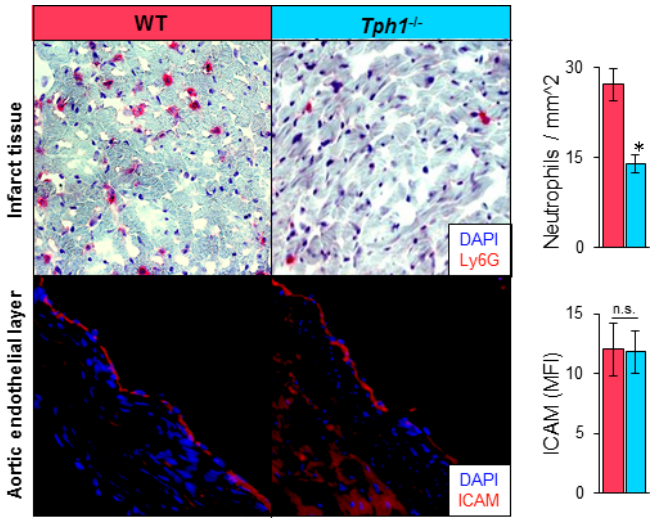

FIGURE 1 Top: Neutrophil infiltration in infarct tissue. Bottom: ICAM expression on aortic roots. 24 h I/R, students t-test *= p<0.05, n≤6/group

Tph1$^{-/-}$ mice show less neutrophil infiltration into infarct tissue after 24 h of myocardial I/R compared to WT (14 vs. 28 cells/mm^2 tissue; Fig. 1 top). Blood neutrophil levels were similar. Analysis of aortic root cross sections showed similar ICAM expression in both genotypes (Fig. 1 bottom).

Conclusions: Serotonin triggers neutrophil recruitment *in vitro* and transmigration *in vivo* during acute inflammation as it occurs upon bacterial infection or during reperfusion after myocardial infarction. In contrary to what was proposed in earlier studies, this effect seems to be mediated by direct stimulation of blood neutrophils by 5-HT and is independent of EC-derived adhesion molecules.

OC 27.4 | Circulating Microparticles in Cardiovascular Disease: Predictive Value in CABG Patency

M. Brambilla[1], P. Canzano[1], L. Lodi[1], L. Rossetti[1], C. Tedesco[1], L. Cavallotti[1], A. Parolari[2,3], F. Veglia[1], E. Tremoli[1], M. Camera[1,4]

[1]Centro Cardiologico Monzino IRCCS, Milan, Italy, [2]Università degli Studi di Milano, Dipartimento di Scienze Biomediche per la Salute, Milan, Italy, [3]IRCCS Policlinico San Donato, San Donato Milanese, Italy, [4]Università degli Studi di Milano, Dipartimento di Scienze Farmacologiche e Biomolecolari, Milan, Italy

Background: Microvesicles (MV) are biomarkers of vascular injury and inflammation in several cardiovascular diseases (CVD) including atherothrombosis where elevated levels of MV are correlated with disease severity. Graft patency is one of the major determinant of long-term outcome following coronary artery bypass grafting (CABG). The issue of identifying predictors of graft patency has been addressed by several studies but none has assessed the potential involvement of MV.

Aims: To elucidate whether a specific signature of MV is associated with CABG occlusion.

Methods: MV analysis was carried out in platelet free plasma (PFP) collected from 179 patients the day before CABG (T0). After 18 months, a CT scan evaluation of graft patency was performed. The number of MV, their cell origin and the expression of platelet activation markers (Pselectin, CD40L, TF) were evaluated in PFP by flow cytometry. Thrombin generation was measured by CAT assay.

Results: Patent and occluded grafts were observed in 75% and in 25% of patients, respectively. Analysis of MV signature at T0 indicated that patients that would have had occluded bypass at follow up had higher number of MV derived from activated-platelet while no significant differences were observed in monocyte-, granulocyte- and endothelium-derived MV. Occluded patients had 5- and 3-times more TF$^+$ MV (p=0.0008) and AnnV$^+$ MV (p=0.05), respectively, compared to patent ones. Of interest, the MV-associated thrombin generation capacity significantly correlated with the number of TF$^+$/AnnV$^+$ MV (p=0.03). A reclassification analysis indicated that the inclusion of the number of TF$^+$/AnnV$^+$ MV to CVD risk factor model resulted in a significant improvement in predicting CABG occlusion (IDI=0.190, p=0.001).

Conclusions: These data show that patients that would have had occluded bypass-graft had a significant higher number of MVs compared to patients with patent graft. Moreover they provide the evidence that the signature of MV before CABG surgery has a predictive value of graft patency.

OC 27.5 | Proteomic Analysis of Premature Myocardial Infarction Subjects Indicates Impairment in ‚Hedge Hog' Signaling Protein DYNC2H1

M. Ghatge, A. Sharma, R.K. Vangala

Manipal University/Thrombosis Research Institute, Proteomics and Coagulation Unit, Bangalore, India

Background: Premature Coronary Artery Disease (PCAD) is highly prevalent in Asian Indians and lacks association of most risk factors. The plasma proteomic profiling, along with network statistics holds enormous potential in the identification of novel biomarkers and also gain a better understanding of the diseases.

Aims: This study is aimed at assessing the differential proteomic profile associated with PCAD and identifying factors unique to the Asian Indians.

Methods: The global proteomic analysis was performed by using 2DE coupled with MALDI-TOF for protein identification. The differentially expressed proteins identified were used in the construction of protein-protein interaction network using STRING v10. Furthermore, all the proteins in the network were classified into CAD associated and non-CAD proteins. The average shortest path length between known CAD and non-CAD proteins was identified using Pesca v.3.0.8 (Cytoscape). The top 3 (5%) proteins were selected for ELISA based biological validation on (n= 40 CAD patients & n= 40 Controls). SVM analysis was used to prioritize the top protein and was validated on (n= 440 samples).

Results: We have identified 26 significantly differentially expressed proteins, of which 12 proteins (FN1, APOA1, ALB, FGG, FGB, C3, C4B, F2, HLA-DQB1, HP, FGA, ACTB) were known to be associated with CAD. Whereas 14 proteins (ACTN3, AKAP9, CD5L, DYNC2H1, ERVW-1, FAM190B, FER, GC, KDM2A, PLK3, SH3D21, SPATA8, TTR, ZNF624) were novel proteins with respect to CAD. Based on average shortest path length the top 3 proteins (DYNC2H1, PLK3, FER) were identified. The SVM analysis suggested that DYNC2H1 with the classification accuracy of 63.64% and AUC of 0.719 was a top scoring protein. The increased levels of DYNC2H1 showed 3.81 fold risk in CAD patients (95%CI; 2.27-6.38, p< 0.001).

Conclusions: These findings suggest that network-based shortest path analysis is useful in the omics-based novel biomarker identification. Our data also suggests that DYNC2H1 could be an important predictor of PCAD.

OC 41.1 | Role of Endothelial NF-κB Signalling in Atherosclerosis

M. Mussbacher, M. Salzmann, H. Volek, M. Kuttke, B. Hoesel, J. Basilio, A. Assinger, J. Schmid

Medical University Vienna, Vascular Biology and Thrombosis Research, Vienna, Austria

Background: Endothelial cell activation via the transcription factor NF-κB constitutes one of the first steps in atherogenesis, leading to the recruitment of leukocytes to the arterial wall. The central activator of NF-kB is IκB kinase 2 (IKK2), which phosphorylates its inhibitor, resulting in release of NF-κB and induction of genes involved in the development of atherosclerotic plaques and inflammatory responses.

Aims: We aim to study the role of endothelial IKK2 in the development of atherosclerosis to elucidate the underlying mechanisms linking endothelial inflammation and atherosclerosis.

Methods: We established a conditional transgene mouse model mimicking chronic endothelial inflammation by crossing mice containing an inducible, aortic endothelial-specific Cre recombinase with a strain bearing constitutive active IKK2 (caIKK2) downstream of a loxP-flanked stop cassette. CaIKK2-mice were crossed on an ApoE deficient background and fed a cholesterol-rich diet for 10 weeks to investigate the role of caIKK2 in the development of atherosclerosis.

Results: Aortic mRNA levels of the activation markers E-selectin, ICAM-1, and VCAM-1 were significantly upregulated after induction of caIKK2. Lymphocyte and granulocyte numbers were found to be significantly reduced in the circulation, with a parallel increase in aortic draining lymph nodes. To monitor potential changes in aortic gene expression due to inflamed endothelial cells, we performed RNA-sequencing of wildtype and caIKK2 aortas. Evaluation of the results with *Ingenuity Pathway Analysis* software revealed that the most upregulated pathways were associated with B- and T-cell signalling. Upon feeding the mice a cholesterol-rich diet for 10 weeks, increased atherosclerotic plaque areas could be observed in aortas from caIKK2 mice.

Conclusions: In summary, endothelial expression of caIKK2 led to endothelial cell activation resulting in an accelerated development of atherosclerosis, which was associated with increased infiltration of B and T cells.

OC 41.2 | Autophagy Is Required for Endothelial Cell Alignment and Atheroprotective Signaling Under Physiological Blood Flow

A.-C. Vion[1,2], M. Kheloufi[1,2,3], A. Hammoutene[1,2], J. Poisson[1,2], J. Lasselin[1,2], C. Devue[1,2], I. Pic[1,2], N. Dupont[2,4], J. Busse[5], K. Stark[5], J. Lafaurie-Janvore[6], A. Barakat[6], X. Loyer[1,2], M. Souyri[7], B. Viollet[2,8,9], P. Julia[10], A. Tedgui[1], P. Codogno[2,4], C.M. Boulanger[1,2], P.-E. Rautou[1,2,11]

[1]INSERM, U 970, Paris, France, [2]Université Paris Descartes, Sorbonne Paris Cité, Paris, France, [3]Université Paris Diderot, Sorbonne Paris Cité, Paris, France, [4]INSERM U 845, Necker Growth and Signaling Research Center, Paris, France, [5]Medizinische Klinik I, Klinikum der Universität München, Munich, Germany, [6]CNRS - Ecole Polytechnique UMR 7646, LadHyX - Mechanics & Living Systems; Cardiovascular Cellular Engineering, Palaiseau, France, [7]CNRS, UMR 7622, Paris, France, [8]Institut Cochin INSERM U 1016, Paris, France, [9]CNRS, UMR 8104, Paris, France, [10]Hôpital Européen Georges Pompidou, AP-HP, Service de Chirurgie Cardiaque et Vasculaire, Paris, France, [11]Hôpital Beaujon, AP-HP, DHU Unity, Pôle des Maladies de l'Appareil Digestif, Service d'Hépatologie, Centre de Référence des Maladies Vasculaires du Foie, Clichy, France

Background: Atherosclerotic lesions usually develop in curvature or branch point of the vasculature due to low shear stress while high shear stress areas are devoid of plaques. Endothelial inflammation, apoptosis and senescence are involved but the mechanisms remain elusive. Autophagy is a protective mechanism allowing recycling of defective organelles and proteins to maintain cellular homeostasis.

Aims: Our aim was to understand the role of autophagy in atheroprotective effect of high shear stress.

Methods: We used parallel plate chamber in vitro to generate different shear stress conditions on endothelial cell deficient (shRNA Atg5) or not in autophagy. In vivo, we silenced autophagy in endothelial cell specifically using *Atg5$^{flox/flox}$; VE-cadherin-cre and Atg7$^{flox/flox}$; VE-cadherin-cre* mice.

Results: We first demonstrated in human and murine arteries that atheroprotective high shear stress activates endothelial autophagic flux. On the opposite, endothelial cells exposed to atheroprone low shear stress were characterized by inefficient autophagy. *In vitro*, low shear stress activated mTOR, inhibited AMPKα and blocked the autophagic flux contributing to the decrease in autophagy. Both in cultured endothelial cells and in transgenic mice, deficiency in endothelial autophagy was associated with a defect in endothelial cells alignment in flow direction, a hallmark of endothelial cell health. Cultured endothelial cells deficient in autophagy presented a senescent profile under high shear stress and displayed an enhanced inflammatory response when co-stimulated with TNFα. In transgenic mice, high shear stress areas of aortas harbored increased senescence and apoptosis. Finally, in transgenic hypercholesterolemic mice, deficiency in autophagy lead to increased plaque burden in areas usually athero-resistant.

Conclusions: Altogether, these results show that adequate endothelial autophagic flux under high shear stress limits atherosclerotic plaque formation by preventing inflammation, senescence and apoptosis.

OC 41.3 | Immune Regulation by Oral Tolerance Induces Alternative Activation of Macrophages and Reduces Markers of Plaque Vulnerability in Apobtm2Sgy/Ldlrtm1Her/J Mice

L.N.R. Thota[1], L. Mundkur[1], T. Ponnusamy[1], R.K. Vangala[2]

[1]Thrombosis Research Institute, Molecular Immunology, Bangalore, India, [2]Thrombosis Research Institute, Proteomics & Coagulation, Bangalore, India

Background: Atherosclerosis, a well-accepted autoimmune disease needs a novel therapeutic approach in restoring the tolerance and methods for stabilizing the vulnerable plaque. Our earlier studies have shown that an oral tolerance to recombinant molecule expressing three peptides derived from ApoB100, human HSP60 (hHSP60) and outer membrane protein of Chlamydia pneumonia (Cpn) (AHC) protective role in controlling atherosclerosis in mice.

Aims: To explore the effect of immune tolerance to established by AHC molecule in controlling advanced atherosclerosis and inducing plaque stabilization in ApoBtm2Sgy/Ldlrtm1Her/J mice.

Methods: Groups of ApoBtm2Sgy/Ldlrtm1Her/J mice were given a diet rich in cholesterol (HFD) for 10 weeks to establish atherosclerosis. Diseased mice, orally dosed for 5 times with AHC molecule or ova-albumin as a control on alternate days and HFD was continued for another 12 weeks before sacrificing.

Results: Tolerance was associated with significantly higher regulatory T cells both in aortic sinus and spleen with higher mRNA expression of CTLA4 (3 fold), Foxp3 (1.4 folds) and TGF-b (1.62) in the aorta. Tregs cells were found to induce alternate activation of macrophages to M2 phenotype (arginase1, IL-10, TGF-β) with a reduction in plaque inflammation (IL-23, iNOS, TNF-α). AHC treatment showed evidence of plaque stabilization as observed by the reduction in plaque necrosis in aortic sinus (35.8%) and in the brachiocephalic artery (26%), with reduced expression of Tissue factor and MMP9. Macrophage apoptosis was reduced and collagen content enhanced by treatment.

Conclusions: Our results suggest that tolerance to atherogenic peptides in a multi-antigenic construct increases regulatory T cells which activate M2 macrophages, prevent T cell proliferation and reduce plaque vulnerability and inflammatory markers thus providing evidence for plaque stabilization in mice with advanced atherosclerosis.

OC 41.4 | IL-33 Stimulates the Release of Procoagulant Microvesicles from Human Monocytes and Differentially Increases Tissue Factor in Human Monocyte Subsets

S. Stojkovic[1], Å. Thulin[2], L. Hell[3], B. Thaler[1], S. Rauscher[4], J. Baumgartner[1], M. Gröger[4], C. Ay[3], S. Demyanets[5], C. Neumayer[6], I. Huk[6], A. Spittler[4], K. Huber[7], A. Siegbahn[2], J. Wojta[1,4,8], M. Åberg[2]

[1]*Medical University of Vienna, Department of Internal Medicine II, Vienna, Austria,* [2]*Uppsala University, Department of Medical Sciences, Clinical Chemistry and Science for Life Laboratory, Uppsala, Sweden,* [3]*Medical University of Vienna, Department of Internal Medicine I, Clinical Division of Hematology and Hemostaseology, Vienna, Austria,* [4]*Medical University of Vienna, Core Facilities, Vienna, Austria,* [5]*Medical University of Vienna, Department of Laboratory Medicine, Vienna, Austria,* [6]*Medical University of Vienna, Department of Surgery, Division of Vascular Surgery, Vienna, Austria,* [7]*Wilhelminen Hospital, 3rd Medical Department for Cardiology and Emergency Medicine, Vienna, Austria,* [8]*Ludwig Boltzmann Cluster for Cardiovascular Research, Vienna, Austria*

Background: Monocytes and monocyte-derived MVs are the main source of circulating TF. An increase in monocyte TF expression and circulating procoagulant MVs contribute to a prothrombotic state in patients with cardiovascular disease. IL-33 is a pro-inflammatory cytokine involved in atherosclerosis and several other chronic inflammatory diseases, but its role in regulating thrombosis is still unclear.

Aims: In this study, we aimed to investigate the effects of IL-33 on the procoagulant properties of human monocytes and monocyte-derived MVs.

Methods: Protein levels were analyzed by WB, flow cytometry, or ELISA and gene expression by real-time PCR. The MVs were detected by flow cytometry and the procoagulant properties of monocytes and MVs were determined by a FX-activity assay.

Results: IL-33 induced a time- and concentration-dependent increase of TF mRNA and protein levels in isolated human monocytes via binding to the ST2-receptor and activation of the NF-kB-pathway. The IL-33 treated monocytes also released procoagulant CD14+TF+ MVs and IL-33 was found to increase the TF activity of both the isolated monocytes and of the monocyte-derived MVs.

The intermediate monocytes (IM) displayed the highest ST2-receptor expression, followed by non-classical monocytes (NCM), and classical monocytes (CM). IL-33 induced a significant increase of TF only in the IM ($p< 0.01$), with only a tendency detected in NCM ($p=0.06$) and no increase observed in CM.

We extended our data by measuring plasma levels of IL-33 and CD14+TF+ MVs in 20 patients with carotid artery stenosis undergoing carotid endarterectomy. Plasma IL33 positively correlated with CD14+TF+ MVs ($r=0.480$, $p=0.032$) but not with CD14+ MVs ($r=0.397$, $p=0.083$).

Conclusions: We hereby provide novel evidence that the proinflammatory cytokine IL-33 induces differential TF expression and activity in monocyte subsets and the release of procoagulant MVs both *ex* and *in vivo*. In this manner, IL-33 may contribute to the formation of a prothrombotic state in cardiovascular disorders.

OC 41.5 | Mir-146a from the Hematopoietic Compartment is Not Involved in Atherosclerosis Development Despite Provoking an Increased Inflammation and NET Formation

A.B. Arroyo Rodríguez[1], A. del Monte[2], A.M. De los Reyes García[1], N. García Barberá[1], M.S. Caleprico[2], M.J. Andrés Manzano[2], V. Roldán[1], R. Teruel Montoya[1], V. Vicente[3], R. González Conejero[1], V. Andrés[2], C. Martínez[1]

[1]*Servicio de Hematología y Oncología Médica, Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, Murcia, Spain,* [2]*Centro Nacional de Investigaciones Cardiovasculares Carlos III (CNIC), Madrid, Spain,* [3]*Servicio de Hematología y Oncología Médica, Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, CB15/00055-CIBERER, Murcia, Spain*

Background: Atherosclerosis is a chronic inflammatory disorder in which monocytes and macrophages recruited in atherosclerotic plaques activate pro-inflammatory pathways. Mir146a negatively regulates the IRAK1/TRAF6/NF-kB pathway. Moreover, systemic overexpression of miR146a decreases inflammation and atherosclerosis. We recently described that the rs2431697 (TT) variant of *MIR146A*, associated with lower levels of miR-146a, predicts adverse cardiovascular events in patients with atrial fibrillation by promoting an increased inflammatory state.

Aims: To evaluate the role of miR-146a from the hematopoietic compartment in the development of atherosclerosis in a mouse model.

Methods: $LDLr^{-/-}$ mice irradiated with lethal γ-rays doses (N=30) were transplanted with bone marrow (BM) ($0.5e10^6$ cells/mouse) of wild-type (WT) or $miR146a^{-/-}$ mice. Animals were feeded by fat-rich diet with cholesterol. Plasma was obtained for chemistry, hematology, IL-6 (ELISA), DNA (sytox green), and elastase (ELISA) quantification. Expression in thoracic artery of miR-146a and its targets (*Irak1*, *Traf6*, *and Tlr4)* were measured by qRT-PCR. Plaque size was quantified in aortic arch by Oil-Red staining and in heart valves by immunohistochemistry.

Results: Hematological count and lipid profile were not different between groups, neither were atherosclerotic lesion sizes. However, IL-6 levels were higher in mice transplanted with$miR-146a^{-/-}$ BM (209.8±97.8 *vs*. 6.5±2.7 pg/mL; $p< 0.05$), as well as DNA (348 *vs* 177 ng/ml; $p< 0.05$) and elastase (229 vs 113 ng/ml; $p< 0.01$). *Irak1*, *Traf6* and *Tlr4* expression were also higher ($p< 0.05$) in mice transplanted with $miR-146a^{-/-}$BM.

Conclusions: miR-146a deficiency in the hematopoietic compartment is not sufficient to aggravate atherosclerosis despite increasing inflammation. Interestingly, we showed for the first time a potential role of miR-146a in NET formation. Future studies are necessary to unravel the mechanisms of this regulation and the pathophysiologic impact.

COAGULANT & ANTICOAGULANT MECHANISMS

OC 02.1 | Maintaining Extraembryonic Expression Allows Generation of Adult Mice with Tissue Factor Pathway Inhibitor Gene Disruption

M. Storage[1], Q. Yang[1], M. Zhan[1], A. Mast[2], R. Sood[1]

[1]*Medical College of Wisconsin, Department of Pathology, Milwaukee, United States,* [2]*Blood Research Institute, BloodCenter of Wisconsin, Milwaukee, United States*

Background: The Kunitz1 domain of TFPI binds the active site of fVIIa and is required for inhibition of Tissue Factor/Factor VIIa activity. TFPI-Kunitz1 domain-deficient mice die *in utero*; the critical vascular site of pathology remains unknown. TFPI is highly expressed on trophoblast cells of the placenta. The interface of maternal blood and extraembryonic trophoblast cells is a potential target of pathological coagulation resulting in fetal growth restriction and death.

Aims: To examine if maintaining extraembryonic expression of TFPI allows *in utero* survival and generation of mice lacking TFPI Kunitz1 domain.

Methods: Mice with floxed K1 TFPI domain ($TFPI^{K1\ Lox/Lox}$) were crossed with an epiblast-specific Cre strain ($Meox2Cre^{tg/+}$) to generate $Meox2Cre^{tg/+}$ $TFPI^{K1\ Lox/Lox}$ experimental animals (Table 1). These animals delete the floxed TFPI K1 domain in the embryo while maintaining expression in trophoblast and primitive endoderm cells of the placenta. Embryos, placentae, pups and adult animals were observed for phenotypes and evaluated by real time PCR, western blot analysis and histology.

Results: Cre-Lox strategy resulted in expected Mendelian frequency of TFPI K1 domain-deficient embryos and pups
(Table 1). Real time genomic PCR and RT-PCR on embryos confirmed 95 to 99% deletion of TFPI K1 domain and a similar reduction in transcript expression. Western blotting confirmed the absence of full length protein in adult animals (Figure 1A). Most TFPI deficient animals (termed $TFPI^{K1\_Lo}$) exhibited a normal life span. Lowest expression (≤ 1%) correlated with non-specified acute illness between 3 to 5 months of age and presence of large ischemic regions in the brain (Figure 1B).

Conclusions: Severe deficiency of TFPI is compatible with normal mouse development, if extraembryonic expression is maintained. Brain ischemia is the most prominent phenotype of severely deficient animals. These results highlight a critical role of Tissue Factor/Factor VIIa inhibition by TFPI in extraembryonic circulation and in the brain.

TABLE 1 Results of genetic crosses showing expected Mendelian frequencies of live TFPIK1_Lo pups

Genetic Cross	Stage of Analysis	Genotypes Observed				#$TFPI^{K1\_Lo}$ Expected

OC 02.2 | Prostacyclin Prevents Deep Vein Thrombosis in COX-2 Knockout Mice

P. Amadio, E. Tarantino, L. Sandrini, E. Tremoli, S.S. Barbieri

Centro Cardiologico Monzino, Milan, Italy

Background: Venous thrombosis is a common condition that often leads to pulmonary thromboembolism and death. Cyclooxygenase (COX)-1 and -2, catalyzing prostanoids from arachidonic acid, play a critical role in the occurrence of thrombotic events.

Aims: To investigate the molecular mechanisms underlying venous thrombosis (VT) focusing on the impact of COX-2 deletion.

Methods: Thrombi were induced by inferior vena cava ligation (IVCL); thromboelastomethry, mass weight and histology and venous ultrasonography approaches were used to assess the effect of COX-2 ablation in mice ($COX\text{-}2^{-/-}$). Tissue factor (TF), Annexin A2 (ANXA2) and S100A10 were analysed in venous thrombi and in peritoneal macrophages (PM) isolated from WT and $COX\text{-}2^{-/-}$ mice.

Results: COX-2 deletion predisposes to VT as suggested by greater clot firmness and clot elasticity, by higher plasma levels of functional fibrinogen, factor VIII and PAI-1 activity, and proved by bigger thrombi detected after IVCL compared to WT mice. $COX\text{-}2^{-/-}$ thrombi have greater fibrin content, higher number of $F4/80^{+}$, TF^{+} and $ANXA2^{+}$ cells, and lower $S100A10^{+}$ cells. Remarkably, monocyte depletion reduced thrombus size in mutant mice, suggesting a key role of $COX\text{-}2^{-/-}$ monocytes in this experimental setting. Interestingly, COX-2 deletion increased ANXA2, reduced S100A10, promoted assembly of ANXA2/p50NF-kB complex and its nuclear accumulation, and induced TF in PM, whereas ANXA2 silencing decreased dramatically TF. Finally, Carbaprostacyclin treatment prevented VT formation in mutant mice, and reduced the ANXA2 binding to p50NF-kB subunit and its nuclear trafficking, and decreased TF in COX-2-/- PM.

Conclusions: The increased activation of haemostatic system observed in $COX\text{-}2^{-/-}$ mice may partly explain their predisposition to thrombosis. In addition, COX-2 deletion promotes macrophage TF activity by nuclear accumulation of ANXA2 sustaining venous thrombus growth, which suggests a new role for ANXA2 in venous thrombosis.

OC 02.3 | Deficiency of Platelet eNOS Produces a Pro-thrombotic Phenotype

S. Momi, G. Guglielmini, E. Falcinelli, P. Gresele

University of Perugia, Medicine, Perugia, Italy

Background: Mice deficient of eNOS ($eNOS^{-/-}$) are characterized by endothelial dysfunction, hypertension and cardiac dysfunction. However, their thrombotic phenotype is controversial and it has not been fully explored.

Aims: Aim of our study was to clarify the role of NO, and in particular of platelet-derived NO, on arterial and venous thrombosis in mice.

Methods: Wild type (WT) mice made thrombocytopenic were transfused with highly-purified $eNOS^{-/-}$ platelets to generate chimeric mice selectively lacking platelet eNOS. Pulmonary thromboembolism (PT) was induced by i.v. collagen+epinephrine (coll+epi); arterial thrombosis by photochemical damage to the femoral artery; inferior vena cava thrombosis by the partial flow restriction method; platelet production of NO was analysed by DAF-FM DA; platelet activation by flow cytometry.

Results: Highly purified platelets from WT, but not from $eNOS^{-/-}$, mice release NO upon collagen-induced activation. Platelets from $eNOS^{-/-}$ mice show enhanced adhesion to collagen under high shear rate flow condition. I.v. coll+epi-induced in vivo platelet activation is significantly greater (38±4 vs 25±6% of P-Sel positive platelets, $p< 0.05$) and PT mortality is significantly increased in $eNOS^{-/-}$ than in WT mice. Femoral artery thrombosis occurs in a shorter time (7.7±0.3 min vs 11.9±0.7 min, $p< 0.05$) and with larger thrombi (0.59±0.02 mg vs 0.27±0.01 mg, $p< 0.05$) in $eNOS^{-/-}$ mice. Chimeric mice lacking eNOS only in platelets show a significantly shorter time to occlusion (8.2±0.4 min, $p< 0.05$ vs control). Inferior vena cava thrombus weight is enhanced in $eNOS^{-/-}$ mice (16.4±12.3mg vs 11±2.5mg, $p=0.02$).

Conclusions: Our data show that mouse platelets produce NO, that NO-released by platelets regulates platelet deposition on collagen, that endogenous NO exerts an antithrombotic activity in vivo both in the arterial and venous circulation and that platelet-derived NO contributes to this effect.

OC 02.4 | Amyloid Precursor Protein is a Regulator of Venous Thromboembolism in Mice

I. Canobbio[1], S. Momi[2], C. Visconte[1], G.F. Guidetti[1], M. Zarà[1], J. Canino[1], E. Falcinelli[2], P. Gresele[2], M. Torti[1]

[1]*University of Pavia, Department of Biology and Biotechnology, Pavia, Italy,*
[2]*University of Perugia, Department of Internal Medicine, Perugia, Italy*

Background: The amyloid precursor protein (APP), primarily known as the precursor of amyloid peptides that accumulate in the brain of Alzheimer's disease patients, is also an abundant platelet protein whose physiological function remains largely unknown.

Aims: In this work, we investigate the role of APP in hemostasis and thrombosis.

Methods: Platelet activation, blood coagulation, arterial and venous thrombosis were compared in APP knockout (APPKO) versus wild type (WT) mice.

Results: *Ex vivo* aggregation, secretion, and integrin aIIb3 inside-out activation induced by a wide panel of agonists were normal in APP-deficient platelets, indicating that this protein is dispensable for basic platelet functions. Nevertheless, the number of circulating platelets was reduced by about 20% in APPKO mice and their size was slightly increased. The absence of APP was associated to enhanced proplatelet formation by bone marrow megakaryocytes. Tail bleeding time was comparable in control and APPKO mice and, *in vivo*, the absence of APP did not alter thrombus formation in the femoral artery. By contrast, in a model of vein thrombosis induced by flow restriction in the inferior vena cava, APPKO mice developed much larger thrombi than control animals. Consistent with this, analysis of pulmonary thromboembolism revealed that larger vessels were occluded in APPKO mice. APPKO mice displayed an accelerated APTT but not PT time compared to WT mice, when measured in the presence of platelets. Moreover, the activity of factor XIa, but not factor XIIa, was higher in APPKO mice. APPKO mice presented a significantly higher number of circulating platelet-leukocyte aggregates and neutrophils displayed a constitutive stronger tendency to protrude extracellular traps.

Conclusions: These results indicate that platelet APP limits venous thromboembolism, through a negative regulation of both fibrin formation and neutrophil function.

OC 02.5 | Absence of Platelet Thrombin Receptor Par4 Prevents Thrombotic and Stroke-like Phenotypes of Thrombomodulin Deficient mice

M. Storage, Q. Yang, M. Zhan, R. Sood

Medical College of Wisconsin, Milwaukee, United States

Background: Thrombomodulin (Thbd) is a multifunctional membrane glycoprotein with pleiotropic functions. It forms a high affinity complex with thrombin and suppresses excessive activation of blood clotting. Mice with Thbd deletion in the endothelium succumb to severe and fatal thrombosis at an early age.

Aims: To determine if absence of thrombin receptor, Par4, ameliorates thrombotic phenotype of endothelial-specific and global Thbd deficient mice.

Methods: We crossed Par4 null and Thbd floxed mice with endothelial- and epiblast-specific Cre strains (Tie2Cre and Meox2Cre respectively) to generate $Par4^{-/-}$ $Tie2Cre^{tg}$ $Thbd^{Lox/Lox}$ (comparison group $Par4^{+/+}$ $Tie2Cre^{tg}$ $Thbd^{Lox/Lox}$) and $Par4^{-/-}$ $Meox2Cre^{tg}$ $Thbd^{-/-}$ (comparison group $Par4^{+/+}$ $Meox2Cre^{tg}$ $Thbd^{-/-}$) mice in C57Bl6 genetic background. Animals were observed and characterized by PCR, immunohistochemistry and histology.

Results: $Tie2Cre^{tg}$ $Thbd^{Lox/Lox}$ mice recapitulated the previously described spontaneous and severe thrombosis seen in the extremities.

Some animals exhibited circling behavior without signs of limb injury, indicative of stroke. Epiblast restricted Thbd-deficiency resulted in live Meox2Cre^{tg} Thbd$^{-/-}$ embryos in normal Mendelian frequency at term, but these exhibited high neonatal lethality (~1/3rd surviving) (Table 1). About half of the pups that survived the first 3 weeks succumbed to severe tail and limb thrombosis or exhibited circling behavior by 8 to 10 weeks of age. The thrombotic and stroke-like phenotypes of Thbd-deficient animals were not observed in the absence of Par4 in both models, resulting in dramatically improved survival (Figure 1). In contrast to amelioration of thrombotic disease in adult animals, the absence of Par4 did not significantly improve survival of Thbd-deficient neonates (Table 1).

TABLE 1 Genetic distribution showing live endothelial and global Thbd-deficient pups at 3 weeks of age

Genetic Cross	Genotypes of pups				Expected Thbd$^{-/-}$	95% confidence interval for observed Thbd$^{-/-}$
	Thbd$^{Lox/+}$	Thbd$^{Lox/-}$	Meox2Cre^{tg} Thbd$^{+/-}$	Meox2Cre^{tg} Thbd$^{-/-}$		
Male Meox2Cre^{tg} Thbd$^{+/-}$ X Female Thbd$^{Lox/Lox}$	53	39	45	12	25%	4.2 - 13.7%
Male Par4$^{-/-}$ Meox2Cre^{tg} Thbd$^{+/-}$ X Female Par4$^{-/-}$ Thbd$^{Lox/Lox}$	23	24	28	10	25%	5.2 -18.5%
Male TieCre^{tg} Thbd$^{+/-}$ X Female Thbd$^{Lox/Lox}$	13	18	18	7	25%	5.2 - 24.1%
Male Par4$^{-/-}$ Tie2Cre^{tg} Thbd$^{+/-}$ X Female Par4$^{-/-}$ Thbd$^{Lox/Lox}$	6	8	4	7	25%	12.1- 49.4%

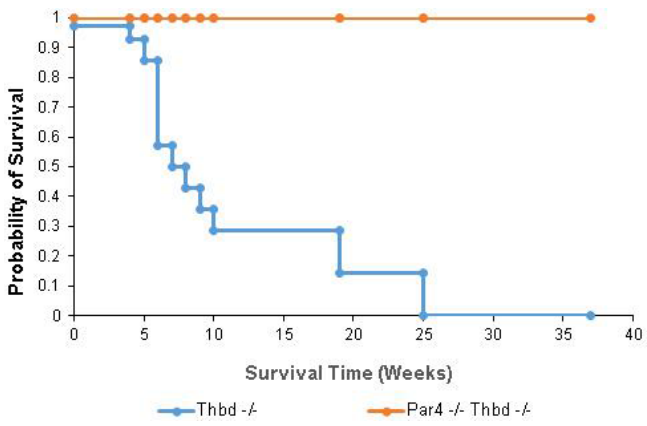

FIGURE 1 Kaplan-Meier plot comparing survival of Thbd-null weanlings in the presence or absence of Par4 expression

Conclusions: Global deficiency of Thbd results in thrombotic and stroke-like phenotypes similar to endothelial-specific gene deletion. Thrombin receptor Par4 plays a key role in mediating these phenotypes in both models.

OC 14.1 | Revisiting Antithrombotic Therapeutics; Sculptin a Novel Class of Specific, Competitive, Reversible, Scissile and Tight Binding Inhibitor of Thrombin

A. Iqbal[1,2], M. Barbugiani Goldfeder[1,2], R. Marques-Porto[1], H. Asif[3], J. Gabriel de Souza[1,2], F. Faria[1,2], A.M. Chudzinski-Tavassi[1,2]

[1]Butantan Institute, Laboratory of Biochemistry and Biophysics, Sao Paulo, Brazil, [2]Butantan Institute, Centre of Excellence for New Target Discovery (CENTD), Sao Paulo, Brazil, [3]Butantan Institute, Laboratory of Gene Expression in Eukaryotes, Sao Paulo, Brazil

Background: Thrombin is a multifunctional enzyme with a key role in the coagulation cascade. Its functional modulation can culminate into normal blood coagulation or disorders like thrombosis. Thus, the identification of novel potent and specific inhibitors of thrombin are of immense importance.

Aims: To characterize sculptin, a novel, reversible, potent and specific inhibitor of thrombin and its anti-thrombotic effect.

Methods: Sculptin was identified in transcriptomics profile of the salivary glands from tick *Amblyoma cajanensis*. Recombinant sculptin was investigated using bioinformatics, phylogenetic, mass spectrometry, inhibition and binding kinetics, global coagulation assays.

Results: Here we report, sculptin a novel class of direct thrombin inhibitor identified in transcriptomics profile of the salivary gland from tick. It consists of 168 residues with four exactly similar repeats of 34 amino acids and evolutionary diverged from classical hirudin. Sculptin is a specific and reversible inhibitor of thrombin with K_i of 18.5 ± 2.2 pM. It is slowly consumed by thrombin and loses its inhibition activity. Likewise, sculptin is hydrolyzed by factor Xa and each polypeptide fragment was able to inhibit thrombin independently. A single domain of sculptin alone retained ~45% of inhibitory activity, which we proposed to bind thrombin in a bivalent fashion. The formation of a small turn/ helical-like structure by active site binding residues of sculptin might have made it a more potent thrombin inhibitor than hirudin analogs. In addition, it prolongs coagulation via both extrinsic and intrinsic pathways.

Conclusions: Sculptin is a novel class of specific, competitive, reversible, scissile and tight binding inhibitor of thrombin. A single domain of sculptin is more potent thrombin inhibitor than hirudin analogs i.e. Bivalirudin. Taken together, our data allow us to conclude that sculptin and its independent domain(s) have strong potential to become a novel antithrombotic therapeutics.

OC 14.2 | Study of the Antithrombin Folding through the N-glycosylation

S. Águila[1], G. Luengo-Gil[1], N. Bohdan[1], S. Espín[1], V. Vicente[1,2], J. Corral[1,2], I. Martínez Martínez[1,2]

[1]Servicio de Hematología y Oncología Médica, Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, Murcia, Spain, [2]Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Instituto de Salud Carlos III (ISCIII), Madrid, Spain

Background: As a member of the serpin superfamily, antithrombin (AT) has propensity to polymerize during the folding process due to certain factors, although the mechanism is still unknown. AT is an N-glycoprotein and N-glycosylation is a post-translational modification that plays a key role in the folding of proteins.

Aims: To use the N-glycosylation as a tool to study the folding of AT.

Methods: Recombinant expression of AT variants created by mutagenesis. EndoH treatment, electrophoresis and western blot analysis of variants.

Results: Eighteen variants with one new N-glycosylation sequence in each one of the beta-strands were constructed-Table and Fig. Only 8 mutants became glycosylated and were secreted, but only 3 of them retained their anticoagulant activity. Two mutants were secreted at very low levels. All glycosylated mutants polymerized and the extra glycan was sensitive to EndoH, except in 2 cases. Two non-glycosylated mutants were also sensitive to EndoH. Polymerization and low secretion levels of P172N/D174T and L146T seemed to be caused by the mutation as no extra glycosylation was produced. Most of the mutations at A-sheet induced polymerization andat B-sheet clearly affected the secretion levels. Two out of 3 mutants at C-sheet were glycosylated, secreted and were functional.

Conclusions: Mutations creating new N-glycosylation sitesat strands s1A, final region of s2A, s5A, final region of s6A, s1B, s4B, and s3C were not glycosylated, suggesting that folding of these strands precedes N-glycosylation. Moreover, these mutations mostly impaired the inhibitory function of AT. For all mutations glycosylated, the extra glycan did not follow the proper maturation through the Golgi, affecting in some cases the accessibility of other glycans. Our data suggest that A and B-sheets are crucial for protein folding since most N-glycosylation mutations at these regions provoke polymerization or low secretion. These results broaden our knowledge on AT folding and may help to rationally design drugs to impair polymerization.

Mutants	Structure location	Extra glycan	EndoH sensitivity	Polymerization	Secretion level	Anti FIIa activity

OC 14.3 | Palmitoylation of the Cytoplasmic Domain of Tissue Factor Regulates its Encryption, Mediated through Alteration in the Orientation of the Transmembrane Domain

C. Ettelaie[1], M. Collier[2], J. Greenman[1], A. Maraveyas[3]

[1]University of Hull, School of Life Sciences, Hull, United Kingdom, [2]University of Leicester, Cardiovascular Sciences, Leicester, United Kingdom, [3]University of Hull, Hull York Medical School, Hull, United Kingdom

Background: The release of tissue factor (TF) maintains the balance of haemostasis. One enigma in the regulation of TF cofactor activity has been the ability of this protein to exist on the surface of the cells in encrypted form without triggering coagulation. As such, the de-encryption of TF leads to the availability of this protein as a coagulation

cofactor. Palmitoylation of TF was one of the earliest post-translational modifications that was reported and occurs on Cys245 within human TF.

Aims: In this study we examined the role of Cys245 and transmembrane domain of TF on the encryption of its activity.

Methods: The pCMV-Ac-TF-tGFP was mutated to express TF with Cys245→Ser and Cys245→Phe substitutions to prevent or mimic palmitoylation respectively. Additionally, the transmembrane domain was shortened by deleting Ser241-Leu242, or made inflexible by substituting Gly225 with Val. Endothelial cells devoid of exogenous TF were transfected to express the proteins and the cellular/cell-surface TF antigen, factor Xa generation, and factor VIIa binding potentials were assessed in resting cells and PAR2-activated cells. In addition, to prevent TF de-palmitoylation the expression of palmitoyl deacylase enzymes in the cells was suppressed.

Results: Substitution of Cys245 with Ser resulted in increased TF activity in resting cells while Phe-substitution of this residue resulted in rapid suppression of TF activity. Either shortening of the transmembrane domain, or replacing the flexible Gly225 also prevented the activation of the otherwise wild-type TF in cells. Finally, suppression of palmitoyl deacylase suppressed the TF activity following PAR2 activation.

Conclusions: Palmitoylation of TF incorporates the proximal boundary region of the cytoplasmic-transmembrane domain into the membrane altering the orientation of the transmembrane domain and altering the membrane span that may be accommodated. This in turn may prevent the incorporation of TF within lipid raft regions necessary for the increased activity of TF.

OC 14.4 | Characterization of the p.Arg393Cys Variant of Antithrombin. Extracellular Formation of Antithrombin-albumin Disulphide Linked Dimers through a Conformational Dependent Mechanism and Role in Thrombosis

M. Toderici[1], M.E. de la Morena-Barrio[1,2], C. de Cos[3], A. Miñano[1], S. Espín[1], J. Padilla[1], V. Vicente[1,2], J. Corral[1,2]

[1]*Servicio de Hematología y Oncología Médica, Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, Murcia, Spain,* [2]*CIBERER, Madrid, Spain,* [3]*Hospital Puerta del Mar, Cádiz, Spain*

Background: Antithrombin (AT) is an anticoagulant serpin whose deficiency significantly increases the risk of thrombosis. The conformational sensitivity of this serpin explains why certain *SERPINC1* missense mutations are able to affect its structural stability with pathogenic consequences.

Aims: To characterize new pathogenic and prognosis effects of *SERPINC1* mutations associated with conformational changes of AT.

Methods: *SERPINC1* and plasma AT was studied by molecular and biochemical methods including proteomic and functional analysis of purified proteins in 2 members of a family with AT deficiency: a 20 year-old male with deep-vein thrombosis and pulmonary embolism and his asymptomatic mother.

Results: The *SERPINC1* p.Arg393Cys mutation affecting the P1 residue of the reactive center loop fully explained the type II RCL deficiency observed. This variant (AT Milano), allowed the interaction with albumin through disulphide bonds. However, analysis of plasma AT of carriers by native gels revealed 2 different variants with similar levels. Heat (42˚C) induced in plasma the transformation of the variant with faster mobility (mutant monomer) into the variant with slow mobility (dimer of mutant AT with albumin), as demonstrated by biochemical and proteomic analysis. The dimer, which was purified by heparin affinity and gel filtration, has no anticoagulant activity but higher heparin affinity than the wild-type molecule. Thus, formation of dimers impaired the anticoagulant capacity of carriers as they reduce the activity of wild-type molecules, particularly under low heparin concentrations.

Conclusions: The p.Arg393Cys mutation caused an AT variant with null anticoagulant activity that has conformational sensitivity, as demonstrated in P1 variants. Transformation to the latent conformation, allowed the formation in plasma of dimers with albumin through a disuphide bond, with dominant negative effect, that might exacerbate the risk of thrombosis under stress conditions.

OC 14.5 | Involvement of Heparanase Procoagulant Domain in Bleeding and Wound Healing

Y. Crispel[1], S. Ghanem[1], J. Attias[1], E. Peled[1], I. Kogan[1], B. Brenner[1], Y. Nadir[2]

[1]*Rambam Health Care Campus, Haifa, Israel,* [2]*Rambam Health Care Campus, Thrombosis and Haemostasis Unit, Haifa, Israel*

Background: Heparanase, known to be involved in angiogenesis and metastasis, was shown to form a complex with tissue factor (TF) and to enhance the generation of factor Xa. Our study demonstrated that peptides derived from TF pathway inhibitor (TFPI)-2 impeded the procoagulant effect of heparanase and attenuated inflammation, tumor growth and vascularization.

Aims: The present study aimed to identify the procoagulant domain in the heparanase molecule and to evaluate its effects in a model of wound healing that involves inflammation and angiogenesis.

Methods: Twenty-four potential peptides derived from heparanase, were generated and their effect was studied in an assay of factor Xa generation. Peptides 14 and 16 that demonstrated the best procoagulant effect were studied in a bleeding mouse model and in a wound healing mouse model.

Results: Peptides 14 and 16 increased factor Xa levels by 2-3 fold and at high levels caused consumption coagulopathy. The TFPI-2 derived peptides explored in our previous study were found to inhibit the procoagulant effect induced by the peptides 14 and 16. In the bleeding model, time to clot formation was shortened by 50% when peptides 14 or 16 were topically applied or injected subcutaneously ($p<0.001$). In the wound healing model the wound became more vascular and its size was reduced to 1/5 compared to controls, upon one week of exposure to peptides 14 or 16 applied topically or injected subcutaneously ($p<0.001$).

Conclusions: The putative heparanase procoagulant domain was identified. Peptides derived from this domain significantly shortened bleeding time and enhanced wound healing.

OC 15.1 | Proteolytic Activity of Single-chain Prekallikrein

I. Ivanov[1], M.-F. Sun[1], A. Matafonov[1,2], D. Gailani[1]

[1]*Vanderbilt University Medical Center, Departments of Pathology, Microbiology and Immunology, Nashville, United States,* [2]*Tomsk Polytechnic University, Department of Bioengineering and Organic Chemistry, Tomsk, Russian Federation*

Background: During the process of plasma contact activation factor XII (FXII) and prekallikrein (PK) undergo reciprocal activation, forming factor XIIa (FXIIa) and kallikrein (KLK). Recently, we showed that FXII in its single-chain precursor form exhibits proteolytic activity toward PK that is enhanced by polyanions such as polyphosphate. This activity could serve as a trigger for contact activation when FXII and PK are exposed to a surface.
Aims: To determine if single-chain PK has proteolytic activity toward its substrates FXII and high molecular weight kininogen (HK).
Methods: We prepared recombinant wild type PK (PK-WT), and PK variants with alanine replacing arginine at the activation cleavage site (PK-R371A) or serine in the catalytic active site (PK-S559A). PK-R371A cannot be converted to KLK by FXIIa, and is constrained in a single chain form. We also prepared FXII-WT, and a variant with alanine replacing the active site serine (FXII-S554A). We tested the ability of PK species to cleave FXII species or HK in the absence or presence of polyanions (polyphosphate or DNA).
Results: No PK species cleaved FXII-S544A in the absence of a polyanion, however, both PK-WT and PK-R371A cleaved FXII-S544A to a form representing FXIIa in the presence of polyphosphate. The PK-WT-mediated reaction was substantially faster than reactions with PK-R371A. PK-R371A, but not PK-S559A, increased the rate of FXII-WT "autoactivation" in the presence of DNA. Both PK-WT and PK-R371A cleave HK in reactions that are inhibited by the serpin C1-Inhibitor.
Conclusions: Similar to FXII and the fibrinolytic enzymes tPA and urokinase, PK exhibits proteolytic activity in its single-chain form and, therefore, is not a true zymogen. While the capacity of single chain PK-R371A to cleave FXII and HK is considerably weaker than that of KLK, the activity could be relevant for initiation of contact activation (when KLK levels are low), and to basal bradykinin generation through cleavage of HK.

OC 15.2 | The Proline Rich Domain of Factor XII Mediates Contact Activation

C. Naudin[1], A. Di Gennaro[1], E.X. Stavrou[2,3], T. Renné[1,4]

[1]*Karolinska Institutet, Department of Molecular Medicine and Surgery, Stockholm, Sweden,* [2]*Case Western Reserve University, University Hospitals, Department of Medicine, Cleveland, United States,* [3]*Louis Stokes Veterans Administration Hospital, Department of Medicine, Cleveland, United States,* [4]*Institute of Clinical Chemistry and Laboratory Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*

Background: Factor XII is activated to its enzyme by plasma kallikrein or by its unique property to autoactivate when bound to negatively charged surfaces. The mechanism for autoactivation is not completely understood. New interest in this pathway has emerged by the recognition that several biologic substances support FXII autoactivation and due to the observation that FXII deficient ($FXII^{-/-}$) mice are protected from thrombosis in several murine models.
Aims: Determine the molecular domains responsible for FXII contact activation. We used a combination of recombinant FXII mutants, FXII domain-specific antibodies and murine arterial and venous thrombosis models.
Methods: We cloned and recombinantly expressed 19 FXII deletion mutants and studied their susceptibility to kaolin and polyphosphate-induced contact activation *in vitro*. We then reconstituted $FXII^{-/-}$ mice with FXII deletion mutants and challenged them in models of contact activation-mediated thrombosis.
Results: Each FXII deletion mutant was used to reconstitute FXII deficient human plasma. With the exception of the FXII mutant that lacked the proline-rich region, the remaining mutants normalized the prolonged aPTT and corrected thrombin generation to normal. Reconstituting $FXII^{-/-}$ mice with full length FXII restored the time to carotid artery occlusion induced by $FeCl_3$ and resulted in fatal pulmonary emboli (PE) in the collagen-epinephrine model. In contrast, $FXII^{-/-}$ mice reconstituted with the FXII variant lacking the proline-rich region exhibited significantly prolonged time to carotid artery occlusion and survived the fatal collagen-epinephrine PE challenge. We generated an antibody against the proline-rich domain and confirmed that it ameliorates thrombosis *in vitro* and *in vivo*.
Conclusions: The FXII proline-rich region mediates surface activation of zymogen FXII and its inhibition represents a novel therapeutic approach to interfere with thrombotic disorders.

OC 15.3 | Physiological Activation of Factor XII Occurs on the Platelet Surface in a Zinc-dependent Manner

P. Bendapudi, K. DeCeunynck, S. Koseoglu, R. Bekendam, R. Flaumenhaft

Beth Israel Deaconess Medical Center, Hemostasis and Thrombosis, Boston, United States

Background: Factor XII (FXII) inhibition could allow antithrombotic therapy with minimal risk of hemorrhage. FXIIa activity is typically measured in plasma assays following addition of negatively charged activators. However, the physiological mechanism of FXII activation during thrombosis is poorly understood.
Aims: To explore the relative contributions of endothelium and platelets to FXII activation during thrombus formation.
Methods: We used antibody X210-C01, a specific inhibitor of mouse and human FXIIa, in the mouse cremaster laser injury model in order to test the effect of FXIIa inhibition *in vivo*. Fluorogenic and chromogenic assays of thrombin and FXIIa generation were utilized in conjunction with platelet flow cytometry.

Results: Treatment with X210-C01 abolished both platelet accumulation and fibrin formation following laser injury of mouse arterioles. We next explored the differential contributions of platelets and endothelium to FXII-mediated thrombin generation. X210-C01 inhibited platelet-dependent thrombin generation in a dose-dependent fashion, while blocking tissue factor (TF) and factor VIIa (FVIIa) with specific antibodies had no effect. By contrast, thrombin generation by TNF-stimulated endothelium was unaffected by X210-C01 but required FVIIa and TF. Evaluation of the interaction between FXII and platelets by flow cytometry showed that FXII-FITC binds to stimulated platelets in a specific and saturable manner in the presence of Zn^{2+}. This effect was reversed by addition of cold FXII in molar excess and partially reversed by lactadherin, a specific inhibitor of phosphatidylserine. Both platelet-dependent thrombin and FXIIa generation were inhibited by the presence of CaEDTA, a specific zinc chelator, while CaEDTA had no impact on standardized clotting times.

Conclusions: Our findings demonstrate a Zn^{2+}-dependent, FXII-mediated pathway for thrombin generation on platelets that is distinct from fluid-phase coagulation as measured by clinical assays.

OC 15.4 | Neutralizing Blood-borne Polyphosphate In vivo Provides Safe Thromboprotection

A. Di Gennaro[1], L. Labberton[1,2], E. Kenne[1], A.T. Long[2], K.F. Nickel[2], R.A. Rigg[1,3], J.S. Hernandez[4], L. Butler[1,2], C. Maas[5], E.X. Stavrou[6], T. Renné[1,2]

[1]Karolinska Institutet, Molecular Medicine and Surgery, Stockholm, Sweden, [2]Institute of Clinical Chemistry and Laboratory Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, [3]School of Medicine, Oregon Health & Science University, Department of Biomedical Engineering, Portland, United States, [4]Mayo Clinic in Arizona, Division of Laboratory Medicine, Scottsdale, United States, [5]University Medical Center Utrecht, Department of Clinical Chemistry and Haematology, Utrecht, The Netherlands, [6]Louis Stokes Veterans Administration Hospital, Department of Medicine, Division of Hematology and Oncology, Cleveland, United States

Background: Polyphosphate is an inorganic polymer that initiates fibrin formation by activating the factor XII-driven intrinsic pathway of coagulation. *E. coli* exopolyphosphatase (PPX) is a cytoplasmic polyphosphate that catalyzes the hydrolysis of intracellular polyphosphate.

Aims: We develop PPX-based recombinant specific inhibitors of polyphosphate and show that targeting blood-borne polyphosphates confers potent thromboprotection in a factor XII-dependent manner in human blood and murine thrombosis models.

Methods: We cloned and recombinantly expressed PPX mutants. We examined fibrin formation in plasma, procoagulant activity of activated platelets and interference with thrombus formation in flowing blood by targeting polyphosphate with PPX variants. Additionally, we tested the *in vivo* anticoagulant activities of PPX variants in murine thrombosis models.

Results: Using 14 PPX deletion mutants that systematically lack single and combination of PPX domains we found that full size PPX specifically degrades polyphosphate while a PPX variant lacking domains 1 and 2 (PPX_Δ12) binds to the polymer without degrading it. Both PPX and PPX_Δ12 interfered with polyphosphate-driven thrombin formation in human plasma. PPX and PPX_Δ12 interfered with polyphosphate-related procoagulant platelet activity in a factor XII-dependent manner, reduced fibrin accumulation and impeded thrombus formation in blood under flow. PPX and PPX_Δ12 *in vivo* infusions protected wild-type mice from arterial thrombosis and protect animals from activated platelet-induced venous pulmonary embolisms. Despite their potent thromboprotective activities targeting polyphosphates did not increase bleeding from injury sites and did not increase blood loss from wounds.

Conclusions: Our data identify the first selective polyphosphate inhibitors, indicate that polyphosphate drives thrombosis in vivo via factor XII activation and reveal that targeting polyphosphate represents a new approach for interference with thrombotic events without increased bleeding risk.

OC 15.5 | Essential role of High-molecular-Weight Kininogen in Endotoxemia

A. Yang[1,2], B. Wang[1], Z. Xie[1], R.W. Colman[2], J. Dai[2,3], Y. Wu[1,2]

[1]Soochow University, Cyrus Tang Hematology Center, Collaborative Innovation Center of Hematology, Suzhou, China, [2]Temple University School of Medicine, The Sol Sherry Thrombosis Research Center, Philadelphia, PA, United States, [3]Rutgers-New Jersey Medical School, Department of Pathology and Laboratory Medicine, Newark, NJ, United States

Background: Endotoxemia causing systemic inflammation results from persistence of lipopolysaccharide (LPS) in circulation. Which host proteins in plasma exploited by LPS to form endotoxemia remains unknown. Studies have suggested that plasma contact activation system (CAS) is associated with endotoxemia, however, the role of each CAS component in endotoxemia has never been characterized.

Aims: To determine the role of the CAS component in the formation of endotoxemia.

Methods: We generated kininogen 1-knockout (*Kng1*$^{-/-}$) mice by disrupting exons 2 and 3 of *Kng1* gene. The mice lacking each CAS component and their littermate controls were intraperitoneally injected with LPS, followed by observation of survival and measurement of cytokines. Histological changes in organs were observed by H&E staining. Plasma LPS levels were measured by LAL assay. Surface plasmon resonance and LPS-conjugate pull-down assay were used to examine the binding capacity and site of HK with LPS. The dynamic binding of HK and its metabolites to LPS were analyzed in a BODIPY FL-LPS fluorescence assay.

Results: *Kng1*$^{-/-}$ mice were resistant to LPS-induced mortality with significant amelioration of inflammation and organ injury; however, mice lacking prekallikrein and Factor XII exhibited comparable survival rate with WT mice. Circulating LPS levels were significantly reduced in *Kng1*$^{-/-}$ mice. Replenishment of *Kng1*$^{-/-}$ mice with human HK recovered LPS levels and rendered them susceptible to LPS-induced mortality. HK bound to LPS via O-polysaccharide/core oligosaccharide portion. LPS induced HK cleavage to two chain form (HKa) containing heavy chain (HC) and light chain (LC). HKa and LC but not HC disaggregated LPS. LC bound to LPS with a Kd of 1.52 nM. The binding site in LC to LPS was localized at a DHG15 amino acids region of Domain 5 (D5).

A monoclonal antibody against D5 significantly reduced LPS-induced mortality and circulating LPS levels in wild-type mice.

Conclusions: HK, as a major LPS carrier in circulation, is essential for endotoxemic shock.

OC 16.1 | Expression Patterns of F8 Promoter-binding-TFs and F8 Promoter Methylation in Different Endothelial Cells

M.A. Jamil[1], N. Nuesgen[1], J. Oldenburg[1], O. El-Maarri[1,2]

[1]*University of Bonn, Institute of Experimental Haematology and Transfusion Medicine, Bonn, Germany,* [2]*Lebanese American University, Department of Natural Sciences, Beirut, Lebanon*

Background: F8 deficiency causes hemophilia A. Main source of F8 production and secretion is the liver sinusoidal endothelial cells (HHSEC), whereas other endothelial cells also express and secrete F8 but to a less extent; this variability in expression could be caused by epigenetic regulation and/or by differential expression of transcription factors (TFs) binding to the promoter region.

Aims: To study epigenetic regulation and TFs binding sites in 1 kb upstream of F8-TSS.

Methods: Toward explaining the molecular reasons for differences in expression of F8 between different endothelial cells, we used TRANSFAC-database to identify potential-TF binding to the F8 promoter and determine their expression levels in adult and fetal HHSEC and in human umbilical vein endothelial cells (HUVEC) using Illumina human ht12-v4 arrays. Additionally, we analyzed methylation of the F8 promoter region using Illumina-EPIC methylation arrays.

Results: : F8 expression is highest in adult HHSEC, followed by fetal HHSEC than by HUVEC. We found 10 CpGs in the 1 kb upstream of F8-TSS, whose methylation patterns distinguish HUVECs from both fetal and adult HHSEC but with no significant separation power between adult and fetal HHSEC. Twenty TFs matrices were found to bind to the 1 kb region upstream of F8-TSS. These matrices represent unique 155 TFs having 247 probes. After background filtering, 78 out of 155 TFs remained in our dataset having in total 103 probes. We than identified differential expressed TFs that are specifically over expressed in F8 expressing cells. We found that 2 TFs were common between adult and fetal HHSEC against HUVEC. We also found 4 and 7 TFs specific for fetal HHSEC and adult HHSEC respectively in comparison to HUVECs.

Conclusions: In summary, we detected TFs predicted to bind the F8 promoter that are specifically expressed in adult HHSEC. These TFs could be linked to expression and thus secretion potential of F8 by HHSEC.

OC 16.2 | Different N-glycosylation of Factor VIII: Similarities and Differences of Plasma Derived and Recombinant Factor VIII Products

M. Malisauskas, J. Anzengruber, P. Bärnthaler, M. Feichtinger, F. Scheiflinger, B. Reipert

Shire, Vienna, Austria

Background: Neutralizing antibodies against FVIII are a major complication in current therapy for hemophilia A patients. Despite progress in explaining the unwanted immune responses, the cause for development of these antibodies remains unclear. Clinical evidence suggests that there are differences in terms of immunogenicity between plasma derived (pdFVIII) and recombinant FVIII (rFVIII) products, and among different rFVIII. These differences may be attributed to differences in protein glycosylation, which can affect clearance and antigen presentation of FVIII.

Aims: We performed a head-to-head N-glycan analysis of FVIII molecules found in pdFVIII and rFVIII products to identify potential differences and similarities between pdFVIII and rFVIII products.

Methods: N-glycosylation of one pdFVIII and six rFVIII products were analyzed. Each product was prepared by trypsin digestion followed-up with N-glycan release after PNGase F cleavage. The released N-glycans were purified and permethylated, and then analyzed by MALDI-TOF MS. The data were processed using Data explorer® software.

Results: Some N-Glycan epitopes are conserved in both rFVIII and pdFVIII (e.g. high mannose). For the first time, we report the presence of N-glycolylneuraminic acid (Neu5Gc) found on highly purified pdFVIII. rFVIII expressed in HEK cell lines contains glycan epitopes which are absent in pdFVIII (e.g. fucosylated LacdiNAc (LDNF). N-glycan capping with sialic acid differs among the products, and rFVIII expressed in HEK cell lines contain the lowest degree of terminal sialic acid (Table 1).

Conclusions: Plasma derived FVIII and rFVIII show many similarities in N-glycan profile and composition. Surprisingly, rFVIII proteins expressed in HEK cells show the greatest differences to pdFVIII, containing epitopes not detected on pdFVIII. Moreover, we identified Neu5Gc on pdFVIII; thus, this sugar cannot be considered a non-self-epitope found only on rFVIII proteins.

TABLE 1 Terminal N-glycan structure on rFVIII

Terminal glycan structures	rFVIII products						
	pdFVIII	A	B	C	D	E	F
n=1-6 High mannose	+	+	+	+	+	+	+
Blood group ABO	+	–	–	–	–	–	–
N-Acetylneuraminic acid (NANA)	+	+	+	+	+	+	+
N-Glycolylneuraminic acid (Neu5Gc)	+	+	+	+	–	–	+
Fucosylated LDN (LDNF)	–	–	–	–	+	+	–
N-glycan capping with sialic acid	71%	63%	73%	64%	42%	19%	69%

OC 16.3 | Factor VIII with 237 Amino Acids B-domain Has Extended Half-life in Mice

E. Bloem, D.M. Karpf, P.L. Nørby, P.B. Johansen, M. Loftager, H.H. Petersen, G.E. Blouse, L. Thim, G. Bolt, M. Kjalke

Novo Nordisk A/S, Måløv, Denmark

Background: FVIII consists of a light chain (A3-C1-C2) non-covalently linked to a heterogeneous heavy chain (A1-A2-B). Miao *et al.* (Blood 2004) reported increased expression of FVIII with a 226 amino acid (aa) B-domain compared to B-domain deleted and full-length FVIII. This FVIII variant is therefore used in gene therapy studies (Ward, Blood 2011; McIntosh, Blood 2013).

Aims: To characterise FVIII comprising the 226 N-terminal aa fused to the 11 C-terminal aa of the endogenous B-domain (FVIII-237).

Methods: PK of FVIII-237 and FVIII with other lengths of the B-domain was evaluated in *F8*-KO mice. *In vivo* effect of FVIII-237 and FVIII with a 21 aa B-domain (FVIII-21, NovoEight®) were evaluated in a tail vein transection model in *F8*-KO mice. *In vitro* activity was measured in a chromogenic assay. Binding studies were performed using ELISA and surface plasmon resonance (SPR). U87-MG cell binding was quantified using ELISA.

Results: FVIII-237 had specific activity comparable to that of FVIII-21. FVIII-237 was equally effective in reducing bleeding in *F8*-KO mice as FVIII-21. FVIII-237 had a half-life of 10-12h compared to 7-8h for FVIII-21. FVIII with other lengths of the B-domain did not have further increased half-life. Binding studies did not identify any difference in affinity for VWF or a VWF fragment D'D3A1. Interestingly, cell binding was markedly reduced for FVIII-237 compared to FVIII-21. However, binding studies did not show any reduced affinity to low density lipoprotein receptor related protein 1 (LRP) or cluster II thereof, but the maximal binding capacity was reduced. Likewise, the affinity of FVIII-237 for phospholipids (25%PS/75%PC) was not reduced.

Conclusions: FVIII with a 237 aa B-domain had 1.5-fold increased half-life in *F8*-KO mice. This increased half-life appeared to be independent on affinity for VWF, LRP or phospholipids with 25% PS. However, cell surface binding was markedly reduced suggesting reduced interaction with other cellular components.

OC 16.4 | Altered Cleavage of Human Factor VIII at the B-domain and Acidic Region 3 Interface Enhances *in vitro* and *in vivo* Function

G.N. Nguyen[1,2], C.M. Wood[1,2], D.E. Sabatino[1,2,3]

[1]The Children's Hospital of Philadelphia, Raymond G. Perelman Center for Cellular and Molecular Therapeutics, Philadelphia, United States, [2]The Children's Hospital of Philadelphia, Division of Hematology, Philadelphia, United States, [3]Perelman School of Medicine, University of Pennsylvania, Department of Pediatrics, Philadelphia, United States

Background: Furin plays a major role in the proteolytic cleavage of B-domain deleted human factor VIII (hFVIII-BDD), leading to a secretion predominantly in the heterodimer form. Our previous studies demonstrated that when the majority of the furin recognition site (1645-RHQR-1648) is deleted, BDD is cleaved exclusively between S1657 and D1658 in the a3 region.

Aims: Based on our previous results indicating the superiority of hFVIII furin deletion variants and canine FVIII (cFVIII), we hypothesized that modifications of the a3 cleavage site sequence to that of cFVIII (P1657/E1658), with or without furin deletions, may further result in enhanced efficacy.

Methods: hFVIII variants were purified or introduced into AAV8-TTRm-hFVIII to assess hemostatic function.

Results:

SDS-PAGE gel revealed that Δ3 and SP/DE had a 3-fold increase in single chain (SC) polypeptide compared to BDD, while Δ3-SP/DE was secreted almost entirely in the SC form similar to cFVIII (89%). While one-stage aPTT showed no significant difference, two-stage aPTT illustrated that Δ3, SP/DE, and Δ3-SP/DE had a 2-fold increase in activity compared to BDD. When hemophilia A (HA) mice were injected with recombinant protein (10μg/kg) before a tail clip assay, BDD reduced blood loss significantly compared to HA mice injected with PBS (426μL). At the same dose, Δ3, SP/DE, and Δ3-SP/DE were able to reduce blood loss further, comparable to wild-type (WT) mice (58μL). In the gene therapy setting (1e11 vg/mouse), Δ3-SP/DE exhibited a 2-fold increase in expression (97ng/mL) while SP/DE (23ng/mL) resulted in lower FVIII levels compared to BDD (39ng/mL). When these AAV-treated mice underwent a hemostatic tail-clip challenge, BDD decreased blood loss significantly (232μL) compared to HA mice (518μL). Interestingly, both SP/DE (39μL) and Δ3-SP/DE (49μL) further reduced blood loss, comparable to WT mice (31μL).

TABLE 1 Summary of In Vitro Data

Variant		Single Chain (%)	1-stage aPTT ($x10^3$ U/mg) (±SEM)	2-stage aPTT ($x10^3$ U/mg) (±SEM)	Tail Clip Blood Loss (μl) (±SEM)
BDD	hFVIII-BDD	23	10.5 (±0.7)	320.2 (±22.1)	201 (±22)
Δ3	hFVIII-del1645-1647	60	10.6 (±1.5)	673.7 (±17.8)	68 (±16)
SP/DE	hFVIII-S1657P/D1658E	69	12.7 (±0.9)	564.1 (±17.4)	92 (±29)
Δ3-SP/DE	hFVIII-del1645-1647-S1657P/D1658E	99	8.8 (±0.7)	692.0 (±14.0)	98 (±22)

Conclusions: These data suggest that these variants with varying degrees of intracellular processing have enhanced hemostatic function both *in vitro* and *in vivo*.

OC 16.5 | Probing Changes in Activated Factor VIII Upon Complex Formation with Activated Factor IX on Phospholipid Membranes

J. van Galen[1], E.H.T.M. Ebberink[1], N. Freato[1], C. van der Zwaan[1,2], M.G. Boon-Spijker[1], K. Mertens[1,3], M. van den Biggelaar[1], A.B. Meijer[1,2,3]

[1]*Sanquin Research, Department of Plasma Proteins, Amsterdam, The Netherlands,* [2]*Sanquin Research, Department of Research Facilities, Amsterdam, The Netherlands,* [3]*Utrecht University, Utrecht Institute for Pharmaceutical Sciences, Utrecht, The Netherlands*

Background: The crystal structures of factor VIII (FVIII) and electron microscopy structures of membrane-bound FVIII have provided new insight into the structure and function of this cofactor. The changes in activated FVIII(a) that occur upon assembly with activated factor IX (FIXa) on phospholipid membranes, however, remain unclear. Hydrogen-Deuterium eXchange Mass Spectrometry (HDX-MS) now allows for probing alterations in surface accessibility and/or secondary structure of amino acid regions in FVIIIa upon complex formation with FIXa on phospholipid vesicles.

Aims: To assess the molecular changes in FVIIIa upon assembly of the FVIIIa-FIXa complex on phospholipid membranes.

Methods: Thrombin-activated FVIII was incubated with phospholipid vesicles with or without FIXa in a buffer containing deuterated water. HDX-MS analysis was employed to identify regions in FVIIIa with an altered deuterium uptake upon addition of FIXa.

Results: HDX-MS analysis of FVIIIa in absence of FIXa revealed that residues along the A1-A2 and A2-A3 interface showed a marked increase in deuterium incorporation. This suggests that the A2 domain dissociates from FVIIIa. This finding is compatible with the observation that FVIIIa activity is dampened by spontaneous dissociation of the A2 domain. In presence of FIXa, this increased deuterium incorporation along the A domain interfaces was not observed. Instead, mainly region L631-Y636 revealed a reduced deuterium uptake implying that it may directly interact with FIXa. Site-directed mutagenesis confirmed that this region supports the enzymatic activity of FIXa. Intriguingly, the FVIII crystal structure by Shen et al. shows that region L631-Y636 is covered by the acidic a1 and a2 regions, which are flanked by thrombin cleavage sites.

Conclusions: We propose that activation of FVIII liberates region L631-Y636, which contributes to the stimulation of the enzymatic activity of FIXa.

OC 26.1 | A Novel Mouse Model of Carotid Artery Thrombosis for the Evaluation of Thrombolytic Therapies

J. Maclean[1,2,3], A. Samson[1,2,3], S. Sturgeon[3], A. Tomkins[1,2], L. Ju[1,2,3], S. Jackson[1,2,3], S. Schoenwaelder[1,2,3]

[1]*Heart Research Institute, Thrombosis Research Group, Sydney, Australia,* [2]*University of Sydney, Thrombosis Research Group, Sydney, Australia,* [3]*Australian Centre for Blood Diseases, Monash University, Thrombosis Research Group, Melbourne, Australia*

Background: Acute ischaemic stroke is a major cause of disability and death. Currently, only 10% of stroke patients are eligible for rtPA treatment, the only approved thrombolytic agent. The lack of other efficacious therapies is partly due to the paucity of suitable autologous clot-induced stroke models that allow the better understanding of the pathogenesis of stroke and provide insights to the development of effective therapies.

Aims: To develop a mouse model of stroke triggered by *in situ* large artery thrombosis that allows real-time monitoring of recanalization by thrombolysis, in combination with post-recovery functional deficit analysis.

Methods: We developed a mouse *in situ***C**arotid **A**rtery **T**hrombosis (iCAT) stroke model. Occlusive thrombi were created by electrolytic injury to the carotid artery, with transient contralateral carotid occlusion. Cerebral blood flow was monitored using laser speckle contrast imaging at occlusion and 24h post occlusion. The effect of thrombolytic agents on arterial thrombosis was monitored by carotid arterial blood flow for 60min post occlusion, and the impact on brain injury assessed by cerebral perfusion and infarction, and neurological deficits at 24hrs post occlusion.

Results: In our iCAT model, blood flow impairment correlated with brain infarction. These defects were closely associated with neurological deficits and mobility impairment, as analysed with modified Bederson's scoring and open field analysis methodology developed in-house (Samson *et al*., 2015). Intravenous administration of thrombolytic agents (rtPA or integrilin) post occlusion resulted in partial clot lysis and restoration of carotid blood flow in 30% of cases, mild reduction in cerebral infarction and a marked improvement in functional outcome.

Conclusions: This iCAT stroke model represents a new and clinically relevant tool to investigate thrombosis mediated stroke, and can provide multiparameter insights into the cerebral perfusion and functional effects of new thrombolytic agents for stroke.

OC 26.2 | Development of an Inducible Mouse Model for Factor X Deficiency

O.D. Christophe[1], A. Hamieh[1], V. Muczynski[1,2], C. Loubière[1], S. Verhenne[1], C.V. Denis[1], P.J. Lenting[1]

[1]*Inserm Unité 1176, Univ. Paris-Sud, Univ. Paris-Saclay, Le Kremlin Bicetre, France,* [2]*Inovarion, Paris, France*

Background: A complete absence of coagulation factor X (FX) seems incompatible with live, as no patients are known with a complete absence of FX activity. Indeed, inactivation of the *F10* gene in mice

results in about 50% embryonic death, while the remaining mice display neonatal death due to bleeding complications.

Aims: Our goal was to develop and characterize a viable model of inducible FX deficiency.

Methods: C57Bl/6 mice were created containing a *F10* gene with loxP sequences and the *Cre* gene under control of the murine Mx1-promoter (F10-loxP/Cre+). Deficiency is induced upon polyinosynic/polycytidicylic acid (pI:pC) treatment. F10-loxP/Cre- mice were used as control.

Results: Treatment with pI:pC left FX activity in control F10-loxP/Cre- mice unaffected, whereas it led to a severe FX deficiency in F10-loxP/Cre+ mice (< 5% in RVV-X activity assay). Despite this loss of FX activity and antigen, mice were viable and no spontaneous deaths were observed over a 10-month period. Nevertheless, internal hematomas were regularly observed in mice in post-mortem autopsies. Blood count was similar to that of control mice.

Hemostatic activity was analyzed following standardized transection of the caudal vein, which allows distinguishing between primary and secondary hemostasis. Overall, F10-loxP/Cre+ mice were characterized by a strongly increased blood loss over a 60-min period, compatible with the severe FX deficiency. However, whereas control and FVIII-deficient mice ceased bleeding within the first 3 minutes (primary hemostasis), a significant increase in blood loss was observed for F10-loxP/Cre+ mice during this period.

Conclusions: To conclude, we have generated a new viable model of inducible FX-deficiency. Initial analysis confirms the bleeding tendency upon inactivation of the FX gene. Our model will be useful to further study the role of FX in hemostasis, but also in other (patho)-physiological processes.

OC 26.3 | Gene-based FVIIa Prophylaxis Modulates the Spontaneous Bleeding Phenotype of Hemophilia A Rats

S.M. Zintner[1], J.C. Small[1], M.J. Kjelgaard-Hansen[2], B. Wiinberg[2], P. Margaritis[1]

[1]*Children's Hospital of Philadelphia, Pediatrics, Philadelphia, United States,* [2]*Novo Nordisk A/S, Haemophilia Research, Måløv, Denmark*

Background: Gene-based continuous expression of FVIIa successfully treated canine hemophilia[1], however a dose-relationship in preventing spontaneous bleeds was not established in this large animal model. The hemophilia A (HA) rat model also exhibits spontaneous bleeds, and may be a suitable animal model to address this unresolved question.

Aims: To investigate how different circulating levels of ratFVIIa modulate the spontaneous bleeds in HA rats.

Methods: We introduced an intracellular protease cleavage site between the heavy and light chains of ratFVII, resulting in its secretion as ratFVIIa. Stable cell lines expressing ratFVIIa were used for recombinant protein purification. Liver-directed, adeno-associated viral vector (AAV8) mediated ratFVIIa gene transfer was used to obtain sustained expression of ratFVIIa in HA rats, thereby modeling FVIIa prophylaxis. Spontaneous bleeds in naïve and AAV-treated rats were recorded over 16 weeks. Transgene expression above baseline was monitored by ELISA. Spontaneous bleeds were treated on-demand with purified ratFVIIa.

Results: Recombinant ratFVIIa was hemostatic following on-demand administration in HA animals. Naïve HA rats (n=13) exhibited 22 bleeds (1.7 per rat). AAV-treated HA rats (n=34) exhibited 38 bleeds (1.1 per rat) in a ratFVIIa concentration ([ratFVIIa]) dependent manner, as assessed by proportion of bleeding rats at different mean [ratFVIIa] expression: 12/13 (92%) naïve HA rats bled compared to 12/15 (80%) and 9/19 (47%) rats with [ratFVIIa] < 500 or >500 ng/ml, respectively. No bleeds were observed at mean [ratFVIIa] >1250 ng/ml (n=7).

Conclusions: HA rats can be successfully treated with ratFVIIa on-demand. Importantly, using a gene-based FVIIa prophylaxis in HA rats, we determined for the first time that ratFVIIa circulating concentration >500 ng/ml above baseline can reduce spontaneous bleeds, while levels >1250ng/ml can essentially prevent them.

OC 26.4 | Distinct Pathogenesis of Cancer-associated Venous Thrombosis Identifies Tissue Factor-phospholipid Interactions as Selective Antithrombotic Target in vivo

K. Stark[1], I. Schubert[1], U. Joshi[2], S. Pfeiler[2], T. Schmidergall[1], S. Stockhausen[1], N. Mackman[3], B. Engelmann[2], S. Massberg[1]

[1]*Ludwig-Maximilians-University, Cardiology, Munich, Germany,* [2]*Ludwig-Maximilians-University, Laboratoriumsmedizin, Munich, Germany,* [3]*University of North Carolina at Chapel Hill, Chapel Hill, United States*

Background: Pancreatic cancer patients are at high risk of developing venous thromboembolism, which is a leading cause of mortality in this population. How exactly malignant tumors promote deep venous thrombosis (DVT) remains unclear. Here, we addressed the thrombogenic action of microparticles (MP) shed by pancreatic tumor cells in a murine model of DVT.

Aims: It is unkown, if the mechanisms that trigger cancer-associated DVT are similar on a cellular and molecular level to those found in non-malignant thrombosis. Identification of differences in the pathophysiology of cancer-associated DVT could have important therapeutic implications, requiring specific pharmacological approaches distinct from those used to prevent or treat non-malignant thrombosis.

Methods: Flow reduction in the inferior vena cava was induced and thrombi were harvested after 48 hours in *IL4-R/Iba, low-hTF, and SELP*$^{-/-}$mice. MPs were isolated from FG, L3.6pl, and KCP pancreatic adenocarcinoma cell lines or healthy donors. Thrombus formation was visualized by intravital 2-photon microscopy. Mouse primary vein endothelial cells were used for cell culture.

Results: MP derived from pancreatic cancer cell lines caused excessive DVT compared to blood cell derived MP from healthy donors. Unlike blood MP, the prothrombotic activity of pancreatic cancer cell-derived MPs (pcMP) did not depend on platelets or myeloid leukocytes. Instead,

pcMP induced DVT depends on tissue factor delivered by tumor MP and released from host endothelial cells once they are in contact with pcMPs. During cancer-associated thrombosis, the association of TF with the phospholipids is essential and inhibition of this interaction attenuates cancer-associated DVT without affecting normal hemostasis.
Conclusions: Together, distinct prothrombotic pathways drive the pathogenesis of cancer-associated DVT compared to non-malignant DVT. Modulation of phospholipids could serve as a selective novel target for prevention of VTE in cancer patients.

OC 26.5 | Recombinant Destabilase-isopeptidase Stimulates Destruction of Preformed Cross-linked (Old) Thrombi in Rats

S. Kalabushev[1], V. Lazarev[2], V. Manuvera[2], D. Akhaev[1], I. Baskova[1]

[1]Lomonosov Moscow State University, Moscow, Russian Federation, [2]Federal Scientific Clinical Center of Physical-Chemical Medicine, Moscow, Russian Federation

Background: The problem of struggle with old (cross-linked) thrombi is one of the urgent problems of cardiovascular surgery. Proteolytic enzymes can lyse only fresh-formed thrombi. Cross-linkings, slowly formed by blood plasma trans-glutaminases (e.g. factor XIIIa), protect thrombi from proteinase-associated dissolution. The mechanism of cross-links degradation was discovered with the discovery of ε-(γ-Glu)-Lys-isopeptidase, destabilase of the medicinal leech.
Aims: We compared arterial isopeptidase thrombolytic activity of destabilase with proteinase thrombolytic activity of plasmin (streptokinase-activated).
Methods: The study was conducted with 27 male Sprague Dawley rats (weight 450-550 g, age 5 months). All animals were surged to provoke 10% FeCl3-induced arterial thrombosis in carotid artery. Groups in the study: 24h after the surgery animals of Group 1 were intravenously injected saline, Group 2 - streptokinase, Group 3 - destabilase, Group 4 - streptokinase & destabilase. 48h after surgery thrombi were removed, weighted and dissolved in 2% acetic acid.
Results: Streptokinase potentiated thrombolysis by 36% vs. saline. Destabilase administration decreased weight of arterial thrombi vs. saline- and streptokinase-treated rats by 74,6% and 59,3% respectively. Joint use of destabilase and streptokinase decreased weight of thrombi vs. saline and streptokinase by 80,8% and 69,1% respectively. Moreover, the quantity fibrin soluble in 2% acetic acid is higher in the destabilase-exposed thrombi than in any other.
Conclusions: Proteolytic mechanism of thrombolysis discovered by Sherry S.et al. (1954) is only one part, but not thrombolysis itself. The second part is isopeptidolysis, dissolving of cross-links, which appears on the late stage of thrombi formation. Degradation of isopeptide bonds by destabilase is a crucial parameter for stabilized fibrin lysis. It results in slow spontaneous transition of the old thrombi from solid to soluble state. Thus, Destabilase is able to perform proteolysis-independent thrombolysis.

OC 40.1 | Cleaved Kininogen as a Biomarker for Bradykinin Production

Z.L.M. Hofman[1,2], S. de Maat[1], C. Suffritti[3], C.L.R. van Doorn[1], D. Csuka[4], A. Zanichelli[3], N. Veszeli[4], G. Pasterkamp[1], T. Renné[5,6], M. Cicardi[3], H. Farkas[4], E. Hack[2], C. Maas[1]

[1]University Medical Center Utrecht, Laboratory of Clinical Chemistry and Hematology, Utrecht, The Netherlands, [2]University Medical Center Utrecht, Laboratory for Translational Immunology, Utrecht, The Netherlands, [3]Luigi Sacco Hospital Milan, University of Milan, Department of Biomedical and Clinical Sciences, Milan, Italy, [4]Semmelweis University, 3rd Department of Internal Medicine, Budapest, Hungary, [5]Karolinska Institutet and University Hospital, Department of Molecular Medicine and Surgery, Stöckholm, Sweden, [6]University Medical Center Hamburg-Eppendorf, Institute of Clinical Chemistry and Laboratory Medicine, Hamburg, Germany

Background: High molecular weight kininogen (HK) is the cofactor of the plasma contact system. HK deficiency prolongs clotting times in vitro, but not in vivo, suggesting that the physiological role of HK is unrelated to clotting. When plasma kallikrein (PK) cleaves HK, cleaved HK (cHK) and the inflammatory peptide bradykinin (BK) are generated (Fig 1). Patients with hereditary angioedema (HAE) experience recurrent tissue swelling attacks, in which BK is heavily implicated. Direct analysis of BK in plasma is challenging, but immunoblotting studies previously established that cleaved HK is a surrogate marker for BK release.
Aims: To develop an enzyme-linked immunosorbent assay (ELISA) method for cHK to facilitate clinical diagnostics and research.
Methods: Nanobodies against cHK were selected by phage-display. Samples were diluted in buffer containing protease inhibitors to prevent pre-analytical cHK generation and a polyanionic compound was used to improve assay sensitivity by increasing the avidity of the binding interaction. Proof-of-principle clinical validation studies were performed in HAE patient cohorts and analysed using 1-way ANOVA.

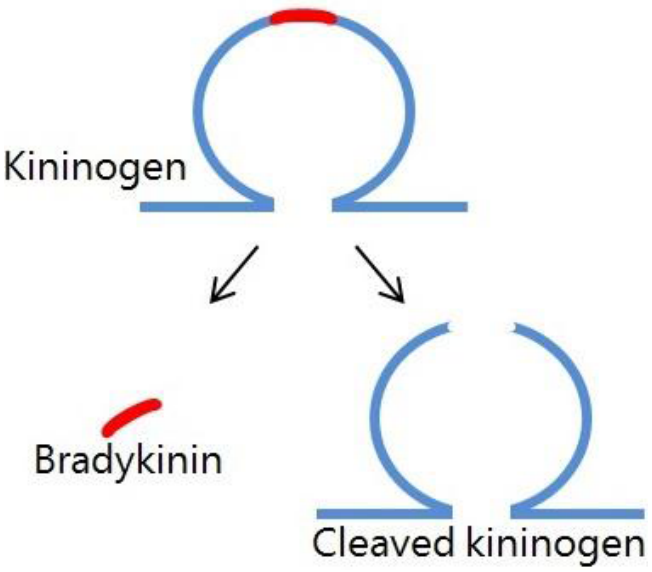

FIGURE 1 Schematic drawing of kininogen cleavage. Kallikrein cleavage of kininogen generates bradykinin and cleaved kininogen

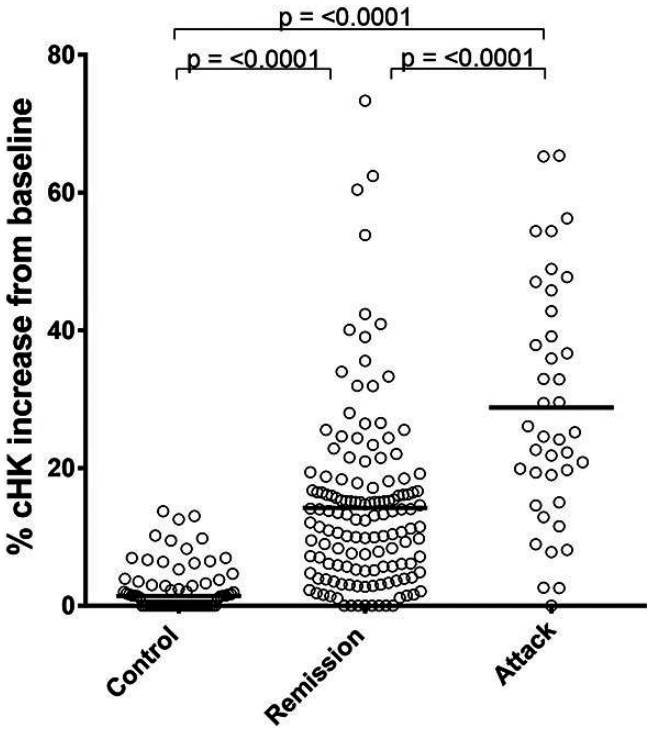

FIGURE 2 cHK levels are increased in HAE. ELISA detection of cHK, bars represent medians, circles samples measured

Results: We developed a nanobody specific for cHK. When we trigger PK activity in plasma, cHK becomes rapidly detectable and remains stable. By comparison, when plasmin activity is triggered in plasma, cHK is only transiently detected. We found that additional cleavage of cHK by plasmin eliminates nanobody recognition. Next, we went on to investigate the levels of cHK in plasma of HAE patient samples (n=178) and controls (n=68). Normal pooled plasma contains low levels of cHK (2-6%). These are significantly elevated in HAE patients that are in clinical remission (n=138) and further elevated during swelling attacks (n=40) (Fig 2).

Conclusions: We developed a detection method for cHK and clinically validated it. We propose that cHK constitutes a promising surrogate biomarker for BK release that should prove useful for investigation of BK-mediated pathology.

OC 40.2 | The Pharmacokinetic Profiles of Intravenously and Subcutaneously Administered Recombinant Factor IX Fc-XTEN in Cynomolgus Monkeys

A. van der Flier[1], A. Ismail[1], N. Moore[1], Z. Liu[1], S. Bardan[1], L. Kurt[1], B. Yang[1], C. Liu[1], V. Schellenberger[2], J. Salas[1], R. Peters[1]

[1]Bioverativ Inc, Waltham, United States, [2]Amunix, Mountain View, United States

Background: Previously we have reported the engineering of rFIXFc-XTEN, a recombinant Factor IX monomeric Fc fusion protein, containing the R338L (Padua) variant for improved activity, combined with a 72 amino acid XTEN insertion in the cleavable activation domain (ASH2015/2016). rFIXFc-XTEN shows in vivo bleeding efficacy and improved pharmacological parameters for subcutaneous dosing in hemophilia B mice.

Aims: Determine the intravenous (IV) and subcutaneous (SC) pharmacokinetic and pharmacodynamic profiles of rFIXFc-XTEN in non-human primates.

Methods: Recombinant FIXFc-XTEN was produced in HEK293 cells and affinity purified. Three cynomolgus monkeys per cohort were dosed with rFIXFc-XTEN (100 IU/kg) by either intravenous or subcutaneous injection. Plasma FIX antigen and FIX activity levels were monitored by rFIXFc-XTEN specific ELISA and FIXFc-XTEN capture chromogenic activity assay, respectively. PK parameters were estimated using Phoenix WinnonLin software. In addition, pre- and post-dosing hematologic and coagulation parameters in blood were assayed.

Results: In cynomolgus monkeys, the IV dosed rFIXFc-XTEN showed a half -life of approximately 43 hours and an AUC/D of 0.301 (h*kg/mL). Subcutaneous dosing of rFIXFc-XTEN showed a prolonged half life of 69 hours and an AUC/D of 0.136 (h*kg/mL). The bioavailability was 45% and clearance 7.5 mL/hr/kg). No adverse effects were observed in this non human primate PK study as determined by various blood parameters.

Conclusions: These non-human primate PK data correlate well with previous findings in HemB mice and support the potential of once weekly or less frequent subcutaneous dosing of rFIXFc-XTEN in humans.

OC 40.3 | Activated FXI Regulates the Catalytic Activity of ADAMTS13 by Removing the CUB Domains

C. Puy, K.S. Garland, T. Shirai, S.E. Reitsma, J. Zilberman-Rudenko, A. Gruber, O.J.T. McCarty

Oregon Health & Science University, Portland, United States

Background: ADAMTS13 cleaves and inactivates von Willebrand factor (VWF), which binds collagen, facilitating platelet adhesion under vascular injury. But is still uncertain how ADAMTS13 activity is regulated. Thrombin and plasmin have been shown to cleave ADAMTS13. Based on the fact that elevated levels of FXI is an independent risk factor for deep vein thrombosis and ischemic stroke, we hypothesize that FXIa inactivates ADAMTS13 leading to platelet aggregation and thrombus formation.

Aims: To determine the functional role of inactivation of ADAMTS13 by FXIa.

Methods: Recombinant ADAMTS13 (250 nM) was incubated with FXIa (50 nM) for increasing times (0-3 hours) at 37°C before being analyzed by western blot using an anti-ADAMTS13 antibody against the two CUB domains (C-terminal) or against the metalloproteinase (MET) domain (N-terminal). ADAMTS13 activity was measured by a fluorogenic substrate (FRETS).

Results: Our results show that FXIa caused the disappearance of the ADAMTS13 band (~200 kDa) and the appearance of a band at ~150 kDa when the samples were analyzed with the anti-MET antibody

and a ~50 kDa band when the samples were analyzed with the anti-CUB antibody. The presence of aprotinin, which inhibits FXIa activity, blocked the degradation of ADAMTS13. Kallikrein or FXIIa were unable to cleave ADAMTS13. Using a cell surface immunoassay we observed that after incubation with FXIa, the detection of the CUB domain from ADAMTS13 was lost from endothelial cells surface. The incubation of ADAMTS13 with FXIa caused an increase in ADAMTS13 activity as measured by using FRETS.

Conclusions: ADAMTS13 circulates in a closed conformation, which is maintained by a CUB-spacer domain binding interaction. ADAMTS13 becomes conformationally activated through interaction of its CUBs domains with VWF. Here we show that FXIa-mediated deletion of ADAMTS13-CUB domains enhances its capacity to cleave FRETS and blocks the interaction with VWF. Our results suggest that FXIa may limit ADAMTS13-mediated VWF inactivation.

OC 40.4 | A Small-Molecule and Direct Inhibitor of Factor Xia Provides Strong Antithrombotic Activity with Low Bleeding in Non-Human Primate Model of Arterial Thrombosis

P. Wong[1], M. Quan[2], C. Watson[1]

[1]*Bristol-Myers Squibb, Cardiovascular Drug Discovery Biology, Pennington, United States,* [2]*Bristol-Myers Squibb, Discovery Chemistry, Pennington, United States*

Background: Factor XIa (FXIa) is a novel target for safer antithrombotic therapy. BMS-724296 (BMS) is a selective, reversible and direct inhibitor of human FXIa with Ki of 0.8 nM.

Aims: BMS has been studied in rabbits, but not in higher species. To strengthen FXIa as an antithrombotic target, we examined BMS in cynomolgus monkey models.

Methods: Arterial thrombosis was produced in the carotid artery by electrical stimulation in anesthetized monkeys. Hemostasis was assessed using a provoked kidney bleeding time (KBT) model. In vivo thrombosis, KBT as well as ex vivo clotting times were monitored in the same animal. BMS (0.025+0.05, 0.05+0.1, 0.102+0.2 and 0.4+0.8 (mg/kg+mg/kg/h)) (n=5-6 per group) or vehicle (n=8) were administered intravenously as a bolus dose plus infusion from 30 min prior to initiation of thrombosis until the end of the experiment. Thrombus weight reduction, KBT and clotting times were determined. Clotting times, including activated partial thromboplastin time (aPTT) and prothrombin time (PT), were measured.

Results: BMS at 0.025+0.05, 0.05+0.1, 0.102+0.2 and 0.4+0.8 mg/kg+mg/kg/h reduced thrombus weight by 0±0, 35±7*, 72±4* and 85±4%*, respectively (*P< 0.05, vs. vehicle). BMS at the top dose of 0.4+0.8 (mg/kg+mg/kg/h) did not increase KBT when compared to vehicle (109±6 sec vs. 111±23 sec in vehicle). BMS at 0.4+0.8 (mg/kg+mg/kg/h) increased ex vivo aPTT by 2.9±0.2-fold without changing PT (1.0±0.0-fold). In companion monkey studies, the standard of care antiplatelet agent clopidogrel at a clinically-equivalent dose (0.3 mg/kg/day given orally for 3 days) reduced thrombus weight by 49±6%, but increased KBT by 7.4±0.4-fold (756±44 sec vs. 103±5 sec in vehicle, n=6/group).

Conclusions: BMS produces strong antithrombotic activity with limited impact on hemostasis as compared to clopidogrel in monkeys. These results support that FXIa inhibition is a safer antithrombotic target, and a small-molecule FXIa inhibitor is currently under clinical investigation (ClinicalTrials.gov Identifier: NCT02902679).

OC 40.5 | New Implications of the Deleterious Role of Furin Processing on Factor VIII Biology

B.J. Samelson-Jones[1,2], J.I. Siner[1], T.V. Daniel[2], V.R. Arruda[1,2]

[1]*The Children's Hospital of Philadelphia, Department of Pediatrics, Philadelphia, United States,* [2]*University of Pennsylvania Perelman School of Medicine, Department of Pediatrics, Philadelphia, United States*

Background: We recently reported that processing by furin has deleterious effects on B-domain deleted Factor VIII (FVIII-BDD) biological activity (Siner *et al* JCI Insight 2016). FVIII-BDD lacking the furin recognition motif (FVIII-ΔF) demonstrated 1) increased secretion from mammalian cells and transduced hepatocytes after liver-directed gene therapy (LDGT) in hemophilia A (HA) models and 2) increased pro-coagulant activity. These results were the opposite of what was previously assumed, but not tested, for decades. Based on this experience, we have now re-examined two related aspects of FVIII biology. First, we investigated the only reported HA causing missense mutation (R1645C) within the furin recognition motif. Second, since dicoumarol, which is structurally related to warfarin, is a known inhibitor of furin, we explored the role of dicoumarol and warfarin on FVIII levels.

Aims: To determine if R1645C changes the expression or specific activity of FVIII-BDD. To test if warfarin/dicoumarol increase FVIII levels due to furin inhibition.

Methods: We used mammalian cell culture and HA mice expressing FVIII variants after LDGT.

Results: FVIII-BDD-R1645C and FVIII-BDD exhibited comparable expression and specific activity, which it is unlikely to cause HA. We observed that the amount of FVIII-BDD secreted from BHK cells increased in a dose-dependent manner with increasing amounts of dicoumarol. The amount of circulating FVIII-BDD in mice fed warfarin decreased after warfarin was discontinued. The relative magnitude of this decrease was significantly larger in mice expressing FVIII-BDD than FVIII-ΔF. This result suggests that this decrease was partly due to the inhibitory effect of warfarin on furin being relieved.

Conclusions: Mutations in the furin site are unlikely to cause HA. Initial results support the hypothesis that warfarin inhibition of furin may be at least partially responsible for the transient increased FVIII levels in patients receiving warfarin and may not impose safety concerns after warfarin therapy.

OC 43.1 | A Non-circulating Pool of Factor XI

B.M. Mohammed[1], Q. Cheng[1], A. Matafonov[1,2], C. Puy[3,4], A. Gruber[3,4], O.J.T. McCarty[3,4], D. Gailani[1]

[1]*Vanderbilt University School of Medicine, Pathology, Microbiology, and Immunology, Nashville, United States,* [2]*Tomsk Polytechnic University, Bioengineering and Organic Chemistry, Tomsk, Russian Federation,* [3]*Oregon Health & Science University, Biomedical Engineering, Portland, United States,* [4]*Oregon Health & Science University, Division of Hematology / Medical Oncology, Portland, United States*

Background: The homologous plasma proteins prekallikrein (PK) and factor XI (FXI) circulate as complexes with high molecular weight kininogen (HK). While it is clear that the PK-HK complex interacts with the vascular endothelium, there is conflicting information regarding HK-dependent or HK-independent FXI binding to endothelium.
Aims: To study the distribution of FXI in the vasculature.
Methods: C57Bl/6 wild-type (WT) mice, or FXI deficient ($FXI^{-/-}$) mice in which human FXI was expressed by hydrodynamic tail injection (HTI), received intravenous infusions of saline (0.9% NaCl), unfractionated heparin, polyphosphate (60-100 phosphate units), or an enzyme that digests glycosaminoglycans (GAGs - heparinase I/III or chondroitinase ABC). Blood was collected at intervals after infusion and plasma was analyzed by western blot for FXI, PK, HK, and factor XII (FXII).
Results: There was significant (>3-5 fold) increases in plasma FXI antigen in WT mice within five minutes of heparin or polyphosphate infusion, but not saline. There were similar increases 30 min after infusion of heparinase or chondroitinase. Levels of PK, FXII and HK did not change with any treatment. Treatment of whole blood ex vivo in a similar manner did not increase plasma FXI, indicating that the increase in FXI in mice is due to release of protein associated with the blood vessel. The releasable non-circulating FXI fraction could be reconstituted in $FXI^{-/-}$ mice by expression of human FXI using HTI. Immunohistochemical analyses of murine saphenous arteries with anti-mouse FXI IgG (14E11) showed FXI associated with the vessel endothelium in WT, but not $FXI^{-/-}$ mice.
Conclusions: Most of the FXI in the vasculature of mice appears to form a non-circulating pool associated non-covalently with blood vessel endothelium. The ability to release FXI with polyanions or by digestion of GAGs suggest that binding is mediated by the interaction between anion binding sites on FXI and endothelial cells surface GAGs.

OC 43.2 | Complex Formation with Pentraxin-2 Regulates Factor X Plasma Levels and Macrophage Interactions

V. Muczynski[1,2], G. Aymé[1], V. Regnault[3], M. Vasse[1,4], D. Borgel[1,5], P. Legendre[1], A. Bazaa[1], A. Harel[1], C. Loubière[1], P.J. Lenting[1], C.V. Denis[1], O.D. Christophe[1]

[1]*INSERM U 1176, Univ. Paris-Sud, Université Paris-Saclay, Le Kremlin-Bicêtre, France,* [2]*Inovarion, Paris, France,* [3]*INSERM U 1116, Université de Lorraine, Vandoeuvre-lès-Nancy, France,* [4]*Hôpital Foch, Biology Department, Suresnes, France,* [5]*Assistance Public-Hôpiteaux de Paris, Hôpital Necker, Service d'Hématologie Biologique, Paris, France*

Background: Recently, we have identified scavenger receptor-AI (SR-AI) as a receptor for coagulation factor X (FX), mediating the formation of a FX-reservoir at the macrophage surface (Muczynski, Blood 2016 127:778). However, a third component was suspected to play a role in the formation of this complex as well.
Aims: We aimed to identify the third component that contributes to the formation of the FX-reservoir.
Methods: Protein- and cell-biological approaches were combined with animal experiments and analysis of human plasmas.
Results: We identified pentraxin-2 as a partner for FX and SR-AI. PTX2 prevents internalization of FX by SR-AI, while it also interferes with SR-AI-mediated internalization of PTX2. Binding studies reveal that FX, SR-AI and PTX2 independently bind to each other (Kd,app: 0.2-0.7 microM). Surprisingly, immune-precipitation experiments revealed that FX and PTX2 circulate as a complex in plasma, and complex formation involves the FX activation peptide. No binding of PTX2 to other vitamin K-dependent proteins was observed. shRNA-mediated inhibition of PTX2 levels in mice resulted not only in reduced levels of PTX2, but also in similarly reduced FX levels. Moreover, PTX2 and FX levels were correspondingly reduced in SR-AI-deficient mice. Analysis of 71 human plasma samples uncovered a strong correlation between FX and PTX2 plasma levels. Furthermore, plasma samples of patients with reduced FX levels (congenital/acquired FX deficiency or after anti-vitamin K treatment) were characterized by concomitantly decreased PTX2 levels.
Conclusions: In conclusion, we identified PTX2 as a novel partner for FX, and both proteins cooperate to prevent their SR-AI-mediated uptake by macrophages. Interestingly, their respective plasma levels are inter-dependent. These findings seem of relevance in perspective of ongoing clinical trials, in which plasma-depletion of PTX2 is used as a therapeutical approach in the management of systemic amyloidosis.

OC 43.3 | Role of the Thrombomodulin - Endothelial Protein C Receptor System in New Vessel Formation Following Ischemia

M.L. Bochenek[1,2], J. Orth[1], S. Reyda[2], H. Spronk[3], T. Münzel[1], W. Ruf[2], K. Schäfer[1]

[1]*University Medical Center, Johannes Gutenberg University, Cardiology I, Mainz, Germany,* [2]*University Medical Center Mainz, Center for Thrombosis and Hemostasis, Mainz, Germany,* [3]*Maastricht University / Cardivascular Research Institute Maastricht (CARIM), Internal Medizin, Maastricht, The Netherlands*

Background: Coagulation proteases play crucial roles during the acute response to endothelial cell injury, chronic vascular healing processes and neovascularization. The role of coagulation signaling in angiogenic processes is less well understood.
Aims: To study the effect of coagulation receptors in ischemia-induced new vessel formation.
Methods: The mouse model of unilateral hindlimb ischemia (HLI) was used to induce new vessel formation and perfusion of the distal hindlimbs was monitored over four weeks using Laser Doppler perfusion imaging (LDPI). Gastrocnemius (GC) muscles of the ischemic and contralateral control hindlimb were analyzed.
Results: Reperfusion of the injured limb was increased in mice hypercoaguable due to a point mutation in the thrombomodulin (TM)

gene ($TM^{Pro/Pro}$ mice) at all time points examined (n=10; P< 0.05). CD31-positive endothelial cells and F4/80-positive macrophages were elevated already in uninjured $TM^{Pro/Pro}$ mice (P< 0.01; P< 0.05) and further increased following ischemia (P< 0.0001 and P< 0.05 respectively). Total cellularity and the number of PCNA-positive proliferating endothelial cells was also significantly upregulated in $TM^{Pro/Pro}$ animals compared to controls (P< 0.0001). Because $TM^{Pro/Pro}$ mice are deficient in thrombin binding and Protein C (PC) activation, we next analyzed mice with endothelial cell deletion of the PC signaling co-receptor endothelial PC receptor (EPCR). $EPCR^{flfl}$/Tie2.Cre mice (n=8) showed reduced hindlimb reperfusion following ischemia, indicating that increased thrombin generation rather than loss of PC signaling the likely cause for enhanced angiogenesis of $TM^{Pro/Pro}$ mice. Consistently, mice lacking the thrombin receptor protease activated receptor-1 (PAR1) showed reduced hindlimb re-perfusion under ischemic conditions (n=5; P< 0.001).

Conclusions: Our results indicate that increased thrombin-PAR1 signaling contributes to the pro-angiogenic phenotype of hyperthrombotic $TM^{Pro/Pro}$ mice.

OC 43.4 | Protective Function of Tissue Factor in Diabetic Nephropathy

J. Manoharan, H. Wang, S. Ghosh, M.M. Al-Dabet, K. Shahzad, B. Isermann

Otto-von-Guericke-University, Department of Clinical Chemistry and Pathobiochemistry, Magdeburg, Germany

Background: Diabetic nephropathy (dNP) is considered to be an inflammatory disease. dNP is closely linked with coagulation activation, which is promoted by tissue factor (TF). TF promotes factor X activation (which aggravates dNP) and signalling *via* PAR2. In addition, TF may regulate cellular function *via* its cytoplasmic domain. Of note, deficiency of TF's cytoplasmic tail (TFCT) protects from experimental glomerulonephritis. Thus, TF may convey disruptive or protective effects in dNP.

Aims: To evaluate the role of TF in dNP.

Methods: First, we analysed expression of TF in control and diabetic (DM) mice (immunoblotting; immunohistochemistry). To evaluate the role of TF in podocytes, we depleted TF in podocytes ($TF^{loxP/loxP}$ x Pod^{cre+}) mice and induced persistent hyperglycemia by injecting streptozotocin in $TF^{loxP/loxP}$ x Pod^{cre+} and wild type (WT) mice. Glomerular injury was analysed by PAS staining, electron microscopy, immunohistochemistry, immunoblotting, and qPCR.

Results: In diabetic $TF^{loxP/loxP}$ x Pod^{cre+} mice albuminuria is increased compared to WT DM. Increased glomerular damage is supported by increased mesangial matrix accumulation, loss of podocytes (Wilms´ Tumor 1 - positive), and increased glomerular basement membrane thickness in diabetic $TF^{loxP/loxP}$ x pod^{cre+} mice. Interestingly, expressions of podocin and nephrin were not altered, suggesting that TF impairs podocyte function independent of these important regulators of podocyte function. Indeed, in dNP the interaction of ß1 integrin and TF was reduced while phosphorylation of TFCT was increased. Loss of TF in podocytes increased active ß catenin and expression of epithelial-mesenchymal transition markers.

Conclusions: Loss of podocyte TF-expression aggravates glomerulopathy in dNP. The current data suggest a critical role of TF in podocytes, which is required for normal podocyte function. Further studies have been initiated to determine the significance of TFCT and the TF-ß1 integrin interaction in podocytes in health and disease.

OC 43.5 | Factor XII Protects Neurons from Serum Deprivation-induced Apoptosis

S. Martinez de Lizarrondo[1], E. Garnier[1], C. Ali[1], A. Chevilley[1], D. Vivien[1,2], F. Docagne[1]

[1]INSERM UMR-S U 1237, Caen, France, [2]Caen University Hospital, Department of Cell Biology, Caen, France

Background: Factor XII (FXII) is a serine protease that participates in the intrinsic coagulation pathway. Several studies have shown a deleterious role for plasmatic FXII in cerebral ischemia and traumatic brain injury. However, the impact of FXII on neuronal cell death remains unknown.

Aims: We investigated the role of FXII and its active counterpart (FXIIa) in neuronal apoptotic cell death.

Methods: We used a model of apoptotic death of murine primary neuronal cultures through serum deprivation.

Results: We observed that both FXII and FXIIa protect primary cortical neurons against apoptotic cell death induced by serum deprivation in a dose-response manner. This effect is blocked by corn trypsin inhibitor (CTI), an inhibitor of the FXII proteolytic domain, suggesting that the antiapoptotic effect of FXIIa is dependent on its proteolytic activity. As potential effectors of this anti-apoptotic effect, we focused on two members of the Erb family of receptors which are expressed by neurons and have been shown to interact with other serine proteases: EGFR and c-Met. EGFR is able to interact with other serine proteases presenting an EGF domain (such as FXII) and c-Met is known to display anti-apoptotic effect in neurons. Interestingly, the anti-apoptotic effect of FXII was blocked by an EGFR inhibitor (AG1478) and the anti-apoptotic effect of FXIIa by a blocking antibody against c-Met. Further experiments demonstrated that the anti-apoptotic effect of FXIIa can be blocked by an antibody against the main ligand for c-met, hepatocyte growth factor. This suggests that FXIIa activates the latent HGF secreted by stressed neurons, thereby leading to c-met activation and anti-apoptotic effects.

Conclusions: Altogether, our results demonstrate a potent anti-apoptotic effect of FXII and FXIIa involving EGFR, HGF and c-MET. Therefore, inhibition of FXII in neurological disorders may have deleterious effects by preventing its beneficial effects in neuronal survival.

OC 55.1 | Multi-ethnic Genome-wide Association Study Identifies New Loci Regulating Factor VIII and von Willebrand Factor

Background: Factor VIII (FVIII) and its carrier protein von Willebrand factor (vWF) are key players in hemostasis. Plasma levels of these factors have been associated with risk of arterial and venous thrombosis and with hemorrhagic disorders.

Aims: To identify novel genes regulating plasma levels of FVIII and vWF.

Methods: We meta-analyzed genome-wide association results from up to 46,232 individuals of European, African, East Asian, and Hispanic ancestry. All studies performed linear regression analysis according to an additive model of inheritance between genome-wide 1000 Genomes imputed variants and natural log transformed phenotype levels, with adjustments for age, sex, and ancestry-informative principal components. Inverse variance weighted meta-analysis was performed within each ancestry group and then combined for a trans-ancestry meta-analysis. Additionally, in order to reveal genes of pleiotropic effect and increase analytical power, a joint analysis of FVIII and vWF was performed using the aSPU model. Finally, *in vitro* gene silencing in cultured endothelial cells was performed for the main candidate genes in order to elucidate the functional gene in each region.

Results: We identified significant associations with vWF at 8 known loci and 9 new loci, including *ST3GAL4*, *C2CD4B*, *TAB1/SYNGR1*, *PDHB*, *FCHO2*, *HLA-DGA1*, *GIMAP7*, *OR13C5*, and *DAB2IP*. Five known and 6 new loci were associated with FVIII, including *FCHO2*, *HLA-DQA1*, *TC2N*, *RPL3*, *SOX17/RP1*, and *LINC00583*. Of these, *SOX17/RP1* and *LINC00583* were uniquely associated with FVIII. Joint analyses of FVIII and vWF data identified 2 newly associated loci near *RAB5C* and *ARSA* genes.

Conclusions: This represents the largest meta-analysis to date to identify genetic determinants regulating FVIII and vWF plasma levels, and new associations were identified. *In vitro* functional follow-up preliminary data contribute to elucidate the role of these novel findings in regulating plasma levels.

OC 55.2 | Exome Enriched Genome-wide Association Analysis Identifies Novel Influence from The *ADCY2* Locus on Circulating Levels of Factor VII Activating Protein (FSAP) Activity

M. Olsson[1], T.M. Stanne[1], A. Pedersén[1], E. Lorentzen[1], E. Kara[2], A. Martinez-Palacian[2], G. Engström[3], O. Melander[3], S.M. Kanse[2], C. Jern[1]

[1]*University of Gothenburg, Gothenburg, Sweden,* [2]*Oslo University Hospital and University of Oslo, Oslo, Norway,* [3]*Lund University, Malmö, Sweden*

Background: Factor VII activating protein (FSAP) plays a role in haemostasis and vascular remodeling. The minor allele of the G534E SNP (Marburg-1; MAF ~0.05 in Caucasians) in the FSAP encoding gene hyaluronan binding protein 2 (*HABP2*) is associated with reduced FSAP activity, and associations have also been reported with stroke, carotid stenosis, and liver fibrosis.

Aims: We sought to identify novel genetic determinants of circulating FSAP activity.

Methods: Plasma concentrations of FSAP activity were measured in samples from 3,260 subjects from the Sahlgrenska Academy Study on Ischemic stroke (SAHLSIS) and the Malmö Diet Cancer study (MDC). For stroke cases (n=600) samples were collected 3 months post-stroke. Genotypes from Illumina chips enriched with 240k exome variants were imputed using the UK10K reference. Genome-wide association scans were conducted to identify genetic variants associated with FSAP activity using age, sex, cohort, and case-control status as covariates. Gene-based tests were used to analyze directly typed rare variants. *Habp2* gene expression was evaluated in primary mouse hepatocytes.

Results: The strongest association was found at the *HABP2* locus with the known Marburg-1 variant as the lead SNP (P value=7.0×10^{-142}). Additional genome-wide significance was found at 5p15 with the lead SNP upstream of adenylate cyclase 2 (*ADCY2*) (rs35510613; P value=1.3×10^{-8}). *HABP2* was significant also in the rare variant analysis. *ADCY2* encodes a protein that catalyzes cAMP formation. Therefore, hepatocytes were treated with the cAMP modifiers, forskolin and 8-CPT-cAMP, and a significant increase in *Habp2* gene expression was observed.

Conclusions: In addition to the *HABP2* locus, the *ADCY2* locus was identified as a potential regulator of FSAP activity, and this finding is supported by *in vitro* data showing that cAMP modifiers influence *Habp2* gene expression. The identification of a novel regulator of FSAP expression will help to further understand the role of FSAP in diseases.

OC 55.3 | High Levels of Latent Antithrombin in Plasma from Patients with Antithrombin Deficiency. New Conformational Mutations and Pleiotropic Deficiency

M.E. de la Morena-Barrio[1,2], E. Sandoval[3], P. Llamas[4], E. Wypasek[5], M. Toderici[1], J. Navarro-Fernández[1], A. Rodríguez-Alen[3], N. Revilla[1], R. López-Gálvez[1], A. Miñano[1], J. Padilla[1], B. de la Morena-Barrio[1], J. Cuesta[3], J. Corral[1,2], V. Vicente[1,2]

[1]Servicio de Hematología y Oncología Médica, Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, Murcia, Spain, [2]CIBERER, Madrid, Spain, [3]Servicio de Hematología y Hemoterapia, Hospital Virgen de la Salud, Toledo, Spain, [4]Servicio de Hematología y Hemoterapia, Fundación Jiménez Díaz, Madrid, Spain, [5]John Paul II Hospital, Institute of Cardiology, Jagiellonian University Medical College, Krakow, Poland

Background: Antithrombin (AT) is an anticoagulant serpin that efficiently inhibits multiple procoagulant proteases. The cost for the structural flexibility required for this function is the vulnerability to mutations that impact its folding pathway. Most conformational mutations identified in serpins cause polymerization. Only 3 mutations in *SERPINC1* affecting 2 residues have been found to favor the transformation to the latent conformation, another hyperstable non-anticoagulant form with strong antiangiogenic activity, which constitutes 3% of plasma AT in healthy subjects.

Aims: To identify mutations causing AT deficiency by favoring the transition to latent conformation.

Methods: 141 unrelated patients with congenital AT deficiency were evaluated by sequencing (Sanger and NGS), electrophoretic assays able to quantify latent AT in plasma and functional methods. Recombinant expression (HEK-EBNA) of selected mutants was also done.

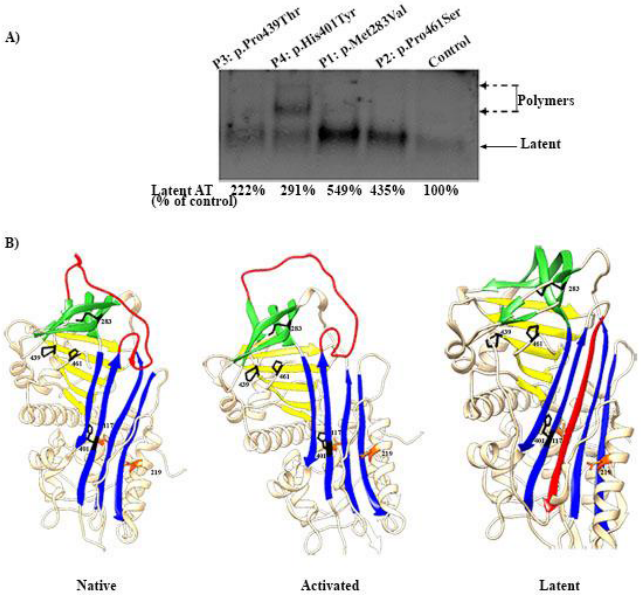

FIGURE 1 Variants associated with high latent levels. A)PAGE of plasma latent AT. B)Residues(black) whose variant favors latent AT(orange, yet described)

Results: 4 cases (2.8% of patients and 4.5% of mutations) had higher levels of latent AT than controls: p.Pro439Thr, p.Pro461Ser, p.Met283Val, and p.His401Tyr (Fig 1), the last also with circulating polymers.

Heating of plasma at 42°C exacerbated the transformation to latent conformation in p.Pro439Thr and p.Pro461Ser.

The conformational effect of p.Met283Val, the mutation associated with the highest levels of latent AT (689%), was verified in a recombinant model.

AT deficiency in these cases should be classified as pleiotropic based on the impaired reactivity and the low heparin affinity of the variant.

Despite high levels of latent AT (up to 80 µg/mL in p.Met283Val), no vascular defects were described in carriers of these mutations.

Conclusions: Our study identifies new residues involved in the structural stability of AT and potentially of other serpins. High levels of endogenous latent AT seem to play a minor antiangiogenic effect. Finally, pleiotropic deficiencies may be caused by mutations inducing transformation to the latent conformation.

OC 55.4 | Spatio-temporal Analysis of Hemostasis by Immunofluorescence Microscopy Following Transection of the Murine Caudal Vein

V. Muczynski[1,2], O.D. Christophe[1], P.J. Lenting[1], C.V. Denis[1]

[1]INSERM U 1176, Univ. Paris-Sud, Université Paris-Saclay, Le Kremlin-Bicêtre, France, [2]Inovarion, Paris, France

Background: Hemostasis is an orchestrated process aiming to minimize blood loss. Previously, microscopical analysis of skin biopsies from healthy persons and hemorrhagic patients provided a first insight into this process. However, novel microscopical techniques now allow us to visualize the involvement of individual proteins during clot formation that seals the vessel wall.

Aims: We analyzed sections of transected mouse tails via immunofluorescence microscopy using antibodies against proteins relevant for hemostasis.

Methods: Tail sections were prepared at different time-points (20sec-20min) after transection of the caudal vein in wt-, FVIII-deficient & VWF-deficient mice. Sections were stained with antibodies against fibrinogen/fibrin (Fn), VWF, platelet-integrin CD41 & the red blood-cell antigen Ter119. Analysis included widefield and confocal microscopy.

Results: Both VWF and platelets could be observed in tissues-sections taken 20 sec after the tail transection, underscoring their role in primary hemostasis. Surprisingly, Fn was also present, indicating that VWF-driven primary hemostasis and coagulation-dependent Fn formation act in parallel immediately following injury. In VWF-deficient mice (which do not stop bleeding), platelets were more dispersed within the wound, forming instable clumps seemingly attached to the Fn-network. Fn formation was delayed in FVIII-deficient mice, but seemed to reach normal levels within minutes compared to wt-mice. Unexpectedly, we observed a near complete co-localization between

VWF and Fn in both wt- and FVIII-deficient mice, pointing to a previously unrecognized, physiologically relevant interaction between VWF and Fn.

Conclusions: We used a standardized bleeding model to monitor the involvement of specific proteins in a spatio-temporal manner during clot formation. This approach reveals that primary hemostasis and the coagulation cascade proceed in parallel to limit blood loss, and two main components (VWF and Fn) co-localize in this process.

OC 55.5 | Water Channel Aquaporin-1 Regulates the Platelet Procoagulant Response and *in vivo* Thrombus Formation

E.O. Agbani[1], C.M. Williams[1], M.T.J. VanDenBosch[2], S.F. Moore[1], A. Mauroux[1], L. Hodgson[3], A.S. Verkman[4], I. Hers[1], A.W. Poole[1]

[1]*University of Bristol, School of Physiology, Pharmacology and Neuroscience, Bristol, United Kingdom,* [2]*British Columbia Cancer Research Centre, Genome Sciences Centre, British Columbia, Canada,* [3]*University of Bristol, Wolfson Bio-Imaging Facility, Bristol, United Kingdom,* [4]*University of California San Francisco, Departments of Medicine and Physiology, San Francisco, USA., United States*

Background: We recently showed that the mechanism of platelet procoagulant membrane dynamics is dependent upon a coordinated system of fluid entry. We now hypothesise that the water channel aquaporin-1 (AQP1) is a molecular mediator of this event.

Aims: To establish the role of AQP1 in platelet procoagulant response and thrombosis *in vivo*.

Methods: Western blotting, immunocytochemistry and immunogold labelling, super-resolution microscopy, 4D live-platelet imaging and FLIM-FRET, thromboelastometry and $FeCl_3$ model of arterial thrombosis.

Results: We found AQP1 expression in human and mouse platelets was localised to internal tubular membrane structures, likely the open cannanicular system. Interactions between AQP1 and ERM proteins (Ezrin, Radixin, Moesin) were minimal, but the ablation of AQP1 significantly altered moesin phosphorylation. While membrane ballooning in response to fibrillar collagen was unaffected by AQP1 deletion, $AQP1^{-/-}$ platelets showed a marked reduction in procoagulant-spreading (64.1±2.3% vs 14.14±3.9%) and microvesiculation (356±58 vs 142±16/view) under this condition. Furthermore, haemostasis after tail bleeding remained unaffected, but thrombus formation *in vivo* was markedly suppressed by 79.3±8.8% in $AQP1^{-/-}$ mice after $FeCl_3$ injury to carotid arteries. In addition, *in vitro* platelet exchange experiments showed a platelet-specific delay in clotting time and clot formation time.

Conclusions: AQP1 is a key regulator of the platelet procoagulant response. Our data suggest AQP1 may modulate coagulation after injury or pathologic stimuli without affecting normal haemostasis, making it a suitable target for the control of thrombotic events. Thus, AQP1 inhibitors may represent a novel class of antiprocoagulant antithrombotics.

OC 71.1 | The Phosphate Transporter XPR1 Regulates Platelet Polyphosphate Metabolism

M. Allende[1], S. Gambaryan[2], D. Firsov[3], T. Renné[1,4]

[1]*Karolinska Institutet, Stockholm, Sweden,* [2]*Institute of Evolutionary Physiology, Russian Academy of Science, St. Petersburg, Russian Federation,* [3]*University of Lausanne, Lausanne, Switzerland,* [4]*University Medical Center Hamburg-Eppendorf, Hamburg, Germany*

Background: Platelet polyphosphate (polyP) is a procoagulant inorganic molecule that drives thrombosis. PolyP functions as storage pool for phosphate and intracellular levels of polyP and phosphate are linked in prokaryotes. Xenotropic and polytropic virus receptor 1 (XPR1) regulates phosphate homeostasis in mammalians.

Aims: We hypothesized that XPR1 regulates platelet polyP levels with implications for thrombosis.

Methods: PolyP levels and chain length were analyzed in cells including human megakaryocytes dependent on knockdown or overexpression of XPR1. We produced XPR1 gene-floxed mice and crossed them with animals expressing Cre recombinase under the control of the platelet factor 4 promoter to ablate XPR1 expression in platelets.

Results: Antibodies against the N- and C-terminal region of the protein detected XPR1 in membranes of human and mouse platelets. XPR1 overexpression dose-dependently significantly reduced polyP levels in HEK293 and MEG-01 cells, respectively. Vice versa, down-regulation of the transporter with XPR1-specific siRNA largely increased polyP levels. Modulation of XPR1 affected long chain but not short chain polyP. Based on the cellular data transgenic mice with platelet specific deletion of XPR1 will be phenotyped in platelet-mediated murine thrombosis models to unravel the role of XPR1 in thrombosis.

Conclusions: XPR1 expression modulates intracellular polyP levels and alters polyP size distribution with implications for thrombosis. Thus XPR1 is a promising anticoagulant drug target.

OC 71.2 | Lack of FXI on Top of Platelet Depletion Does Not Increase Gastrointestinal Bleeding in Mice

M.V. Schmidt, J. Mueller, S. Heitmeier, F. Buehning, U. Lange, A. Buchmueller, V. Laux

Bayer AG, Wuppertal, Germany

Background: Gastrointestinal (GI) bleeding is one of the most prominent bleeding complications in patients at high risk for thrombotic events who are treated with anti-coagulants in combination with anti-platelet drugs. Therefore, better anti-coagulants showing strong anti-thrombotic potency without GI bleeding complications are needed. Factor XI (FXI) inhibition is regarded as potent and safe with respect to thrombosis prevention and acute bleeding. However, the effects of FXI depletion on GI bleeding especially in combination with platelet depletion have not yet been tested.

Aims: Therefore, our aim was to investigate the impact of FXI deficiency, platelet depletion, and a combination thereof on GI bleeding in mice.
Methods: For this purpose, we used wild type (WT) or FXI knockout mice (FXI-ko). To mimic platelet inhibition, the platelet depleting antibody R300 (0.3 mg/kg i.v.) was applied. GI bleeding was induced by oral treatment with 20 mg/kg indomethacin (IMC). To quantify GI blood loss hemoglobin (HB) levels were measured 24 hours after IMC application. Haemoccult tests of gastric content and feces were used to identify blood loss via gastrointestinal lesions.
Results: Upon GI bleeding induction with IMC, FXI-ko mice showed no additional HB decrease compared to WT mice (-10% HB and -9.1% HB, respectively). In WT mice, platelet depletion (>95%) dose-dependently promoted blood loss upon IMC application to up to 40% HB reduction. Even on top of platelet depletion, blood loss via GI bleeding was not increased in FXI-ko mice compared to WT mice.
Conclusions: To develop potent and safe new anticoagulants, we evaluated the effect of FXI inhibition in combination with platelet depletion in a newly developed GI bleeding model in mice. FXI inhibition did not show increased GI bleeding tendency, even on top of platelet depletion. Therefore, targeting FXI might represent a potent and safe new anti-thrombotic treatment regime.

OC 71.3 | Defining Differential Effects of Direct fXa *versus* fIIa Inhibition on Coagulation and Inflammation

S. Nazir, K. Shahzad, I. Gadi, M. Al-Dabet, S. Kohli, S. Ranjan, B. Isermann

University Clinic Magdeburg, Magdeburg, Germany

Background: Thrombin is the key protease in regard to thrombus formation. However, in regard to protease dependent signaling other coagulation proteases, including fXa, likewise convey cellular effects.
Aims: We postulate that inhibition of fXa or fIIa convey different effects in regard to inflammation despite comparable anticoagulant efficacy.
Methods: WT mice were treated with different doses of dabigatran (direct fIIa inhibitor) or rivaroxaban (direct fXa inhibitor) or PBS (control) for 1 week. We then conducted tail-bleeding assay, arterial injury induced thrombosis formation, or LAD ligation (ischemic/reperfusion) induced myocardial infarction.
Results: Using *in vivo* assays we determined doses of rivaroxaban and dabigatran conveying comparable effects in regard to bleeding and thrombosis. Using - in regard to hemostasis - equally potent dosages of fIIa and fXa inhibitors we analyzed the impact of direct fIIa and fXa inhibition on myocardial infarction. Direct fIIa and fXa inhibition resulted in comparable infarct size. However, while an anti-inflammatory was observed following direct fXa inhibition, this was not apparent following direct fIIa inhibition. Furthermore, fXa inhibition, but not fIIa inhibition, reduced expression of pro-inflammatory cytokines (IL-6, TNF-alpha), NF-κB activation, and macrophages infiltration in infarcted heart tissue. Mechanistically, fIIa inhibition, but not fXa inhibition, resulted in lower endogenous protein C (PC) activation. Importantly, the protective effects following fXa inhibition were lost following inhibition of endogenous aPC (mAb MPC1609).
Conclusions: Taken together, these results demonstrate that inhibition of fIIa and fXa can convey distinct anti-inflammatory effects despite equal anticoagulant efficacy. Following direct fXa inhibition sufficient thrombin to promote protein C activation appears to be available, resulting in preserved thrombin-dependent protein C activation and cytoprotection.

OC 71.4 | Characterization of Activated Protein C (APC) Antibodies: Preferential Inhibition of APC's Anticoagulant Activity over Cytoprotective Activity

L.O. Mosnier[1], C. Patel[2], X.-Y. Zhao[3], S. Yegneswaran[2]

[1]*The Scripps Research Institute, Department of Molecular Medicine, La Jolla, United States,* [2]*Bayer, US Innovation Center, Hematology Research, San Francisco, United States,* [3]*Bayer, US Innovation Center, Biologics Research, San Francisco, United States*

Background: APC is a major endogenous anticoagulant, making it an attractive target for hemophilia bypass therapy when factor replacement is not possible. APC also mediates beneficial cytoprotective activities that require endothelial protein C receptor-dependent activation of protease-activated receptor (PAR) 1. A complication for targeting APC is the deleterious effects associated with inhibition of its cytoprotective effects.
Aims: To characterize the selectivity of the humanized anti-APC antibody (Ab) 4885 and its parental murine Ab HAPC1573 for inhibition of APC's anticoagulant versus cytoprotective activities.
Methods: Anticoagulant activity was measured using APTT and thrombin generation (TG) assays and cytoprotective activity by PAR1 cleavage assays and endothelial barrier function using iCelligence.
Results: The Abs specifically bound APC (Kd 3-7 nM) and inhibited APC anticoagulant activity in APTT and TG assays (>95% inhibition at 1:4 APC:Ab molar ratio [mr]). Both Abs prevented APC-mediated degradation of FVIIIa (>90%) and FVa heavy chain (~86%) and protected FVa activity (~75%) in prothrombinase assays. APC-mediated PAR1 peptide cleavage at both Arg41 and Arg46 was inhibited by ~50%. Titration of Ab 4885 showed a reduction of APC-mediated protection against thrombin-induced endothelial permeability to a plateau of ~55% of normal at ≥1:15 mr APC:Ab. Nevertheless, PAR1 cleavage on EA.hy926 endothelial cells as measured by disappearance of the Arg46-sensitive ATAP2 epitope was not significantly reduced by either Abs at a 4-fold mr Ab:APC. APC barrier protection was also unaffected under these conditions. Thus, Ab 4885 has ≥10-fold selectivity for inhibition of APC anticoagulant versus barrier protective activities.
Conclusions: The APC anticoagulant pathway is activated disproportionally in hemophilia and APC may directly contribute to bleeding. We demonstrate that Ab 4885 and HAPC1573 are functionally selective for preferential inhibition of anticoagulant activity versus cytoprotective activities of APC.

OC 71.5 | Establishment of a Reporter Cell Line for the Functional Screening of Vitamin K Cycle Enzymes

J.-K. Tie, D.-Y. Jin, D. Stafford

University of North Carolina at Chapel Hill, Biology, Chapel Hill, United States

Background: Vitamin K-dependent (VKD) carboxylation is a post-translational modification that is essential for the function of coagulation factors. Defects in carboxylation cause mainly bleeding disorders. VKD carboxylation requires three membrane proteins: gamma-glutamyl carboxylase (GGCX), vitamin K epoxide reductase (VKOR), and vitamin K reductase (VKR). Although the genes encoding GGCX and VKOR are known, the identity of VKR remains elusive. This is mainly because traditional biochemical approaches for protein identification are unsuccessful for identifying membrane proteins.

Aims: The goal of this study is to establish a reporter cell line that can accommodate the genome-scale loss-of-function screening of vitamin K cycle enzymes.

Methods: We fused the gla domain of factor IX (FIXgla) and an HPC4 tag to a single transmembrane domain protein. We expressed the chimeric protein, which functions as a cell surface reporter protein, in mammalian cells, and used immuno-staining, fluorescence confocal imaging, and fluorescence-activated cell sorting (FACS) to distinguish the carboxylation status of the reporter cells.

Results: We cultured reporter cells with vitamin K or warfarin, and stained them with fluorescence labeled antibodies of anti-carboxylated FIXgla and HPC4 tag. Figure 1A shows that the chimeric reporter protein is properly expressed on the cell surface, and the two-color antibody staining distinguishes the cells' carboxylation status. Flow cytometry analysis shows that carboxylated or uncarboxylated cells can be clearly separated from the unstained cells (Figure 1B). Furthermore, when a mixture of carboxylated and uncarboxylated reporter cells were co-stained by these two fluorescence labeled antibodies, cells that lost their carboxylation function are clearly separated from the carboxylated cells.

Conclusions: Our results suggest that the established reporter cell line, in combination with FACS, is a powerful tool for high-throughput loss-of-function screening for enzymes of the vitamin K cycle.

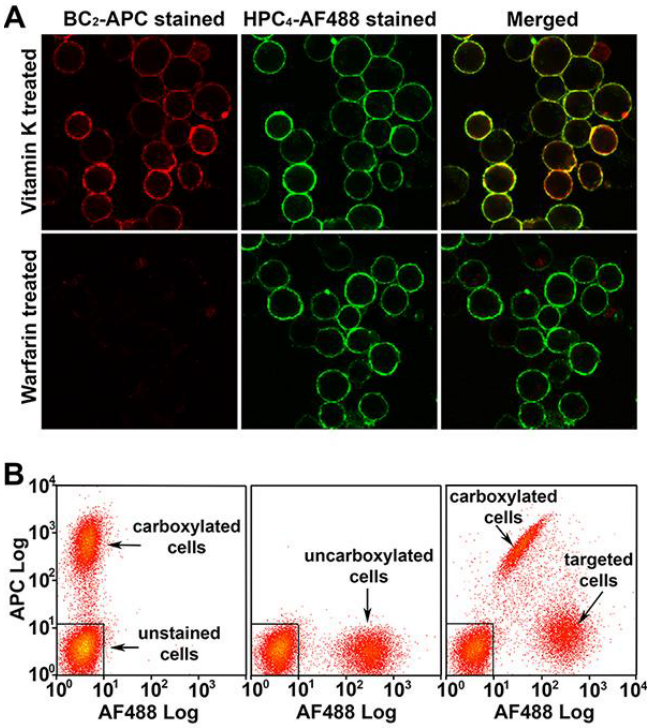

FIGURE 1 (A) Confocal images of carboxylated (top) and uncarboxylated (bottom) reporter cells. (B) FACS analysis of the immune-stained reporter cells

OC 72.1 | The Role of Fibrinogen's αC Regions in the Early Stages of Fibrin Polymerization

A.D. Protopopova[1], R.I. Litvinov[1,2], D.K. Galanakis[3], N.A. Barinov[4], C. Nagaswami[1], A.R. Mukhitov[1], D.V. Klinov[4], J.W. Weisel[1]

[1]University of Pennsylvania, School of Medicine, Cell and Developmental Biology, Philadelphia, United States, [2]Kazan Federal University, Kazan, Russian Federation, [3]SUNY at Stony Brook School of Medicine, Stony Brook, United States, [4]Scientific Research Institute of Physical-Chemical Medicine, Moscow, Russian Federation

Background: The C-terminal parts of fibrinogen's (Fg's) Aα chains called the αC regions are ≈400-residues long, mostly disordered and flexible. They are thought to mediate intermolecular interactions during fibrin formation, although many aspects of their structure and functions remain unknown.

Aims: To study the involvement of the Fg's αC regions in the early stages of fibrin formation and structural consequences of their presence or absence.

Methods: We used high-resolution atomic force microscopy to image Fg monomers and fibrin oligomers made from a plasma-purified full-length human Fg or a Fg sub-fraction I-9 lacking most of the αC regions. To correlate structural and functional data, we used concurrent dynamic turbiditimetry, confocal microscopy, and scanning electron microscopy.

Results: The incidence of the αC regions was 50% in the full-length Fg compared to 19% in Fg I-9. The residual αC regions in Fg I-9 were shorter than in the full-length Fg. More αC regions were seen in fibrin oligomers than in corresponding Fg monomers; but in the full-length Fg, unlike Fg I-9, the αC regions' length increased upon oligomerization, suggesting exposure and involvement of the αC regions. Dynamic turbidity correlated with confocal and scanning electron microscopy imaging of clots and revealed a significant effect of the αC regions on fibrin polymerization kinetics and the final clot structure. Specifically, in Fg I-9 an average lag time was longer than in full-length Fg and the rate of lateral aggregation was smaller indicating impaired protofibril formation and lateral aggregation. The lower maximum turbidity of I-9 clots corresponded to confocal and scanning electron microscopy data showing that fibrin fibers formed from Fg I-9 were thinner than those formed from the full-length Fg.

Conclusions: These results provide a direct structural basis for the functional role of the αC regions in the early stages of fibrin polymerization, with important implications for clot structure and thrombus properties in vivo.

OC 72.2 | The Role of Thrombin Exosites 1 and 2 in the Activation of Factor XI by Thrombin

V. Patel[1,2], K. Chen[2], B. Leslie[2], A. Stafford[2], J. Fredenburgh[2], J. Weitz[2]

[1]McMaster University, Medical Sciences, Hamilton, Canada, [2]McMaster University and Thrombosis and Atherosclerosis Research Institute, Medicine, Hamilton, Canada

Background: There is mounting evidence that the contact pathway is important for thrombus stabilization and growth. Thrombin activation of factor (F) XI is one mechanism by which the contact pathway is bypassed in thrombosis.

Aims: To examine the role of the exosites of thrombin in activating FXI using exosite-binding aptamers and exosite-impaired thrombin variants.

Methods: FXI was incubating with α-thrombin, exosite-1-deficient thrombin (γ-thrombin), or exosite-2 mutant thrombin (RA-thrombin) for 30 minutes at 37°C and FXIa generation was monitored by chromogenic activity after hirudin addition. Studies were done in the absence or presence of dextran sulfate with molecular weights of 500,000 (DS-500) or 5,000 (DS-5) or exosite 1 or 2 directed DNA aptamers (HD1 and HD22, respectively).

Results: Titration of DS-500 in the FXI activation by α-thrombin resulted in a bell-shaped curve with the peak at 2 μg/ml. This suggests that DS serves as a template to promote FXI activation by formation of a ternary complex. Similar profiles were observed when activation was catalyzed by γ-thrombin and RA-thrombin, suggesting that either exosite can mediate ternary complex formation. The DS-5 titration using α-thrombin also showed a bell-shaped curve, however, γ-thrombin and RA-thrombin did not promote activation. This suggests that longer DS chains are required to mediate ternary complex formation. In the presence of DS-500, HD22 attenuates FXI activation by α-thrombin 2-fold more than HD1. This suggests that while both exosites are necessary in the activation of FXI, exosite 2 has a more significant role. In the presence of DS-5, HD22 attenuated FXI activation, whereas HD1 had only a modest effect.

Conclusions: Although either exosite of thrombin can mediate the ternary complex formation necessary for FXI activation by thrombin, exosite-2 appears to be more important. Involvement of the exosites is also dependent on the template length.

OC 72.3 | Clot-bound Thrombin Characterization of Plasma Clots in a Flow Reactor

L.M. Haynes, T. Orfeo, K.E. Brummel-Ziedins

University of Vermont, Biochemistry, Colchester, United States

Background: Thrombin binds to fibrin via exosite mediated interactions, remaining a functional enzyme that stabilizes clots. The amount of thrombin incorporated in the clot is a function of both thrombin generation intensity and clot structure.

Aims: To characterize clot-bound thrombin activity in a plasma-based system under venous flow conditions.

Methods: Pooled citrated normal human plasma was diluted (1:4) with citrate containing buffer and clotting was initiated with either tissue factor or aPTT reagent under static conditions in the bottom of a flow chamber (50 mm x 7 mm x 0.25 mm; 87.5 μL). A fluorescent, thrombin-specific substrate (SN-59; 100 μM) containing buffer was flowed through the chamber (92 sec^{-1}) and the effluent collected dropwise into 2% SDS for 1000 sec. The fluorescence intensity of the effluent directly correlates with the amount of active/available clot-bound thrombin. In some experiments, antithrombin (0.5 μM; AT) and/or unfractionated heparin (0.5-4 U/mL; UFH) was included in the flowing solution. To induce hemophilia B, an inhibitory α-factor IX mAb (0.1 mg/mL) was incubated with the plasma.

Results: Fibrin-adhered thrombin formed under all conditions was stable for 1000 sec. UFH alone did not inhibit clot-bound thrombin while AT with UFH, inhibited 60-70% of thrombin activity. AT alone in the flowing solution decreased thrombin activity by 30%, suggesting the constant resupply of AT from the flowing phase can have a more rapid impact on clot-bound thrombin activity than expected from plasma based closed systems. Induced hemophilia B clots had 25% less clot-bound thrombin activity than normal clots, consistent with discordant fibrin structure and thrombin generation.

Conclusions: Under flow, the majority of thrombin activity associated with plasma clots is not derived from α_2-macroglobulin-thrombin complexes and is thus available to interact with macromolecular substrates. This pool of fibrin-associated thrombin appears to be more susceptible to AT inhibition than previously expected.

OC 72.4 | Thrombospondin 1 is Required for Fibrin Accumulation during Thrombus Formation

S. Grover, K. De Ceunynck, S. Schulman, R. Flaumenhaft, B. Furie

BIDMC/Harvard Medical School, Hemostasis and Thrombosis, Boston, United States

Background: Thrombospondin 1 (TSP1) is a homo-trimeric matricellular glycoprotein previously implicated in the pathogenesis of arterial thrombus formation. While TSP1 is considered an important mediator of platelet activation, a role for TSP1 in the regulation of fibrin formation has yet to be established.

Aims: To determine whether TSP1 is required for fibrin accumulation during thrombus formation.

Methods: Laser-injury induced thrombus formation was assessed in cremaster muscle arterioles of TSP1 knockout mice or mice infused with an anti-TSP1 antibody (A6.1) by wide-field fluorescence microscopy. Accumulation of TSP1 at the site of vascular injury was assessed in the presence or absence of the GPIIb/IIIa antagonist eptifibatide.

Results: Supportive of a role in thrombus formation, TSP1 was found to accumulate at the site of vascular injury ($P < 0.0001$). Localization of TSP1 by confocal microscopy revealed accumulation predominantly

occurred at the interface of the platelet thrombus and vessel wall. The proximity of TSP1 to the vascular wall led us to investigate whether TSP1 could regulate fibrin generation at the site of injury. TSP1 knockout mice demonstrated impaired accumulation of fibrin (60%) and platelets (80%) after laser-induced injury (P< 0.05). Similar findings were obtained after infusion of the C-terminal binding anti-TSP1 antibody A6.1 (P< 0.05); confirming that TSP1 is required for the generation of fibrin *in vivo*. Treatment with eptifibatide, a selective platelet inhibitor, partially reduced TSP1 accumulation
(60%, P< 0.01) indicating that platelets, although a major source of injury resident TSP1, may not be the only cellular contributor.
Conclusions: These data suggest that fibrin accumulation occurs in a TSP1 dependent manner during thrombus formation.

OC 72.5 | A Critical Role of Factor XI Feedback Activation for Placental Hemostasis

A. Jämsä[1], H.M.H. Spronk[2], D. Gailani[3], N. Mackman[4], T. Renné[1,5]

[1]*Karolinska Institutet, Molecular Medicine and Surgery, Clinical Chemistry, Stockholm, Sweden,* [2]*Maastricht University Medical Center, Department of Internal Medicine, Cardiovascular Research Institute Maatricht, Laboratory for Clinical Thrombosis and Haemostasis, Maastricht, The Netherlands,* [3]*Vanderbilt University, Hematology/Oncology Division, Nashville, United States,* [4]*University of North Carolina at Chapel Hill, Department of Medicine, Division of Hematology and Oncology, Chapel Hill, United States,* [5]*University Medical Center Hamburg-Eppendorf, Institute of Clinical Chemistry and Laboratory Medicine, Hamburg, Germany*

Background: Blood coagulation factor XI (FXI) can be activated by factor XII or thrombin. While factor XII-mediated FXI activation has a crucial role for thrombosis, a potential *in vivo* function of thrombin-driven FXI activation (feedback activation) has remained enigmatic.
Aims: We aimed to analyze the *in vivo* role of FXI-feedback activation.
Methods: To target the FXI-feedback loop, low tissue factor (TF) mice were bred with FXI- and FXII-null animals.
Results: We found that combined deficiency in TF and FXI was associated with embryonic lethality. In contrast, mice with combined deficiency in TF and factor XII were viable and did not differ from low TF animals. $FXI^{-/-}$/low TF embryos develop normally and were found within the expected Mendelian distribution at late gestation but suffered from morphological signs of degeneration. Bioinformatics of RNA-seq data from $FXI^{-/-}$/low TF embryonic tissues revealed defective thrombin signaling but normal vessel homeostasis in the placenta. Histological analyses of $FXI^{-/-}$/low TF placentas showed enlarged maternal blood spaces, disruptions in trophoblast cell layer and hemorrhage of maternal blood in the labyrinth, a pathology more severe than in placentas of low TF mice. Expression of FXI in pregnant mice prevented bleeding in $FXI^{-/-}$/low TF placentas and rescued the lethal phenotype of $FXI^{-/-}$/low TF mice.
Conclusions: Our study suggests a critical role for FXI feedback activation for placental hemostasis and development. The data identify an unexpected role for FXI in reproduction with possible implications for pharmacological targeting of the protease.

COAGULATION SIGNALING & IMMUNITY

OC 05.1 | The Lipid-raft Organizer Tetherin Negatively Regulates Platelet Receptor Function

X. Zhao[1], D. Alibhai[1], J.L. Hutchinson[1], S. Cross[1], C.M. McKinnon[1], R. Aungraheeta[1], A. Poole[1], G. Banting[2], S.J. Mundell[1]

[1]*School of Physiology, Pharmacology and Neuroscience, Faculty of Biomedical Sciences, University of Bristol, Bristol, United Kingdom, Bristol, United Kingdom,* [2]*School of Biochemistry, University of Bristol, Bristol, United Kingdom, Bristol, United Kingdom*

Background: Tetherin (also known as CD317 or BST2) is a lipid raft-associated transmembrane protein that regulates host response to viral infection by inhibiting viral particle release (1). This integral membrane protein, reported to play a role in lipid raft organization (2), is expressed in platelets although its physiological function is unknown. The function of a number of platelet receptors appears to be dependent upon their residence in lipid rafts although little is known about the mechanisms regulating their surface compartmentalisation.
Aims: To characterize the physiological relevance of tetherin in relation to platelet function.
Methods: Platelet receptor function was assessed in tetherin (-/-) and wild-type (WT) mouse platelets as previously described (3).
Results: Studies in tetherin (-/-) platelets established that this protein negatively regulates platelet aggregation downstream of a number of platelet receptors. CRP, and thrombin-stimulated platelet aggregation was significantly enhanced in tetherin (-/-) platelets with greatest effects evident at sub-maximal agonist concentrations. This effect was maintained in the presence of $P2Y_{12}R$ antagonists indicative of a more direct effect on GPVI and PAR4 receptor activity. Subsequent study established that reduced tetherin expression enhanced signalling downstream of GPVI and PAR4. Importantly there was no significant change in the surface expression of either GPVI or PAR4 as assessed by FACs. Initial studies in cell lines suggest that both GPVI and PAR4 receptor have the potential to interact with tetherin.
Conclusions: We demonstrate for the first time the physiological relevance of tetherin showing that it negatively regulates the function of a number of lipid raft associated platelet receptors.

OC 05.2 | bPAR-1 Protects Mice from Influenza A Virus Infection by Regulating Vascular Permeability and the Innate Immune Response

S. Antoniak[1,2], K. Tatsumi[2,3], N. Mackman[2]

[1]*University of North Carolina, Pathology and Laboratory Medicine, Chapel Hill, United States,* [2]*University of North Carolina, Hematology/Oncology, Chapel Hill, United States,* [3]*Kindai University Faculty of Medicine, Department of Physiology and Regenerative Medicine, Osaka, Japan*

Background: Protease-activated receptor 1 (PAR-1) is activated by a variety of proteases and exhibits biased signaling. Activation of PAR-1

on endothelial cells by high doses of thrombin increases permeability whereas activation by APC or low doses of thrombin decreases permeability. One study proposed that interaction of PAR-1 with EPCR promotes barrier protective signaling.

Aims: We investigated the role of PAR-1 in influenza A virus (IAV) infection of mice.

Methods: Wild-type (WT) and *Par1*$^{-/-}$ mice were infected intranasal with 0.02 HAU H1N1/PR8 virus. Survival, immune cell infiltration, inflammation and vascular permeability in the lung was analyzed up to 14 days after infection. We also determined the effect of deleting PAR-1 in different cell types, including lung epithelial cells (*Par1*$^{fl/fl}$,SPC-Cre), myeloid cells (*Par1*$^{fl/fl}$,LysM-Cre) or endothelial cells and hematopoietic cells (*Par1*$^{fl/fl}$,Tie2-Cre). *Par1*$^{fl/fl}$ served as controls.

Results: *Par1*$^{-/-}$ mice exhibited a lower survival rate (34.3%) compared to WT control mice (75.8%) after IAV infection ($P< 0.05$). This was associated with higher neutrophil counts and CXCL1 levels at day 3, and increased vascular permeability in the lungs at day 7 in *PAR1*$^{-/-}$ compared to WT mice. The survival rate of *Par1*$^{fl/fl}$,SPC-Cre mice (68.2%) after infection was not different to controls (73.3%). *Par1*$^{fl/fl}$,LysM-Cre mice had similar survival after infection compared to controls (65.0% vs. 68.2%). Interestingly, *Par1*$^{fl/fl}$,Tie2-Cre mice had lower survival rate (36.4%) compared to littermate control mice (66.7%) after infection, although it did not reach statistical significance (P=0.28). Importantly, only *Par1*$^{fl/fl}$, Tie2-Cre mice exhibited increased neutrophil numbers, CXCL1 levels and vascular permeability after IAV infection as observed in *Par1*$^{-/-}$ mice.

Conclusions: Our results suggest that activation of PAR-1 on the endothelium may limit the increased permeability caused by IAV infection. PAR-1 also contributed to the innate immune response to IAV infection.

OC 05.3 | PAR-1 Limits Coxsackievirus B3 Hepatitis in vivo and in vitro

S. Antoniak[1,2], K. Burkey[2], K. Tatsumi[2,3], N. Mackman[2]

[1]*University of North Carolina, Pathology and Laboratory Medicine, Chapel Hill, United States,* [2]*University of North Carolina, Hematology/Oncology, Chapel Hill, United States,* [3]*Kindai University Faculty of Medicine, Department of Physiology and Regenerative Medicine, Osaka, Japan*

Background: Coxsackievirus B3 (CVB3) can cause severe myocarditis and hepatitis. Recently, we showed that protease-activated receptor 1 (PAR-1) enhances anti-viral responses and reduces CVB3 myocarditis. Also, CVB3 uses autophagy to increase its replication.

Aims: We investigated the role of PAR-1 on hepatocytes during CVB3 infection in innate immune responses, cellular infectivity and viral replication.

Methods: CVB3 hepatitis was analyzed in wild-type (WT), *Par1*$^{-/-}$ and mice with PAR-1 deficient hepatocytes (PAR1$^{fl/fl}$,Alb-Cre). PH5CH8 hepatocytes were used for in vitro experiments. PH5CH8 cells were stimulated with poly I:C or infected with CVB3 to analyze immune responses, virus adhesion, uptake, replication, and cytopathology with or without PAR-1 activation. Last, we analyzed different pathways to assess how PAR-1 affects virus life cycle.

Results: *Par1*$^{-/-}$ mice exhibited reduced innate immune responses and increased virus load in the liver after CVB3 infection. PAR1$^{fl/fl}$,Alb-Cre mice also showed an increased virus load compared to controls. In vitro experiments revealed that PAR-1 stimulation increased the poly I:C induction of interferon responses, and reduced uptake but not adhesion of CVB3 in PH5CH8 cells. Further, PAR-1 stimulation reduced CVB3 replication and cytopathology in PH5CH8. As expected, the CVB3 cytopathic effects were dependent on pathways associated with autophagy. PAR-1 stimulation enhanced CVB3-dependent p44/42 activation. Interestingly, treatment with PI3K inhibitors or the microtubule inhibitor increased whereas inhibition of Ca^{2+} or MEK1 signaling abolished PAR-1 mediated cytoprotection.

Conclusions: PAR-1 activation enhances TLR3-dependent innate immune responses, and reduces CVB3 uptake and replication in PH5CH8 hepatocytes. The observed PAR-1-mediated effects on the CVB3 life cycle were due to an enhancement of Ca^{2+} and MEK1-p44/42 signaling, and possible reduced PI3K activation, autophagy and microtubules rearrangement subsequently improving hepatocyte viability after CVB3 infection.

OC 05.4 | Protease Activated Receptor-1 (PAR-1) Impedes Tumor Progression by Promoting Tumor Cell Apoptosis

G. Adams[1], E. Laws[2], L. Rosenfeldt[1], M. Frederick[1], A. Remiker[1], E. Mullins[1], M. Flick[1], K. Steinbrecher[2], J. Palumbo[1]

[1]*Cincinnati Children's Hospital Medical Center, Cancer and Blood Diseases Institute, Cincinnati, United States,* [2]*Cincinnati Children's Hospital Medical Center, Gastroenterology, Hepatology & Nutrition, Cincinnati, United States*

Background: Thrombin-mediated activation of Protease Activated Receptor-1 (PAR-1) has been implicated as a mechanism coupling thrombin to tumor progression, particularly in the prostate and intestine. However, the role of PAR-1 in these contexts has never been directly evaluated.

Aims: To directly determine the role of PAR-1 in prostate and intestinal tumor progression

Methods: PAR-1$^{-/-}$ mice were interbred with TRAMP mice, which carry prostate epithelia-specific expression of SV40T, or APC$^{Min/+}$ mice, which carry a mutation in the adenomatous polyposis coli gene resulting in intestinal adenomatosis.

Results: TRAMP/PAR-1$^{-/-}$ mice evaluated at 30 weeks of age had dramatically larger prostate tumors than control mice. PAR-1$^{-/-}$ prostate tumors also demonstrated more frequent neuroendocrine (NE) differentiation, an established marker of advanced disease in this tumor model. To evaluate tumorigenesis prior to the NE switch, prostates were harvested from 12 week old mice. At this early time point the degree of dysplasia and carcinoma *in situ* was similar between genotypes, as was quantitation of prostate epithelial proliferation. However, transformed prostate epithelia from PAR-1$^{-/-}$ mice demonstrated significantly less evidence of apoptosis. Analyses of the role of PAR-1 in APC$^{Min/+}$ intestinal tumorigenesis paralleled these results. Quantitative analyses of the intestines revealed that

PAR-1 deficiency resulted in a 3-fold increase in intestinal adenomas. Markers of adenoma proliferation were similar between genotypes, but apoptosis was considerably decreased in PAR-1$^{-/-}$ adenomas.

Conclusions: These studies challenge the prevailing view that PAR-1 drives cancer progression. These studies reveal a surprising role for PAR-1 in *inhibiting* tumor progression in the context of spontaneously arising tumors in the prostate and intestinal epithelia. Here, loss of PAR-1 resulted in diminished tumor cell death, suggesting that PAR-1 signaling promotes apoptosis in certain contexts.

OC 05.5 | PAR2 Mutant Mice Provide New Insights into Protease Signaling Specificity in the Tumor Microenvironment

C. Graf[1], P. Wilgenbus[1], W. Ruf[1,2]

[1]*Johannes Gutenberg University Medical Center, Center for Thrombosis and Hemostasis, Mainz, Germany,* [2]*The Scripps Research Institute, Department of Immunology and Microbial Science, La Jolla, United States*

Background: Tissue factor (TF) signaling through protease activated receptor (PAR) 2 plays a pivotal role in promoting tumor progression. TF-associated protease activate PAR2 in two distinct signaling complexes, i.e. the TF-FVIIa complex directly cleaving PAR2 and the TF-FVIIa-FXa coagulation initiation complex in which FXa cleaves PAR2 following recruitment of the endothelial protein C receptor (EPCR). It remains unclear which proteases in the tumor microenvironment (TME) contribute to PAR2-mediated tumor progression.

Aims: We generated PAR2 mutant mice that are resistant to cleavage by FXa (PAR2 G37I) or by all proteases (PAR2 R38E) to provide new insight into candidate coagulation proteases contributing to tumor development.

Methods: We analyzed tumor growth effects of PAR2 mutation with transplanted tumors and the PyMT model of spontaneous breast cancer. We characterized the composition of the TME by flow cytometry and mRNA expression profiling.

Results: Cleavage resistant PAR2 R38E mice recapitulated the delayed tumor progression and growth of PAR2-/- mice in the PyMT model, whereas tumor growth was selectively attenuated in FXa-resistant PAR2 G37I mice. Attenuated tumor growth was also seen with tumors transplanted onto PAR2 G37I mice, demonstrating that host PAR2 signaling promoted tumor progression. Immuno-suppressive myeloid-derived suppressor cells (MDSC) were reduced in PAR2 mutant mice relative to WT. We show that FVII and FX are expressed by tumor-associated macrophages (TAM) in advanced tumors. While overall numbers of TAM were unchanged in advanced tumors of PAR2 mutant mice, markers of alternative macrophage activation, including the neutrophil and MDSC attracting chemokines, were significantly reduced. Conversely, the tumor stroma of PAR2 mutant mice was characterized by an expansion of CD8$^+$ T cells of relevance for tumor surveillance.

Conclusions: These data provide evidence that FXa signaling through PAR2 modulates macrophage polarization and promotes tumor evasion through immune suppression.

OC 20.1 | Contributions of Complement-Dependent Membrane Perturbations to Myeloid Cell TF Activation in Venous Thrombosis

S. Subramaniam[1,2], K. Jurk[1], L. Hobohm[1], S. Jäckel[1], M. Saffarzadeh[1], K. Schwierczek[1], P. Wenzel[1], F. Langer[3], C. Reinhardt[1], W. Ruf[1,4]

[1]*Center for Thrombosis and Hemostasis (CTH), University Medical Center of the Johannes Gutenberg University, Mainz, Germany,* [2]*McAllister Heart Institute, University of North Carolina, Chapel hIll, United States,* [3]*II. Medizinische Klinik und Poliklinik, Onkologisches Zentrum, Hubertus Wald Tumorzentrum-Universitäres Cancer Center Hamburg,, Hamburg, Germany,* [4]*Department of Immunology and Microbial Sciences, The Scripps Research Institute, La Jolla, CA, United States*

Background: Genetic dispositions leading to hyperactive complement are known contributors to vascular and thromboembolic diseases, such as paroxysmal nocturnal hemoglobinuria and antiphospholipid syndrome. Although C5-inhibitors are being used to treat these diseases, the links between complement and hemostatic systems are poorly understood.

Aims: To evaluate in a venous thrombosis model the previously demonstrated contributions of PDI-catalyzed thiol-disulfide exchange and complement to TF activation and fibrin formation.

Methods: We characterized C3$^{-/-}$ and C5$^{-/-}$ mice in tail bleeding assay, in vitro platelet activation and the flow-restriction IVC thrombosis model. Since thrombosis is dependent on both leukocytes and platelets, we quantified vessel wall platelet and leukocyte interaction and fibrin formation at by intravital microscopy. We quantified leukocyte procoagulant phosphatidylserine (PS) exposure by imaging annexin 5 staining on GR1$^+$ leukocytes. To explore TF activation in human blood, we measured procoagulant activity in LPS-stimulated whole blood in vitro.

Results: C3$^{-/-}$ mice showed prolonged initial and total bleeding times, reduced thrombus size, fibrin and platelet deposition in the IVC model, and less platelet activation in vitro. Early fibrin formation at the vessel wall was dependent on PDI and TF expression by myeloid cells, but not NETs. In contrast, C5$^{-/-}$ mice had no apparent defect in initial hemostasis and vessel wall platelet deposition in vivo or platelet activation in vitro. However, fibrin formation, PS exposure on adherent leukocytes, and thrombus sizes measured 48h after induction of IVC were significantly reduced in C5$^{-/-}$ mice. In vitro LPS stimulation of human monocytes showed that TF procoagulant activity was markedly reduced with the PDI inhibitor Rutin or αC5 and αC7, but not αC9.

Conclusions: These data show that complement is crucial for leukocyte PS exposure and myeloid cell TF- and PDI-dependent fibrin formation, but C3 is specifically required for platelet activation.

OC 20.2 | Deep Vein Thrombosis Suppresses Peripheral T Cell Effector Function

J. Prochaska[1], N. Luther[2], M. Brähler[2], A. Schulz[3], P. Wild[4], C. Becker[5]

[1]University Medical Center of the Johannes Gutenberg University Mainz, Center for Thrombosis and Hemostasis / Center for Cardiology - Cardiology I / German Center for Cardivoascular Research (DZHK), Partner site Rhine Main / Center for Translational Vascular Biology (CTVB), Mainz, Germany, [2]University Medical Center of the Johannes Gutenberg University Mainz, Department of Dermatology, Mainz, Germany, [3]University Medical Center of the Johannes Gutenberg University Mainz, Preventive Cardiology and Preventive Medicine, Center for Cardiology / Center for Translational Vascular Biology (CTVB), Mainz, Germany, [4]University Medical Center of the Johannes Gutenberg University Mainz, Preventive Cardiology and Preventive Medicine, Center for Cardiology / Center for Thrombosis and Hemostasis / German Center for Cardiovascular Research (DZHK), Partner site Rhine Main / Center for Translational Vascular Biology (CTVB), Mainz, Germany, [5]University Medical Center of the Johannes Gutenberg University Mainz, Department of Dermatology / Center for Thrombosis and Hemostasis, Mainz, Germany

Background: Recent experimental studies shed light on the role of the immune system in the pathophysiology of venous thrombosis. However, data from human studies investigating the effects of deep vein thrombosis (DVT) on T cell effector function is currently limited.
Aims: To investigate the functional state of T lymphocytes in DVT patients compared to healthy subjects.
Methods: A total of 20 healthy individuals and 18 DVT patients were enrolled in a translational study, which comprised clinical and laboratory phenotyping. For immunological characterization, T cell surface marker expression and cytokine competence were assessed. The frequency of regulatory T cells was determined as CD4+CD25highIFN-gneg cells in stimulated samples. For the analysis of clinically-relevant subgroups, information on etiology, site and thrombotic burden of DVT were integrated.
Results: Overall, DVT patients showed significantly reduced production of IFN-g in CD4+ (DVT: 7.03±4.06 vs. controls: 12.68±6.29; p=0.002) and CD8+ cells (DVT: 19.03±10.82 vs. controls: 29.70±11.34; p=0.005) in comparison to controls. Reduced effector cytokine competence was associated with an increase in regulatory T cells (p=0.011) and C-reactive protein (CRP_{DVT}: 11.00 (4.18/25.67) vs. $CRP_{controls}$: 1.15 (0.48/4.76); p< 0.0001). The difference in IFN-g production was most pronounced for proximal DVT, provoked etiology, and high thrombotic burden (for all, p< 0.05) compared to healthy subjects. In linear regression analysis with adjustment for age, sex and CRP, an independent negative effect of DVT on IFN-g production (beta-estimate: -5.98, 95%CI -10.0/-1.96; p=0.006) was confirmed.
Conclusions: In this study, DVT was associated with lower peripheral T cell inflammatory competence and increased levels of inflammation and regulatory T cells. Significant T cell suppression was observed in provoked but not unprovoked DVT suggesting that alterations in T cell function may rather precede than result from thrombosis.

OC 20.3 | IFNγ Induces the Formation of NETs in Venous Thrombosis

F.-R. Bertin[1], S. Laurance[1], C. Lemarie[1], M. Blostein[2]

[1]Lady Davis Institute for Medical Research, Montreal, Canada, [2]Lady Davis Institute – Jewish General Hospital, Montreal, Canada

Background: Recent studies demonstrate that innate immune cells promote venous thrombosis through the activation of the coagulation cascade and platelets. Neutrophils contribute to venous thrombosis through the release of neutrophil extracellular traps (NETs) but the mechanism triggering their formation remain unknown. Recent data demonstrate that IFNγ induces the formation of NETs.
Aims: We hypothesize that IFNγ promotes venous thrombosis.
Methods: We used IFNγ, Tbet (the transcription factor regulating the expression of IFNγ) deficient (-/-) or wild type (WT) mice. Venous thrombosis was induced using the flow restriction model in the inferior vena cava, as has been previously published.
Results: Absence of Tbet or IFNγ decreases the formation of thrombi after venous thrombosis induction, suggesting that the Tbet+ /IFNγ producing cells are required for the early development of venous thrombosis. The number of NETs formed during thrombosis was significantly lower in Tbet-/- and IFNγ-/- mice. NET formation was also decreased in WT mice treated with an IFNγ blocking antibody. Injection of IFNγ in IFNγ-/- mice rescued the phenotype. Natural killer (NK) cells are the main producers of IFNγ. Thus, NK cells were specifically depleted with an antibody prior to venous thrombosis induction. NK cell depletion results in smaller thrombi suggesting that NK cells are required for thrombus development. Additionally, NK cell depletion results in decreased NET formation. In vitro, we show that WT neutrophils release fewer NETs when co-cultured with IFNγ-/- NK cells.
Conclusions: We demonstrate that IFNγ production is crucial for thrombus development by promoting the formation of NETs by neutrophils and that NK cells are key effector cells in this process.

OC 20.4 | Natural IgM Binding Oxidation-specific Epitopes Protect from Microvesicle-driven Thrombosis

G. Obermayer[1,2], T. Afonyushkin[1,2], F. Puhm[1,2], M. Schwameis[3], W. Schrottmaier[4], B. Jilma[3], A. Assinger[4], C. Binder[1,2]

[1]Medical University of Vienna, Department of Laboratory Medicine, Vienna, Austria, [2]Austrian Academy of Sciences, Research Center for Molecular Medicine, Vienna, Austria, [3]Medical University of Vienna, Department of Pharmacology, Vienna, Austria, [4]Medical University of Vienna, Institute of Physiology, Vienna, Austria

Background: Natural IgM are germline encoded antibodies that exhibit crucial homeostatic housekeeping functions. A large part of natural IgM has been found to bind oxidation-specific epitopes, such as malondialdehyde (MDA)-adducts. Microvesicles (MVs) are a subtype of extracellular vesicles and important mediators of coagulation. We have recently shown that 50% of circulating MVs are recognized by MDA-specific natural IgM antibodies.

Aims: To investigate whether MDA-specific natural IgM influence the procoagulatory properties of MVs.

Methods: To study the effect of the MDA-specific IgM LR04 on coagulation in vitro, rotational thromboelastometry (ROTEM), platelet aggregation, fibrin and thrombin generation (FG, TG) activated partial thromboplastin time (aPTT) and prothrombin time (PT) were used. Murine pulmonary embolism (PAE) and tail bleeding models were used to assess effects of LR04 in vivo.

Results: While LR04 caused a delay of all clotting parameters in ROTEM, it had no influence on washed platelet aggregation or aPTT and PT, which are MV-insensitive. In contrast, LR04 significantly delayed TG and FG in platelet poor MV-containing plasma. This effect was blocked by the P1 peptide, a mimotope of MDA that is bound by LR04. Neither a control IgM, nor an MDA-specific IgG, nor F(ab´)2 fragments of LR04 displayed anticoagulatory properties. LR04 also delayed MV-induced TG in factor VII and XII deficient plasma, indicating that the effect is independent of intrinsic or extrinsic activation. Importantly, in PAE, co-injection of LR04 significantly increased 30-minute survival of mice injected with thrombogenic MVs. On the other hand, injection of LR04 had no effect on tail bleeding.

Conclusions: Our study identifies a hitherto unknown protective role of MDA-specific natural IgM antibodies in MV-induced coagulation and thrombosis. These anti-thrombotic effects require the full IgM structure and are exerted on the common pathway of the coagulation cascade. Our findings may open new avenues in the prevention of thrombosis.

OC 20.5 | Hemodynamic Force Triggers NETosis within Sterile Thrombotic Occlusions

S. Diamond, X. Yu

University of Pennsylvania, Institute for Medicine and Engineering, Philadelphia, United States

Background: Neutrophil extracellular traps (NETs) are released by neutrophils encountering infectious pathogens, especially during sepsis. Additionally, NETosis occurs intravascularly during venous and arterial thrombosis, disseminated intravascular coagulation, trauma, and autoimmune vasculitis.

Aims: We tested if hemodynamic forces trigger NETosis during sterile thrombosis.

Methods: We imaged NETs with Sytox-Green during microfluidic perfusion of Factor XIIa-inhibited or thrombin-inhibited human whole blood over collagen (± tissue factor).

Results: For constant pressure-drop perfusions at initial inlet venous or arterial wall shear rates (100 or 1000 s^{-1}), platelets rapidly accumulated in the microchannels at either flow condition, however subsequent neutrophil infiltration with concomitant NETosis was detected only at the arterial condition. Shear-induced NETs (SINs) at 30 min were >150-fold greater at arterial conditions in the absence of thrombin and >80-fold greater in the presence of thrombin, relative to the venous condition. With or without thrombin, venous perfusion for 15 min generated no NETs, but an abrupt shift-up to arterial perfusion triggered NETosis within 2 min, eventually reaching levels by 30 min that were 60-fold greater than microchannels without perfusion up-shift. Aspirin inhibition of platelet deposition led to attenuated neutrophil accumulation at venous flow, but did not block SINs upon shift-up to arterial flow. SINs contained citrullinated histone H3 and were DNase-sensitive, but were not blocked by inhibitors of PSGL-1, CD18, or HMGB1.

Conclusions: The interstitial shear stress on clot-entrapped neutrophils is sufficient to drive NETosis. This is the first demonstration that hemodynamic forces trigger NETosis during sterile occlusive thrombosis.

OC 42.1 | Functional Characterization of Characterization of RIG-I Like Receptors (RLRs) in Megakaryocytes and Platelet

D. Pandey[1], C. Heuer[2], J. Tossounidis[2], S. Endres[2], S. Rothenfusser[2]

[1]Ludwig-Maximilians-Universität München, Department of Clinical Pharmacology, Department of Medicine IV, Munich, Germany, [2]Ludwig-Maximilians-Universität München, Department of Clinical Pharmacology, Department of Medicine IV, Munich, Germany

Background: Beyond their central role in hemostasis, platelets are an important component of the innate immune system contributing to detection and effector responses to microbial pathogens through Toll-like and NOD-like receptors. Hemorrhagic viral infections are commonly associated with virus-induced thrombocytopenia. Apart from TLRs, viruses can be sensed by cytoplasmic RLRs.

Aims: We asked whether RLRs are present in megakaryocytes and platelets and how their activity contributes towards host responses during virus infections.

Methods: As a cell culture model, we used the megakaryocytic cell lines DAMI and Meg01. In addition, mouse megakaryocytes were isolated from bone marrow. Vesicular stomatitis virus (VSV), VSV-M51N and Sendai virus were used to infect cells. Differentiation of DAMI cell into polyploid megakaryocytes was determined by FACS analysis. Expression of interferon-stimulated genes (ISGs) was analyzed by RT-PCR and secretion of the cytokine was measured by ELISA.

Results: We could detect RIG-I and MDA5 along with other PRRs in DAMI, Meg01, and murine megakaryocytes. Stimulation of megakaryocytic cell lines with RLRs-specific agonists polyI:C and pppRNA, as well as viral infections, elevated secretion of IP10 and expression of ISGs indicating that RIG-I and MDA5 are functional in these cells. Unlike type-I interferon, Sendai virus did not inhibit the PMA-induced polyploidy in DAMI cells suggesting that viruses may not directly inhibit megakaryocyte differentiation. In vivo, treatment of mice with polyI:C showed an increased RIG-I and MDA5 expression in megakaryocytes and platelets.

Conclusions: Our results show that megakaryocytes do have functional RLRs and that they potentially participate in host innate immune responses against viruses. During viral infections, upregulated RLRs in megakaryocytes are transferred to their progeny, platelets. We hypothesize that platelets after acquiring RLRs from megakaryocytes are able to detect viruses and contribute to host responses during virus infections.

OC 42.2 | SERPINE2 Expression and Function in Neutrophils

K. Aymonnier[1], L. Venisse[1], Y. Boulaftali[2], V. Arocas[2], M.-C. Bouton[2]

[1]*Université Paris Diderot, Sorbonne Paris Cité, INSERM U 1148, Paris, France,* [2]*INSERM U 1148, Paris, France*

Background: Serpin E2 orProtease Nexin-1 (PN-1) is a tissue serpin, known as the most potent endogenous inhibitor of thrombin. PN-1 can regulate coagulation, tissue remodelling, cell behaviour by inhibiting proteases like coagulation factors or furin. Vascular cells, platelets and inflammatory cells express PN-1. However its potential role in regulating inflammatory processes is not known. PN-1 has been detected in monocytes/macrophages, but no data are available concerning its expression and potential function in neutrophils (PMNs).

Aims: We studied PN-1 expression in PMNs and its potential role in their inflammatory functions.

Methods: PMNs isolated from human blood or from Wild-Type (WT) or PN-1 Knock-Out (KO) mice bone marrow were activated by different agonists. Expressions of PN-1 and surface integrins were quantified and analysed by western blot and flow cytometry. The production of reactive oxygen species (ROS) as well as myeloperoxidase (MPO) and furin activities were quantified using specific fluorometric substrates. Vascular recruitment of PMNs was analysed by intravital microscopy in mesenteric vessels stimulated with leukotriene B4 (LTB4).

Results: We demonstrated the presence of PN-1 in PMNs in the cytosol, in the azurophilic granules as a degraded form and in the specific granules as a covalent complex. PN-1 was overexpressed after LPS stimulation of PMN. No difference was observed in MPO activity and integrin expression between WT and KO activated PMNs. ROS generation was significantly decreased in KO *vs* WT PMNs. PMNs recruitment was much less important in inflamed mesenteric vessels of KO mice than in those of WT mice. Fig 1. Diminish... Interestingly, PMNs from KO mice exhibit a higher furin activity than WT PMNs.

Conclusions: PN-1 is a serpin regulating positively PMNs functions. Because furin mediates the activation of proteins involved in the expression of adhesion molecules, PN1 may regulate neutrophil adhesion and recruitment via its ability to inhibit furin.

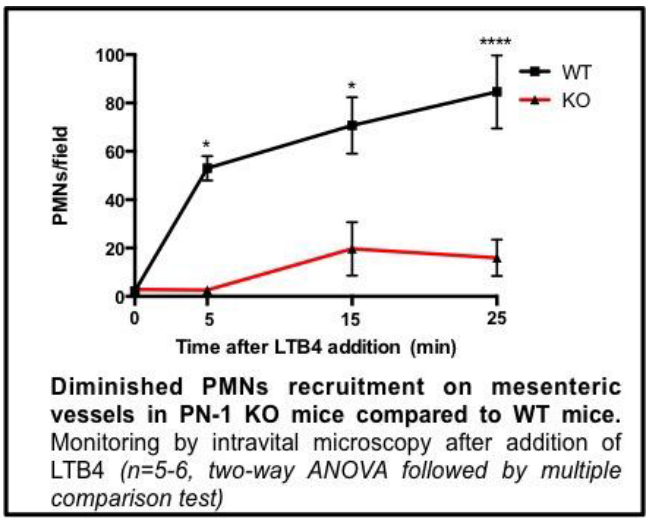

FIGURE 1 Diminished PMNs recruitment on mesenteric vessels in PN-1 KO mice compared to WT mice

OC 42.3 | Biophysical Regulation of Leukocyte Recruitment by the 3-Dimentional Structure of Platelet Thrombi

I. Alwis[1], Y. Yuan[1], Z. Kaplan[2], F. Tovar-Lopez[3], W. Nesbitt[2], A. Ju[1], S. Jackson[1]

[1]*Heart Research Institute and Charles Perkins Centre, Camperdown, Australia,* [2]*Monash University, Melbourne, Australia,* [3]*Royal Melbourne Institute of Technology, Melbourne, Australia*

Background: Biochemical signals (pro-inflammatory molecules) generated at sites of tissue injury are considered the dominant factor regulating the efficiency of leukocyte recruitment to sites of endothelial injury. The importance of biophysical elements in regulating leukocyte recruitment is largely unknown.

Aims: To investigate how the 3D structure of microvascular thrombi regulates the efficiency of leukocyte recruitment to sites of vessel injury.

Methods: To examine leukocyte-platelet thrombi recruitment *in vivo* we used a murine model of thrombosis induced by localized needle injury, and in a model of intestinal ischemia reperfusion (I/R) injury. *In vitro* studies involved perfusing neutrophils over platelet thrombi on microfluidic devices that incorporated 3D, platelet coated posts.

Results: During intestinal I/R injury and localized needle injury there was a direct correlation between the size of platelet thrombi and the extent of intravascular leukocyte recruitment. Computational fluid dynamics analysis revealed a central role for local blood flow changes around the margins of thrombi (low-shear pockets) in facilitating leukocyte arrest. These localized flow disturbances increased intravascular leukocyte accumulation to thrombi by up to 40-fold relative to inflamed endothelium alone. Similarly enhanced leukocyte recruitment also occurred in the low shear pockets around *in vitro* thrombi. Studies using 3D posts confirmed a critical role for the luminal extension of platelets (thrombus height) in regulating the efficiency of leukocyte recruitment, with tall (40μm) platelet-coated posts enhancing leukocyte recruitment >6-fold relative to shorter (10μm) posts.

Conclusions: These studies demonstrate the existence of a biophysical mechanism of leukocyte recruitment, mediated by the 3D structure of platelet thrombi, which plays a major role in enhancing leukocyte recruitment *in vivo*. This biophysical leukocyte recruitment mechanism may help explain the potent pro-inflammatory properties of microvascular platelet thrombi.

OC 42.4 | Plasmin and Plasminogen Induce Macrophage Reprogramming and Regulate Key Steps of Inflammation Resolution via Annexin A1

M.A. Sugimoto[1], A.L.C. Ribeiro[1], B.R.C. Costa[1], J.P. Vago[1], K. Maciel Lima[1], F.S. Carneiro[1], M.M.O. Ortiz[1], G.L. Negreiros Lima[1], A.A.F. Carmo[1], R.M. Rocha[2], D.A. Perez[2], A.C. Reis[2], V. Pinho[2], L.A. Miles[3], C.C. Garcia[4], M.M. Teixeira[2], L.P. Sousa[1]

[1]Federal University of Minas Gerais, Faculty of Farmacy, Belo Horizonte, Brazil, [2]Federal University of Minas Gerais, Institute of Biological Sciences, Belo Horizonte, Brazil, [3]The Scripps Research Institute, Department of Cell and Molecular Biology, La Jolla, United States, [4]Oswaldo Cruz Institute, Laboratory of Respiratory Viruses, Rio de Janeiro, Brazil

Background: Participation of the plasminogen/plasmin (Plg/Pla) system in the productive phase of inflammation is well known, but its involvement in the resolution phase remains unclear.

Aims: To investigate the potential role of Plg/Pla in key events during the resolution of acute inflammation and its underlying mechanisms.

Methods: BALB/c mice received an intrapleural (i.pl.) injection of Plg or Pla (2µg/cavity) and, after different time points cells were recovered from the pleural cavity to have their profile investigated. Also, an acute pleurisy model was performed by the i.pl. injection of LPS (250ng/cavity). We also applied a therapeutic protocol by i.pl. injection of 2 µg of Plg or Pla after inflammation was established.

Results: The injection of Plg/Pla into the pleural cavity of mice induced a time-dependent influx of mononuclear cells that were primarily macrophages of anti-inflammatory (M2 - F4/80^{high} Gr1^{-} CD11b^{high}) and pro-resolving (Mres - F4/80^{med} CD11b^{low}) phenotypes, without changes in the number of macrophages with the pro-inflammatory profile (M1 - F4/80^{low} Gr1^{+} CD11b^{med}). Pleural injection of Plg or Pla also increased M2 markers (CD206 and Arginase-1) and M2 secretory products (IL-6 and TGF-β) without affecting expression of iNOS (M1 marker). During the resolving phase of LPS-induced inflammation, when M2 and Mres macrophages predominate, we found increased Plg expression and Pla activity, further supporting a link between the Plg/Pla system and macrophage reprogramming. Indeed, Plg or Pla given at the peak of inflammation promoted resolution by decreasing neutrophil numbers and increasing neutrophil apoptosis and efferocytosis. Next, we have confirmed the ability of Plg/Pla system to promote efferocytosis and override the pro-survival effect of LPS, both via AnxA1.

Conclusions: The results demonstrate a key role for the Plg/Pla system in the resolution of the inflammatory response whereby the effects induced by Plg are mediated by the anti-inflammatory and pro-resolving molecule AnxA1.

OC 42.5 | Alternative Proteolytic Activation of Human Prothrombin by a Bacterial Serine Protease

G. Pontarollo, L. Acquasaliente, D. Peterle, I. Artusi, V. De Filippis

University of Padua, Department of Pharmaceutical and Pharmacological Sciences, Padua, Italy

Background: Factor Xa (FXa) converts inactive prothrombin (ProT) to active α-thrombin (αT) by cleaving ProT at R271-T272 and R320-I321. The signature of αT activation is the formation of a buried salt bridge between the N-terminus of the I321 and the negative D524. Exogenous proteases, such as ecarin from the viper snake venom, proteolytically activate ProT by cleavage at R320-I321. Non-proteolytic activation of ProT can be achieved by staphylocoagulase, a protein from *S. aureus* interacting with D524 through its N-terminal Ile-Val dipeptide. Little is known about the possibility that bacterial proteases can activate ProT.

Aims: Investigate blood clotting induced by subtilisin, a serine protease from *B. subtilis*, taken as the prototype member of the subtilase superfamily.

Methods: Proteolysis of ProT by subtilisin (2000:1, w/w) was monitored by SDS-PAGE. Hydrolytic activity was determined on S2238 substrate. The cleavage sites were identified by mass spectrometry. Fibrin generation and platelet activation were monitored by turbidimetry or impedance aggregometry.

Results: As with FXa, subtilisin cleaves ProT at R271-T272 but, at variance with FXa, it attacks ProT at A470-N471 in the autolysis loop, generating σPre2 (Fig. 1). Purified σPre2 hydrolyzes S2238 with a K_m identical to that of αT but with a k_{cat} 120-fold lower. The raise of thrombin-like activity is caused by the formation of the N471-D524 salt bridge. σPre2 is able to generate fibrin clot from fibrinogen, either purified or in human plasma, even though with a 150-fold lower efficiency. A similar trend is observed for the aggregation of platelets, either isolated by gel-filtration or in whole blood. Strikingly, addition of subtilisin (50 nM or 2 µM) to whole blood samples induced clot formation.

Conclusions: Subtilisin converts ProT to the active σPre2, which is able to generate fibrin and aggregate platelets. These results are consistent with clinical studies demonstrating a positive relation between bacterial infections and thrombotic risk.

OC 56.1 | Different Roles for Platelet Glycoprotein VI and CLEC2 during Gram Negative Pneumonia Derived Sepsis

T.A.M. Claushuis[1], A.F. de Vos[1], B. Nieswandt[2], L. Boon[3], J.J.T.H. Roelofs[4], O.J. de Boer[4], C. van't Veer[1], T. van der Poll[1,5]

[1]Academic Medical Center, Center for Experimental and Molecular Medicine, Amsterdam, The Netherlands, [2]University of Würzburg, Rudolf Virchow Center for Experimental Biomedicine, Würzburg, Germany, [3]Bioceros, Utrecht, The Netherlands, [4]Academic Medical Center, Department of Pathology, Amsterdam, The Netherlands, [5]Academic Medical Center, Division of Infectious Diseases,, Amsterdam, The Netherlands

Background: Glycoprotein (GP)VI and C-type lectin-like receptor (CLEC-)2 are platelet receptors implicated in platelet activation. Their role in sepsis is unknown.

Aims: To assess the role of GPVI and CLEC2 in the host response and prevention of bleeding during pneumonia derived sepsis.

Methods: Mice treated with platelet GPVI antibody JAQ1, CLEC2 antibody INU-1 or IgG control were infected with Klebsiella pneumoniae via

the airways and sacrificed after 12, 36 or 42 hours. Additionally, mice were treated with platelet depleting antibody a-GPIb and sacrificed 42 hours after Klebsiella infection. Human whole blood or isolated neutrophils were stimulated with GPVI ligand CRP-XL and assessed by flow cytometry.

Results: GPVI depleted mice showed increased bacterial growth in lung and bronchoalveolar lavage fluid (BALF) compared to control mice 36 and 42 hours after infection. CLEC2 depletion did not influence Klebsiella growth, despite abundant presence of podoplanin in the lung. GPVI depleted mice showed increased activation of neutrophils and coagulation, and higher levels of chemokines and cytokines in their lungs. GPVI depletion also reduced platelet influx, platelet-neutrophil complex formation and platelet activation in BALF, which was not seen in CLEC2 depleted mice. In human whole blood, GPVI signalling via platelets increased platelet-neutrophil complexes and neutrophil activation. GPVI depleted mice displayed some bleeding during infection, but not to the extent as observed in platelet depleted mice. CLEC2 depleted infected mice had no bleeding and in thrombocytopenic mice neutrophil depletion did not abrogate bleeding upon infection.

Conclusions: These results suggest that GPVI enforces local host defense during pneumonia derived sepsis and mediates local platelet activation and platelet-neutrophil complex formation. Vascular integrity during sepsis is partially regulated by GPVI, but CLEC2 or neutrophils are not crucially involved herein.

OC 56.2 | Inhibition of Factor XI Activation by Factor XIIa Blocks Coagulopathy and Provides Organ Protection and Survival Benefit in a Baboon Model of *S. aureus* Sepsis

R. Silasi[1], R.S. Keshari[1], W.J. van Rensburg[2], G. Regmi[1], C. Lupu[1], C.U. Lorentz[3], E.I. Tucker[3], D. Gailani[4], A. Gruber[5], O.J.T. McCarty[5], F. Lupu[1]

[1]Oklahoma Medical Research Foundation, Cardiovascular Biology, Oklahoma City, United States, [2]University of the Free State, Cell Biology and Hematology, Bloemfontein, South Africa, [3]Aronora, Inc., Portland, United States, [4]Vanderbilt University School of Medicine, Pathology, Nashville, United States, [5]Oregon Health and Science University School of Medicine, Biomedical Engineering, Portland, United States

Background: *S. aureus* sepsis can induce severe inflammatory response syndrome (SIRS) even during successful antibiotic therapy. Some forms of sepsis are characterized by fulminant disseminated intravascular coagulation (DIC). Systemic anticoagulants have long been tested or used to treat DIC in large trials, without evidence of overall outcome benefit. Differences in microbe-specific host responses contributing to the failure of anticoagulation trials in humans remain unclear.

Aims: We hypothesized that contact activation of FXI contributes to the pathogenesis of S. aureus-induced SIRS and DIC. We aimed to determine whether inhibition of FXI activation by FXIIa improves the outcome of SIRS and DIC in a model of acute fulminant sepsis.

Methods: We used a monoclonal antibody, xisomab 3G3, to selectively inhibit FXI activation by FXIIa in a baboon model of severe S. aureus sepsis. Baboons were challenged with 10^{10} heat-inactivated

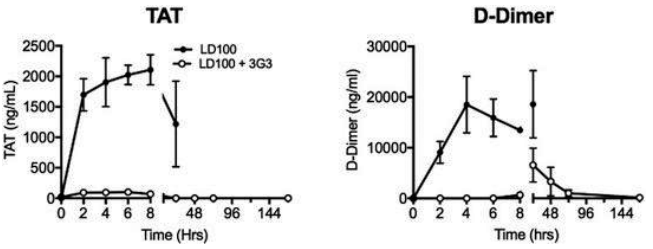

FIGURE 1 Time course of TAT and D-dimer levels in plasma

S. aureus by intravenous (i.v.) infusion over 2 h, with or without pretreatment with 1 mg/kg of intravenous xisomab 3G3. Animals were monitored for 7 days; during this time, blood samples and vital sign data were collected.

Results: Pretreatment with xisomab 3G3 drastically decreased heat-inactivated *S.aureus*-induced coagulopathy as reflected by clotting times, thrombin-antithrombin (TAT) complexes, fibrinogen and platelet consumption, fibrin deposition in tissues and D-dimers.

The antibody also protected key organs (liver, pancreas and kidney), as shown by reduced changes in transaminases, amylase, glycemia, creatinine and urea. Similarly, serum lactate dehydrogenase, nucleosomes and myeloperoxidase were significantly decreased showing lower inflammation and cytotoxicity in the treated group. All four animals pretreated with xisomab 3G3 survived while all three non-treated animals developed terminal organ failure.

Conclusions: Contact activation of FXI plays a key role in the pathogenesis of *S. aureus*-induced SIRS, DIC and multiple organ failure.

OC 56.3 | Targeting Coagulase Activity in *S. aureus* Bacteremia: A Prospective Randomized Controlled Trial of Staphylothrombin Inhibition

M. Peetermans[1], T. Vanassche[1], L. Liesenborghs[1], O. Gheysens[2], M. Jacquemin[1], J. Verhaegen[3], M.F. Hoylaerts[1], W. Peetermans[4], P. Verhamme[1]

[1]KU Leuven, Center for Molecular and Vascular Biology - Department of Cardiovascular Sciences, Leuven, Belgium, [2]KU Leuven, Nuclear Medicine, Leuven, Belgium, [3]KU Leuven, Clinical Microbiology, Leuven, Belgium, [4]KU Leuven, Infectious Diseases, Belgium

Background: *S. aureus* coagulases trigger blood clotting. The coagulase-prothrombin complex, i.e. „staphylothrombin", is not inhibited by standard anticoagulants, but can be targeted by direct thrombin inhibitors (DTIs). In preclinical models, DTIs improve outcome of *S. aureus* infection.

Aims: To study the feasibility and safety of staphylothrombin inhibition with DTIs in patients with *S. aureus* bacteremia. Secondary outcomes: D-dimers as a marker of coagulation activation; inflammatory and microbiological parameters; clinical outcomes.

Methods: Between March 2013 and April 2016, a single-centre, randomized controlled, open-label trial was conducted in the University Hospital Leuven, comparing DTIs to standard enoxaparin in patients with *S. aureus* bacteremia. The trial was approved by the Ethical Committee; informed consent was obtained for all patients. (NCT01911624).

Ninety-four consecutive patients with *S. aureus* positive blood cultures and without contra-indication for thromboprophylaxis were randomized to either DTI (oral dabigatran 110 mg bid or IV argatroban) for 7-10 days, or to standard enoxaparin 40 mg od SC.

Results: Randomization was feasible for one third of *S. aureus* bacteremic patients. Levels of dabigatran inhibited staphylothrombin. We observed similar clinically relevant bleeding and thrombotic complications in both groups. Adjunctive treatment with DTIs was associated with a faster decrease in D-dimers (-783 +- 234 ng/mL vs. -189 +- 156 ng/mL) (p=0.04) and a trend towards a lower number of persistent positive blood cultures. No differences in inflammatory parameters or other clinical outcomes were noted.

Conclusions: Targeting coagulase activity with DTIs is feasible in a subset of patients with *S. aureus* bacteremia; with comparable safety to standard thromboprophylaxis. The more rapid resolution of D-dimers warrants further study of staphylothrombin inhibition in *S. aureus* bacteremia, preferably aided by rapid microbiological diagnostics and using strategies without concomitant anticoagulant effect.

OC 56.4 | PF4 Binds and Stabilizes Neutrophil Extracellular Traps: Implications in Sepsis

K. Gollomp[1], I. Johnston[2], G. Zhao[3], F. Diarra[3], L. Zhai[3], M. Poncz[3], M.A. Kowalska[3]

[1]*The Children's Hospital of Philadelphia, Hematology, Philadelphia, United States,* [2]*The University of Pennsylvania, Philadelphia, United States,* [3]*The Children's Hospital of Philadelphia, Pediatrics, Philadelphia, United States*

Background: In response to inflammation, neutrophils release NETs, histone-decorated DNA that ensnares pathogens but also damages host tissue. We found that platelet factor 4 (PF4) binds to released NETs, inducing NET compaction and enhanced resistance to nuclease digestion. We also previously observed that mice that overexpress PF4 have improved survival in a model of sepsis.

Aims: Using in vitro and in vivo models, we examined whether PF4 interacts with NETs in a way that mitigates their toxicity.

Methods: Neutrophils were treated with LPS to induce NET release and then exposed to recombinant PF4 or buffer without PF4. Samples where then flowed through human endothelial umbilical vein cell (HUVECs) lined microfluidic channels that had been stimulated with tumor necrosis factor (TNF) α. EC viability was assessed 24-hours post NET exposure. PF4-deficient mice (mPF4$^{-/-}$) and wildtype (WT) controls were injected with LPS and euthanized 2-8 hours post injection. Plasma levels of DNA, citrullinated histones (cit-His), and myeloperoxidase (MPO) were quantified via ELISA and Western blot.

Results: In a microfluidic model, the presence of PF4 led to NET compaction and decreased NET adhesion to ECs. At 24 hours, channels incubated with NET+ PF4 contained higher numbers of viable ECs compared to channels incubated with NETs alone (Figure 1). Following LPS injection, both mPF4$^{-/-}$ and WT mice had similar increases in levels of TNFα. However, mPF4$^{-/-}$ mice had higher levels of DNA, cit-His and MPO.(Figure 2).

Conclusions: In vitro, the presence of PF4 protected ECs from NET associated damage. In a murine model of endotoxemia in which we previously showed improved survival in mice expressing PF4, the presence of PF4 did not alter the initial inflammatory response, but did lead to decreased plasma markers of NET release. Together, these findings suggest that the survival advantage observed in PF4$^{+/+}$ mice is in part due to PF4-induced NET compaction and EC protection.

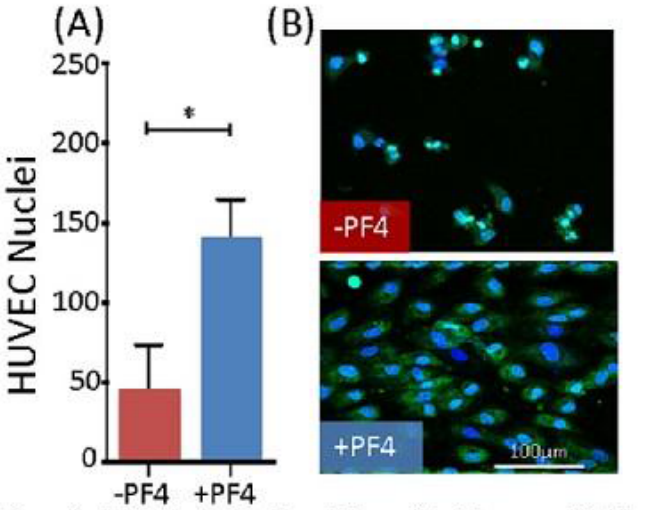

Figure 1. PF4 protects ECs from NET mediated damage. (A) LPS stimulated NETs with and without PF4 25µg/mL, flowed through microfluidic channels lined with TNFα exposed HUVECs and incubated for 24 hours at 37• Celsius. Residual adherent HUVEC nuclei counted using ImageJ (NIH). 2 channels per arm, 3 10x hpf counted per arm. *p = 0.0002 using a two tailed student T test **(B)** Representative confocal image of HUVEC cells following NET incubation. Blue=DNA, Green=Calcein AM

FIGURE 1 PF4 protects ECs from NET mediated damage

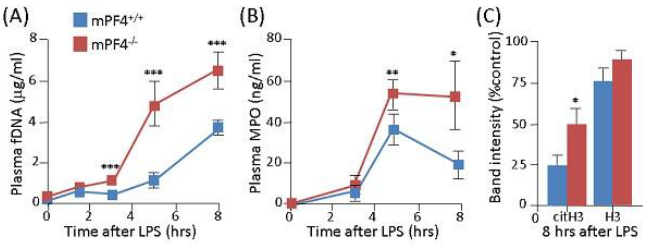

Figure 2: PF4$^{-/-}$ mice have increased plasma levels NET markers following LPS injection. (A) PF4-deficient mice (mPF4$^{-/-}$) and wildtype (mPF4$^{+/+}$) controls were injected with LPS and euthanized at different time points. Plasma levels of DNA were measured using a fluorescent plate assay with SYTOX green staining. Mice expressing PF4 had significantly lower plasma levels of DNA compared to mPF4$^{-/-}$ mice. ***=p<0.005 using a two-tailed student T test **(B)** Following LPS injection, mPF4$^{-/-}$ animals had lower levels of plasma MPO compared to WT controls. These difference reached statistical significance 5 and 8 hours post LPS exposure. *=p<0.05 **p<0.001 **(C)** Measuring Western Blot band intensity, mPF4$^{-/-}$ animals had increased levels of plasma histones H3 as compared to WT controls 8 hrs after LPS injection. This difference was statistically significant with citrullinated histones (citH3) *=p<0.05.

FIGURE 2 PF4-/- mice have increased plasma levels of NET markers following LPS injection

OC 70.1 | Von Willebrand Factor-platelet Microthrombi Phagocytosis by Macrophages as a New Homing Mechanism for Tissue Entry and Fibrosis

R. Fortna[1], N. Prévost[2]

[1]Northwest Pathology, Bellingham, United States, [2]Kyoto Gakuen University, Kameoka, Japan

Background: In cancers, tumor fibrosis constitutes a risk factor for metastasis. For their growth, tumors are dependent on a sustained influx of cytokines-releasing leukocytes, mostly macrophages. Another consequence of this chronic inflammatory state is the release of von Willebrand factor (VWF) by tumor blood vessels.

Aims: Because blood platelets are known to mediate the entry of immune cells into inflamed tissues and because VWF has been linked to fibrosis, we have hypothesized that VWF would support the formation of microthrombi which and act as homing signal for fibrosis-causing tumor-associated macrophages (TAMs).

Methods: Immunohistological analysis was performed on biopsies taken from cancer patients to assess the presence of macrophage-platelet-VWF clusters. Complementary in vitro studies were performed to elucidate the molecular mechanisms underlying macrophage binding to VWF-bound platelets.

Results: Immunohistological studies performed revealed the existence of a distinct TAM population, one that presents with strong VWF and integrin αIIb co-staining. Strikingly, those VWF+/αIIb+ TAMs were only found in highly fibrotic regions. In vitro studies confirmed the importance of VWF-borne microthrombi for macrophage homing as well as the importance of integrin αMβ2. These studies also yielded a novel finding: the ability of macrophages to transition from arrest to extravasation only takes place after internalization of VWF-platelet clusters has occurred.

Conclusions: We have identified a novel mechanism through which macrophages infiltrate tumor territory, one that is dependent on their binding and engulfing of VWF-borne microthrombi. Furthermore this TAM sub-population appears to bear strong pro-fibrotic potential. These observations suggest that the disruption of VWF-platelet-leukocyte interactions may help curtail tumor inflammation and fibrosis and, ultimately decrease the metastatic potential of certain tumors.

OC 70.2 | Interferon-induced Transmembrane 3 (IFITM3) on Megakaryocytes and Platelets Regulates Fibrinogen Endocytosis and Thrombosis During Inflammation

R. Campbell[1], B. Manne[1], S. Saperstein[1], H. Schwertz[1,2], J. Rowley[1,3], A. Weyrich[3], M. Rondina[1,3,4]

[1]University of Utah, Molecular Medicine, Salt Lake City, United States, [2]University of Utah, Division of Vascular Surgery, Salt Lake City, United States, [3]University of Utah, Internal Medicine, Salt Lake City, United States, [4]George E. Wahlen VAMC GRECC, Salt Lake City, United States

Background: IFITM3, an interferon (IFN) responsive gene, restricts pathogen replication through vesicular trafficking mechanisms. IFITM3 in megakaryocytes (MKs) and platelets has not been examined.

Aims: We examined the expression, regulation, and function of IFITM3 in MKs and platelets under inflammatory conditions.

Methods: Cultured murine MKs were left alone or stimulated with IFNα. IFITM3 expression and localization was determined in MKs and developing proplatelets. Fibrinogen (Fgn) endocytosis, a clathrin-mediated event requiring $\alpha_{IIb}\beta_3$, was measured in IFN-stimulated MKs and platelets from wild type (WT) and *Ifitm*$^{-/-}$ mice. Integrin $\alpha_{IIb}\beta_3$ activation, aggregation, and thrombosis was determined in WT and *Ifitm*$^{-/-}$ mice basally and upon IFN-stimulation. Co-immunoprecipitation identified putative interaction partners for IFITM3. IFITM3 expression, Fgn content, and platelet aggregation was also measured in platelets from patients with systemic inflammation and healthy control subjects.

Results: Upon IFNa stimulation *in vitro*, IFITM3 surface expression and Fgn endocytosis in MKs significantly increased. IFITM3 upregulation was STAT1 dependent. Super-resolution microscopy demonstrated that IFITM3 co-localized with $\alpha_{IIb}\beta_3$. IFNα stimulation *in vivo* concordantly increased platelet Fgn endocytosis, $\alpha_{IIb}\beta_3$ activation, aggregation, and death from thrombosis in WT mice. In contrast, *Ifitm*$^{-/-}$ mice were completely rescued from IFN-induced platelet hyperreactivity and thrombosis ($p< 0.05$ vs. WT for all comparisons). Clathrin and α_{IIb} were confirmed to closely interact with IFITM3. Platelets from patients with systemic inflammation mirrored findings in murine models, with significant increases in IFITM3 expression (~20-fold increase in protein), $\alpha_{IIb}\beta_3$ expression, Fgn content, and aggregation.

Conclusions: IFITM3 is a novel regulator of MK and platelet Fgn endocytosis under inflammatory stimuli in humans and mice. Moreover, IFITM3 is necessary for IFN-induced platelet hyperreactivity and thrombosis.

OC 70.3 | Platelet exosomes Promote Vaso-occlusive Thrombosis in Sickle Cell Disease

M. Jimenez, M. Bennewitz, T. Brzóska, M. Scott, M. Neal, M. Gladwin, P. Sundd

University of Pittsburgh, Pittsburgh, United States

Background: Acute painful vaso-occlusive crisis (VOC) is the predominant reason for emergency medical care among Sickle Cell Disease (SCD) patients. VOC involves microvascular thrombosis across

multiple organs, but the mechanism that promulgates widespread thrombosis in SCD is largely unknown.

Aims: To determine whether caspase-1-mediated shedding of IL-1β-containing platelet exosomes promotes vaso-occlusive thrombosis in SCD.

Methods: We used our experimental model of lung vaso-occlusion in transgenic, humanized SCD mice, which is triggered by intravenous challenge with nanogram levels of the TLR4 ligand, lipopolysaccharide (LPS). Thrombosis was visualized in real time *in vivo*, using multi-photon-excitation microscopy of intact lung in live SCD mice. SCD or control human blood was perfused through microfluidic channels *in vitro* and neutrophil-platelet aggregation was visualized using fluorescence microscopy. Platelet derived exosomes were characterized using nanoparticle tracking and biochemical approaches.

Results: Vaso-occlusive thrombosis in the lung involved blockade of pulmonary arterioles by neutrophil-platelet aggregates, which was associated with an increase in peripheral blood levels of platelet exosomes. *In vitro* microfluidic studies revealed increased neutrophil-platelet aggregation in LPS-treated SCD patient blood compared with healthy controls, and this correlated with increased numbers of IL-1β containing platelet exosomes. The shedding of exosomes was secondary to the activation of platelet NLRP3-ASC-Caspase-1 inflammasome. Inhibition of caspase-1 attenuated shedding of platelet exosomes and neutrophil-platelet aggregation in SCD human blood *in vitro* and lung vaso-occlusion in SCD mice *in vivo*.

Conclusions: Inflammasome-mediated caspase-1 activation in platelets promotes shedding of IL-1β-containing exosomes in SCD. These exosomes trigger vaso-occlusive thrombosis through the formation of neutrophil-platelet aggregates in the lung.

OC 70.4 | Visualising LPS-induced Platelet Adhesion and Activation in Lungs Using Immunohistochemistry and Intravital Microscopy

S.J. Cleary[1], E. Lefrançais[2], B. Mallavia[2], M.R. Looney[2], C.P. Page[1], S.C. Pitchford[1]

[1]*King's College London, Sackler Institute of Pulmonary Pharmacology, Institute of Pharmaceutical Science, London, United Kingdom,* [2]*University of California San Francisco, Pulmonary, Critical Care, Allergy and Sleep Medicine, Department of Medicine, San Francisco, United States*

Background: Platelets can accumulate in lungs as a result of exposure to bacterial lipopolysaccharides (LPS), but the mechanisms underlying this response are incompletely understood.

Aims: To measure platelet activation and adhesion in the mouse lung microcirculation following LPS inhalation using immunohistochemistry and intravital microscopy.

Methods: Frozen lung sections were collected from PBS control mice (n=6) or mice treated with 5 mg/kg LPS (n=7, O55:B5, i.n., +48h). Immunohistochemistry and image analysis were used to measure the number of CD41+ platelets, activation status (platelet CD41 expression), and platelet/neutrophil interactions by evaluating platelet association with neutrophil elastase. Using the same LPS challenge protocol, platelets in the lungs of *Pf4-cre×mTmG* mice (n=4, cells not expressing *Pf4* are tomato fluorescent protein+, platelets expressing *Pf4* are green fluorescent protein+) were imaged using a thoracic window and multiphoton microscopy in order to test the effect of LPS on platelet adhesion in the living lung. Comparisons are t tests (*), or 2-way ANOVA with repeated measures and Holm's *post hoc* test ($^{\#}$), *=p< 0.05, **=p< 0.01, ***=p< 0.001.

Results: LPS increased platelet numbers (60%**) in lung sections and the CD41 expression of platelets (38%**) on both platelets associated with neutrophils (39%$^{\#\#}$) and platelets not associated with neutrophils (37%$^{\#\#}$). Platelets associated with neutrophil elastase had higher CD41 expression in both PBS (12%$^{\#\#}$) and LPS treated mice (16%$^{\#\#\#}$). Frame-to-frame tracking of intravital video microscopy revealed an increased number of adherent platelets per frame in the pulmonary microvasculature following LPS inhalation (47%*).

Conclusions: LPS-induced platelet activation and adhesion in the pulmonary circulation can be measured using two imaging technologies. Spatial patterns of platelet activation are supportive of the existence of both neutrophil independent and neutrophil associated platelet activation following inhalation of LPS.

OC 70.5 | PLD1 Regulates TNF-mediated Protection against Responses to LPS

C. Kaup[1], M. Klier[1], M.-A. Urbahn[1], I. Krüger[1], R. Steubing[1], P. Lang[2], M. Elvers[1]

[1]*University Clinic of the Heinrich-Heine University, Research Group Molecular Hemostasis, Düsseldorf, Germany,* [2]*Heinrich-Heine-University, Institute of Molecular Medicine II, Düsseldorf, Germany*

Background: Phospholipase D1 (PLD1) is an important cell signaling enzyme in inflammatory cells, platelets and other cells that hydrolyzes phosphatidylcholine to phosphatidic acid (PA) and choline. PA is known to act as second messenger because it can bind and activate a multitude of proteins including kinases, phosphatases etc. to control cell migration, proliferation and cell survival. Deficiency of PLD1 protects mice against arterial thrombosis because thrombus formation under high shear is impaired in these mice. Moreover, PLD1 is important for the inflammatory response including cytokine release; however, nothing is known about the impact of PLD1 in sepsis.

Aims: The aim of this project is to analyze the role of PLD1 in sepsis as a systemic inflammatory response.

Methods: In vitro and in vivo analysis of PLD1 deficient mice after injection of LPS.

Results: LPS induced sepsis led to an increase of acute phase cytokines such as TNF-a and interleukin (IL)-6 in plasma of wildtype mice while levels were reduced in PLD1 deficient mice. Western blot analysis revealed that PLD1 is important for the phosphorylation of Mek1/2

and Erk1/2 upon LPS-induced inflammation pointing to a crucial role for PLD1 as regulator of TNF-a expression beside reduced TNF-a release. Moreover, PLD1 deficiency prevented LPS-induced liver and lung damage as shown by reduced cell apoptosis and decreased fibrin deposition in lungs. PLD1 deficient platelets contributed to preserved outcome of PLD1 deficient mice after sepsis. Defective platelet integrin activation and reduced thrombin generation was shown to be causative for reduced thrombosis in lungs and liver thereby protecting these mice from ischemic organ damage.

Conclusions: This study reveals an important role for PLD1 in the regulation of TNF-a expression and release, cell apoptosis and organ damage after LPS-induced sepsis in mice.

DIAGNOSTICS AND OMICS

OC 35.1 | Exome Sequencing as a First Tier Genetic Test for Hemostatic Diseases

W. van Heerde[1], A. Simons[2], S. Schoormans[3], S. Krouwel[3], M.R. Nijziel[4]

[1]Radboudumc, Dept of Laboratory Medicine, Laboratory of Hematology, Hemophilia Care Center, Nijmegen, The Netherlands, [2]Radboudumc, Dept of Human Genetics, Nijmegen, The Netherlands, [3]Radboudumc, Dept of Laboratory Medicine, Laboratory of Hematology, Nijmegen, The Netherlands, [4]Radboudumc, Dept of Hematology, Hemophilia Care Center, Expertise Center for Hemophilia and Rare Bleeding Disorders, Nijmegen, The Netherlands

Background: Hemostatic diseases are characterized by a susceptibility to develop hemorrhages because of genetic defects in one or more components of the hemostatic balance. At least 135 genes/loci are known as genetic causes for hemostatic disorders. We recently implemented Whole Exome Sequencing (WES) allowing analysis of a large panel of genes in one single test.

Aims: We performed WES analysis in patients with a severe bleeding phenotype with an ISTH BAT score above 8 and compared the data with the patients' phenotype.

Methods: WES started with the screening of genetic abnormalities in a predefined haemostatic panel. The hemostatic gene panel contains 135 genes proven to be involved in hemostatic disease including genes involved in primary hemostasis and secondary hemostasis. Second, if the haemostatic panel was negative, exome wide analysis was performed. The patients' phenotype was analysed using standard diagnostic assays.

Results: 43 patients were tested with the panel. 9 patients carried a pathogenic mutation causative for the disease explaining the laboratory/clinical phenotype; 6 with an autosomal dominant mutation (*VWF*, *RUNX1*, *MYH9*), 2 with a homozygous autosomal recessive mutation (*ITGA2B*, *P2RY12*) and 1 with an X-linked hemizygous mutation (*F8*).12 patients were heterozygous carriers of mutations genes involved in primary/secondary hemostasis either a combination of mutation in *VWF* gene and autosomal recessive genes or two autosomal recessive genes.

Conclusions: WES is a fast and cost efficient approach to detect genetic abnormalities in a large set of genes. Since the overall yield to detect pathogenic mutations was approximately 34% with the conventional targeted gene analysis approach, we implemented WES as a first tier diagnostic test for hemostatic abnormalities. Based on our experience we expect to resolve more hemostatic disorders due to the detection of combinations of autosomal recessive abnormalities particularly in primary hemostasis, a domain with a large number of unresolved clinical cases.

OC 35.2 | A Role for Chromatin Architecture in the Expression of the Fibrinogen Gene Cluster

C. Espitia, R.J. Fish, M. Neerman-Arbez

University of Geneva, Department of Genetic Medicine and Development, Geneva, Switzerland

Background: Fibrinogen is a hexameric protein encoded by a coordinately regulated, evolutionarily conserved three-gene cluster. Fibrinogen expression is thought to be regulated by a combination of proximal promoters and enhancer elements. Intriguingly, there are interaction sites for proteins involved in chromatin looping flanking the locus. These regions may act as insulators, demarcating a chromatin domain boundary and serving to loop regulatory elements into proximity of the three fibrinogen genes, facilitating their co-regulation.

Aims: To further our understanding of fibrinogen gene regulation, our study aims to uncover new enhancer elements, detect chromatin interactions in and around the fibrinogen gene cluster, and study how such interactions influence fibrinogen gene expression.

Methods: Cell-based luciferase gene reporters and a transgenic zebrafish assay were used to test regulatory sequences *in vitro* and *in vivo*, respectively. Chromatin interactions were assessed by chromosome conformation capture (3C). The importance of chromatin looping sites for fibrinogen expression was tested using CRISPR-Cas9 genome editing in fibrinogen-expressing cells. Fibrinogen mRNA expression was measured by qRT-PCR and protein levels by ELISA.

Results: We identified two new liver enhancers flanking the fibrinogen gene cluster. We demonstrated that the fibrinogen gene cluster is looped into a chromosomal domain, with proximity-based interactions detected between sites flanking the locus. Further sub-looping was detected, particularly in cells that express fibrinogen. After targeted removal of chromatin interaction sites flanking one side of the locus, previously detected interactions were disrupted and de novo interactions detected. In cells with targeted disruption of the fibrinogen locus looping, fibrinogen mRNA and protein production were halved.

Conclusions: We have assessed the chromatin conformation of the fibrinogen gene cluster and demonstrated that chromatin architecture contributes to fibrinogen gene expression.

OC 35.3 | A Survey of *F8* and *F9* Variants in *my Life, our Future* for Evidence of Alternative Splicing in Hemophilia

J. Johnsen[1,2], M. Kircher[3], S. Fletcher[1], H. Huston[1], K. Lannert[1], S. Roberge[1], B. Martin[3], N. Josephson[4], J. Shendure[3], S. Ruuska[1], M. Koerper[5], J. Morales[6], G. Pierce[5], D. Aschman[7], B. Konkle[1,2]

[1]Bloodworks Northwest, Research Institute, Seattle, United States, [2]University of Washington, Department of Medicine, Seattle, United States, [3]University of Washington, Department of Genome Sciences, Seattle, United States, [4]Seattle Genetics, Inc., Bothell, United States, [5]National Hemophilia Foundation, New York City, United States, [6]Bioverativ, Waltham, United States, [7]American Thrombosis and Hemostasis Network, Riverwoods, United States

Background: Hemophilia A and B are rare X-linked bleeding disorders. *My Life, Our Future* (MLOF) is a U.S. national collaboration to clinically genotype patients with hemophilia A and B and establish a research repository.

Aims: We hypothesized that aberrant splicing is an under-recognized pathogenic mechanism in hemophilia. We studied *F8* and *F9* gene variants in MLOF to predict alternative splicing *in silico* in hemophilia A and B.

Methods: We studied *F8* and *F9* gene variants along with disease status, gender, and baseline factor level in the first 3000 subjects enrolled in MLOF. We used splice prediction tools (dbscSNV, Jian et al. 2014; SPIDEX, Xiong et al, 2015) to assess annotated splice variants and to seek signatures of other DNA variants predicted to impact *F8* and *F9* splicing.

Results: A total of 893 *F8* and *F9* gene DNA variants, excluding inversions, large insertions and deletions, were found in the first 3000 subjects enrolled in MLOF. Of these, 824 were classified as likely causative (629 in *F8;* 195 in *F9*). 51 were clinically categorized as splice variants (38 in *F8;* 13 in *F9*). Most of these variants were also identified by splice prediction algorithms (32/38 in *F8*; 11/13 in *F9*). Additionally, 50 other candidate splice variants were identified (34 in *F8*; 16 in *F9*). Interestingly, 30 variants were positioned distant (>10bp) from canonical splice sites. Collectively, the predicted splice variants were annotated as intronic (n=44), synonymous (n=5), missense (n=34), in-frame deletion (n=1), frameshift (n=6), and nonsense (n=3). Predicted splice variants were associated with half the baseline factor levels of variants not predicted to impact splicing (hemophilia A, FVIII: 3.6 +/- 7.5 *vs.* 6.2 +/- 9.0, p = 0.001; hemophilia B, FIX: 2.3 +/- 4.7 *vs.* 4.7 +/- 7.3, p < 0.01).

Conclusions: These data suggest that aberrant splicing is diverse and more common in hemophilia than previously suspected, and that predicted splice variants are associated with more severe disease.

OC 35.4 | Development of an Antidote-controlled RNA Probe for Molecular Thrombi Imaging

B. Powell Gray[1,2], K.-A. Steen-Burrell[2], B. Sullenger[1], Diagnostics and OMICs

[1]Duke University Medical Center, Surgery, Durham, United States, [2]Duke University Medical Center, Durham, United States

Background: Vascular thrombosis is both a major underlying factor in many cardiovascular diseases worldwide and a major post-surgical complication. Early detection and treatment of thrombi improves outcomes for patients as the responsiveness of thrombi to fibrinolytic treatment decreases with thrombus age. The serine protease, thrombin, plays a central role in thrombogenesis and remains associated with the thrombus thereby facilitating further activation of coagulation factors and platelets after initial clot formation. Therefore, targeting and imaging clot-bound thrombin may provide a way of distinguishing newly formed thrombi from older, constituted ones.

Aims: The goal of this study is to develop the thrombin-targeting RNA aptamer Tog25t into a diagnostic probe for detecting blood clots via subtraction imaging.

Methods: The RNA aptamer Tog25t was conjugated to the near-infrared dye AF680 to detect clot-bound thrombin and a complementary antidote oligonucleotide was used to remove clot-bound aptamer, creating a subtraction image. Tog25t-AF680 was assessed for its in vitro binding capability to newly formed human plasma clots using fluorescence reflectance imaging and for its in vivo binding capability to a murine jugular clot using small animal near infrared fluorescent imaging.

Results: In comparison to a labeled non-binding control RNA, we observed a greater than 6-fold increase in near-infrared fluorescence (NIRF) target-to-background ratio (TBR) with Tog25t-AF680 in human plasma clots. Upon treatment with the antidote oligonucleotide (AO4), approximately 57% of the fluorescent signal disspated within 10 minutes of incubation. Tog25t-AF860 also targets jugular thrombi *in vivo* in an antidote-reversible fashion.

Conclusions: Our results suggest that thrombin is a suitable target for imaging newly formed clots. This thrombin-targeting near-infrared probe has the potential to be used as a diagnostic tool for arterial and venous thrombosis and may further advance our understanding of the role of thrombin in vivo.

OC 35.5 | The Design of a Novel Catheter to Deliver and Monitor Heparin Anticoagulation Therapy: Validation in a Small Cohort

J. Wang, J. Jokerst

University of California, San Diego, La Jolla, United States

Background: Heparin anticoagulation therapy has a narrow therapeutic window and is the second most common ICU medication error. The aPTT monitors heparin, but suffers from long turnaround times and a

variable reference range. Here, we describe a novel catheter to deliver heparin and monitor activity in real-time with potential applications for patients on perfusion and extracorporeal membrane oxygenation.

Aims:

Aim 1. Validate ultrasound-based measurement of heparin levels in human samples.

Aim 2. Build and validate smart catheter to deliver heparin and monitor anticoagulation.

Methods: This technique uses novel photoacoustic ultrasound with a heparin-sensitive phenothiazinium molecule in tandem with an embedded catheter to monitor anticoagulation (**Fig. 1a**). First, we used this phenothiazine to measure the photoacoustic signal of whole human blood with different concentrations of heparin and correlated the signal to the aPTT. We then created a hydrogel on the surface of the catheter via silica nanoparticles, agarose, and the phenothiazine and measured heparin (0-50 U/mL).

Results: Clinically relevant heparin concentrations (aPTT: 30 -250 s) were measured in blood with a detection limit of 0.28 U/mL. We validated this imaging approach by correlation to the aPTT (Pearson's r = 0.86; p< 0.05) as well as with protamine sulfate (**Fig. 1b**). This technique also has good utility with low molecular weight heparin (enoxaparin) including a detection limit in blood of 72 µg/mL.. We tuned the surface charge of the hydrogel on the catheter surface to -15 mV, and this material retained >90% of the phenothiazinium reporter (**Fig. 2a**). The detection limit of the catheter was 1 U/mL with good reversibility via protamine sulfate (**Fig. 2b**). The catheter´s response time is < 30 s.

Conclusions: This is the first report of non-invasive imaging to monitor heparin. This utility offers an instantaneous response and will be coupled to smart infusion pumps for real-time control of heparin therapy.

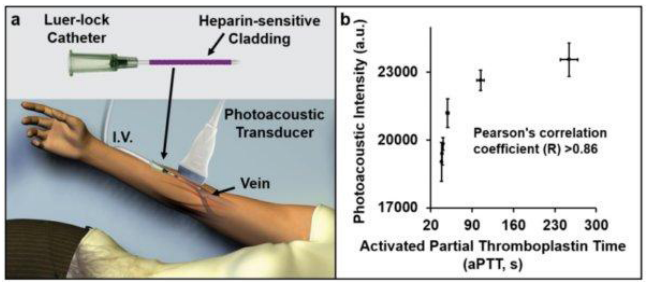

FIGURE 1 a) Schematic of device. b) Correlation of imaging signal with aPTT in six human whole blood samples with different heparin concentrations

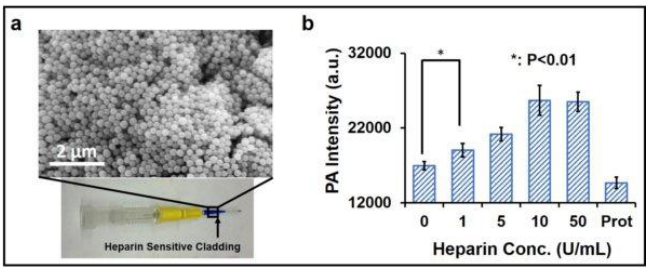

FIGURE 2 Catheter is coated with a hydrogel (a) containing the phenothizinium to measure heparin (b) with protamine sulfate reversibility (Prot.)

OC 51.1 | Impact of Genetic Variation on the Plasma Proteome in the Tromsø Study

E.N. Smith[1,2], T. Solomon[3], J. Lapek[4], S.B. Jensen[5], K. Hindberg[5], N. Latysheva[5], W.W. Greenwald[6], H. Matsui[7], S.K. Brækkan[5], D.J. Gonzalez[4], K.A. Frazer[1,2,7], J.B. Hansen[5,8]

[1]University of California San Diego, Pediatrics and Rady's Children's Hospital, La Jolla, United States, [2]University of Tromso, K. G. Jebsen - Thrombosis Research and Expertise Center (TREC), Tromsø, Norway, [3]University of California San Diego, Biomedical Sciences Graduate Program, La Jolla, United States, [4]University of California San Diego, Pharmacology, La Jolla, United States, [5]University of Tromso, Department of Clinical Medicine and K. G. Jebsen - Thrombosis Research and Expertise Center (TREC), Tromsø, Norway, [6]University of California San Diego, Bioinformatics and Systems Biology Graduate Program, La Jolla, United States, [7]University of California San Diego, Institute for Genomic Medicine, La Jolla, United States, [8]University Hospital of North Norway, Division of Internal Medicine, Tromsø, Norway

Background: Plasma proteins are involved in normal hemostasis and may be risk biomarkers of thrombotic diseases. It is, however, unclear how genetic variations contribute to protein levels estimated by mass spectrometry and whether these variants affect plasma protein level estimates through biological or technical mechanisms.

Aims: Our aim was to identify and characterize common and rare genetic variants associated with plasma protein levels assayed by mass spectrometry.

Methods: We performed exome sequencing or exome array genotyping of 200 participants recruited from the general population (the Tromsø Study). Additionally, EDTA-anticoagulated plasma was isolated and profiled for protein levels using TMT-multiplexed mass spectrometry. Mass spectra were mapped to peptides and proteins using Proteome Discoverer and the Uniprot protein sequence database. Mixed models were used to test for associations between common genetic variants near the protein's locus (cis) and peptide or protein levels. Analysis of rare genetic variation is ongoing.

Results: We quantified levels of 6,734 peptides that map to 748 Uniprot protein IDs (PIDs) and 692 gene loci. Common genetic variation was associated with 63 of the 748 PIDs as well as 230 of the 6,734 peptides. By examining the coding impact of the most associated SNP, we found that almost 30% of the variants associated with peptide levels were missense mutations that disrupted the peptide sequence and caused mis-mapping of the peptide. In some cases, these missense mutations had functional effects on the peptide, such as rs854560 (L55M) in Paraoxonase 1 (PON1), which decreases PON1 mRNA and plasma levels, while others may not be functional and confound mass spectrometry protein level estimation.

Conclusions: We identified cis common variation associated with plasma peptide and protein levels and showed that genetic variation often alters mass spectrometry estimates of peptide levels that may

be important to take into account when identifying or assaying protein biomarkers.

OC 51.2 | Effect of Endogenous Sex Hormone Levels Overall, and as Markers for Polycystic Ovary Syndrome and Primary Ovarian Insufficiency on Risk of Venous Thromboembolism

L.J.J. Scheres[1,2], A. van Hylckama Vlieg[2], B.E. Ballieux[3], B.C.J.M. Fauser[4], S. Middeldorp[1], S.C. Cannegieter[2,5]

[1]*Academic Medical Center, Department of Vascular Medicine, Amsterdam, The Netherlands,* [2]*Leiden University Medical Center, Department of Clinical Epidemiology, Leiden, The Netherlands,* [3]*Leiden University Medical Center, Department of Clinical Chemistry and Laboratory Medicine, Leiden, The Netherlands,* [4]*University Medical Center Utrecht, Department of Reproductive Medicine & Gynecology, Utrecht, The Netherlands,* [5]*Leiden University Medical Center, Department of Internal Medicine, Section of Thrombosis and Hemostasis, Leiden, The Netherlands*

Background: The risk of venous thromboembolism (VTE) in women of fertile age can largely be attributed to exogenous hormone exposure such as oral contraceptive (OC) use. The influence of endogenous sex hormone levels or disturbances of these hormones, such as in polycystic ovary syndrome (PCOS) or primary ovarian insufficiency (POI) on VTE risk is uncertain.

Aims: To assess the risk of VTE for levels of endogenous sex hormones
1) overall and
2) as markers for PCOS and POI.

Methods: Female participants of the MEGA-study (case-control study on VTE risk factors) ≤45 years who provided a blood sample in the absence of OC exposure or pregnancy were included. Sex-hormone binding globulin (SHBG), Estradiol (E2), Follicle stimulating hormone (FSH) and testosterone (TT) were measured. The free androgen index (FAI), used to determine (abnormal) androgen status, was calculated (100 x [testosterone/SHBG]).VTE risk was assessed for 1) hormones according to quartiles based on control levels, in FAI categories of < 1.5,1.5-3.0,3.0-4.5,>4.5 and 2) on clinical cut-off values used to diagnose PCOS and POI. Logistic regression models were constructed to estimate odds ratios (OR) with 95% confidence intervals (95%CI) adjusting for age and body mass index.

Results: A total of 679 women (376 cases, 303 controls) were eligible for the analyses.
1) We found a dose-response association for increased SHBG levels and VTE risk (Table 1). For FAI we found a U-shaped association with VTE risk (Table 2). There was no apparent association observed between levels of E2 or TT and VTE risk.
2) FSH levels ≥40 U/L, indicating POI, were possibly associated with decreased VTE risk, OR 0.7 (95%CI 0.3-1.3) as compared with levels < 40 U/L. A FAI>4.5, indicating PCOS, was associated with markedly increased VTE risk especially in participants who had not used OC at time of VTE: OR 5.1 (95%CI 1.0-26.2).

Conclusions: Endogenous sex-hormones overall and as markers for PCOS and POI are promising potential indicators of VTE risk.

OC 51.3 | Risk Prediction of Recurrent Venous Thrombosis in All Patients with a First Venous Thrombotic Event: Results from the MEGA Follow-up Study

J. Timp[1], S. le Cessie[1,2], L. Flinterman[1], A. van Hylckama Vlieg[1], F. Rosendaal[1,3], S. Cannegieter[1,3,4]

[1]*Leiden University Medical Center, Clinical Epidemiology, Leiden, The Netherlands,* [2]*Leiden University Medical Center, Medical Statistics, Leiden, The Netherlands,* [3]*Leiden University Medical Center, Einthoven Laboratory for Experimental Vascular Medicine, Leiden, The Netherlands,* [4]*Leiden University Medical Center, Internal Medicine, Leiden, The Netherlands*

Background: The decision on the optimal duration of anticoagulant treatment after a first venous thrombosis (VT) is challenging. The predictive performance of 3 existing models for recurrence in patients with unprovoked VT is suboptimal in external validation studies and is heavily dependent on the definition of unprovoked VT.

Aims: To develop a prediction model for all patients with VT, provoked ánd unprovoked, with inclusion of a large set of clinical and laboratory candidate predictors (n=39) to obtain maximum discriminatory power.

Methods: Patients with first VT without cancer were followed for recurrence between 1999 and 2010 (MEGA follow-up study). Blood was sampled 3m after discontinuation of anticoagulation. Clinical and laboratory parameters were collected for each patient. A prediction model was developed using Cox regression analyses and a backward selection procedure (p< 0.15). Provoked recurrences were censored.

TABLE 1 Odds ratios (OR) with 95% confidence intervals (CI) for sex hormone binding globulin (SHBG) levels per quartile

TABLE 2 Odds ratios (OR) with 95% confidence intervals (CI) for FAI in participants who did not use oral contraceptives at time of VTE

FAI	Cases (n)	Controls (n)	OR (95%CI)	OR* (95%CI)	OR** (95%CI)
Total	72	271			
FAI <1.5	41	135	1 (reference)	1 (reference)	1 (reference)
FAI 1.5-3.0	25	106	0.8 (0.4-1.4)	0.9 (0.5-1.5)	0.8 (0.4-1.4)
FAI 3.0-4.5	2	27	0.2 (0.1-1.1)	0.3 (0.1-1.4)	0.3 (0.1-1.2)
FAI >4.5	4	3	4.4 (0.9-20.4)	6.7 (1.3-34.2)	5.1 (1.0-26.2)

* Adjusted for age
** Adjusted for age and BMI

The performance of the model was estimated by means of Harrell's C-statistic.

Results: 3750 Patients were followed from discontinuation of anticoagulation for a median of 5.7 years (IQR;3.2-7.4), during which 507 unprovoked recurrences were identified. A full model, including 9 clinical and 7 laboratory parameters, showed good discriminative performance with a C-statistic of 0.73 (95%CI;0.71-0.76); 2-yr predicted risks ranged from 0-54% which coincided with observed risks. 13% of patients with provoked first VT had a two-yr predicted risk of >10%. For leaner versions of the full model the predictive performance decreased with each simplification (Table). In choosing a final model, a balance needs to be found between its predictive performance and clinical usefulness. Results from internal and external validation analyses will be available at the congress.

Conclusions: This model, including various clinical and laboratory parameters is able to accurately distinguish patients regarding their risk of recurrent VT, hence allowing refined assessment of the optimal duration of anticoagulant treatment.

OC 51.4 | Discovery of Plasma Biomarkers of Future Incident Venous Thromboembolism by Untargeted MS-Based Proteomics

S.B. Jensen[1], K. Hindberg[1], E.N. Smith[1,2], T. Solomon[3], J. Lapek[4], N. Latysheva[1], S.K. Brækkan[1], D.J. Gonzalez[4], K.A. Frazer[1,2,5], J.-B. Hansen[1,6]

[1]UiT - The Arctic University of Norway, K. G. Jebsen TREC, Clinical Medicine, Tromsoe, Norway, [2]University of California San Diego, Pediatrics and Rady's Children's Hospital, La Jolla, United States, [3]University of California San Diego, Biomedical Sciences Graduate Program, La Jolla, United States, [4]University of California San Diego, Pharmacology,, La Jolla, United States, [5]University of California San Diego, Institute for Genomic Medicine, La Jolla, United States, [6]University Hospital of North Norway, Division of Internal Medicine, Tromsø, Norway

Background: Current plasma components associated with risk of venous thromboembolism (VTE) do not adequately predict first VTE at an individual level. Thus, there is a major unmet need for discovery of novel plasma protein biomarkers to improve risk stratification and advocate targeted prevention actions in order to prevent VTE. Identification of predictive plasma biomarkers of VTE in a prospective population-based cohort by an untargeted approach has not previously been undertaken.

Aims: To identify plasma protein biomarkers associated with future risk of VTE by an untargeted mass spectrometry (MS)-based approach on blood plasma sampled prior to VTE events.

Methods: We conducted a nested case-control study of 100 VTE cases and 100 age- and sex-matched controls randomly sampled from the general population (the Tromsø Study 1994-2012). Proteomic profiles of EDTA-anticoagulated plasma samples were generated using Proteome Discoverer (ver. 2.1) and the Uniprot protein sequence database to analyze data from an untargeted TMT-multiplexing LC-MS3 shot-gun proteomics approach. Statistical analysis was done in R. The study was approved by the regional research ethics committee and all subjects gave informed written consent.

Results: A total of 6734 peptides mapping to 708 protein IDs were quantified. Proteins differently expressed in VTE cases and controls were identified by two-sample t-test, non-parametric analysis, and multiple linear regression (significance level 0.05), and revealed 29, 26, and 28 proteins, respectively. In total, 47 unique candidates were identified. Among the most interesting was Transthyretin, which was also differently expressed between groups after Bonferroni correction for multiple testing.

Conclusions: We have, by untargeted MS-based proteomics, identified several candidate proteins that were differentially expressed in plasmas from subjects with and without future development of VTE. Our findings will be validated by targeted proteomics in a large case-cohort study.

OC 51.5 | D-dimer Measured at Diagnosis Improves the Prediction of Major Bleeding Events during the 1-yr after an Incident VTE

H.S. Johnsen[1], E. Bjøri[1], K. Hindberg[1], S.K. Brækkan[1,2], J.B. Hansen[1,2]

[1]UiT - The Arctic University of Norway, K.G Jebsen - Thrombosis Research and Expertise Center (TREC), Tromsø, Norway, [2]University Hospital of North Norway, Division of Internal Medicine, Tromsø, Norway

Background: Currently available prediction tools do not provide accurate prediction of bleeding risk in patients on anticoagulant treatment for acute venous thromboembolism (VTE). D-dimer is measured to exclude the suspicion of VTE, but circumstantial evidence suggest that d-dimer is also associated with bleeding risk under various conditions.

Aims: To investigate whether d-dimer measured at the time of VTE-diagnosis is associated with major bleeding (MB) within the first year after diagnosis, and assess whether addition of d-dimer to a well-established prediction model (HAS-BLED) improves prediction of MB.

Methods: Cases with first VTE and d-dimer measured at diagnosis (n=555) aged 28-102 years, were sampled from the general population (The Tromsø study). Information on clinical variables, including HAS-BLED components (hypertension, abnormal renal/liver function, history of stroke or bleeding, age≥65, and drug- or alcohol abuse), was collected from medical records at the time of objectively confirmed VTE. MB-events (according to ISTH criteria) were registered up to one year after VTE-diagnosis. Multivariable Cox-regression models were used to calculate hazard ratios (HR) of MB across categories of d-dimer, and area under the curve (AUC) was used to compare the predictive abilities of a modified HAS-BLED with and without d-dimer.

Results: There were 52 MBs within one year after VTE-diagnosis. The risk of MB increased across quintiles of d-dimer ($p< 0.01$), and patients with d-dimer in the upper 20th percentile (>10.7 µg/ml) had a 2.2-fold (95% CI 1.1-4.6) higher risk of MB compared to the lower 40th percentile (0-2.8 µg/ml) in analyses adjusted for age, sex, duration of anticoagulant treatment, CRP and comorbidity. By adding one point for d-dimer (>10.7 µg/ml) to the HAS-BLED score, AUC increased from 0.60 (0.53-0.67) to 0.64 (0.55-0.72).

Conclusions: D-dimer measured at diagnosis was associated with risk of MB and improved the prediction of MB by HAS-BLED. Our results should be confirmed in larger cohorts.

OC 65.1 | Commutability - The Importance of Valid Material for Proficiency Testing Purposes

I. Jennings, D. Kitchen, S. Munroe-Peart, S. Kitchen, T. Woods, I. Walker

UK NEQAS (Blood Coagulation), Sheffield, United Kingdom

Background: External Quality Assessment (EQA) may identify problems in laboratories, and highlight differences between methods. Spiking of plasma may be employed to mimic clinical samples. Such material should give similar results to clinical samples (ie, be commutable) to ensure appropriate conclusions can be drawn.

Aims: We describe data from UK NEQAS BC exercises where spiked samples were tested alongside matched *ex vivo* samples.

Methods: Normal plasma was spiked with dabigatran, rivaroxaban, enoxaparin or unfractionated heparin (UFH). FVIII deficient plasma was spiked with FVIII concentrate. Samples were sent to participating centres and results for spiked and patient samples were compared.

Results: Similar precision was seen for patient and spiked material for assays of rivaroxaban (CVs 16.5% & 18.2%) dabigatran assays (CV 15.1% & 16.7%). For rivaroxaban, the pattern of results for widely used kits was the same but for dabigatran some kits showed differences between spiked and patient samples. For enoxaparin, agreement was seen between results for samples from a pool of plasma from patients receiving the drug and spiked samples ($r=0.84$); ranking of results was similar between different kits. For a pooled plasma from patients receiving UFH, the median APTT ratio was lower than for a spiked sample with similar anti Xa activity (1.35vs1.90, $p< 0.001$) with no correlation in ranking of reagents. For FVIII assays results with different reagent sets varied by 12% for an Advate-spiked sample, compared to 2% for a post infusion sample; for rFVIIIFc, the difference between methods was < 8% for spiked and *ex vivo* samples.

Conclusions: Spiked material is suitable for EQA only if commutability is demonstrated. Our data show commutability of results for plasma spiked with rivaroxaban, enoxaparin, and some FVIII concentrates. For some tests, notably APTT for UFH, there are marked differences between patient and spiked samples. There is a danger of inappropriate conclusions arising over methods used with non-commutable samples.

OC 65.2 | Chromogenic and One Stage FIX Assays in the Presence of Idelvion (rFIX-FP), Alprolix (rFIXFc) Benefix and Replenine: Data from a UK NEQAS for Blood Coagulation Survey

S. Kitchen[1], I. Jennings[1], M. Makris[2], D. Kitchen[1], T. Woods[1], I. Walker[1]

[1]UK NEQAS Blood Coagulation, Sheffield, United Kingdom, [2]University of Sheffield, Sheffield, United Kingdom

Background: Two extended half life FIX concentrates have recently been licensed. Some 1-stage FIX assays underestimate FIX-activity (FIX:Ac) but data is limited for most 1-stage FIX APTT and the chromogenic FIX assays.

Aims: To assess the use of multiple different APTT reagents and 2 chromogenic assays in samples containing FIX concentrates.

Methods: Samples were collected from different severe Haemophilia B subjects after infusion of Replenine or Benefix. Severe haemophilia B plasma was spiked with either Replenine, Benefix, Idelvion or Alprolix. All 6 samples were lyophilised and distributed through the UK NEQAS for Blood Coagulation programme to 68 UK haemophilia centres and 8 centres in Europe for FIX:Ac assay using the method in routine use for post infusion monitoring.

Results: Results with methods used by 3 or more centres are summarised in the table. Mean differences between results with different methods were < 25% for the samples containing Replenine. For samples containing Benefix FIX results were around 1/3 higher by 1-stage than chromogenic. For Idelvion FIX:Ac was markedly underestimated in 1-stage assays using AFS or CK Prest and markedly overestimated

TABLE 1

		n	Post Replenine	Spiked Replenine	Post Benefix	Spiked Benefix	Spiked Idelvion	Spiked Alprolix
Calculated FIX in spiked samples		-	-	50 IU/dL	-	70 IU/dL	60 IU/dL	60 IU/dL
	AFS	19	41.8	51.5	68.8	83	31.5	65.5
	AFSL	4	49	51.5	81.9	89.9	50.7	75.4
One stage methods Median (IU/dL)	CK Prest	5	51	55	76.5	86	32	48
	Pathromtin	4	42.7	46.5	57.6	66.5	52.6	46.9
	PTT Auto	3	46.3	50.7	80.5	82.6	52	40
	SynthaSIL	32	45	48.1	74	79.9	65.5	60.7
Chromogenic Median (IU/dL)	Hyphen	10	44	46.7	47.9	54.4	99.4	54.0
	Rossix	13	45	45	55	63	116	66.0

using either chromogenic assay. For Alprolix FIX activity was markedly underestimated in assays using CK Prest , Pathromtin SL or PTT Auto, although numbers of centres were low so more data are needed for robust conclusions to be drawn. For Benefix and Replenine there was an excellent correlation between results obtained on the post infusion and spiked samples indicating that the two materials were behaving in a similar way.

Conclusions: Our data suggest that chromogenic FIX or 1-stage FIX assays with Actin FS or CK Prest should not be used to monitor Idelvion. Either chromogenic assay could be used to monitor Alprolix. Based on our limited data one stage assay with CK Prest, APTT Auto or Pathromtin SL are expected to underestimate Alprolix activity.

OC 65.3 | The ECAT External Quality Assessment Programme: Larger Variation in FVIII Activity < 0.05 IU/ml with One-stage Assay Compared to Chromogenic Assay

I. van Moort[1], P. Meijer[2], F.W.G. Leebeek[3], M.H. Cnossen[1], M.P.M. de Maat[3]

[1]Erasmus University Medical Center - Sophia Children's Hospital, Pediatric Hematology, Rotterdam, The Netherlands, [2]ECAT Foundation, Voorschoten, The Netherlands, [3]Erasmus University Medical Center, Hematology, Rotterdam, The Netherlands

Background: Currently, both one-stage (OSA) and chromogenic substrate assay (CSA) are used to measure factor VIII (FVIII) activity and therefore to diagnose and monitor treatment in hemophilia A patients. Consequently, it is of clinical importance to identify analytical variation in OSA and CSA.

Aims: To quantify and specify the variation in FVIII activity when testing by OSA and CSA.

Methods: Seventeen samples distributed by the ECAT foundation between 2010-2016 with FVIII values between < 0.01 IU/ml and 1.94 IU/ml were analyzed by >200 laboratories worldwide. Measured FVIII levels and coefficient of variation (CV) for both OSA and CSA were compared and subgroup analysis was performed for most commonly used kits (n>10).

Results: Only minimal differences were observed between measured FVIII levels for OSA and CSA; for example in plasma from a healthy subject the measured FVIII activity (median±IQR) was 1.00±0.14 IU/ml for the OSA and 0.97±0.11 IU/ml for the CSA (p=0.10) and a hemophilia A patient 0.01±0.02 IU/ml OSA and 0.01±0.01 IU/ml CSA (p=0.29). The CV of both tests was negatively associated with FVIII levels (Figure 1). In addition, the CV was larger in the OSA when FVIII< 0.05 IU/ml with a maximal CV of 75% for the OSA and 48% for CSA. Subgroup analysis for OSA for different equipment, type of deficient plasma and calibration techniques was not possible, as most laboratories obtained these products from the same company. Comparison between activators did no show differences in FVIII results (p>0.05). For CSA, the measured FVIII levels were similar for the different kits.

Conclusions: The coefficient of variation in FVIII OSA measurements is larger compared to CSA when FVIII is < 0.05 IU/ml. Consequently, larger variation in FVIII testing might increase the risk on misclassification of hemophilia severity.

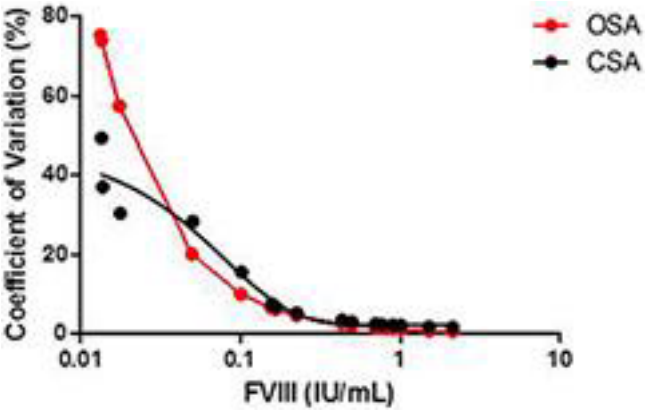

FIGURE 1 Coefficient of variation of FVIII activity measurements in the ECAT program (n>200)

OC 65.4 | North American Special Coagulation Laboratories (NASCOLA): Laboratory Practices for aPTT Based One-stage Factor Assays and their Outcomes on Results: A Survey

D. Castellone[1], K. Moffat[2], E. Plumhoff[3]

[1]New York Presbyterian Hospital - Columbia, Clincial Laboratories, New York, United States, [2]Hamilton Regional Hospital, Laboratory Medicine, Ontario, Canada, [3]Mayo Clinic, Rochester, United States

Background: Inter-laboratory variability has been observed when reviewing international proficiency test (PT) results for one-stage factor assays. The greatest variability is seen in aPTT based assays at lower ranges (< 10% /< 0.01U/mL).

Aims: To survey members of NASCOLA to determine current practices for performing one-stage factor assays and if certain laboratory practices can be identified that contribute to PT variability.

Methods: A survey of 22 questions was sent to NASCOLA labs inquiring how they performed one-stage aPTT factor assays. Laboratories provided information regarding type of instrumentation, number of factor dilution run; calibration curve questions included type, number of points, number of curves used, upper and lower limit of detection and how results were reported. Responses were anonymous prior to analysis. PT results (2012-15) were reviewed to determine if specific practices could be identified that contributed to variability of results.

Results: Thirty NASCOLA laboratories responded. Five different families of coagulation analyzers were used. A minimum of three dilutions are run in 93% of labs; the highest dilution at 1:320, and the lowest at 1:2.5. Most common starting dilution is 1:10 (48%). Calibration curve fits were polynomial (61%) with 57% running 6 or more points; 50% included a zero point. Forty percent of laboratories construct a low curve in addition to a standard calibration curve. Results were extrapolated by 13% of laboratories, however all laboratories reported very low levels as < the lowest point.

Conclusions: This NASCOLA survey confirms wide variability in laboratory practices of factor assays. Lack of consensus on how calibration curves are prepared is likely a contributing factor. Variability includes number of points; curve fit and whether multiple curves are used. and extrapolated results. Adapting recently published consensus guidelines for the performance of one stage factor assays (CLSI; 2016) may help to minimize variability in practice and ultimately in PT results.

OC 65.5 | Efficiency of Bayesian Logic in Detecting and Characterizing Loss of Precision, and or Loss of Accuracy: Application to aPTT Statistical Process Control

F. Sobas[1], K. Bourazas[2], E. Jousselme[1], C. Nougier[1], C. Négrier[1], P. Tsiamyrtzis[2]

[1]Hôpitaux Est de Lyon, Laboratoire d'Hématologie, Bron, France, [2]Athens University of Economics and Business, Department of Statistics, Athens, Greece

Background: A preliminary study („Use of prior manufacturer specifications with Bayesian logic eludes preliminary phase issues in quality control: An example in a hemostasis lab", Blood Coagul Fibrinolysis 2015, 26: 590-596) showed how the conventional preliminary phase can be avoided using Bayesian logic. The first Bayesian tool used to this end is the Predictive Control Chart (PCC), intended to detect outliers. Holistic monitoring will require to identify not only outliers but trends in the mean and the inter assay SD of the process. Two new Bayesian tools (Location and Scale Predictive Residual CUSUM (PRC)) charts are introduced, aiming to identify such trends in the process without any preliminary phase.

Aims: To illustrate the reliability of mathematical simulations with real-life med lab out-of-control (OOC) case studies especially at the early method startup phase.

Methods: From Instrumentation Laboratory (IL), Bedford, MA, USA: ACL TOP 750 analyzer, HemosIL Synthasil and HemosIL Normal Control Assayed: aPTT (activated partial thromboplastin time) prior target = 29 seconds. Calibration of Bayesian tools: PCC with Alarm as with 1_3s ; Location PRC: Alarm for a change in

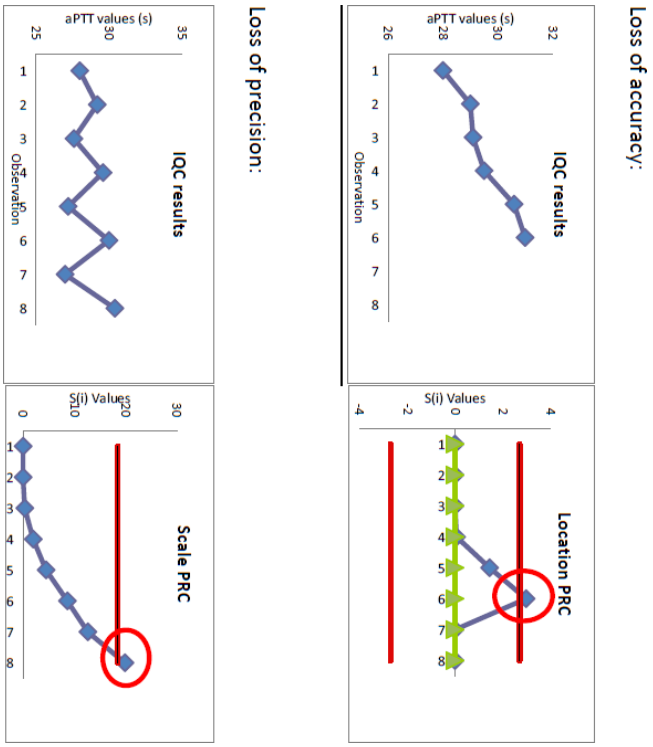

FIGURE 1 loss of accuracy scenario and loss of precision scenario

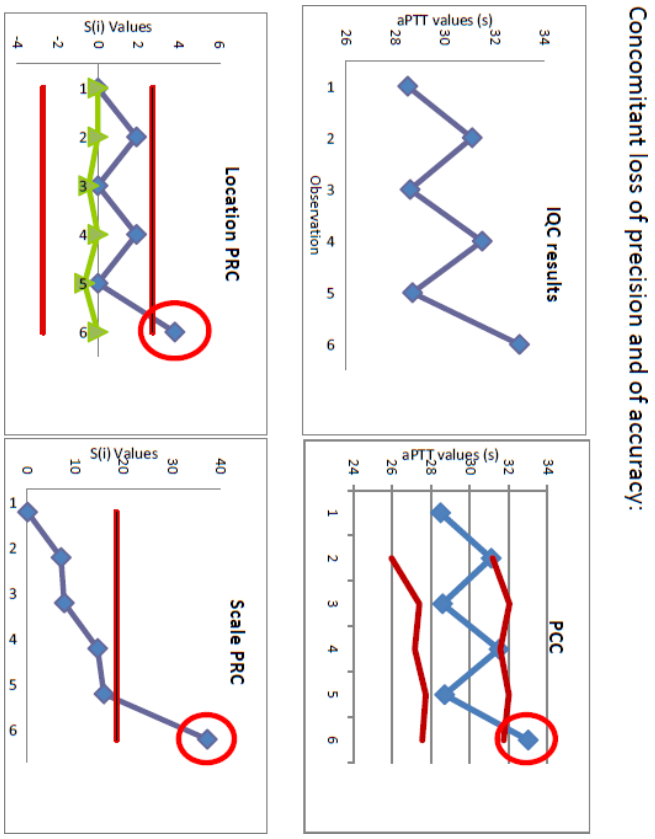

FIGURE 2 Concomitant loss of accuracy and precision scenario

terms of 1.5 SD shift (corresponding to aPTT uncertainty of measurement) ; Scale PRC: Alarm for 50% increase in inter-assay SD (50% with respect to our proper inter-assay SD value and what it is required for unfractionated heparin (UFH) treatment monitoring with aPTT in terms of precision).Three OOC scenarios were tested as of observation 2.

Results: The different kinds of scenario were detected and categorized very early and in online fashion, without any preliminary phase as required in conventional approach (figure 1 and 2).

Conclusions: Using Bayesian logic, laboratory IQC management becomes central to very efficient patient management, with a focus on quality in the spirit of the 2012 version of the ISO 15189 norm.

FIBRINOLYSIS & PROTEOLYSIS

OC 01.1 | The Plasminogen Receptor Plg-R_{KT} is Expressed on Platelets and Co-localises with Platelet-derived Plasminogen upon Stimulation

C.S. Whyte[1], N.A. Booth[1], M.M. Jalal[1], R.J. Parmer[2,3], L.A. Miles[4], N.J. Mutch[1]

[1]*University of Aberdeen, School of Medicine, Medical Sciences and Nutrition, Aberdeen, United Kingdom,* [2]*University of California San Diego, Department of Medicine (9111H), San Diego, United States,* [3]*Veterans Administration San Diego Healthcare System, San Diego, United States,* [4]*The Scripps Research Institute, Department of Molecular Medicine, La Jolla, United States*

Background: Binding of plasminogen to cell surfaces dramatically accelerates rates of activation. We have shown binding of exogenous plasminogen to PS-exposing and spread platelets. Platelet α-granules are reported to contain plasminogen but mechanisms of endocytosis and retention are unclear. Recently, a novel transmembrane lysine-dependent receptor for plasminogen, Plg-R_{KT}, has been described on macrophages.

Aims: To examine expression of Plg-R_{KT} on platelets and determine whether platelet-derived plasminogen associates with this receptor upon endocytosis.

Methods: Plasminogen in releasate from thrombin-stimulated platelets ± εACA was quantified by ELISA. Platelets were separated by ultracentrifugation into soluble protein and membrane fractions and the presence of Plg-R_{KT} identified by Western blotting. Exposure of platelet-derived plasminogen and Plg-R_{KT} was investigated using flow cytometry and confocal microscopy after stimulation of platelets with thrombin and convulxin (CVX) or collagen.

Results: Plasminogen was detected in the releasate of activated platelets (0.08 nmol/10^8 plts), but was significantly augmented by pre-treatment of platelets with εACA (0.33 nmol/10^8 plts). εACA is a lysine analogue that competes for plasminogen binding sites, suggesting that platelet-derived plasminogen associates with the membrane via a lysine-dependent mechanism. Membrane accumulation of platelet-derived plasminogen on activated platelets was confirmed by flow cytometry. A 17 kDa band, consistent with Plg-R_{KT}, was detected in lysate and membrane fraction of platelets. Confocal microscopy revealed the presence of platelet-derived plasminogen on both spread and balloon shaped PS-exposing platelets which concentrated in ‚caps' on the PS-exposing platelets. Plg-R_{KT} co-localized with platelet-derived plasminogen on the activated platelet-membrane.

Conclusions: Platelets express Plg-$R_{KT,}$ which potentially functions in retention of platelet-derived plasminogen and may facilitate cell-surface mediated plasminogen activation.

OC 01.2 | Dysregulation of Metabolic Homeostasis in Plasminogen Receptor$_{KT}$ (Plg-R_{KT}) Deficient Mice

L. Miles[1], N. Baik[1], H. Bai[2,3], J. Wang[4], F. Samad[4], R. Parmer[2,3]

[1]*The Scripps Research Institute, Molecular Medicine, San Diego, United States,* [2]*University of California San Diego, Medicine, La Jolla, United States,* [3]*Veterans Administration San Diego Healthcare System, San Diego, United States,* [4]*San Diego Biomedical Research Institute, San Diego, United States*

Background: Inhibition of the plasminogen activation system is linked to adipose fibrosis and insulin resistance in response to a high fat diet. However, the role of molecules that promote plasminogen activation has not been studied extensively. Plg-R_{KT} is a novel transmembrane plasminogen receptor that promotes plasminogen activation and localizes plasmin activity on cell surfaces.

Aims: To test the hypothesis that Plg-R_{KT} regulates systemic metabolic homeostasis and promotes healthy adipocyte function.

Methods: Plg-R_{KT} null mice and wild-type littermates were fed a high fat (60%) diet (HFD) for 16 weeks.

Results: Plg-$R_{KT}^{-/-}$ mice gained significantly more weight than Plg-$R_{KT}^{+/+}$ littermates (final wt., 54±0.9 g vs 39± 3.6 g, respectively, P< 0.01 n=8). Echo MRI measurements showed that total fat mass was significantly greater in HFD- Plg-$R_{KT}^{-/-}$ mice compared with HFD-Plg-$R_{KT}^{+/+}$ littermates (20.8±0.7 g vs 14.7±2.7 g, respectively, P< 0.05, n=8), epididymal adipose tissue weight was significantly less, while liver weights were significantly greater. Histological analysis showed dramatically greater levels of lipid accumulation in liver in HFD- Plg-$R_{KT}^{-/-}$ mice, consistent with decreased ability of Plg-$R_{KT}^{-/-}$ adipose tissue to store lipid, and enhanced ectopic fat accumulation, a hallmark of Type 2 Diabetes. Furthermore, greater fibrin and collagen deposition and greater accumulation of inflammatory cells was observed in adipose tissue of Plg-$R_{KT}^{-/-}$ mice. And Plg-$R_{KT}^{-/-}$ mice exhibited more severe blunting of glucose tolerance and less efficient insulin-mediated suppression of plasma glucose. In insulin signaling studies, Akt phosphorylation was 80% lower in adipose tissue of Plg-$R_{KT}^{-/-}$ mice.

Conclusions: Plg-R_{KT} coordinately regulates multiple aspects of adipose function and metabolic homeostais by maintaining an anti-fibrotic adipose environment, promoting insulin sensitivity and adipogenesis and maintaining an anti-inflammatory adipose environment.

OC 01.3 | Neutrophil Extracellular Traps In Thrombi from Patients with Acute Ischemic Stroke

E. Laridan[1], F. Denorme[1], L. Desender[1], O. François[2], T. Andersson[2,3], H. Deckmyn[1], K. Vanhoorelbeke[1], S.F. De Meyer[1]

[1]KU Leuven Campus Kulak Kortrijk, Laboratory for Thrombosis Research, Kortrijk, Belgium, [2]AZ Groeninge, Department of Medical Imaging, Kortrijk, Belgium, [3]Karolinska Institutet, Department of Clinical Neuroscience, Stockholm, Sweden

Background: Little is known about the exact composition of thrombi causing ischemic stroke. Yet, such information is essential to improve current thrombolytic therapy. For unknown reasons, t-PA mediated thrombolysis often fails, suggesting the presence of unknown components that resist classical fibrinolysis and could be involved in thrombus stabilization. Recently, neutrophil extracellular traps (NETs) have been reported in various settings of thrombosis but their presence in ischemic stroke thrombi remains unknown.

Aims: To determine the presence of neutrophils and more specifically NETs in ischemic stroke patient thrombi.

Methods: Sixty-eight thrombi retrieved from ischemic stroke patients following endovascular treatment were characterized by immunostaining for citrullinated histone H3 (H3Cit), CD66b and neutrophil elastase. Extracellular DNA was visualized via DAPI. Per thrombus, H3Cit and neutrophil amount was quantified and correlated with stroke etiology and thrombus age. Extracellular DNA was targeted by ex vivo lysis with DNase1 and t-PA on eight patient thrombi.

Results: Neutrophils were detected extensively throughout all thrombi. H3Cit, a hallmark of NETs, was observed in almost all thrombi and H3Cit-positive area varied up to 13.45% within thrombi. Co-localization of H3Cit with extracellular DNA released from neutrophils confirmed the presence of NETs. H3Cit presence was significantly higher in thrombi from cardioembolic origin compared to other etiologies (3.07 % ± 2.21 % vs 1.57 % ± 1.23 %, p< 0.05). Older thrombi contained significantly more neutrophils as well as H3Cit compared to fresh thrombi (p< 0.001 and p< 0.05). Interestingly, ex vivo lysis of patient thrombi was more successful when adding DNase1 to standard t-PA (p< 0.01).

Conclusions: Our study demonstrates the presence of neutrophils, and for the first time, the presence of NETs in human stroke thrombi. Initial evidence is provided that targeting NETs with DNase 1 might open novel treatment avenues for acute ischemic stroke therapy.

OC 01.4 | A Hepatocyte Transcriptional Repressor DACH1 Exacerbates Defective Fibrinolysis in Obesity

Z. Zheng, I. Tabas

Columbia University, Department of Medicine, New York City, United States

Background: Increased risk of thrombosis accounts for enhanced clinical events observed in patients with metabolic syndrome. While recent work describes impaired fibrinolytic activity as a main driver for increased risk of thrombosis, the mechanisms linking defective fibrinolytic activity to metabolic syndrome has yet to be fully elucidated. Previously, we showed a transcriptional co-repressor DACH1 positively correlates with increasing BMI in human liver biopsies. Elevated DACH1 in hepatocyte activates the ER stress and causes defective insulin signaling in obese mice.

Aims: To explore the mechanisms whereby hepatic DACH1 signaling exacerbates the dysfunction of fibrinolysis in obesity.

Methods: Diet-induced obese mice with hepatocyte-*Dach1* deletion were subjected to bleeding, fibrinolytic activity assays, and FeCl3-induced arterial thrombotic injuries. Then we explore the mechanism of how DACH1 regulates the transcription of genes involved in fibrinolysis in human hepatocytes.

Results: Hepatocyte-*Dach1* deletion in obese mice significantly
1) elongates the tail bleeding time, and
2) time to occlude carotid in FeCl3-induced arterial thrombosis model,
3) increases liver tissue plasminogen activator (tPA, or Plat) mRNA, circulating tPA, tPA enzymatic activity, and fibrin-degradation products, consistent with hyperfibrinolysis.

Specifically silencing hepatic *Plat* gene in hepatocyte-DACH-knockout mice reversed these effects. We found a striking correlation between higher human liver DACH1 protein levels and lower plasma tPA activities from very lean to extreme obese individuals.

Conclusions: This study provided a novel pathway linking obesity with defective fibrinolysis through hepatic DACH1-tPA signaling. DACH1 has never before been implicated in blood coagulation and fibrinolysis.

Moreover, the findings reveal that regulation of tPA in hepatocytes, a cell type previously unappreciated as playing a major role in tPA biology, is a key determinant of the tPA/PAI1 balance in blood and its effects on bleeding and thrombosis.

OC 01.5 | Enhanced Fibrinolysis Using Magnetically Driven Functionalized Microwheels

D. Disharoon, O. Tasci, K. Neeves, D. Marr, K. Rana

Colorado School of Mines, Golden, United States

Background: The efficacy of fibrinolytic agents is limited by delivery to and penetration into an occlusive embolus or thrombus. These transport limitations are particularly acute for occlusions of small arteries that are not accessible to catheters and rely on diffusion of fibrinolytics.
Aims: Use magnetic powered microwheels (µwheels) functionalized with tissue type plasminogen activator (tPA) to achieve faster lysis than comparable concentration of free tPA.
Methods: Under a 9 mT magnetic field rotating at 100 Hz, superparamagnetic beads (1 µm) conjugated to biotinylated recombinant tPA form wheel-like assemblies that roll along the surface in unidirectional and corkscrew motions. Fibrin gels were formed using recalcified plasma and thrombin (4.5 nM) in a microfluidic device between two reservoirs of plasma (Fig. 1A). Fibrinolysis by tPA-wheels with an effective tPA concentration of 3.6 ug/mL was compared to 1 and 10 ug/mL soluble tPA.
Results: High µwheel translation speeds (4.5 ± 3.8 µm/s) relative to lysis rates caused accumulation at the gel interface, resulting in a local tPA concentration of up to 180 ug/mL. µWheels driven with unidirectional and corkscrew motions lyse fibrin gels at rates of 4.8 ± 0.3 and 9.6 ± 1.5 µm/min, compared to rates for 1 and 10 ug/mL tPA of 0.81 ± 0.25 and 5 ± 1.5 µm/min (Fig. 1B-D).

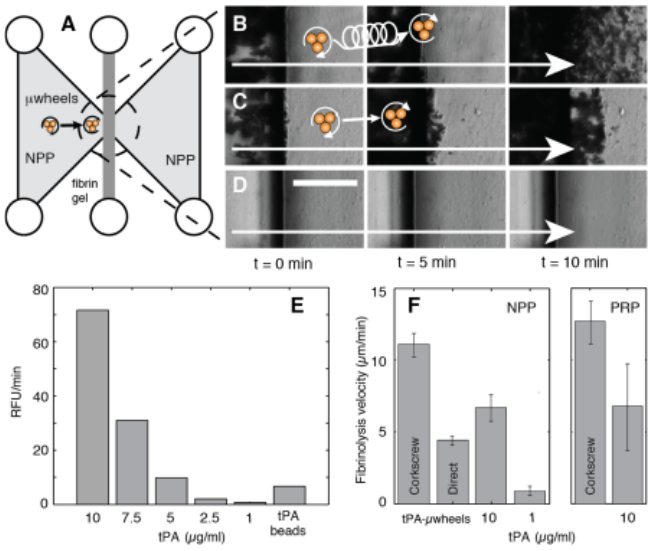

FIGURE 1 Colloids bearing tPA (3.6 ug/mL) lyse fibrin gels faster than 10 ug/mL free tPA when driven in a corkscrew motion by a magnetic field

Conclusions: tPA-functionalized µwheels controlled by an external programmable magnetic field enhance fibrinolysis compared to soluble tPA. Increases lysis is due to the high localized concentration of tPA, and penetration of tPA-loaded beads, especially those with a corkscrew motion, into fibrin gels.

OC 19.1 | Fibrinolysis with Clot-specific Thrombin-cleavable Microplasminogen is a Potential Alternative to Plasminogen Activators

T. Bonnard[1,2], Z. Tennant[1,2], B. Niego[3], R. Kanojia[2,4], K. Alt[1,2,4], S. Jagdale[1,2], L. Soon Law[2], S. Rigby[4], R.L. Medcalf[3], K. Peter[4], C.E. Hagemeyer[1,2]

[1]Australian Centre for Blood Diseases, Monash University, NanoBiotechnology Laboratory, Melbourne, Australia, [2]Baker Heart and Diabetes Institute, Vascular Biotechnology Laboratory, Melbourne, Australia, [3]Australian Centre for Blood Diseases, Monash University, Molecular Neurotrauma and Haemostasis Laboratory, Melbourne, Australia, [4]Baker Heart and Diabetes Institute, Atherothrombosis and Vascular Biology Laboratory, Melbourne, Australia

Background: Thrombolytic therapy is currently exclusively provided by plasminogen activators (PAs). Despite proven benefits, their use is limited by haemorrhagic/neurotoxic side effects and thrombolysis failure. We developed a novel thrombolytic molecule composed of microplasminogen engineered to be activated by thrombin (HtPlg) fused to an activation-specific anti-GPIIb/IIIa single-chain antibody (SCE5).
Aims: We studied the thrombolytic capacities and bleeding side effect of SCE5-HtPlg, evaluating its potential to overcome limitations of PAs.
Methods: We tested the efficacy of SCE5-HtPlg to lyse human blood clots *in vitro* under conditions which mimic thrombolysis resistance from mature thrombi (4 h) *versus* immature clots (30 min). We further measured the thrombolytic capacities in a mouse model of pulmonary embolism and evaluated the safety profile with tail bleeding and intracranial haemorrhage (ICH) measurements.
Results: The SCE5-HtPlg yielded efficient clot degradation in the *in vitro* thrombolysis assay. Clot maturation time significantly delayed urokinase (uPA) induced lysis, but did not affect the thrombolysis profile of SCE5-HtPlg ($p < 0.05$, n=4). In the *in vivo* lung embolism model, SCE5-HtPlg treatment at 4 µg/g bodyweight (BW) and uPA at 500 U/g BW resulted in similar 4-fold reduction of pulmonary fibrinogen deposition compared to saline ($p < 0.01$, n=3). At these therapeutic doses, uPA significantly prolonged the bleeding time compare to saline ($p < 0.001$, n=3) whereas the SCE5-HtPlg did not. We did not observe accumulation of haemoglobin or albumin in brain samples from mice treated with 4 µg/g SCE5-HtPlg compared to saline control ($p=0.77$ and $p= 0.79$, respectively, n=3), suggesting a lack of ICH and blood-brain barrier breakdown.
Conclusions: Thrombolysis provided by the novel thrombin-activated fibrinolytic drug SCE5-HtPlg has the potential to overcome limitations of PAs currently in clinical use. Future studies will confirm these results using *in vivo* models of thrombosis resistant to lysis by PAs.

OC 19.2 | Coagulation Factor XIIIa Is Inactivated during Thrombolytic Treatment

W. Hur[1], L. Machan[2], C. Kastrup[1]

[1]University of British Columbia, Michael Smith Laboratories, Vancouver, Canada, [2]University of British Columbia, Surgery, Vancouver, Canada

Background: Coagulation factor XIIIa (FXIIIa) is a transglutaminase that covalently crosslinks fibrin and several other coagulation factors to stabilize blood clots and reduce blood loss. Although the activity and the mechanism of activation had been well characterized, the mechanisms of inactivation are less clear.

Aims: Determine the extent that FXIIIa is inactivated by fibrinolytic enzymes and the implications in thrombolytic therapy.

Methods: Using blood collected from both healthy and patients treated for deep vein thrombosis, the inactivation of FXIIIa by plasmin and tPA was measured using Western blotting.

Results: Here we show that plasmin can cleave FXIIIa. FXIIIa was efficiently cleaved by plasmin in buffer and in plasma, whereas its zymogen, FXIII, was not. We have preliminary data suggesting that FXIIIa is degraded in a subset of patients treated with thrombolytics. In blood collected prior to tPA administration, FXIIIa was stable in all patients; however, in a subset of patients, FXIIIa was degraded in blood collected immediately after the completion of thrombolytic therapy.

Conclusions: These results indicate that the fibrinolytic system can regulate the coagulation system's crosslinking agent, and this provides an additional point of regulation of clotting. The potential implications are that pathophysiological or therapeutic conditions that increase fibrinolysis may inhibit crosslinking and stabilization of fibrin.

OC 19.3 | Fibrinolytic System Components Uniquely Affect the Resolution of Deep Vein Thrombosis: Comparison of α2-antiplasmin and Tissue Plasminogen Activator

S. Singh, A. Houng, G. Reed

University of Tennessee Health Science Center, Medicine, Memphis, United States

Background: Patients with deep venous thrombosis are treated with anticoagulants to prevent thrombus extension. However, thrombus resolution (fibrinolysis) is minimal, which may lead to recurrent embolism and post-thrombotic syndrome.

Aims: To determine the potential causes of impaired fibrinolysis, we examined the expression of fibrinolytic system components in experimental venous thrombi and compared the effects of tissue plasminogen activator (tPA) and α2-antiplasmin (α_2AP) inhibition on thrombus resolution.

Methods: Venous thrombi were examined in mice one and seven days after inferior vena cava ligation. Fibrinolytic components were detected by immunostaining. Plasmin generation and clot lysis were assessed. Data were analyzed by Student's t-test or a one way ANOVA.

Results: Occlusive venous thrombi were comparable in size at day one and seven post-IVC ligation (p=0.68). Urokinase and PAI-1 expression were significantly increased in 1 day thrombi as compared to sham mice (p< 0.01), tPA expression was minimal-absent. Plasminogen (Pg) and α_2AP were significantly increased (p< 0.001) throughout the thrombus. We examined whether insufficient Pg activation or plasmin inhibition were responsible for impaired thrombus dissolution. Mice were treated with recombinant (r-) tPA or an antibody that inhibits α_2AP, 1 day post IVC ligation. A therapeutic r-tPA dose and a higher dose (1.2 and 5 mg/kg) had no significant effect, but α_2AP inhibition significantly reduced thrombus weight, 7 days after treatment (p< 0.001). Plasma clot lysis showed that α_2AP inhibition enhanced plasmin activity and fibrinolysis.

Conclusions: Despite the presence of fibrinolytic components, fibrinolysis is suppressed in venous thrombi. Inactivation of α_2AP was more effective at dissolving existing thrombi than pharmacologic doses of r-tPA. We conclude that α_2AP contributes to persistence of venous thrombi in vivo and α_2AP inhibition may have therapeutic value.

Funded in part by NIH (NINDS NS089707 and by NHLBI HL092750) to Guy Reed.

OC 19.4 | CVD-risk Associated Lipid Levels Associate Not Only with Increased Fibrinogen Concentration but also with Altered Plasma Clot Properties in a Healthy Population

Z. De Lange, B. Kahler, C.M. Smuts, M. Pieters

North-West University, Centre of Excellence for Nutrition, Potchefstroom, South Africa

Background: Blood lipid levels are known to be related to fibrinogen concentration. *In vitro* and clinical studies have also indicated effects on fibrin clot structure and lysis. It is less clear whether the relationship between blood lipids and fibrinogen also extends to altered clot properties in a population setting.

Aims: To investigate the relationship between total (TC), low-(LDL-C) and high density lipoprotein (HDL-C), non-HDL cholesterol and triglycerides (TG) with total and gamma' fibrinogen concentration as well as plasma clot properties.

Methods: This cross-sectional study included 1250 healthy participants. Blood lipids were measured (Cobas Integra 400 plus) and LDL-C calculated. Clot properties [lag time, slope, maximum absorbance and clot lysis time (CLT)] were determined (turbidimetry) and total fibrinogen (Clauss assay) and gamma' (ELISA) measured. Lipids were divided into healthy and cardiovascular disease (CVD) risk categories and differences in fibrinogen and clot properties investigated using t-tests and ANCOVA.

Results: Increased LDL-C, non-HDL-C and decreased HDL-C were associated with increased total fibrinogen concentration and a prothrombotic clot phenotype. Adjustment for total fibrinogen nullified the association with clot properties except for CLT which remained

TABLE 1 Direction of associations between risk related lipid categories and clot properties

CVD-risk lipid category	Total fibrinogen	Fibrinogen γ´	Lag time	Slope		Maximum absorbance		CLT	
↑TC	-	-	-	↑	-	↑	-	↑	↑
↑LDL-C	↑	-	-	↑	-	↑	-	↑	↑
↑Non-HDL-C	↑	-	-	↑	-	↑	-	↑	↑
↓HDL-C	↑	-	-	↑	-	↑	-	↑	↑
↑TG	-	-	-	↓	-	↓	-	↑	↑

- No association; ↑ Increase; ↓ Decrease; Second column for slope, maximum absorbance and CLT present associations after adjustment for total fibrinogen

increased in all CVD-risk lipid categories. There was no association between any of the lipids and gamma´ fibrinogen. Increased TG were however associated with decreased slope and maximum absorbance.

Conclusions: CVD-risk associated lipid levels were not only associated with increased total fibrinogen concentration but also with a pro-thrombotic clot phenotype in this healthy population. Additional factors other than increased fibrinogen, contributed to slower lysis in individuals with CVD-risk lipid levels. Fibrinogen gamma' levels showed no association with any of the blood lipids. The relationship of TG needs to be investigated further.

OC 19.5 | Recombinant ADAMTS-4 Enhances tPA-mediated Fibrinolysis in Ischemic Stroke

S. Martinez de Lizarrondo[1], M. Pruvost[1], A. Anfray[1], C. Ali[1], J. Montaner[2], M. Rubio[1], M. Gauberti[1,3], D. Vivien[1,4]

[1]INSERM UMR-S U 1237, Caen, France, [2]Vall d'Hebron Institute of Research (VHIR), Barcelona, Spain, [3]Caen University Hospital, Department of Diagnostic Imaging and Interventional Radiology, Caen, France, [4]Caen University Hospital, Department of Cell Biology, Caen, France

Background: Thrombolysis using intravenous administration of tissue-type plasminogen activator (tPA) remains the only approved pharmacological treatment to induce arterial recanalization in acute ischemic stroke. Notably, a growing body of evidence suggests that some metalloproteases play a role in fibrinolysis regulation and could accordingly be used to increase tPA efficiency.

Aims: To investigate the interactions between a disintegrin and metalloproteinase with thrombospondin motifs-4 (ADAMTS-4, a metalloprotease mainly involved in the degradation of chondroitin sulfate proteoglycans) and the fibrinolytic system and its potential use as an ischemic stroke treatment.

Methods: Clot lysis and substrate cleavage experiments were performed to explore the effects of ADAMTS-4 on the fibrinolytic system. Then, to investigate the effects of ADAMTS-4 on tPA efficiency as a stroke treatment, we performed an experimental model of thromboembolic stroke in mice allowing tPA-induced reperfusion, including experiments with ADAMTS-4 knockout mice. Lastly, we investigated the interactions between plasmatic ADAMTS-4 levels and different stroke outcomes in a cohort of ischemic stroke patients.

Results: We demonstrated that ADAMTS-4 increases tPA fibrinolytic activity in plasma by cleaving plasmin(ogen) in a dose and time-dependent manner, thereby increasing the resulting proteolytic activity of plasmin. Accordingly, concomitant administration of ADAMTS-4 with tPA improved stroke outcome in mice. In contrast to exogenously administered recombinant ADAMTS-4, endogenous ADAMTS-4 did not play a key role in stroke outcome according to our human and transgenic mice experiments.

Conclusions: Recombinant ADAMTS-4 enhances tPA-mediated fibrinolysis and reduces ischemic lesion size after thromboembolic stroke.

OC 28.1 | Blocking of Tissue Factor Signaling in Breast Cancer Inhibits Tumor Metastasis

B. Ünlü[1], B. Kocatürk[1], W. Ruf[2], H.H. Versteeg[1]

[1]Leiden University Medical Center, Department of Thrombosis and Hemostasis, Leiden, The Netherlands, [2]The Scripps Research Institute, Department of Immunology and Microbiology, La Jolla, United States

Background: Tissue Factor (TF) expression in breast cancer is associated with higher tumor grade, metastasis and poor survival. Classically, it has been thought that TF influences cancer progression through two distinct pathways; it facilitates cellular signaling pathways to promote tumor growth and it initiates blood coagulation to promote survival of metastatic cells. However, the role of TF signaling in metastasis has never been addressed.

Aims: To investigate whether TF signaling influences metastasis and to address the cellular processes associated with TF-dependent metastasis.

Methods: Effects of TF signaling in metastasis *in vivo* were studied after graftment of MDA-MB-231-mfp cells, a highly aggressive subclone of the claudin-low breast cancer cell line MDA-MB-231, in a NOD-Scid-gamma (NSG) mouse breast cancer model. Effects of TF on metastasis *in vitro* were studied using a matrigel invasion assay. TF-dependent gene regulation was studied using real time PCR.

Results: We show *in vivo* that the monoclonal TF antibody 10H10, which blocks TF signaling, inhibits metastasis 10-fold, irrespective of its effects on primary tumor growth, and 10H10 reduces invasion by 3-fold. As 10H10 does not inhibit TF-dependent coagulation and thus

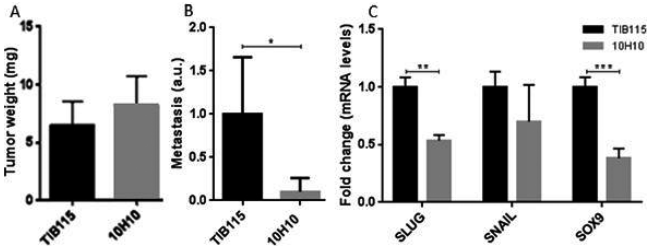

FIGURE 1 A) Tumor weight with 10H10 or control antibody B) Metastasis in the lungs C) Reduced CSC marker gene expression after 10H10 treatment in vitro

survival of metastatic cells, we argued that TF signaling is directly responsible for pro-metastatic events in the primary tumor. TF signaling inhibition by 10H10 led to a reduction in cancer stem cells (CSCs) in mammosphere assays and in mouse models for CSC behavior; and a 2-fold reduction of SLUG and SOX9 expression, the combination of which influences CSC genesis. Finally, in tumor specimens from 574 patients we found an association between TF expression and the CSC marker aldehyde dehydrogenase 1 (ALDH1) (P=0.001);TF expression was also highly associated with metastasis in ER-negative tumors (P< 0.005).

Conclusions: TF signaling inhibition leads to a reduced CSC transcriptional program, a reduction in primary tumor-resident cancer stem cells and thus a reduction in metastasis.

OC 28.2 | Thrombin Cleavage of Osteopontin Plays an Important Role in Melanoma Growth and Progression

S. Peraramelli[1], Q. Zhou[1], J. Kim[2], T. Myles[1], J. Morser[1], L. Leung[1]

[1]*Stanford University, Hematology, Stanford, United States*, [2]*Stanford University, Pathology and Dermatology, Stanford, United States*

Background: Osteopontin (OPN) is a matricellular multifunctional protein with a highly conserved RGD domain that binds to a wide range of integrins. Thrombin cleavage at Arg153 generates OPN-R and OPN-CTF (C-terminal fragment). OPN-R, with SVVYGLR at its C-terminus, binds to a new subset of integrins ($\alpha4\beta1$and $\alpha9\beta1$) (Fig.1).

OPN expression is markedly increased in inflammatory conditions. It has been reported that growth of B16 melanoma is suppressed in OPN knock-out (KO) mice. However, despite extensive studies on the importance of OPN in cancer progression, the role of thrombin cleavage of OPN is unknown.

Aims: To investigate the role of thrombin cleavage of OPN in B16 melanoma growth.

Methods: Mice with OPN resistant to thrombin cleavage were generated by replacing Arg153 with Ala (OPN_{R153A}; OPN knock in [KI]). B16 cells were inoculated subcutaneously in mice, and tumor growth was

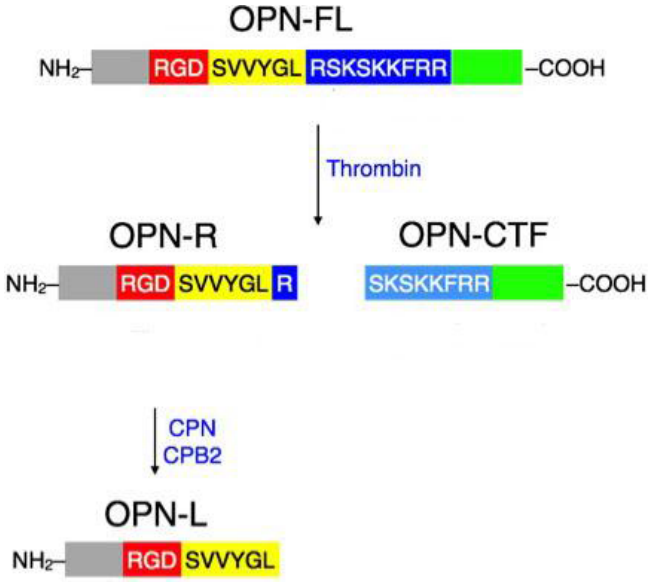

FIGURE 1 Schematic representation of thrombin and CPB2-mediated OPN cleavages

monitored. B16 cell adhesion and migration in response to various forms of recombinant OPN were performed *in vitro*.

Results: Robust tumor growth was observed in wild-type (WT) mice while being suppressed to the same extent in both OPN KO and OPN_{R153A}-KI mice when monitored as volume over time or weight upon sacrifice (Fig.2).

B16 cell adhesion assays showed a 4-fold increase in adhesion to OPN-R compared to OPN-full length (OPN-FL). Migration assays showed a 2-fold increase with OPN-R and OPN-CTF compared to OPN-FL. Preliminary histology showed a trend of more necrosis in OPN KO and KI compared to WT not related to tumor weight.

Conclusions: Our data provides the first *in vivo* demonstration of the importance of thrombin cleavage of OPN in cancer biology. Despite the presence of RGD and the other functional domains in OPN_{R153A}, the OPN KI mice demonstrated diminished B16 tumor growth equal to its absence, indicating that thrombin cleavage of the host OPN plays a critical role in melanoma growth *in vivo*.

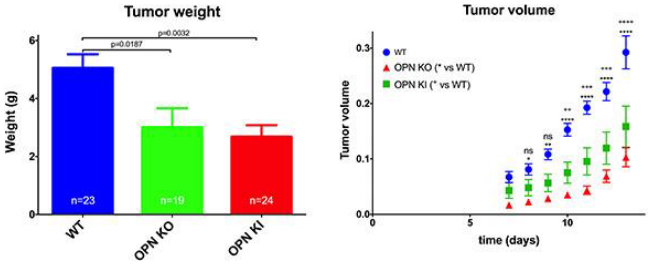

FIGURE 2 Decreased B16 tumor growth in OPN KO and OPNR153A KI mice compared to WT mice

OC 28.3 | Thrombin-PAR-1 Promotes Pancreatic Ductal Adenocarcinoma Through Tumor Cell Expression of Urokinase Plasminogen Activator and Receptor

M. Flick[1], A. Smith[1], J. Palumbo[1], J. Luyendyk[2], Y. Yang[3], S. Konieczny[3]

[1]Cincinnati Children's Hospital Medical Center, Cincinnati, United States, [2]Michigan State University, East Lansing, United States, [3]Purdue University, West Lafayette, United States

Background: Pancreatic ductal adenocarcinoma (PDAC) accounts for greater than 85% of pancreatic cancer cases and is associated with extremely poor patient survival. Analyses of PDAC in patients and animal models have demonstrated that it is associated with robust coagulation system activity driven by high tissue factor (TF) expression in the tumor cells.

Aims: To determine the mechanisms of tumor cell associated thrombin/PAR-1 function in driving PDAC tumor cell growth.

Methods: Tumor cell lines (termed KPC2) were derived from mice in which PDAC was induced by activation of two key pancreatic cancer alleles, *Kras*^{G12D} and *Trp53*^{R172H}. Tumor growth of KPC2 cells were evaluated either (*i*) in mice with genetically imposed deficits in coagulation and fibrinolytic system components or (*ii*) using KPC2 cells in which tumor-derived factors including TF, PAR-1, urokinase plasminogen activator (uPA), and uPA receptor (uPAR) were genetically reduced by shRNA or eliminated using CRISPR-Cas9.

Results: In transplant studies, primary tumor growth and experimental metastasis of KPC2 cells were significantly reduced by reduction of TF expression by the tumor cells or reduction of prothrombin in the microenvironment (*i.e.*, fII^{low} mice which constitutively express 10% of normal prothrombin). Knockdown of PAR-1 in KPC2 cells resulted in significantly diminished tumor growth whereas knockout of PAR-1 completely prohibited tumor growth. PAR-1 deficiency was linked to diminished expression of uPA and uPAR by KPC2 cells. Notably, knockout of either uPA or uPAR in KPC2 cells resulted in a similar significant reduction in tumor growth and metastasis. Analysis of parental KPC2 cells in knockout mice indicated that PDAC tumor cell growth was linked to plasminogen but independent of plasmin-mediated fibrinolysis.

Conclusions: Our results suggest that thrombin/PAR-1 can drive PDAC growth and dissemination in part through mechanisms linked to expression of uPA/uPAR by the tumor cell and plasminogen activation in the microenvironment.

OC 28.4 | Mechanisms Linking Fibrin(ogen) Structure/Function to Tumor Metastasis

A.S. Remiker, L.A. Rosenfeldt, G.N. Adams, M.J. Flick, M.D. Frederick, J.S. Palumbo

Cincinnati Children's Hospital Medical Center, Hematology, Cincinnati, United States

Background: Fibrin(ogen) is a multifunctional protein that can form a polymer and engage multiple cell types, including platelets and immune cells, by serving as a ligand for several cell surface receptors. Fibrinogen is a major determinant of metastasis; however, the mechanisms by which fibrin(ogen) drives metastasis have remained elusive.

Aims: Determine the role of fibrin polymerization and fibrin(ogen) engagement of integrins $\alpha_{IIb}\beta_3$ and $\alpha_M\beta_2$ in metastasis.

Methods: We performed experimental metastasis assays using Lewis lung carcinoma in immunocompetent mice carrying specific fibrinogen structure/function alterations.

Results: Mice carrying a mutant fibrinogen that retains clotting function but lacks the $\alpha_M\beta_2$ binding motif (Fib$\gamma^{390\text{-}396A}$) developed significantly fewer pulmonary metastases than controls, suggesting that fibrin(ogen)-a_Mb_2 interactions drive metastasis. Notably, soluble fibrinogen retains the capacity to interact with numerous ligands, but is a poor ligand for a_Mb_2. Metastatic potential in Fib^{AEK} mice carrying fibrinogen "locked" in the soluble state was diminished relative to control mice. However, Fib^{AEK} mice had elevated metastatic potential relative to mice with complete fibrinogen deficiency. Metastasis in Fib$\gamma^{\Delta5}$ mice, carrying fibrinogen lacking the γ chain $a_{IIb}b_3$ binding motif, was indistinguishable from controls.

Conclusions: These studies suggest that thrombin-mediated fibrin polymerization promotes metastasis, but soluble fibrinogen retains some significant prometastatic capacity. These data also imply a role for fibrin(ogen)-leukocyte interactions mediated by a_Mb_2 in metastasis. Surprisingly, loss of the fibrinogen γ chain $\alpha_{IIb}\beta_3$ binding motif had no impact on metastasis. These results suggest that platelets might bind polymerized fibrin at other sites, and/or fibrin interactions with other matrix proteins capable of binding $a_{IIb}b_3$ (e.g., fibronectin, vWF) are sufficient to support platelet functions required for metastasis.

OC 28.5 | Biomarkers of Inflammation and Coagulation in Long-term Survivors of an Adult Cancer - Results from the Gutenberg Health Study

M. Panova-Noeva[1,2], A. Schulz[2,3], N. Arnold[2,3], M.I. Hermanns[2,3], J.H. Prochaska[1,2], D. Laubert-Reh[2,3], H.M. Spronk[4], M. Blettner[2,5], M. Beutel[2,6], N. Pfeiffer[2,7], T. Münzel[2,8,9], K.J. Lackner[2,10], H. ten Cate[4], P.S. Wild[1,2,3]

[1]University Medical Center of the Johannes Gutenberg-University Mainz, Center for Thrombosis and Hemostasis (CTH), Mainz, Germany, [2]University Medical Center of the Johannes Gutenberg-University Mainz, Center for Translational Vascular Biology (CTVB), Mainz, Germany, [3]University Medical Center of the Johannes Gutenberg-University Mainz, Preventive Cardiology and Preventive Medicine, Center for Cardiology, Mainz, Germany, [4]Maastricht University Medical Center, Cardiovascular Research Institute Maastricht (CARIM), Maastricht, The Netherlands, [5]University Medical Center of the Johannes Gutenberg-University Mainz, Institute of Medical Biostatistics, Epidemiology and Informatics (IMBEI), Mainz, Germany, [6]University Medical Center of the Johannes Gutenberg-University Mainz, Department of Psychosomatic Medicine and Psychotherapy, Mainz, Germany, [7]University Medical Center of the Johannes Gutenberg-University Mainz, Department of

Ophthalmology, Mainz, Germany, [8]University Medical Center of the Johannes Gutenberg-University Mainz, Center for Cardiology I, Mainz, Germany, [9]DZHK (German Center for Cardiovascular Research), Partner Site RhineMain, Mainz, Germany, [10]University Medical Center of the Johannes Gutenberg-University Mainz, Institute for Clinical Chemistry and Laboratory Medicine, Mainz, Germany

Background: Cancer is among the leading causes of morbidity and mortality worldwide. The advancements in treatment and improved detection of early cancers resulted in a steady increase of cancer survivors over the years. However, the long term toxic effects of chemotherapy and radiotherapy resulted in increasing incidence of cardiovascular disease (CVD) in survivors.

Aims: To explore the associations of inflammatory and coagulation biomarkers as well as multiple cardiovascular risk factors (CVRFs) in long-term cancer survivors (cancer diagnose ≥ five years) from a large adult population-based study sample.

Methods: Biomarkers and presence of CVRFs and were compared in individuals with (n=723) and without (n=13626) history of cancer from the Gutenberg Health Study.

Results: Long-term cancer survivors showed higher fibrinogen concentration (ß:7.30, 95%CI:1.53-13.1), vWf (ß:5.29, [0.35-10.2]) and FXI levels (ß:2.65, [0.17-5.14]), compared to individuals without cancer history, independently of age, sex, CVRFs, CVD and antithrombotic therapy. Cancer survivors with CVD presented particularly higher vWf (143±48%) and lower protein S levels (94±26%) compared to survivors without CVD (vWF:124±40%; protein S:107±17%), in an age and sex weighted analysis. A history of cancer increases mortality by 73% independent from the presence of traditional CVRFs. Worst survival was found in individuals with history of cancer and presence of CVD.

Conclusions: This is a first population-based study investigating inflammation and coagulation profile in long-term cancer survivors. Cancer survivors showed a worse inflammation and coagulation profile and increased overall mortality, independent of traditional CVRFs, compared to individuals without history of cancer. These results underline the need to further investigate plasma biomarkers as complementary cardiovascular risk predictors in cancer survivors.

OC 54.1 | Intermolecular Interactions in Double-stranded Half-staggered Fibrin Oligomers

A. Zhmurov[1], A.D. Protopopova[2], R.I. Litvinov[2,3], P. Zhukov[1], A.R. Mukhitov[2], J.W. Weisel[2], V. Barsegov[1,4]

[1]Moscow Institute of Physics and Technology, Dolgoprudny, Russian Federation, [2]University of Pennsylvania, Perelman School of Medicine, Department of Cell & Developmental Biology, Philadelphia, United States, [3]Institute of Fundamental Medicine and Biology, Kazan Federal University, Kazan, Russian Federation, [4]University of Massachusetts at Lowell, Department of Chemistry, Lowell, United States

Background: The structural scaffold of the blood clot is provided by the filamentous fibrin network, which ultimately consists of fibrin monomers. Upon polymerization, fibrin forms several important intermediate structures fibrin oligomers, protofibrils and fibrin fibers. Due to their transient nature, the atomic structure of these polymeric structures is nearly impossible to determine using experimental techniques.

Aims: The internal structure of the fibrin polymer is necessary to understand the mechanical properties of the fibrin polymers. The aim of this work was to determine the structure of the fibrin oligomers in an atomistic level of detail.

Methods: We used combined experimental and computational techniques, including atomic force microscopy, detailed analysis of the crystal structures available from the PDB, multiscale MD simulations and Monte Carlo docking.

Results: We obtained the atomic structure of the two-stranded half-staggered fibrin oligomer (Figure 1). We added to this structure the missing residues that were not resolved previously by X-ray crystallography. The resolved structure allowed us to identify the amino-acid residues that are important in formation of the double-stranded fibrin oligomers. We also showed how the formation of inter-monomer contacts change the flexibility of fibrin oligomers.

Conclusions: The atomic model computationally reconstructed and experimentally validated in this work represent a significant development necessary for structure-based understanding of unique biochemical and material properties of fibrin polymers.The structures are availible for downloading in the PDB format at http://faculty.uml.edu/vbarsegov/research/fibrin.html

OC 54.2 | Role of Fibrinogen αC Domain in Fibrin Fibre Lateral Aggregation and αC Connector Region In Longitudinal Fibre Growth; Complex Interactions of the αC Region that Regulate Clot Structure and Function

H. McPherson[1], C. Duval[1], N. Asquith[1], M. Domingues[2], S. Baker[1], V. Ridger[3], S. Connell[4], H. Philippou[1], R. Ajjan[1], R. Ariëns[1]

[1]University of Leeds, Leeds Inst. of Cardiovascular & Metabolic Medicine, Leeds, United Kingdom, [2]University of Lisbon, Institute of Molecular Medicine, Lisbon, Portugal, [3]University of Sheffield, Department of Infection, Immunity and Cardiovascular Science, Sheffield, United Kingdom, [4]University of Leeds, Molecular & Nanoscale Physics Group, Leeds, United Kingdom

Background: Fibrinogen (FGN) α-chain is the largest FGN chain, two thirds extend from the D-region (221-610) to form a connector region (221-392) and a globular αC domain (392-610). The αC domain and its connector contain sites for α_2-antiplasmin cross-linking and α-α chain cross linking by FXIII. Previous data on FGN truncated at 251 (middle of connector region) indicated that the αC region is important for lateral aggregation of fibres.

Aims: To investigate the influence of the αC region components on clot structure and function with two new FGN variants deleting the connector region and/or the C-terminal globular domain.

Methods: Two recombinant FGNs truncated at residues 390 (loss of the αC domain) and 220 (removal of connector region + αC domain) and WT FGN were produced in CHO cells. FGNs were characterised by SDS-PAGE for integrity, homogeneity and cross-linking by FXIII. Clot structure was studied by turbidity and confocal microscopy with alexa-488 FGN variants.

Results: Two FGNs were produced with a truncated α-chain of expected size (α390 42kDa and α220 25kDa). Turbidity showed decreased maximum absorbance for α390 (0.27) compared to WT clots (0.49), but higher for α220 (0.73). Lag time was increased (150 α390 and 152 α220 vs 112 WT sec) and clotting rate was reduced in both truncations compared to WT (0.034 α390 and 0.020 α220 vs 0.063 WT OD/min). SDS-PAGE showed reduced α-chain but normal γ-chain cross-linking for both α-truncations. Confocal microscopy showed that FGN α390 formed denser clots with thinner fibres and smaller pores, while α220 produced less dense clots containing thick, short and bundled fibres with large pores.

Conclusions: Our data show a clear role for the αC domain in lateral aggregation, but crucially indicate a new role for the αC connector region in longitudinal fibre growth. These findings highlight the importance and complexity of the FGN αC region in clot structure and function.

OC 54.3 | Pharmacologic Enhancement of the Fibrin(ogen)-integrin αMβ2 Interaction Reduces Acetaminophen-induced Liver Injury in Mice through Induction of Matrix Metalloproteinase 12

A. Kopec[1,2], N. Joshi[1,2], A. Pant[1,2], H. Cline-Fedewa[1], M. Flick[3], J. Luyendyk[1,2,4]

[1]Michigan State University, Pathobiology & Diagnostic Investigation, East Lansing, United States, [2]Michigan State University, Institute for Integrative Toxicology, East Lansing, United States, [3]Cincinnati Children's Hospital Medical Center, Division of Experimental Hematology & Cancer Biology, Cincinnati, United States, [4]Michigan State University, Pharmacology & Toxicology, East Lansing, United States

Background: Acetaminophen (APAP) overdose is a leading cause of acute liver failure and is linked to activation of the coagulation cascade and deposition of fibrin in the liver. We have shown previously that fibrin(ogen) engagement of the leukocyte $\alpha_M\beta_2$ integrin stimulates expression of matrix metalloproteinase 12 (MMP12) by liver macrophages and promotes liver repair after APAP overdose.

Aims: Because this particular function of fibrin(ogen) can be targeted, in principle, without causing bleeding, we sought to determine the effect of the novel $\alpha_M\beta_2$ allosteric agonist leukadherin-1 (LA-1) on liver injury and hepatic MMP12 expression after APAP overdose.

Methods: Wild-type (WT) C57BL/6J mice were given a hepatotoxic dose of APAP (300 mg/kg, ip) and then treated with LA-1 (0.4 mg/kg, ip) or vehicle (0.4% DMSO in saline) after liver injury had developed (i.e. at 6 and 12 h later). Extent of liver injury was examined 24 h after APAP challenge.

Results: LA-1 treatment significantly reduced APAP-induced liver injury, reducing both ALT levels and hepatic necrosis. Moreover, LA-1 also dramatically enhanced hepatic expression of MMP12 mRNA relative to APAP-treated mice given vehicle. Importantly, in APAP-treated Fib$\gamma^{390\text{-}396A}$ mice, which express a mutant form of fibrin(ogen) incapable of binding $\alpha_M\beta_2$ integrin, hepatic MMP12 mRNA levels were drastically suppressed. Rescue of APAP-challenged Fib$\gamma^{390\text{-}396A}$ mice with recombinant MMP12 (rMMP12) protein markedly reduced hepatic hemorrhage and congestion, decreased ALT levels and restored hepatocyte proliferation to levels seen in APAP-treated WT mice.

Conclusions: The results indicate that LA-1 treatment attenuates APAP-induced liver injury in mice, in part by inducing MMP12 expression, and administration of rMMP12 improves APAP-induced liver injury phenotype. The results suggest that fibrin(ogen)-$\alpha_M\beta_2$ integrin-dependent pathway can be pharmacologically targeted to drive induction of MMP12 and promote liver repair after APAP overdose.

OC 54.4 | Functional Characterisation of Fibrinogen γ' Truncations

H. McPherson[1], C. Duval[1], M. Domingues[2], S. Baker[1], V. Ridger[3], S. Connell[4], H. Philippou[1], R. Ajjan[1], R. Ariëns[1]

[1]University of Leeds, Leeds Inst. of Cardiovascular & Metabolic Medicine, Leeds, United Kingdom, [2]University of Lisbon, Institute of Molecular Medicine, Lisbon, Portugal, [3]University of Sheffield, Department of Infection, Immunity and Cardiovascular Science, Sheffield, United Kingdom, [4]University of Leeds, Molecular and Nanoscale Physics Group, Leeds, United Kingdom

Background: Fibrinogen (FGN) γ' is a splice variant, in which the C-terminal 4 residues of the γ-chain are replaced with 20 different residues that are more negatively charged. We previously showed that plasma-purified γA/γ' FGN influences polymerisation and protofibril formation resulting in clots with reduced protofibril packing and heterogeneous networks.

Aims: Determine the mechanism by which γ' influences fibrin structure.

Methods: Recombinant FGN with γ'-chain truncations (γ'0, 0-12 and 0-16: deleting all, 8 and 4 residues from the C-terminus respectively), full-length FGN γ' and γA were produced in CHO cells as homodimers. Integrity of the FGN chains was established by SDS-PAGE. Fibrin formation and fibrinolysis was characterised by turbidity and confocal microscopy with alexa 488 FGNs.

Results: SDS-PAGE confirmed different γ' lengths were produced with intact α and β-chains. Turbidity showed marginally decreased maximum absorbance + or - FXIII between γ' truncations and γA. Average clotting rate (10^{-3}OD/sec) was slower with increasing γ' length, both - FXIII (γ' 0.36, γ'0-16 0.37, γ'0-12 0.46) and + FXIII (γ' 0.39, γ'16 0.50, γ'12 0.48) compared to γA (0.87) and (0.92). No differences were seen with fibrinolysis for any truncations + or - FXIII compared to γA. Confocal microscopy showed no differences in the number of fibres between the truncations and γA. However, the truncated fibres were less straight compared to γA, and fibre straightness correlated negatively with γ' length.

Conclusions: Differences in clot structure for plasma purified γA/γ′ are not fully reproduced in this recombinant protein and its truncations. It is unknown what causes this discrepancy but unidentified plasma factors may play a role. Further work is needed to test if γ′ is modified in circulation, the two tyrosine residues in recombinant FGN γ′ chain are sulphated or if differences are due to homodimer versus heterodimer formation.

OC 54.5 | Interaction of Fibrin with the VLDL Receptor: Mapping the VLDL Receptor-binding Site in Fibrin βN-domains

L. Medved, S. Yakovlev

University of Maryland Baltimore, School of Medicine, Department of Biochemistry and Molecular Biology & Center for Vascular and Inflammatory Diseases, Baltimore, United States

Background: Our previous studies revealed that interaction of fibrin with the very low density lipoprotein receptor (VLDLR) promotes transendothelial migration of leukocytes and thereby inflammation and localized complementary binding sites to fibrin βN-domains and CR domains of VLDLR. Since this interaction is a potential therapeutic target for controlling fibrin-dependent inflammation, one of the major goals of our current studies is to establish its molecular mechanism and develop its specific inhibitors.

Aims: The major objectives of the present study were to further clarify the molecular mechanism of fibrin-VLDLR interaction and identify amino acid residues in fibrin βN-domains involved in this interaction.

Methods: Recombinant VLDLR(1-8) fragment containing all CR domains of VLDLR and dimeric $(\beta 15\text{-}66)_2$ fragment corresponding to a pair of fibrin βN-domains were expressed in *E. coli*. Various mutants of $(\beta 15\text{-}66)_2$ were generated by site-directed mutagenesis. Interaction of VLDLR(1-8) with $(\beta 15\text{-}66)_2$ and its mutants was studied by ELISA and SPR.

Results: We found that interaction of $(\beta 15\text{-}66)_2$ with VLDLR(1-8) strongly depends on ionic strength and chemical modification of all Lys or Arg residues in $(\beta 15\text{-}66)_2$ results in abrogation of this interaction. To identify which of these residues are involved in the interaction, we mutated Lys and Arg in each of the three positively charged Lys/Arg clusters of $(\beta 15\text{-}66)_2$ and tested affinities of the resultant mutants to VLDLR(1-8). The experiments revealed that the 2nd and 3rd clusters make the major contribution to this interaction while contribution of the 1st cluster is moderate.

Conclusions: The results obtained identified Arg and Lys residues in fibrin βN-domains that are critical for fibrin-VLDLR interaction. They provide valuable information for the development of specific inhibitors of this interaction. They also suggest that this interaction employs the "double-Lys/Arg" recognition mode proposed for the interaction of the LDL receptor family members with their ligands.

HEMORRHAGIC DISORDERS, HEMOPHILIA

OC 07.1 | ThromboGenomics: HTS Diagnosis of Inherited Bleeding, Thrombotic, Coagulation and Platelet Disorders

K. Downes[1,2,3], K. Freson[4], K. Gomez[5], on behalf of ThromboGenomics and the Genomic Medicine Centre at Cambridge University Hospitals (GMC@CUH)

[1]University of Cambridge, Department of Haematology, Cambridge, United Kingdom, [2]NHS Blood and Transplant, Cambridge Biomedical Campus, Cambridge, United Kingdom, [3]Genomic Medicine Centre at Cambridge University Hospitals, Cambridge, United Kingdom, [4]KU Leuven, Center for Molecular and Vascular Biology, Department of Cardiovascular Sciences, Leuven, Belgium, [5]Royal Free London NHS Foundation Trust, Haemophilia Centre and Thrombosis Unit, London, United Kingdom

Background: Inherited bleeding, thrombotic, coagulation and platelet disorders (BPDs) have a range of frequencies from 1:5000 live male births for haemophilia to rare platelet disorders with only a few cases described.

Aims: ThromboGenomics uses targeted High Throughput Sequencing to provide an efficient and timely molecular diagnosis for patients suspected of having an inherited BPD caused by variants in one of the 78 ISTH-SSC approved Tier 1 BPD genes.

Methods: Over 1,000 samples have been sequenced using ThromboGenomics, with 670 in partnership with the GMC@CUH as a clinical diagnostic service. We have reported clearly pathogenic (class 5) or likely pathogenic (class 4) variants in 60% of coagulation cases, 52% of platelet cases and 54% of thrombotic cases. To assess the proportion of novel pathogenic variants identified through ThromboGenomics we used the Human Gene Mutation Database (HGMD).

Results: In patients with coagulation disorders, 25% of the clearly or likely pathogenic variants reported were not listed in HGMD. For the platelet and thrombotic disorders, 62% and 58%, reported clearly and likely pathogenic variants were not in HGMD. The high proportion of novel variants reflects the molecular heterogeneity of the group of rare diseases under investigation. The relatively high percentage of clearly pathogenic variants in the coagulation disorders is due to the established variant databases for haemophilia and von Willebrand disease. The reported clearly pathogenic and likely pathogenic variants with clinical information (Human Ontology Phenotype [HPO] terms) are deposited in ClinVar to support sharing of data improving the robustness of clinical reporting.

Conclusions: Through ThromboGenomics and BRIDGE-BPD we have succeeded in linking an international gene discovery project with the delivery of an affordable diagnostic service. The high case load of ThromboGenomics has allowed the identification of more than 150 novel pathogenic BPD variants for deposition in a publically accessible database.

OC 07.2 | An International Prospective Cohort of Rare Bleeding Disorders: Results of a Follow-up Study on Patients with Factor XIII Deficiency (PRO-RBDD)

M. Menegatti[1], R. Palla[2], M. Boscarino[2], S. Halimeh[3], M.A. Daoud[3], M. Borhany[4], N. Fatima[4], N. Ozdemir[5], S.M. Siboni[2], D. Mikovic[6], M. Saracevic[6], A. Mumford[7], A. Background: The PRO-RBDD was designed to collect data on clinical manifestations, laboratory phenotype and treatment (on-demand or prophylaxis) of patients with FXIII deficiency. Data collection began in February 2013 and was organized into two different datasets:

1) historical data, collected at baseline;

2) follow-up data, collected every six months, over three years.

A previous analysis focused on the historical data suggested that 15% of FXIII:C could be needed to prevent spontaneous major bleedings (central nervous system and gastrointestinal tract bleeding, haemarthrosis and haematomas).

Aims: To evaluate benefits and complication of long term treatment, in patients with FXIII deficiency, with particular attention to those with FXIII:C < 15%, during the follow-up period.

Methods: Bleeding incidence and cumulative incidence of the first bleeding treated with replacement therapy were calculated in patients in on-demand therapy and in prophylaxis.

Results: Data on 61 FXIII-deficient patients (31 F; 30 M) from 13 Hemophilia Treatment Centres were registered. Forty patients had FXIII:C < 15%. Patients were followed-up for a median of 926 days (IQR: 721-1099). Table 1 reports the bleeding incidence in patients in on-demand therapy compared to those in prophylaxis (9-59U/Kg/month FXIII concentrate); a significant reduction of bleeding episodes in prophylaxis was observed in all patients and particularly in those with FXIII:C< 15%.

TABLE 1 bleeding incidence

All patients		Patients with FXIII:C <15	
on-demand	on prophylaxis	on-demand	on prophylaxis
0.90	0.26	1.57	0.27
IR=0.29, IC95% 0.23-0.37		IR=0.17, IC95% 0.14-0.23	

Table 2 reports the cumulative incidence of the first bleeding treated with replacement therapy at 1300 days of follow up in patients in on-demand therapy compared to those on prophylaxis; a reduction of bleeding episodes in prophylaxis was observed in all patients and particularly in those with FXIII:C< 15%.

TABLE 2 cumulative incidence

All patients		Patients with FXIII:C <15	
on-demand	on prophylaxis	on-demand	on prophylaxis
36%, 95%CI 15-55	7%, 95%CI 0-15	60%, 95%CI 20-80	8%, 95%CI 0-18
Log-Rank test 0.007		Log-Rank test 0.0001	

No adverse events were observed.

Conclusions: In conclusion, the beneficial effect and the safety of FXIII prophylaxis to prevent major bleeding episodes is confirmed, making this treatment strongly recommendable in FXIII-deficient patients.

OC 07.3 | Profile of Mutations Identified in the 3Winters-IPS Project on a Cohort of European Patients with Previously Diagnosed Type 3 von Willebrand Disease

Sacco University Hospital & School of Medicine, Hematology and Transfusion Medicine, Milano, Italy

Background: Type 3 von Willebrand disease (VWD3) is a rare autosomal recessively inherited bleeding disorder resulting from mutations in the von Willebrand factor gene (*VWF*). VWD affects approximately 1:10^6 outbred populations, but is found in higher proportions of consanguineous families.

Aims: To determine the genetic basis of VWD in a cohort of European patients said to have VWD3.

Methods: Patients classified with VWD3 were recruited into the study following informed consent. DNA was extracted from buffy coat. Venous blood samples provided measurement of VWF levels. PCR and Sanger sequencing/ next generation sequencing and multiplex-ligation dependent probe amplification were used in Hamburg and Sheffield to confirm previously identified mutations or to seek previously unidentified mutations.

Results: 84 individuals from 15 European centres with a VWD3 diagnosis were analysed, comprising 55 (65%) females and 29 (35%) males. Most had 2 mutations, n=73; 43 were homozygous (51%) and 32 compound heterozygous (38%). 9 patients (11%) had a single heterozygous mutation identified. 4 mutation types were common; small deletion (30.2%), nonsense (25.2%), splice (21.4%), and missense (19.5%). Large deletions of ≥1 exon comprised 3.1% and large duplication 0.6%. Disease severity was assessed through VWF:Ag level, with 29 individuals having VWF:Ag < 1IU/dL. 32 had levels ≥1 and < 5, whilst 23 were suspected of being infused with factor concentrate (VWF:Ag levels up to 94 IU/dL). 11 cases were suggested to have severe type 1, 6 severe type 2 and other VWD types, 11. 14 patients had 1 or 2 missense changes, 9/14 lost a cysteine residue of which 3 were classified as VWD3.

Conclusions: Null mutations comprised 81% of variants identified, replicating previous findings in similar cohorts. Only 3 missense alleles were present in the propeptide, the majority were found in exons 36-51.

OC 07.4 | Endoplasmic Reticulum Stress and the Unfolded Protein Response in Congenital FVII Deficiency

E. Andersen[1,2,3], M.E. Chollet[1,2], C.F. Myklebust[1,2], M. Pinotti[4], F. Bernardi[4], E. Skarpen[5], P.M. Sandset[1,2,3], G. Skretting[1,2]

[1]Oslo University Hospital, Rikshospitalet, Dept. of Haematology, Oslo, Norway, [2]Oslo University Hospital, Rikshospitalet, Research Institute of Internal Medicine, Oslo, Norway, [3]University of Oslo, Institute of Clinical Medicine, Oslo, Norway, [4]University of Ferrara, Dept. of Life Sciences and Biotechnology, Ferrara, Italy, [5]Oslo University Hospital, Institute for Cancer Research, Oslo, Norway

Background: The *F7* gene mutations p.Q160R (FVII-Q100R), p.I289del (FVII-del229I) and p.A354V-p.P464Hfs (FVII-A294V;404delC) are associated with very low circulating factor VII (FVII) levels (FVII deficiency) and a bleeding phenotype. The secretory defects seen in patients can be attributable to misfolded mutant FVII. Accumulation of misfolded proteins within the endoplasmic reticulum (ER) can cause ER stress and activation of the unfolded protein response (UPR). However, little is known about the effects of misfolded FVII on these responses.

Aims: To investigate ER stress and UPR responses in cells expressing FVII-Q100R, FVII-del229I and FVII-A294V;404delC.

Methods: HEK293 cells transiently expressing wild-type or mutant FVII were used as cellular model. FVII antigen was measured by ELISA and intracellular localization was assessed by confocal immunofluorescence microscopy. Binding of chaperones to FVII was investigated by non-reducing SDS-PAGE and Western analysis. ER stress was assessed by luciferase reporter assay. UPR mediators were measured by Western analysis and qRT-PCR.

Results: FVII antigen levels in medium from cells expressing the FVII mutants were severely reduced (FVII-Q100R) or undetectable (FVII-del229I, FVII-A294V;404delC). Increased colocalisation with ER marker PDI and a stronger association to the chaperones GRP-94 and BiP of FVII mutants compared to the wild-type was observed. Elevated ER stress and activation of UPR signalling were detected in cells expressing FVII mutants.

Conclusions: FVII-Q100R, FVII-del229I and FVII-A294V;404delC were poorly secreted, possibly due to a misfolding process resulting in defective intracellular trafficking. Furthermore, FVII mutants had increased association with chaperones indicating retention in ER inducing ER stress and activation of UPR. Small molecules that are known to alleviate ER stress could represent a therapeutic option for FVII deficiency caused by misfolded proteins.

OC 07.5 | Characterization of GGCX Mutations Identified in VKCFD1 Patients

S. Ghosh[1], K.J. Czogalla[1], J. Müller[1], K. Hoening[2], V. Hornung[2,3], M. Watzka[1], J. Oldenburg[1]

[1]Institute for Experimental Haematology and Transfusion Medicine, University Clinic, Bonn, Germany, [2]Institute of Molecular Medicine, University Hospital, Bonn, Germany, [3]Ludwig-Maximilians-Universität München, Gene Center and Department of Biochemistry, Munich, Germany

Background: Vitamin K Dependent Coagulation Factor Deficiency type 1 (VKCFD1) is a rare hereditary bleeding disorder caused by mutations in gamma-glutamyl carboxylase (GGCX) gene. GGCX gamma carboxylates vitamin K dependent (VKD) proteins, including blood clotting factors which is essential for maintaining hemostasis. Until now there are 26 GGCX missense mutations reported to cause VKCFD1.

Aims: The aim of this study is to characterize the effect of all GGCX missense mutations on VKD coagulation factors and to evaluate the effective dose of vitamin K (K) needed for patient treatment.
Methods: A GGCX knockout (KO) HEK293T cell line was generated by CRISPR/Cas9 technology. The cDNAs of GGCX together with F10 or protein C were cloned into a bicistronic vector. GGCXKO cells were transfected with wild-type (WT) and mutant variants and were treated with different K concentrations to determine half maximal effective concentrations (EC50). The amount of carboxylation was measured by ELISA based assay.
Results: CRISPR/Cas9 gene editing resulted in GGCX deficient cells. Compared to WT GGCX, most missense mutations revealed decreased carboxylation levels for F10 and protein C. However, elevated K concentrations rescued the amount of carboxylation for some mutations V255M, R325Q, R476H and mutations R83P, W157R, S300F showed very less recovery in carboxylation levels even at high K concentrations.
Conclusions: Our data suggest that patients with mutations V255M, R325Q, R476H will show reversible phenotype where therapy with K will lead to normal coagulation. The EC50 calculated by our assay will be an indication for the therapeutic dosage. Patients with mutations R83P, W157R, S300F will never reach physiological coagulation under high dose of K treatment.
This suggests that mutations showing recovery with high K treatment can be in regions pertaining to propeptide or K binding. Hence, this approach will elucidate structural regions involved in carboxylation, propeptide or substrate binding.

OC 08.1 | A Discontinuous Autoinhibitory Module Masks the A1 Domain of VWF

W. Deng, Y. Wang, S.A. Druzak, J.F. Healey, A.K. Syed, P. Lollar, R. Li

Emory University, Pediatrics, Atlanta, United States

Background: In the absence of shear an isolated fragment containing the A1 domain (defined here as residues 1272-1458) but not full-length VWF binds GPIbα spontaneously, suggesting the presence of an autoinhibitory module (AIM) in VWF, but its structure remains unclear. Two VWF fragments containing residues 1238-1472 (termed longA1) and 1261-1472 (shortA1), respectively, exhibit disparate binding affinities for GPIbα and the platelet.
Aims: To understand why shortA1 binds GPIbα much better than longA1 or full-length VWF.
Methods: Both shortA1 and longA1 proteins are expressed from transfected baby hamster kidney cells. Their binding to purified GPIb-IX and human platelets are detected by ELISA and flow cytometry. Their dynamics are characterized by hydrogen-deuterium exchange (HDX) mass spectrometry.
Results: Both proteins are monomeric in solution as judged by gel filtration chromatography and sedimentation velocity analytical ultracentrifugation, although shortA1 is much more prone to aggregation. ShortA1 binds GPIbα with ~40 nM affinity, while longA1 binding to GPIbα mimics that of full-length VWF. Residues in longA1, particularly those in N- and C-terminal sequences flanking the A1 domain, and in helix a1, loops a1b2 and b3a2 of A1, reported markedly reduced HDX than their counterparts in shortA1. This HDX-protected region in A1 overlaps with the GPIbα-binding interface and is clustered with type 2B VWD mutations. HDX of ristocetin-bound longA1 mimics that of shortA1. Binding of ristocetin to 1458-1472 in longA1 desorbs residues 1238-1271 from A1, as judged by changes in HDX, and enables longA1 binding to GPIbα.
Conclusions: The N- and C-terminal sequences flanking A1 (1238-1271, 1459-1472) form cooperatively an integrated AIM that interacts with the HDX-protected region in A1 and impedes its binding to GPIbα. The masking of the A1 domain by a discontinuous AIM has significant implications for the pathogenesis of type 2B VWD and the shear-induced activation of VWF activity.

OC 08.2 | Allele-specific Inhibition of von Willebrand Factor p.Cys2773Ser Restores a Severe Multimerization Defect

A. de Jong, R.J. Dirven, J.A. Oud, D. Tio, J. Eikenboom

Leiden University Medical Center, Einthoven Laboratory for Vascular and Regenerative Medicine, Department of Thrombosis and Hemostasis, Leiden, The Netherlands

Background: Treatment of von Willebrand disease (VWD) focusses on increasing von Willebrand factor (VWF) levels through administration of desmopressin or VWF concentrates. Both therapies usually raise VWF sufficiently, however the production of mutant VWF remains uninterrupted. Persistence of mutant VWF could itself lead to hemostatic problems like thrombocytopenia in type 2B VWD or the development of angiodysplasia. Inhibition of mutant *VWF* in dominant-negative VWD might overcome these effects.
Aims: Correct the abnormal multimer pattern of the dominant-negative VWF p.Cys2773Ser mutation applying allele-specific inhibition.
Methods: Allele-specific inhibition of *VWF* was performed by small interfering (si)RNAs. The siRNAs were not developed against the mutation itself, but to single nucleotide polymorphisms (SNPs) in *VWF*. This allows application of the siRNAs to different mutations, provided the patient is heterozygous for the specific SNP. siRNA mediated allele-specific inhibition was studied in HEK293 cells transiently transfected with two different VWF constructs that carried either of the two alleles of a SNP with one of the alleles also carrying VWF p.Cys2773Ser. Multimerization improvements were visualized by multimer analysis.
Results: Efficient and allele-specific siRNAs were identified for four different SNPs. Transfection of normal VWF and VWF p.Cys2773Ser resulted in an abnormal multimer pattern similar to the pattern in a heterozygous patient carrying this mutation. siRNA mediated allele-specific inhibition of the mutant allele by targeting the SNP allele linked to p.Cys2773Ser clearly improved, or for some siRNAs even restored, the multimer pattern.

Conclusions: siRNAs can discriminate *VWF* alleles by discrepancy of one nucleotide of a SNP. The clear phenotypic improvements observed after inhibition of the *VWF* p.Cys2773Ser allele show that siRNA mediated allele-specific inhibition of dominant *VWF* alleles is a promising therapeutic approach for dominant-negative VWD.

OC 08.3 | Altered Sialylation in Patiens with Low von Willebrand Factor Levels

S. Aguila[1], M. Lavin[1,2], N. Dalton[3], M. Byrne[2], T. Brophy[3], A. Chion[1], J. Di Paola[4], J. O'Donnell[1,2,3]

[1]*Irish Centre for Vascular Biology, Royal College of Surgeons in Ireland, Dublin, Ireland,* [2]*National Centre for Hereditary Coagulation Disorders, St. James's Hospital, Dublin, Ireland,* [3]*Institute of Molecular Medicine, Trinity College Dublin, Haemostasis Research Group, Dublin, Ireland,* [4]*University of Colorado and Children's Hospital Colorado, Pediatrics and Human Medical Genetics and Genomics Program, Aurora, United States*

Background: Von Willebrand disease is the most commonly inherited bleeding disorder. However, the mechanism responsible for VWD in patients with mild reduction of VWF levels (30-50 IU/dL), remains poorly understood. Interestingly, mutations in *VWF* gene occur in less than 50% of these patients.

Aims: To investigate the VWF glycosylation profile in patients with low VWF levels.

Methods: We study a low VWF Irish cohort (n=126) with historically low VWF:Ag, and/or VWF:RCo, and/or VWF:CB. To characterize the glycosylation of VWF, we developed a series of novel lectin ELISAs (SNA, MAAII, RCAI, ECA, UEAI) using a deglycosylated capture antibody coupled with high sensitivity/HRP for detection.

Results: Concerning the clearance of VWF, 94% patients presented a normal VWFpp:VWFAg ratio and it is mirrored with clearance data after DDAVP administration. In contrast, VWF glycosylation profile was significantly different between low VWF patients vs healthy donors. In particular, α(2-6) sialic acids content was significantly reduced and subterminal β-galactoses detection was higher in patients vs controls. Interestingly, we found an inverse correlation between VWF half-life and galactose exposure in patients with shorter VWF half-life. No significant differences were detected in α(2-3) sialic acids, lactosamine extensions or H-antigen. To characterize the physiological modifications on VWF glycans, we studied pre- and post-DDAVP samples and found that VWF presented more α(2-6) sialic acid and less α(2-3) sialic acid 1 hour post-DDAVP infusion, when compared to pre-DDAVP VWF.

Conclusions: In summary, altered α(2-6) sialic acids content is a common feature in patients witn low VWF levels, which might affect VWF clearance through galactose receptors. However, these changes in the glycosylation could also suggest an alteration in the folding and trafficking of VWF. Further, physiological modifications observed in VWF carbohydrates during its secretion and circulation might explain the normal VWF clearance.

OC 08.4 | The N-terminal TIL'-E' Domains of von Willebrand Factor Requires a Structurally Intact VWD3 Domain for Optimal Factor VIII Binding

M. Przeradzka[1], H. Meems[1], C. van der Zwaan[1,2], M. van der Biggelaar[1], K. Mertens[1,3], A.B. Meijer[1,2,3]

[1]*Sanquin Research, Plasma Proteins, Amsterdam, The Netherlands,* [2]*Sanquin Research, Research Facilities, Amsterdam, The Netherlands,* [3]*Utrecht Institute for Pharmaceutical Sciences, Utrecht University, Pharmaceutical Sciences, Utrecht, The Netherlands*

Background: Von Willebrand factor (VWF) protects factor VIII (FVIII) from rapid clearance from the circulation. Current view is that the major binding site for FVIII is within the N-terminal TIL'-E' domains of mature VWF. However, multiple point mutations outside these domains have been identified that have been associated with bleedings because of markedly reduced FVIII plasma levels.

Aims: The aim of this study is to assess the role of the N-terminal TIL'-E'-VWD3-C8_3-TIL3-E3 domains of VWF for FVIII binding.

Methods: C-terminal truncated domain variants of the TIL'-E'-VWD3-C8_3-TIL3-E3 fragment were obtained. To prevent dimerization cysteine residues at positions 1099 and 1142 were substituted into serine residues. Solid-phase competition assays and Surface Plasmon Resonance analysis were employed to evaluate the binding efficacy to FVIII. Chemical foot-printing mass spectrometry using lysine directed mass tags was utilized to explore structural implications of the truncations.

Results: Binding studies revealed that deletion of the E3 domain did not affect the binding of the fragment to FVIII. Deletions of the TIL3 followed by the C8_3 domain gradually decreased the FVIII binding efficiency. Notably, the TIL'-E' fragment almost did hardly show any interaction with FVIII suggesting that the VWD3 domain is indispensable for binding of TIL'-E' to FVIII. Chemical foot-printing revealed that lysine residues within the VWD3 domain demonstrated increased exposure to the solvent upon subsequent deletion of the E3, TII3-E3 and C8_3-TII3-E3 domains. This implies structural alterations in the VWD3 upon deletion of the C-terminal domains.

Conclusions: This study shows that subsequent C-terminal deletions of the D3 subdomains decreases ability of the D'D3 fragments to bind FVIII.We propose that the VWD3 domain supports the interaction of TIL-E' with FVIII and that the C-terminal domains are required to maintain the structural integrity of the VWD3 domain.

OC 08.5 | The Redox State of the von Willebrand Factor A2 Domain Disulphide Bond Controls Platelet GPIbα Binding

D. Butera[1], F. Passam[2], L. Ju[3], P. Hogg[1,4]

[1]Centenary Institute, Camperdown, Australia, [2]St George Clinical School, Kogarah, Australia, [3]Heart Research Institute and Charles Perkins Centre, Sydney, Australia, [4]University of Sydney, Sydney, Australia

Background: Platelet adhesion and thrombus formation is strictly dependent on VWF interaction with platelet GPIbα receptor in the shear forces found in arterioles and stenosed vessels. GPIbα binding to the VWF A1 domain is controlled by the force-sensing A2 domain. A disulphide bond linking adjacent cysteine residues 1669 and 1670 at the C-terminus of the A2 domain acts like a plug that when dislodged by sufficient shear force destabilizes the core and initiates unfolding of the domain and GPIbα and ADAMTS13 access.

Aims: We have quantified the redox state of the Cys1669-Cys1670 disulphide plug in healthy donor plasma VWF and assessed the functions of the different redox forms.

Methods: Redox state measurements were performed by differential cysteine alkylation and mass spectrometry, and GPIbα binding and ADAMTS13 proteolysis by standard assays.

Results: Unexpectedly, cysteines 1669 and 1670 exist in three different redox forms: an oxidised disulphide bond (~25%), S-glutathionylation of Cys1670 (~35%) and a reduced dithiol (~40%). Approximately three quarters of circulating VWF, therefore, contains an inactive A2 domain plug. As anticipated, disabling the plug in recombinant VWF by mutating the cysteines results in enhanced unfolding of the A2 domain and ADAMTS13 cleavage. Contrary to expectations, though, disabling the plug inhibits rather than promotes platelet GPIbα binding.

Conclusions: These results indicate that only one quarter of circulating VWF has an intact disulphide plug and binds GPIbα effectively.

OC 10.1 | An Engineered Serpin for the Treatment of Haemophilia

S. Polderdijk[1], T. Adams[1], L. Ivanciu[2], R. Camire[2], T. Baglin[3], J. Huntington[1]

[1]University of Cambridge, Department of Haematology, Cambridge, United Kingdom, [2]University of Pennsylvania, Philadelphia, United States, [3]Addenbrooke's Hospital, Cambridge, United Kingdom

Background: Haemophilia caused by deficiency in either component of the intrinsic Xase complex, factor (f) VIII or fIX. A small amount of fXa is initially produced by the extrinsic Xase complex (fVIIa and tissue-factor), but is insufficient to overcome the multiple anticoagulant mechanisms to produce a stable haemostatic clot. Tissue-factor pathway inhibitor (TFPI) and antithrombin (AT) both directly inhibit fXa, and activated protein C (APC) proteolytically inactivates the intrinsic Xase and the prothrombinase complexes. Conventional treatment of haemophilia is replacement of the missing factor, but the short half-life necessitates frequent intravenous infusions and renders prophylaxis incomplete. A fraction of haemophilia sufferers also develop inhibitory antibodies, requiring the use of ‚bypassing agents', such as NovoSeven and FEIBA, to treat bleeds. An alternative approach is to inhibit anticoagulation.

Aims: We decided to target APC, in part due to the reduced bleeding severity in haemophilia patients with partial APC resistance (fV_{Leiden}). The endogenous inhibitors of APC are members of the serpin family, notably protein C inhibitor (PCI) and α_1-antitrypsin (α_1AT), however, both suffer from poor reactivity and selectivity towards APC.

Methods: By mutating residues in and around the reactive centre P1-P1´ bond of α_1AT we were able to dial in specificity for APC.

Results: The lead variant, SerpinPC, inhibits APC with a rate constant of 15,000 $M^{-1}s^{-1}$ without inhibiting thrombin, fXa or any other relevant coagulation protease. SerpinPC had no effect on PT or APTT in normal plasma, but rescued thrombin generation in the presence of soluble thrombomodulin. Importantly, SerpinPC was found to restore haemostasis in haemophilia mice in three different models, even at low doses.

Conclusions: Good subcutaneous bioavailability and the one-week half-life of a_1AT suggest that a once fortnightly subcutaneous injection might provide effective prophylaxis for all haemophilia sufferers.

OC 10.2 | Antithrombin Resistance and Heparosan Conjugation Synergistically Extend the *in vivo* Half-life of FVIIa

M.B. Hermit[1], P.S. Gandhi[1], C. Behrens[1], M. Dainiak[1], O.H. Olsen[1], A.A. Pedersen[1], G. Andersen[1], K. Lamberth[1], J.J. Hansen[1], M.A. Zundel[1], P.L. Deangelis[2], F.M. Haller[3], E. Cló[1], J. Breinholt[1], M. Åkesson[1], M.S. Jensen[1], H. Pelzer[1], L. Hansen[1], H. Stennicke[1], I. Hilden[1], H. Østergaard[1]

[1]Novo Nordisk A/S, Global Research, Måløv, Denmark, [2]Oklahoma Health Sciences Center, Dept of Biochemistry and Molecular Biology, Oklahoma City, United States, [3]Caisson Biotech LLC, Oklahoma City, United States

Background: Long-acting bypassing agents allowing for safe and efficacious prophylactic treatment of haemophilia patients with inhibitors represent a clear medical need. Previous studies have shown that the half-life of FVIIa can be extended 5-7 fold through PEG attachment or other principles, however, at the expense of significant activity loss.

Aims: Here, a combined mutagenesis and polymer-conjugation approach was undertaken to increase the half-life of FVIIa beyond this limit while preserving activity.

Methods: FVIIa variants were screened for proteolytic activity in the presence of FX and phospholipid and for antithrombin (AT) reactivity with heparin as co-factor. Selected variants were conjugated to a linear 40-kDa heparosan polymer (HEPtune®, Caisson Biotech) through N-glycans on FVIIa. Pharmacokinetics was determined in Sprague-Dawley rats after IV administration and potency in FVIII inhibited human whole-blood using thrombelastography.

Results: Since inhibition by AT constitutes the major clearance pathway of FVIIa *in vivo*, a screen for substitutions conferring AT resistance was performed. From a library of 400 variants, a T293K substitution

was identified that reduced AT reactivity to less than 10% of FVIIa while preserving activity. Reflecting the *in vitro* AT resistance, minimal complex formation with AT was observed when tested in a rat PK model. Interestingly, while resulting in an only modest increase of half-life (≤2 fold) on its own, combination of T293K with a glyco-conjugated 40-kDa heparosan resulted in a half-life 15-fold longer than FVIIa. To compensate for the impairment of activity due to polymer conjugation additional mutational optimization was performed. Following screening of 300 variants, a variant was identified carrying substitution L288Y.

Conclusions: The L288Y T293K FVIIa variant conjugated with 40-kDa heparosan exhibited a half-life of 15.2 ± 0.8 hrs compared to 1.0 ± 0.1 hrs for FVIIa in rats, and potency on par with FVIIa in haemophilia A-like human whole blood.

OC 10.3 | Pharmacokinetic and Activity Levels Achieved with Daily Subcutaneously Administered CB 2679d/ISU304 in Hemophilia B Dogs

H. Levy[1], T. Nichols[2], E. Merricks[2], R. Raymer[2], A. Hetherington[1]

[1]*Catalyst Biosciences, South San Francisco, United States,* [2]*University of North Carolina at Chapel Hill, Department of Pathology and Laboratory Medicine, Chapel Hill, United States*

Background: The rapid clearance of factor IX (FIX) necessitates frequent intravenous (IV) administrations to achieve effective prophylaxis for patients with hemophilia B. Subcutaneous (SQ) administration would be a preferred route for convenience and less pain, but has been limited by low bioavailability and potency of the marketed FIX products. CB 2679d is a rFIX with enhanced biological properties and was developed using a rational protein design approach. CB 2679d has resistance to inhibition by ATIII, increased affinity for FVIIIa, increased catalytic activity and a resultant 20-fold enhanced potency *in vitro* (clotting activity) and *in vivo* (tail clip model) and 8-fold increased duration of aPTT activity *in vivo* compared with wild-type rFIX dosed at the same mass.

Aims: Determine pharmacokinetics of daily SQ CB 2679d.

Methods: CB 2679d 300 IU/kg was injected SQ daily for 6 days in hemophilia B dogs and was sampled at 0, 6, 24, 30, 48, 54, 72, 78, 96, 102, 120, 126, 144, 168, 176, 192, 200, 219, 240, 248, 264, 272, 288, 312, 336 and 360 hours. rhFIX antigen in canine plasma was determined by ELISA using an Affinity Biologicals kit. FIX activity was measured in duplicate, using a single-stage aPTT-based FIX clotting assay. The assay was performed on an ACL-TOP instrument using Instrumentation Laboratories reagents.

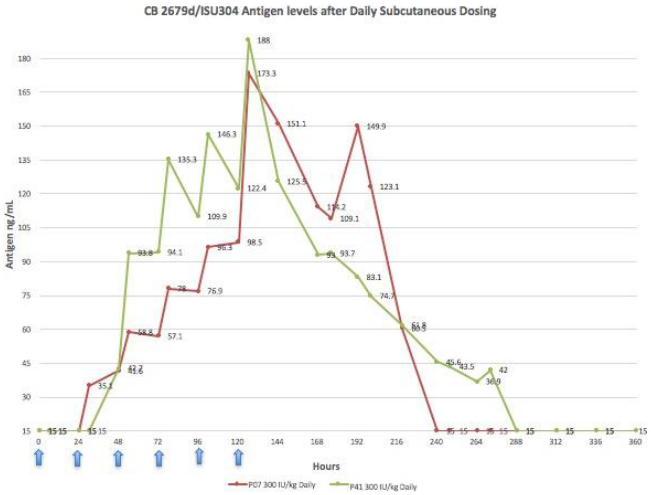

FIGURE 1 Blood Factor IX antigen levels after daily subcutaneous dosing of CB 2679d

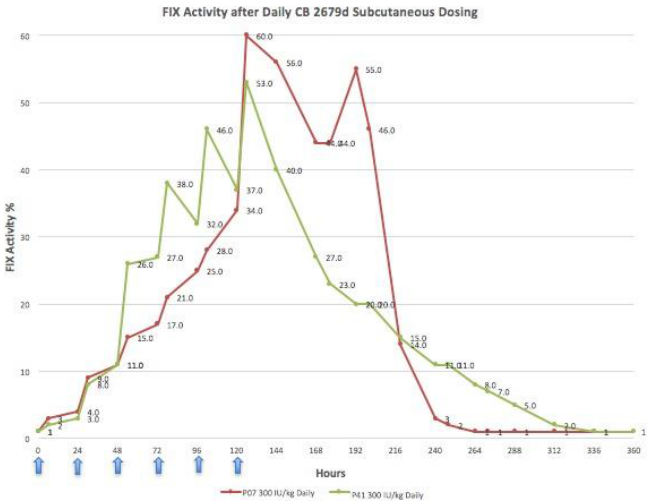

FIGURE 2 Blood Factor IX activity after daily subcutaneous dosiing of CB 2679d

Results: Daily SQ dosing of CB 2679d after 6 doses had peak rhFIX levels of 188 and 173.3 ng/mL at 126 hours. Trough activity levels 24 hours after 6 daily doses were 125.5 and 151.1 ng/mL respectively. Daily SQ dosing of CB 2679d after 6 doses had peak FIX activity levels of 60 and 53% at 126 hours. Trough activity levels 24 hours after 6 daily doses were 56 and 40% respectively. There were no emergent clinical adverse events or lab abnormalities recorded.

Conclusions: The progressive increase in FIX activity levels after daily SQ dosing of CB 2679d supports the initiation of the Phase 1 SQ dosing study in individuals with hemophilia B with the target of achieving normal FIX activity trough levels.

OC 10.4 | FcRn Mediated Recycling of Recombinant VWF D'D3-albumin Fusion Protein /rVIII-SingleChain Complex Is a Mechanism for FVIII Half-life Extension

J. Chia[1], I. Glauser[1], A. Andrews[1], T. Weimer[2], M. Wilson[1], A. Verhagen[1]

[1]CSL Limited, Research, Bio21 Institute, Melbourne, Australia, [2]Csl Behring, Marburg, Germany

Background: Effective prophylactic treatment for severe haemophilia A requires intravenous administration of coagulation factor VIII (FVIII) 2-3 times a week due to the short in vivo half-life of FVIII products. FVIII circulates in complex with von Willebrand factor (VWF) and strategies to directly extend its half-life have had limited success as they do not overcome the VWF clearance mechanisms that also control FVIII clearance. A recombinant VWF D'D3 albumin fusion protein (rD'D3-FP) has been developed to extend the in vivo half-life of co-administered FVIII. The D'D3 domain of VWF interacts with FVIII, while the albumin moiety is able to engage the recycling pathway mediated by the neonatal Fc receptor, FcRn. In this study, we investigate the fate of internalised D'D3-FP/rVIII-SingleChain complex in cells expressing FcRn.

Aims: To determine whether rD'D3-FP has the potential to facilitate the recycling of associated rVIII-SingleChain via the FcRn mediated pathway.

Methods: The intracellular trafficking of rD'D3-FP and rD'D3-FP/ rVIII-SingleChain complex was examined in human 293 Freestyle™ cells stably expressing human FcRn alpha chain and beta 2 Microglobulin. Cells were pulsed for 10 minutes with fluorescent conjugates at pH 5.5 to facilitate FcRn mediated uptake via the albumin moiety of rD'D3-FP. Fresh media was then added and co-localisation with the early endosome (EEA1+), recycling endosome (Rab11+) and lysosome (CD63+) examined by immunofluorescence confocal microscopy after various chase periods.

Results: Following internalization, rD'D3-FP and the rD'D3-FP/ rVIII-SingleChain complex were first detected within the early endosome before entering the $Rab11^+$ recycling endosome and exiting the cells. Minimal co-localisation with the lysosomal compartment was observed.

Conclusions: We have demonstrated recycling of the rD'D3-FP/ rVIII-SingleChain complex, supporting a potential role for rD'D3-FP in further half-life extension of FVIII for the treatment of hemophilia A.

OC 10.5 | Half-life Extension of FVIII by Coadministration of a Recombinant D´D3 Albumin Fusion Protein

S. Pestel[1], E. Raquet[1], M. Mischnik[1], P. Claar[1], A. Andrews[2], E. Herzog[1], T. Weimer[1]

[1]CSL Behring GmbH, Pharmacology/Toxicology, Marburg, Germany, [2]CSL Limited, Research, Melbourne, Australia

Background: Recombinant D'D3-FP, the D'D3 domain of von Willebrand factor (VWF) fused to albumin, is a novel pharmaceutical compound in development intended to be used in combination with rVIII-SingleChain for treating hemophilia A patients. rD'D3-FP is designed to compete with endogenous VWF for binding to FVIII at respective molar excess, and, by its long half-life ($t_{1/2}$), to further improve the pharmacokinetic (PK) properties of rVIII-SingleChain in circulation.

Aims: The aim of the studies was to describe PK of rD'D3-FP in FVIII ko mice, rats and rabbits, and to investigate its impact on the PK of coadministered rVIII-SingleChain. Further, activated partial thrombin time (aPTT) and thrombin generation were monitored as pharmacodynamics (PD) readouts in FVIII ko mice over time.

Methods: rD'D3-FP was administered intravenously (i.v.) at a dose range of 0.15-30 mg/kg, alone or in combination with rVIII-SingleChain (100-1000 IU/kg). As appropriate, (co)administration of human plasma-derived (pd)VWF was used as control. Plasma PK of rD'D3-FP, VWF and FVIII (antigen and/or activity levels) was monitored for up to 72-168 h. Thrombin generation and aPTT were assessed in FVIII ko mice.

Results: Studies confirmed an extension of rD'D3-FP plasma exposure by 6-60 fold as compared to human pdVWF across species. This led to a dose-dependent prolongation of the terminal $t_{1/2}$ of rVIII-SingleChain by 1.5-3.0 fold in FVIII ko mice, 1.4-7.6 fold in rats and 1.2-3.8 fold in rabbits upon rD'D3-FP coadministration as compared to rVIII-SingleChain alone. The effect was even more pronounced when compared to rVIII-SingleChain co-administered with pd VWF, leading to improvements of 1.5-11.3 fold in rats and 2.0-8.2 fold in rabbits. In line, a prolongation of PD effects (correction of thrombin generation and aPTT) was shown in FVIII ko mice.

Conclusions: Studies in FVIII ko mice, rats and rabbits supported further improvement of rVIII-SingleChain PK upon coadministration with rD'D3-FP.

OC 13.1 | *SPK-9001*: Adeno-associated Virus Mediated Gene Transfer for Haemophilia B Achieved Durable Endogenous Prophylaxis at Levels of Activity Sufficient to Achieve Significant Mean Reduction in Annual Bleeding and Infusions Rates in Preliminary Data from an On-going Phase 1/2a Trial

L. George[1], A. Giermasz[2], S. Sullivan[3], J. Ducore[2], J. Rasko[4], B. Samelson-Jones[1], C. Mcguinn[5], J. Teitel[6], A. Galvao[1], R. Camire[1], A. Luk[7], F. Wright[7], K. Wachtel[7], M. Carr[7], X. Anguela[7], K. High[7]

[1]The Children's Hospital of Philadelphia, Pediatric Hematology, Philadelphia, United States, [2]UC Davis School of Medicine, Sacramento, United States, [3]Mississippi Center for Advanced Medicine, Madison, United States, [4]Royal Prince Alfred Hospital, Sydney, Australia, [5]Weill Cornell Medicine, New York, United States, [6]St. Michael's Hospital, Toronto, Canada, [7]Spark Therapeutics, Philadelphia, United States

Background: Earlier AAV-8 mediated gene transfer at 2 x10^{12} vg/kg in haemophilia B demonstrated long-term mean FIX levels of ~5.1%. While clinical improvement was clear, these levels fall short of those obtainable with extended half-life FIX prophylaxis. Natural history data suggest levels of ~12% may eliminate spontaneous hemarthroses.

Aims: Sustained, endogenous FIX:C (≥12%) adequate to prevent spontaneous bleeding without prophylactic injections of exogenous FIX.

Methods: Investigational product, *SPK-9001*, utilizes a hepatotropic recombinant AAV capsid (Spark100) and a codon-optimised cassette encoding FIX Padua, a natural variant with 5-8x greater specific activity than wild-type FIX. Laboratory values, bleeding frequency, FIX consumption were monitored after vector infusion and compared to participants data for the year prior to vector administration.

Results: We infused 10 participants (ages 18-53 years, baseline FIX:C ≤2% and Spark100 NAb titer of ≤1:1) with 5 x10^{11}vg/kg of *SPK-9001*. In participants who have reached 12 weeks of follow-up, the mean steady-state FIX:C was ~29%. Asymptomatic increases in hepatic transaminases were observed in 2 participants resulting in a tapering course of prednisolone. Elevation of hepatic transaminases were resolved after the initiation of steroids. No participants reported study-related SAEs or development of FIX inhibitor. Discontinuation of prophylaxis occurred the day after vector infusion in all cases. Only 1 participant, with significant underlying hemophilic arthropathy, has required FIX injections for suspected bleeds. The cumulative FIX reduction for all participants amounts to >1.4M IUs.

Conclusions: These preliminary clinical data demonstrated high and consistent levels of sustained vector-derived FIX:C after gene transfer. Levels of FIX:C achieved by *SPK-9001* at 5x10^{11} vg/kg permitted termination of prophylaxis, prevention of bleeding, and markedly reduced factor use; while yielding the lowest (< 20%) reported incidence of capsid-specific T-cell immune response.

OC 13.2 | Updated Results from a Dose-escalation Study in Adults with Severe or Moderate-severe Hemophilia B Treated with AMT-060 (AAV5-hFIX) Gene Therapy: up to 1.5 Years Follow-up

W. Miesbach[1], M. Tangelder[2], K. Meijer[3], M. Coppens[4], P. Kampmann[5], R. Klamroth[6], R. Schutgens[7], G. Castaman[8], E. Seifried[9], J. Schwaeble[9], H. Bonig[9], F. Cattaneo[10], F. Leebeek[11]

[1]*University Hospital Frankfurt, Medical Clinic II and Institute of Transfusion Medicine and Immunohaematology, Frankfurt, Germany,* [2]*uniQure biopharma, B.V., Amsterdam, The Netherlands,* [3]*University Medical Center Groningen, Groningen, The Netherlands,* [4]*Academic Medical Center, University of Amsterdam, Amsterdam, The Netherlands,* [5]*Rigshospitalet/Copenhagen University Hospital, Copenhagen, Denmark,* [6]*Vivantes Klinikum, Berlin, Germany,* [7]*University Medical Center Utrecht, Utrecht, The Netherlands,* [8]*Azienda Ospedaliera Universitaria Careggi, Florence, Italy,* [9]*University Hospital Frankfurt, Institute of Transfusion Medicine and Immunohaematology, Frankfurt, Germany,* [10]*Chiesi Farmaceutici, SpA, Parma, Italy,* [11]*Erasmus MC, Rotterdam, The Netherlands*

Background: Gene transfer for hemophilia offers the potential to convert the disease from a severe to mild phenotype with a single treatment. AMT-060 consists of an AAV5 vector containing a codon-optimized wildtype hFIX gene under control of a liver-specific promoter.

Aims: This phase 1/2 study investigates the safety and efficacy of AMT-060 at 2 dose levels in adults with moderate-severe or severe hemophilia B.

Methods: Multi-national, open-label, dose-escalating study in patients (pts) with factor IX (FIX) activity ≤2% of normal, and a severe bleeding phenotype (prophylactic exogenous FIX; or on-demand exogenous FIX, plus ≥4 bleeds/year or hemophilic arthropathy). Pts received either 5x10^{12} gc/kg (n=5) or 2x10^{13} gc/kg (n=5) of AMT-060 iv. Efficacy assessments include endogenous FIX activity (measured ≥10 days after use of exogenous FIX); reduction of exogenous FIX use; and annualized spontaneous bleeding rates. Safety assessments include treatment related adverse events, immunological and inflammatory biomarkers.

Results: There were no screening failures due to AAV5 antibodies. Mean FIX activity in the lower dose cohort was 5.2% (min-max, 3.0-6.8%; n=4; 1 patient remaining on prophylaxis excluded) during 1 year of follow-up, and 6.9% (min-max, 3.1-12.7%; n=5) in the higher dose cohort during 26 weeks follow-up. Eight of 9 pts on FIX prophylaxis discontinued use after AMT-060 infusion. Follow-up to up to 1.5 years will be presented, with annualized reduction of exogenous FIX use and spontaneous bleeding rates. Mild, temporary elevations in ALT were observed in 3 pts with higher mean FIX activity (6.3-12.7%; 1 in the lower and 2 in the higher dose cohort). Each received a tapering course of prednisolone. ALT elevations were not associated with changes in FIX activity or a capsid-specific T-cell response.

Conclusions: Patients continue to show sustained clinical benefit and endogenous FIX activity with no T-cell activation ≥1 year after a single infusion of AMT-060.

OC 13.3 | An Analysis of Bleeding Rates and Factor IX Consumption in the Phase I/II BAX 335 Gene Therapy Trial in Subjects with Hemophilia B

J. Chapin[1], H. Rottensteiner[2], F. Scheiflinger[2], P.E. Monahan[1]

[1]*Shire plc, Cambridge, United States,* [2]*Shire plc, Vienna, Austria*

Background: Adeno-associated virus (AAV)-based gene therapy is a promising technology to treat hemophilia B (HB). BAX 335 (AAV8.sc-TTR-FIXR338Lopt) contains the *F9* R338L gain-of-function transgene in an AAV8 capsid. Here we present an interim analysis of clinical endpoints from the multi-center phase I/II safety and efficacy study of BAX 335 (NCT01687608).

Aims: To describe clinical outcomes of subjects treated with BAX 335.

Methods: Adult males (18-75) with moderate-to-severe HB (FIX≤2%) were eligible. Subjects received BAX 335 in 3 ascending cohorts: 2E^{11} vector genomes (vg)/kg (C1), 1E^{12} vg/kg (C2), and 3E^{12} vg/kg (C3).

Standard of care treatment was allowed as needed during the study period, including exogenous FIX for bleeding episodes or prophylaxis. This study was approved by internal review boards; subjects provided informed consent prior to enrollment.

Results: 8 subjects received BAX 335 in 3 cohorts: C1 n=2, C2 n=4, and C3 n=2. 6/8 subjects were using prophylaxis prior to study enrollment. Median peak FIX levels were 3.5% (C1), 12.0% (C2), and 45.0% (C3). Only 2 subjects had sustained FIX expression at 1 year. Annualized bleeding rates (ABR) and FIX consumption (FC) were evaluated after 8 subjects reached 1 year of follow-up. The median ABR prior to gene therapy was 9.6 (0-24) and decreased to 6 (1-12) after 12 months. Median FC decreased by 43.4% (221250 IU to 99941 IU; p=0.009). Median number of infusions decreased from 49.5 (12-96) to 17.5 (1-55). Median time to first bleed was 48.5 days (d), with higher dose cohorts associated with longer times (C1=13.5 d, C2=48.5 d, C3=168.5 d) and higher peak FIX expression.

Conclusions: BAX 335 resulted in reduced FC and ABR related to the peak and duration of FIX expression in the majority of subjects. Even transient expression of FIX resulted in disease modification of HB. One subject continues to have sustained FIX=20% after 2.5 years of follow-up. A next-generation FIX gene therapy candidate is currently in development.

OC 13.4 | Immunogenicity and Efficacy of FIX-Padua in Distinct Canine Models of Severe Hemophilia B Following AAV Gene Therapy to Skeletal Muscle or Liver

B.J. Samelson-Jones[1,2], R.A. French[1], N.B. Martin[1], T.C. Nichols[3], R.M. Camire[1,2], V.R. Arruda[1,2]

[1]*The Children's Hospital of Philadelphia, Department of Pediatrics, Philadelphia, United States,* [2]*University of Pennsylvania Perelman School of Medicine, Department of Pediatrics, Philadelphia, United States,* [3]*University of North Carolina at Chapel Hill, Department of Pathology and Laboratory Medicine, Chapel Hill, United States*

Background: Hemophilia B (HB) is an X-linked bleeding disorder caused by a deficiency in Factor IX (FIX). Ongoing gene therapy trials for HB using adeno-associated viral (AAV) vectors encoding FIX-Padua, a hyperactive FIX variant which exhibits ~8-fold increase in specific activity, offers a strategy to lower the AAV dose to minimize cellular immune responses while providing therapeutic levels.

Aims: Here we report new data AAV-cFIX-Padua in inhibitor-prone or with preexisting inhibitors to cFIX in HB dogs, respectively. These dogs have an underlying null mutation in the cF9 gene and typically a single injection of cFIX wild-type protein results in high titer inhibitors.

Methods: 3 adult dogs received intravascular delivery to the skeletal muscle or liver of $3x10^{12}$vg/kg of AAV-cFIX-Padua.

Results: Dog U04 achieved FIX activity levels of 45-60%; dog U05 reached a plateau of 75-100% circulating cFIX activity levels. Neither dog has developed inhibitors to cFIX or non-neutralizing (NNA) IgG1 and IgG2 against cFIX. Notably, immune tolerance has been maintained despite challenge with cFIX-wild type protein.

Table 1: Summary of AAV cFIX-Padua (1 to 3 x 10^{12} vg/kg)

HB Dog	Target	FIX (% of normal) Activity	FIX (% of normal) Antigen	Specific activity	Bleeds/Month Pre	Bleeds/Month Post
U01*	liver	81	10.9	8.6	7/49	0/42
U02	liver	30	4.4	8.5	0/32	0/60
U03*	liver	180	26	8.5	6/32	0/60
U06	liver	44	3.9	12	0/11	0/41
U04	muscle	53	7.7	7.3	8/13	0/31
U05	muscle	91	10.2	9.6	1/17	0/25
M55-CH	muscle	8	1.5	8.6	0/7	0/90
M59-CH	muscle	3.5	0.35	9.2	0/6	0/90
N07-CH	muscle	5.5	0.65	9.0	2/6	0/79
					24/173	0/518

- Dogs with pre-existing inhibitor to cFIX
- UO: null mutation model
- CH: missense mutation model

These are the first data showing complete normalization of HB phenotype by muscle gene therapy, a highly attractive strategy for those patients with underlying liver disease that precludes inclusion in liver-based strategies. In additional, dog U03 with pre-existing inhibitor to cFIX received AAV-FIX Padua liver gene therapy with rapid elimination of the inhibitor but with a long-lasting NNA IgG2 specific to cFIX for 400 days, when challenged with cFIX-WT protein, an anamestic response were noted with low inhibitor titers, IgG2 but high levels of NNA IgG1 that spontaneously resolved and cFIX reached 80%.

Conclusions: Taken together, these three dogs and 6 previous reported HB dogs (Table 1), expression of cFIX Padua exhibits ~8-fold specific activity and is both efficacious (no bleeding episodes in cumulative 518 months post gene therapy) without increased immunogenicity or evidence of thrombogenicity.

OC 13.6 | Development of SHP654, a Highly Efficient AAV8-based BDD-FVIII Gene Therapy Vector for Treatment of Hemophilia A

F.G. Falkner[1], F. Horling[1], J. Lengler[1], M. Weiller[1], J. Mayrhofer[1], M. Turecek[1], P.E. Monahan[2], W. Hoellriegl[1], H. Rottensteiner[1], F. Scheiflinger[1]

[1]*Shire plc, Vienna, Austria,* [2]*Shire plc, Cambridge, United States*

Background: A recently initiated AAV5-based hemophilia A gene therapy clinical trial showed that by systemic administration of a very high vector dose (6x10E13 vg/kg) FVIII levels in the normal range can be achieved. While these data are promising they highlight the need for more efficient vectors to reduce constraints imposed by vector production and dose-dependent toxicities at high doses.

Aims: To develop a gene therapy candidate product that is built on AAV8, the prototypic liver-specific AAV serotype, and an expression cassette that confers strong and liver-specific expression of a B-domain deleted Refacto-type variant of FVIII.

Methods: The expression cassette was designed to harbor a strong yet compact liver-specific TTR promoter/enhancer, a CpG-depleted and codon-optimized BDD-FVIII coding sequence, and a short synthetic poly A element. To cope with the packaging size limit of AAV, non-essential DNA stretches were largely removed and a single-stranded genome architecture was chosen.

Results: Initial testing of several FVIII gene therapy vectors failed to identify a candidate expressing sufficient amounts of FVIII in FVIII ko mice. We therefore initiated a screening program for improved FVIII coding sequences using a combination of available codon-optimization algorithms and manual sequence editing. Altogether more than 50 codon-optimized BDD FVIII sequences were screened for FVIII expression. This approach resulted in identification of SHP654, a vector that expressed 74-fold higher levels of FVIII than the corresponding wild-type nucleotide sequence. SHP654 proved to be also producible with high yields. An improved formulation buffer allows higher strength formulations, prevents adsorption onto contact materials and ensures stability of the vector.

Conclusions: The features of SHP654 make it a promising drug candidate for FVIII gene therapy with the potential to effectively treat hemophilia A patients by doses in the 10^{12} vg/kg range.

OC 22.1 | CRISPR/Cas9-engineered VWF Knockout BOECs Have Increased Angiogenic Properties

M. Schillemans, M. Hofman, J. Westeneng, M. Fernandez-Borja, C. Margadant, R. Bierings

Sanquin Research, Plasma Proteins, Amsterdam, The Netherlands

Background: Von Willebrand factor (VWF) is a pleiotropic protein that takes a central position in the maintenance of vascular homeostasis. VWF is synthesized by endothelial cells where it is stored in rod-shaped storage organelles called Weibel-Palade bodies (WPBs). Apart from its well established role in hemostasis, several lines of evidence have also implicated VWF in angiogenesis. This includes complications such as angiodysplasia that are often found in Von Willebrand disease (VWD) patients. However, studies in VWD patient-derived blood outgrowth endothelial cells (BOECs), which can be regarded as endothelial pathological deficiency models of VWD, have failed to unequivocally support these findings.

Aims: We used CRISPR/Cas9 genome editing to genetically ablate VWF expression in BOECs in order to study the implications of loss of VWF on angiogenic parameters.

Methods: Cord blood-derived BOECs (cBOECs) were transduced with gRNAs targeting VWF to generate $VWF^{-/-}$ cBOECs. True VWF null cBOECs were selected using a high throughput screen, validated by next generation sequencing and were phenotypically characterized, including analysis of the angiogenic potential in the absence of VWF.

Results: Clonal $VWF^{-/-}$ lines were obtained which contained CRISPR-induced frameshifting mutations around the gRNA target sites. $VWF^{-/-}$ cBOECs were entirely devoid of WPBs, which led to alternative routing of WPB cargo such as P-selectin, CD63, Ang-2, IL-6 and IL-8. Ang-2 was no longer retained in endothelial cells but constitutively secreted as evidenced by the increased levels of Ang-2 in unstimulated conditioned media. In scratch wound assays, spheroid assays and proliferation assays we found that $VWF^{-/-}$ cBOECs have increased angiogenic potential. Interestingly, we found that surface levels of $\alpha_V\beta$-3 and $\alpha5\beta$-1integrin were altered on $VWF^{-/-}$ cBOECs.

Conclusions: CRISPR targeted knockouts of VWF in BOECs further substantiate the role of VWF in angiogenesis and provide additional mechanistic detail how VWF controls vascular homeostasis.

OC 22.2 | Von Willebrand Factor Free-thiols Are Critical for Function under High Shear Stress

H. O'Brien[1], F. Zhang[2], S. Shapiro[3], P. Henne[1], A. Riera[1], A. Doerr[1], C. Speak[1], M. Laffan[1], T. McKinnon[1]

[1]Imperial College London - Hammersmith Hospital Campus, London, United Kingdom, [2]Lehigh University, Bethlehem, United States, [3]Imperial College London, London, United Kingdom

Background: Von Willebrand Factor is a multimeric protein critical for platelet capture under high shear stress. Several studies have shown that Von Willebrand Factor contains a number of free thiols that may mediate its function. While this has been investigated using a plate and cone viscometer, no studies have addressed the role of VWF free-thiols under conditions of acute high shear stress.

Aims: To determine the effect of VWF free-thiols on function under physiological and pathological shear stress

Methods: VWF was purified from Haemate P by gel filtration or recombinantly expressed in HEK293T cells. Free-thiols were blocked with N-ethylmaleimide (NEM) or Maleimide-PEO2-biotin. Flow assays were performed using plasma free blood supplemented with VWF and perfused over collagen or VWF coated surfaces. Analysis of the VWF-collagen interaction was performed using atomic force microscopy (AFM).

Results: NEM blockade of VWF free-thiols reduced VWF mediated platelet capture to collagen in a shear dependent manner; with no effect at low shear and platelet capture virtually abolished at high shear (above $3000s^{-1}$). The effect was mediated by free-thiols in the C-terminal domains and was not due to an effect on platelet capture. Under extreme pathological shear and in flow chambers mimicking stenotic vessels, the formation of thick VWF fibres on collagen was inhibited by blocking VWF thiols. Interestingly some free-thiols in VWF were lost after collagen binding and AFM measurements demonstrated that the strength of the VWF-collagen bond was significantly reduced with NEM-VWF Moreover, NEM-VWF failed to effectively incorporate into long VWF fibres formed independently of collagen and platelets. Finally, molecular simulation studies on the VWF C-domains demonstrated alterations in free-thiol content following the application of force.

Conclusions: Free-thiols residues in VWF are essential for proper collagen binding under shear stress, possibly by mediating a conformational change in the VWF molecule.

OC 22.3 | Mouse VWF Propeptide Regulates Platelet Thrombus Formation *in vitro*

O. Rawley[1], C. Brown[2], C. Dwyer[2], J. Mewburn[3], C. Zhang[4], J.W. Dennis[5], D. Lillicrap[2]

[1]*Queen's University, Department of Pathology and Molecular Medicine, Kingston, Canada,* [2]*Queens University, Department of Pathology and Molecular Medicine, Kingston, Canada,* [3]*Queens University, Department of Medicine, Kingston, Canada,* [4]*Lunenfeld-Tanenbaum Research Institute, Toronto, Canada,* [5]*University of Toronto, Department of Molecular Genetics and Microbiology, Toronto, Canada*

Background: The VWF propeptide (VWFpp) critically mediates VWF multimerization and trafficking to Weibel-Palade bodies, from where mature VWF and VWFpp are co-secreted. While the hemostatic roles of mature VWF are well defined, an independent hemostatic function for the VWFpp remains to be determined.
Aims: To investigate a functional role for the VWFpp in mediating thrombus generation.
Methods: Mouse VWFpp and variants thereof were transiently expressed in HEK293T cells and purified via nickel affinity chromatography. Platelet thrombus generation was assessed using whole blood from ADAMTS13$^{-/-}$ or VWF/ADAMTS13$^{-/-}$ mice in a collagen-based flow chamber system. Platelet thrombi were visualized using a Quorum WaveFX-X1 spinning disk confocal microscope. The VWFpp glycosylation profile was investigated by liquid chromatography tandem mass spectrometry.
Results: In the absence of VWF, VWFpp alone was incapable of supporting platelet thrombus formation on a collagen-coated surface (surface coverage VWFpp vs negative control; 3.6 ± 0.8% vs 2.0 ± 0.3%, p=0.99). Reconstitution of mouse VWF was required to restore the ability to form a platelet thrombus (17.2 ± 3.4%). Notably, subsequent addition of VWFpp significantly enhanced thrombus formation compared with VWF alone (28.4 ± 4.1%, p=0.0169). Similarly, addition of exogenous VWFpp to whole blood of ADAMTS13$^{-/-}$ mice promoted more extensive thrombus growth compared with whole blood alone (21.2 ± 5.0% vs 7.9 ± 2.6%). To investigate factors regulating this activity, the VWFpp glycosylation profile was evaluated. LC-MSMS identified 20 discrete N-linked glycan structures occupying 3 sites; N99, N156 and N666. Importantly, removal of the glycans at N156 and N666 via site directed mutagenesis significantly delayed initial thrombus formation in both ADAMTS13$^{-/-}$ and VWF/ADAMTS13$^{-/-}$ models.
Conclusions: Mouse VWFpp enhances platelet thrombus formation *in vitro*, a process that is regulated, at least in part, by the VWFpp N-linked glycans.

OC 22.4 | Protein Kinase C Signaling Dysfunction in von Willebrand Disease Type 2B Platelets

C. Casari[1,2], D.S. Paul[2], R.H. Lee[2], R. Piatt[2], O.D. Christophe[1], P.J. Lenting[1], C.V. Denis[1], W. Bergmeier[2,3]

[1]*INSERM U 1176, Univ. Paris-Sud, Université Paris-Saclay, Le Kremlin-Bicêtre, France,* [2]*McAllister Heart Institute, University of North Carolina, Chapel Hill, United States,* [3]*University of North Carolina at Chapel Hill, Department of Biochemistry and Biophysics, Chapel Hill, United States*

Background: von Willebrand disease (VWD)-type 2B is characterized by gain-of-function mutations in von Willebrand factor (VWF) enhancing its binding affinity for the platelet receptor GPIbα. VWD-type 2B patients display a bleeding tendency associated with loss of high molecular weight VWF multimers and thrombocytopenia of varying degrees. We recently demonstrated that a marked defect in agonist-induced activation of the small GTPase, Rap1 and integrin αIIbβ3 in VWD-type 2B platelets, also contributes to the bleeding tendency. Two pathways contribute to Rap1 activation in platelets: rapid activation mediated by the calcium-sensing guanine nucleotide exchange factor, CalDAG-GEFI (CDG1), and sustained activation dependent on signaling by protein kinase C (PKC) and the ADP receptor, P2Y12.
Aims: Here, we investigated the molecular mechanisms underlying impaired platelet Rap1 signaling in VWD-type 2B.
Methods: To investigate which Rap1 signaling pathway is affected, we induced VWD-type 2B in *wild-type*, *Caldaggef1*$^{-/-}$ and *Adam17*$^{fl/fl}$*PF4-Cre*$^{+}$ mice by hydrodynamic injection of VWF/p.V1316M.
Results: In flow cytometry studies using JON/A-PE, which irreversibly binds to the activated form of integrin αIIbβ3, we demonstrate that platelet dysfunction in VWD-type 2B affects PKC-mediated, but not CDG1-mediated activation of Rap1. Consistently, downstream of PKC, we observed impaired granule release and decreased PKC substrate phosphorylation in response to agonist stimulation. Interestingly, the defect in PKC signaling was caused by a significant increase in PKC substrate phosphorylation in circulating VWD-type 2B platelets, suggesting that the VWF-GPIbα interaction leads to PKC pre-activation and subsequent desensitization of this pathway. This conclusion is supported by the fact that VWD-type 2B mice also exhibited marked shedding of platelet GPIbα, a cellular response known to be triggered by PKC signaling.
Conclusions: Our studies identify altered PKC signaling as the underlying cause of platelet hypofunction in VWD-type 2B.

OC 22.5 | Silent von Willebrand Factor Variant c.4146G>T (p.Leu1382=) Causes Type 1 von Willebrand Disease via Disruption of an Exonic Splice Enhancer Motif

A.H. Mufti, N.H. Alyami, I.R. Peake, A.C. Goodeve, D.J. Hampshire

University of Sheffield, Department of Infection, Immunity and Cardiovascular Disease, Sheffield, United Kingdom

Background: Type 1 von Willebrand disease (VWD1) is caused by mutations resulting in quantitative deficiency of von Willebrand factor (VWF). Mutation screening of a patient diagnosed with mild VWD1 highlighted a silent variant (c.4146G>T; p.Leu1382=) in exon 28 which tracked with disease phenotype within the family.
Aims: To investigate whether the c.4146G>T variant caused the mild VWD1 phenotype and to determine the disease mechanism involved.
Methods: The influence of the variant on protein expression was analysed via transfection or co-transfection of reference (R; c.4146G)

and non-reference (NR; c.4146T) bacterial expression plasmids in HEK293T cells, and measuring VWF:Ag levels using ELISA. RNA was also isolated from expression plasmids and quantified using duplex TaqMan® gene expression analysis. Half-life of expressed mRNA was determined at 0, 2, 3 and 4 hours (h) post-treatment with actinomycin D. *In silico* analyses were performed to predict variant effect on RNA splicing motifs. Influence on exonic splice enhancer (ESE) motifs was determined using a plasmid-derived ESE-dependent splicing assay.

Results: A significant reduction in VWF secretion was observed for the NR allele in both the homozygous and heterozygous states when compared to R allele alone (~39% and ~24% respectively). A similar reduction in RNA quantity following NR allele expression and a significant reduction in mRNA half-life (R: t½=2:38h; NR: t½=1:44h, ~40% decrease) was also observed. *In silico* analyses predicted disruption of an existing ESE motif in exon 28, which was confirmed *in vitro*.

Conclusions: Silent variant c.4146G>T causes mild VWD1 by disrupting an ESE motif in VWF exon 28 resulting in reduced mRNA half-life of the ‚mutant' allele, subsequently leading to reduced RNA and protein expression. This represents a novel disease causing mechanism not previously reported in VWD.

OC 24.2 | Non-neutralizing FVIII Antibodies after Successful ITI Influence FVIII Pharmacokinetics

C. Heller, S. Schultze-Strasser, D. Stichel, A. Orlowski, D. Schwabe, C. Königs

University Hospital Frankfurt, Goethe University, Department of Pediatrics and Adolescent Medicine, Frankfurt am Main, Germany

Background: Inhibitor development is still the most severe complication in modern hemophilia A treatment and the eradication of inhibitors during immune tolerance induction (ITI) is a great challenge. After successful ITI lower factor VIII (FVIII) levels are observed in some patients.

Aims: The analysis aimed to collect clinical and pharmacological data and to correlate the data to the presence and type of FVIII antibodies.

Methods: A total of 51 patients with severe hemophilia A were included in this analysis. 11 patients had undergone a successful ITI in the past. Data on treatment FVIII trough levels, incremental recovery, Bethesda Units were collected and plasma was analyzed for FVIII specific antibodies, which were further characterized.

Results: All patients received prophylactic treatment with recombinant or plasma-derived FVIII. Incremental recoveries ranged from 0,7 to 3,3. As expected, recoveries increased with age. Bethesda titers of all patients were negative. Antibodies to FVIII were detected in 11 patients with 5 patients showing specific competition. All 11 patients had a history of inhibitors and a successful ITI. These antibodies included the IgG subclasses 1 or 4. Cognate epitopes on FVIII were located in both, the heavy and the light chain of FVIII including the A2, C1 and / or C2 domain. The presence of antibodies correlated with a lower recovery (0,7 to 2,3) in this cohort.

Non-neutralizing antibodies against FVIII could be detected only in patients with a history of successful ITI and not in patients who never developed an inhibitor. Of note, antibody negative, post ITI patients were older and time since ITI success was longer compared to antibody positive patients.

Conclusions: Non-neutralizing antibodies seem to influence pharmacokinetic parameters of FVIII, mainly in patients with history of FVIII inhibitor and ITI.

OC 24.3 | Intracranial Haemorrhage in Neonates with Haemophilia - Vaginal or Caesarean Section?

N.G. Andersson[1,2], E. Chalmers[3], G. Kenet[4], R. Ljung[2], A. Mäkipernaa[5], H. Chambost[6], PedNet Group

[1]Skåne University Hospital, Centre of Thrombosis and Haemostasis, Malmö, Sweden, [2]Lund University, Skåne University Hospital, Paediatrics, Lund, Sweden, [3]Royal Hospital for Children, Department of Haematology, Glasgow, United Kingdom, [4]Tel Hashomer and the Sackler Medical School, National Hemophilia Center, Tel Aviv, Israel, [5]Hospital for Children and Adolescents, University of Helsinki, Paediatric Haematology, Helsinki, Finland, [6]Children Hospital La Timone, APHM, and Inserm, Aix-Marseille University, Paediatric Haematology Oncology Department, Marseille, France

Background: In the neonatal period, haemophilia patients have a high risk of intracranial haemorrhage (ICH) compared to the normal population. The optimal mode of delivery - vaginal or Caesarean section (CS) - for a haemophilia carrier is still debated. Knowledge of a family history of haemophilia could influence the mode of delivery and the rate of ICH.

Aims: To determine the incidence of ICH in newborns with haemophilia and the relationship with mode of delivery and knowledge of family history of haemophilia.

Methods: All children included in the PedNet Registry by 1 January 2015 with severe and moderate haemophilia A and B were enrolled (n=994). The outcomes ICH, mode of delivery and family history of haemophilia were recorded. The PedNet Registry is approved by ethical boards in all 31 participating centres and includes all consecutive children with haemophilia born after Jan 1, 2000.

Results: Twenty ICH (2.0%) occurred in 994 neonates. There was no statistical difference in the rate of ICH regarding the mode of delivery: The incidence of ICH after all vaginal deliveries was 2.3% (15/631) and 1.4% (8/560) for non-instrumental vaginal delivery compared to 1.7% (5/295) after CS with no statistical difference. Neonates born by instrumental delivery were more likely to have a diagnosis of ICH compared to a non-instrumental vaginal delivery ($P< 0.001$; RR 6.9) or after a CS ($P< 0.001$; RR 5.8). There was no significant difference between the group with and without a known family history (2.5% 8/322 vs 2.4% 7/292 ; p=0.37) regarding incidence of ICH. CS was more likely to be performed in the group with a known family history (169/495, 34%) than in the sporadic group (123/480, 26%, P=0.004).

Conclusions: Vaginal instrumental delivery was found to be a risk factor for ICH but otherwise the mode of delivery - vaginal or CS - had no impact on the rate of ICH. The knowledge of family history changed the mode of delivery but not the occurrence of ICH.

OC 24.4 | Thai Pediatric Bleeding Assessment Tool (BAT) for the Screening of Mild Bleeding Disorders

S. Pakdeeto[1], R. Natesirinilkul[2], P. Komwilaisak[3], S. Arj-Ong Vallipakara[4], M. Rand[5], V. Blanchette[5], N. Sirachainan[1]

[1]Faculty of Medicine Ramathibodi Hospital, Mahidol University, Department of Pediatrics, Bangkok, Thailand, [2]Faculty of Medicine, Chiang Mai University, Department of Pediatrics, Chiang Mai, Thailand, [3]Faculty of Medicine, Srinagarind Hospital, Khon Kaen University, Department of Pediatrics, Khon Kaen, Thailand, [4]Faculty of Medicine Ramathibodi Hospital, Mahidol University, Section for Clinical Epidemiology and Biostatistics, Bangkok, Thailand, [5]The Hospital for Sick Children, Department of Pediatrics, Toronto, Canada

Background: Mild bleeding disorders might be underdiagnosed due to difficulty in reporting subjective hemorrhagic symptoms in a consistent format. BATs include the Pediatric Bleeding Questionnaire (PBQ) which was developed for children with bleeding disorders and the International Society on Thrombosis and Haemostasis (ISTH)-the -BAT that has been studied mainly in adults. In Thailand, currently there is no standardized bleeding questionnaire.

Aims: To develop a Thai pediatric-BAT for screening mild bleeding disorders in children.

Methods: This was a multicenter case control study approved by local research ethics boards. A Thai pediatric-BAT was first developed by translating the PBQ and ISTH-BAT into Thai language. After validation, the questionnaire was administered to consented patients diagnosed with mild bleeding disorders and normal subjects; bleeding scores were calculated using the PBQ and ISTH-BAT scoring keys. The Receiver-operator curve (ROC) analysis, sensitivity, specificity and likelihood ratios were used to determine the cutoff value of bleeding scores in patients and controls.

Results: Of a total of 203 subjects from 3 medical centers in Thailand, 67 were patients and 136 were normal controls. The median (range) age in patients and controls were 5.4yrs (0.01-16.2) and 4.1yrs (0.1-18.0) years, respectively. The median PBQ and ISTH-BAT scores in VWD, platelet disorders, mild hemophilia and controls were 5, 6, 4.5 and 0, respectively. The cutoff value of 2 had similar sensitivity and specificity of 91.2% (PBQ score) and 94.1% (ISTH-BAT score). The likelihood ratio using the PBQ score for a positive bleeding score (≥ 2) was 12.38 (95% CI 6.79-22.6) while for the ISTH-BAT score was 14 (95% CI 14-26.4).

Conclusions: The Thai pediatric-BAT with bleeding score ≥ 2 using either the PBQ or ISTH-BAT scoring key can be used as a tool for screening mild bleeding disorders in children to guide the need for further investigation. Further prospective study in children with suspected bleeding disorders is required.

OC 24.5 | Tranexamic Acid in Adolescent Girls with Heavy Menstrual Bleeding

S. Saini[1], H. Ziegler[1], M. Christian-Rancy[1], S. Ahuja[2], K. Hege[3], S. Savelli[4], S. Vesely[5], S. O'Brien[1,6]

[1]Nationwide Children's Hospital, Columbus, United States, [2]Rainbow Babies & Children's Hospitals, Cleveland, United States, [3]Riley Hospital for Children at IU Health, Indianapolis, United States, [4]Akron Children's Hospital, Akron, United States, [5]University of Oklahoma Health Science Center, Oklahoma City, United States, [6]Ohio State University, Columbus, United States

Background: Heavy menstrual bleeding (HMB) occurs in up to 40 % of adolescent girls, significantly impacting their daily activities. Identifying new treatment strategies for HMB is particularly important for adolescents for whom hormonal contraception may not be preferable.

Aims: To perform an open label, multi-institutional, single arm, efficacy study of tranexamic acid (TA) in decreasing menstrual blood flow (MBL) and increasing health-related quality of life (HRQoL) in girls, age 10-19 years, with HMB.

Methods: IRB approval was obtained from each participating site. Informed consent was obtained from each subject. Girls with baseline hemoglobin < 8 grams/dL or taking hormonal contraception were excluded. Patients were treated with oral TA 1.3 grams thrice a day during the first five days of menses and monitored over the course of 4 menstrual cycles (1 baseline; 3 treatment cycles). The assessment of MBL and HRQoL was done using the Menorrhagia Impact

TABLE 1 Study Schema

TABLE 2 Results

OUTCOME VARIABLE	BASELINE	ON TREATMENT WITH TRANEXAMIC ACID	p VALUE (difference of mean; 95% CI)
PBAC score	255.1 (n = 24)	154.6 (n = 24)	< 0.001 (100.5; 46.30 to 154.74)
Total MIQ score. Range: 4 - 22	9.56	7.15	< 0.001 (2.41; 1.33 to 3.49)
MIQ 1 score: perceived blood loss. Range: 1 - 4	3.00	1.90	< 0.001 (1.09; 0.76 to 1.43)
MIQ 2 score: limitation on school attendance. Range: 1 - 5	1.64	1.40	0.47 (0.24; -0.43 to 0.91)
MIQ 3 score: limitation on physical activities. Range: 1 - 5	2.08	1.40	0.002 (0.68; 0.28 to 1.08)
MIQ 4 score: limitation on social activities. Range: 1 - 5	1.96	1.33	0.01 (0.63; 0.171 to 1.084)
MIQ 5 score: perceived change in menstrual blood loss from last cycle. Range: 0 - 2	0.68	0.86	0.20 (-0.18; -0.45 to 0.1)
MIQ 6: meaningful change for the patient. Range: 0 - 1	0.20	0.65	<0.001 (-0.46; -0.68 to -0.23)
(a)Mean hemoglobin (grams/dL) (b)Mean ferritin (nanograms/dL)	(a) 12.67 Range: 10.4 - 15.3 (b) 25.94 Range: 4 - 82	(a) 12.84 (n = 22) Range: 10.6 - 14.7 (b) 26.34 (n = 22) Range: 5 - 59	(a) 0.94 (0.01; -0.23 to 0.25) (b) 0.62 (2.13; -6.58 to 10.84)

score (MIQ), Pictorial Blood Assessment Chart (PBAC), hemoglobin and ferritin. MIQ is a validated tool to assess the influence of HMB on HRQoL. In previous studies, ≥ 1 point increase in score has been shown to be indicative of clinically significant improvement. A paired t-test was used to analyze the data.

Results: 30 patients were enrolled in the study. Of these, 25 (83.33%) completed baseline and at least 2 of 3 treatment cycles and were deemed evaluable. Mean age was 14.7 years (range 11-18). 8 (32%) had an identified bleeding disorder. The total MIQ score improved from an average of 9.56 pre-treatment to 7.15 on treatment (n = 25, $p < 0.001$). Overall, there was a significant decrease in PBAC scores when using TA (n = 24; $p < 0.001$). There was no significant improvement noted in hemoglobin or ferritin concentrations during the time frame of the study.

Conclusions: Use of tranexamic acid in adolescent females with HMB leads to clinically meaningful reduction in MBL.

OC 23.1 | A Novel Platform for Immune Tolerance Induction in Hemophilia A Mice

S. Merlin[1], E. Borroni[1], V. Bruscaggin[1], W. Tulalamba[2], M. Chuah[2], V. Arruda[3], T. Vandendriessche[2], M. Prat[1], A. Follenzi[1]

[1]*University of Piemonte Orientale, Department of Health Science, Novara, Italy,* [2]*Free University of Brussels (VUB), Department of Gene Therapy & Regenerative Medicine, Brussels, Belgium,* [3]*Perelman School of Medicine at University of Pennsylvania, The Children's Hospital of Philadelphia, Philadelphia, United States*

Background: Hemophilia A (HA) is caused by factor VIII (FVIII) deficiency. FVIII is mainly produced in the liver by sinusoidal endothelial cells (LSEC). Several attempts have been carried out to cure HA, but the immune response to FVIII is still the main issue to overcome.

Aims: To investigate the role of LSEC, the natural site of FVIII synthesis, in tolerance induction after HA gene transfer (GT) using LV-expressing FVIII driven by the endothelial-specific VE-cadherin (VEC) promoter ± miRNA target sequences (miRTs).

Methods: We prepared LV containing BDD-hFVIII, RH-hFVIII or codon optimized hFVIII (co-hFVIII) cDNAs under the control of VEC promoter alone or in combination with miRT142.3p (silencing in hemopoietic cells) and miRT122 (silencing in hepatocytes) and injected HA mice naïve or previously immunized with FVIII. To study the role of LSEC in Tregs induction we depleted Tregs before and after GT.

Results: C57Bl/6 HA mice injected with LV.VEC.FVIII±122-142 reached long-term phenotypic correction up to 1y with FVIII activity up to 12% using more active forms of FVIII. LV.VEC.FVIII±122-142 injection in FVIII-immunized mice resulted in FVIII activity and reversion of inhibitor titers. Tregs depletion before GT resulted in inhibitors formation and low FVIII levels. Tregs depletion after GT lead to inhibitor formation and decreased FVIII activity followed by recover of FVIII activity and reduction of inhibitor titers. Finally, injection of LV.VEC.FVIII in two additional HA mouse strains, B6/129 and BALB/c, resulted in long-term FVIII activity and absence of inhibitors as well.

Conclusions: We first report FVIII expression on its natural site of production with therapeutic levels without inhibitor formation. In FVIII-immunized HA mice inhibitors were eradicated in a Tregs-dependent mechanism. Transgenes expression on the natural sites of synthesis provides both efficacy and safety for long-term correction of hemophilia and likely to others genetic disease.

OC 23.2 | Cellular and transcriptional immune profiling of early factor VIII responses in hemophilia A mice

J.D. Lai[1], C. Hough[1], R. Hartholt[2], I. Peyron[2], D. Cartier[1], K. Nesbitt[1], B. Vidal[1], A. van Velzen[3], J. den Haan[4], J. Voorberg[2], D. Lillicrap[1]

[1]*Queen's University, Pathology & Molecular Medicine, Kingston, Canada,* [2]*Sanquin Research, Plasma Proteins, Amsterdam, The Netherlands,* [3]*Emma Children's Hospital Academic Medical Center, Pediatric Hematology, Amsterdam, The Netherlands,* [4]*VU Medical Center, Molecular Cell Biology and Immunology, Amsterdam, The Netherlands*

Background: Developing factor VIII (FVIII) inhibitory antibodies is the most serious complication in hemophilia A treatment, representing a significant health and economic burden. A better understanding of the innate immune responses leading to this outcome may provide insight into inhibitor prevention.

Aims: To identify early mediators of FVIII immunity and to outline the reactionary immune profiles in the spleen and liver.

Methods: C57Bl/6 *F8* E16 knockout mice were infused with 5 µg (1700 IU/kg) of recombinant FVIII. Spleens were frozen at various time points post-infusion and stained for FVIII and cellular markers. Splenic and liver RNA expression analysis was performed 3 hours post-infusion of 0.6 µg (200 IU/kg) FVIII by nCounter technology using a 561 gene immunology panel.

Results: FVIII localization did not change over 2.5 hours. We observed significantly higher co-localization of FVIII with MARCO+ cells compared to Siglec1 and SIGNR1 (Pearson's R: 0.72 +/- 0.06 versus 0.58 +/- 0.07 and 0.5 +/- 0.09; $p < 0.0001$). FVIII exhibited little co-localization with CD11c+ dendritic cells and the macrophage mannose receptor, CD206 (0.22 +/- 0.1, 0.146 +/- 0.03, respectively). Splenic mRNA immune profiling identified 5 immune transcripts that were elevated or reduced by at least 1.5-fold. We observed significant upregulation in Tnfaip6 and Lif (3.6- and 2.5-fold; p=0.02, 0.04) and downregulation in Cxcr4, Cish, and IL17r (2.2-, 2.2-, 1.6-fold; p=0.002, 0.02, 0.03). In contrast, the tolerogenic liver immune profile showed increases in Ikbkap and Traf2 expression (4.2-, 1.9-fold; p=0.03, p=0.003) and a decrease in Casp1, Alas1, Fcgr1 and Ccl5 (2.6-, 2.4-, 3.6-, 3.7-fold; p=0.04, 0.0004, 0.002, 0.04).

Conclusions: FVIII has the greatest affinity for marginal zone macrophages (MARCO+) in the spleen upon infusion. Targeting genes that are implicated in immunity in the spleen and tolerance in the liver may lead to therapeutic interventions to prevent FVIII inhibitors.

OC 23.3 | Interleukin-6 Inhibition Reduces Factor VIII Inhibitor Formation in Factor VIII-deficient Mice

M.R. Rollins[1], J.A. Taylor[2,3]

[1]Portland VA Research Foundation, Portland, United States, [2]Oregon Health & Science University, The Hemophilia Center, Portland, United States, [3]Portland VA Medical Center, Portland, United States

Background: The biggest issue facing the hemophilia A community in industrialized nations today is risk of inhibitor development. Thirty percent of patients with severe Factor VIII (FVIII) deficiency develop inhibitors. Immune tolerance therapy for the treatment of inhibitors is resource intensive, takes up to 33 months, and is only 70% effective. In addition, most inhibitors develop in the first 50 exposure days. There is growing evidence that interleukin 6 (IL-6) is involved in the pathogenesis of inhibitor development. For instance, in mice induced to develop high inhibitor levels, increased effector T-cell responses were identified in the presence of elevated expression of IL-6. Several IL-6 inhibitors are clinically available and there is low morbidity associated with their administration.

Aims: The aim is to determine if IL-6 blockade prevents inhibitor formation.

Methods: Inbred Exon 16-deleted FVIII-deficient mice were injected with weekly doses of Factor VIII (100 U/kg) for 7 weeks, then euthanized at 9 weeks of study. A similarly-treated cohort was supplemented with anti-IL-6 antibody on weeks 1, 4, and 7. Plasma obtained from both groups at weeks 3, 5, 7, and 9 was evaluated for the presence of FVIII inhibitors via speed of clot formation using Pathromtin activation on a CoaScreener.

Results: At the 9 week timepoint, 4/10 (40%) of mice receiving FVIII alone had clot time delayed ≥4 seconds versus untreated controls. In contrast, 1/10 (10%) of mice receiving supplemental IL-6 experienced the same delay. At 7 weeks, 9/11 (82%) of mice receiving FVIII alone had clot times delayed ≥2 seconds versus controls. In contrast, 3/11 (27%) of mice receiving supplemental IL-6 experienced the same delay. A 4 second delay in this assay corresponds with an inhibitor Bethesda Unit >2.

Conclusions: IL-6 inhibition reduces the development of FVIII inhibitors in FVIII-deficient mice. These data suggest that the administration of anti-IL-6 therapy may significantly reduce the incidence of inhibitor formation in hemophilia A.

OC 23.4 | Inhibition of the bruton's tyrosine kinase alters the anti-FVIII memory B-cell response in mice with severe hemophilia A

S. Delignat, J. Russick, B. Gangadharan, M. Ing, S. Kaveri, S. Lacroix-Desmazes

UMR S 1138 - Centre de Recherche des Cordeliers, Paris, France

Background: Thirty percent of severe hemophilia A patients develop anti-factor VIII (FVIII) inhibitory antibodies after FVIII replacement therapy. Immune tolerance induction (ITI) upon daily injection of large amounts of FVIII is to date the only treatment to eradicate FVIII inhibitors. It is efficient in only 60-80% of the patients. Recently, the success of ITI was associated with a lower inhibitor peak following initiation of the treatment, suggesting that strategies dedicated to prevent the recall humoral response may improve the rate of ITI success.

Aims: We evaluated whether blocking B-cell receptor (BCR) signalisation by the inhibition of the Bruton's tyrosine kinase (BTK) reduces the anti-FVIII immune response in a mouse model of severe hemophilia A.

Methods: A new highly selective inhibitor of BTK, (R)-5-amino-1-(1-cyanopiperidin-3-yl)-3-(4-[2,4-difluorophenoxyl] phenyl)-1H pyrazole-4-carboxamide (PF-06250112), was administered to FVIII-deficient mice by gavage to inhibit BCR signaling. A preventive 4-weeks treatment of naive mice was first evaluated. We also assessed the efficiency of BTK inhibition on ongoing anti-FVIII immune responses in FVIII-sensitized mice and on the *in vivo* differentiation of adoptively-transferred memory B cells.

Results: We first confirmed the efficacy of PF-06250112 in preventing *in vitro* and *in vivo* BCR-mediated B cell activation. We then

observed that inhibition of BTK during the initiation phase of the anti-FVIII immune response does not prevent the development of anti-FVIII antibodies in mice. In contrast, the anti-FVIII memory B-cell response was drastically reduced in PF-06250112-treated mice as compared to control mice (1.0±0.3 versus 124.0±115.7 arbitrary units anti-FVIII IgG, P=0.010).

Conclusions: We propose that the inhibition of BTK using PF-06250112 at the time of initiation of ITI may prevent the reactivation of FVIII-specific memory B cells and increase the chances for ITI success.

OC 23.5 | Targeted Depletion of Gut Microbes Increases Factor VIII Inhibitor Development in Hemophilia A Mice

J.L. Tarrant, M.C. Cormier, K. Nesbitt, C. Dwyer, C. Hough, D. Lillicrap

Queen's University, Pathology and Molecular Medicine, Kingston, Canada

Background: To date no studies have investigated the role of the gut microbiome in the anti-FVIII immune response. Ligation of the aryl hydrocarbon receptor (AhR) activates Tregs and down regulates Th17 cells. Specific ampicillin sensitive gut microbes convert dietary tryptophan into AhR ligands.

Aims: To assess if targeted modification of the gut microbiome, to deplete AhR ligands, in immature FVIII KO mice influences inhibitor incidence following administration of recombinant FVIII.

Methods: A minimally immunogenic regimen of FVIII in C57Bl FVIII KO mice was devised (0.5 IU recombinant FVIII twice weekly for 2 weeks). Immediately following weaning, 10 mice were transferred into a flexible film isolator for the study duration. Mice were gavaged twice daily with 500mcg ampicillin for 7 days. These microbiome manipulated mice (MMM) were fed autoclaved chow and sterile water during the remaining 6 weeks of the study. The MMM and controls (housed under regular conditions with no antibiotic exposure) were administered the FVIII regimen described. Mice were sampled weekly from the start of FVIII injections until euthanasia 4 weeks later.

Results: One of the MMM died following anesthesia during sampling (all mice otherwise appeared healthy throughout). 7 out of 9 surviving MMM developed anti-FVIII IgG antibodies detectable by ELISA at the penultimate week and study endpoint (median titre 1:320, range 0-5120), whereas only one of the control mice had detectable IgG at these times. Bethesda assay of plasma samples obtained at the end of the study demonstrated a mean inhibitor titre of 1.4 BU in MMM and 0.3 BU in control mice. Similarly, IgM had been detectable by the end of the study in 9 out of 10 MMM, but only in 1 of the 10 control mice.

Conclusions: Targeted depletion of tryptophan converting bacteria results in increased incidence of inhibitory antibodies in this hemophilia mouse model and highlights a role for the gut microbiome in modulating the immune response to therapeutic FVIII.

OC 31.1 | The Common VWF Variants p.T789A/p.Y795= Modify VWF Expression and Half-life in a Murine Model

L.L. Swystun[1], K. Ogiwara[1], A. Mufti[2], C. Notley[1], K. Nesbitt[1], J. Eikenboom[3], A. Goodeve[2], D.J. Hampshire[2], D. Lillicrap[1]

[1]Queen's University, Department of Pathology and Molecular Medicine, Kingston, Canada, [2]University of Sheffield, Department of Infection, Immunity and Cardiovascular Disease, Sheffield, United Kingdom, [3]Leiden University Medical Center, Department of Thrombosis and Hemostasis, Leiden, The Netherlands

Background: The common *VWF* single nucleotide variants rs1063856 (c.2365A>G; p.T789A) and rs1063857 (c.2385T>C; p.Y795=) are in strong linkage disequilibrium (>99%) and associate with increased VWF:Ag and risk for thrombosis. Our previous studies suggest the non-reference (NR) allele increases VWF synthesis by enhancing mRNA half-life.

Aims: To characterize the influence of the VWF p.T789A/p.Y795= variants on VWF expression, half-life, and FVIII levels in a mouse model.

Methods: The human reference (R) allele is poorly conserved across species. The murine VWF (mVWF) wild-type (WT) cDNA contains the NR allele and was "humanized" by site-directed mutagenesis (c.2365G>A/c.2367T>C, c.2385C>T). *In vivo* expression was assessed through hydrodynamic injections in VWF/FVIII double knockout (DKO) mice. The half-life of plasma-derived mVWF generated in VWF/FVIII DKO mice and recombinant human (hVWF) was measured. rs1063856/rs1063857 genotype and VWFpp/VWF:Ag ratio was assessed in a cohort of 369 healthy individuals.

Results: In VWF KO mice, p.A789T (16.7%, p=0.059) and p.A789T/p.Y795= (25%, p=0.032) had decreased expression compared with WT mVWF, while p.Y795= expressed alone did not (94%, p=0.9). In VWF KO mice, infusion with p.A789T/p.Y795= mVWF (FVIII-free) had a shorter half-life than WT (2.53 vs 5.98 h, p< 0.0001) and impaired stabilization of endogenous FVIII:C (AUC=80% decrease, p< 0.001). In contrast, when recombinant p.T789A/p.Y795= hVWF was co-infused with recombinant hFVIII into VWF/FVIII DKO mice, VWF (38.1 vs 39.7 min, p=0.66) and FVIII (39.95 vs 35.56 min, p=0.5) half-life was not different from WT. In healthy human subjects, the NR allele was associated with decreased VWFpp/VWF:Ag ratio (NR/NR: 1.16, n=35; NR/R: 1.23, N=159, p=0.09; R/R: 1.29, N=175, p=0.01).

Conclusions: The p.T789A/p.Y795= variants associate with increased VWF levels in mice as well as humans. This effect may be related to both clearance and biosynthetic-related mechanisms.

OC 31.2 | Macrophage Scavenger SR-AI Mediates von Willebrand Factor Clearance

A. Mohamadi[1], N. Wohner[1], V. Muczynski[1,2], G. Ayme[1], C. Denis[1], O.D. Christophe[1], P. Lenting[1]

[1]Institut National de la Santé et de la Recherche Médicale, UMR_S 1176, Univ. Paris-Sud, Université Paris-Saclay, Le Kremlin-Bicêtre, France, [2]Inovarion, Paris, France

Background: Previously, we identified macrophage-LRP1 to mediate VWF clearance in a flow-dependent manner. However, its contribution to VWF clearance is moderate at best, suggesting that also other macrophage-receptors contribute to VWF elimination.

Aims: To identify alternative macrophage-receptors involved in VWF clearance.

Methods: Cell- and solid-phase binding studies using recVWF variants were performed to analyze VWF-receptor interactions. Scavenger Receptor-AI (SR-AI)-deficient mice were used to determine VWF propeptide (VWFpp)/VWF:Ag ratios (a measure for VWF clearance).

Results: Although we confirmed that only active VWF binds to LRP1, we nevertheless observed efficient binding of inactive VWF to monocyte- and THP1-derived macrophages, suggesting that other VWF-receptors exist. In search for alternative receptors, we focused on SR-AI, a macrophage-specific receptor. In solid-phase binding assays, VWF bound efficiently to SR-AI (half-max binding 6±2 nM). Binding to SR-AI was calcium-dependent and inhibited by 72±4% in the combined presence of two MoAbs against the VWF A1- & D4- domains. Recombinant VWF D'-D3-, A1- and D4-domain fragments displayed dose-dependent binding to SR-AI, indicating the presence of multiple binding sites.

In cell-binding assays using macrophages and SR-AI-transfected HEK293-cells, marked co-localization of VWF and SR-AI was detected, and cellular binding was significantly reduced by the anti-A1/D4-domain MoAb combination. VWFpp/VWF:Ag ratios following expression of human VWF in wt-, SR-AI- and LRP1-deficient mice, were significantly lower in SR-A1-deficient mice compared to wt-mice & LRP1-deficient mice (0.7±0.2 vs 1.3±0.1 & 1.1±0.1; p< 0.0001). Interestingly, VWF-clearance mutants VWF/p.R1205H (Vicenza) and VWF/p.S2179F but not the type 2B mutant VWF/p.V1316M had increased binding to SR-AI.

Conclusions: We have identified SR-AI as a novel macrophage-specific receptor for VWF. Enhanced binding of VWF mutants to SR-AI may contribute to the increased clearance of these mutants.

OC 31.3 | Real-time Intravital Imaging and Quantification of VWF Clearance by Endothelial Cells and Macrophages in the Murine Liver

L.L. Swystun[1], C. Notley[1], J. Mewburn[2], I. Georgescu[1], K. Nesbitt[1], K. Schledzewski[3], C. Géraud[3], S. Goerdt[3], D. Lillicrap[1]

[1]*Queen's University, Department of Pathology and Molecular Medicine, Kingston, Canada,* [2]*Queen's University, Department of Medicine, Kingston, Canada,* [3]*University of Heidelberg, Department of Dermatology, Venereology and Allergology, University Medical Center and Medical Faculty, Mannheim, Germany*

Background: Kupffer cells (KCs), liver sinusoidal endothelial cells (LSECs), and the LSEC receptor stabilin-2 (Stab2) contribute to VWF clearance. *STAB2/VWF* DKO mice have 2.2-fold increased half-life of human VWF compared to VWF KO controls.

Aims: To characterize the role of KCs, LSECs, and Stab2 in VWF clearance using intravital microscopy, IHC, and *in vivo* clearance studies.

Methods: Fluorescent polystyrene microspheres (50 nm) were coated with human plasma-derived VWF (pdVWF), glycine (which does not bind LSECs), or BSA (an LSEC ligand). Coating was confirmed using IF on Stab2 expressing cells and by solid phase assay. In *VWF* KO mice, LSECs (CD31) and KCs (F4/80) were labelled using fluorescent antibodies. The liver was exteriorized by midline laparotomy, and microspheres were injected via jugular catheter. Association of fluorescent microspheres with LSECs and KCs was visualized in real time by spinning disc confocal microscopy. IHC was performed on livers from VWF KO mice infused with human pdVWF. VWF half-life was measured in *STAB2/VWF* DKO mice.

Results: Microspheres were observed binding to LSECs and KCs within 5 minutes of infusion. Clearance of both VWF (68.74%, p< 0.0001) and BSA (64%, p< 0.0001)-coated microspheres was mediated predominantly by LSECs as compared to uncoated (17%) and glycine-coated microspheres (20.9%). Using IHC, infused VWF was confirmed to associate with LSECS (CD31 and Stab2), and KCs (F4/80) in the liver.

Clodronate liposome-induced depletion of macrophages (including KCs) increased VWF half-life in *STAB2/VWF* DKO mice 1.5-fold (235.4 min) compared to liposome controls (156.2 min, p=0.018). Cyclophosphamide-induced LSEC cytotoxicity increased VWF half-life 1.3-fold in *STAB2/VWF* DKO mice (206.1 min, p= 0.042) compared to controls (158.8 min).

Conclusions: VWF interactions with LSECs and KCs can be observed in real time with intravital microscopy. IHC and LSEC and KC depletion studies confirm the role of both cell types in VWF clearance.

OC 31.4 | A Novel Macrophage-mediated Pathway Regulates Enhanced Clearance of Hyposialylated von Willebrand Factor *In vivo*

S. E. Ward[1,2], J.M. O'Sullivan[1,2], C. Drakeford[1,2], S. Aguila Martinez[1,2], M. Lavin[1,2], R. Preston[2], A. Chion[1,2], J.S. O'Donnell[1,2]

[1]*Trinity College Dublin, Haematology, Dublin, Ireland,* [2]*Royal College of Surgeons in Ireland, Irish Centre for Vascular Biology, Dublin, Ireland*

Background: von Willebrand Factor (VWF) is a plasma sialoglycoprotein which plays a critical role in haemostasis. While the biosynthesis and function of VWF are well characterized, the mechanisms underlying VWF clearance remain poorly understood. However, increased clearance is important in the etiology of von Willebrand disease.

Aims: To define the mechanisms involved in the enhanced *in vivo* clearance of hyposialylated VWF.

Methods: The asialoglycoprotein receptor (ASGPR) plays a key role in clearing hyposialylated VWF. To investigate if other receptors and/or cell types may also be important, $VWF^{-/-}$ and $Asgr1^{-/-}$ mice were crossed creating a novel dual $VWF^{-/-}/Asgr1^{-/-}$ knockout model. Human VWF (pdVWF) was modified using specific neuraminidases creating two glycoforms; α2-3NeuVWF and α2-3,6,8,9NeuVWF. *In vivo* clearance of these glycoforms was studied in $VWF^{-/-}/Asgr1^{-/-}$ mice.

Results: Although previous studies described a critical role for ASGPR in regulating clearance of hyposialylated VWF, we observed markedly enhanced clearance of both α2-3NeuVWF and α2-3,6,8,9NeuVWF in $VWF^{-/-}/Asgr1^{-/-}$ mice (T½= 8.2±0.6 and 3.2±0.4 vs. 50.6±2 mins for pdVWF, respectively). Importantly, the enhanced clearance of hyposialylated VWF was not significantly attenuated in the presence or absence of ASGPR. In contrast however, clearance of hyposialylated VWF in $VWF^{-/-}/Asgr1^{-/-}$ mice was reduced in the presence of asialoorsomucoid (p< 0.05). Furthermore, immunohistochemistry demonstrated localization of asialo-VWF within hepatic macrophages. Finally, in vivo macrophage depletion with liposomal clodronate also significantly attenuated the enhanced clearance of hyposialylated VWF in $VWF^{-/-}/ASGPR1^{-/-}$mice (p< 0.05).

Conclusions: Collectively, these findings demonstrate that a novel macrophage-dependent pathway is a critical modulator of the enhanced clearance of hyposialylated VWF. Given that quantitative variations in N- and O-linked sialylation has been described in specific patient cohorts, these findings are of direct clinical importance.

OC 31.5 | Genetic Variability and Glycans Modulate the Interaction between VWF and the Sinusoidal Endothelial Clearance Receptor Stabilin-2

L.L. Swystun[1], A.S. Paine[1], C. Notley[1], J. Lai[1], K. Nesbitt[1], K. Schledzewski[2], C. Géraud[2], S. Goerdt[2], W. Hopman[3], R.R. Montgomery[4], P.D. James[5], D. Lillicrap[1]

[1]*Queen's University, Department of Pathology and Molecular Medicine, Kingston, Canada,* [2]*University of Heidelberg, Department of Dermatology, Venereology and Allergology, University Medical Center and Medical Faculty, Mannheim, Germany,* [3]*Queen's University, Department of Public Health Sciences, Kingston, Canada,* [4]*Medical College of Wisconsin, Department of Pediatrics, Milwaukee, United States,* [5]*Queen's University, Department of Medicine, Kingston, Canada*

Background: Stabilin-2 (Stab2) binds, internalizes and clears human VWF. Stab2 contains an X-link carbohydrate binding domain and repeating fasciclin and EGF-like domains. Common single nucleotide variants (SNVs) in *STAB2* associate with VWF (rs4981022, -3.6%) or FVIII (rs12229292, 3.1%) in normal individuals. The rare *STAB2* SNV p.E2377K associates with higher VWF-FVIII levels (33.7%, 26.8%).

Aims: To characterize the genetic and biochemical mechanisms that regulate VWF-Stab2 interactions.

Methods: Human VWF half-life was measured in *VWF/STAB2* DKO mice. Endocytosis of VWF by Stab2 transfected HEK-293 cells was observed by immunofluorescence. *STAB2* variant pathogenicity was analyzed with Alamut software. SNVs in *STAB2* were genotyped in 165 type 1 VWD index cases.

Results: Stab2 expressing cells demonstrated enhanced uptake of de-N-glycosylated VWF compared to plasma derived VWF (210%, p< 0.0001). The half-life of de-N-glycosylated VWF was 3-fold longer in *STAB2/VWF* DKO mice (24.1 min) than VWF KO mice (8.1 min, p< 0.0001). VWF internalization was decreased by preincubation of Stab2-expressing cells with the polysaccharide ligands hyaluronic acid (-81.1%, p=0.0002), unfractionated heparin (-95.7%, p< 0.0001), mannan (-93.6%, p< 0.0001) and dermatan sulfate (-75.7%, p=0.0002).

In silico analysis suggests the Stab2 p.E2377K SNV may be damaging to protein function. In HEK 293 cells p.E2377K Stab2 demonstrated decreased expression (1.2 vs 12.5% positive, 48% decreased MFI) and overall VWF binding (28%, p< 0.0001) compared to wild-type.

In type 1 VWD patients, the *STAB2* SNV rs12229292 associated with elevated VWF:Ag (β:3.8%; CI:0.8, 6.8; p=0.014) and FVIII:C (β:1.9%; CI:-3.8, 7.6; p=0.51). rs4981022 associated with lower VWF:Ag (β:-2.8%; CI:-5.5, -0.1; p=0.041) and FVIII:C (β:-1.4%; CI:-6.5, 3.6; p=0.58).

Conclusions: Binding of VWF to Stab2 is not N-linked glycan-dependent and can be inhibited by Stab2 polysaccharide ligands. SNVs in *STAB2* modify its interaction with VWF and contribute to altered levels of plasma VWF in VWD.

OC 38.1 | Correcting the Bleeding Phenotype in Hemophilia A Using Lentivirally FVIII-corrected Endothelial Cells Differentiated from Hemophilic Induced Pluripotent Stem Cells (iPSCs)

C. Olgasi[1], S. Merlin[1], A. Lombardo[2], A. Raya[3], M. Messina[4], P.C. Schinco[4], A. Follenzi[1]

[1]*Università del Piemonte Orientale, Department of Health Sciences, Novara, Italy,* [2]*Tiget, H San Raffaele, Milano, Italy,* [3]*Center of Regenerative Medicine, Barcelona, Spain,* [4]*A.O.U. Città della Salute e della Scienza, Torino, Italy*

Background: Hemophilia A (HA) is caused by factor VIII (FVIII) gene mutations. Somatic cells can be reprogrammed to generate autologous, disease-free iPSCs and differentiated into cells relevant for gene and cell therapy.

Aims: To generate patient-specific iPSCs after cell reprogramming of CD34+ cells from peripheral blood and differentiation into FVIII-secreting endothelial cells (EC) after genetic correction by lentiviral vectors (LV).

Methods: CD34+ cells isolated from healthy and HA donors and reprogrammed with a Cre-Lox LV carrying OCT4-SOX2-KLF4 and miRNA302/367. iPSCs were characterized for stem cell markers, telomeres length and karyotype analysis. Germ layers markers expression and differentiation potential assessed on embryoid bodies (EB). iPSCs were differentiated in EC and characterized by FACS and RT-PCR. HA EC were transduced with LV carrying GFP and/or FVIII under the control of EC-specific promoter (VEC) and transplanted in NOD/SCID-gNull (NSG) HA mice. Cell engraftment and proliferation analyzed by immunofluorescence.

Results: iPSCs were differentiated into endothelial cells (EC) with an optimized protocol, acquired endothelial-like morphology, expressed ECs markers and were able to form tubules when cultured in matrigel. EC transplanted intraportally in NSG mice, engrafted and proliferated in the livers up to 12 weeks and confirmed by FACS analysis to be GFP and CD31+ representing the 30% of liver non-parenchymal cells. Moreover, transplanted cells formed vessels-like structure in the host liver. Finally, we transplanted HA-IPSC-derived ECs corrected by

LV-VEC-FVIII in NSG-HA mice that showed a reduced bleeding time and a stable 5% FVIII activity after 12 weeks.

Conclusions: These data will be instrumental to assess engraftment, proliferation and the FVIII expression from differentiated EC, gene corrected and reprogramming factor-free iPSCs to confirm the suitability of this approach for HA gene-cell-therapy.

OC 38.2 | Inhibitory Nanobodies against Antithrombin Correct Thrombin Generation and Reduce Bleeding in FVIII-deficient Mice

G. Aymé[1], C.V. Denis[1], A. Mohamadi[1,2], O.D. Christophe[1], P.J. Lenting[1,2]

[1]*Inserm Unité 1176, Univ. Paris-Sud, Univ. Paris-Saclay, Le Kremlin-Bicêtre, France,* [2]*E-Rare SMART-HaemoCare Consortium, Le Kremlin-Bicêtre, France*

Background: Inhibition of natural anticoagulant factors (antithrombin (AT), TFPI, ...) defines a novel strategy for improving hemostasis in hemophilia patients. Targeting these anticoagulants is associated with improved clinical phenotype in these patients, both with and without inhibitors.

Aims: Assessing the use of anti-AT nanobodies as a new strategy to rebalance the hemostatic system by improving thrombin generation in hemophilia A.

Methods: Llama-derived nanobodies against AT were generated. Engineered bi- and multivalent variants where tested for inhibition of AT activity, thrombin generation (TGT) in factor VIII (FVIII)-deficient plasma and hemostatic activity in a tail vein-transection bleeding model.

Results: Among the isolated nanobodies, several showed reactivity to AT of several species including murine AT, which facilitates in vivo analysis. Three variants (KB-AT-002/003, KB-AT-113, KB-AT-1123) revealed a high affinity for AT (apparent Kd < 1 nM) and proved their effectiveness in blocking the activity of the AT (inhibition 50-100%). In a thrombin generation assay using FVIII-deficient plasma, normalization of the endogenous thrombin potential was observed in the presence of each of these nanobodies. In addition, KB-AT-113 and -1123 were able to normalize other TGT-parameters as well, such as peak-height, lag-time and time-to-peak, in a manner similar to FVIII at 1 U/ml. In vivo, the intravenous injection of KB-AT-113 in FVIII-deficient mice significantly reduced blood loss compared to vehicle-treated mice.

Conclusions: Inhibitory anti-AT nanobodies efficiently correct the hemostatic deficit in the absence of FVIII in vitro and in vivo. The particular characteristics of nanobodies (subcutaneous application, high stability at room temperature and ease of production in microorganisms) make them promising tools for low-cost treatment of hemophilia. Their small size may also facilitate gene therapeutic approaches.

OC 38.3 | Exploring Chaperone-like Compounds as Innovative Therapeutic Strategy for Hemophilia B

S. Pignani[1], M. Ferrarese[1], S. Lombardi[1], S. Marchi[2], A. Todaro[1], P. Pinton[2], F. Bernardi[1], M. Pinotti[1], A. Branchini[1]

[1]*University of Ferrara, Department of Life Sciences and Biotechnology, Ferrara, Italy,* [2]*University of Ferrara, Department of Morphology, Surgery and Experimental Medicine, Section of Pathology, Oncology and Experimental Biology, Ferrara, Italy*

Background: Missense mutations impairing protein folding are a frequent cause of human disease. Small molecules with chaperone activity and able to assist protein folding could rescue protein biosynthesis, with therapeutic implications. This could be relevant in coagulation factor disorders that would benefit even from a tiny increase of functional protein levels (>2%).

Aims: To characterize intracellular processing of a panel of FIX missense variants causing severe Hemophilia B (HB) and to challenge them with chaperone-like drugs.

Methods: Transient and stable expression of recombinant FIX (rFIX) variants in mammalian cells to create HB cellular models followed by evaluation of secreted/intracellular protein levels (ELISA, Western Blotting) and intracellular trafficking (Immunofluorescence) upon treatment.

Results: Transient expression studies indicated that the selected model mutations Y115C, Y161C, R294Q, Y305C, F424L and Y450C severely impair FIX secretion (0.2-0.8% of wild-type), which recapitulates finding in HB patients. Co-localization studies on stable cells showed that missense variants scarsely co-localized with the Golgi apparatus, which could underlie an altered trafficking due to mis-folding. The observation that cell treatment with the proteasome inhibitor MG-132 increased secreted rFIX levels for some variants supports partial intracellular degradation of mis-folded proteins.

These findings prompted us to challenge a first model mutation with Na-PBA, a chaperone-like compound succesfully exploited for other proteins. Intriguingly, these pilot studies on the rFIX-305C variant showed that treatment with 0.1-1 mM NaPBA induced a 2-fold increase in secreted rFIX levels in a dose-dependent manner.

Conclusions: Our data, besides contributing to dissect the molecular basis of Hemophilia B, provide a preliminary but intriguing experimental evidence for the rescue of HB-causing missense variants with pharmacological chaperones.

OC 38.4 | Development of Nanobodies Fused to Albumin Binding Peptide: A Tool to Increase Plasmatic Levels of Endogenous Proteins

C. Kawecki, G. Ayme, C. Casari, P. Legendre, O.D. Christophe, P.J. Lenting, C.V. Denis

INSERM U 1176, Univ. Paris-Sud, Université Paris-Saclay, Le Kremlin-Bicêtre Cedex, France

Background: Many hemorrhagic disorders are characterized by partial quantitative deficiencies in plasmatic levels of coagulation factors. Type 1 von Willebrand disease (VWD-type 1), a typical example of these quantitative disorders, is characterized by reduced levels of circulating von Willebrand factor (VWF), and a corresponding bleeding tendency. VWF mediates platelet aggregation/adhesion to damaged endothelium and carries factor VIII (FVIII). Current treatment options include replacement therapy by intravenous injection of VWF-concentrates, or by intravenous injection of Desmopressin (DDAVP), provoking the release of intracellular VWF and increasing FVIII levels.

Aims: Our aim is to develop a new therapeutic approach to increase the plasmatic level of VWF by prolonging its half-life in plasma.

Methods: A series of non-inhibitory nanobodies against human/murine VWF was generated. Nanobodies were fused to an albumin-binding peptide (ABP).

Results: A bivalent construct of such nanobody fused to ABP (KB-VWF-013bv_ABP) was constructed. KB-VWF-013bv_ABP bound efficiently to VWF and albumin *in vitro*. Half-life of human VWF was prolonged about 7-fold when it was pre-incubated with KB-VWF-013bv_ABP prior to intravenous (IV) injection. IV-injection of this bivalent construct into wild-type C57B6 mice resulted in increased levels of endogenous VWF (15±7 fold at 3 days and 8±5 fold at 7 days after injection). FVIII levels increased concomittantly (7±3 fold and 6±3 fold, respectively). Subcutaneous injection resulted in increased levels of VWF at day 3 and 7 (4±1 fold in both cases).

Conclusions: These results clearly show that KB-VWF-013bv_ABP is able to bridge VWF and albumin, leading to an important increase of VWF half-life, thereby increasing endogenous plasma levels. Fusion of the same ABP to nanobodies targeting other relevant proteins (eg factor IX) could be used to increase the endogenous level of coagulation factors in other hemorrhagic disorders characterized by quantitative deficiencies.

OC 38.5 | Development of a Gene Therapy Strategy for von Willebrand Disease Based on Dual Adeno-associated Virus Vectors

E. Barbon[1], C. Kawecki[2], A. Sakkal[1], F. Collaud[1], M. Simon-Sola[1], S. Charles[1], O.D. Christophe[2], C.V. Denis[2], P.J. Lenting[2], F. Mingozzi[1,3]

[1]*Genethon and INSERM U 951, Evry, France,* [2]*INSERM U 1176, Univ. Paris-Sud, Université Paris-Saclay, Le Kremlin-Bicêtre, France,* [3]*University Pierre and Marie Curie - Paris 6 and INSERM U 974, Paris, France*

Background: Von Willebrand disease (VWD) is the most common inherited bleeding disorder in humans, caused by quantitative or qualitative defects in von Willebrand factor (VWF). Current therapies have still limitations mostly related to their short-term efficacy. In this context, VWD represents a potential target for gene therapy approaches, as a single treatment could potentially results in a long-term correction of the disease.

Aims: Develop an innovative gene therapy strategy for VWD based on dual overlapping adeno-associated virus vectors (AAV).

Methods: In our approach the large 8.4 kb VWF coding sequence is split in two AAV vectors, thus permitting to overcome the AAV size limitation (5 kb). In this system each AAV delivers one half of the VWF cDNA with an overlapping region, which mediates the reconstitution of the entire genome by homologous recombination. We injected each vector in the tail vein of VWF KO mice, at a dose of 2E+13 vg/kg, and assessed the circulating VWF levels by ELISA assay 4 and 6 weeks post-administration.

Results: We generated a dual AAV8 vector expressing murine VWF under the control of the liver specific human alpha-1 antitripsin promoter (hAAT). The two halves of the transgene expression cassette (5‘ and 3‘ cassette) contained in the dual AAV share a homologous region of 400 base pairs. Delivery of the two vectors resulted in detectable levels of VWF expressed by the liver (up to 3% of normal) at 6 weeks post-administration. Conversely, circulating murine VWF levels were undetectable in control mice injected with the 5‘ or the 3‘-cassette alone.

Conclusions: Results obtained in VWF KO mice demonstrate that, taking advantage of the ability of the dual AAV vector system to reconstitute a full-length cDNA in hepatocytes, we were able to express the large gene of VWF from the liver. Future experiments will be aimed at optimizing the dual AAV in order to increase expression levels and to subsequently evaluate biochemically the effect of VWF transgene expression on the hemorrhagic phenotype.

OC 37.1 | Influence of Phospholipid Configuration of APPT Reagents in the Diagnosis of Mild Haemophilia A with Discrepancy

B. Gillet, M. Sigaud, M. Fouassier, C. Ternisien, M. Trossaërt

Nantes University Hospital, Centre de Traitement de l'Hémophilie, Nantes, France

Background: Mild haemophilia A (MHA) is defined by a level of FVIII:C between 5-40 IU/dL. In some cases, discrepancies between chronometric and chromogenic assays have been described inducing difficulties to define the severity of their disease.

Aims: Evaluation of the impact of APTT reagents with different phospholipids configuration on FVIII:C results in MHA patients with discrepancy.

Methods: 29 patients with a MHA and previously diagnosed with discrepant FVII:C results were studied. The discrepancy is defined by a APTT FVIII:C / chromogenic FVIII:C ratio < 0.5 or >1.5. Among those patients 18 have the same mutation of the F8 gene: p.Phe2146Ser.

Five APTT reagents (Ck prest®-Stago, Actin FS®- Siemens, APTT-SP®, SynthASil SF®, SynthAFax®-Werfen) were used and BIOPHEN FVIII:C Hyphen as chromogenic assay. Measurements were run on an ACL TOP device with the same calibrator (Siemens©).

Results: In patients with standard discrepancy (APTT /chromogenic ratio >1.5) this discrepancy is confirmed with all APTT reagents. For patients with APTT /chromogenic ratio < 0.5) no difference (p>0.05) was found between APTT reagents except for patients with the p.Phe2146Ser mutation. For those patients, when using APTT-SP®, SynthASil SF® or SynthAFax® there was no discrepancy between chronometric and chromogenic assays. In contrary, when using Ck prest® or Actin FS, we still found the initially described discrepancy (p=0,0002).

Conclusions: In this study we observed discrepancies in several mutations between APTT assays and chromogenic assay. In patients with p.Phe2146Ser, the discrepancy seems to be more linked to the composition of phospholipids in APTT reagents than to the method (chronometric or chromogenic) used for FVIII:C measurement. This mutation modifies the C1 domain of the FVIII protein which is known to interact with phospholipids. Further studies are needed to define how this mutation interacts with phospholipids and which the most relevant test is.

OC 37.2 | Desmopressin in Hemophilia: The Need for a Clinical Response Definition and Individualized Test Regimen Based on FVIII: C Values One Hour after Infusion

S.C.M. Stoof[1], L.M. Schütte[1], F.W.G. Leebeek[1], M.H. Cnossen[2], M.H.J.A. Kruip[1]

[1]*Erasmus University Medical Center, Hematology, Rotterdam, The Netherlands,* [2]*Erasmus University Medical Center - Sophia Children's Hospital, Pediatric Hematology, Rotterdam, The Netherlands*

Background: Due to inter-individual variation in desmopressin response, non-severe hemophilia A (HA) patients require testing prior to therapeutic treatment. However, adequate response or frequency of blood sampling are not defined in international guidelines. Consequently, various definitions and blood sampling protocols are used. Interestingly, sustainability of desmopressin response is not incorporated.

Aims: To study desmopressin response rates in a cohort of non-severe HA patients using currently accepted desmopressin response definitions. This, in order to formulate a response definition which includes information on sustainability. This study aims to launch a standardized blood sampling protocol which is widely applicable.

Methods: Currently used desmopressin response definitions in non-severe HA were derived from a literature search. Actual response rate according to the varying definitions was analyzed in 105 non-severe HA patients in the Erasmus MC hemophilia treatment center. In this study, sustained response was defined as FVIII:C ≥ 0.30 IU/ml three and six hours after desmopressin infusion.

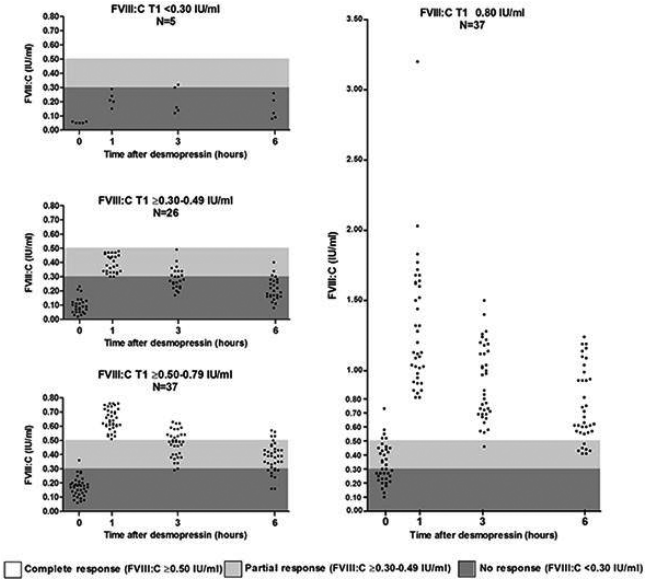

FIGURE 1 FVIII:C before and after desmopressin test in several subgroups based on FVIII:C levels measured one hour (T1) after desmopressin

Results: Five response definitions were evaluated, three of which included only FVIII:C cut-off levels and two also incorporating FVIII:C-fold increase of baseline value. Strikingly, FVIII:C-fold increase showed no association with response sustainability. FVIII:C 1 hour after infusion (< 0.30, ≥0.30-0.49, ≥0.50-0.79 or ≥0.80 IU/ml) was however indicative of response after 6 hours: 100% of patients with FVIII:C ≥0.80 IU/ml after 1 hour had a sustained response after 6 hours (Figure).

Conclusions: We suggest a desmopressin response definition based on clinically relevant FVIII:C levels, e.g. 0.30 and 0.50 IU/ml, and an individualized blood sampling regimen. Patients with FVIII:C < 0.30 IU/ml after 1 hour (non-responders) or ≥0.80 IU/ml will not require subsequent blood sampling. However, patients with FVIII:C ≥0.30-0.79 IU/ml after 1 hour should undergo blood sampling after 6 hours to determine response sustainability.

OC 37.3 | The Role of Vascular Remodeling and Clotting Factor Thresholds in the Context of Hemophilic Joint Bleeding: Results from a Prospective Imaging Study in Patients with Hemophilia and Advanced Arthropathy

R.F. Barnes[1], E.J. Cooke[1,2], T.J. Cramer[1], J.Y. Zhou[1], G. Foster[3], A. Iorio[3], A. von Drygalski[1,2]

[1]*University of California San Diego, Medicine, San Diego, United States,* [2]*The Scripps Research Institute, Molecular and Experimental Medicine, La Jolla, United States,* [3]*McMaster University, Health Research Methods, Evidence and Impact (HEI), Hamilton, Canada*

Background: Raising clotting factor (CF) troughs to prevent hemophilic joint bleeding is gaining popularity. Ideal levels and the role of individual pharmacokinetic (PK) parameters are unknown.

Aims: We studied PK, joint- and patient-specific parameters on hemophilic joint bleeding.

Methods: Thirty-one adults with hemophilia and ≥ 1 arthropathic joint (defined by abnormal radiographic Pettersson Score [PS]) were studied prospectively for 2 yrs with Musculoskeletal Ultrasound of major joints (n≈600 joint exams) during pain-free intervals and during painful events for bleed status. Microvascular perfusion was determined by Power Doppler (PD). CF infusion logs and plasma levels allowed PK calculations (1/2 life; area under curve [AUC]; time spent below CF activity thresholds) during and between bleeds. PK modeling estimated AUC and time spent below 5, 10, 15 or 20 units/dL for the 15 days prior to each bleed, and for random periods in the same patients and those without bleeding events.

Results: Of 23 reported painful events, 15 were associated with bleeding. Bleeds were not preceded by lower AUC, time spent below particular CF levels, or lower CF consumption compared to random control periods before and after bleeding. PK parameters were comparable in patients having painful events without bleeding or patients with no painful events. At baseline, only PS were higher in patients with future bleeds (p = 0.02), while age, weight, vascular PD signal and clinical joint scores were similar compared to patients without future bleeds. During painful events, only bleeding joints had increased vascular PD signal and flow intensity that were 2-3 times greater compared to non-bleeding joints (both p = 0.03).

Conclusions: Joint bleeds were not explained by fluctuations below individual CF thresholds, but linked to pronounced vascular remodeling. This suggests that raising CF troughs may not entirely control bleeding and that vascular remodeling and leak may contribute.

OC 37.4 | Development and Validation of the "Joint Activity and Damage Exam" (JADE) for Quantitation of Structural Abnormalities by Musculoskeletal Ultrasound (MSKUS) in Hemophilic Joints: Intra- and Inter-rater Reliability

L. Volland[1], J.Y. Zhou[1], R.F.W. Barnes[1], R. Kruse-Jarres[2], B. Steiner[2], D.V.Q. Quon[3], C. Bailey[3], M. Brackman[1], E.Y. Chang[4,5], A. von Drygalski[1,6]

[1]University of California San Diego, Medicine, San Diego, United States, [2]Washington Center for Bleeding Disorders, BloodWorks Northwest, Seattle, United States, [3]Orthopaedic Hemophilia Treatment Center, Orthopaedic Institute for Children, Los Angeles, United States, [4]VA San Diego Healthcare System, Radiology, San Diego, United States, [5]University of California San Diego, Radiology, San Diego, United States, [6]The Scripps Research Institute, Molecular Medicine, La Jolla, United States

Background: Several semi-quantitative scales using musculoskeletal ultrasound (MSKUS) to assess hemophilic arthropathy have been proposed. However, a quantitative method to measure tissues, osteochondral surfaces and vascular perfusion is missing.

Aims: To develop, standardize and validate a quantitative protocol to measure tissue abnormalities with MSKUS in hemophilic arthropathy.

Methods: Thirty-one adults with hemophilia were studied prospectively for 2 yrs with MSKUS at regular intervals (n≈600 joint exams; ≈6000 images). Based on the spectrum of pathologies, a quantitative algorithm to measure osteochondral surface defects, cartilage thickness, soft tissue expansion, microvascular perfusion abnormalities (Power Doppler [PD]) and to detect effusions was developed for ankles, elbows, and knees (Joint Activity and Damage Exam [JADE]). To study feasibility and intra-/inter-rater reliability, 8 hemophilia providers experienced in MSKUS performed anatomical landmark recognition and measurements on 45 knee MSKUS images, with repetition 1 month later. Similar assessments were performed by 23 *in*experienced MSKUS providers post training. A radiologist was the adjudicator. Intra-class correlation coefficients and Fleiss' Kappa were calculated with AgreeStat 2015.6. Study procedures complied with the UCSD Human Research Protection Program.

Results: Recognition of anatomical landmarks was nearly 100% for all providers. Measurements of structures were feasible to as little as 1/10th of a millimeter. Intra-/inter-rater reliability of cartilage thickness, osteochondral surface defects, soft tissue expansion, effusions and PD signals ranged from substantial to nearly perfect (Correlation Coefficient and Fleiss' Kappa 0.63-0.94; Table 1/2).

Conclusions: JADE is the first quantitative MSKUS algorithm of precise measurements in hemophilic joints. High intra-/inter-rater reliability should enable easy quantification of progression of hemophilic arthropathy, which will benefit clinical practice and multi-center research.

TABLE 1 Intra-Class Correlation Coefficient for Knee Measurements

	Experienced Providers				Inexperienced Providers
Measurement	Inter-Rater Reliability First Assessment	Inter-Rater Reliability Second Assessment	Intra-Rater Reliability	Inter-Rater Reliability with Adjudicator	Inter-Rater Reliability
Cartilage Thickness Point 1	0.79	0.84	0.80	0.78	0.73
Cartilage Thickness Point 2	0.92	0.92	0.90	0.93	0.88
Osteochondral Interface	0.70	0.83	0.85	0.73	0.70
Soft Tissue Expansion	0.89	0.84	0.84	0.89	0.63

TABLE 2 Fleiss' Kappa for Knee Measurements

	Experienced Providers				Inexperienced Providers
	Inter-Rater Reliability First Assessment	Inter-Rater Reliability Second Assessment	Intra-Rater Reliability	Inter-Rater Reliability with Adjudicator	Inter-Rater Reliability
Power Doppler	0.91	0.94	*	0.92	**
Anechoic vs. Mixed Echogenicity	0.88	0.90	*	0.70	**
Simple vs. Complex Effusion	0.88	0.90	*	0.69	**

OC 37.5 | Evaluation of the Hemostatic Effect of the Combination of Factor Concentrate with Tranexamic Acid (TXA) in vitro Using Global Assays

M. Janbain[1], J.C. Bordet[2], C. Leissinger[1], C. Negrier[3], Y. Dargaud[3]

[1]*Tulane School of Medicine, Hematology and Medical Oncology, New Orleans, United States,* [2]*Laboratoire d'Hématologie Centre de Biologie Est, Lyon, France,* [3]*Unité d'Hémostase Clinique Hôpital Cardiologique Louis Pradel, Lyon, France*

Background: Prophylaxis is the gold standard for the treatment of severe hemophilia(sH). However, there is a need for low cost,safe,and well tolerated therapies that have the potential to enhance prophylaxis. Such therapies may reduce the frequency of factor infusions,thereby improving adherence and reducing the cost of prophylaxis. The addition of TXA to factor concentrates may be one strategy for optimizing prophylaxis.

Aims: We aimed to study whether the clot stability in patients with sHA is improved with the combination of TXA and low FVIII plasma concentration(achieved in prophylactic setting).

Methods: Following informed consent, the whole blood(WB) and plasma(PL) obtained from 12 adult patients with sHA were studied in vitro after spiking the samples to achieve a final concentration(FC) of 0,3,10 and 30IU/dL of FVIII with or without adding TXA at FC of 0.1mg/ml. WB was assessed with ROTEM in the presence of t-PA in 6 patients. Thrombin generation(TG) was measured in PL of 6 patients. The clots obtained from TG reaction, were analyzed using electron microscopy. Diameters of randomly selected 100 fibrin fibers were measured in each clot. Results obtained with FVIII alone were compared to those with FVIII+TXA.

Results: A dose dependent improvement of TG and fibrin clot structure was observed after adding FVIII alone(p=0.024). The addition of TXA had no effect on TG capacity. However,in the presence of TXA better fibrin clot structure was observed. Fibrin fiber diameters were significantly decreased with TXA+FVIII compared to FVIII(p=0.007), suggesting a strong fibrin network as thin fibrin fibers are characteristic of a robust fibrin mesh. In the presence of TXA,ROTEM analysis was not suitable to evaluate the resistance of clots against fibrinolysis, the test being too sensitive to the effect of TXA. In all patients,ROTEM was fully normalized after addition of TXA only with no exogenous FVIII.

Conclusions: Our results suggest a potential benefit of TXA when used in combination with FVIII in prophylactic setting.

OC 36.1 | Results from Italian Registry of Activated Prothrombin Complex Concentrate in Acquired Hemophilia A: The FAIR Study

E. Zanon[1], M. Milan[1], G. Gamba[2], G. Giuffrida[3], A. Falanga[4], A.B. Federici[5], I. Cantori[6], S. Siragusa[7], M.G. Mazzucconi[8], G. Piseddu[9], A. Rocino[10], R.C. Santoro[11], S. Pasca[1], C. Lodigiani[12]

[1]*University Hospital of Padua, Hemophilia Center, Padua, Italy,* [2]*University of Pavia, Internal Medicine and Medical Therapy, Pavia, Italy,* [3]*University of Catania, Catania, Italy,* [4]*Hospital Papa Giovanni XXIII, Immunohematology and Transfusion Medicine, Bergamo, Italy,* [5]*'L.Sacco' University Hospital, Hematology and Transfusion Medicine, Milan, Italy,* [6]*Hospital of Macerata, Transfusion Medicine, Macerata, Italy,* [7]*University of Palermo, Hematology and Bone Marrow Transplantation, Palermo, Italy,* [8]*'Sapienza' University of Rome, Hemophilia Center, Rome, Italy,* [9]*'Santissima Annunziata' Hospital, Hemophilia and Thrombosis Center, Sassari, Italy,* [10]*ASL 1 Neaples, Hemophilia and Thrombosis Center, Neaples, Italy,* [11]*'Pugliese-Ciaccio' Hospital, Hemophilia Center, Catanzaro, Italy,* [12]*Humanitas Clinical Institute, Rozzano, Italy*

Background: Bypassing agents are the first line therapy in patients with acquired hemophilia A (AHA). Activated prothrombin complex concentrate (aPCC) proved to be effective and safe but its use is not fully standardized.

Aims: To evaluate dosage, days of treatment, efficacy and safety of aPCC in an Italian population of AHA patients with acute bleeding.

Methods: The FAIR Registry is a retrospective-prospective study started in Dec 2012. All patients (pts) with AHA treated with aPCC and diagnosed within the previous ten years if retrospective pts and up to the end of Dec 2015 if prospective ones were initially enrolled.

Results: Statistical analyses were performed on 31 retrospective and 25 prospective pts, 50% males, mean age 69.9±15.1 years. 51.8% were idiopathic AHAs. 101 total bleeds were reported, 65.3% of which in the retrospective group. 84.1% were spontaneous, 71.3% involving muscles or skin. aPCC as first line therapy was used in 82.2% of cases, median dose 72.6±26.6 IU/kg, median frequency: 12 hours (IQR 0-84)

and median number of doses: 9 (IQR 1-104). Treatment was continued for a median of 8 days (IQR 1-48). aPCC was considered effective in the 96.4% and was associated with antifibrinolytics in 39.6% of cases, being higher in the prospective group (p< 0.05). Low-dose aPCC as short-term prophylaxis to prevent recurrences was started after the first episode in 26.8% of pts, in a mean dose of 54.2±23.0 IU/kg, continued up to a mean of 20.5±17.6 days, more frequent in prospective pts (p< 0.05). Anamnestic response was reported in 6/101 of treatments, 2 in the prospective group, median inhibitor titer was 9.3 BU (IQR 0.6-41.8) and increased after a median of 6 days (IQR 2-19) from first treatment start. No thrombotic events were reported. 8 pts died, one uncontrolled bleeding was AHA related.

Conclusions: aPCC proved to be effective and safe in the treatment of bleeds in AHA. Low-dose aPCC as secondary short-term prophylaxis seems to prevent bleeding recurrences.

OC 36.2 | Low Dose of aPCC as Short-term Prophylaxis after the End of Initial Treatment of Acquired Hemophilia a to Reduce Bleeding Recurrences: Data from the FAIR Registry

E. Zanon[1], S. Pasca[1], G. Gamba[2], G. Giuffrida[3], A. Falanga[4], A.B. Federici[5], I. Cantori[6], S. Siragusa[7], M.G. Mazzucconi[8], G. Piseddu[9], A. Rocino[10], R.C. Santoro[11], C. Lodigiani[12]

[1]University Hospital of Padua, Hemophilia Center, Padua, Italy, [2]University of Pavia, Pavia, Italy, [3]University of Catania, Catania, Italy, [4]'Papa Giovanni XIII' Hospital, Immunohematology and Transfusion Medicine, Bergamo, Italy, [5]'L.Sacco' University Hospital, Hematology and Transfusion Medicine, Milan, Italy, [6]Hospital of Macerata, Transfusion Medicine, Macerata, Italy, [7]University of Palermo, Hematology and Bone Marrow Transplantation, Palermo, Italy, [8]'Sapienza' University of Rome, Hemophilia Center, Rome, Italy, [9]'Santissima Annunziata' Hospital, Hemophilia and Thrombosis Center, Sassari, Italy, [10]ASL 1 Neaples, Hemophilia and Thrombosis Center, Neaples, Italy, [11]'Pugliese-Ciaccio' Hospital, Hemophilia Center, Catanzaro, Italy, [12]Humanitas Clinical Institute, Rozzano, Italy

Background: Bypassing agents are the first line therapy in patients with acquired haemophilia A (AHA). Activated prothrombin complex concentrate (aPCC) proved to be effective as initial treatment, but 20% of patients (pts) had recurrences. aPCC as short-term prophylaxis to reduce subsequent bleeds is not still clear.

Aims: To evaluate whether a short-term prophylaxis with low dose of aPCC can reduce bleeding recurrences after initial AHA treatment, maintaining safety.

Methods: The FAIR Registry is a retrospective-prospective study that collected data on all pts with AHA treated with aPCC in 12 Italian Hemophilia Centers. All statistical analyses were carried out in the 56 pts included in the registry, 31 retrospective (from 2003 to 2012) and 25 prospective (from 2013 to 2015).

Results: 31 retrospective and 25 prospective pts were evaluated, 51.8% were idiopathic AHAs. 101 bleeds requiring treatment were reported, 84.1% spontaneous, 71.3% involving muscles or skin. Major bleeds were 38,6%. aPCC was used as first line therapy in 82.2% events and administered in a median dose of 72.6 ± 26.6 IU/kg. Time of treatment was 8 days (IQR 1-48), without significant differences between the two groups. aPCC was considered effective in 96,4% of cases. Low-dose aPCC as short-term prophylaxis was started after first episode in 15/56 pts, 60% of whom prospective, in a mean dose of 54.2±23.0 IU/kg, higher (61.4±23.4 IU/kg) in the prospective group than in the retrospective one (44.3±19.7 IU/kg) and it was continued up to a mean of 20.5±17.6 days, similar in both groups. A total of 32 bleeding recurrences were reported, 87.5% in the retrospective group. Only 9.4% occurred during short-term prophylaxis (p< 0.05). In our Registry no thromboembolic events were found.

Conclusions: Initial AHA treatment with aPCC proved to be highly effective, but a consecutive low dose as short-term prophylaxis seems to demonstrate a significant reduction in bleeding recurrences maintaining safety profile.

OC 36.3 | Blood Pump Hemocompatibility: in vitro and in vivo Evaluation of von Willebrand Factor Degradation

P.A. Coghill[1], Z. Azartash-Namin[1], J.R. Stanfield[1], T.A. Snyder[1], J.W. Long[2]

[1]Vadovations, Inc, Oklahoma City, United States, [2]Integris Baptist Medical Center, Advanced Cardiac Care, Oklahoma City, United States

Background: Approximately 40% of heart failure patients who receive an implantable rotary blood pump (RBP) suffer from gastrointestinal bleeding complications, which arise from the degradation of high molecular weight (HMW) von Willebrand Factor (VWF). While standardized test methods exist to address the simple task of pre-clinical hemolysis testing, no accepted standards or regulatory guidance exist for assessing VWF compatibility.

Aims: In this study, we investigated (i)how various experimental factors influence VWF compatibility in RBPs and (ii)methods for evaluating prototype RBP VWF compatibility during in vivo testing.

Methods: .Human blood bank plasma was circulated through bench-top flow loops with a HeartWare HVAD and Levacor (LEV), Thoratec-SJM HeartMate II (HMII) and CentriMag (CM), and Vadovations prototype blood pump (V-O VAD) while a control loop was rocked at 1Hz. The pumps were operated to generate 4L/min against 75mmHg. Samples were collected at pre-test, 0, 30 and 60 min, then hourly for 6h and analyzed for VWF collagen binding activity (VWF:CB) and VWF antigen level (VWF:Ag) using commercially available kits. Healthy ovines were also implanted with the V-O pump for up to 90 days, and plasma samples were analyzed for VWF:CB using a modified commercially available kit. VWF multimer profiles of in vitro and in vivo plasma samples were visualized using gel electrophoresis and near-IR in-gel scanning and analyzed using standard densitometry techniques.

Results: VWF:CB/Ag remained near baseline levels after 6h in the LEV and V-O pumps. In the HVAD, HMII and CM pumps, VWF:CB/Ag at 6h was decreased by 33%, 40% and 41%, respectively. These three pumps also degraded HMW VWF while the LEV and V-O pumps did

not. The V-O pump also preserved VWF:CB and HMW VWF in ovines out to 90 days.

Conclusions: RBP prototypes can be tested both in vitro and in vivo for VWF compatibility. Standardizing these test methods would improve the pre-clinical device design process and potentially enhance patient quality of life.

OC 36.4 | Relationship of Markers of Inflammation, Infection, and Endothelial Function to Mortality and Severity of Coagulopathy in Patients with Sepsis-associated DIC

A. Walborn[1], P. Patel[2], D. Hoppensteadt[2], M. Mosier[3], M. Rondina[4], J. Fareed[2]

[1]Loyola University Medical Center, Pharmacology, Maywood, United States, [2]Loyola University Medical Center, Pathology, Maywood, United States, [3]Loyola University Medical Center, Surgery, Maywood, United States, [4]University of Utah School of Medicine, Department of Internal Medicine, Salt Lake City, United States

Background: Sepsis-associated disseminated intravascular coagulation (DIC) is a complex clinical scenario involving derangement of many processes, including hemostasis. Assessment of markers of these aspects of disease, including inflammation, endothelial function, and endogenous anticoagulants may provide insight into DIC pathophysiology and lead to improved methods for assessment of patient and response to treatment.

Aims: To measure biomarkers representative of multiple systems involved in DIC development in a cohort of patients with sepsis and DIC and determine the association of these markers with DIC score and mortality.

Methods: Plasma samples were collected from 102 patients with sepsis and suspected DIC at ICU admission. CD40L, PAI-1, nucleosomes, PCT, endocan, MP-TF, TFPI, and F1.2 were measured using commercially available ELISA kits. Protein C activity was measured using a clot-based assay. IL-2, IL-4, IL-6, IL-8, IL-10, VEGF, IFNγ, TNFα, IL-1α, IL-1β, MCP-1, and EGF were measured using biochip technology.

Results: Significant differences in levels of Protein C (p=0.0093), PCT (p=0.0005), IL-6 (p=0.0199), IL-8 (p=0.0149), PAI-1 (p=0.0153), and endocan (p=0.0252) were observed between survivors and non-survivors. Significant variation of Protein C (p=0.0017), nucleosomes (p=0.05), PCT (p< 0.0001), IL-6 (p=0.001), IL-8 (p=0.0025), IL-10 (p=0.0115), TNFα (p=0.0209), IL-1β (p=0.0324), MCP-1 (p=0.0209), and EGF (p=0.0002) were observed based on DIC score.

Conclusions: Markers from multiple systems perturbed in DIC were associated with mortality, suggesting that while these systems are not routinely evaluated in the normal course of patient care, dysfunction of these systems contributes significantly to mortality. In addition, several inflammatory cytokines also showed an association with DIC score. This suggests that while inflammation contributes to DIC, other processes play a large role in patient outcome.

OC 36.5 | Angiopoietin-2 Levels in the Risk Stratification and Mortality Outcome Prediction of Sepsis Associated Coagulopathy

S. Statz[1], A. Walborn[2], M. Williams[3], D. Hoppensteadt[1], M. Mosier[4], M. Rondina[5], J. Fareed[1]

[1]Loyola University Medical Center, Pathology, Maywood, United States, [2]Loyola University Medical Center, Pharmacology, Maywood, United States, [3]University of Indiana Medical School, Medicine, Indianapolis, United States, [4]Loyola University Medical Center, Surgery, Maywood, United States, [5]University of Utah School of Medicine, Department of Internal Medicine, Salt Lake City, United States

Background: Angiopoietin-2 (Ang-2) is a 70 kDa glycoprotein which plays multiple roles in angiogenesis, inflammation, and vascular development. Ang-2 is upregulated in vascular stress, and circulates at high levels in certain pathologic conditions such as sepsis. Ang-2 upregulation may be related to the severity of sepsis associated coagulopathy (SAC), and therefore it may have a predictive role in the clinical outcome of this syndrome.

Aims: The aim of this study is to measure Ang-2 levels in a defined cohort of patients with sepsis and suspected disseminated intravascular coagulation (DIC), to compare the circulating levels of this biomarker to controls, and to demonstrate its predictive value for the clinical outcome and severity of SAC.

Methods: Plasma samples were collected from 102 patients with sepsis and suspected DIC at ICU admission and immediately frozen at -80°C for batch analysis. Control plasma represented 50 normal samples which were commercially obtained from George King (Orland Park, KS). Ang-2 levels were quantified using a sandwich ELISA method (R&D Systems, Minneapolis, MN, USA). This method employs a monoclonal antibody specific for human Ang-2. DIC scores in all 102 patients were evaluated using the ISTH scoring algorithm.

Results: Table 1 shows that in comparison to normal levels, the samples collected from all patients showed significantly higher levels of Ang-2 for all groups (p=0.0005). Table 2 shows that the Ang-2 levels were also significantly different between the survivors and non-survivors for 28-day mortality outcome by the Mann-Whitney test (p=0.001).

TABLE 1 Ang-2 Levels in Patients with Sepsis and Suspected DIC Broken Down by ISTH DIC Score

Category	Normals	+ Sepsis - DIC	+ Sepsis + Non-Overt DIC	+ Sepsis + Overt DIC
ISTH DIC Score	N/A	0-2	3-4	≥ 5
n	50	20	57	24
Ang-2 Mean ± SEM (ng/mL)	1.87 ± 0.15	8.34 ± 2.50	11.53 ± 1.40	29.44 ± 6.27
Ang-2 Std. Deviation (ng/mL)	1.07	11.19	10.54	30.73

TABLE 2 Significant Difference in Ang-2 level between Survivors and Non-Survivors

	Survivors	Non-Survivors
n	86	15
Ang-2 Mean ± SEM (ng/mL)	12.54 ± 1.54	30.17 ± 8.62
Ang-2 Std. Deviation (ng/mL)	14.28	33.39

Conclusions: This study demonstrates that Ang-2 levels are significantly upregulated in SAC, and this biomarker can be used to risk stratify the severity of this disease. Ang-2 level can also be used to differentiate non-overt and overt DIC. Furthermore, Ang-2 level at the time of initial diagnosis provides a predictive biomarker for mortality outcome.

OC 47.1 | Pharmacodynamic Data and Coagulation Biomarkers in Persons with Hemophilia A (PwHA) with Inhibitors: Results from the HAVEN 1 Emicizumab (ACE910) Phase 3 Study

J.I. Adamkewicz[1], C. Schmitt[2], A. Calatzis[3], G. Young[4], C. Negrier[5], M. Callaghan[6], J.M. Venstrom[1], E. Asikanius[2], G. Levy[1], B. Kim[1]

[1]Genentech Inc., South San Francisco, United States, [2]F. Hoffmann-La Roche Ltd, Basel, Switzerland, [3]Roche Diagnostics International Ltd, Rotkreuz, Switzerland, [4]Children's Hospital Los Angeles, University of Southern California Keck School of Medicine, Los Angeles, United States, [5]Louis Pradel University Hospital, university Claude Bernard Lyon 1, Lyon, France, [6]Children's Hospital of Michigan, Detroit, United States

Background: Emicizumab is a novel, subcutaneously administered bispecific humanized monoclonal antibody in development for prophylactic treatment of PwHA with and without FVIII inhibitors. Emicizumab bridges FIXa and FX, replacing the function of missing FVIII, with resultant downstream thrombin generation and coagulation.

Aims: To evaluate the effects of emicizumab in HAVEN 1 as determined by laboratory assays.

Methods: Frozen plasma samples from persons receiving emicizumab in HAVEN 1 (NCT02622321) were analyzed at central laboratories. Emicizumab concentration was measured by immunoassay. Pharmacodynamic (PD) effects were assessed using a FVIII chromogenic activity assay containing human factors (Hyphen Biophen FVIII:C) as well as by FXIa-triggered thrombin generation (TG). In addition, aPTT, PT, Clauss fibrinogen and antigen levels of FIX, FX, vWF, D-dimer and prothrombin fragment 1.2 [PF1.2] were determined. Data are presented for n=103 patients with exposure to emicizumab.

Results: Mean chromogenic FVIII activity increased from < 1% at baseline to approximately 30% during maintenance dosing (Wk 5 onwards); reported activity was strongly correlated with emicizumab concentration [**Fig 1**]. TG peak height (PH) also correlated with emicizumab levels, reaching 109.8 ± 34.6 nM (mean±SD) at Wk 25. In contrast, elevated baseline aPTT was normalized (< 40 sec) after the first dose of emicizumab and showed no further concentration-response [**Fig 2**]. FIX:Ag and FX:Ag (binding targets of emicizumab), vWF:Ag, and PT did not change significantly over time. D-dimer and PF1.2 were largely within normal limits and were not correlated to emicizumab levels.

Conclusions: Emicizumab had a concentration-dependent PD effect on TG and FVIII activity (Hyphen chromogenic assay). aPTT was normalized at subtherapeutic emicizumab levels. FIX and FX levels, and a panel of coagulation assays including D-dimer, were unaffected by emicizumab, in alignment with the overall safety profile of the molecule.

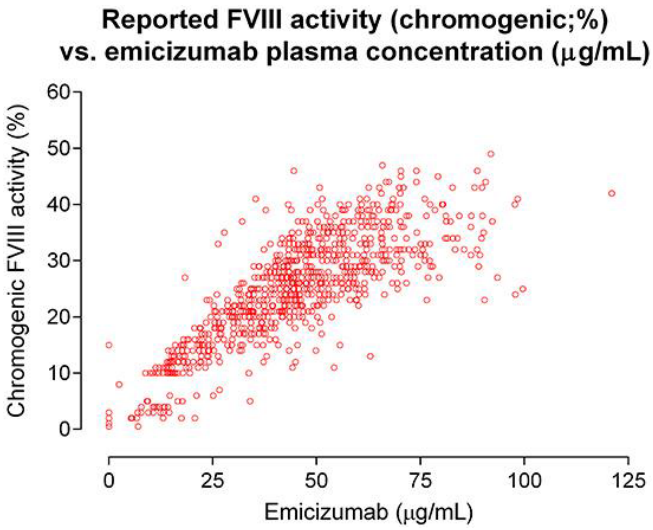

FIGURE 1 Reported FVIII activity (chromogenic;%) vs. emicizumab plasma concentration (ug/ml)

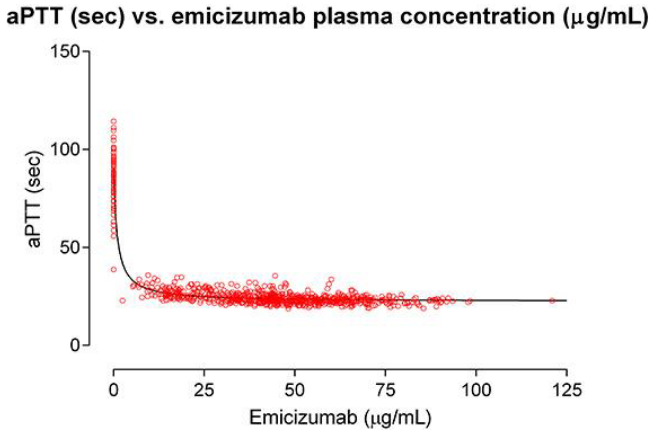

FIGURE 2 aPTT (sec) vs. emicizumab plasma concentration (ug/ml)

OC 47.2 | Synergistic Interplay of A Sequence Identical Analog of ACE910, a Bispecific Antibody, and a Bypassing Reagent and its Components

R. Hartmann[1], T. Feenstra[1], S. Knappe[1], L.A. Valentino[2], F. Scheiflinger[1], M. Dockal[1]

[1]*Shire plc, Vienna, Austria,* [2]*Shire plc, Chicago, United States*

Background: Investigational non-factor products such as ACE910, an antibody to FIX(a) and FX(a), may offer new treatment options for hemophilia patients with inhibitors. The unregulated mechanism of action of ACE910, however, raises questions regarding clinical safety and efficacy.

Aims: To detect the source of excessive in vitro coagulation with a sequence identical analog of ACE910 (SIA) combined with bypassing agent FEIBA.

Methods: SIA was analyzed in thrombin generation (TG) experiments using platelet poor plasma (PPP) from hemophilia A inhibitor patients and hemophilia A plasma reconstituted with platelets from 16 healthy donors (PRP). A normal TG range was established in healthy donor plasma. Therapeutic doses of SIA (20-600nM) were tested alone and with FEIBA (0.05-1U/mL) or rFVIIa (0.88-5.25µg/mL). To measure FEIBA components' contribution to the synergistic effect with SIA, PPP was spiked with purified plasma proteins. Clot formation was analyzed in FVIII-inhibited blood by ROTEM and T-TAS.

Results: Normal peak thrombin range was 47-144nM (PPP) and 88-231nM (PRP). rFVIIa and FEIBA had a synergistic effect on TG in combination with SIA in PPP and PRP. Combined with rFVIIa (0.88µg/mL) or FEIBA (0.5U/mL), SIA (600nM) induced a ~2- and ~16-fold increase over SIA alone. SIA+rFVIIa did not reach the normal range, while SIA+FEIBA far exceeded it. Clot formation in FVIII-inhibited whole blood confirmed the synergistic effect of SIA+FEIBA. Adding individual FEIBA components to PPP showed that FIX was, with a half-maximal effect, the main driver for enhanced TG, followed by FIXa.

Conclusions: Excessive thrombin generation and faster clot formation occurred when combining SIA at presumed clinical concentrations (ACE910 study NCT02622321) with FEIBA. In vitro, this effect is mainly mediated by FEIBA component FIX. ACE910 binds to FIX and FIXa, and displays its pro-coagulant effect via an unregulated mechanism. Therefore, careful judgment is required in treating breakthrough bleeds with FEIBA.

OC 47.3 | Challenges in Quantifying FVIIIa-mimetic Bispecific Antibody Activity Relative to FVIII for Hemophilia A Treatment

A. Goodman[1], D. Rabinovich[1], M. Aleman[2], E. Kistanova[1], B. Pearse[3], N. Leksa[1], R. Peters[1]

[1]*Bioverativ, Waltham, United States,* [2]*Bioverativ, Protein Therapeutics, Waltham, United States,* [3]*Magenta Therapeutics, Cambridge, United States*

Background: A new generation of potential hemophilia A therapies seeks to improve dosing regimens and enable prophylactic treatment of patients with and without inhibitors. With a variety of mechanisms of action across these therapies, benchmarking their activity against Factor VIII (FVIII) is important, but challenging. Here, we focus on activated FVIII (FVIIIa)-mimetic bispecific antibodies (bsAbs).

Aims: Using a number of activity assays, we compared an emicizumab biosimilar (Emi-bsim) and a Bioverativ bsAb, BS-026125, to recombinant FVIII (rFVIII).

Methods: Activity of Emi-bsim, BS-027125, their respective bivalent homodimers, and rFVIII was measured by factor Xa (FXa) generation assay, thrombin generation assay (TGA) triggered with factor XIa, and activated partial thromboplastin time (aPTT) triggered with Actin FSL.

Results: Although Emi-bsim was highly active across all assays, the concentration at which it achieved peak activity was disparate between them. BS-027125 was highly active in aPTT, but relatively less active in TGA. Similar to Emi-bsim, BS-027125 showed inconsistencies between concentration and peak activity across assays. For both bsAbs, lag time and peak height in TGA correlated with different levels of rFVIII activity. Interestingly, both Emi-bsim bivalent homodimers exhibited significant activity in several assays, while only the BS-027125 FIXa bivalent homodimer retained moderate activity in the FXa generation assay. As expected, rFVIII loses all activity in the absence of phospholipids (PL) in FXa generation assay. In contrast, Emi-bsim has very significant activity in the absence of PL, while BS-027125 shows minimal PL-independent activity.

Conclusions: Overall, the bsAbs demonstrate little consistency between the three assays tested here, which makes benchmarking against FVIII activity difficult. This suggests a need for a deeper understanding of the mechanisms and hemostatic potential of these FVIIIa-mimetic bsAbs.

OC 47.4 | Mode of Enhancement in the Global Hemostatic Potentials with Concomitant Use of Bypassing Agents and Emicizumab in Hemophilia A Patients with Inhibitor Evaluated by ROTEM

K. Yada[1], K. Nogami[1], T. Kitazawa[2], K. Hattori[2], M. Shima[1]

[1]*Nara Medical University, Pediatrics, Kashihara, Japan,* [2]*Chugai Pharmaceutical Co., Ltd,, Tokyo, Japan*

Background: Emicizumab is a novel therapeutic bispecific antibody in development for treatment of patients with hemophilia A (PWHA) with and without FVIII inhibitors. The additive hemostatic effect on concomitant use of emicizumab and the bypassing agents (BPAs) for breakthrough bleeding among PWHA with inhibitor has been demonstrated in vitro by clot waveform analysis(#1388 ASH2016).

Aims: In the present study, we aimed to elucidate the global hemostatic function during the concomitant therapy with BPAs and emicizumab by $CaCl_2$-triggered ROTEM.

Methods: The hemostatic potentials were evaluated in the citrated whole blood samples obtained from mild or severe PWHAs (N=6)

added *in vitro* with an anti-FVIII polyclonal antibody (10BU/ml) and supplemented with the various plasma concentration of APCC (0-0.8 U/ml) or rFVIIa (0, 2.2 and 6.6 μg/ml) in the presence of emicizumab (0, 10, 30 and 100 μg/ml). The parameters, CT, CFT, MCF and alpha angle (α), for each sample were compared to the normal controls (938±127s, 330±86s, 43±5mm and 41±7deg as average±SD, respectively).

Results: The presence of emicizumab dose-dependently shortened CT and CFT from 5258±669s and 1807±303s to 1112±147s and 427±137s respectively. The spike of APCC to the samples without emicizumab facilitated a dose-dependent enhancement in the ROTEM pattern represented by shortening of CT+CFT, maximally ~90% reduction compared to its absence. Interestingly, APCC also demonstrated ~90% reduction of CT+CFT on top of the shortening caused by emicizumab, suggestive of the additive effect(Fig.1A). Addition of rFVIIa to both samples with and without emicizumab resulted in a dose-dependent reduction of CT+CFT but showed milder additive shortening on top of that by emicizumab than the addition of APCC(Fig.1B).

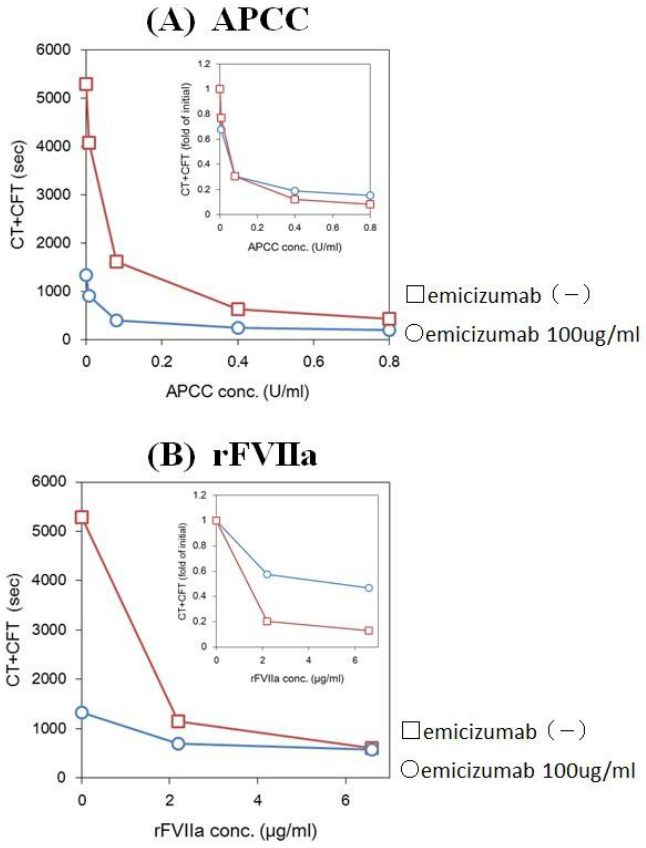

FIGURE 1 Effect on CT+CFT of APCC or rFVIIa with/without emicizumab

Conclusions: In conclusion, the spiking experiments by ROTEM clarified the different mode of enhancing effect on the hemostatic function between APCC and rFVIIa in combination with emicizumab, and would be useful to predict and adjust their enhancing effect.

OC 47.5 | Identification of FIXa- and FX-specific Antibodies for the Generation of Bispecific Antibodies with FVIIIa-like Activity

N. Leksa[1], B. Pearse[2], A. Goodman[1], T. Wang[3], L. Culyba[4], D. Rabinovich[1], O. Mercury[1], L. Liu[5], C. Graff[6], J. Kulman[7], R. Peters[1]

[1]*Bioverativ, Waltham, United States,* [2]*Magenta Therapeutics, Cambridge, United States,* [3]*Merck, Cambridge, United States,* [4]*Jounce Therapeutics, Cambridge, United States,* [5]*Compass Therapeutics, Cambridge, United States,* [6]*Biogen, Cambridge, United States,* [7]*Codiak BioSciences, Cambridge, United States*

Background: Recently, there has been an increased focus on developing factor VIII (FVIII)-independent therapies for the treatment of Hemophilia A, particularly for inhibitor patients. One approach is to replace FVIII with a bispecific antibody (bsAb) capable of mimicking the cofactor function of FVIII.

Aims: To identify a bsAb specific for factor IXa (FIXa), not FIX, and factor X (FX), not FXa, to replicate the cofactor function of activated FVIII (FVIIIa).

Methods: We leveraged the Adimab in vitro yeast presentation platform with FACS-based selection to identify panels of antibodies specific for FIXa and FX. A variety of FIX and FX constructs were used for positive and negative selections, as well as for specificity screening after individual clones were isolated. Based on desired specificity profiles, select antibodies were reformatted into bsAbs and screened for the ability to promote activation of FX in the presence of FIXa, calcium, and phospholipids. BsAbs with detectable activity in the FXa generation assay were further tested in a one-stage clotting assay to identify a lead.

Results: We identified >200 unique antibodies specific for FIXa and >250 unique antibodies specific for FX. These antibodies, when formatted into bsAbs, mimic the specificity of FVIIIa for FIXa and FX and some promote FXa generation. A further subset of bsAbs maintained significant activity in a one-stage clotting assay. Of those, BS-027025 had the highest FVIIIa-like activity. Affinity maturation of the anti-FIXa arm led to a bsAb (BS-027125) which achieved >90% FVIIIa-like activity as determined by one-stage clotting.

Conclusions: The Adimab platform offers a diversity and experimental flexibility not afforded by standard immunization methods and allowed for the unprecedented identification of hundreds of antibodies able to differentiate between the zymogen and active forms of FIX and FX. Furthermore, this specificity-based approach successfully led to the generation of bsAbs capable of replicating the cofactor function of FVIIIa.

OC 49.1 | VKA-related Major Bleeding in VTE Patients is Associated with a High Mortality Rate and is Rarely Treated with Prohemostatic Agents: Results from the RIETE Registry

A. Stehouwer[1], F. Moustafa[2], P. Kamphuisen[3], J.C. Sahuquillo[4], A. Samperiz[5], M. Alfonso[6], F. Pace[7], J.M. Surinach[8], A. Blanco-Molina[9], P. Mismetti[10], M. Monreal[11], RIETE Investigators

Municipal de Badalona, Internal Medicine, Barcelona, Spain, [5]Hospital Reina Sofía, Internal Medicine, Tudela. Navarra, Spain, [6]Complejo Hospitalario de Navarra, Pneumology, Pamplona, Spain, [7]Ospedale San Camilo, Emergency Medicine, Rome, Italy, [8]Hospital Vall d´Hebrón, Internal Medicine, Barcelona, Spain, [9]Hospital Universitario Reina Sofía, Internal Medicine, Cordoba, Spain, [10]CHU Saint-Etienne, Department of Internal Medicine, Saint-Etienne, France, [11]Hospital Universitari Germans Trias i Pujol de Badalona, Internal Medicine, Barcelona, Spain

Background: Major Bleeding (MB) is the most feared complication in patients receiving anticoagulant therapy for venous thromboembolism (VTE). However real-world data on the management and outcomes of MB is scarce.

Aims: We assessed the management and outcomes of VTE patients presenting with MB under therapy with vitamin K antagonists (VKA) for VTE.

Methods: We used prospectively collected data from consecutive patients enrolled in the RIETE database (Registro Informatizado Enfermedad Trombo Embólica, NCT02832245). Bleeding events were classified as ‚major' if they were overt and required a transfusion of two units or more of blood, or were retroperitoneal, spinal or intracranial, or when they were fatal.

Results: From January 2013 to December 2016, 15480 VTE patients receiving long-term therapy with VKA were recruited. During the course of therapy, 263 (1.7%) had MB: 85 gastrointestinal, 72 intracranial, 45 hematoma, 16 genitourinary, and 45 other sites. Overall, at the time of the MB, 22% of patients had an INR < 2.0, 27% 2-3, 35% >3, and in 16% no INR was available. Prohemostatic agents (PCC, aPCC or recombinant FVIIa) were used in 11% of patients with MB (33% in those with intracranial hemorrhage (ICH)), and vitamin K in 105 (40%). During the first 48 hours after MB, 41 (16%) patients died, 38 (14%) of fatal bleeding and 26 (10%) with ICH. Fourteen (5.3%) had a recurrent VTE, and no patient had a rebleeding. From Day 3 to Day 30, 13 additional patients died, 4 had VTE recurrence and one re-bleeding. 105 of 222 (47%) patients who survived restarted anticoagulant therapy.

Conclusions: In clinical practice, VKA-related major bleeding is rarely treated with prohemostatic agents, despite the high rate of fatal bleeding. All fatal bleeds occurred within the first 48 hours after bleeding. After a major bleeding, less than half of the patients restart anticoagulation.

TABLE 1 Outcomes after major bleeding, according to bleeding site

		Intra-Cranial	Gastro-Intestinal	Hematoma	Genito-Urinary	Other
Patients, N		72	85	45	16	45
Day 2	Death	26 (36%)	7 (8.2%)	0	1 (6.3%)	7 (16%)
	Fatal Bleeding	26 (36%)	6 (7.1%)	0	0	6 (13%)
	Rebleeding	0	0	0	0	0
	Recurrent VTE	5 (6.9%)	5 (5.9%)	3 (6.7%)	1 (6.2%)	0
Day 30	Death	29 (40%)	14 (16%)	1 (2.2%)	2 (13%)	8 (18%)
	Fatal Bleeding	26 (36%)	6 (7.1%)	0	0	6 (13%)
	Rebleeding	0	0	0	0	1 (2.2%)
	Recurrent VTE	6 (8.3%)	7 (8.2%)	3 (6.7%)	1 (6.2%)	1 (2.2%)

OC 49.2 | Hypofibrinolysis on ROTEM Early after Traumatic Injury Represents a Heterogenous Group with Significant Variation in Both Fibrinolytic Activity and Mortality

L.S. Gall[1], K. Brohi[1], C. Gaarder[2], J.C. Goslings[3], N.P. Juffermans[4], M. Maegele[5], P.I. Johansson[6], R.A. Davenport[1], on behalf of the International Trauma Research Network (INTRN)

[1]Centre for Trauma Sciences, Blizard Institute, Queen Mary University of London, Bart's and the London School of Medicine & Dentistry, London, United Kingdom, [2]Oslo University Hospital, Traumatology, Oslo, Norway, [3]Academic Medical Center Amsterdam, Trauma Unit, Amsterdam, The Netherlands, [4]Academic Medical Center Amsterdam, Department of Intensive Care Medicine, Amsterdam, The Netherlands, [5]University of Witten/Herdecke / Cologne-Merheim Medical Centre, Department for Traumatology and Orthopaedic Surgery, Cologne, Germany, [6]Copenhagen University Hospital, Rigshospitalet, Section for Transfusion Medicine, Copenhagen, Denmark

Background: An early hypofibrinolytic phenotype after major trauma, with increased mortality has recently been described using thromboelastography. The biomarker profile and clinical significance of this diagnosis for antifibrinolytic therapy in traumatic haemorrhage is unclear.

Aims: To quantify the mediators of fibrinolytic activation and clinical characteristics of trauma patients with hypo- vs hyperfibrinolysis.

Methods: Prospective study of adult patients with severe injury and evidence of bleeding at five European trauma centres. No patients received tranexamic acid. Blood was drawn on admission for ROTEM and fibrinolytic marker analyses. Maximal Lysis (ML) was normal if 5-15% (ML_{NORMAL}) with hypo- and hyperfibrinolysis defined as < 5% (ML_{LOW}) and >15% (ML_{HIGH}). Groups were further subdivided using a D-dimer (DD) threshold of 30,000ng/ml into DD_{LOW} and DD_{HIGH}.

Results: In 928 patients analysed, DD in the ML_{LOW} group varied greatly with a ten-fold difference between patients who died vs survived (103,200 vs 13,670ng/ml, p< 0.0001). We found no difference in mortality within the DD_{LOW} group (ML_{LOW} vs ML_{HIGH}, 3.8 vs 10.5%, p=0.11) or compared to patients with ML_{NORMAL} (7.1%, ns). Regardless of ML, mortality was increased in the DD_{HIGH} groups (Figure 1). Plasmin-Antiplasmin (PAP) levels in the DD_{HIGH} groups were elevated in both hypo- and hyperfibrinolysis (ML_{LOW} vs ML_{HIGH}: PAP 12,196

vs 24,185µg/L, ns) and significantly higher than ML_{NORMAL} (PAP: 2583µg/L, p< 0.05). In the DD_{HIGH} groups, patients with ML_{LOW} were less shocked, had lower tPA (12.0 vs 41.8ng/ml, p< 0.05) and higher α2-antiplasmin levels than the ML_{HIGH} patients.

Conclusions: Patients with DD_{LOW}, regardless of ML have a low mortality rate. ROTEM hypofibrinolysis is a heterogeneous group with significant variation in biomarker-defined fibrinolytic activity. Patients with DD_{HIGH}, irrespective of ML, share an early hyperfibrinolytic biomarker profile.

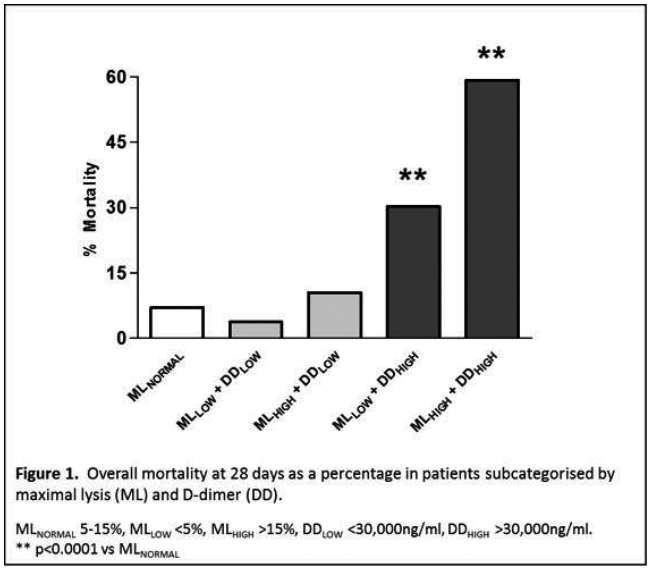

Figure 1. Overall mortality at 28 days as a percentage in patients subcategorised by maximal lysis (ML) and D-dimer (DD).

ML_{NORMAL} 5-15%, ML_{LOW} <5%, ML_{HIGH} >15%, DD_{LOW} <30,000ng/ml, DD_{HIGH} >30,000ng/ml.
** p<0.0001 vs ML_{NORMAL}

FIGURE 1 Overall mortality at 28 days as a percentage in patients subcategorised by maximal lysis (ML) and D-dimer (DD)

OC 49.3 | Data-driven ROTEM and TEG Algorithms for the Management of Trauma Haemorrhage

K. Baksaas-Aasen[1], S. van Dieren[2], K. Balvers[2], N.P. Juffermans[3], P.A. Næss[1], C. Rourke[4], S. Eaglestone[4], S.R. Ostrowski[5], J. Stensballe[6], S. Stanworth[7], M. Maegele[8], J.C. Goslings[2], P.I. Johansson[5], K. Brohi[4], C. Gaarder[1]

[1]*Oslo University Hospital, Department of Traumatology, Oslo, Norway,* [2]*Academic Medical Center, Department of Surgery, Amsterdam, The Netherlands,* [3]*Academic Medical Center, Department of Intensive Care Medicine, Amsterdam, The Netherlands,* [4]*Queen Mary University of London/ Blizard Institute, Centre for Traume Sciences, London, United Kingdom,* [5]*Rigshospitalet/Copenhagen University Hospital, Section for Transfusion Medicine/Capital Region Blood Bank, Copenhagen, Denmark,* [6]*Copenhagen University Hospital, Rigshospitalet, Department of Anaesthesiology, Centre of Head and Orthopaedics, Copenhagen, Denmark,* [7]*NHS Blood and Transplant/ Oxford University Hospital NHS Trust, Radcliffe Department of Medicine, Oxford, United Kingdom,* [8]*University of Witten/Herdecke / Cologne-Merheim Medical Centre, Department for Traumatology and Orthopedic Surgery, Cologne, Germany*

Background: Trauma induced coagulopathy (TIC) may exacerbate bleeding and is associated with high morbidity and mortality. Current resuscitation strategies are often non-specific and do not correct this coagulopathy.

Aims: We aimed to develop pragmatic data-driven algorithms for management of TIC during trauma haemorrhage for viscoelastic haemostatic assays (VHAs).

Methods: Admission data from conventional coagulation tests (CCT), rotational thrombelastometry (ROTEM) and thrombelastography (TEG) were collected prospectively at 6 European trauma centres during 2008-2013. To identify significant VHA parameters for the detection of TIC (defined as INR >1.2), hypofibrinogenaemia (< 2.0g/L) and thrombocytopenia (< 100 $x10^9$/L), univariate regression models were constructed and area under the curves (AUCs) were calculated.

Results: 287 adult trauma patients (ROTEM in 2019 and TEG in 968) were enrolled. FIBTEM clot amplitude at 5 minutes (CA5) had the largest AUC and 10mm was found to detect hypofibrinogenaemia with 70% sensitivity. The corresponding value for Functional Fibrinogen (FF) TEG Maximum Amplitude (MA) was 19mm. Thrombocytopenia was detected with 74% sensitivity using the calculated threshold EXTEM-FIBTEM CA5 30mm, corresponding rTEG-FF TEG MA was 46mm. TIC was identified by EXTEM CA5 41mm with 73% sensitivity and rTEG MA 64mm with 80% sensitivity. For hyperfibrinolysis, the relationship between viscoelastic lysis parameters and clinical outcomes resulted in threshold values of 85% for EXTEM Li30 and 10% for rTEG Ly30.

Based on these analyses we constructed algorithms for ROTEM, TEG and CCTs to be used in addition to baseline ratio driven transfusion and tranexamic acid (TXA).

Conclusions: A systematic approach to define threshold parameters for ROTEM and TEG has been described. These parameters were incorporated into algorithms to support data-driven adjustments of resuscitation with available therapeutics, in order to optimize damage control resuscitation practice.

OC 49.4 | Management of Hemorrhage Using Self-propelling Particles to Deliver Thrombin or Tranexamic Acid

J.R. Baylis[1], A.E. St. John[2], M.M. Lee[1], X. Wang[2], E.B. Lim[2], M.L. Statz[2], D. Chien[2], E. Simonson[3], J.S.J. Yoon[1], A. Kazerooni[1], M.H. Thomson[1], R.T. Liggins[3], S.A. Stern[2], N.J. White[2], C.J. Kastrup[1]

[1]*University of British Columbia, Michael Smith Laboratories, Vancouver, Canada,* [2]*University of Washington, Emergency Medicine, Seattle, United States,* [3]*Centre for Drug Research and Development, Vancouver, Canada*

Background: Bleeding is a major cause of morbidity and mortality in multiple clinical situations, including trauma and surgery. Bleeding is especially problematic when it originates from non-compressible anatomic locations or when the source of bleeding is not easily visualized. Topical hemostatic agents have limited efficacy because they cannot penetrate to reach damaged vasculature to form stable clots which can resist fibrinolysis or mechanical rupture. Self-propelling particles loaded with existing hemostatic agents could overcome these limitations by increasing their penetration to form robust and stable clots.

Aims: To demonstrate the safety and efficacy of a self-propelling particle-based hemostatic agent *in vitro* and *in vivo* using preclinical models of bleeding and fibrinolysis.

Methods: Self-propelling calcium carbonate particles were combined with tranexamic acid and thrombin. These formulations were tested in *in vitro* models of bleeding and fibrinolysis, in two mouse models of hemorrhage, and one pig model of severe junctional hemorrhage.

Results: By propelling tranexamic acid and thrombin, their ability to form clots and inhibit fibrinolysis were significantly increased. The formulation significantly decreased bleeding in both mouse models, and significantly increased survival in the pig model of severe hemorrhage. In these models, the formulation was superior to typical hemostatic interventions, such as topical thrombin or kaolin. No adverse effects were observed.

Conclusions: Self-propelling particles and dressings are effective at stopping bleeding *in vivo* and may be useful for delivering a variety of clinically approved hemostatic agents for managing bleeding. These particles present an attractive new route of administration for hemostatic agents, which could expedite their administrations and increase their ease of use.

OC 49.5 | A Chimeric Factor VIIa Molecule Shows Reduced Thrombogenicity in Animal Models

D. Stafford[1], B. Cooley[2], W. Bergmeier[3], Y. Boulaftali[4], D. Feng[1], V. Zachary[5], R. Jenny[5], D. Monroe[6], M. Griffith[7]

[1]*University of North Carolina, Department of Biology, Chapel Hill, United States,* [2]*University of North Carolina, Department of Pathology, Chapel Hill, United States,* [3]*University of North Carolina, Department of Biochemistry and Biophysics, Chapel Hill, United States,* [4]*Institut National de la Santé et de la Recherche Médicale, Le Laboratoire de Recherche Vasculaire Translationnelle, Paris, France,* [5]*Haematologic Technologies, Inc., Essex Junction, United States,* [6]*University of North Carolina, Department of Medicine, Chapel Hill, United States,* [7]*Chimera BioTechnology, San Juan Capistrano, United States*

Background: We have engineered a Chimeric factor VIIa molecule (ChFVIIa) that has the Gla and EGF1 of factor IX and the EGF2 and catalytic domain of factor VIIa (FVIIa). In a mouse model of hemophilia, the mouse ChFVIIa was as effective as mFVIIa in stopping bleeding (Blood. 2014;123:1764-1766). ChFVIIa does not bind to tissue factor (TF) so we have postulated that ChFVIIa will have reduced thrombogenicity.

Aims: The goal of these studies was to compare FVIIa and ChFVIIa in three animal models of thrombosis.

Methods:

1. Wild type mice were injected with with human TF and mChFVIIa or FVIIa. Mice were sacrificed and their lungs examined for thrombi using fluorescently labeled fibrinogen.
2. Hemophilia B mice were administered AAV vectors carrying mFVIIa or mChFVIIa sequences. Hemostasis was assessed by tail bleeding and survival was monitored.
3. Rabbits were injected with 50 µg/kg human FVIIa or ChFVIIa. Stasis was created in both jugular veins and maintained for 30 minutes. The veins were opened to detect thrombi.

Results:

1. Mice that were injected with human TF and FVIIa showed strong lung fluorescence indicative of significant fibrin accumulation in the lungs. By contrast, mice injected with TF and mChFVIIa had no lung fluorescence above background.
2. Over six months, mice expressing mChFVIIa had an 0.85 probability of survival whereas for mice expressing mFVIIa the value was 0.55. Littermate animals expressing mChFVIIa had equivalent (or shorter) tail bleeding times compared to mice expressing mFVIIa indicating similar levels of hemostatic function.
3. For the jugular vein stasis model in rabbits, proteins were assayed for clotting activity and factor Xa generation. In animals given equivalent amounts of activity, 6 out of 6 rabbits that received FVIIa formed a visible thrombus. By contrast, no rabbits given the same dose of ChFVIIa formed a visible thrombus.

Conclusions: These studies provide evidence that the reduced TF binding of ChFVIIa can translate into reduced risk of thrombosis in some vascular settings.

OC 50.1 | Modulation of F8 Secretion by Autophagy Related Proteins

H. Singer[1], N. Nüsgen[1], B. Pezeshkpoor[1], J. Oldenburg[1], O. El-Maarri[1,2]

[1]*Institute for Experimental Haematology and Transfusion Medicine, University Clinic Bonn, Bonn, Germany,* [2]*Lebanese American University, Department of Natural Sciences, Beirut, Lebanon*

Background: The F8 protein interacts with several intracellular proteins that control and facilitate its secretion. Known interaction proteins include Calnexin, Calreticulin and BIP in ER, LMAN1 and MCFD2 in the ERGIC compartment and recently we identified GABARAP as a potential interacting partner in the GOLGI. The later belongs to the Atg8 like molecules that play a key function in the autophagy process. This suggested that an autophagy or non-typical autophagy related function of Atg8-like proteins could play a role in fine-tuning/modulating the secretion of F8.

Aims: In this study we explored such contribution of key components of autophagy machinery on the F8 secretion; namely we investigated the effect of GABARAP, GAPARAPL1 and ATG7. In addition known influential proteins on the secretion, LMAN1, MCFD2, Calnexin, Calreticulin were also included.

Methods: We used siRNA as well as CRISPR/Cas9 mediated knockout (KO) in order to study the individual effect/contribution of each protein to the secretion of F8 in a stable F8 secreting HEK cell.

Results: Our results show the expected decrease in F8 secretion in the KOs of LMAN1 and MCFD2 (60% and 70% reduction, respectively, compared to mock), while the KOs of other proteins showed effects going in opposite directions. KOs of GABARAP and Calreticulin are showing a clear decrease in F8 activity (both up to 25-30% reduction), while KOs of GABARAP-L1, ATG7 and Calnexin show a clear increase of F8

secretion: GABARAP-L1 KO increases F8 activity up to 70% compared to mock. Moreover KOs of ATG7 or Calnexin increase F8 activity up to 90% compared to mock in our stable F8 secreting cell system. Confocal microscopy depicts GABARAP as bulky pericentriolar fraction and as small vesicular structures in the cytoplasm, both co-localizing with F8.

Conclusions: Based on these results we postulate that GABARAP and autophagy related proteins modulate the secretion of F8 through both typical autophagy and non-autophagy related pathways.

OC 50.2 | Clustered F8 Missense Mutations Cause Hemophilia A Phenotypic Heterogeneity by Combination of Altered Splicing, Protein Secretion and Activity

I. Donadon[1,2], J. McVey[3], I. Garagiola[4], M. Mortarino[4], A. Branchini[1], F. Peyvandi[4,5], F. Bernardi[1], M. Pinotti[1]

[1]University of Ferrara, Ferrara, Italy, [2]ICGEB, Trieste, Italy, [3]Surrey University, Surrey, United Kingdom, [4]Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico and Fondazione Luigi Villa, Milan, Italy, [5]Università degli Studi di Milano, Department of Pathophysiology and Transplantation, Milan, Italy

Background: Pleiotropic effects of mutations, scarcely investigated in hemophilia A (HA), hamper the elucidation of genotype-phenotype relationships. Missense mutations, frequent in HA, might impair FVIII mRNA processing, protein biosynthesis, activity and/or half-life.

Aims: To quantitatively evaluate the pleiotropic effects of the *F8* p.Arg2016Trp/c.6046C>T (exon 19, A3 domain) mutation, one of the most prevalent FVIII amino acid substitutions (>60 cases).

Methods: CHO cells were transduced with lentiviral expression vectors for recombinant (r)FVIII variants to evaluate secreted FVIII antigen (FVIII:Ag) and activity (FVIII:C) by ELISA and chromogenic assays. FVIII mRNA splicing was evaluated by RT-PCR on RNA from: 1) patients' leukocytes and 2) HepG2 cells transfected with *F8* minigene variants.

Results: The rFVIII-2016W displayed reduced secretion (FVIII:Ag 11.0±0.4% of wt) and activity (FVIII:C 6.0±2.9%). *F8* mRNA studies demonstrated that the c.6046C>T change also decreases correct splicing to 70±5%, predicted to lower further FVIII:C (4.2±2%), consistent with FVIII:C levels observed in patients with the mutation (1-5%). Through an antisense U7snRNA targeting the mutated exon 19 region we identified a splicing enhancer, potentially affected by other HA-missense mutations. Strikingly, the c.6037G>A (p.Gly2013Arg) reduced exon inclusion to 41±3% and the c.6053A>G (p.Glu2018Gly) to 28±2% of wt, similarly (26±2%) to the c.6113A>G, (p.Asn2038Ser), a variant affecting the 5'splice splice. At protein level, the p.Gly2013Arg similarly reduced FVIII:Ag (7.0±0.9%) and FVIII:C (8.4±0.8%), while the p.Glu2018Gly produced a dysfunctional molecule (FVIII:Ag, 69.0±18.1%; FVIII:Cc, 19.4±2.3%). However, the rFVIII2038Ser displayed normal FVIII:Ag and FVIII:C.

Conclusions: The integrated approach of analysing mRNA and protein levels highlights the combination of both pathogenic mechanisms triggered by clustered mutations, which accounts for a gradient of residual FVIII:C recapitulating the HA coagulation phenotypes.

OC 50.3 | Vascular Remodeling in Hemophilic Arthropathy is Exacerbated by Defective TAFIa-mediated Inactivation of SDF1α (CXCL12)

T.L. Wyseure[1], J.Y. Zhou[2], E.J. Cooke[1,2], P.J. Declerck[3], J.C.M. Meijers[4], A. von Drygalski[1], L.O. Mosnier[1]

[1]The Scripps Research Institute, Molecular Medicine, La Jolla, United States, [2]University of California, Division of Hematology/Oncology, Medicine, San Diego, United States, [3]University of Leuven, Pharmaceutical and Pharmacological Sciences, Leuven, Belgium, [4]Sanquin Research, Amsterdam, The Netherlands

Background: Vascular remodeling after hemophilic joint bleeding promotes rebleeding, but mechanisms are unknown. In hemophilia, activation of the procarboxypeptidase thrombin-activatable fibrinolysis inhibitor (TAFI) is impaired and TAFI was recently shown to inhibit vascular remodeling. SDF1α, an elevated angiogenic mediator in hemophilic arthropathy, contains a C-terminal (CT) Lys required for binding to CXCR4, and may be negatively regulated by activated TAFI (TAFIa).

Aims: To determine the contribution of defective inactivation of SDF1α by TAFIa on vascular remodeling in hemophilic joints.

Methods: TAFIa-mediated cleavage of SDF1α was determined by W-blot and transwell migration assays. Hemarthrosis was induced by a knee puncture in $FVIII^{-/-}$ mice and in WT and $TAFI^{-/-}$ mice treated with a transient FVIII inhibitor. AMD3100 (CXCR4 antagonist) treatment started at 2 days post injury. Vascular remodeling was assessed by histology and Power Doppler (PD) at week 4 post injury.

Results: TAFIa cleaved the CT-Lys of SDF1α and attenuated SDF1α-induced cell migration. After joint injury, SDF1α primarily localized with $αSMA^{+}$ remodeled vessels. The active vs. total SDF1α ratio was increased in $TAFI^{-/-}$ and $FVIII^{-/-}$ compared to WT mice. $FVIII^{-/-}$ and $TAFI^{-/-}$ mice were treated with AMD3100 to determine the contribution of the SDF1α/CXCR4 pathway. AMD3100 did not promote joint tissue hemorrhaging. PD signals in the joints were increased (3.5-fold; $p< 0.001$) in untreated $FVIII^{-/-}$ and $TAFI^{-/-}$ mice, but not in AMD3100-treated mice. Vessel diameters and perivascular αSMA expression were increased untreated but not in AMD3100-treated $FVIII^{-/-}$ and $TAFI^{-/-}$ mice ($p< 0.01$), indicating reduced vascular remodeling after hemarthrosis.

Conclusions: Due to the TAFI activation defect in hemophilia, active SDF1α accumulated on synovial vessels after hemarthrosis. Excessive CXCR4-mediated recruitment/proliferation of αSMA-expressing perivascular cells to the injured joint led to aberrant vascular remodeling, which was prevented by CXCR4 antagonism.

OC 50.4 | 90-bp Insertion of Deep Intron between E18 and E19 (E18ins90bpE19) May Be a Hot-spot Mutation for Mild Hemophilia A Patients without Found DNA Mutation

C.-Y. Chang[1], S.-N. Cheng[2], S.-H. Hu[3], T.-Y. Wu[4], S.-Y. Lin[5], Y.-C. Chen[6]

[1]Taipei Medical University, Graduate Institute of Clinical Medicine, School of Medicine, Taipei Medical University Hospital, Division of Pediatric Hematology/Oncology, Hemophilia Center, Taipei, Taiwan, Republic of China, [2]Tri-Service General

Hospital, Hemophilia Care and Research Center, Tungs' Taichung MetroHarbor Hospital, Department of Pediatrics, National Defense Medical Center, Department of Pediatrics, Taichung, Taiwan, Republic of China, [3]Tri-Service General Hospital, Hemophilia Care and Research Center, Taipei, Taiwan, Republic of China, [4]Tri-Service General Hospital, Hemophilia Care and Research Center, Taiwan, Taipei, Taiwan, Republic of China, [5]Taipei Medical University, Graduate Institute of Clinical Medicine, School of Medicine, Taipei Medical University Hospital, Department of Internal Medicine, Taipei, Taiwan, Republic of China, [6]Tri-Service General Hospital, Hemophilia Care and Research Center, Division of Hematology/Oncology, Department of Internal Medicine, National Defense Medical Center, Taipei, Taiwan, Republic of China

Background: Identifying genetic mutations in hemophiliacs is important for disease diagnosis and genetic counseling. There are 2~7% of Hemophilia A (HA) patients whose mutations cannot be found by DNA analysis and it increases up to 10~18% in mild HA patients.

Aims: We aimed to identify the genetic defects by mRNA analysis in mild-type HA patients without DNA mutation.

Methods: From our 49 mild-type HA patients of 35 unrelated families from two hemophilia centers, who had undergone genetic tests from 2008 to 2016, we collected those patients without found DNA mutation and performed mRNA analysis. Total cellular RNA was reverse-transcribed to cDNA. F8 cDNA was amplified as eight fragments using nested PCR.

Results: There were 10 mild-type HA patients from 6 unrelated families without found mutation, which accounted for 17.1% (6/35). The median age was 18 years old, ranging from 2 to 73. The average FVIII:C level was 12.3%, ranging from 6.5% to 28.9%. Nine of the 10 (90%) patients were confirmed to have F8 gene mutation. Eight patients from 5 unrelated families were remarkably found to have both presence of normal 585 bp and aberrant 675 bp fragments. Sequencing of the aberrant 675 bp fragment showed that there were two separate insertion of 35 bp and 55 bp from intron 18. It confirmed that there was 90 bp of intron 18 insertion between exon 18 and exon 19 (E18ins90bpE19) in mRNA, which was reported as a result of c.5999-277G>A in deep intron. Another one patient was found to have exon 19 spliced out and the last one patient remained nonconclusive.

Conclusions: Our study demonstrates that mRNA analysis was an effective assay for mild-type HA patients who was wild type by DNA analysis and the undetected rate can be reduced from 17.1% (6/35) to 2.9% (1/35). The E18ins90bpE19 (90-bp insertion of deep intron between E18 and E19) may be a hot spot for mild-type hemophilia without found DNA mutation.

OC 50.5 | Imbalance between Wound Healing and Inflammation in Hemophilia

L.M. Knowles, D. Lessig, M. Bernard, E.C. Schwarz, H. Eichler, J. Pilch

Saarland University Medical Center, Homburg/Saar, Germany

Background: Macrophages are master regulators of inflammation and wound healing. As such they play an important role in hemophilia, which is associated with delayed tissue regeneration and bleeding-induced joint inflammation.

Aims: Determine if macrophage function is deregulated in hemophilia and if this affects the balance between tissue regeneration and inflammation.

Methods: Monocytes from hemophilia patients and healthy individuals were treated with M-CSF or GM-CSF and probed for morphological features of macrophage differentiation by phase contrast microscopy. TNFα, CD163 and CD206 were measured by fluorescence microscopy, CD14/CD16 and Tie2 by flow cytometry. Wound infiltration of macrophages was determined by probing for invasive podosomes in clotted plasma. Phagocytosis was assessed by measuring the uptake of fluorescent latex beads and red blood cells.

Results: Morphological analysis of hemophilia macrophages revealed a defect in cell polarization and filopodia formation. The deficit was most pronounced in response to M-CSF, which induced TNFα/CD163 expression in monocytes from healthy donors but failed to do so in hemophilia monocytes. In contrast, expression of TNFα and CD206 in response to GM-CSF was largely maintained. Using flow cytometry, we detected a significant reduction of Tie2 on hemophilia monocytes. This phenotypical change was associated with impaired regenerative macrophage functions such as clot infiltration and red blood cell phagocytosis in hemophilia. CD14 and CD16 on hemophilia monocytes was not affected.

Conclusions: Our data indicate that M-CSF-mediated regenerative macrophage functions such as clot invasion and red blood cell phagocytosis are deregulated in hemophilia and that these deficits correlate with reduced Tie2 expression on hemophilia monocytes. Given the central role of red blood cells in promoting hemophilic arthropathy, we speculate that hemophilia macrophages take on a so far unappreciated role in joint inflammation.

OC 61.1 | Mutational Repertoire in the SIPPET Cohort and Prediction of FVIII Inhibitor Risk

Background: *F8* mutation type is the main predictor of inhibitor development in patients with hemophilia A. Mutations expected to allow a residual synthesis of FVIII are likely to play a protective role towards alloantibody formation by inducing immune tolerance. According to the expected full or partial impairment of FVIII synthesis, *F8* mutations are commonly classified as null and non-null; however there is no consensus in the definition of two groups.

Aims: The association existing between mutation type and inhibitor risk was explored in a cohort of 231 patients with severe hemophilia A, enrolled in the SIPPET trial.

Methods: Mutational scanning of the *F8* gene was accomplished by long-range PCR, direct sequencing and MLPA. The functional effects of missense and splicing variants were predicted by multiple web-based tools. FVIII antigen levels were measured in patient plasma using the Asserachrom ELISA kit. Kaplan Meier and Cox regression survival analyses were performed to assess the risk of inhibitor development.

Results: The genetic defects found in the analyzed patients, consisting of inversions of intron 22 (n=110) and intron 1 (n=6), large deletions (n=16), nonsense (n=38), frameshift (n=28), missense (n=19) and splicing (n=14) mutations, of which 35 previously unreported, were reclassified in null and non-null according to in-silico analyses and FVIII antigen levels.

A 2-fold increase in inhibitor risk development for "in-silico null" mutations compared to "in-silico non-null" mutations [hazard ratio 2.08, 95% confidence interval (CI), 0.84 to 5.17] and a 3-fold increase in inhibitor risk development for "antigen negative" mutations compared to "antigen positive" mutations [hazard ratio 3.09, 95% CI, 0.76 to 12.6] were found.

Conclusions: Our findings confirm an association between the synthesis of minute amounts of FVIII and inhibitor protection and underline the importance to investigate *F8* mutations with further in-silico analyses in order to predict the risk of inhibitor development.

OC 61.2 | Improved Immunogenicity Prediction Using Composite Variables that Incorporate the Known Patient, Product and Therapy Related Risk Factors for Inhibitor Development with Immunologic Parameters from the HLA-class-II (HLAcII)-factor (F)VIII Peptidome

B. Luu[1], M. Hofmann[2], V. Diego[1], M. Almeida[1], J. Hernandez[1], A. Morelli[3], A. Ameri[4], R. Rajalingam[5], L. Almasy[6], J. Powell[7], J. Blangero[1], E. Maraskovsky[3], T. Howard[1,8,9]

Background: T-cells are critical for inhibitor development in HA. We hypothesize that combining known variables of inhibitor risk with parameters from individual HLAcII/FVIII peptidomes will enhance predictive power. Dendritic cells (DCs) express HLAcII repertoires & present peptides to T-cells *in vivo*. We used DC protein presentation assays (PPAs) to measure therapeutic FVIII proteins (tFVIIIs) for these parameters.

Aims: Reassess known patient, product & therapy-related variables of inhibitor risk in combination with measured peptidomic parameters.

Methods: Used DCs in 2 PPAs. In PPA 1, DCs from donors 1-12 were incubated with 5 r-tFVIIIs: 1 full-length (FL), 3 B-domain deleted (BDD), 1 BD-truncated (BDT). In PPA 2, DCs from donors 13-24 were incubated with 1 of 5 tFVIIIs: BDT-rFVIII±VWF, FL-rFVIII±VWF, pdFVIII+VWF. After lysis, HLAcII/peptide complexes were purified as DR, DQ & DP bound peptides with monoclonal anti-DR, DQ & DP. Eluted peptidomes were LC-MS/MS sequenced. Peptides were ID'd & compared to the reference human proteome and unique sequences of BDD/T &*F8* ns-SNPs. All individually sequenced peptides (IPSs) from each donor were assembled as groups of overlapping peptides (GOPs) along FVIII (Fig.1).

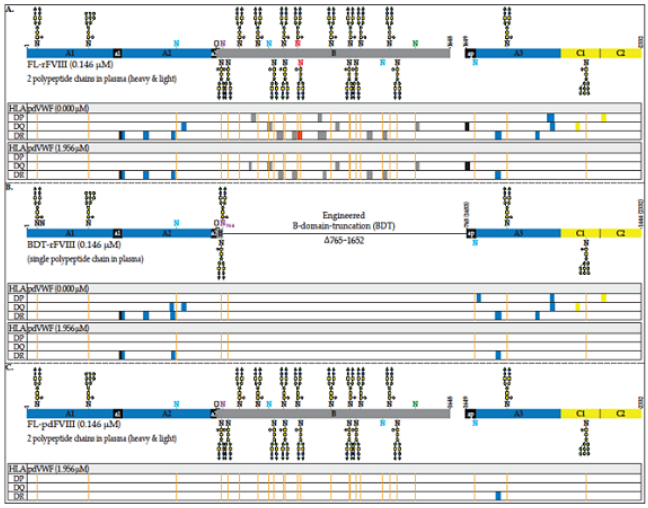

FIGURE 1 Representative Individual HLAcII-Petidomes for Various FVIII Therapeuitics

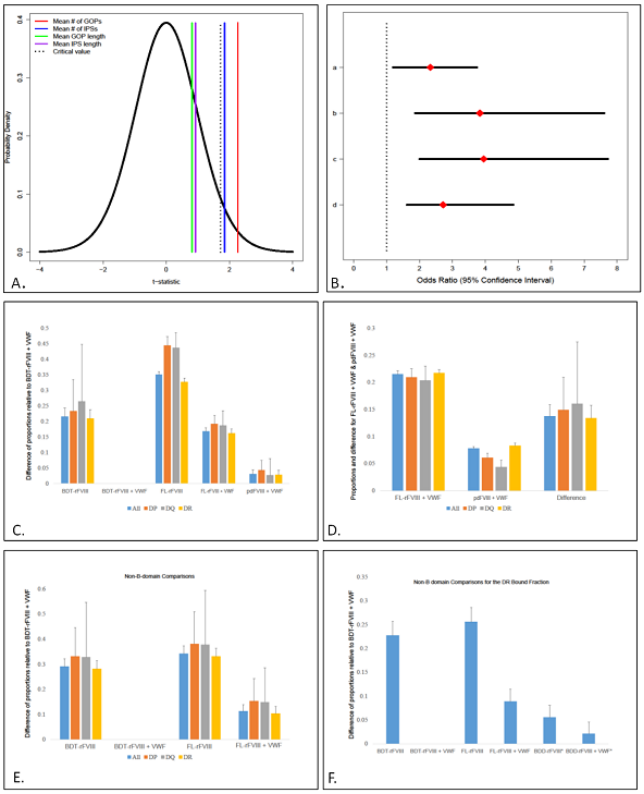

FIGURE 2 A-F Reassessing the Known Patient, Product & Treament Related Variables of Inhibitor Risk in Combination with Parameters of the FVIII Peptidome

Results: The number of GOPs & IPSs from FL-rFVIII were greater in PPA 2 vs 1, likely due to its higher concentration (Fig.2A). We found a protective effect of glycosylation with non-glycosylated sites at significantly greater risk of being in the bound fraction of potential epitopes (Fig.2B, a-c). We examined inhibitor development in patients with F8 missense mutations and found a greater risk when in the bound fraction (Fig.2B, d). We found that BDT-rFVIII+VWF yielded significantly less bound peptides in comparisons with all other tFVIIIs, and that FL-rFVIII yielded significantly more peptides than pdFVIII (Fig.2C-F).

Conclusions: Concentration, glycosylation & VWF co-administration significantly influenced the number of GOPs & IPSs, which both significantly affected the inhibitor risk of F8 missense mutations.

OC 61.3 | Immune Monitoring by Epigenetic Cell Counting - Application in the Hemophilia Inhibitor PUP Study (HIPS)

B. Gangadharan[1], B.M. Reipert[1], C.J. Hofbauer[2], F. Scheiflinger[1], J. Bowen[3], E. Donnachie[4], K. Fijnvandraat[5], J. Klintman[6], R. Gruppo[7], C. Male[8], S. Meeks[9], C. McGuinn[10], M. Recht[11], M.V. Ragni[12], H. Yaish[13], E. Santagostino[14], D.L. Brown[4]

[1]Baxalta, part of Shire, Vienna, Austria, [2]Shire, Cambridge, United States, [3]Rho, Inc, Chapel Hill, United States, [4]University Texas Health Science Center at Houston, Houston, United States, [5]Amsterdam Hemophilia Treatment Center, Amsterdam, The Netherlands, [6]Lund University Malmö, Malmö, Sweden, [7]Cincinnati Children's Hospital Medical Center, Cincinatti, United States, [8]Medical University of Vienna, Vienna, Austria, [9]Aflac Cancer and Blood Disorders Center, Emory University, Atlanta, United States, [10]Weill Cornell Medicine, New York, United States, [11]Oregon Health & Science University, Portland, United States, [12]University of Pittsburgh Medical Center, Pittsburgh, United States, [13]University of Utah School of Medicine, Salt Lake City, United States, [14]Maggiore Hospital Policlinico and University of Milano, Milano, Italy

Background: The Hemophilia Inhibitor PUP Study (HIPS) is a prospective multicenter observational study with the primary objective to elucidate immune system changes in severe hemophilia A patients during their first 50 exposure days (EDs) to FVIII (clinicaltrials.gov NCT01652027). Immune monitoring in a prospective multi-center study in PUPs has been challenging because of the lack of suitable technology applicable to small volumes of frozen blood samples.

Aims: Here, we asked if key immune regulatory cells such as FoxP3$^+$ T cells (Tregs), pro-inflammatory Th17 cells or granulysin+ NK cells, can be monitored in the circulation of patients by longitudinal epigenetic cell counting (www.epiontis.com).

Methods: Quantitative PCR-based methylation assays were used to quantify Tregs, Th17 cells, granulysin$^+$ NK cells and CD3$^+$ T cells, prior to the first dose of FVIII and after ED 1, 5, 10, 20, 30, 40 and 50. A cohort of 20 healthy adults was included for comparison. Comprehensive antibody analytics was done as described in Hofbauer 2015.

Results: Analysis of samples for ten HIPS subjects (age range: 0.4 - 13 months at ED1) was completed. Blood concentrations of Tregs prior to first FVIII exposure were in the range of healthy adults in most patients and remained fairly stable throughout the study. TH17 cell counts prior to first FVIII exposure were very low when compared to healthy adults and remained at low levels.

Granulysin$^+$ NK cell counts prior to first FVIII exposure were below the range of healthy adults but underwent considerable variation

during the study in most patients. Correlation analyses to the presence of FVIII-specific antibodies are ongoing.

Conclusions: Epigenetic cell counting using frozen blood samples provided robust results for monitoring immune cell populations during the first 50 ED of PUPs to FVIII. Normal levels of FoxP3^{+} Tregs and very low levels of TH17 cells indicate an early window of opportunities for immune tolerance induction.

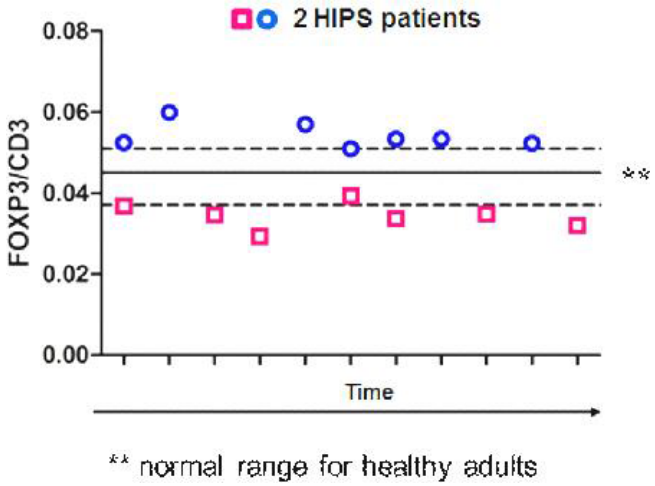

FIGURE 1 Epigenetic counting of FoxP3+ Tregs

OC 61.4 | Comparative Profiling of HLA-DR and HLA-DQ Associated FVIII Peptides Presented by Monocyte-derived Dendritic Cells

I. Peyron[1], R.B. Hartholt[1], L. Pedro-Cos[1], F.P.J. van Alphen[2], N. Lardy[3], A.B. Meijer[1,2,4], J. Voorberg[1]

[1]Sanquin Research and Landsteiner Laboratory, Academic Medical Center, University of Amsterdam, Plasma Proteins, Amsterdam, The Netherlands, [2]Sanquin Research and Landsteiner Laboratory, Academic Medical Center, University of Amsterdam, Research Facilities, Amsterdam, The Netherlands, [3]Sanquin Research and Landsteiner Laboratory, Academic Medical Center, University of Amsterdam, Immunogenetics, Amsterdam, The Netherlands, [4]Utrecht Institute for Pharmaceutical Sciences, Utrecht University, Pharmaceutics, Utrecht, The Netherlands

Background: The development of anti-factor VIII (FVIII) antibodies represents a major complication in the treatment of hemophilia A patients. The initiation of the anti-FVIII immune response involves the internalization and subsequent presentation of FVIII-derived peptides on MHC class II on the surface of professional antigen-presenting cells. Previously, we identified the FVIII-derived peptides that are presented on HLA-DR. Both HLA haplotypes DRB1*15 and DQB1*06:02 have been associated with higher incidence of inhibitor in hemophilia A patients, suggesting that HLA-DQ participates in the development of anti-FVIII antibodies.

Aims: To identify the repertoire of FVIII-derived peptides presented on HLA-DQ.

Methods: Monocyte-derived dendritic cells from 11 HLA-typed healthy donors were pulsed with recombinant full-length FVIII. HLA molecules were purified using monoclonal antibodies directed against HLA-DR (L243) or HLA-DQ (SPV-L3) and FVIII-derived peptides were identified by mass-spectrometry.

Results: The number of FVIII peptides eluted from HLA-DR was 3.85 fold higher compared to HLA-DQ (33.6±15.6 vs. 8.7±8.5, mean±SD). This was consistent with a higher number of total peptides eluted from HLA-DR compared to HLA-DQ and a higher expression level of HLA-DR compared to HLA-DQ. We found that FVIII peptide repertoire eluted from HLA-DQ overlapped with HLA-DR. Four FVIII derived peptides were exclusively identified on HLA-DQ. With the exception of one donor, no B domain derived peptides were found on HLA-DQ while several B domain-derived peptides were presented by HLA-DR.

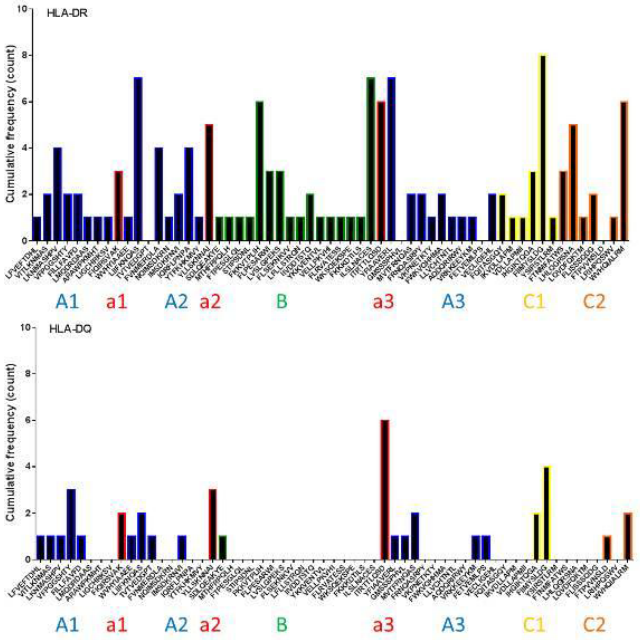

FIGURE 1 Comparative profiling of FVIII presentation on HLA-DR and HLA-DQ

Conclusions: HLA-DQ presents a smaller set of FVIII-derived peptides that overlap with HLA-DR. This suggests that HLA-DQ increases the amount of peptides that are presented to T cells. Since T-cell activation requires the recognition of a unique peptide-HLA combination by their TCR, it does not exclude that presentation of FVIII-derived peptides by HLA-DQ activates a distinct repertoire of FVIII-specific T-cells.

OC 61.5 | Differential Effects of von Willebrand Factor on Processing and Presentation of Factor VIII-derived Peptides

C. Lubich, K. Steinitz-Trost, B. Binder, T. Prenninger, F. Scheiflinger, B.M. Reipert

Baxalta, part of Shire, Vienna, Austria

Background: Neutralizing antibodies against factor VIII (FVIII) remain the major challenge in hemophilia A care. Previous studies proposed von Willebrand factor (VWF) to affect FVIII immunogenicity by reducing the uptake of FVIII by antigen presenting cells (APCs) (Dasgupta S 2007). Sorvillo 2016 showed VWF to bind to human dendritic cells and modulate patterns of FVIII-derived peptides presented on MHC-class II, when FVIII was complexed with VWF.

Aims: Here, we asked if VWF modulates presentation of FVIII-derived peptides and subsequent stimulation of peptide-specific T-cells.

Methods: FVIII-specific $CD4^+$ T cell hybridoma libraries were generated using humanized HLA-DRB1*1501 (human MHC-class II) hemophilic mice (Steinitz 2012). APCs derived from the mice or from HLA-DRB1*1501 homozygous human subjects were challenged with FVIII (with or without VWF) and subsequently co-incubated with the hybridoma libraries. Stimulation of T-cells was assessed by IL-2 release into cell culture supernatants. $CD4^+$ T cell hybridoma clones, specific for 10 different FVIII peptides presented by HLA-DRB1*1501, were tested.

Results: The presence of VWF during incubation of APCs with FVIII reduced the subsequent activation of 4/10 T cell hybridoma clones. The reduction was almost complete in one of the clones and about 50% in the other 3 clones. Activation of the remaining 6 T cell hybridoma clones was not affected. The presence of an irrelevant control protein instead of VWF did not have any effect.

Conclusions: Our data suggest that VWF has distinct effects on the presentation of some FVIII peptides but not on others. We hypothesize that VWF may alter the sorting of FVIII into endolysosomal compartments of APCs, thereby modifying the patterns of FVIII peptides generated and presented on MHC-class II as well as the subsequent activation of T cells. It remains to be shown if this alteration would have any effect on the induction of anti-FVIII antibodies or the induction of immune tolerance.

OC 62.1 | Platelet-targeted Hyperfunctional FIX Gene Therapy of Hemophilia B Mice

J. Schroeder[1], M. Jozwiak[1], P. Monahan[2], Q. Shi[1]

[1]*Medical College of Wisconsin, Blood Research Institute, Children's Research Institute, Milwaukee, United States,* [2]*University of North Carolina at Chapel Hill Gene Therapy Center, NC, United States*

Background: While platelet gene therapy can restore hemostasis and induce immune tolerance in hemophilia B mice, the levels of platelet-FIX (plt-F9) in transduced recipients were only around 3% of normal whole blood even when a lethal 11Gy total body irradiation (TBI) was employed.

Aims: To improve the efficacy of plt-F9 gene therapy, it is desirable to optimize our vector.

Methods: A novel lentiviral vector, 2bCoF9R338L harboring a codon-optimized FIX Padua cassette was used to introduce plt-F9 expression in $F9^{null}$ mice by transduction and transplantation of hematopoietic stem cells under a sub-lethal 6.6Gy TBI.

Results: Both antigen and activity levels of plt-F9 from 2bCoF9R338L-transduced recipients were significantly higher than those from normal 2bF9-transduced animals. There are an approximately 5.8-fold higher antigen and a 28-fold higher activity level in the 2bCoF9R338L group compared to in the 2bF9 group. Using a 6-hour tail bleeding test, we showed that the hemophilic phenotype was fully rescued in the treated animals. All 2bCoF9R338L-transduced recipients' tail bleeding clotted within 6 hours and the remaining hemoglobin level was of 69.3±8.8%, which were not significantly different from those of the wild type controls. In contrast, none of the $F9^{null}$ control mice clotted within 6 hours and the remaining hemoglobin level (40.5±1.9%) was significantly lower than in the 2bCoF9R338L group. Importantly, none of the 2bCoF9R338L-transduced $F9^{null}$ mice developed anti-F9 inhibitors even after extensive rhF9 immunization in the presence of adjuvant. In contrast, all $F9^{null}$ control mice developed anti-F9 inhibitors when the same immunization protocol was employed. Of note, anaphylaxis can occur in these $F9^{null}$ mice with rhF9 infusion if the immune system was primed by FIX.

Conclusions: Platelet-targeted codon-optimized gain-of-function FIX gene therapy is a promising approach for gene therapy of hemophilia B.

OC 62.2 | SHP648: A High Performing Next Generation FIX Gene Therapy Vector Based on AAV8

F. Horling[1], F.G. Falkner[1], M. Chuah[2], J. Lengler[1], J. Mayrhofer[1], M. Klugmann[1], S. Coulibaly[1], W. Hoellriegl[1], P.E. Monahan[3], T. Vandendriessche[4], F. Scheiflinger[1], H. Rotteinsteiner[1]

[1]*Shire plc, Vienna, Austria,* [2]*VU Brussels, Brussels, Belgium,* [3]*Shire plc, Cambridge, United States,* [4]*VU Brusssels, Brussels, Belgium*

Background: In the BAX 335 hemophilia B gene therapy trial using an AAV8-based vector and expressing the Padua FIX variant, high levels of expression were seen, however, sudden drops in activity were observed in some patients. A root cause analysis pointed to exaggerated immunogenicity as the potential cause for the drop of FIX expression.

Aims: To develop a next generation FIX gene therapy vector with a reduced immunogenic risk and an improved expression efficiency.

Methods: Vector improvement was initiated with the replacement of the FIX Padua coding sequence by codon-optimized and CpG-depleted sequences.

Results: Screening of these constructs identified a sequence that induced FIX Padua expression approximately two-fold in FIX knock-out mice compared to the BAX 335 vector. Next, we showed that a series of single-stranded (ss) vectors showed FIX expression levels that were similar compared to the corresponding self-complementary (sc) vectors. Finally, the strength of the promoter was increased by inserting the recently described liver-specific regulatory element CRM8 (Chuah et al., 2014, Nair et al., 2014) upstream

of the TTR promoter. Testing the resulting vectors in an in-vitro biopotency assay using human liver cells showed a robust 5-fold increase in FIX expression by the CRM8 element. Consistent with the in vitro results, the ss version including the CRM8 element further improved expression in FIX knock-out mice approximately two-to three-fold.

Conclusions: SHP648 represents a next generation ss AAV8-based FIX vector with enhanced performance and reduced immunogenic risk. These features increase the safety profile and are expected to allow for lower dosing.

OC 62.3 | Preventive Immune Suppression Using CTLA-4 IgGs Enables Re-administration in AAV8 Gene Therapy

M. Frentsch[1], A. Sada Japp[1], N. Matzmohr[1], A. Thiel[1], F. Scheiflinger[2], B.M. Reipert[2], M. de la Rosa[2]

[1]*Berlin-Brandenburg Center for Regenerative Therapies, Charité, Berlin, Germany,* [2]*Shire plc, Vienna, Austria*

Background: Gene therapy using adeno associated virus serotype 8 (AAV8) is considered one of the most promising technologies to treat monogenic diseases such as hemophilia A and B. A major drawback of AAV8 gene therapy is that it can be only applied once due to formation of anti-AAV8 immunity. Re-administration might be required to boost suboptimal expression levels of the target transgene. We developed a strategy using immune suppression to enable re-administration of AAV8-human-FIX (AAV8-huFIX) gene therapy.

Aims: To boost human FIX (huFIX) plasma levels using repeated dosing with an AAV8-huFIX gene therapy vector in the presence of an immune suppressive regimen.

Methods: AAV8-huFIX gene therapy vector was applied to C57BL/6 mice in the presence or absence of immune suppressive regimens. Anti-AAV8 immunity after AAV8 gene therapy was assessed by analyzing neutralizing antibodies (Nabs) and binding antibodies (Babs) to AAV8 using an in vitro and ELISA assay, respectively. AAV8-specificT cell responses were analyzed by IFNg ELISPOT and FACS. HuFIX plasma levels were determined by FIX antigen ELISA.

Results: Abatacept (CTLA-4 IgG fusion protein), a marketed drug that blocks the CD80/CD86-CD28 interaction, was tested alone and in combination with the calcineurin inhibitor Tacrolimus. Both products induced highly efficient inhibition of anti-AAV8 Nabs and AAV8-specific T cell responses after AAV8 gene therapy: Neither anti-AAV8 Nabs nor Babs were detectable even after two doses of AAV8-huFIX treatment, neither were T cell responses. Furthermore, immunosuppression did not affect huFIX expression in mice. Boosting of huFIX plasma levels from about 2 to 20 µg/ml was achieved by first applying a low dose of AAV8-huFIX followed by a second higher dose of AAV8-huFIX in the presence of abatacept. No toxic side effects were observed.

Conclusions: Abatacept can enable re-administration of AAV8-huFIX to boost suboptimal FIX levels in patients.

OC 62.4 | Modulation of AAV Vector Dosing and Avoidance of Capsid Immune Responses via Repeated Co-administration of Vector with Tolerogenic Rapamycin Nanoparticles

A. Meliani[1,2], F. Boisgerault[2], S. Marmier[1], R. Hardet[1], G. Ronzitti[2], F. Collaud[2], S. Charles[2], L. van Wittenberghe[2], B. Marolleau[2], P. Ilyinskii[3], C. Roy[3], A. Michaud[3], C. Leborgne[2], O. Christophe[4], T.K. Kishimoto[3], F. Mingozzi[1,2]

Background: Gene therapy for Hemophilia B (HB) using adeno-associated viral vectors (AAV) showed promising results in preclinical and clinical trials. However, Immune responses to AAV represent an important issue since anti-capsid neutralizing antibodies develop at high titers post-vector administration, impeding effective AAV re-dosing. Additionally, capsid-specific T cell responses can drive clearance of AAV transduced cells, resulting in short-lived transgene expression.

Aims: Assess the efficacy of a novel strategy to mitigate immunogenicity of AAV vectors based on the co-administration of the vector with PLGA-nanoparticles containing rapamycin (SVP-Rapa).

Methods: Hemostatically normal and HB mice were first injected with an AAV8 vectors expressing luciferase together with SVP-Rapa or empty nanoparticles (SVP-empty), then re-administered few weeks later with an AAV8 expressing human FIX (hFIX) together with SVP-Rapa or SVP-empty. Anti-AAV8 antibodies levels, capsid-specific T cells, and hFIX antigen levels in plasma were measured. Specific immunoassays were used to further understand the mechanisms of action of SVP-Rapa. The safety and efficacy of the approach was also tested in non-human primates (NHP).

Results: Co-administration of AAV with SVP-Rapa inhibits the formation of anti-AAV antibodies, allowing successful vector re-injection in both mice and NHP. Modulation of AAV vector immunogenicity appeared to be antigen-specific, as treated animals showed normal immune responses to subsequent challenges with unrelated antigens. Additionally, depletion experiments suggested a role of regulatory T cells as mediators of this mechanism. We also demonstrated that SVP-Rapa efficiently control memory responses and CD8+ T cell responses to the AAV capsid. Results were also confirmed in HB mice, were vector dose modulation via repeated administrations was successfully implemented.

Conclusions: These results validated the use of SVP-Rapa to mitigate AAV vector immunogenicity allowing for efficient vector re-administration.

OC 62.5 | CRISPR/Cas9-mediated Genome Editing via Postnatal Injection of AAV Vector Cures Hemophilia B in Mice

T. Ohmori[1], Y. Nagao[2], H. Mizukami[3], A. Sakata[4], S.-I. Muramatsu[5], K. Ozawa[6], S.-I. Tominaga[1], Y. Hanazono[7], S. Nishimura[4,8,9], O. Nureki[10], Y. Sakata[4]

Background: Hemophilia B, a bleeding disorder caused by mutations in *F9*, is considered an appropriate target for genome editing technology.

Aims: Here, we considered the clustered regularly interspaced short palindromic repeat (CRISPR)/Cas9 system for the treatment of hemophilia B.

Methods: We used an adeno-associated virus 8 (AAV8) vector to deliver gene-editing tools *in vivo*. Genomic mutations were detected using T7 endonuclease I assay or next generation sequencer. Phenotypic corrections were assessed by plasma coagulation factor IX (FIX) activity, thrombin generation, intravital microscopy, and bleeding time.

Results: The administration of AAV8 vector harboring *Staphylococcus aureus* Cas9 (SaCas9) and single guide RNA (sgRNA) to wild-type adult mice induced a double-strand break (DSB) at the target site of *F9* in hepatocytes, sufficiently developing hemophilia B. The SaCas9/sgRNA-expressing AAV8 vector together with the repairing homologous sequence significantly, but marginally, increased in FIX levels in hemophilia B mice. Alternatively, the SaCas9/sgRNA-expressing AAV8 vector targeting the intron 1 together with the *F9* cDNA more efficiently restores hemostasis via both processes of non-homologous end-joining and homology-directed repair following DSB. Notably, these therapies also cure neonate mice with hemophilia, which cannot be achieved with conventional gene therapy with AAV vector. The phenotypic correction after the neonatal injection was sustained life-long although the AAV genome quickly diluted out. Finally, the ongoing hemophilia therapy targeting antithrombin gene with antisense oligonucleotide might be replaced by that with SaCas9/sgRNA-expressing AAV8 vector.

Conclusions: Our results suggest that CRISPR/Cas9-mediated genome editing using an AAV8 vector provides a flexible approach to induce DSBs at target genes in hepatocytes and could become an attractive strategy for hemophilia gene therapy.

OC 75.1 | Pharmacological Intervention and Improved Platelet-factor VIII Functionality Enhanced Efficacy of in vivo Platelet-targeted Gene Therapy of Murine Hemophilia A via Intraosseous Delivery

X. Wang, R. Fu, C. Miao

Seattle Children's Research Institute, Seattle, United States

Background: Factor VIII (FVIII) expressed and stored in platelets is protected from neutralization by anti-FVIII antibodies following gene therapy of hemophilia A (HemA). Partial phenotypic correction was achieved in HemA mice following intraosseous (IO) infusion of lentiviral vectors (LVs) carrying a human FVIII transgene (F8/N6) driven by the megakaryocyte-specific Gp1bα promoter.

Aims: We aimed at developing a protocol for effective gene therapy of murine HemA by improving LV transduction efficiency using pharmacological agents to suppress the innate and adaptive immune responses and increasing platelet-FVIII functionality using new hFVIII variants with higher secretion efficiency and function.

Methods: C57BL6 mice or HemA mice were pretreated with dexamethasone (Dex) (IP, 5 mg/kg at -24h, -4h, 4h and 24h) and anti-CD8α monoclonal antibody (mAb) (IP, 4 mg/kg on day -1, 4, 11, 16 and 21), or Dex only. IO infusion of MND-GFP-LVs driven by a ubiquitous MND promoter or G-F8/N6-LVs and G-F8X10K12-LV driven by Gp1bα promoter was performed on day 0. GFP or FVIII expression was evaluated overtime.

Results: For MND-GFP-LV treated mice, higher numbers of GFP+HSCs were observed in drugs + LVs treated mice compared with LV-only treated mice (48.3% vs 44.4% on day 7; and 10.7% vs 2.6% on day 160). Furthermore, compared with G-F8/N6-LV, G-F8X10K12-LV + Drugs produced a 75% increase of platelet-FVIII antigen levels by FVIII-specific ELISA, less blood loss in tail clipping assay, and relatively higher peak height thrombin and total thrombin in thrombin generation assay. However, inhibitory antibodies were detected in G-F8X10K12-LV treated mice.

Conclusions: Administration of Dex and anti-CD8α mAb improved lentiviral transduction efficiency and persistence of transduced cells, leading to over 10% GFP+HSCs in treated mice up to 160 days. IO delivery of G-F8X10K12-LV combined with the drug treatment improved phenotype correction in HemA mice, indicating that this strategy can be used as a potential novel treatment for hemophilia.

OC 75.2 | Persistent Expression of FVIII Following Intravenous Administration of Lentiviral Vectors in Neonatal Hemophilia A Mouse and Dog Models

T. Liu[1], D. Drager[1], S. Patarroyo-White[1], A. Seregin[1], A. Cantore[2], L. Harpell[3], D. Lillicrap[3], L. Naldini[2], R. Peters[1]

[1]Bioverativ, Waltham, United States, [2]San Raffaele Telethon Institute for Gene Therapy, Milan, Italy, [3]Queen's University, Kingston, Canada

Background: AAV based gene therapy for Factor VIII (FVIII) and Factor IX has demonstrated promising clinical benefit when tested in a sub population of hemophiliac subjects; however, the high frequency of preexisting anti-AAV antibodies (abs), small cargo capacity and non-integrating nature of AAV may prevent the use of AAV approach to achieve lifelong cure for all hemophilia patients. Lentiviral vector (LV) technology may circumvent these problems with its large capacity, ability to sustain transgene expression via integration, extremely low incidence of preexisting anti-LV abs, and encouraging efficacy and safety profile demonstrated in pre-clinical and clinical studies.

Aims: Evaluate the potential use of LV-FVIII for the treatment of hemophilia A (HemA).

Methods: Codon optimized Human FVIII (cohFVIII) variants were cloned into a liver specific LV expression system and LV-FVIII mediated FVIII expression was assessed in HemA mice/dogs post Intravenous (IV) delivery of LV at 1.5E10 or 1.3E9 transducing units/kg dose respectively.

Results: Significant improvement on FVIII expression was observed in HemA mice for all cohFVIII variants, with the lead candidate driving 100-fold higher FVIII expression compared to unmodified FVIII; Inclusion of XTEN, a non-structured poly-peptide in B-domain region of FVIII further increased FVIII level by 5-fold, resulted in 30-50IU/mL long-term FVIII expression, represent 30 to 50-fold of normal FVIII level. Furthermore, anti-FVIII abs. were only detected in mice with supra physiological level of FVIII expression, but no cytotoxic T lymphocyte response was observed against LV transduced cells in anti-FVIII abs. positive mice. LV-cohFVIIIXTEN was then evaluated in HemA dog neonates, 30-100% FVIII activity was achieved post IV delivery of LV with no adverse event observed.

Conclusions: LV-FVIII treatment had achieved curable level of persisting FVIII expression in HemA mice and dogs, may potentially be used for the treatment of HemA.

OC 75.3 | Vector Dose-dependent Delayed CD8+ T Cell-mediated Clearance of AAV Encoded Antigen in the Liver

R.W. Herzog, G.Q. Perrin, S. Kumar

University of Florida, Pediatrics, Gainesville, United States

Background: Hepatic AAV gene transfer should be ideal for the treatment of hemophilia. However, $CD8^+$ T cell responses against the viral capsid may target transduced hepatocytes even months after gene transfer. This is reminiscent of similarly delayed responses against hepatitis viruses.

Aims: To develop a model for $CD8^+$ T cell activation in the liver, we performed hepatic gene transfer with an AAV8 vector expressing ovalbumin (OVA).

Methods: Three different doses (low: $1x10^8$ vg, medium: $1x10^9$ vg, and high: $1x10^{10}$ vg) of AAV8-OVA were injected IV into in C57BL/6 mice.

Results: Dose dependent OVA expression resulted in distinctly different immune responses. Only the mid dose showed circulating OVA-specific $CD8^+$ T cells, which emerged at 2 weeks in 40-50% of mice and reached a high frequency (5-35%) that was maintained for >3 months. Nonetheless, OVA expression lasted for >2 months, indicating an inability to eliminate the liver-expressed antigen. This was attributed to expression of inhibitory molecules. Loss of OVA expression at ~2.5 months correlated with downregulation of PD-1 and up-regulation of IFN-g expression. PD-$1^{-/-}$ mice also developed circulating OVA-specific $CD8^+$ T cells. However, none of the PD-$1^{-/-}$ mice had systemic OVA expression at 2 or 4 weeks, indicating rapid target clearance. Significantly increased numbers of $CD8^+$ T cells were also observed in liver sections of mice that lost expression (e.g. in low-dose transduced mice) despite absence of circulating OVA-specific $CD8^+$ T cells, suggesting that a localized immune response was responsible for the loss of expression in these animals. At the high dose, OVA expression was sustained without $CD8^+$ T cell response.

Conclusions: At limited vector doses, $CD8^+$ T cell responses that are not functionally competent may develop. Upon down regulation of negative checkpoint receptors, a functional response emerges. These responses may not always be detectable in circulation, are not dependent on systemic antigen delivery, and can even occur in TLR9-deficient mice.

OC 75.4 | Prophylactic Platelet Factor (F) VIII Infusions Established from Induced Pluripotent Stem Cell (iPSC)-derived Megakaryocytes in Hemophilia A

R. Lyde[1], H. Ahn[2], K. Vo[1], D. Jarocha[2], L. Zhai[2], S. Sullivan[3], V. Arruda[2], D. Sabatino[2], R. Camire[1,2], D. French[2], M. Poncz[1,2]

[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, United States, [2]Childrens Hospital of Philadelphia, Philadelphia, United States, [3]University of Mississipi Medical Center, Jackson, United States

Background: Ectopically expressed FVIII in megakaryocytes (MKs) and platelets (pFVIII) is stored in a-granules and released at sites of vascular injury by activated platelets (Plts), restoring hemostasis in $FVIII^{null}$ mice, even in the presence of neutralizing inhibitors. Expressing FVIII in Plts, however, has limitations that make pFVIII gene therapy through bone marrow transplantation in severe hemophilia A patients with intractable inhibitors problematic.

Aims: We propose an alternative strategy based on infusing iMKs derived from iPSCs and expressing either human B-domain-deleted (BD) FVIII or a R1645H BDFVIII variant with greater specific activity.

Methods: Plts isolated from *P38*, transgenic mice expressed pFVIII, and iMKs that expressed pFVIII after transfection with *Cxcl4* promoter-driven pFVIII lentiviruses were utilized. In vitro assays of efficacy were done using rotational thromboelastography (ROTEM) and in vivo studies were done using both the tail clip assay and a $FeCl_3$ carotid artery injury model.

Results: pFVIII-iMKs were successfully established and did not show any injury while expressing pFVIII. Both *P38* Plts infused into *F8*-/- murine whole blood

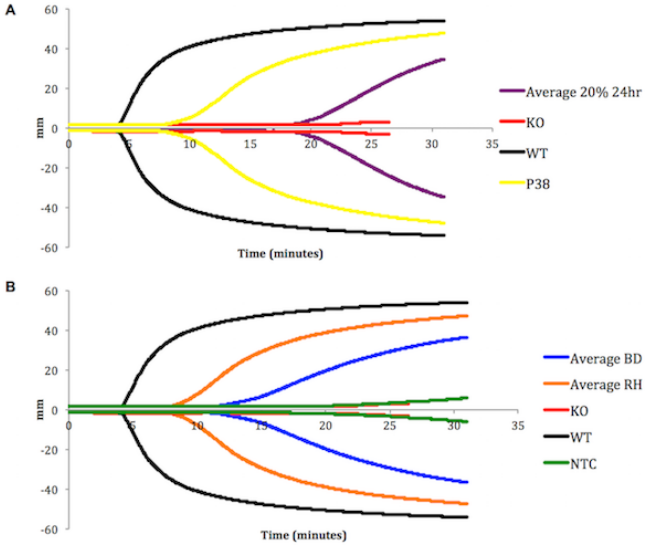

FIGURE 1 In vitro efficacy of P38 platelets and pFVIII-iMKs in mouse FVIII KO whole blood by ROTEM

(Fig. 1A) and pFVIII-iMKs (Fig. 1B) demonstrated hemostatic efficacy by ROTEM that was additive with recombinant FVIIa (not shown). *P38* Plts infused into *F8-/-* mice were hemostatically effective for up to 72 hrs post-infusion in the tail clip assay

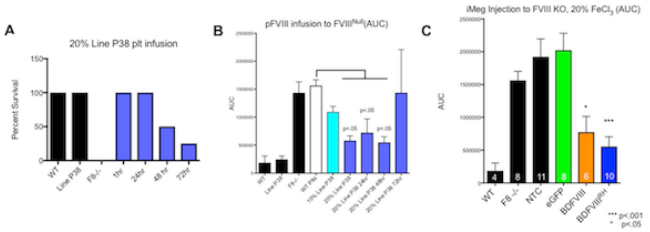

FIGURE 2 In vivo efficacy of FVIII expressing P38 and iMegs-derived Plts in mice tail clip and FeCl3 carotid artery injury models

(Fig. 2A) and up to 48 hrs in the $FeCl_3$ injury model (Fig. 2B). Infused pFVIII-iMKs release Plts and these were hemostatically effective as well in clodronate liposome-pretreated *F8-/-* mice (Fig. 2C).

Conclusions: Plt-delivered FVIII may be a useful, long-lasting prophylactic agent in lieu of present-day bypassing agents and may be used additively in complement with them. Such Plts may be derived from iPSCs established from the effected patient or from "universal" iPSCs modified to minimize its antigenicity when differentiated into iMKs.

OC 75.5 | Targeted FVIII Expression under the Control of its Native Promoter for Hemophilia A Gene and Cell Therapy

R. Famà, S. Merlin, E. Borroni, V. Bruscaggin, S. Zucchelli, A. Follenzi

University of Piemonte Orientale, Health Sciences, Novara, Italy

Background: Despite the development of blood products and recombinant FVIII has improved the patients quality of life, replacement therapy do not represent yet a definitive cure for Hemophilia patients.Thus other therapeutic approaches, such as gene and cell therapy, are required.

Aims: We studied the activity of F8 promoter (pF8) sequence to drive transgene expression in a Lentiviral Vector construct to verify the feasibility of expressing FVIII under its natural promoter for gene therapy approaches.

Methods: In silico analysis of Transcriptional Factors (TF) consensus sequences predicted the presence of several cell-specific TF validated by a luciferase specific assay . We injected LV.pF8.hFVIII in hemophilic mice and aPTT assay measured FVIII activity. We transplanted LV-pF8.FVIII transduced human cord-blood CD34+ cells in busulfan-treated NOD/SCID gamma-null HA-mice (NSGHA).

Results: pF8 study showed its ability to drive transgene expression in hepatic endothelium, splenic macrophages and, generally, in myeloid cells by *in vivo* and *ex-vivo* LV delivery. We injected LV.pF8.hFVIII in hemophilic mice and aPTT assay demonstrated FVIII activity in therapeutic range (up to 12% of normal FVIII activity) without antibodies formation up to 1 year and consistent blood loss reduction. Using more active forms of FVIII cDNA we improved FVIII activity levels in HA mice. Moreover LV pF8.hFVIII injection in FVIII-immunized HA mice resulted in therapeutic FVIII activity and reversion of inhibitor titers. Transplantation of LV-pF8.FVIII transduced human cord-blood CD34+ cells in busulfan-treated NSGHA mice showed therapeutic levels of FVIII activity up to 10% of normal with a 30% of cell chimerism.

Conclusions: Our results demonstrate that pF8 is differentially active in cell-subpopulations of several organs contributing to identify the FVIII producing cells and targeting transgene expression in these cells by LV produced FVIII in therapeutic range in HA mice without immune response in two different hemophilic mouse strains.

MANAGEMENT OF THROMBOEMBOLISM

OC 12.1 | Prevalence of Major Medical Illnesses Associated with Venous Thromboembolism Risk in US Hospitals

A.T. Cohen[1], W. Huang[2], R.A. Harrington[3], S.Z. Goldhaber[4], R.D. Hull[5], A.F. Hernandez[6], C.M. Gibson[7], F.A. Anderson[2]

[1]Guy's and St Thomas' NHS Foundation Trust, Department of Haematology, London, United Kingdom, [2]University of Massachusetts, Medical School, Worcester, United States, [3]Stanford University, Department of Medicine, Stanford, United States, [4]Brigham and Women's Hospital, Harvard Medical School, Cardiovascular Division, Boston, United States, [5]University of Calgary, Faculty of Medicine, Calgary, Canada, [6]Duke University and Duke Clinical Research Institute, Division of Cardiology, Durham, United States, [7]Beth Israel Deaconess Medical Center, Boston, United States

Background: Major medical illnesses contribute greatly to population-attributable risk for venous thromboembolism (VTE). Recent annual numbers of episodes of each medical illness have not been described.

Aims: To estimate the annual number and diagnoses of medical illnesses in US acute-care hospital discharges at risk of VTE.

Methods: The American College of Chest Physicians (ACCP) 2012 guideline described major medical illnesses that place patients at risk of VTE (respiratory failure, chronic obstructive pulmonary disease, heart failure, pneumonia, other infections, stroke, rheumatologic disorders). These were examined in Y2014 US hospital discharges using the first three diagnosis codes derived from the Clinical Classification System in the National Inpatient Sample (a database of acute-care hospital discharges from the US Agency for Health Care Quality and Research).

Results: In Y2014 there were 20.8 million discharges from US acute-care hospitals with a diagnosis of a medical illness. Respiratory failure, heart failure, and infections were the commonest major medical diagnoses associated with risk of VTE. Overall, 7.2 million (35%) discharges met the Y2012 ACCP criteria for VTE prophylaxis for at least 6-14 days. 1.36 million patients had a diagnosis of cancer, and 2.79 million were aged ≥ 75. Based on age ≥ 75 or a history of cancer, 3.48 million discharges have an extended duration of risk of VTE and warrant thromboprophylaxis for up to 42 days according to the APEX[1] study (NCT01583218) (Table).

Conclusions: Among Y2014 US hospital discharges there are 7.2 million with acute major medical illnesses at risk of VTE as described by the ACCP. Respiratory diseases, heart failure, and infections were the commonest acute medical conditions warranting thromboprophylaxis. Almost half are at extended duration of risk of VTE based solely on age or a history of cancer.

TABLE 1 Number of Acutely Ill Medical Discharge Diagnoses from US Acute-Care Hospitals in 2014 with ACCP Guideline-Defined Risk of VTE: By Diagnosis and Age

	Overall number	Age group in years (n) 18-39	Age group in years (n) 40-59	Age group in years (n) 60-74	Age group in years (n) 75+	Cancer (n)
Number	20,815,620	5,684,465	4,867,461	4,902,047	5,361,647	
Respiratory failure / Chronic obstructive pulmonary disease	2,567,991	115,325	592,080	946,425	914,160	483,350
Heart failure	2,338,371	69,890	413,485	727,450	1,127,546	402,395
Pneumonia	1,653,541	107,505	344,915	509,035	692,085	382,025
Other infections	1,621,960	157,105	390,595	502,095	572,165	353,820
Stroke	574,850	15,675	118,960	187,240	252,975	92,790
Arthrophathy/spondylopathy	545,560	70,850	187,495	144,510	142,705	60,410
Any of the above	7,209,343	457,865	1,653,601	2,306,431	2,791,446	1,365,111
Apex 2-criteria 1	3,484,731	-	207,895	485,390	2,791,446	1,336,801

[1]Based on age ≥ 75 and/or a cancer history. VTE history (8%) and D-dimer+ (62%) in APEX were additional independent risks; these data were not available.

OC 12.2 | Venous Thromboembolism and Physical Function in the Nurses' Health Study

K. Hagan[1], L. Harrington[2], J. Kim[3], F. Grodstein[1], C. Kabrhel[1,4]

[1]Brigham and Women's Hospital, Harvard Medical School, Channing Division of Network Medicine, Boston, United States, [2]Harvard T.H. Chan School of Public Health, Department of Nutrition, Boston, United States, [3]Harvard T.H. Chan School of Public Health, Department of Epidemiology, Boston, United States, [4]Massachusetts General Hospital/Harvard Medical School, Center for Vascular Emergencies, Boston, United States

Background: Physical function is integral to healthy aging and is a strong predictor of mortality in older adults. Limited research has examined the impact of venous thromboembolism (VTE) on physical function.

Aims: We prospectively examined the relationship of VTE and physical function among 82,118 women from the Nurses' Health Study, ages 46-72 at baseline in 1992; including 1,857 women with incident VTE during follow-up through 2012.

Methods: Physical function was measured by the Medical Outcomes Short Form-36 physical function scale, administered every four years starting in 1992. Participants reported physician-diagnosed VTE on biennial questionnaires. We investigated the association between an incident VTE and change in physical function score over the five 4-year periods using multivariate linear regression. We utilized linear mixed models to estimate slopes of decline over the 20-year follow-up period comparing women with vs. without VTE.

Results: We observed a substantial decrease in physical function score over 4-years comparing women with vs. without an incident VTE (multivariable adjusted mean difference=-6.89, 95% CI:-7.84,-5.93).

TABLE 1 Association between VTE, DVT, and PE and 4-year change in physical function score among women in the Nurses' Health Study.

	NHS (n=82,118)
VTE (DVT and PE)	
Age adjusted	-7.33 (-8.29, -6.38)
Multivariable adjusted	-6.89 (-7.84, -5.93)
DVT only	
Age adjusted	-6.05 (-7.41, -4.69)
Multivariable adjusted	-5.77 (-7.14, -4.42)
PE only	
Age adjusted	-8.36 (-9.69, -7.03)
Multivariable adjusted	-7.76 (-9.09, -6.43)

This difference was even greater among women reporting a pulmonary embolism (multivariable adjusted mean difference=-7.76, 95% CI:-9.09,-6.43). We also compared physical function trajectories over the 20 years of follow-up separately in participants with no VTE, and women with incident VTE during one of the 4-year periods.

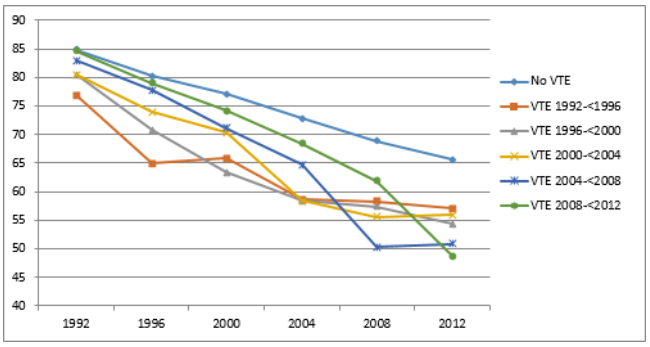

FIGURE 1 Age-adjusted physical function scores from 1992 to 2012 among women from the Nurses' Health Study

We found the sharpest decline in physical function during the time period in which the VTE occurred. Over the 20 years, those with incident VTE had worse rates of decline than those with no VTE (mean difference per 4-years=-1.71, 95% CI:-2.13,-1.28).

Conclusions: In this large cohort of women, VTE was strongly associated with physical function decline, with the greatest decline in the years immediately following the VTE. If confirmed, these results suggest it may be important to consider approaches to ameliorating functional deficits after VTE diagnosis.

OC 12.3 | Catheter-related Venous Thromboembolism in Hospitalized Pediatric Patients with Inflammatory Bowel Disease: A Retrospective Study Assessing Prevalence, Characteristics and Role of Anticoagulant Thromboprophylaxis with Enoxaparin

J. Meldau, C. Hennessey, C. Guelcher, D. Carrie, M. Guerrera, Y. Diab

Children's National Medical Center, Hematology and Oncology, Washington, United States

Background: Hospitalized children with active inflammatory bowel disease (IBD) frequently require a central venous catheter (CVC). Since IBD confers an increased risk of venous thromboembolism (VTE), these patients have a higher risk for CVC-related VTE. Data in children are limited and likely underestimate the true incidence of these events. Furthermore, the role of anticoagulant thromboprophylaxis (AT) has not been adequately explored. In 2014, we introduced a protocol to consider initiating AT with enoxaparin after CVC placement in any patient admitted with active IBD.

Aims: To describe prevalence and characteristics of CVC-related VTE in hospitalized pediatric patients with active IBD and report efficacy and safety of AT with enoxaparin.

Methods: We conducted a retrospective study of patients who were admitted to our center in the last 2 years with active IBD and required CVC during hospitalization. Since CVCs in IBD patients are placed by interventional radiology, we used radiology data mining software to identify potential cases. The medical charts of potential cases were reviewed to identify cases that met inclusion criteria and collect rele-

TABLE Summary of characteristics and outcome measures

Characteristic	AT (N=17)[1]	No AT (N=23)	P value[2]
Female gender	11 (65%)	11 (48%)	0.3
Age (years)	14 (8-18)	14 (5-20)	0.8
IBD phenotype	Crohn's Disease [N=10 (59%)]; Ulcerative Colitis [N=7 (41%)]	Crohn's Disease [N=16 (70%)]; Ulcerative Colitis [N=7 (30%)]	0.5
Duration of hospitalization (days)	24 (10-47)	15 (3-72)	0.06
CVC-related VTE	0/17 (0%)	5/23 (22%) [3]	**0.04**
Nadir Hb during hospitalization (g/dL)	7.8 (5.8-10.8)	8.1 (5.6-13.8)	0.3
RBC transfusions during hospitalization	1 (0-7)	0 (0-7)	0.06
RBC transfusions per day of hospitalization	0.04 (0-0.19)	0 (0-0.3)	0.1

AT=Anticoagulant Thromboprophylaxis; IBD=Inflammatory Bowel Disease; CVC=Central Venous Catheter; VTE=Venous Thromboembolism; Hb=Hemoglobin; RBC=Red Blood Cell.

[1] All patients received primary AT (15 patients) or secondary AT (2 patients) with enoxaparin according to an institutional weight- and age-based dosing protocol.

[2] Continuous variables are presented as median and range and are compared using the Mann-Whitney U-test. Categorical data are presented as frequency and percentage and are compared using the Chi-square test. P value < 0.05 was considered statistically significant.

[3] All patients developed symptomatic proximal deep vein thrombosis confirmed by Doppler ultrasound.

vant data. To assess efficacy and safety outcomes, we compared the frequency of radiologically confirmed CVC-related VTE, nadir hemoglobin and red blood cell transfusion requirements in patients who received AT with enoxaparin to those who didn't. Mann-Whitney U or Chi-square tests were used to compare the two groups.

Results: A total of 40 patients met inclusion criteria. Of the 40 patients, 17 received AT with enoxaparin. Refer to summary table for results of data analysis.

Conclusions: Our study suggests a higher frequency of CVC-related VTE in hospitalized children with active IBD than previously reported. Moreover, our data suggest that AT with enoxaparin is effective and appears to be safe in this population. The results of this study support the need for a prospective study to define incidence and risk factors for VTE in children with IBD, and evaluate role of AT.

OC 12.4 | External Validation and Comparison of the Improve Risk Assessment Model with the Geneva Risk Assessment Model in the ESTIMATE Cohort

M. Blondon[1], D. Spirk[2], N. Kucher[3], D. Aujesky[3], D. Hayoz[4], J. Beer[5], M. Husmann[6], B. Frauchiger[7], W. Korte[8], W. Wuillemin[9], H. Bounameaux[1], M. Righini[1], M. Nendaz[1]

[1]Geneva University Hospitals and Faculty of Medicine, Geneva, Switzerland, [2]University of Bern / Institute of Pharmacology, Bern, Switzerland, [3]University Hospital Bern, Bern, Switzerland, [4]Cantonal Hospital Fribourg, Fribourg, Switzerland, [5]Cantonal Hospital Baden, Baden, Switzerland, [6]University Hospital Zurich, Zurich, Switzerland, [7]Cantonal Hospital Frauenfeld, Frauenfeld, Switzerland, [8]Cantonal Hospital St. Gallen, St. Gallen, Switzerland, [9]Cantonal Hospital Lucerne and University of Bern, Lucerne, Switzerland

Background: Improved thromboprophylaxis for acutely ill medical patients is needed and relies on valid predictions of thrombotic risks. The Improve risk assessment model (RAM) was only validated in North America and different classifications of low-risk patients were proposed.

Aims: To validate the Improve RAM in a Swiss cohort and to compare it to the Geneva RAM.

Methods: Medical inpatients from 3 academic and 5 non-academic hospitals were prospectively followed for 90 days in 2010-2011 (ESTIMATE study). The primary outcome was venous thromboembolism (VTE) or VTE-related death, which was adjudicated independently. We assessed and compared discriminative performance and calibration of the RAMs, using time-to-event methods taking into account the competing risk of death. Patient informed consent was obtained following the agreement of ethics committees.

Results: Of 1478 patients with a mean age of 65 years, about 60% received thromboprophylaxis during their hospitalization (median duration of 8 days). The cumulative incidence functions of VTE at 30 and 90 days were 1.1% and 1.6% (n=30), with a mortality at 90 days of 19.3% (n=292). Discriminative performances of the Improve RAM and the Geneva RAM were similar at 30 and 90 days, with 30d time-dependent AUC of 0.78 (95%CI 0.67-0.88) and 0.80 (0.72-0.88), respectively. An Improve low-risk score (< 3 points, 68% of patients) *vs*. Geneva low-risk score (< 3 points, 35% of patients) had sensitivities of 73% *vs*. 90% and 0.8% *vs*. 0.6% risk of VTE at 3 months. Among patients without thromboprophylaxis, corresponding numbers were 54% *vs*. 85% and 1.4% *vs*. 0.7%. High-risk groups had 4.7% *vs*. 2.8% risk of VTE at 3 months, respectively.

Conclusions: The discrimination of the Improve RAM is good and comparable to that of more complex scores such as the Geneva RAM. More patients are classified as low-risk in the Improve RAM, however with possibly lower sensitivity and greater VTE risks. A lower threshold to define the low-risk Improve group may be advisable.

OC 12.5 | Genetics InFormatics Trial (GIFT) of Warfarin to Prevent Deep Venous Thrombosis: Improvement in Time Spent in the Therapeutic INR Range

B. Gage[1], A.R. Bass[2], H. Lin[1,3], S. Woller[4], S. Stevens[4], N. Al-Hammadi[5], T. Rodriguez Jr.[5], J.P. Miller[1], G. McMillin[6], R. Pendleton[6], A. Jaffer[7,8], C. King[5], B. DeVore[5], R. Porche-Sorbet[5], L. Napoli[6], K. Merritt[2], A. Joykutty[9], G. Hyun[10], J. Anderson[4], W. Hollomon[2], R. Barrack[5], R. Nunley[5], G. Moskowitz[5], V. Davila-Roman[5], C. Eby[5]

[1]Washington University in St. Louis, General Medical Sciences Campus Box 8005, Saint Louis, United States, [2]Hospital for Special Surgery, New York, United States, [3]University of Massachusetts Medical School, Worcester, United States, [4]Intermountain Healthcare, Salt Lake City, United States, [5]Washington University Medical Center, Saint Louis, United States, [6]University of Utah School of Medicine, Salt Lake City, United States, [7]Rush University Medical Center, Chicago, United States, [8]New York Presbyterian/Queens hospital, New York, United States, [9]University of Central Florida College of Medicine, Orlando, United States, [10]Saint Louis University, Saint Louis, United States

Background: Whether genotype-guided dosing improves the percentage of time spent in the therapeutic INR range (PTTR) is controversial.

Aims: We conducted a multicenter, randomized controlled trial of patients ≥ 65 years of age initiating warfarin prior to elective hip or knee arthroplasty.

Methods: Participants were genotyped for 4 polymorphisms: VKORC1-1639G>A, CYP2C9*2, CYP2C9*3, and CYP4F2 V433M. For the first 11 days of therapy, warfarin dosing was guided by www.WarfarinDosing.org, which incorporated genotype in patients randomized to pharmacogenetic dosing. Recommended doses of warfarin were open label, but participants and providers were blinded to study arm. A priori, we defined a high-risk subgroup as participants for whom genetic and clinical algorithms had significantly (≥ 1 mg) different estimates of the therapeutic warfarin dose. We calculated PTTR during days 4 - 28 of therapy using a therapeutic range of 1.96 - 3.04 for patients with a target INR of 2.5, and 1.36 - 2.24 for patients with a target INR of 1.8.

Results: 1588 participants (64% female, 91% Caucasian) had at least 1 INR value after a warfarin dose and were included. The mean PTTR was 66.1% in participants randomized to genotype-guided dosing and 62.0% with clinical dosing. The mean improvement (95% CI) was 4.1%

(1.8 - 6.4); P < 0.001. Among patients with a target INR of 2.5, the mean PTTR was 57.6% with genotype-guided dosing and 53.8% with clinical dosing (mean difference 5.8% (95% CI 2.6 - 9.0); P < 0.001). Among the 654 high-risk participants, mean PTTR was 66.8% with genotype-guided and 58.9% with clinical dosing (mean difference 7.9% (95% CI 4.3 - 11.4); P < 0.001). In contrast to these benefits, there was no significant improvement in PTTR in subgroups who had a low-risk genotype or who self-identified as African-American.

Conclusions: In a cohort of mostly Caucasian patients initiating warfarin therapy, genotype-guided dosing improved INR control.

Funding: NIH (R01 HL097036) and CMS; ClinicalTrials.gov NCT01006733.

OC 25.1 | The Impact of Residual Pulmonary Obstruction on the Long-term Outcome of Patients with Pulmonary Embolism

R. Pesavento[1], L. Filippi[2], P. Prandoni[3], for The Scope Investigators group

[1]*University of Padua, Dept. of Internal Medicine, Padova, Italy,* [2]*University of Padua, Dept.Of Internal Medicine, Padova, Italy,* [3]*University of Padua, Dept. of Cardiothoracic Sciences, Padova, Italy*

Background: In several patients, after a first episode of acute pulmonary embolism (PE), the risk of recurrent venous thromboembolism (VTE) is high and that of chronic thromboembolic pulmonary hypertension (CTEPH) is not negligible. Currently, there is virtually no way to identify patients with PE in whom the risk of late complications is high enough to justify indefinite anticoagulation. The impact of residual pulmonary obstruction (RPO) on the outcome of patients with pulmonary embolism (PE) is uncertain.

Aims: To determine the risk of recurrent VTE and/or CTEPH over a 3-year follow-up in a wide cohort of PE patients with and without RPO.

Methods: In a nationwide, multicentre, prospective cohort study, consecutive patients with first, objectively confirmed acute PE were prospectively followed for up to 3 years. Patients with severe cardiopulmonary diseases, low expected survival or refusal to provide informed consent were excluded. A perfusional lung scan was performed after 6 months and RPO was assessed using the Meyer score. Scintigraphic images, recurrent VTE and CTEPH were centrally adjudicated by an independent committee.

Results: 647 consecutive patients were followed for 3 years and received a lung scan at 6 months. Pulmonary perfusion defects were found in 324 patients (50.1%; 95%CI, 46.2 to 54.0). Recurrent VTE and/or CTEPH developed in 34 (10.5%) patients with RPO and in 15 (4.6%) without it leading to an adjusted hazard ratio of 2.42 (95%CI, 1.31 to 4.46).

Conclusions: Residual pulmonary obstruction, as assessed with perfusion lung scanning six months after an episode of PE, is an independent predictor of recurrent VTE and/or CTEPH.

OC 25.2 | The Impact of Increased Systolic Pulmonary Artery Pressure on the Late Outcome of Patients with Pulmonary Embolism

R. Pesavento[1], L. Filippi[1], P. Prandoni[2], for the Scope Investigators Group

[1]*University of Padua, Dept. of Internal Medicine, Padova, Italy,* [2]*University of Padua, Dept. of Cardiothoracic Sciences, Padova, Italy*

Background: In several patients, after a first episode of acute pulmonary embolism (PE), the risk of recurrent venous thromboembolism (VTE) is high and that of chronic thromboembolic pulmonary hypertension (CTEPH) is not negligible. The current strategies proposed to identify high-risk patients to be treated with indefinite anticoagulation remain suboptimal and controversial. The impact of asymptomatic increased systolic pulmonary artery pressure(sPAP) on the outcome of patients with PE is uncertain.

Aims: To determine the risk of recurrent VTE and/or CTEPH over a 3-year follow-up in a wide cohort of PE patients with and without asymptomatic increased sPAP.

Methods: In a nationwide, multicentre, prospective cohort study, consecutive patients with first, objectively confirmed acute PE were prospectively followed for up to 3 years. Patients with severe cardiopulmonary diseases, low expected survival or refusal to provide informed consent were excluded. An echocardiographic examination was performed after 6 weeks and after 6 months. Increased sPAP was defined for values > 36 mmHg. Recurrent VTE and CTEPH were centrally adjudicated by an independent committee.

Results: 518 consecutive patients were followed for 3 years and received an echocardiographic examination at 6 weeks and at 6 months. An increased sPAP was found in 79 (15.3%) patients after 6 weeks and in 61 (11.8%) after six months. Recurrent VTE and/or CTEPH developed in 14 (17.7%) patients with an increased sPAP after six weeks and in 29 (6.6%) without it leading to an adjusted hazard ratio of 2.82 (95%CI, 1.46 - 5.41). Recurrent VTE and/or CTEPH developed in 12 (19.6%) patients with increased sPAP after six months and in 31 (6.8%) without it leading to an adjusted hazard ratio of 4.04 (95%CI, 2.03 - 8.04).

Conclusions: Asymptomatic increased systolic pulmonary artery pressure, as assessed with echocardiography, six weeks or six months after an episode of PE, is an independent predictor of recurrent VTE and/or CTEPH.

OC 25.3 | High Sensitivity of a Non-invasive Screening Strategy for Chronic Thromboembolic Pulmonary Hypertension after Acute Pulmonary Embolism

Y.M. Ende-Verhaar[1], D. Ruigrok[2], H.J. Bogaard[2], M.V. Huisman[1], L. Meijboom[3], A. Vonk Noordegraaf[2], F.A. Klok[1]

[1]*LUMC, Thrombosis and Hemostasis, Leiden, The Netherlands,* [2]*VU Medical Center, Pulmonology, Amsterdam, The Netherlands,* [3]*VU Medical Center, Radiology, Amsterdam, The Netherlands*

Background: A non-invasive screening algorithm for chronic thromboembolic pulmonary hypertension (CTEPH) after acute pulmonary embolism (PE) consisting of a prediction score and ECG/NT-proBNP assessment (*Figure 1*) was recently constructed, aiming at faster and easier CTEPH detection than current practice.

Aims: The algorithm was applied to 54 consecutive patients with confirmed CTEPH to accurately evaluate the sensitivity of the algorithm for this rare disease. In addition, the reproducibility of the individual items of the algorithm was studied.

Methods: Two independent researchers calculated the prediction score based on clinical characteristics at PE diagnosis, and evaluated the ECG and NT-proBNP level assessed at CTEPH diagnostic work-up. Interobserver agreement for assessment of the prediction score, RV/LV ratio measurement on CTPA as well as ECG reading was evaluated by calculating kappa statistics.

Results: Median time between PE diagnosis and presentation with CTEPH was 8 months (interquartile range 5-13). 52 patients (96%, 95%CI 87-100%) had a high prediction score and/or CTEPH specific symptoms. The ECG/NT-proBNP combination was abnormal in 49 of 52 patients (94%, 95%CI 84-99%). The sensitivity of the algorithm was 91% (95%CI 79-97%), indicating that 27 of 30 cases of CTEPH would have been detected when applying the screening algorithm to 1000 random PE survivors with a 3% CTEPH incidence (projected negative predictive value 99.7%; 95%CI 99.1-99.9%). The interobserver agreement for calculating the prediction score, RV/LV ratio measurement and ECG reading was excellent with a kappa of 0.96, 0.95 and 0.89 respectively.

Conclusions: All components of the algorithm were highly reproducible. 91% of the CTEPH patients would have been identified by the algorithm, underlining its adequate sensitivity. Prospective validation of the algorithm in consecutive PE patients is required before it can be implemented in clinical practice.

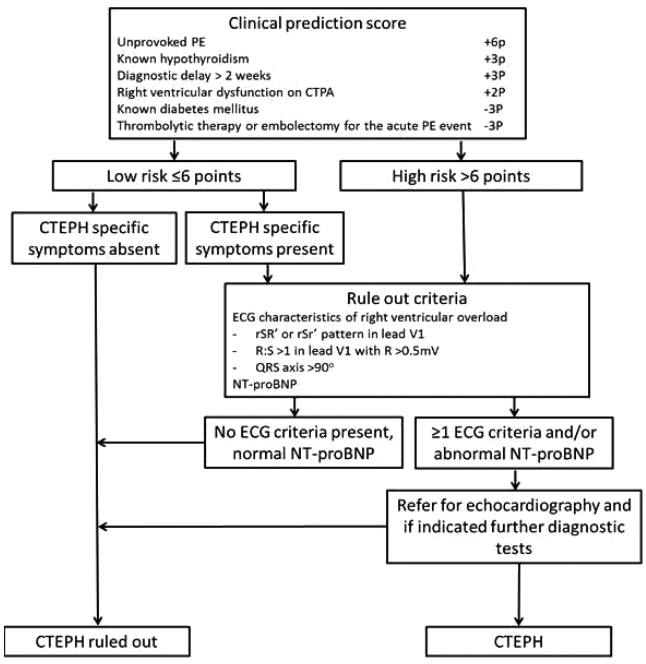

FIGURE 1 Screening algorithm for CTEPH after acute PE consisting of the CTEPH prediction score, CTEPH specific symptoms and the rule out criteria

OC 25.4 | Residual Vein Thrombosis and Serial D-Dimer for the Long-term Management of Patients with Deep Venous Thrombosis

P. Prandoni, The Morgagni Investigators

University of Padua, Cardiovascular Sciences, Padua, Italy

Background: The optimal long-term strategy for preventing recurrent venous thromboembolism (VTE) in patients with deep-vein thrombosis (DVT) is uncertain.

Aims: Assessing the value of residual vein thrombosis (RVT) and serial D-dimer determinations for identifying patients with DVT in whom anticoagulation can be safely discontinued.

Methods: In 620 consecutive outpatients with a first proximal DVT who had completed at least three momths of anticoagulation (unprovoked in 483, associated with weak risk factors in 137), the ultrasound presence of RVT was assessed and defined as an incompressibility of at least 4 mm. In 517 patients without RVT and with negative D-dimer, anticoagulation was stopped and D-dimer was repeated after one and three months. Anticoagulation was resumed in 63 of the 72 patients in whom D-dimer reverted to positivity.

Results: During a mean follow-up of three years, recurrent VTE developed in 40 (7.7%) of the 517 patients, leading to an annual rate of 3.6% (95% CI, 2.6 to 4.9): 4.1% (95% CI, 2.9 to 5.7) in individuals with unprovoked DVT, and 2.2% (95% CI, 1.1 to 4.5) in those with DVT associated with weak risk factors. Of the 233 males with unprovoked DVT, 17 (7.3%) developed events in the first year of follow-up. Major bleeding complications occurred in 8 patients while on anticoagulation, leading to an annual rate of 1.2% (95% CI, 0.6 to 2.4).

Conclusions: Discontinuing anticoagulation in patients with a first episode of proximal DVT based on the assessment of RVT and serial D-dimer leads to an overall annual rate of recurrent VTE lower than 5.0%, which is the rate reputed as acceptable by the Subcommittee on Control of Anticoagulation of the ISTH. However, in males with unprovoked DVT there is room for further improving the long-term strategy of VTE prevention.

OC 25.5 | Site and Mortality of Major Bleedings in Patients Treated with Individual Doacs

L. Franco[1], C. Becattini[1], J. Beyer-Westendorf[2], R. Re[3], S. Espinoza Tofalos[4], C. Nitti[5], F. Pomero[6], L. Masotti[7], R. Cappelli[8], G. Manina[9], S. Cattinelli[10], G. Agnelli[1]

[1]University of Perugia, Perugia, Italy, [2]University Hospital ‚Carl Gustav Carus', Technische Universität Dresden, Dresden, Germany, [3]Ospedale Maggiore della Carità, Novara, Italy, [4]Careggi University Hospital, Firenze, Italy, [5]Ospedali Riuniti di Ancona, Ancona, Italy, [6]Santa Croce Hospital, Cuneo, Italy, [7]Santa Maria Nuova Hospital, Firenze, Italy, [8]University of Siena, Siena, Italy, [9]Lodi Hospital, Lodi, Italy, [10]Cattinara Hospital, Trieste, Italy

Background: Limited direct comparisons on the prevalent site and case-fatality of major bleedings (MBs) occurring during treatment with individual direct oral anticoagulants (DOACs) are available.

Aims: To compare the prevalent bleeding site and case-fatality of MBs occurring while on treatment with different DOACs.

Methods: Patients hospitalized for DOAC-associated MB were included in a multicenter study. The primary study outcome was death at 30 days. **Results:** 302 MBs occurred while on treatment with dabigatran (72 patients), rivaroxaban (184 patients) or apixaban (46 patients). Rivaroxaban patients were younger (77 ± 11 years vs. 83 ± 7 years vs. 80 ± 9 years), had higher prevalence of previous bleeding (OR 2.33, 95% CI 1.25-4.32 and OR 3.42, 95% CI 1.51-7.74) and of venous thromboembolism as indication for treatment (23% vs. 0% vs. 6%) and a lower prevalence of previous stroke (17% vs. 29 vs. 30%) than dabigatran and apixaban patients.

Presentation as intracranial hemorrhage (ICH), gastrointestinal or genitourinary bleeding was observed in similar proportions of dabigatran, rivaroxaban and apixaban patients after adjusting for age, previous bleeding and previous stroke (Table 1). Fresh frozen plasma or prothrombin complex concentrates were used in similar proportions of dabigatran, rivaroxaban or apixaban patients.

TABLE 1 Bleeding sites of individual DOAC after adjusting for age, previous bleeding and previous stroke

	N (%)	aOR, 95% CI vs. dabigatran	aOR, 95% CI vs. rivaroxaban
Rivaroxaban intracranial hemorrhage	45 (24)	1.24 (0.55-2.83)	-
Rivaroxaban gastrointestinal bleeding	78 (42)	1.00 (0.48-2.10)	-
Rivaroxaban genitourinary bleeding	19 (10)	1.12 (0.27-4.70)	-
Apixaban intracranial hemorrhage	17 (37)	1.41 (0.51-3.88)	1.13 (0.46-2.77)
Apixaban gastrointestinal bleeding	15 (33)	0.77 (0.32-1.89)	-
Apixaban genitourinary bleeding	3 (6)	1.43 (0.23-9.03)	1.28 (0.29-5.65)
Dabigatran intracranial hemorrhage	19 (26)	-	-
Dabigatran gastrointestinal bleeding	33 (46)	0.77 (0.29-2.08)	-
Apixaban genitourinary bleeding	3 (4)	-	-

Death at 30 days occurred in 31 patients (10%). Presentation as ICH (HR 8.59; 95% CI 3.19-23.12) or shock (HR 7.37; 95% CI 2.69-20.13), INR at admission (HR 1.54; 95% CI 1.12-2.12) and previous stroke (HR 3.60; 95% CI 1.54-8.42) were independent predictors of death. No association was observed between death and treatment individual DOACs.

Conclusions: In our study on MBs while on DOACs, no difference was observed in the presentation as ICH, gastrointestinal or genitourinary bleeding across individual agents. Presentation as ICH or shock and not the individual DOAC are predictors of death at 30 days.

OC 33.1 | The Role of Time in Therapeutic Range on Bleeding Risk Prediction in Atrial Fibrillation Patients under Vitamin K Antagonist Therapy

J.M. Rivera-Caravaca[1], F. Marín[2], M.A. Esteve-Pastor[2], M. Valdés[2], V. Vicente[1], G.Y.H. Lip[3,4], V. Roldán[1]

[1]Hospital General Universitario Morales Meseguer, Instituto Murciano de Investigación Biosanitaria (IMIB-Arrixaca), Department of Hematology and Clinical Oncology, Murcia, Spain, [2]Hospital Clínico Universitario Virgen de la Arrixaca, Instituto Murciano de Investigación Biosanitaria (IMIB-Arrixaca), Department of Cardiology, Murcia, Spain, [3]University of Birmingham, Institute of Cardiovascular Sciences, City Hospital, Birmingham, United Kingdom, [4]Aalborg Thrombosis Research Unit, Department of Clinical Medicine, Aalborg University, Aalborg, Denmark

Background: Vitamin K antagonists (VKAs) remain widely used as oral anticoagulation (OAC) in atrial fibrillation (AF). However, bleeding risk with VKAs is closely related to the quality of anticoagulation, as reflected by time in therapeutic range (TTR).

Aims: We aim to compare the discrimination performance of four different bleeding risk scores and to investigate if adding TTR would improve their predictive value and clinical usefulness.

Methods: We included 1361 AF patients clinically stable on VKA for at least 6 months. Bleeding risk was assessed by the HAS-BLED, ATRIA, ORBIT and HEMORR$_2$HAGES scores. Major bleeding events were recorded after a median of 6.5 (IQR 4.3-7.9) years. The study protocol was approved by the Ethics Committee from our institution and performed in accordance with the Declaration of Helsinki. All patients gave informed consent.

Results: During follow-up, 250 patients suffered major bleeds and 52 patients died due to bleeding. Comparison of receiver operating characteristic (ROC) curves demonstrated that HAS-BLED had the best performance of the four tested scores (c-index: 0.62), but adding the ‚labile INR' criteria (i.e. TTR< 65%) to ATRIA, ORBIT and HEMORR$_2$HAGES increased their ability of discrimination and predictive value (c-indexes 0.75, 0.73 and 0.72, respectively), with significant improvements in reclassification and discriminatory performance (all p< 0.001). Decision curve analyses (DCA) also showed improvements of the clinical usefulness and a net benefit of the 3 modified risk scores (by addition of TTR< 65%).

TABLE 2 Comparison of the ROC curves, IDI and NRI of the modified bleeding risk scores (by addition of labile INR defined as time in therapeutic rang

	C-index	95% CI	z statistic*	p*	IDI	p	NRI	p
vs. ATRIA								
ATRIA + TTR <65%	0.751	0.727-0.774	7.514	<0.001	0.0326	<0.001	0.1527	<0.001
vs. ORBIT								
ORBIT + TTR<65%	0.733	0.709-0.757	5.087	<0.001	0.0270	<0.001	0.1097	<0.001
vs. HEMORR2HAGES								
HEMORR2HAGES + TTR <65%	0.729	0.704-0.752	4.689	<0.001	0.0159	<0.001	0.0598	0.007

CI = confidence interval; IDI = integrated discriminatory improvement; NRI = net reclassification index; TTR = time in therapeutic range. *for c-index comparison.

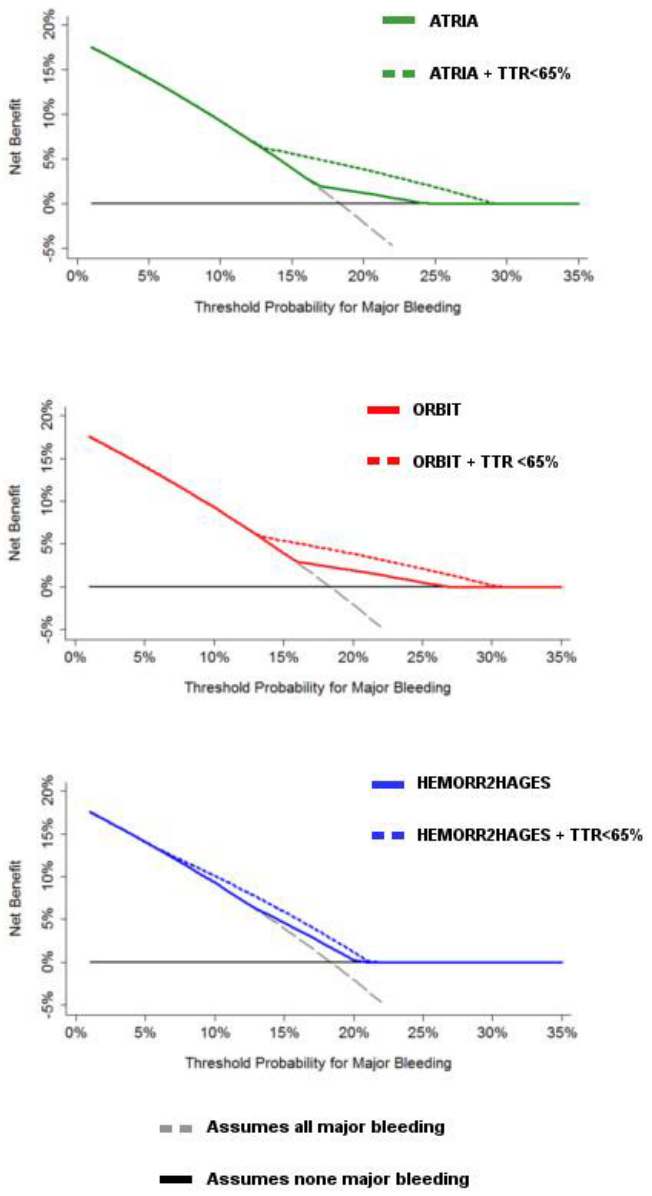

FIGURE 1 Decision curves for the original and modified bleeding risk scores (adding TTR<65%)

Conclusions: In AF patients taking VKAs, the HAS-BLED score had the best predictive ability. Adding labile INR (TTR<65%) to ATRIA, ORBIT and HEMORR$_2$HAGES scores improved their predictive value for major bleeding leading to improved clinical usefulness and higher net benefit compared to the original scores. This suggests that these 3 scores would perform suboptimally in VKA users by not considering 'labile INR' as a bleeding criterion.

OC 33.2 | Persistence of Oral Anticoagulant Treatment for Atrial Fibrillation in The Netherlands: A Surveillance Study

W. Lijfering[1], M. Teichert[2], N. van Rein[2], F. Klok[2], F. Rosendaal[2], F.J.M. van der Meer[2], M. Huisman[2], S. Cannegieter[2]

[1]*Leiden University Medical Center, Clinical Epidemiology, Leiden, The Netherlands,* [2]*Leiden University Medical Center, Leiden, The Netherlands*

Background: The efficacy of oral anticoagulant treatment is to a large degree determined by treatment adherence.

Aims: To assess the treatment persistence of direct oral anticoagulants (DOACs) and of vitamin K antagonists (VKAs) in patients with atrial fibrillation.

Methods: Observational study in two registries.

1. A database of Dutch Community Pharmacies with individual patient data on DOAC use from 1-1-2012 to 1-4-2016 (covering the whole of the Netherlands, 17.5 million inhabitants).

2. A database of the Leiden Anticoagulation Clinic with individual patient data from 1-1-2004 to 1-1-2012 (covering the greater Leiden area, n=500 000). The final study sample of 87412 patients included 13878 apixaban-, 34167 rivaroxaban-, 29288 dabigatran- and 10079 VKA users. Main outcome measures were persistence to oral anticoagulant treatment identified as time from start of DOAC treatment to withdrawal of the initial DOAC or end of study period whichever came first, or as time from start of anticoagulant treatment until completely discontinuing anticoagulant treatment.

Results: DOAC users were younger than VKA users (70 vs 73 years). In DOAC users, 11% had withdrawn from their initial DOAC treatment within 6 weeks, another 24% had withdrawn at 6 months (35% total), 43% had withdrawn at 1 year, and 71% at 4 years of follow-up. Approximately a fifth of those who had withdrawn their initial DOAC treatment switched to another anticoagulant (VKA or another DOAC). Of DOAC users, 34% had completely discontinued with their anticoagulant treatment at 1 year and 66% at 4 years. These numbers

were 22% and 36% in VKA users, respectively. Multivariable analyses showed that female sex, young age and non-adherence were predictors for discontinuation of DOAC treatment.

Conclusions: Persistence to oral anticoagulant treatment use in patients with atrial fibrillation is low and 12% (at 1 year)-35% (at 4 years) lower in DOAC users than VKA users. Further research to investigate the reasons and consequences of early stopping DOAC treatment is warranted.

OC 33.3 | Atrial Fibrillation, Stroke, and Mortality in Patients on Hemodialysis - Prospective Results of the Vienna InVestigation of AtriaL Fibrillation and Thromboembolism in HemoDIalysis Patients (VIVALDI)

O. Königsbrügge[1], E. Grilz[1], S. Schmaldienst[2], M. Auinger[3], M. Lorenz[4], R. Klauser-Braun[5], J. Kletzmayr[5], M. Antlanger[6], F. Posch[1,7], I. Pabinger[1], M. Säemann[8], C. Ay[1]

[1]Medical University of Vienna, Medicine I, Clinical Division of Hematology and Hemostaseology, Vienna, Austria, [2]Kaiser-Franz-Josef-Spital, Department of Medicine I, Vienna, Austria, [3]Hietzing Hospital, Department of Medicine III, Vienna, Austria, [4]Vienna Dialysis Center, Vienna, Austria, [5]Donauspital, Department of Medicine III, Vienna, Austria, [6]Medical University of Vienna, Medicine III, Vienna, Austria, [7]Medical University of Graz, Graz, Austria, [8]Wilhelminenspital, Department of Medicine VI, Vienna, Austria

Background: Atrial fibrillation (AF) is a major risk factor for stroke. However, it is not well investigated in patients with end-stage renal disease (ESRD) on maintenance hemodialysis (HD).

Aims: To assess the association of AF, stroke, and mortality in patients on HD.

Methods: VIVALDI is a prospective population-based study in Vienna, Austria, investigating the risk of stroke in patients on HD with approval of the ethics committee. All participating patients gave written consent. Independent experts adjudicated the composite endpoint of ischemic stroke, transient ischemic attack (TIA), and systemic embolism (SE). Presence of AF was recorded at baseline or as new AF during follow-up and modeled as a time-dependent variable for risk of the endpoint, considering death and kidney transplantation as competing risk events.

Results: The study encompassed 625 patients (median age: 66 years; 229 [36.6%] women), followed for 515 days in median. At baseline, 165 patients (26.4%) had AF and 41 patients developed AF during observation (8.9%). 59 patients (9.4%) received kidney transplants and 135 (21.6%) died. During follow-up 20 primary endpoints (3.2%) occurred (14 ischemic strokes, 2 TIAs, 4 SEs) with an incidence rate of 2.66 per 100 patient-years. In multivariable regression analysis adjusted for sex and BMI, patients with AF had a 2.5-fold increased risk of stroke (95%CI 1.0-6.0) compared to patients without AF (figure 1). Stroke was further associated with age (subdistribution hazard ratio [SHR] 1.03 per year, 95%CI 1.00-1.07), diabetes (SHR 3.1, 95%CI 1.3-7.6) and the CHA2DS2-Vasc score (SHR 1.7 per point, 95%CI 1.3-2.4). AF doubled the risk of mortality (HR 2.0, 95%CI 1.4-2.8) in multivariable regression analysis adjusted for age and sex (figure 2). The risk of death was especially high in patients with new onset AF (HR 4.7, 95%CI 2.7-8.2).

Conclusions: Patients with ESRD on HD who have AF are at increased risk of stroke and mortality. Risk evaluation using clinical characteristics can identify patients at high risk.

OC 33.4 | Direct Oral Anti-coagulants (DOACs) Are Associated with Decreased Mortality Compared to Warfarin among Hospitalized Patients with Non-valvular Atrial Fibrillation

A. Israel, Y. Schwarz, O. Salomon, Y. Sidi

Sheba Medical Center, Tel Hashomer, Israel

Background: Direct Oral Anticoagulants (DOACs) are increasingly used as an alternative for traditional antithrombotic therapy for stroke prevention in patients with non-valvular atrial fibrillation (AF).

Aims: To evaluate the real world efficacy and safety of DOACs compared with Warfarin in terms of overall mortality, CVA events occurrence and gastrointestinal (GI) bleeding.

Methods: We performed a retrospective cohort study on patients admitted to medicine wards of Sheba Medical Center, a tertiary medical center, with non-valvular AF, and treated with either DOACs or Warfarin, between the years 2010 and 2016. We excluded patients with former Deep Venous Thrombosis (DVT), and solid tumors. We used propensity score matching to match, for each patient treated on DOACs, a patient of similar age, gender, Charlson comorbidity index, CHADS-VASC, and GFR, but treated with Warfarin. Mortality events were obtained from the national population registry. We used Cox proportional hazards to compare overall mortality, and the occurrence of CVA and GI bleeding leading to subsequent hospitalization.

Results: Among 7261 patients treated with oral anti-coagulants for AF or flutter, and who did not have valvular disease, DVT or solid tumors, 1813 patients were treated with DOACs, and were matched by propensity score to patients with similar baseline characteristics and treated with Warfarin. During a mean follow-up of 2.8 years, 907 mortality events, 441 CVA events, and 99 GI bleeding events were recorded. Overall mortality was significantly decreased in the DOAC group vs. Warfarin (HR=0.57; p< 0.001), as well as the number of CVA and GI bleeding events (HR=0.81; p< 0.02).

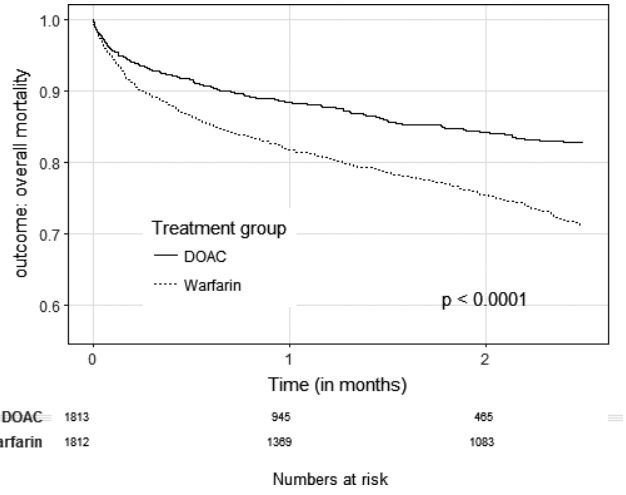

FIGURE 1 Kaplan-Meier plot: overall mortality

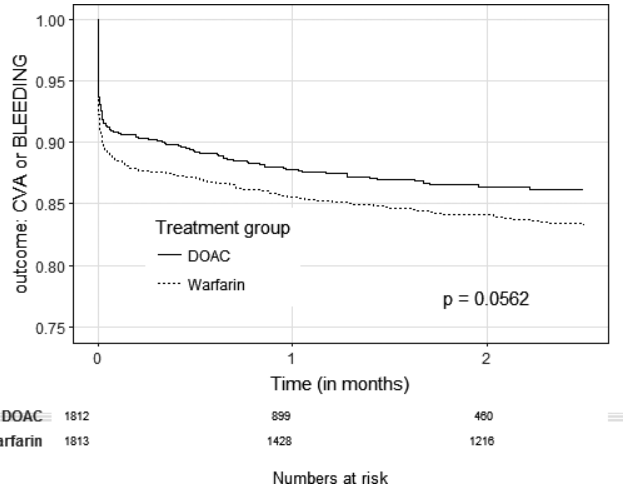

FIGURE 2 Kaplan-Meier plot: CVA and gastrointestinal bleeding events

Conclusions: In this retrospective study based on a cohort of patients hospitalized in a large tertiary medical center, and followed subsequently, decreased overall mortality was found in patients treated with DOACs, compared to patients with similar baseline characteristics and treated with Warfarin.

OC 33.5 | Perioperative Outcomes of Direct Oral Anticoagulants vs. Warfarin in Atrial Fibrillation: A Meta-analysis of Phase III Trials

B. Nazha[1], B. Pandya[1], J. Cohen[2], M. Zhang[3], A.C. Spyropoulos[4]

[1]Staten Island University Hospital - Northwell Health, Staten Island, United States, [2]Division of Hospital Medicine, North Shore-LIJ Department of Medicine, Manhasset, United States, [3]Biostatistics Unit, Feinstein Institute for Medical Research, Department of Medicine, Northwell Health, Manhasset, United States, [4]Hofstra Northwell School of Medicine, The Merinoff Center for Patient-Oriented Research - The Feinstein Institute for Medical Research, Northwell Health at Lenox Hill Hospital, New York, United States

Background: Direct Oral Anticoagulants (DOACs) are surpassing Warfarin as the anticoagulant of choice for stroke prevention in Atrial Fibrillation (AF). DOACs outcomes in perioperative settings have not been well elucidated and remain a source of concern for clinicians.

Aims: To evaluate the perioperative safety and efficacy of DOACs vs. Warfarin in AF patients.

Methods: We reviewed the literature for data from Phase III randomized controlled trials comparing DOACs to Warfarin in the perioperative period among AF patients. Sub-studies from 4 trials (RE-LY, ROCKET AF, ARISTOTLE, ENGAGE-AF) were included in the meta-analysis. DOACs as a group and Warfarin were compared in terms of the 30-day pooled risk for Stroke/Systemic Embolism (SSE), Major Bleed (MB) and death, according to whether the study drug was interrupted or not perioperatively. The overall Relative Risk (RR) was estimated using a random effects model. The I^2 test was used to assess heterogeneity in RR among the studies.

Results: Under an interrupted anticoagulation strategy, there was no significant difference between DOACs vs. Warfarin for SSE [41 events/9260 procedures vs. 31/7168, RR=0.95, 95% CI= (0.59, 1.55)], MB [218/9175 vs. 136/7078, RR=1.05, 95% CI= (0.85, 1.30)], and death [69/9260 vs. 38/7168, RR=1.24; 95% CI= (0.76, 2.04)].

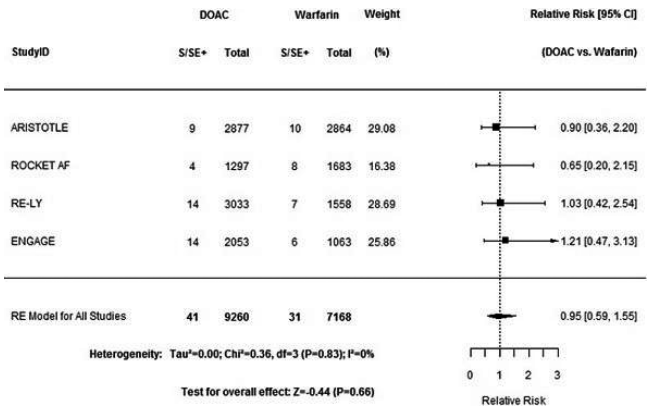

FIGURE 1 Forest Plot of Stroke/Systemic Embolism Outcomes (DOACs vs. Warfarin) under an Interrupted Perioperative Anticoagulation Strategy

In the uninterrupted strategy, DOACs had significantly fewer MB compared to Warfarin [97/4540 vs. 98/2985, RR=0.62, 95% CI= (0.47, 0.82)], and similar rates of SSE [29/4519 vs. 31/2971, RR=0.70, 95% CI= (0.41, 1.18)] and death [62/4457 vs. 54/2971, RR=0.77, 95% CI= (0.53, 1.12)].

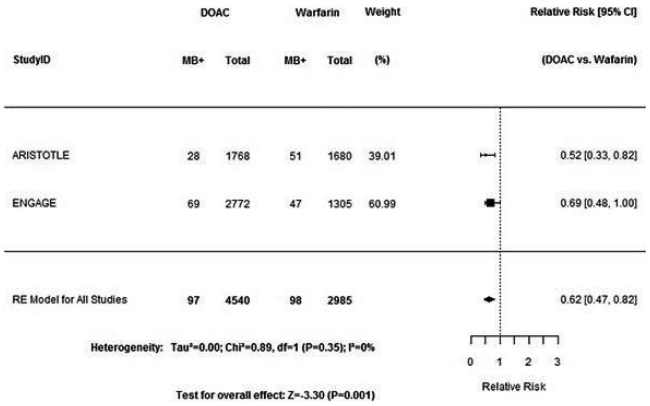

FIGURE 2 Forest Plot of Major Bleed Outcomes (DOACs vs. Warfarin) under an Uninterrupted Perioperative Anticoagulation Strategy

The studies were homogeneous (I^2= 0.0) for all calculated pooled associations except for the RR of death in the interrupted strategy (I^2= 26.3%).

Conclusions: The short-term safety and efficacy of DOACs and Warfarin are similar in AF patients perioperatively. Under an uninterrupted anticoagulation strategy, DOACs are associated with a 38% lower risk of MB compared to Warfarin.

OC 39.1 | Long-term Risk of Recurrent Venous Thromboembolism with and without Effective Antithrombotic Therapy

M.H. Prins[1], A.W.A. Lensing[2], P. Prandoni[3], J. Beyer-Westendorf[4], B. van Bellen[5], A.F. Pap[2], M. Gebel[2], P. Verhamme[6], P.S. Wells[7], J.I. Weitz[8]

[1]University of Maastricht, Department of Epidemiology and Technology Assessment, Maastricht, The Netherlands, [2]Bayer AG, Wuppertal, Germany, [3]University of Padua, Department of Cardiothoracic & Vascular Sciences, Padua, Italy, [4]University Hospital ‚Carl-Gustav Carus', Department of Vascular Medicine, Dresden, Germany, [5]Hospital Beneficência Portuguesa, São Paulo, Brazil, [6]University of Leuven, Vascular Medicine and Hemostasis, Leuven, Belgium, [7]University of Ottawa and the Ottawa Hospital Research Institute, Department of Medicine, Ottawa, Canada, [8]Thrombosis and Atherosclerosis Research Institute and McMaster University, Hamilton, Canada

Background: There is uncertainty about the appropriate duration of anticoagulation in patients with venous thromboembolism (VTE) and practice varies between countries.

Aims: To provide estimates of the risk of recurrent VTE, with and without effective antithrombotic therapy, according to the risk factor profile.

Methods: We used data from two large randomized trials (EINSTEIN-Extension and EINSTEIN-Choice) that compared rivaroxaban (20 mg or 10 mg) with placebo or aspirin (100 mg) for extended VTE treatment in patients who had already received 6 to 12 months of anticoagulation. The index VTE events were centrally classified using the following hierarchy:

1) unprovoked, or provoked with a

2) major permanent risk factor (i.e. cancer),

3) minor permanent risk factor (i.e. inflammatory bowel disease, lower extremity paralysis/paresis, congestive heart failure, BMI > 30, creatinine clearance < 50 ml/min, family history of VTE, hereditary/acquired thrombophilia),

4) minor transient risk factor (i.e. immobilization, travel > 8 h, hormonal therapy, pregnancy or puerperium, leg injury with impaired mobility, or

5) major transient risk factor (i.e. major surgery or trauma).

Results: A total of 2832 patients received rivaroxaban (10 or 20 mg) and 1721 received placebo or aspirin.

TABLE 1 Incidence of recurrent VTE according to risk factor profile of index event, n/N, %

	Rivaroxaban 10/20 mg N=2832		Placebo or aspirin N=1721	
Unprovoked VTE	19/1173	1.6%	46/711	6.5%
Provoked, major persisting risk factor	0/82	0%	3/65	4.6%
Provoked, minor persisting risk factor	18/1184	1.5%	35/714	4.9%
Provoked, minor transient risk factor	1/268	0.4%	8/177	4.5%
Provoked, major transient risk factor	0/125	0%	0/54	0%

Conclusions: Although patients with unprovoked VTE are at highest risk of recurrence, those with a minor persisting or transient risk factor also are at a high risk. In patients with these risk profiles, rivaroxaban substantially reduces the incidence of recurrence.

OC 39.2 | External Validation of the DASH Prediction Model: The TRIP (Thrombosis Research Italian Partnership) Collaboration

A. Tosetto[1], E. Antonucci[2], W. Ageno[3], E. Banfi[4], L. Barcella[5], F. Bartolomei[6], P. Bucciarelli[7], B. Cosmi[8], F. Dentali[3], V. De Stefano[6], A. Falanga[5], C. Lodigiani[4], C. Legnani[8], I. Martinelli[7], I. Nichele[1], O. Paoletti[9], D. Poli[2], S. Testa[10], G. Palareti[11]

[1]San Bortolo Hospital, ULSS 8 Berica, Hematology Department, Vicenza, Italy, [2]Thrombosis Centre, AOU Careggi, Florence, Italy, [3]University of Insubria, Department of Internal Medicine, Varese, Italy, [4]Thrombosis and Haemorragic Diseases Unit, IRCCS Humanitas Research Hospital, Milan, Italy, [5]Thrombosis and Hemostasis Center, Department of Immunohematology and Transfusion Medicine, Bergamo, Italy, [6]Institute of Hematology, Catholic University, Rome, Rome, Italy, [7]A. Bianchi Bonomi Hemophilia and Thrombosis Center, Fondazione IRCCS Ca' Granda - Ospedale Maggiore Policlinico, Milan, Italy, [8]S.Orsola-Malpighi University Hospital, Department of Angiology and Blood Coagulation, Bologna, Italy, [9]Hemostasis and Thrombosis Center, AO Istituti Ospitalieri di Cremonas, Cremona, Italy, [10]Hemostasis and Thrombosis Center, AO Istituti Ospitalieri di Cremona, Cremona, Italy, [11]Malattie Cardiovascolari, Università di Bologna, Bologna, Italy

Background: The optimal duration of anticoagulant therapy after the first episode of unprovoked venous thromboembolism (VTE) is controversial. Several clinical prediction rules (CPR) have been developed, but few have been externally validated in an independent cohort.

Aims: We aimed at validating the DASH prediction model, in which a score ≤1 would indicate an annual recurrence risk < 5%, therefore potentially excluding the need of prolonged treatment. We were also willing to evaluate the DASH score in a predefined patient subgroup (elderly vs. younger patients).

Methods: Patients with a proximal unprovoked DVT or PE, who received a full course of VKA or DOAC (>3 months) and having D-dimer measured after treatment withdrawal were eligible. The DASH score was computed based on D-dimer after therapy withdrawal (considered positive when values exceeded a cut-off of 250 ng/ml DDU or 500 FEU), age< 50 at index event, male sex and hormone use at index event. Recurrent VTE events were symptomatic proximal or distal DVT/PE, and were analyzed with a time-dependent analysis. Observed 12 and 24-months recurrence rates were compared to recurrence rates predicted by the DASH model.

Results: We analyzed a total of 827 patients, of whom 100 (12.1 %) had an objectively documented recurrence. On average, recurrence risk factors were less represented than in the original DASH cohort, with a greater proportion of subjects having a „low-risk" (< =1) DASH score (66.3% vs. 51.6%, p< 0.001).

Figure 1, Panel A shows the observed vs. expected cumulative incidence at 2-years for all enrolled subjects, with a slope equal to 0.71 (95% CI 0.51- 1.45). Panel B shows the same data subjects >65 years (dotted line) vs. younger (continuous); c-statistic was lower for subjects >65 years (0.54) vs. younger ones (0.72).

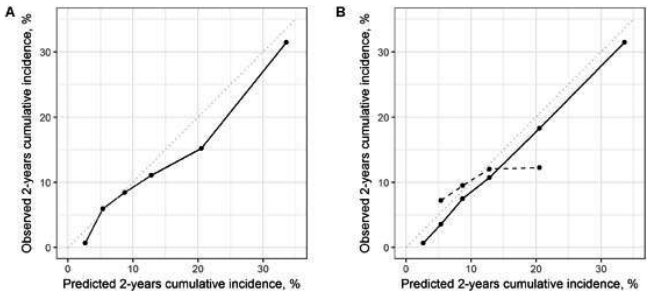

FIGURE 1 Panel A, all data; Panel B, stratified by age

Conclusions: These results confirm the validity of DASH prediction model, particularly in young subjects. The recurrence risk in elderly patients (>65 years) is >5% even with the lowest DASH scores.

OC 39.3 | Extended Anticoagulation with Two Doses of Rivaroxaban (20 mg and 10 mg) for Preventing Recurrent Venous Thromboembolism: A Benefit-risk Analysis of EINSTEIN CHOICE

J.I. Weitz[1], A.W.A. Lensing[2], P.S. Wells[3], M. Gebel[2], A.F. Pap[2], M. Homering[2], J. Beyer-Westendorf[4], H. Bounameaux[5], P. Prandoni[6], M.H. Prins[7]

[1]*Thrombosis and Atherosclerosis Research Institute and McMaster University, Hamilton, Canada,* [2]*Bayer AG, Wuppertal, Germany,* [3]*University of Ottawa and the Ottawa Hospital Research Institute, Department of Medicine, Ottawa, Canada,* [4]*University Hospital ‚Carl-Gustav Carus', Department of Vascular Medicine, Dresden, Germany,* [5]*University Hospitals of Geneva and Faculty of Medicine, Geneva, Switzerland,* [6]*University of Padua, Department of Cardiothoracic & Vascular Sciences, Padua, Italy,* [7]*University of Maastricht, Department of Epidemiology and Technology Assessment, Maastricht, The Netherlands*

Background: Most patients with unprovoked venous thromboembolism (VTE) or with ongoing risk factors receive 6 to 12 months of anticoagulant therapy. The decision to extend therapy depends on the balance between the risk of recurrent VTE if treatment stops and the risk of bleeding if treatment continues. Information on this benefit-risk balance is limited.

Aims: The benefit-risk tradeoff of extended treatment with 20 mg or 10 mg of once daily rivaroxaban was assessed in patients with symptomatic VTE who had completed 6-12 months of anticoagulation and for whom there was equipoise regarding the need for extended anticoagulation.

Methods: One-year cumulative incidences were estimated for recurrent VTE and major bleeding with the Kaplan-Meier method. Benefits and risks were presented using the differences between treatment groups in a hypothetical population of 10,000 VTE patients followed for 1 year.

Results: A total of 1107 patients were treated with rivaroxaban 20 mg, 1127 with rivaroxaban 10 mg, and 1131 with aspirin. The cumulative incidence of recurrent VTE was 1.9% in patients in the rivaroxaban 20 mg group, 1.6% in patients in the rivaroxaban 10 mg group, and 5.0% in patients in the aspirin group. The cumulative incidences of major bleeding were 0.7%, 0.4% and 0.5% in the rivaroxaban 20 mg, rivaroxaban 10 mg, and aspirin groups, respectively. Compared with aspirin in a hypothetical population of 10,000 VTE patients followed for 1 year, treatment with 20 mg or 10 mg of rivaroxaban would result in 312 (95% confidence interval [CI], 145 to 479) and 341 (95% CI, 175 to 507) fewer recurrent VTE events (NNT=33 and 30, respectively) and in 28 (95% CI, -43 to 99) and 0 (95% CI, -60 to 59) more major bleeding events (NNH=356 and >10,000, respectively).

Conclusions: Extended anticoagulation with once daily rivaroxaban (20 mg or 10 mg) provides a clinically important benefit in terms of reduction in recurrent VTE, and both regimens have favorable benefit-risk profiles.

OC 39.4 | Prediction of Major Bleeding (MB) Risk in 2514 High Recurrence Risk Venous Thromboembolism Patients Treated Beyond 3 to 6 Months with Oral Anticoagulation Therapy (OAT)

P. Wells[1], M. Rodger[1], M. Kovacs[2], D. Anderson[3], S. Kahn[4], S. Solymoss[4], C. Kearon[5], V. Shah[6], D. Keeling[7], I. Chagnon[8], R. Zide[9], M. Carrier[1], R. Mallick[1], D. Corsi[1], G. Le Gal[1], S. Schulman[10], S. Kaatz[6]

[1]*University of Ottawa and the Ottawa Hospital Research Institute, Medicine, Ottawa, Canada,* [2]*University of Western Ontario, Medicine, Ottawa, Canada,* [3]*Dalhousie University, Medicine, Halifax, Canada,* [4]*McGill University, Medicine, Montreal, Canada,* [5]*McMaster University, Medicine, Hamilton, Canada,* [6]*Henry Ford Hospital, Medicine, Detroit, United States,* [7]*Oxford University Hospitals*

NHS Foundation Trust, Medicine, Headington, United Kingdom, [8]Universite de Montreal, Medicine, Montreal, Canada, [9]Lahey Hospital and Medical Center, Medicine, Burlington, United States, [10]McMaster University and Thrombosis and Atherosclerosis Research Institute, Medicine, Hamilton, Canada

Background: A tool to predict the risk of MB in patients on extended OAT for venous thromboembolism (VTE), has not been developed. Identifying those with an annual MB rate over 3% is the target at which the risk of continued OAT exceeds benefit.

Aims: To develop a prediction rule for major bleeding that selects a clinically meaningful proportion of patients with a MB risk over 3%.

Methods: a multicentre, multinational prospective cohort study of extended OAT for unprovoked VTE, or provoked VTE with prior VTE. Cancer patients were excluded. Enrollment was after at least 3 months of OAT. All bleeding events were adjudicated. Univariate Cox proportional hazards analysis was used to determine the strength of association between each variable and risk of MB to permit selection of a subset of variables for the subsequent multivariate analysis. Of the 24 variables analysed 10 were found to be strongly associated with MB risk (P< 0.05) (Table 1). A multivariable Cox regression model was built using clinically important, easily measurable variables.

Results: 2514 patients enrolled with > 7100 years of observation. The mean age was 60 years, 64% were male, 92% Caucasian, mean BMI was 31, and 9% were on antiplatelet agents. Patients were followed for a mean of 2.8 years. 90% were on VKAs.121 patients (4.8%) experienced at least one MB episode. The annual rate of MB was 1.7 per 100 patient years of observation (rate constant). All variables in the derived model scored one except anemia (2) [Table 2]. 21% had a score of 2 (MB rate 3.1%, 95% CI=2.3 to 4.2%), 7% scored 3 (MB rate 4.5%, 95% CI=2.7 to 7.1%), and 1% scored ≥ 4 (MB 7.9%%, 95% CI=2.6 to 18.6%). All the fatalities from MB were in these high-risk groups. In the 71% at low risk the MB rate was 1.1%. All differences were statistically significant with p values < 0.0001. The C-index was 0.74.

Conclusions: Almost 30% of patients would score high risk (i.e. >3%) for MB and consider not continuing OAT. If validated (as planned prior to the ISTH) this could change practice.

TABLE 1 One. Significant variables in the univariate analysis

OC 39.5 | External Validation of the VTE-BLEED Score for Predicting Major Bleeding in Stable Anticoagulated Patients with Venous Thromboembolism

F.A. Klok, S. Barco, S. Konstantinides

Center for Thrombosis and Hemostasis (CTH), University Medical Center of the Johannes Gutenberg University, Mainz, Germany

Background: One of the main determinants of establishing the optimal treatment duration of patients with venous thromboembolism (VTE) is the risk of major bleeding during long-term anticoagulant therapy. The 6-variable VTE-BLEED score was recently developed to enable estimation of this bleeding risk.

Aims: This study aimed at externally validating VTE-BLEED.

Methods: This was a post-hoc study of the randomized, double-blind, double-dummy, HOKUSAI-VTE study that compared edoxaban versus warfarin. VTE-BLEED was calculated in all 8,240 study patients. The number of adjudicated major bleeding events during ‚stable anticoagulation', i.e. occurring after day 30, in patients with low (total score < 2 points) and high risk of bleeding (total score ≥2 points) were compared for the overall study population, patients randomized to edoxaban or warfarin, and for important patient subcategories.

Results: During ‚stable' anticoagulation, major bleeding occurred in 1.02% (40/3,903) and 0.82% (32/3,899) of patients treated with warfarin and edoxaban respectively. For the overall study population, the risk of bleeding in the low and high risk groups were 0.51% and 2.03% respectively, for an Odds Ratio of 4.04 (95%CI: 2.51-6.48). Odds Ratios were 2.53 (95%CI: 2.15-2.99) and 1.35 (95%CI: 1.16-1.58) for warfarin and edoxaban respectively. VTE-BLEED was consistently able to identify patients at a 2.5 to 11-fold higher bleeding risk across all the predefined subcategories as well as for the treatment period between day 30 from enrollment to day 180, and beyond day 180.

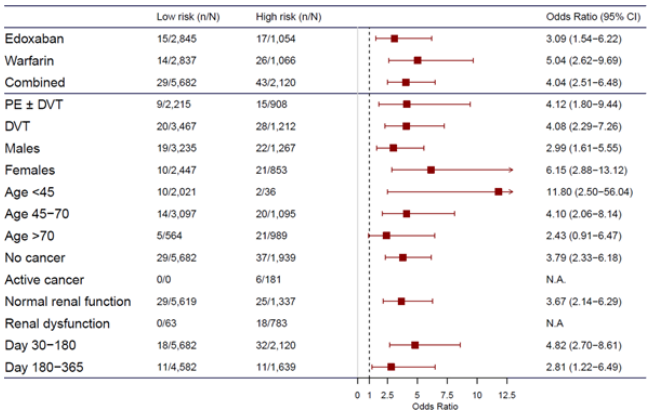

FIGURE 1 Performance of VTE-BLEED in the predefined cohorts and subcategories during ´stable´ anticoagulation

Conclusions: Patients identified as high risk by VTE-BLEED had a 4-fold increased risk of bleeding during the chronic phase of treatment.

OC 52.1 | Evaluation of Interventions for Implementation of Thromboprophylaxis in Hospitalized Patients at Risk for Venous Thromboembolism (VTE): An Updated Cochrane Systematic Review and Meta-analysis of Randomized Controlled Trials (RCT)

S.R. Kahn[1,2,3], D.R. Morrison[1], A. Piché[4], K.B. Filion[1,5], G. Diendere[1], A. Klil-Drori[1], J. Douketis[6], J. Emed[7], A. Roussin[8], V. Tagalakis[1,3], M. Morris[9], W. Geerts[10]

[1]Jewish General Hospital, Centre for Clinical Epidemiology, Montreal, Canada, [2]McGill University, Department Epidemiology, Biostatistics, and Occupational Health, Montreal, Canada, [3]McGill University, Division of Internal Medicine and Department of Medicine, Montreal, Canada, [4]McGill University, Department of Mathematics and Statistics, Montreal, Canada, [5]McGill University, Departments of Medicine and of Epidemiology, Biostatistics, and Occupational Health, Montreal, Canada, [6]McMaster University, Hamilton, Canada, [7]Jewish General Hospital, Department of Nursing, Montreal, Canada, [8]University of Montreal, Montreal, Canada, [9]McGill University, Schulich Library of Physical Sciences, Life Sciences and Engineering, Montreal, Canada, [10]Sunnybrook Health Sciences Centre, Toronto, Canada

Background: While numerous RCTs have shown that the use of thromboprophylaxis (TP) in hospitalized patients at risk for VTE is safe, effective, and cost-effective, TP remains underutilized. System-wide interventions may be more effective to improve the use of TP than relying on individual providers' prescribing behaviors.

Aims: In this update to our 2013 Cochrane review, we aimed to determine the effectiveness of various system-wide interventions designed to increase the use of TP in hospitalized medical and surgical patients at risk for VTE, focusing on RCTs only.

Methods: We conducted a systematic literature search to identify RCTs assessing interventions designed to increase use of TP and/or decrease incidence of VTE in hospitalized patients. We searched Medline, Embase, BIOSIS, CINAHL, Cochrane, Web of Science, LILACS, clinicaltrials.gov, CENTRAL and DARE from inception to July 2015. Data were extracted on study design, setting, intervention, and outcomes, including proportions receiving prophylaxis (RP). We categorized the interventions into 4 groups: education, any alerts, computer alerts, and multifaceted interventions. We performed a random effects meta-analysis if 3 or more studies were available for an intervention group and an outcome. Heterogeneity was assessed using I^2 statistic.

Results: Among 12,920 records identified by our search, 16 RCTs were assessed for eligibility and 11 RCTs (N= 55,197 patients) were included in our review. Among the RCTs, there were sufficient data to pool one outcome (RP) for 3 intervention types (any alerts, computer alerts, and multifaceted (Table).

Conclusions: We found statistically significant improvements in prescription of prophylaxis associated with any alerts and computer alerts. The results of our review will help physicians, hospital administrators and policy makers make practical decisions about adoption of specific system-wide measures to improve prevention of VTE.

Funded by: Canadian Institutes of Health Research.

TABLE Meta-Analysis Results

Intervention	Outcome	Number of Studies	Number of Patients	Risk Difference (RD)(95% CI)	I^2 Statistic for RD	Relative risk (RR) (95% CI)
Any Alerts*	Received Prophylaxis	5	6,523	0.20 [0.15, 0.24]	65%	1.80 [1.37, 2.36]
Computer Alerts*	Received Prophylaxis	3	3,890	0.18 [0.16, 0.21]	0%	1.96 [1.46, 2.64]
Multifaceted **	Received Prophylaxis	5	25,742	0.02 [-0.00, 0.04]	0%	1.04 [0.97, 1.10]

Interventions were categorized into 4 groups: education (e.g., grand rounds, self-administered course), any alerts (e.g., electronic, human), computer alerts, (i.e., electronic alert only), and multifaceted interventions (e.g., combination of education, audit and feedback, and alert). *Clustered trials did not provide sufficient data (intra-cluster correlation (ICC) or adjusted confidence intervals) for us to pool cluster adjusted estimates. **ICCs were available for 4/5 trials included in this meta-analysis. An ICC of 0.00 was used for the 5th trial. All trials in the meta-analysis were clustered designs.

OC 52.2 | Extended Venous Thromboembolism Prophylaxis Comparing Rivaroxaban to Aspirin Following Total Hip or Knee Arthroplasty (EPCAT II)

Wells[15]

[1]Dalhousie University, Halifax, Canada, [2]McGill University, Montreal, Canada, [3]QE II HSC, Nova Scotia Health Authority, Halifax, Canada, [4]University of Montreal, Montreal, Canada, [5]University of Toronto, Toronto, Canada, [6]McGill University, Montreal, Cameroon, [7]McMaster University, Hamilton, Canada, [8]Dalhousie University, Moncton, Canada, [9]Laval University, Quebec City, Canada, [10]Laval University, Montreal, Canada, [11]Dalhousie University, Saint John, Canada, [12]McMaster University, Montreal, Canada, [13]University of Manitoba, Winnipeg, Canada, [14]University of Western Ontario, London, Canada, [15]University of Ottawa, Ottawa, Canada

Background: Deep vein thrombosis (DVT) and pulmonary embolism (PE) are common complications post total hip (THA) and total knee arthroplasty (TKA). Prophylaxis with anticoagulants such as rivaroxaban extended beyond hospital discharged is commonly prescribed. We reasoned aspirin (ASA) would be an attractive alternative for extended prophylaxis because of its potential efficacy, low cost, convenience and few side effects.

Aims: To determine if ASA was as effective and safe as rivaroxaban for extended prophylaxis in patients already having received five days rivaroxaban post THA or TKA.

Methods: This was a 15 centre, double-blind, randomized controlled trial following THR or TKR. All patients received rivaroxaban 10mg orally once daily until post-operative day 5 and then were randomized to continue rivaroxaban 10 mg daily or aspirin 81 mg daily. Prophylaxis was continued for an additional 9 days following TKA or 30 days following THA. Patients were followed for 90 days for the development of symptomatic proximal DVT and PE or bleeding complications. No screening tests were performed.

Results: 3424 patients were included in the intention to treat analysis. This included 1804 patients undergoing THA and 1620 patients receiving TKA. Mean age was 62.8 and 47.8% of patients were male. 12 (0.70%) patients randomized to rivaroxaban experienced DVT or PE compared with 11 (0.64%) of patients randomized to ASA (-0.06%, 95% CI -0.66% to 0.55%; P < 0.0001 for non-inferiority and 0.84 for superiority). 17 (0.99%) of patients receiving rivaroxaban and 22 (1.3%) of patients receiving ASA experienced clinically important bleeding (0.30%, 95% CI 1.07% to -0.47%; P = 0.43). 5 (0.29%) patients receiving rivaroxaban and 8 (0.47%) of patients receiving aspirin experienced major bleeding complications (0.18%, 95% CI 0.65% to -0.29%; P = 0.42).

Conclusions: For patients receiving five days of rivaroxaban following THR or TKR, extended prophylaxis with ASA was at least as effective and safe as rivaroxaban.

OC 52.3 | A landmark analysis of the APEX study comparing extended duration betrixaban with standard duration enoxaparin in hospitalized medically ill patients

A.T. Cohen[1], M. Yee[2], D. Arbetter[2], R.A. Harrington[3], S.Z. Goldhaber[4], R.D. Hull[5], A.F. Hernandez[6], A. Gold[7], C.M. Gibson[2]

[1]Guy's and St Thomas' NHS Foundation Trust, Department of Haematology, London, United Kingdom, [2]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, United States, [3]Stanford University, Department of Medicine, Stanford, United States, [4]Brigham and Women's Hospital, Harvard Medical School, Cardiovascular Division, Boston, United States, [5]University of Calgary, Faculty of Medicine, Calgary, Canada, [6]Duke University and Duke Clinical Research Institute, Division of Cardiology, Durham, United States, [7]Portola Pharmaceuticals, Inc., San Francisco, United States

Background: Medically ill patients are at elevated risk for venous thromboembolism (VTE), with the majority of VTE events occurring after hospital discharge. While standard duration in-hospital thromboprophylaxis decreases the risk of in-hospital VTE, subsequent out of hospital thrombotic events occur when thromboprophylaxis is discontinued after discharge.

Aims: The aim of this APEX sub-analysis is to evaluate the efficacy and safety of extended duration betrixaban vs standard duration enoxaparin in the occurrence of symptomatic VTE (symptomatic DVT, non-fatal PE, and VTE related death) and major bleeding during three separate time periods throughout the study: the standard prophylaxis period, the extended betrixaban period, and the post-betrixaban follow-up period.

Methods: The survival analysis was performed according to the treatment periods and events in previous periods were censored from subsequent ones.

Results: During the standard prophylaxis period, VTE event rates were similar in the betrixaban and enoxaparin arms (HR=0.67, 95% CI=0.24-1.89, p=0.45). Administration of extended duration betrixaban was associated with a decrease in symptomatic events compared to enoxaparin following the standard prophylaxis period through day 35 (betrixaban = 25, enoxaparin = 42, HR = 0.61 (0.38-0.98), p = 0.041) and through day 42 (betrixaban = 27, enoxaparin = 44, HR = 0.61, 95% CI = 0.38-0.99, p = 0.041), as well as the post-betrixaban follow-up period (betrixaban = 2, enoxaparin = 12, HR = 0.17, 95% CI = 0.04-0.74, p = 0.007). No increase in major bleeding was seen at any time point, Table.

Conclusions: Compared to standard duration enoxaparin, betrixaban had similar VTE and major bleeding rates in the standard prophylaxis period. Extended duration thromboprophylaxis with betrixaban significantly reduced symptomatic VTE following hospital discharge in the extended prophylaxis period as well as following discontinuation of study drugs, consistent with a legacy effect, and was not associated with increased major bleeding.

TABLE Symptomatic VTE and Major Bleeding (Kaplan Meier Analysis Hazard Ratios) for the three time periods

	Betrixaban	Enoxaparin	Hazard Ratio (95% CI)	p-value
Standard Prophylaxis Period (Day 1-14)				
Symptomatic VTE	6/3714	9 /3716	0.67 (0.24-1.89)	0.45
Major bleeding	9/3714	9/3716	1.07 (0.43-2.71)	0.88
Extended Duration Betrixaban Period (Day 6-35)				
Symptomatic VTE	25/3661	42/3658	0.61 (0.38-0.98)	0.041
Major bleeding	16/3645	12/3632	1.33 (0.63-2.81)	0.45
Follow-up period, no prophylaxis (Day 35 to 77)				
Symptomatic VTE	2 /3495	12/3493	0.17 (0.04-0.74)	0.007
Major bleeding	0/3488	0/3510	-	-

OC 52.4 | Rivaroxaban Use in Extensive Superficial Thrombophlebitis

A. Webster[1], E. Millen[1], V. Frimpong[2], J. Eggleston[2], D. Thornton[2], H. Briggs[2], T. Stewart[2], R. Clarke-Drury[2], K. Coultas[2], J. Strong[1]

[1]*University Hospitals of Leicester, Haematology, Leicester, United Kingdom,* [2]*University Hospitals of Leicester, DVT Clinic, Leicester, United Kingdom*

Background: Superficial thrombophlebitis (STP) of the legs is now recognised as venous thromboembolic disease. Anticoagulation is required to prevent thromboembolic complications. Data regarding the use of the direct oral anticoagulant drugs in extensive STP is currently unavailable.

Aims: The primary aim was to validate the efficacy of treatment with rivaroxaban in patients with extensive STP. The secondary aim was to assess bleeding complications.

Methods: Over a 24 month period (November 2014 - November 2016) patients with extensive STP were identified using our DAWN VTE database. Extensive STP was defined as being greater than 5cm in length and more than 3cm from the deep venous system. These patients were treated with either low molecular weight heparin (LMWH) or rivaroxaban 15mg once daily for 6 weeks (Rx). Treatment failure was defined as progression to deep vein thrombosis (DVT), non-resolution requiring further treatment or STP recurrence within 100 days. Bleeding complications were defined as a bleeding episode leading to hospital admission or drop in mean haemoglobin level.

Results: 281 patients had extensive STP. 184 (65.5%) were treated with rivaroxaban, 91 (32.4%) were treated with LMWH. 6 patients receiving warfarin are excluded. 16 patients (8.6%) in the rivaroxaban group met the criteria for treatment failure compared to 19 patients (20.9%) in the LMWH group: progression to DVT (n= 8, 1 Rx vs 7 LMWH), non-resolution with need for further treatment of STP (n= 11, 7 Rx vs 4 LMWH), recurrence within 100 days (n=16, 8 Rx vs 8 LMWH). There is a statistically significant difference between the groups for treatment failure (p=0.004). There were no reported bleeding complications in either group.

Conclusions: The use of rivaroxaban appears to be as safe and effective in the treatment of extensive STP as low molecular weight heparin from our small study. It simplifies treatment and represents a saving in drug costs and medical resource.

OC 52.5 | Relationship between DOAC Levels and Subsequent Thromboembolic Events

S. Testa[1], O. Paoletti[1], C. Dellanoce[1], A. Banzato[2], B. Cosmi[3], R. Morandini[1], V. Pengo[2], D. Poli[4], L. Salomone[5], M. Tala[1], R. Testa[6], A. Tripodi[7], G. Palareti[8]

Background: Apixaban, dabigatran and rivaroxaban (DOAC) are administered at fixed dose in relation to clinical indications, individual characteristics and renal function without need of laboratory monitoring. Nevertheless, DOAC plasma concentrations show a high inter-individual variability both at trough and peak level. A post-hoc analyses of phase III trials indicates a relationship between DOAC plasma levels, as measured at trough, and thrombotic and bleeding complications in the follow up period. Thus, it might be informative to check for DOAC levels at steady state in real world patient population to explain bleeding/thrombotic events.

TABLE 1 Clinical characteristics and Ctrough drug levels in the study population

	Dabigatran	Rivaroxaban	Apixaban
Pts (n°)	163	153	194
Age (yr)mean ±SD	75.6±8.7	74.5±6.6	76.3±6.7

Pt 5	rivaroxaban	TIA	26
Pt 6	dabigatran	IMA	91
Pt 7	rivaroxaban	IMA	23
Pt 8	rivaroxaban	IMA	28
Pt 9/Pt 10	apixaban	Systemic embolism/DVT	112/44

Aims: To assess the relationship between DOAC trough anticoagulant level, measured within the first month of treatment, and thromboembolic events observed during 1 year follow up.

Methods: Consecutive naïve patients with Non Valvular Atrial Fibrillation referred to 4 Italian Anticoagulation Clinics, were enrolled in the study for the START-Laboratory Register. Age, $CHADS_2$ Score, HAS-BLED, kidney and liver function, concomitant medications were recorded. DOAC measurement at trough after 2 weeks from starting the drug and within the first month of treatment and clinical follow up were entered into a structured data base.

Diluted thrombin time calibrated for dabigatran, anti-FXa calibrated for rivaroxaban or apixaban were performed to determine plasma drug concentration.

Results: Between September 2015 and September 2016, 510 consecutive patients (163 dabigatran, 153 rivaroxaban, 194 apixaban) were enrolled. Main clinical characteristics, DOAC levels and thrombotic complications are in tables 1-2. We observed 10 thrombotic events (2%), all occurred after the first 6 months of treatment. All events were recorded in patients with drug trough levels below the mean value of biological variability, calculated for each drug.

Conclusions: Our data show a relationship between low DOAC levels and thrombotic events. Further prospective analysis will be needed to confirm this preliminary observation.

OC 60.1 | Short and Long Term Incidence of and Risk Factors for Post Thrombotic Syndrome after a First Deep Vein Thrombosis

Y.M. Ende-Verhaar[1], L.W. Tick[2], F.A. Klok[1], M.V. Huisman[1], F.R. Rosendaal[3], S.C. Cannegieter[3]

[1]LUMC, Thrombosis and Hemostasis, Leiden, The Netherlands, [2]Maxima Medical Center, Internal Medicine, Eindhoven, The Netherlands, [3]LUMC, Clincial Epidemiology, Leiden, The Netherlands

Background: The reported short-term incidences of post-thrombotic syndrome (PTS) after deep vein thrombosis (DVT) vary and the long-term incidence is unknown. Furthermore, studies reporting on risk factors for PTS are contradictory.

Aims: To assess the 0 to 1- and 1 to 7-year PTS cumulative incidence (CInc) in patients with a first DVT, and to evaluate the effect of several risk- and treatment factors.

Methods: Patients with a first DVT of the lower limb included in the MEGA study completed a questionnaire 1 and 7 years after the event. PTS was assessed by a clinical classification score based on the Villalta score. The CInc of PTS between 0 to 1- and 1 to 7-year was determined. The effect of possible risk factors was assessed by determining risk ratios (RR), adjusted for confounders if appropriate.

Results: Questions regarding PTS were completed by 1657 out of 3306 patients in the first questionnaire; 361 patients were diagnosed with PTS, for a 1-year CInc of 21.8% (95%CI 19.9-23.8). Of the 1244 patients without PTS at 1 year who completed the second questionnaire, 117 additional patients developed PTS, for a 9.4% 1-7 year CInc (95%CI 7.9-11.2). At 1 year, the RR for women vs. men was 1.5 (95%CI 1.2-1.9); for height < 165cm vs. 165-180 cm 1.5 (95%CI 1.2-1.9) and for 180-195cm vs. 165-180cm 1.3 (95%CI 1.0-1.7); for weight 85-100kg vs. 60-85kg 1.4 (95%CI 1.1-1.7) and for >100kg vs. 60-85kg 1.5 (95%CI 1.2-2.0). At 7 years, the same association was found for female sex and weight but not for height (*table 1).* Patients with PTS had more often been treated with oral anticoagulation for a period of >180 days and wore elastic compression stockings more frequently than patients without PTS (*table 2).* Provoked/unprovoked DVT, thrombus location, pregnancy, hormone use, factor V Leiden, prothrombin 20210A and FXIII mutation did not affect risk of PTS, either at 1 or 7 years.

Conclusions: The risk of PTS remains substantial up to seven years after a first venous thrombosis, and is highest in women and overweight individuals.

TABLE 1 Risk factors associated with PTS 1 and 7 years after DVT diagnosis. *Adjusted for age and sex. # Adjusted for sex, age and height

OC 60.2 | Rivaroxaban Reduces the Rate of Post-Thrombotic Syndrome After DVT - a Cross-Sectional Study Comparing Rivaroxaban to Warfarin

K.K. Utne[1,2], A. Dahm[3], H.S. Wik[4], L.-P. Jelsness-Jørgensen[1,5], P.M. Sandset[2,4], W. Ghanima[1,2]

[1]Ostfold Hospital Trust, Department of Hematology, Grålum, Norway, [2]University of Oslo, Institute of Clinical Medicine, Oslo, Norway, [3]Akershus University Hospital, Department of Hematology, Akershus, Norway, [4]Oslo University Hospital, Department of Hematology, Oslo, Norway, [5]Østfold University College, Department of Health Science, Fredrikstad, Norway

Background: Post thrombotic syndrome (PTS) is a common sequel after DVT. Poor quality treatment with Vitamin K antagonists (warfarin) is a risk factor for PTS.

Aims: To assess whether treatment with a direct oral factor Xa inhibitor, rivaroxaban, may lower the rate of PTS as compared to warfarin treatment.

Methods: In a cross sectional study we compared the 2-year rate of PTS in patients treated with rivaroxaban versus conventional anticoagulation with enoxaparin and warfarin in 309 patient with first time DVT. PTS was assessed using Patient Reported Villalta Scale (Utne et al Thromb Haemost, 115 (2), 361-7) 24 (+/- 6) months after DVT. PTS was defined as a score >4 points. Health-related quality of life (HRQoL) was assessed by EQ-5D and VEINES-QOL/Sym. Chi square test was performed to compare the rate of PTS between the two groups. Multiple logistic regression was performed to adjust for possible confounders. Regional etics committee approved the study.

Results: Mean age of 309 patients was 61 years (SD 14). Median observation time from diagnosis of DVT (index event) to study inclusion was 25 (interquartile range (IQR) 23-29) months. One hundred and sixty-one (52%) patients were treated with rivaroxaban and 148 (48%) with enoxaparin/warfarin. The prevalence of PTS was 45% versus 59% in patients treated with rivaroxaban versus enoxaparin/warfarin, respectively (p = 0.01). The difference in range of PTS between the two treatment groups remained significant (OR 0.5, 95% CI: 0.3-0.9; p=0.02) in the multivariate analysis after adjustment for possible confounders. Patients treated with rivaroxaban had better HRQoL as assessed by both EQ-5D index value (p=0.05), EQ-VAS (p=0.003), and by VEINES QOL/Sym (p=0.002/0.004).

TABLE Rate and severity of post-thrombotic syndrome according to the Patient Reported Villalta scale

PTS (n%)	Warfarin (n%)	Rivaroxaban (n%)
No	61 (41)	89 (55)
Mild	46 (31)	35 (21)
Moderate	26 (18)	28 (17)
Severe	15 (10)	9 (6)

Conclusions: Treatment of acute DVT with rivaroxaban resulted in statistically significant lower risk of developing PTS and better HRQoL as compared to treatment with enoxaparin/vitamin K antagonist.

OC 60.3 | Development and Validation of a Practical Two-step Prediction Model for Post-thrombotic Syndrome

E. Amin[1,2], S.M.J. van Kuijk[3], M.A. Joore[3], H. ten Cate[1], A.J. ten Cate-Hoek[1]

[1]Maastricht University, Internal Medicine, Maastricht, The Netherlands, [2]Maastricht University Medical Centre+, Clinical Epidemiology and Medical Technology Assessment, Maastricht, The Netherlands, [3]Maastricht University Medical Center +, Clinical Epidemiology and Medical Technology Assessment, Maastricht, The Netherlands

Background: Post-thrombotic syndrome (PTS) occurs in 20-50% of patients following deep vein thrombosis (DVT). Optimizing preventive therapy requires identification of patients at risk for PTS.

Aims: To develop a prediction model for PTS for use in the acute phase of DVT, and secondary use 6 months after the DVT.

Methods: Data from a cohort of 479 DVT patients from the Maastricht University Medical Center+ were used in multivariate logistic regression analyses. The obtained models were internally validated using standard bootstrapping techniques. Indices of the overall performance, discriminative ability, calibrations and characteristics of the models were determined. All analyses were done according to current ISTH definition, as well as the Prandoni definition of PTS.

Results: Depending on PTS definition (ISTH followed by Prandoni), PTS occurence at 6 months was 33.3% and 13.0%, and at 24 months 49.9% and 24.6%. Variables in the baseline model were: age, body mass index, gender, varicosities, DVT recurrence, smoking status and thrombus location. In the secondary model additional variables were residual thrombosis and spontaneous DVT. After internal validation the AUCs were 0.67 and 0.72 for baseline models, and 0.62 and 0.72 for secondary models, all indicating good discriminative ability. Calibration plots showed well calibrated predictions. Efficiency was greatest for the models using the Prandoni definition. At a threshold of 15%, 313/451(69,4%) patients were allocated to a low risk for PTS at the cost of 20/313 (6,4%) missed cases. For the ISTH definition this was 41/451(9.1%) at the cost of 2/41 (4,9%) missed cases.

Conclusions: A model based on readily accessible baseline clinical characteristics can accurately predict the baseline risk for developing PTS at 6 months after DVT. Additional clinical characteristics accurately predict the PTS risk in sub-acute DVT. Risk prediction is more accurate and efficient when the Prandoni definition is used.

OC 60.4 | Development of a Clinical Prediction Model for the Post-Thrombotic Syndrome in a Prospective Cohort of Patients with Proximal DVT: The SOX-PTS Index

A. Rabinovich[1], T. Ducruet[2], S.R. Kahn[3]

[1]Soroka University Medical Center, Faculty of Health Sciences, Ben Gurion University of the Negev, Thrombosis and Hemostasis Unit, Hematology Institute, Beer-Sheva, Israel, [2]University of Montreal, CHU Sainte-Justine Hospital, Montreal, Canada, [3]McGill University, Center for Clinical Epidemiology, Jewish General Hospital, Montreal, Canada

Background: Post-thrombotic syndrome (PTS) is a chronic complication that develops in 20-50% of patients after deep vein thrombosis (DVT). While individual PTS risk factors have been identified, the ability to predict which DVT patients are likely to develop PTS remains limited.

Aims: To develop a clinical prediction index for PTS in patients with proximal DVT.

Methods: The derivation cohort consisted of participants in the SOX trial, a randomized placebo controlled trial of elastic compression stockings vs. placebo stockings to prevent PTS after a first proximal DVT. Outcome was the occurrence of PTS using Ginsberg's criteria. Baseline characteristics evaluated as potential predictors of PTS included sex, age, BMI, ethnicity, anatomic extent of DVT, type of DVT (unprovoked vs. provoked), baseline Villalta score severity category, smoking, right vs. left leg DVT and family history of VTE. Potential predictors were evaluated in a multivariable logistic regression analysis with backward selection. Multiple imputation was done for missing outcome data. Final model performance was assessed for discrimination using the c-index and for calibration using calibration plots. Internal validation was done via nonparametric bootstrapping.

Results: The final model includes 3 independent predictors and has a range of possible scores from 0-4 (Table1; Figure1]). High-risk predictors were:

1) index DVT in iliac vein;

2) BMI>35 kg/m^2; and

3) moderate-severe Villalta severity category at DVT diagnosis.

Compared to patients with a score of 0, those with a score of 4 had an odds ratio of 5.9 (95% CI 2.1-16.6) for developing PTS.

TABLE 1 Clinical prediction index for PTS development in patients with first proximal DVT

Predictor Variables	OR for PTS	95% CI	Points
Iliac DVT	1.96	1.08-3.57	1
Non iliac DVT	1.00		0
BMI≥35	2.17	1.27-3.72	2
BMI<35	1.00		0
Baseline Villalta score category >14 (severe)	2.64	1.41-4.96	2
Baseline Villalta score category 10-14 (moderate)	2.00	1.21-3.29	1
Baseline Villalta score category 0-9 (none or mild)	1.00		0

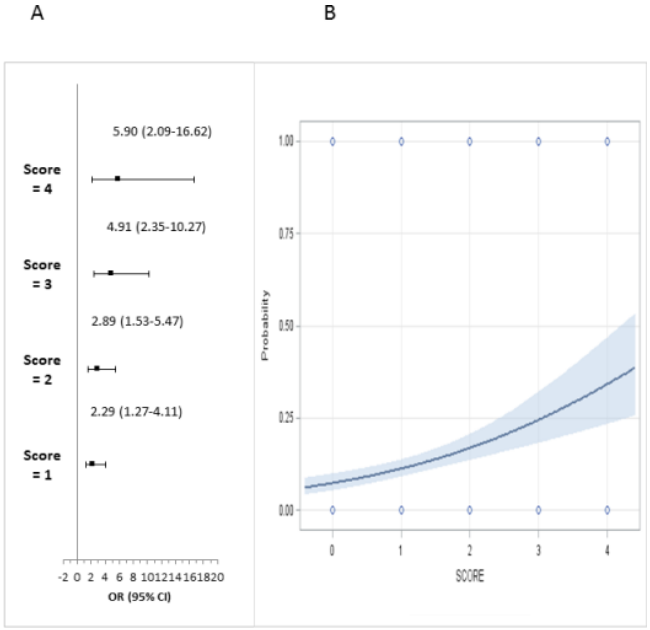

FIGURE 1 A. Odds ratios for PTS according to final score. B. Predicted probabilities with 95% CI according to maximum likelihood estimates

Conclusions: To our knowledge, this is the first clinical prediction index for PTS. We identified three independent predictors that, when combined, predicted risk for PTS after a first proximal DVT. The SOX-PTS index requires external validation before it can be considered for clinical use to inform prognosis or help select DVT patients for measures to prevent PTS.

OC 60.5 | No Compression, Multilayer Compression Bandaging or Compression Hosiery in the Acute Phase of Deep Vein Thrombosis in Relation to the Villalta Score, Health-related Quality of Life, and Costs at 3 Months after the Diagnosis

E. Amin[1], M.A. Joore[1], H. ten Cate[2], A.J. ten Cate-Hoek[3], the IDEAL DVT Investigators

[1]Maastricht University Medical Center, KEMTA, Maastricht, The Netherlands, [2]Maastricht University Medical Center, Internal Medicine, Maastricht, The Netherlands, [3]Maastricht University Medical Center, Thrombosis Expertise Center, Cardiovascular Center, Maastricht, The Netherlands

Background: Deep vein thrombosis (DVT) is a serious condition that affects quality of life and is associated with substantial costs ,especially if its complication post-thrombotic syndrome (PTS) occurs. The effectiveness of compression therapy in the acute phase of DVT is undetermined.
Aims: To assess the impact of compression therapy in the acute phase of DVT on Villalta score, quality of life, and costs.
Methods: A cohort of 864 patients with proximal DVT (nested within the IDEAL DVT study), received multilayer compression bandaging (MCB), compression hosiery (CH) or no compression (NC) in the acute phase of DVT. Signs and symptoms were assessed by the subjective, objective and total Villalta score three months after DVT, a lower score indicating less signs and symptoms. Six weeks and three months after DVT diagnosis, quality of life was measured using the EQ-5D, SF6D and VEINES-QoL. Utility and summary scores were calculated as well as costs.
Results: MCB and CH had lower objective Villalta scores than the NC group (1.47+1.57 and 1.60+1.67 vs 2.21+2.14) p0.000. The subjective and the total Villalta scores were similar across the groups. Six weeks after diagnosis, HRQOL was better in the CH group (EQ-5D 0.86±0.18, SF6D 0.77±0.13, VEINES-QoL 51.47±9.45) compared to MCB (EQ-5D 0.81±0.31, SF6D 0.74±0.13, VEINES-QoL 49.50±10.2),p0.027, p0.008, p0.022 and NC (EQ-5D 0.81±0.24, SF6D 0.73±0.12(p0.002), VEINES-QoL 49.06±9.45(p0.016)). At three months, the CH group performed better on SF6D (0.80±0.12) compared to NC (0.78±0.12) p0.049. Mean therapy costs per patient were highest in the MCB group, followed by HC, and NC.
Conclusions: Compression significantly reduced the objective Villalta by 15%. CH was associated with better quality of life than NC and MCB. Therapy costs are substantially lower with CH than MCB; therefore compression with CH seems to be the preferred option. Implications of lower objective Villalta score at three months as a result of MCB and CH for the development of PTS at a later stage have to be awaited.

OC 73.1 | VTE Risk Factors in an Irish Urban Obstetric Population

F. O'Shaughnessy[1,2,3], J. Donnelly[4], S. Cooley[4], K. Bennett[5], F. Ní Áinle[6,7,8], B. Cleary[1,3]

[1]Rotunda Hospital, Pharmacy Department, Dublin, Ireland, [2]Royal College of Surgeons in Ireland, SPHeRE Programme, Division of Population Health Sciences, Dublin, Ireland, [3]Royal College of Surgeons in Ireland, School of Pharmacy, Dublin, Ireland, [4]Rotunda Hospital, Department of Obstetrics and Gynaecology, Dublin, Ireland, [5]Royal College of Surgeons in Ireland, Division of Population Health Sciences, Dublin, Ireland, [6]Rotunda Hospital, Department of Haematology, Dublin, Ireland, [7]Mater Misericordiae University Hospital, Department of Haematology, Dublin, Ireland, [8]University College Dublin/Conway Institute, School of Medicine/ SPHERE Research Group, Dublin, Ireland

Background: Risk factors for pregnancy-associated venous thromboembolism (VTE) are well reported. However, the prevalence of VTE risk factors in our population is less well described. A deep understanding of the burden of VTE risk within a population is essential when developing and implementing strategies to prevent pregnancy-associated VTE.
Aims: To estimate the prevalence of risk factors for postpartum VTE in an Irish urban population.
Methods: Data were extracted from electronic VTE risk assessments which were routinely completed after delivery in the Rotunda Hospital, Dublin, between Sept 2014 and Dec 2016. Data were imported into SPSS Statistical Software for analysis. Descriptive statistics were used to explore the prevalence of VTE risk factors among the population.
Results: We studied VTE risk factors in 16,218 women, representing 83% of women who attended our institution in the study period. The majority of women (n=13,239, 82%) had at least one risk factor for VTE (Range=0-8, median=2). Half of the women assessed had 2 or more VTE risk factors and therefore would warrant prophylactic anticoagulant therapy according to recent guidelines from the Royal College of Obstetricians and Gynaecologists.

TABLE 1 Number of VTE risk factors recorded in postpartum VTE risk assessments in the Rotunda Hospital (Sept 2014-Dec 2016)

Number of risk factors	Number of women (%) (n=16,218)
0	2979 (18.4%)
1	5081 (31.3%)
2	4594 (28.3%)
3	2474 (15.3%)
4	774 (4.8%)
5	241 (1.5%)
6	54 (0.33%)
7	16 (0.1%)
8	5 (0.03%)

BMI >25kg/m^2, age over 35 years, parity greater than 3, caesarean delivery and instrumental delivery were the most common VTE risk factors recorded (Table 2). In women deemed to be at highest risk of VTE, additional risk factors included post-partum haemorrhage, delivery less than 37 weeks gestation, prior history of VTE and stillbirth. In 16% of women (n=2,663), VTE risk only arose in the intra-partum or post-partum period.

Conclusions: Risk factors for VTE are common and VTE risk is dynamic. Repeated VTE risk assessment is essential throughout pregnancy and into the postpartum period to ensure risk is accurately assessed. Thresholds for initiating prophylactic anticoagulation in the postpartum period must take into account the burden of VTE risk within the population.

TABLE 2 Frequency of VTE risk factors recorded in postpartum VTE risk assessments in the Rotunda Hospital (Sept 2014-Dec 2016)

Patient Related VTE Risk Factors	Number of women (n=16,218)	% (95% CI)	Pregnancy Related VTE Risk FactorS	Number of women (n=16,218)	% (95% CI)	Delivery Related VTE Risk Factors	Number of women (n=16,218)	% (95% CI)
BMI 25kg/m2 or above	5593	34.5% (34.1-34.8)	Parity 3 or above	2989	18.4% (18.2-18.7)	Caesarean Section	5025	31.0% (30.7-31.3)
Age 35 years or above	5380	33.2% (32.8-33.5)	IUGR	256	1.6% (-)	Instrumental Delivery	2486	15.3% (15.1-15.5)
Smoker	1048	6.5% (6.4-6.6)	Multiple Pregnancies	244	1.5% (-)	Delivery at less than 37 weeks´ gestation	806	5.0% (4.9-5.0)
Varicose Veins	298	1.8% (1.8-1.9)	Pre-eclampsia	212	1.3% (-)	PPH 1000ml or transfusion	513	3.2% (3.1-3.2)
High Risk Family History	28	1.8% (1.7-1.8)	Antenatal LMWH indicated	68	0.4% (-)	Prolonged labour	292	1.8% (-)
Significant Medical Co-morbidities	247	1.5% (-)				Manual removal of placenta	204	1.3% (1.2-1.3)
Immobility	214	1.3% (-)				Stillbirth	81	0.5% (-)
Prior VTE	84	0.5% (-)				Systemic Infection	76	0.5% (-)
Thrombophilia	67	0.4% (-)	VTE= Venous Thromboembolism, BMI = Body Mass Index, IUGR=Intrauterine Growth Restriction, PPH=Postpartum Haemorrhage, LMWH = Low Molecular Weight Heparin					

OC 73.2 | Low Persistence to Direct Oral Anticoagulants at Routine Treatment for Acute Venous Thromboembolism

C.E.A. Dronkers[1], W.M. Lijfering[2], M. Teichert[3], F.J.M. van der Meer[1], F.A. Klok[1], S.C. Cannegieter[1,2], M.V. Huisman[1]

[1]Leiden University Medical Center, Department of Thrombosis and Hemostasis, Leiden, The Netherlands, [2]Leiden University Medical Center, Department of Clinical Epidemiology, Leiden, The Netherlands, [3]Leiden University Medical Center, Department of Clinical Pharmacy & Toxicology, Leiden, The Netherlands

Background: Recently, direct oral anticoagulants (DOACs) became the treatment of choice for venous thromboembolism (VTE) in the Netherlands. The main advantages over vitamin K antagonists (VKAs) are that DOACs give possibly less major bleeding and that monitoring nor titration are needed. A drawback of no monitoring is the risk of decrease in drug adherence and persistence.

Aims: To audit treatment persistence of DOAC use in patients identified with acute VTE.

Methods: All patients from the administrative database of Dutch Community Pharmacies from 1 January 2012 - 1 April 2016 who initiated DOAC treatment for VTE in 1538 pharmacies (79% of total) in the Netherlands were included. Persistence to DOACs was identified as time from start of DOAC treatment to discontinuation (stopping DOAC or switch to another DOAC or VKA). Since the minimal

treatment duration with DOAC for acute VTE is 3 months, a cut-off point of 2 months treatment duration was chosen as the period in which discontinuation would be surely premature.

Results: Of 2048 patients, 115 patients used apixaban, 1593 rivaroxaban and 340 dabigatran. The 2-month cumulative incidence of discontinuing DOAC was 27%(95%CI 25-29%) (figure 1). 23% (122 of 531) of these patients switched to an alternative treatment, of whom 118 to VKA and 4 to another DOAC, while the others stopped permanently. In univariate logistic regression analysis, predictors for stopping DOAC or switching to alternative treatment were previous use of VKAs (odds ratio [OR] 1.8; 95%CI 1.2-2.8), type of DOAC (OR for rivaroxaban 2.3 (95%CI 1.4-3.8), OR for dabigatran 3.1 (95%CI 1.8-5.4), both compared to apixaban) and female sex (OR 1.2; 95%CI 0.9-1.4).

Conclusions: The cumulative incidence of stopping DOAC treatment for acute VTE or switching to another anticoagulant within 2 months was 27%. Further research to investigate the reasons and consequences of early stopping is urgently needed.

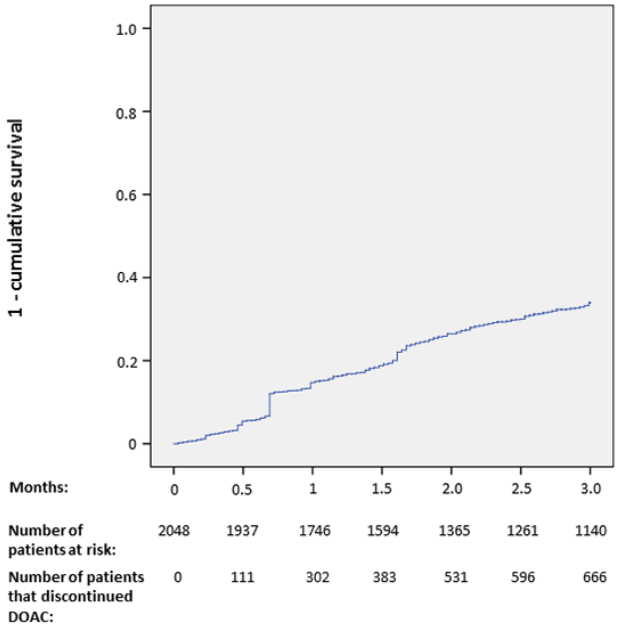

FIGURE 1 Cumulative incidence of discontinuing DOAC within the first 3 months after diagnosis of venous thrombosis

OC 73.3 | Management Strategies and Long-term Outcomes in Patients with Isolated Distal Deep Vein Thrombosis: Findings from the XALIA Study

W. Ageno[1], L.G. Mantovani[2], S. Haas[3], R. Kreutz[4], D. Monje[5], J. Schneider[6], M. van Eickels[6], M. Gebel[7], A.G.G. Turpie[8]

[1]University of Insubria, Department of Clinical and Experimental Medicine, Varese, Italy, [2]University of Milan Bicocca, CESP-Center for Public Health Research, Monza, Italy, [3]Formerly Technical University Munich, Munich, Germany, [4]Charité Universitaetsmedizin Berlin, Institute of Clinical Pharmacology and Toxicology, Berlin, Germany, [5]Bayer Vital GmbH, Leverkusen, Germany, [6]Bayer AG, Berlin, Germany, [7]Bayer AG, Wuppertal, Germany, [8]Hamilton Health Sciences, Medicine, Hamilton, Canada

Background: Isolated distal deep vein thrombosis (IDDVT) accounts for 30-50% of all DVT diagnosed in the lower limbs. Recent studies report conflicting results on the long-term risk of recurrent venous thromboembolism (VTE) and bleeding; thus, the optimal treatment of IDDVT remains controversial.

Aims: To report the results of a subgroup analysis of patients with IDDVT from XALIA.

Methods: XALIA was a prospective, non-interventional study of rivaroxaban in treatment of acute VTE. Patients aged ≥18 years scheduled to receive ≥3 months of anticoagulation with rivaroxaban or standard of care (SOC) were eligible. Patients were followed for ≥12 months. We describe baseline characteristics, management strategies and unadjusted incidence rates of recurrence, major bleeding and all-cause mortality in patients with IDDVT compared with patients with proximal DVT with or without distal vein involvement (PDVT). Only events on treatment were considered.

Results: Overall, 1004 patients with IDDVT and 3098 with PDVT were enrolled; 641 (63.8%) and 1683 (54.3%) received rivaroxaban, respectively. Table 1 shows selected baseline characteristics. Annualized symptomatic recurrent VTE rates with IDDVT were 1.85% (95% CI 0.60-4.31) for rivaroxaban and 3.1% (1.00-7.20) for SOC. For PDVT, recurrence rates were 2.7% (1.79-3.84) and 4.5% (3.23-5.97), respectively. Major bleeding rates with IDDVT were 1.5% (0.40-3.76) for rivaroxaban and 3.1% (0.99-7.13) for SOC, and 1.1% (0.57-1.92) and 3.1% (2.10-4.38), respectively, for PDVT. All-cause mortality was 0.4% (0.01-2.05) and 4.3% (1.71-8.76), respectively, with IDDVT, and 0.9% (0.44-1.69) and 5.6% (4.27-7.30) with PDVT.

Conclusions: Patients with IDDVT were younger, less fragile and less frequently had cancer than patients with PDVT. Patients with IDDVT more often received rivaroxaban and had lower recurrence rates than patients with PDVT. Bleeding rates were similar between the two groups. Rivaroxaban was safe and effective in patients with IDDVT.

TABLE 1 Baseline demographics and clinical characteristics.

Characteristic N (%) unless stated	IDDVT (N=1004)	PDVT (N=3098)
Age (years), mean (SD)	56.5 (17.1)	61.0 (16.7)
Female	551 (54.9)	1394 (45.0)
Creatinine Clearance <50 ml/min	27 (2.7)	173 (5.6)
Cancer	78 (7.8)	352 (11.4)
Known thrombophilia	54 (5.4)	177 (5.7)
Previous VTE	241 (24.0)	749 (24.2)
Previous major bleeding	17 (1.7)	70 (2.3)
Previous hospitalization	159 (15.8)	441 (14.2)
Provoked DVT	416 (41.4)	1053 (34.0)

OC 73.4 | Impact of BMI on Clinical Outcomes in Daily Care DOAC Recipients - Results of the Prospective Dresden NOAC Registry (NCT01588119)

L. Tittl, S. Marten, E. Sebastian, A. Reitter, T. Schreier, J. Beyer-Westendorf

Universitätsklinikum Carl Gustav Carus, Dresden, Germany

Background: Dose adjustment of direct oral anticoagulants (DOAC) for overweight patients is not recommended despite the potential for relative underdosing. At present, the impact of body mass index (BMI) on the effectiveness and safety of DOAC is unclear.

Aims: To evaluate the impact of BMI on clinical outcomes in daily care DOAC recipients.

Methods: Patients from a prospective, non-interventional registry were stratified according to BMI (table 1) and cardiovascular (CV), major bleeding events (MB) and all-cause mortality were evaluated. All outcome events were centrally adjudicated using standard scientific definitions.

Results: Between November 1st 2011 and June 30th 2016, 3273 patients were enrolled into the registry (64.0% received rivaroxaban; 18.9% apixaban; 10.6% dabigatran, 6.4% edoxaban). The mean duration of follow-up was 932±485 days (median 1047 days). With increasing BMI (range 13.7-57.2 kg/m^2), the proportion of patients receiving standard (vs. reduced) DOAC dose increased from 64.7% (underweight) to 78.3% (obesity class II/III; table 1).

Only one patient (BMI 42.2 kg/m^2) received higher dose because of high BMI (rivaroxaban 2x20mg from diagnosis until day 60, followed by 1 x 20 mg).

Although cardiovascular risk profile increased with rising BMI (table 1), rates of all clinical outcomes (CV, MB, all-cause-mortality) were lowest in overweight and obese patients, followed by normal-weight patients (figure 1 a-d).

Underweight patients had considerably higher rates of CV and MB and demonstrated an excess mortality, probably due to a higher prevalence of previous stroke, renal impairment and malignant disease, or DOAC dose reduction, although these observations were based on small numbers only.

Conclusions: In a large set of real-life DOAC recipients we found no indication that elevated BMI is associated with a lack of DOAC effectiveness or safety. Consistent with epidemiological data, increased BMI seems to be associated with a better survival also in DOAC recipients, if compared to underweight patients.

TABLE 1 Patient characteristics of all patients and BMI subgroups

	All patients n=3273	Underweight (<18.5) n=17	Normal (18.5-24.9) n=838	Overweight (25-29.9) n=1384	Obese class I (30-34.9) n=698	Obese class II/III (≥35) n=336
Age, years (mean±SD)	70.6±13.6	66.5±25.1	70.6±16.0	71.4±12.6	70.3±12.0	67.9±12.8
Heart failure, n (%)	824/3273 (25.2)	2/17 (11.8)	190/838 (22.7)	331/1384 (23.9)	188/698 (26.9)	113/336 (33.6)
Arterial hypertension, n (%)	2452/3273 (74.9)	6/17 (35.3)	536/838 (64)	1041/1384 (75.2)	573/698 (82.1)	296/336 (88.1)
Diabetes, n (%)	986/3273 (30.1)	2/17 (11.8)	171/838 (20.4)	375/1384 (27.1)	268/698 (38.4)	170/336 (50.6)
Peripheral arterial occlusive disease/coronary artery disease, n (%)	547/3273 (16.7)	1/17 (5.9)	143/838 (17.1)	221/1384 (16)	118/698 (16.9)	64/336 (19)
Prior TIA, stroke, or systemic embolism, n (%)	394/3273 (12)	3/17 (17.6)	110/838 (13.1)	163/1384 (11.8)	79/698 (11.3)	39/336 (11.6)
Impaired renal function, n (%)	283/3273 (8.6)	3/17 (17.6)	71/838 (8.5)	112/1384 (8.1)	64/698 (9.2)	33/336 (9.8)
active or history of cancer, n (%)	447/3273 (13.7)	4/17 (23.5)	132/838 (15.8)	193/1384 (13.9)	76/698 (10.9)	42/336 (12.5)
Reduced / standard dose, n (%)	891/2381 (27.2/72.7)	6/11 (35.3/64.7)	255/583 (30.4/69.6)	376/1008 (27.2/72.8)	182/516 (26.1/73.9)	72/263 (21.4/78.3)

OC 73.5 | Risk Factors for Death Following Major Bleeding Whilst on Warfarin or Direct Oral Anticoagulants: Results from a Prospective UK Study (ORANGE)

L. Green[1,2,3], J. Tan[1], R. Alikhan[4], N. Curry[5], T. Everington[6,7], R. Maclean[8], K. Saja[9], S. Stanworth[3,5], C. Tait[10], J. Morris[1], P. MacCallum[1,2]

[1]*Barts and the London School of Medicine and Dentistry, Queen Mary University of London, London, United Kingdom,* [2]*Barts Health NHS Trust, London, United Kingdom,* [3]*NHS Blood and Transplant, London, United Kingdom,* [4]*University Hospital of Wales, Cardiff, United Kingdom,* [5]*Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom,* [6]*Hampshire Hospitals NHS Foundation Trust, Basingstoke, United Kingdom,* [7]*Salisbury NHS Foundation Trust, Salisbury, United Kingdom,* [8]*Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom,* [9]*Barking, Havering and Redbridge University Hospitals NHS Trust, London, United Kingdom,* [10]*Glasgow Royal Infirmary, NHS Greater Glasgow and Clyde, Glasgow, United Kingdom*

Background: Major bleeding (MB) is an important complication of oral anticoagulant (OAC) therapy with potentially fatal outcomes. ORANGE was a UK multicentre prospective study that catalogued MB events in patients on warfarin or direct OACs (DOACs).

Aims: To identify the risk factors for death within 30 days of MB episode on OACs.

Methods: MB was defined as bleeding leading to hospitalisation and: death; transfusion of ≥2 units of red cells; ≥20 g/L drop in haemoglobin; bleeding into a critical organ; administration of haemostatic agents. Patients' age, sex, OAC regimen, co-morbidities linked to elevated thrombotic or bleeding risk, bleed sites and provocation were potential risk factors.

Results: We analysed the first MB episode of 2192 patients (53% male; median [IQR] age 80 [72-86] years) from 32 hospitals between Oct 2013 and Sep 2016. Patients (%) were on: warfarin (81); dabigatran (2); rivaroxaban (13); apixaban (4). OAC indications (%) were one or more (so total >100%) of: atrial fibrillation (72), venous thromboembolism (21), metal heart valve (10), others (8). Intracranial, gastrointestinal and other bleeds made up 44%, 32% and 24% respectively of cases. Outcomes at 30 days: 65% discharged; 20% died (median [IQR] days alive: 3 [1-8]); 12% inpatient; 3% lost to follow-up. Logistic regression (n=2132) showed no evidence that OAC type (p=0.99) or indication (p>0.34) were independently associated with mortality. Intracranial haemorrhage (ICH) was associated with 4.3-fold [95% CI: 3.0-6.0] higher odds of death compared with other bleeds. Unprovoked bleeding was associated with over twice the odds of death compared with bleeding from trauma (p< 0.001), surgery (p=0.09) or falls (p< 0.001). Age ≥75 years was also associated with death (p=0.003).

Conclusions: Hospital mortality following MB on OACs is 20%; the adjusted odds of death were similar for warfarin and DOACs. ICH, unprovoked bleeding and age ≥75 years were the strongest predictors of fatality.

OC 76.1 | High Affinity FXII Inhibitor Macrocycle Peptide for Safe Anticoagulation Therapy

R. Prince[1,2], J. Wilbs[3], S.J. Middendorp[3], C. Heinis[3], A. Angelillo-Scherrer[1,2]

[1]*Inselspital, Bern University Hospital, University of Bern, Department of Hematology and Central Hematology Laboratory, Bern, Switzerland,* [2]*University of Bern, Department of Clinical Research, Bern, Switzerland,* [3]*Institute of Chemical Sciences and Engineering, Ecole Polytechnique Fédérale de Lausanne, Lausanne, Switzerland*

Background: Coagulation factor XII (FXII), a serine protease that initiates the contact system, has a *highly conserved* amino acid sequence, suggesting a physiologic function. Mechanistic *in vivo* research indicates that FXII contributes to thrombosis by triggering excessive coagulation. Inhibiting FXII reduces thrombosis without increasing the bleeding risk, a major side-effect of currently used anticoagulants.

Aims: To characterize the first high affinity small molecule FXII inhibitor *in vitro* and *in vivo* in mice.

Methods: Bicyclic peptide synthesis, protease inhibition assays for the following serine proteases: tPA, uPA, factor XIa, plasma kallikrein, thrombin, plasmin, trypsin, factor VIIa, factor Xa, trypsin and factor XIIa, structural model and structure analysis, plasma stability assays, coagulation testing, pharmacokinetics, $FeCl_3$-induced thrombosis mouse model on mesenteric arterioles.

Results: We have generated a highly selective FXII inhibitor based on a macrocyclic peptide format (MW< 2000 kDa). Its potency and stability were improved using various approaches based on unnatural amino acid incorporation. It showed high inhibitory affinity and selectivity with a high stability in plasma (K_i=380±80pM, >200,000-fold selectivity, $t_{1/2}$ plasma >96h) and prolonged intrinsic coagulation in human, mouse and rabbit plasma (EC_{2X} human=1μM). Pharmacokinetic studies in mouse and rabbit showed activity *in vivo* with no signs of toxicity or abnormal bleeding. We then recorded thrombus formation in mouse mesenteric arterioles by intravital

microscopy, a thrombosis model sensitive to defects in the intrinsic pathway of coagulation. The peptide substantially reduces thrombus formation (peptide:3/9(33%), control: 7/8(87%) P< 0.05), full occlusion (peptide:0/9(0%), control:5/8(63%), P< 0.05), time to thrombus formation (peptide:20±3.6min, control:9.6±5.7min).

Conclusions: Our data suggest that FXII inhibition by a peptide macrocycle can potentially offer a safe anticoagulation therapy.

OC 76.2 | Improving the Therapeutic Index with JNJ-375: A Novel Long Acting Exosite-1 Thrombin Inhibitor In Animal Models

M. Chintala[1], Q. Li[1], Z. Huang Devine[1], P. Andrade-Gordon[1], J. Verbeeck[2], T. Baglin[3], J. Huntington[4], D. Grainger[3], R. Mason[3], K. Conde-Knape[2]

[1]*Janssen R&D, Cardiovascular Metabolic Discovery, Spring House, United States,* [2]*Johnson & Johnson Innovation Center, London, United Kingdom,* [3]*XO1, Cambridge, United Kingdom,* [4]*Cambridge University, Cambridge, United Kingdom*

Background: An antibody (Ab) against thrombin exosite-1 was identified from a 54 year-old female who presented with a traumatic subacute subdural hematoma and markedly prolonged coagulation tests at a hospital in Cambridge, UK. The patient made a complete recovery without intervention and had no abnormal bleeding during 8-years of follow-up, despite continuing to present with grossly prolonged coagulation tests. The Ab was characterized by scientists at Cambridge University and the resulting IP was licensed to XO1 Limited, a small biotech company that was later acquired by Janssen Pharmaceuticals, Inc. JNJ-375 is a human IgG4 antibody designed to mimic the patient's IgA antibody, with the same binding properties. JNJ-375 specifically binds to the exosite-1 region on thrombin and does not inhibit the active site.

Aims: Here we compare the antithrombotic efficacy and bleeding risk (therapeutic index, TI) of JNJ-375 with apixaban, a marketed factor Xa inhibitor.

Methods: In rat and monkey models.

Results: In the rat AV-shunt model thrombosis, JNJ-375 inhibited thrombosis (50%) at 0.3 mg/kg and the positive control apixaban (58%) at 1 mg/kg. In the rat tail transection model, JNJ-375 and apixaban significantly increase bleeding at 10 (TI=33) and 3 mg/kg (TI=3), respectively. In the FeCl3 model of venous thrombosis in cynomolgus monkeys, JNJ-375 and apixaban inhibit thrombosis significantly (> 80%) at 1 and 0.1 mg/kg respectively. In the cynomolgus monkey liver laceration bleeding model, JNJ-375 and apixaban significantly increase bleeding time at 40 (TI=40) and 1 mg/kg (TI=10), respectively.

Conclusions: The animal studies described here, demonstrate an improved TI of JNJ-375 over apixaban. In addition to the potential of a lower bleeding risk, JNJ-375 with a projected once monthly dosing regimen (Vs BID for apixaban), likely leading to steady anticoagulation for the duration of the dosing interval may provide better efficacy compared to existing agents. JNJ-375 is currently being investigated in early clinical studies.

OC 76.3 | Different Effects of Heparin and Bilvalirudin on Thrombin-induced Platelet Activation via PAR1 and PAR4

N. Boknäs[1,2], L. Faxälv[2], M. Wallstedt[2], T.L. Lindahl[2]

[1]*Linköping University Hospital, Department of Hematology, Linköping, Sweden,* [2]*Linköping University, Department of Clinical and Experimental Medicine, Linköping, Sweden*

Background: Heparin and bivalirudin are extensively used as antithrombotic agents during percutaneous coronary interventions (PCI). Although several large clinical studies have been performed, there is currently no consensus regarding which one of the two is associated with a superior clinical outcome. Heparin and bivalirudin inhibit thrombin by different mechanisms. Heparin bind strongly to exosite II, wheres bivalirudin inhibit thrombin via dual interaction with exosite I and the active site.

Aims: To characterize the inhibitory effects of heparin and bivalirudin on thrombin-induced platelet activation via PAR1 and PAR4.

Methods: Intracellular calcium measurements and flow cytometry was used to monitor platelet response to thrombin stimulation. Experiments were conducted in the presence of different inhibitors to distinguish between the contribution of PAR1 and PAR4 to platelet activation.

Results: At physiological levels of antithrombin, thrombin inhibition with heparin resulted in a transient calcium spike with a modest inhibition of peak height but no prolonged calcium mobilization, consistent with selective activation of PAR1. This finding was corroborated by experiments conducted in the presence of specific inhibitors of PAR1 and PAR4.

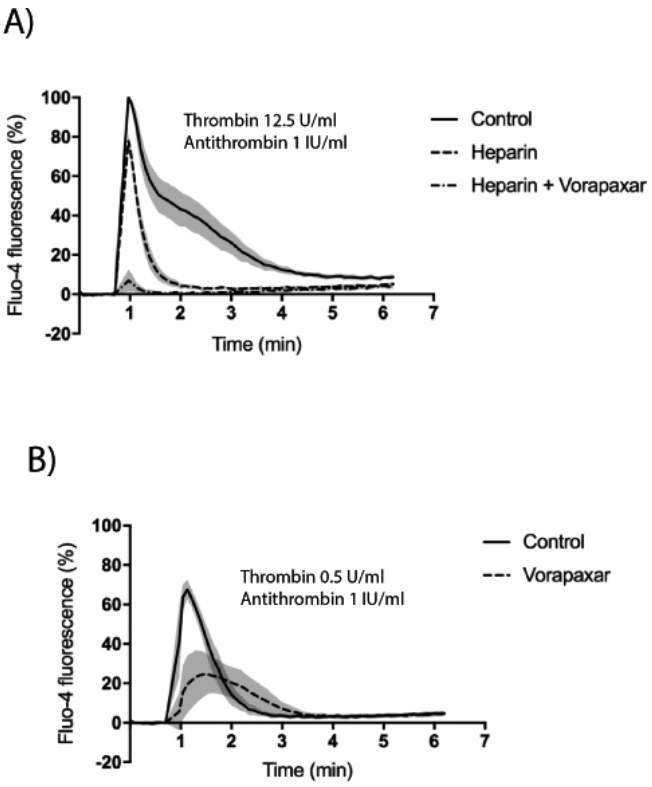

FIGURE 1 Thrombin-triggered calcium transients were measured on washed platelets alone or together with different antagonists as indicated. n ≥ 3

In contrast, thrombin inhibition with bivalirudin resulted in biphasic calcium mobilization, with an initial peak resulting from residual PAR1 activation, and a second delayed peak observed after 10-30 min which was found to be caused primarily by PAR4 activation, supposedly due recovery of thrombin activity as the bivalirudin-Arg3-Pro4 bond is cleaved.

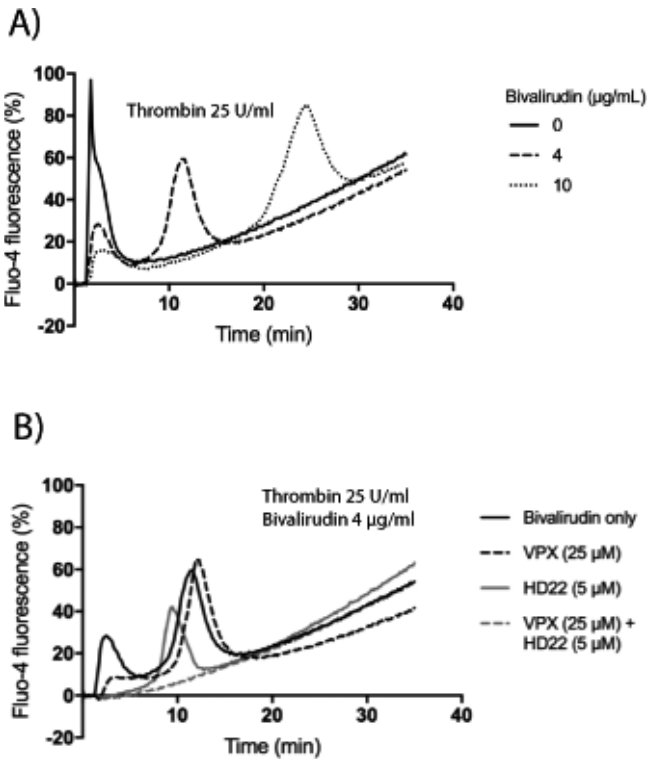

FIGURE 2 Thrombin-triggered calcium transients were measured on washed platelets alone or together with different antagonists as indicated. n ≥ 3

Conclusions: Our study shows that heparin and bivalirudin have different inhibitory effects on thrombin-induced platelet activation via PAR1 and PAR4. These findings could be of clinical relevance in the light of recent findings suggesting a higher rate of stent thrombosis after PCI with bivalirudin, and varying contributions of PAR receptors to thrombin-induced platelet activation among patients from different ethnic groups.

OC 76.4 | Pharmacokinetic and Pharmacodynamic Modeling of Andexanet Alfa Dose to Reverse the Anticoagulant Activity of Factor Xa Inhibitors in Patients with Acute Major Bleeding

J.M. Leeds[1], J.W. Mandema[2], G. Lu[1], J.T. Curnutte[1], T.J. Milling[3], M. Crowther[4], S.J. Connolly[4], P.B. Conley[1]

[1]*Portola Pharmaceuticals, Inc., South San Francisco, United States,* [2]*Certara, Menlo Park, United States,* [3]*Seton Dell Medical School Stroke Institute, Austin, United States,* [4]*McMaster University, Hamilton, Canada*

Background: Andexanet alfa is being investigated for reversal of anticoagulation by factor Xa (FXa) inhibitors. A PK/PD model, developed in healthy subjects, predicted the andexanet regimen required to reverse anticoagulation by FXa inhibitors.

Aims: To validate the PK/PD model using interim data from the ANNEXA-4 study in patients with acute major bleeding.

Methods: In ANNEXA-4, an ongoing prospective, open-label study, bleeding anticoagulated patients received andexanet IV bolus (400 or 800 mg) followed by 120-min infusion (4 or 8 mg/min). Anti-FXa activity was measured before andexanet administration (baseline), at end of bolus (EOB), end of infusion, and 4, 8, and 12 h after infusion. The relationship between baseline anti-FXa activity and reversal in healthy subjects was derived from the PK/PD model and used to provide a predicted percent reversal for patients with acute major bleeding.

Results: From the first interim analysis of ANNEXA-4, 73 patients (apixaban, 39; rivaroxaban, 34) had plasma levels available for model qualification, although ~7 did not meet criteria for inclusion into safety and ~27 did not meet criteria for efficacy analysis. The mean observed percent reversal of anti-FXa activity for rivaroxaban and apixaban was well predicted by the healthy subject PK/PD model; the point estimates fell within the 90% confidence intervals of predicted values. The percent reversal at EOB for rivaroxaban and apixaban were 74.4 [58.3-90.7] and 83.9 [75.3-92.5], compared to 76.3 and 84.1 predicted by the model (Tables 1 and 2). The predicted reversal fit within the observed confidence intervals through the first 4 h for rivaroxaban and apixaban, and extended through all evaluated time points for rivaroxaban and slightly outside of post 4-h time points for apixaban, possibly due to higher baseline anti-FXa activity levels for apixaban.

Conclusions: The PK/PD model in healthy subjects closely predicted the extent of reversal of anti-FXa activity for apixaban and rivaroxaban in patients with major bleeding.

TABLE 1 Comparison of mean predicted percentage of anti-FXa reversal vs. observed reversal for rivaroxaban at different time points

Time	N	Predicted percent reversal	Observed percent reversal [95% CI]
End of bolus (EOB)	32	76.4	74.4 [58.3 to 90.4]
End of infusion	33	78.3	77.4 [67.6 to 87.2]
4 hrs	32	31.8	32.0 [18.0 to 45.9]
8 hrs	33	40.7	43.6 [35.0 to 52.2]
12 hrs	32	51.0	56.9 [50.2 to 63.7]

TABLE 2 Comparison of mean predicted percentage of anti-FXa reversal vs. observed reversal for apixaban at different time points

Time	N	Predicted percent reversal	Observed percent reversal [95% CI]
End of bolus (EOB)	34	84.1	83.9 [75.3 to 92.5]
End of infusion	36	81.4	84.2 [77.3 to 91.1]
4 hrs	33	34.4	27.6 [10.2 to 45.0]
8 hrs	32	40.2	30.6 [25.1 to 36.1]
12 hrs	36	48.6	32.8 [26.1 to 39.5]

OC 76.5 | Plasma Level of Apixaban is Inversely Correlated with Hemoglobin Level due to Apixaban Binding to Deoxy-hemoglobin

R. De Cristofaro, M. Sacco, F. Berruti, S. Lancellotti

Catholic University of the Sacred Heart School of Medicine, Institute of Internal Medicine, Department of Hematology-Oncology, Roma, Italy

Background: Apixaban (APX) was associated with a significantly lower risk of major bleeding than warfarin. However, in the ARISTOTLE trial, a hematoctit < 45% was found as the most relevant risk factor for bleeding (HR=1.38). According with this finding, In a pilot study we found and inverse relationship between plasma level of APX and Hb concentration in patients treated with this drug. Moreover, APX molecule shows structural analogies with bezafibrate, a lipid-lowering agent to treat hyperlipidaemia, which is known to bind to deoxy-hemoglobin.

Aims: This study is aimed at investigating in vitro the possible direct interaction of apixaban with human hemoglobin.

Methods: The oxygen saturation curve of Hb was studied at 577 nm with a tonometer. The P_{50} of oxygen binding was measured as a function of APX concentration. The right docking pose of APX into the binding site of Hb was accomplished using Docking Server, which integrates AUTODOCK 4.0 program for docking calculation. Semiempirical, quantum mechanical methods were used for ligand set up, utilizing MOPAC software.

Results: APX concentrations causes progressive right-shifts of the oxygen dissociation curve of dilute Hb solution. This implies that APX binds to the deoxy form of Hb with a calculated Kd in the micromolar range at 25 °C. In silico analysis showed that APX binds to the deoxy Hb central water cavity, where also bezafibrate binds. In particular, the piperidyl- moiety of APX fits into a cavity surrounded by residues α1Thr134, α 2Pro95, α 2Thr137, α 2Tyr140, α 2Arg141, and β1Trp37 of Hb. The phenoxy ring of APX engages in hydrophobic contacts with Hb α1Lys99, α2Arg141, β1Tyr35 and β1Trp37.

Conclusions: APX interacts with deoxy-Hb and reduces its affinity for oxygen. Thus, in venous circulation, where about 30% of Hb is in its deoxy-form, the hemoprotein can buffer the amount of APX that is able to pass through the red cell membrane due to its high lipophilicity. This phenomenon could significantly change the level of the available drug in the circulation.

PATHOGENESIS OF THROMBOEMBOLISM

OC 21.1 | Development and External Validation of a Risk Assessment Model for Cancer-associated Venous Thromboembolism

I. Pabinger[1], N. van Es[2], G. Heinze[3], F. Posch[1], N. Kraaijpoel[2], H.R. Büller[2], C. Ay[1], on behalf of the contributors to the Vienna Cancer and Thrombosis Study (CATS) and the Multinational Cohort Study to Identify Cancer Patients at High Risk of Venous Thromboembolism (MICA)

[1]*Medical University of Vienna, Clinical Division of Haematology & Haemostaseology, Department of Medicine I, Vienna, Austria,* [2]*University of Amsterdam, Academic Medical Center, Department of Vascular Medicine, Amsterdam, The Netherlands,* [3]*Medical University of Vienna, Section of Clinical Biometrics; Center for Medical Statistics, Informatics and Intelligent Systems, Vienna, Austria*

Background: Venous thromboembolism (VTE) is a frequent complication in cancer patients.

Aims: To develop and externally validate a risk assessment model for cancer-associated VTE.

Methods: Two prospective cohorts of patients with solid cancer, the Vienna Cancer and Thrombosis Study (CATS, n=1,423), and the Multinational cohort study to Identify CAncer patients at high risk of VTE (MICA, n=832), were used for development and external validation of the risk assessment model (**Table 1**). The primary outcome was symptomatic or unsuspected, objectively confirmed VTE at 6 months of follow-up. The cumulative 6-month incidence was 5.7% in CATS (95%CI: 4.5-6.9), and 6.3% (4.7-8.2) in MICA. Tumor sites were categorized into low/moderate, high, and very high VTE risk sites according to Khorana et al. (Blood. 2008).

TABLE 1 Baseline characteristics of the two study populations (total n=2,255)

Cohort	CATS (n=1,423)	MICA (n=832)
Variable	Median [25th-75th percentile], or Absolute count (percent)	Median [25th-75th percentile], or Absolute count (percent)
Age at entry (years)	61.7 [51.6 - 68.5]	63.7 [55.9-70.3]
Female Gender	651 (45.8%)	354 (42.5%)
Body mass index (kg/m²)	25.0 [22.1-28.3]	24.7 [22.5-27.4]
Newly-diagnosed malignancy	1,008 (70.8%)	454 (54.6%)
---Low/Moderate VTE risk tumor site (Breast, Prostate)	379 (26.6%)	271 (32.6%)
---High VTE risk tumor site (Lung, Esophagus, Colorectal, Kidney, Lymphoma, Gynaecologic, Bladder, Other sites)	863 (60.7%)	408 (49.0%)
---Very high VTE risk tumor site (Stomach, Pancreas)	181 (12.7%)	153 (18.4%)
D-Dimer (µg/mL)	0.7 [0.4-1.5]	0.9 [0.5-2.0]

Results: In the CATS cohort, a penalized likelihood regression (LASSO) was used to select predictive variables from a broad set of clinical and laboratory factors, which led to a final model including two variables, the tumor site category (hazard ratio (HR) per 1 category increase=1.96, 95%CI: 1.41-2.72, p=0.0001), and D-Dimer (HR per doubling=1.32, 1.12-1.56, p=0.001). The model discriminated well between cancer patients with and without VTE (C-Index=0.67, 95%CI 0.64-0.68) and was appropriately calibrated. As compared to the Khorana score, the new model correctly re-classified a significant proportion of patients according to their outcome (net reclassification improvement=0.44). In the external validation cohort (MICA study), the resulting nomogram (**Figure 1**) demonstrated good discrimination (C-Index=0.66, 95% CI: 0.58-0.72) and good calibration. Tumor site specific D-Dimer cut-offs over a range of VTE risk thresholds will be presented at the meeting.

Conclusions: An externally validated risk assessment model of only one clinical factor (tumor site) and one biomarker (D-Dimer) predicts

the risk of VTE in cancer patients. This simple model can aid physicians in selecting patients for thromboprophylaxis.

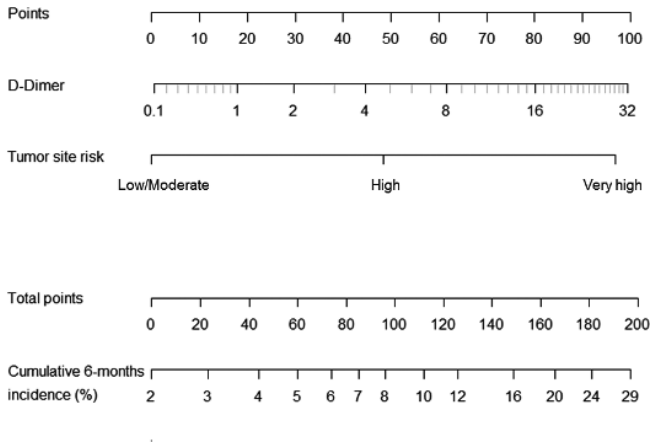

FIGURE 1 Externally-validated nomogram for predicting the risk of VTE in patients with cancer.

OC 21.2 | Comparison of Risk Prediction Scores for Cancer-Associated Venous Thromboembolism: A Prospective Cohort Study

N. van Es[1], M. Di Nisio[2], G. Cesarman[3], A. Kleinjan[1], H.-M. Otten[4], I. Mahé[5], I.T. Wilts[6], D.C. Twint[7], E. Porreca[8], O. Arrieta[3], A. Stépanian[9], K. Smit[7], M. De Tursi[8], S.M. Bleker[10], R. Nieuwland[1], P.W. Kamphuisen[6,11], P.M. Bossuyt[1], H.R. Büller[1]

[1]Academic Medical Center, Amsterdam, The Netherlands, [2]G. D'Annunzio University, Department of Medicine and Ageing Sciences, Chieti, Italy, [3]Instituto Nacional de Cancerología, Mexico City, Mexico, [4]Slotervaartziekenhuis, Amsterdam, The Netherlands, [5]Hôpital Louis Mourier, Paris, France, [6]University Medical Center Groningen, Groningen, The Netherlands, [7]VU Medical Center, Amsterdam, The Netherlands, [8]G. D'Annunzio University, Chieti, Italy, [9]Hôpital Lariboisière, Paris, France, [10]Academic Medical Center, Department of Vascular Medicine, Amsterdam, The Netherlands, [11]Tergooi Hospital, Hilversum, The Netherlands

Background: In ambulatory patients with solid cancer, thromboprophylaxis to prevent venous thromboembolism (VTE) is not recommended. Several risk prediction scores have been developed to identify cancer patients at high risk of VTE, but their clinical usefulness remains a matter of debate.

Aims: To evaluate and directly compare the performance of the Khorana, Vienna, PROTECHT, and CONKO scores (Table) in predicting VTE in ambulatory cancer patients.

Methods: In this multinational, prospective cohort study, patients with advanced cancer were enrolled when they had recently started or were scheduled for chemotherapy. Patients receiving anticoagulants or adjuvant chemotherapy were excluded. The primary outcome was objectively confirmed, symptomatic or incidental deep vein thrombosis or pulmonary embolism over a 6-month follow-up period. The discriminatory performance (c-statistic), the positive predictive value, and the difference between low and high risk patients at the positivity threshold of 3 points were evaluated in a competing risks analysis.

Results: A total of 876 patients with nine different stage III or IV tumor types were enrolled, of whom 260 (30%) had not yet received chemotherapy. Fifty-three patients (6.1%) developed VTE. C-statistics of the scores ranged from 0.50 to 0.57. At the positivity threshold of 3 points, the scores classified 13-34% of patients as high risk; the 6-month VTE incidence in these patients ranged from 6.5% (95% CI, 2.8-12%) for the Khorana score to 9.6% (95% CI, 6.6-13%) for the PROTECHT score. High risk patients had a significantly higher risk of VTE if defined on the Vienna CATS (subhazard ratio 1.7; 95% CI 1.0-3.1) or PROTECHT scores (subhazard ratio 2.1; 95% CI 1.2-3.6; Figure).

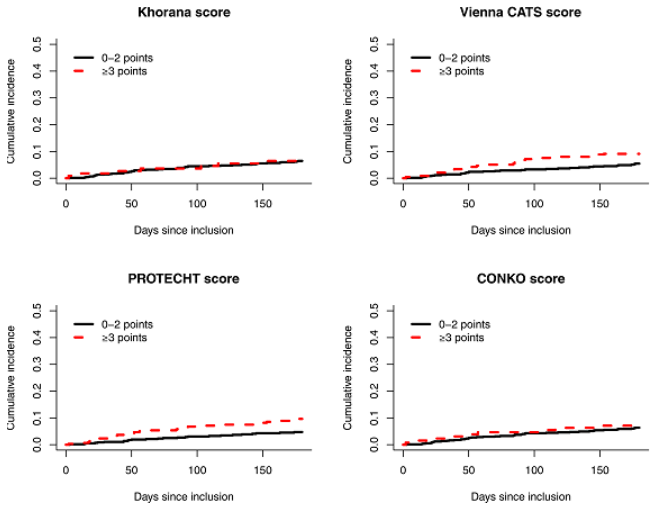

FIGURE Cumulative VTE incidence in low and high risk patients according to the four scores

Conclusions: The prediction scores performed relatively poorly in predicting VTE in cancer patients. The Vienna CATS and PROTECHT scores appear to discriminate better between low and high risk patients, but research is needed to further improve their performance prior to introduction in clinical practice.

TABLE Risk prediction scores

Item	Khorana score (points)	Vienna CATS score (points)	PROTECHT score (points)	CONKO score (points)
Very high risk tumor / high risk tumor	+2 / +1	+2 / +1	+2 / +1	+2 / +1
Hemoglobin <10 g/dL or ESA use	+1	+1	+1	+1
White blood cell count >11 x 10^9/L	+1	+1	+1	+1
Platelet count ≥350 x 10^9/L	+1	+1	+1	+1
Body mass index >35 kg/m2	+1	+1	+1	+1
D-dimer >1.44 g/L	-	+1	-	-
Soluble P-selectin >53.1 g/L	-	+1	-	-
Gemcitabine / platinum-based chemotherapy	-	-	+1 / +1	-
WHO performance status ≥2	-	-	-	+1

OC 21.3 | External Validation of a Risk Score for Occult Cancer in Patients with Unprovoked Venous Thromboembolism: Results from an Individual Patient Data Meta-Analysis

D'Annunzio University, Dipartimento di Medicina e Scienze dell'Invecchiamento, Chieti, Italy, [17]Academic Medical Center, Department of Clinical Epidemiology, Biostatistics, and Bioinformatics, Amsterdam, The Netherlands, [18]Centre Hospitalo-Universitaire de Brest, Service de Médecine Nucléaire, Brest, France

Background: Unprovoked venous thromboembolism (VTE) may be the first sign of occult cancer. A prediction score to identify VTE patients at increased risk of an occult cancer diagnosis was recently proposed (Table).

Aims: To evaluate the performance of the risk prediction score for occult cancer detection in patients with unprovoked VTE.

Methods: Combined data from 10 prospective studies that evaluated cancer screening in patients with unprovoked VTE were used. As in the derivation study, cases were defined as patients in whom cancer was diagnosed between 30 days and 2 years of follow-up. No information was available on chronic lung disease within our database. Therefore, 1 point was assigned to all patients who were former or current smokers as a proxy. Using random effect meta-analyses, the score's discriminatory performance (c-statistic), positive predictive value, and association with occult cancer detection were evaluated. A multivariable analysis was performed to explore the predictive performance of the separate items.

Results: The risk score for occult cancer diagnosis could be calculated in 1,869 of 2,371 patients (79%), who were enrolled in five studies. Twenty-nine patients were excluded because they were diagnosed with cancer within 30 days. Of the remaining 1,840 patients, 65 (3.5%) were diagnosed with cancer over a median follow-up of 402 days. The pooled c-statistic of the continuous score was 0.59 (95% CI 0.52-0.67). Of the 446 patients (24%) classified as ‚high risk' (≥3 points), 26 (5.8%) were diagnosed with cancer compared to 39 of 1,394 (2.8%) low-risk patients (pooled hazard ratio 2.1; 95% CI 1.3-3.4; P=0.004; Figure). In the multivariable analysis, age >70 years was the strongest predictor of occult cancer detection (P=0.0024).

Conclusions: The risk score had a poor overall discriminatory performance. However, when used dichotomously, it was able to discriminate between low and high risk patients. The performance of the score was largely driven by the item age >70 years.

TABLE Risk prediction score of occult cancer detection in patients with venous thromboembolism (Jara-Palomares et al., Chest, 2016)

Item	Points
Male sex	+1
Age >70 years	+2
Chronic lung disease	+1
Anemia (<13 g/dL in males or <12 g/dL in females)	+2
Platelet count ≥350 x 10^9/L	+1
Previous venous thromboembolism / recent surgery	-1 / -2
Classification	
Low risk	≤2
High risk	≥3

Barcelona, Spain, [6]Hospital Olot i Comarcal de la Garrotxa, Department of Internal Medicine, Gerona, Spain, [7]Hospital Sant Pau i Santa Tecla, Department of Internal Medicine, Tarragona, Spain, [8]Vascular Medicine and Haemostasis, University of Leuven, Leuven, Belgium, [9]Hospital Universitari Germans Trias i Pujol de Badalona, Department of Internal Medicine, Barcelona, Spain

Background: The benefits of a diagnostic workup for occult cancer in patients with venous thromboembolism (VTE) are controversial. In a recent study, a prognostic model to identify VTE patients at increased risk for occult cancer was proposed with an internal validity.

Aims: We used the RIETE database to validate the score in a subsequent cohort of patients.

Methods: The following variables scored 1 point: male sex, chronic lung disease and platelet count ≥350 x 10^9/L each; 2 points: age >70 years and anaemia; -1 point: previous VTE; -2 points: recent surgery. We dichotomized patients as having low (≤2 points) or high risk for cancer (≥3 points). We calculated the area under the receiver-operating characteristic curve, and hazard ratio of occult cancer in high-risk score patients.

Results: From 2014 to 2016, 11,695 VTE patients were recruited. At 12 months, there were 2,580 eligible patients. Of these, 93 (3.6%; 95%CI: 2.9 to 4.4%) were diagnosed with occult cancer. Mean age was 64.7 ± 17.6 years, and 51% were female. The most frequent sites were: colorectal (16.5%), lung (14.6%) and hematologic (14.6%). Among 1,849 patients scoring ≤2 points, 46 (2.5%) had occult cancer. Among 731 patients scoring ≥3 points, 47 (6.4%) had cancer (hazard ratio 2.7; 95% CI 1.8-4.1). C-statistic was 0.65 (95% CI 0.59-0.71). At 24 months, 103 of 628 eligible patients (16.4%; 95%CI: 13.6 to 19.5%) were diagnosed with occult cancer. Among 429 patients scoring ≤2 points, 53 (12.4%) had occult cancer. Among 429 scoring ≥3 points, 53 (25.1%) had cancer (hazard ratio 2.3; 95% CI 1.5-3.7; p< 0.01). C-statistic was 0.63 (95% CI 0.57-0.69).

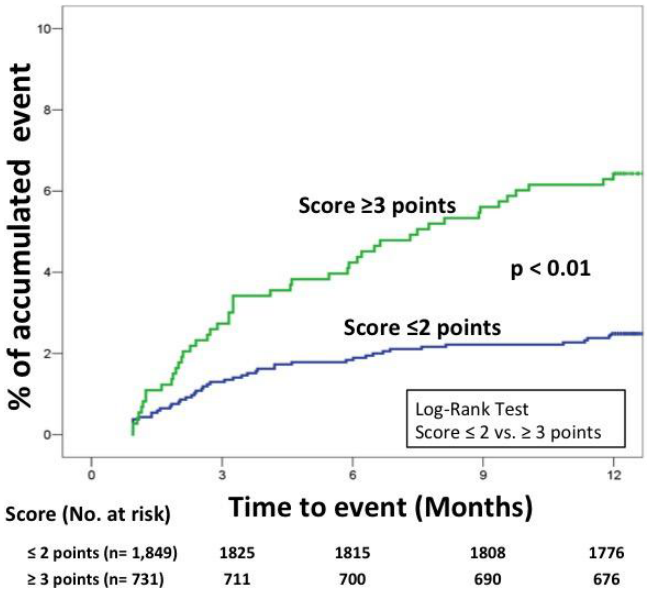

FIGURE 1 Cumulative incidence of occult cancer over 2 years attending score (≤2 vs. ≥3 points). Time-to-event data

Conclusions: We externally validated our score at 12 and 24 months.

OC 21.5 | Thrombin Generation Predicts for Early Cancer Recurrence in Breast Cancer Patients Undergoing Post-surgical Adjuvant Therapy: A Prospective Study

C. Giaccherini[1], M. Marchetti[1], C. Verzeroli[1], G. Masci[2], L. Celio[3], B. Merelli[4], R. Sarmiento[5], S. Brevi[1], S. Gamba[1], V. Milesi[1], L. Russo[1], C.J. Tartari[1], P. Malighetti[6], D. Spinelli[6], F. De Braud[3], R. Labianca[7], G. Gasparini[8], A. Santoro[2], A. Falanga[1]

[1]ASST Papa Giovanni XXIII, Immunohematology and Transfusion Medicine, Bergamo, Italy, [2]IRCCS Humanitas Institute, Medical Oncology, Rozzano, Italy, [3]Fundation IRCCS National Cancer Institute, Milan, Italy, [4]ASST Papa Giovanni XXIII, Medical Oncology, Bergamo, Italy, [5]Hospital San Filippo Neri, Medical Oncology, Rome, Italy, [6]Università degli Studi di Bergamo, Human factor and Technology in Healthcare, Bergamo, Italy, [7]ASST Papa Giovanni XXIII, DIPO, Bergamo, Italy, [8]IRCCS Cancer Institute Giovanni Paolo II, Bari, Italy

Background: Breast cancer screening has greatly increased early diagnoses, so that cancer treatments by surgery and systemic adjuvant chemotherapy (SAC) can be anticipated and reduce the risk of disease recurrence (DR). However, local relapses and distant metastasis may occur in 2-7% and 20% of resected patients, respectively, in the 10 years following surgery. In this setting, the identification of prognostic biomarkers for DR can help to identify high-risk patients who might most benefit from more aggressive therapy.

Aims: This study wants to evaluate whether hemostatic biomarkers may be prognostic of early DR in a group of breast cancer patients undergoing post-surgical SAC.

Methods: Plasma samples from 588 limited-resected breast cancer patients (8M/580F), enrolled in the Italian, prospective, multicenter HYPERCAN study (AIRC 5x1000 grant #12237), were obtained at enrollment before starting SAC and after 1, and 2 years follow-up. Samples were tested for fibrinogen, D-dimer, and thrombin generation (TG). Clinical data and information regarding surgery, cancer subtype, and treatment were recorded. DR was routinely monitored by imaging during post-treatment surveillance.

Results: At enrollment, fibrinogen levels were in the normal range, while D-dimer and TG were increased. During follow-up, D-dimer significantly diminished over time, while no modifications occurred in the other biomarkers. After 2 years follow-up, 5.7% of patients presented with DR. A TG peak value ≥394 nM at enrollment was an independent risk factor for early DR, also after correcting for gender, age and triple-negative subtype (HR=2.28; 95% CI 1.25-4.16; p< 0.01). Differently, DR was not associated with fibrinogen and D-dimer levels.

Conclusions: Our data show, for the first time, the prognostic significance of TG measurement on the risk of early DR in resected breast cancer patients. With a proper validation, this biomarker can be a candidate to tailor a risk-adapted adjuvant treatment.

OC 32.1 | Genetic Associations of a Clinical Pulmonary Embolism among Those with a Venous Thromboembolism: The INVENT Consortium

Jebsen Thrombosis Research and Expertise Centre (TREC), Department of Clinical Medicine, Tromsø, Norway, [19]Harvard T.H. Chan School of Public Health, Department of Epidemiology, Boston, United States, [20]University of Washington, Department of Biostatistics, Seattle, United States, [21]University of Washington, Departments of Medicine, Epidemiology, and Health Services, Seattle, United States, [22]Massachusetts General Hospital, Department of Emergency Medicine, Boston, United States

Background: Pulmonary emboli (PE) can be life-threatening sequelae of deep vein thrombosis (DVT). Little is known about the genetic risk factors for clot embolization in those with DVT.

Aims: We used genome-wide markers from 12 studies of incident venous thromboembolism (VTE) to investigate genetic risks of developing a PE among those with DVT.

Methods: Participants were 8,905 adults (63% women, average age 56 years) who experienced a first VTE in each study. For these analyses, the outcome was a PE diagnosis (n = 3662, 41% of all VTE), with or without a concomitant DVT diagnosis, among those with an incident VTE. The comparison group was those whose incident VTE was a DVT only. In each study, the association between 1000-genomes imputed genetic variation and PE was assessed with an additive genetic model using logistic regression that adjusted for age, sex, and study-specific design variables. Data were meta-analyzed across studies using fixed-effects models with inverse-variance weighting. The threshold of genome-wide statistical significance was set at 5.0E-8.

Results: After applying quality control procedures, 1 locus exceeded the threshold of genome-wide significance: rs6025 (factor V Leiden variant; minor allele frequency [MAF] 0.074): odds ratio (OR) 0.72; p-value 8.2E-11. A high-signal locus (rs9485137; MAF 0.15; OR 1.20; p-value 3.9E-7) was located in *STXBP5-AS1*, which is antisense RNA to *STXBP5*. Several studies have previously reported that the factor V Leiden variant is more strongly associated with DVT alone than with PE. Our results add further evidence and provide an estimate of the difference in relative odds. The *STXBP5-AS1* association is novel. This locus is anti-sense RNA to *STXBP5*, a gene previously implicated in the risk of incident VT. The rs9485137 variant was not in linkage disequilibrium with the *STXBP5* variants.

Conclusions: We identified genetic variation that may be associated with the embolization of clots among those who experience a VTE; replication of the *STXBP5-AS1* locus is needed.

OC 32.2 | Genetic Footprint of Endothelial Cells in Chronic Thromboembolic Pulmonary Hypertension

M.L. Bochenek[1,2], K. Saar[3], F. Marini[4], A. Gerhold-Ay[4], N. Hübner[3], T. Münzel[1], E. Mayer[5], S. Konstantinides[2], K. Schäfer[1]

[1]University Medical Center, Johannes Gutenberg University, Cardiology I, Mainz, Germany, [2]University Medical Center, Johannes Gutenberg University, Center for Thrombosis and Hemostasis, Mainz, Germany, [3]Max Delbrück Center for Molecular Medicine, Berlin, Germany, [4]University Medical Center, Johannes Gutenberg University, Institute of Medical Biostatistics, Epidemiology and Informatics, Mainz, Germany, [5]Kerckhoff Klinik, Thoracic Surgery, Bad Nauheim, Germany

Background: Studies in mice have shown that thrombus neovascularization plays a role during venous thrombus resolution. In specimens from patients with Chronic Thromboembolic Pulmonary Hypertension (CTEPH), characterized by thrombus non-resolution and increased fibrosis, endothelial cell-poor thrombi were observed.

Aims: To determine the genetic footprint of CTEPH endothelial cells and their role in the accumulation of thrombofibrotic material.

Methods: Visually identified endothelial cells outgrown from CTEPH specimens were processed for whole gene microarray analysis. Human Umbilical Vein Endothelial cells (HUVECs) and Human Pulmonary Arterial Endothelial cells (HPAECs) were used as control.

Results: Microarray analysis revealed that out of 26.808 genes examined, the expression of 105 genes was misregulated in CTEPH vs. HUVECs and vs. HPAECs (False Discovery Rate= 0.05). Endothelial (VWF, CDH5, ICAM2) and apoptotic (CASP2, CCND1) markers were expressed on similar level. However, certain proliferation markers (CCNA1, CCND1) were upregulated in CTEPH cells. Pathway analyses using two databases (Gene Onthology, Reactome) revealed misregulation of diverse genes in 14 pathways of biological processes. In brief, CTEPH endothelial cell profiling exhibited a ‚pro-fibrotic', ‚pro-coagulable' and ‚pro-inflammatory' phenotype, as suggested by the upregulation of genes involved in extracellular matrix production (COL1A1, COL1A2, COL3A1, ACTA), degradation (TIMP1,

MMP1, FBN2, CD44, CTSS, CTSK) and cell-matrix adhesion (VCAM1, POSTN, APOD), collagen catabolism (CTSS, CTSK, MRC2, ADAMTS2) or fibril organization (COL1A1, COL1A2, COL3A, ADAMTS2) or procoagulable factors (F3, THBS2) and genes involved in platelet activation (ADAMTS18, MYL9). Results were confirmed via qPCR on the cellular and by immunohistochemistry on the tissue level in CTEPH specimens.

Conclusions: We expect that the microarray data will provide a useful basis for further analyses of selected molecules to better understand the pathophysiology of this disease.

OC 32.3 | Genetic Associations with Recurrent Venous Thromboembolism: A Meta-analysis of Candidate SNPs in 4 Studies

M. Blondon[1], M. Germain[2], S. Armasu[3], A. van Hylckama Vlieg[4], K. Wiggins[5], P.-E. Morange[6], F. Rosendaal[7], D.-A. Tregouët[8], M. de Andrade[3], N. Smith[5]

[1]*Geneva University Hospitals and Faculty of Medicine, Geneva, Switzerland,* [2]*Institut National pour la Santé et la Recherche Médicale (INSERM), Paris, Switzerland,* [3]*Mayo Clinic, Rochester, United States,* [4]*Leiden University Medical Centre, Leiden, Switzerland,* [5]*University of Washington, Seattle, United States,* [6]*INSERM UMR_S 1062, Marseilles, France,* [7]*Leiden University Medical Center, Leiden, United States,* [8]*Sorbonne Université, Paris, France*

Background: Predicting the risk of recurrence in patients with venous thromboembolism (VTE) is critical when assessing the duration of anticoagulation. Genetic polymorphisms are hypothesized to contribute to the individual susceptibility to recurrent VTE.

Aims: To assess, using a meta-analysis of 4 large studies of recurrent VTE, the impact on recurrence of polymorphisms known to associate with incident VTE.

Methods: We identified 25 SNPs in 19 genes (*ABO*, *F2*, *F5*, *F11*, *F13*, *VWF*, *SERPINE1* (PAI-1), *PROC*, *PROCR*, *FGG*, *SERPINC1 (AT)*, *GP6*, *HIVEP1*, *STXBP5*, *KNG1*, *KLKB1*, *TC2N*, *TSPAN15*, and SCL44A2), all of which have been established as causes of incident VTE. Using an additive genetic model that adjusted for sex and age, we tested for association with recurrent VT in 4 studies of VTE in European-ancestry participants: the HVH study (a US HMO-based cohort study), the MARTHA study (a French tertiary center-based case-control study), the MEGA study (a Dutch regional cohort study), and the Mayo study (a US hospital-based cohort study). Relative risk (RR) estimates were meta-analyzed using fixed-effect models. Informed consent was obtained from all participants and protocol approval by medical ethics committee.

Results: Overall, the 4 studies included 8079 participants (57% women) of whom 1674 (20.7%) had a recurrent VTE. Among the 25 candidate SNPs, 7 were nominally associated with recurrent VTE at an alpha-level of 0.05 (Table), in *ABO*, *F5*, *F2*, *F13*, *FGG*, *VWF*, and *STXBP5*. A conservative Bonferroni correction for multiple tests (p-value threshold 0.05/25 = 0.002) identified 3 variants reaching significance: *FV* rs6025 (RR 1.23), *ABO* rs8176719 (RR 1.15) and *STXBP5* rs1039084 (RR 1.16).

TABLE 1 Nominally-significant meta-analytic associations of candidate SNPs with risks of recurrent VTE

GENE	SNP	RISK ALLELE FREQUENCY	META-ANALYTIC HR/OR (95%CI)	P VALUE
ABO	rs8176719 (O blood group)	0.42-0.50	1.15 (1.07-1.24)	<0.001
F5	rs6025 (Leiden)	0.07-0.10	1.23 (1.09-1.37)	0.001
F2	rs1799963 (G20210A)	0.02-0.03	1.36 (1.08-1.71)	0.01
F13	rs5985	0.74-0.77	1.10 (1.00-1.22)	0.047
FGG	rs2066865	0.28-0.33	1.08 (1.0-1.17)	0.04
STXBP5	rs1039084	0.55-0.58	1.16 (1.08-1.24)	<0.001
VWF	rs1063856	0.37-0.40	1.09 (1.01-1.17)	0.03

Conclusions: Several candidate SNPs are associated with the risk of recurrent VTE, including a novel finding in STXBP5. Given the modest individual effect size, determining these SNPs individually is unlikely to confer clinical utility. Future research should focus on the refinement and validation of genetic scores for recurrence.

OC 32.4 | A New Genetic Risk Score for Predicting Venous Thromboembolism Events in Cancer Patients Receiving Chemotherapy

A. Muñoz[1], I. Ortega[2], C. Font[1], V. Pachón[1], V. Castellón[1], V. Martinez[1], M. Salgado[1], E. Martinez[1], J. Calzas[1], J.C. Souto[3], E. Salas[2], J.M. Soria[4]

[1]*Hospital General Universitario Gregorio Marañón, Medical Oncology Service, Madrid, Spain,* [2]*Gendiag.exe, S.L, Esplugues Llobregat, Spain,* [3]*Unitat Hemostasia i Trombosi. Hospital de la Santa Creu i Sant Pau., Barcelona, Spain,* [4]*Biomedical Research Institute Sant Pau (IIB-Sant Pau), Unit of Gemonics of Complex Diseases, Barcelona, Spain*

Background: Risk scores for prediction of VTE associated with chemotherapy (Chemo) show a low/moderate discrimination capacity. Thrombo inCode (TiC) is a tool for predicting the risk of VTE that combines a Genetic Risk Score (GRS) with clinical parameters of the patient.

Aims: To assess whether an adapted version of TiC (TiC-Onco) shows a better predictive capacity than the Khorana score (KS) to identify patients at high risk of VTE associated with Chemo.

Methods: Prospective, observational study including 406 patients with colon, stomach, pancreas and lung cancer receiving Chemo. Informed consent was obtained from all of the participants and the study was approved by a recognized medical ethics committee. The

analysis was performed at 6 months of followed-up. Three predictive models were compared: KS; KS+tumor stage and TiC. Prediction capacity was assessed in terms of AUC, LH+ and LH-.

Results: VTE incidence at 6 months was 18.8%. KS AUC was 0.569 (95% CI, 0502-0637, p = 0.065), sensitivity 21.33, specificity 81.54, LH+ 1.16, LH- 0.96. Discrimination increased significantly with TiC-Onco model AUC 0.751 (95% CI 0.687-0.816, p < 0.0001), sensitivity 73.0, specificity 66.26, LH+ 2.16, 0.41 LH-. TiC-Onco discrimination was significantly higher than KS (p < 0.001). 59 patients who were classified as low and intermediate risk by KS developed VTE. TiC would have identified 41 of them as high-risk for developing VTE.

Conclusions: TiC-Onco has a better predictive capacity to identify patients with a high risk of thrombosis associated with Chemo compared to KS.

OC 32.5 | Prothrombotic Genotypes and the risk of Major Bleeding Events in the First Year after Incident Venous Thromboembolism

H.S. Johnsen[1], E. Bjøri[1], K. Hindberg[1], E.N. Smith[2,3,4], F.R. Rosendaal[1,5], S.K. Brækkan[1,6], K.A. Frazer[1,2], J.B. Hansen[1,6]

[1]UiT - The Arctic University of Norway, K.G Jebsen - Thrombosis Research and Expertise Center (TREC), Tromsø, Norway, [2]University of California San Diego, Rady Children's Hospital, Department of Pediatrics, La Jolla, United States, [3]University of California San Diego, Moores Cancer Center, La Jolla, United States, [4]University of California San Diego, Institute for Genomic Medicine, La Jolla, United States, [5]Leiden University Medical Center, Department of Clinical Epidemiology, Leiden, The Netherlands, [6]University Hospital of North Norway, Division of Internal Medicine, Tromsø, Norway

Background: Prediction of bleeding risk in patients with acute venous thromboembolism (VTE) is pivotal in decisions on duration of anticoagulant treatment (ACT). Prothrombotic genotypes are strongly predictive of venous thrombosis when combined in the de Haan-score, but it remains unsettled whether they protect against major bleeding (MB) during anticoagulation.

Aims: To investigate the impact of the pro-thrombotic genotypes (FVL [rs6025], F2 [rs1799963], ABO [rs8176719], FGG [rs2066865] and F11 [rs2036914]) individually and combined on bleeding risk.

Methods: Patients with a first VTE (n=674) aged 28 to 102 years, were sampled from the general population (The Tromsø study). Prothrombotic genotypes were determined in DNA isolated from whole blood. Patients with major bleeding according to ISTH criteria within one year after the VTE-diagnosis were identified through systematic review of medical records. Cox proportional hazards regression models were used to calculate hazard ratios (HRs) by individual and combined (de Haan 5-SNP score) risk alleles modeled continuously and in ordinal categories.

Results: Within one year of diagnosis, 60 (8.9%) patients had a bleeding event. No risk allele was individually associated with bleeding risk. In combined analyses (de Haan score) adjusted for age, sex and duration of anticoagulation, the hazard ratio per risk-allele increase was 0.98 (95% CI 0.78-1.25) and there was no trend for decreased risk of MB across increasing categories of risk alleles (0-1, 2, 3-4, and ≥ 5 risk alleles). There appeared some difference in the one-year cumulative incidence of MB between patients carrying 0-2 (7.4% (95% CI 5.1-10.6) and ≥ 3 (4.6% (95% CI 2.5-8.1) risk alleles according to de Haan score.

Conclusions: We found no clear association between individual and combined prothrombotic risk alleles and risk of major bleeding within the first year after a venous thrombotic event. These findings suggest that prothrombotic genotypes do not protect against iatrogenic bleeding.

OC 46.1 | Combined Effects of GP6 rs1613662 and Pre-cancer Platelet Count on the Risk of Cancer-related Venous Thromboembolism

H. Skille[1], O.V. Gran[1], B. Paulsen[1], E.N. Smith[2,3,4], T. Solomon[5], S.K. Braekkan[1,6], F.R. Rosendaal[1,7], K.A. Frazer[1,2], J.-B. Hansen[1,6]

[1]UiT - The Arctic University of Norway, K. G. Jebsen TREC - Thrombosis Research and Expertise Center, Tromsø, Norway, [2]University of California San Diego, Department of Pediatrics and Rady's Children's Hospital, La Jolla, United States, [3]University of California San Diego, Moores Cancer Center, La Jolla, United States, [4]University of California San Diego, Institute for Genomic Medicine, La Jolla, United States, [5]University of California San Diego, Biomedical Sciences Graduate Program, La Jolla, United States, [6]University Hospital of North Norway, Division of Internal Medicine, Tromsø, Norway, [7]Leiden University Medical Center, Department of Clinical Epidemiology, Leiden, The Netherlands

Background: Cancer is a strong risk factor for venous thromboembolism (VTE). GP6 encodes a glycoprotein collagen receptor that plays a key role in platelet function, and a missense mutation (rs1613662) in this gene is associated with VTE risk. Platelet count is associated with an increased risk of VTE in cancer patients but not in cancer-free subjects.

Aims: To study the joint effects of GP6 rs1613662 and cancer on risk of VTE stratified by pre-cancer platelet count.

Methods: Cases with a first VTE (n=629) and an age-weighted sub-cohort (n=1862) were recruited from three surveys of the Tromsø study (inclusions in 1994-95, 2001-02 and 2007-08, and follow-up through 2012). Rs1613622 was genotyped in DNA isolated from whole blood. VTEs were considered cancer-related if they occurred up to 6 months before or within 2 years after a cancer diagnosis. Pre-cancer platelet count was dichotomized using the median value ($246x10^9$/L). Cox regression was used to determine age- and sex adjusted hazard ratios (HR) for VTE by cancer status, risk alleles and platelet count.

Results: There were 167 cancer-related VTEs and 354 sub-cohort members were diagnosed with cancer during the study period. The GP6 G allele frequency was 0.15. Cancer patients with 1 or 2 risk alleles had an 11.9-fold (95% CI 8.6-16.9) and 14.2-fold (95% CI 6.3-32.0) increased risk of VTE, respectively, when compared to cancer-free subjects with no risk alleles. In cancer patients with platelet counts >$246x10^9$/L, the risk was 14.1-fold (95% CI 9.1-22.0) increased in those with 1 risk allele and 24-fold (95% CI 8.8-65.7) in those with 2, when compared to cancer-free subjects with no risk alleles. There was

no association between GP6 and VTE in cancer patients with platelet counts ≤246x10^9/L.

Conclusions: Our findings show an allele-dependent increased risk of VTE by GP6 rs1613662 in cancer patients with high platelet count. This suggests that both platelet count and platelet activity play a key role in the pathogenesis of VTE in cancer patients.

OC 46.2 | Incidence and Risk Factors for Central Venous Catheter-related Venous Thromboembolism in Breast Cancer Patients under (Neo)adjuvant Chemotherapy: The CAVECCAS Study

P. Debourdeau[1], M. Espié[2], S. Chevret[2], J. Gligorov[2], A. Elias[3], P.F. Dupré[4], J. Lelong[5], S. Lavau-Denes[6], P.Y. Dubois[7], M.A. Sevestre[8], L. Bastit[9], I. Kalidi[2], S. Villiers[2], A. Hij[2], S. Giachetti[2], C. Frere[10], D. Farge[2]

[1]Sainte Catherine Institute, Avignon, France, [2]Assistance Publique Hôpitaux de Paris, Paris, France, [3]Sainte Musse Hospital, Toulon, France, [4]CHU de Brest, Brest, France, [5]Clinique des Aubépines, Saint-Aubin-sur-Scie, France, [6]CHU de Limoges, Limoges, France, [7]Institut Jean Goudinot, Reims, France, [8]CHU d'Amiens, Amiens, France, [9]Clinique Pasteur, Evreux, France, [10]Assistance Publique-Hôpitaux de Marseille, Marseille, France

Background: In Breast Cancer (BC) patients under (neo)adjuvant chemotherapy, higher risk of venous thromboembolism may be partly related to central venous catheters (CVC).

Aims: To analyse the incidence and risk factors for catheter related thrombosis (CRT).

Methods: The CAVECCAS study is a prospective, multicenter cohort of non-metastatic invasive BC patients undergoing insertion of a single lumen CVC. All patients underwent Doppler US before and 7, 30 and 90 days (D) after CVC insertion. Symptomatic CRT were objectively confirmed. A 6-month clinical follow-up was performed. D-Dimers, thrombin generation, platelet-derived microparticles (Pd-MPs) and Pd-MPs expressing phosphatidyl serin (Pd-MP/PS+) were measured before and at D2 after CVC insertion. Individual thrombophilia risk factors were analysed by a nested case-control study. All subjects provide informed consent to participate in the study which was approved by a recognized medical ethics committee.

Results: Among 524 patients, the overall CRT (14 symptomatic, 46 asymptomatic) incidence rate was 2.18 cases/100 patient-months. The CRT cumulative probability was 9.6% at 3 11.5% at 6 months. After CVC insertion, D-Dimers increased (p< 0.0001) with no significant increase in thrombin generation parameters, while Pd-MPs (p< 0.0001) and Pd-MP/PS+ decreased (p=0.021). Age >50 years (OR, 1.80; 95% CI, 1.01-3.22), BMI> 30 kg/m² (OR, 2.64; 95% CI, 1.46-4.76) and comorbidities (OR, 2.05; 95% CI, 1.18-3.56) were strongly associated with CRT. Using multivariate analysis, BMI>30 kg/m² (OR, 2.66; 95%CI, 1.46-4.84) and lobular carcinoma histology (OR, 2.56; 95%CI, 1.32-4.96) remained the only significant CRT risk factors. Thrombophilia did not account for CRT.

Conclusions: In this large prospective study of BC patients receiving chemotherapy, only clinical parameters identified high risk CRT patients who may be considered for CRT thromboprophylaxis.

OC 46.3 | Statin Use and Venous Thromboembolism in Cancer: A Large, Propensity Score Matched Cohort Study in the United States

J. Brown[1], S. El-Refai[2], V. Adams[3], P. Black[4], J. Talbert[2]

[1]University of Florida, Pharmaceutical Outcomes & Policy, Gainesville, United States, [2]University of Kentucky, Pharmaceutical Outcomes & Policy, Lexington, United States, [3]University of Kentucky, Pharmacy Practice and Science, Lexington, United States, [4]University of Kentucky, Pharmaceutical Sciences, Lexington, United States

Background: Statins have been shown to have a protective effect for venous thromboembolism in the general population suggesting a potential role for statins in VTE prevention.

Aims: To assess the association between statins and the risk for cancer-associated deep vein thrombosis (DVT) and pulmonary embolism (PE).

Methods: Patients with newly diagnosed cancer were identified and followed for up to 1 year in a national healthcare claims database. Three treatment groups were identified based on medication use in the 6-months prior to cancer diagnosis: statin users (treatment group), non-statin cholesterol lowering medication users (active control), and an untreated group. Pairwise propensity score matched groups were compared using competing risks survival models for DVT and PE outcomes reporting the hazard ratios (HR) between the treatment groups. Sensitivity analyses assessed the influence of dose intensity, age, and individual medications on outcomes.

Results: The total cohort included 287,107 patients, which, after matching, were similar on baseline characteristics within each treatment group comparison. The overall model showed a protective effect for statins compared to no treatment, which was attributed to leukemia (DVT, HR=0.77) and colorectal cancers (DVT HR=0.87, PE HR=0.83) when stratified.

There were no protective effects for PE.

With only moderate-to-high statin doses, renal cancers showed an additional protective benefit from DVT with statin use (HR=0.84). There were no differences in outcomes between statins and non-statins and no individual statins produced results different from the class effect.

Conclusions: In this large propensity score matched sample of patients with cancer, statins were shown to have a small protective effect in renal cancer, colorectal cancers, and leukemias for the risk of DVT but not for PE. The lack of effect was consistent across statin dose intensity and was also not found for any of the sensitivity analyses included.

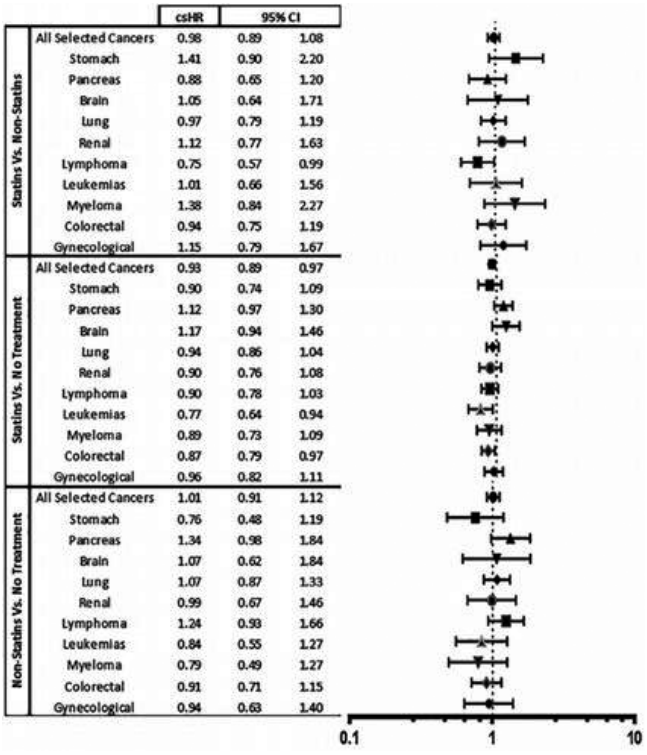

FIGURE 1 Statin treated, non-statin treated, and no treatment hazard ratios of the rate of deep vein thrombosis

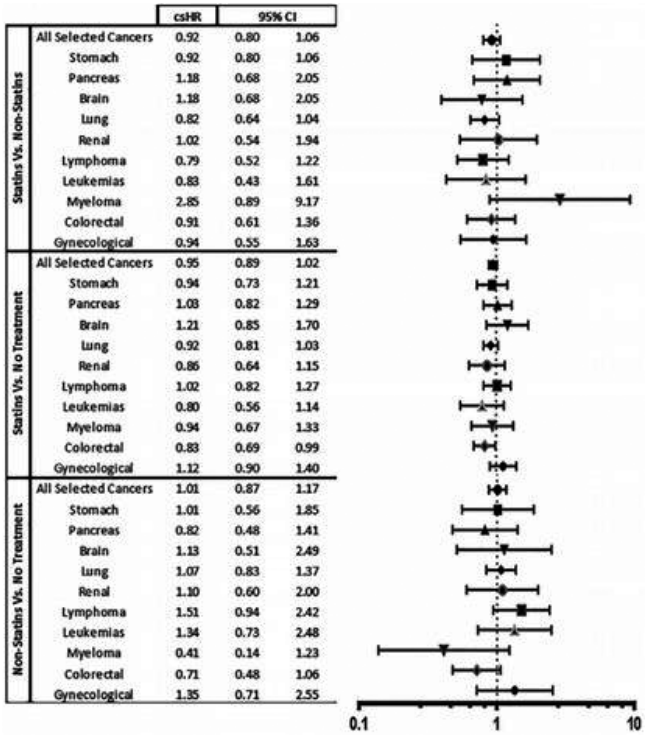

FIGURE 2 Statin treated, non-statin treated, and no treatment hazard ratios of the rate of pulmonary embolism

OC 46.4 | Arterial Thromboembolism in Patients with Cancer: Frequency, Risk Factors and Mortality

E. Grilz[1], O. Königsbrügge[1], F. Posch[1,2], I. Lang[3], I. Pabinger[1], C. Ay[1]

[1]*Medical University of Vienna, Clinical Division of Hematology and Hemostaseology, Department of Medicine I, Vienna, Austria,* [2]*Medical University of Graz, Clinical Division of Oncology, Department of Medicine, Graz, Austria,* [3]*Medical University of Vienna, Clinical Division of Cardiology, Department of Medicine II, Vienna, Austria*

Background: While the relevance of venous thromboembolism (VTE) in patients with cancer is well-recognized, much less is known about arterial thromboembolism (ATE) in these patients.

Aims: To describe the rates of ATE in patients with cancer, explore clinical risk factors and investigate all-cause mortality.

Methods: In this observational cohort study, we included patients with newly diagnosed malignant disease or progressive disease after remission. All patients were prospectively followed for a maximum of 2 years. Study endpoint was symptomatic ATE, which was adjudicated by a committee.

Results: 1387 patients (52.3% male; mean age: 59 years), recruited between Oct. 2003 and Sept. 2013, were included in this analysis. The median observation time was 1.8 years, 125 (9.0%) developed VTE, and 585 (42.2%) patients died during this time. 34 (2.5%, table 1) patients developed ATE within 2 years (13 [38.2%] had myocardial infarctions, 13 [38.2%] strokes and 8 [23.6%] peripheral arterial events). The cumulative 3-month, 6-months, 12 months and 24 months risk of ATE was 0.9% (95%CI: 0.5-1.5), 0.9% (0.5-1.6), 1.6% (1.0-2.4), and 2.6% (1.8-3.5), respectively. In univariable competing risk regression analysis, male sex (subdistribution hazard ratio [SHR]=2.2, 1.1-4.6, p=0.04), higher age (SHR per 10 year increase=1.8, 1.4-2.3, p< 0.001), lung cancer (SHR=2.8, 1.4-5.6, p=0.005), and renal cell carcinoma (SHR=3.5, 1.1-11.5, p=0.04) were associated with a higher ATE risk. In multivariable analysis, lung cancer (SHR=2.9, 1.4-6.2, p=0.005) and higher age (SHR per 10 years increase=1.8, 1.4-2.4, p< 0.001) were independently associated with ATE. In multistate modeling, the occurrence of ATE was associated with a 2.6-fold increased risk of mortality from any cause (hazard ratio [HR]=2.6, 95%CI: 1.6-4.3, p< 0.001).

Conclusions: In contrast to VTE, ATE is a less frequent complication in patients with cancer. Patients with cancer who develop ATE are at an increased risk of mortality.

TABLE 1 ATE rate in different tumor types

Primary Organ	No. of Patients (%)	No. of Patients with ATE (%)
Lung	233 (16.8)	12 (5.2)
Breast	228 (16.4)	0 (0.0)
Brain	193 (13.9)	4 (2.1)
Haematologic Malignancies	175 (12.6)	2 (1.1)
Gastric & Pancreatic	155 (11.2)	3 (1.9)
Colorectal	153 (11.0)	2 (1.1)
Kidney	37 (2.7)	3 (8.1)
Others	213 (15.4)	8 (3.8)

OC 46.5 | Effect of Low Molecular Weight Heparin on Survival of Patients with Resected Non-small Cell Lung Cancer: The Tinzaparin in Lung Tumors (TILT) Randomized Phase III Trial

Background: The antitumoral effects of low-molecular weight heparins remain controversial in the clinical setting. Most previous studies included various cancer types and/or advanced cancers.

Aims: To assess the effect of tinzaparin on overall survival (OS) of patients with non-metastatic resected non-small cell lung cancer (NSCLC).

Methods: Patients with completely resected stage I, II or IIIA NSCLC were randomized within 8 weeks of surgery in a multicenter open trial with blinded adjudication of outcomes (NCT00475098). Randomization was stratified on pathological stage (I vs II-III). Patients in both groups received usual care, patients in the experimental group received subcutaneous tinzaparin 100 IU/kg once a day for 12 weeks. The primary endpoint was OS. Follow-up was planned until 3 years after the inclusion of the last patient.

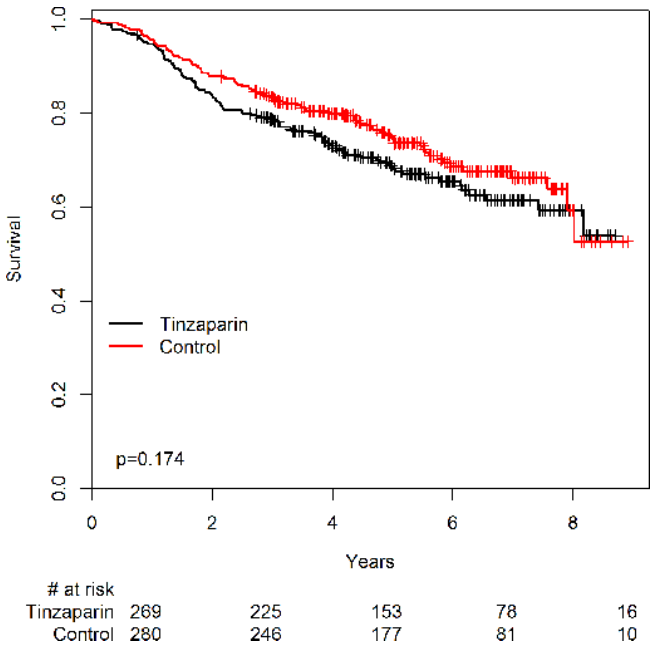

FIGURE Overall survival after randomisation

Results: A total of 553 patients were included, 4 withdrew consent, the remaining 549 patients were randomized to tinzaparin (n= 269) or control (n= 280). Mean age ±SD was 61.6±8.9 years, 356 patients (64.8%) were men, 358 patients (65.2%) had adenocarcinoma, 359 (65.4%) and 190 patients (34.6%) had pathological stages I and II-III, respectively. Median follow-up was 5.7 years. OS was not significantly different between groups (Hazard ratio [HR]=1.24; 95% confidence Interval: 0.92-1.68, p=0.17, figure). In a preplanned subgroup analysis, there was no significant difference in OS between groups in patients with stage I disease (HR=0.97; 0.64-1.47, p=0.90); in patients with stage II-III disease, OS was significantly lower in the tinzaparin group (HR=1.61; 1.03-2.54, p=0.04) but disease-free survival was not significantly different (HR=1.01; 0.64-1.59, p=0.97), and cancer-specific mortality was similar (28/95 *vs* 24/95 patients in the tinzaparin and control groups, respectively).

Conclusions: After complete resection of stage I-IIIA NSCLC, tinzaparin on top of usual care had no detectable impact on overall survival and disease-free survival.

OC 48.1 | Venous Thromboembolism Risk Assessment in 2214 Relatives from 651 Families with Known Thrombophilia Defects

P. Suchon[1], M. Ibrahim[1], A. Robin[2], N. Resseguier[3], M.-C. Barthet[2], D. Brunet[2], N. Saut[2], M.-C. Alessi[1], D.A. Trégouët[4], P.E. Morange[1]

[1]Aix Marseille Univ, INSERM, INRA, NORT, Marseille, France, [2]AP-HM, Service d'Hématologie Biologique, Marseille, France, [3]Aix-Marseille Université, Marseille, France, [4]ICAN Institute for Cardiometabolism and Nutrition, Paris, France

Background: Clinical assessment of venous thromboembolism (VTE) relies on several biomarkers including thrombophilia screening based on 5 defects (antithrombin (AT), protein C (PC), protein S (PS) deficiencies, factor V Leiden (FVL) and prothombin mutation (PTM)). However the clinical VTE pattern often shows wide heterogeneity within relatives of a VTE affected family despite they carry the same thrombophilia defect.

Aims: To assess whether common risk factors for VTE explain the clinical VTE heterogeneity observed in families with inherited thrombophilia.

Methods: Individuals were recruited at the Marseille Hospital Center between 1990 and 2013. A thrombophilia screening was systematically performed together with ABO blood group determination and genotyping of 11 polymorphisms selected because they were reported to associate with VTE in the general population. Individuals were split into 3 groups according to the thrombophilia screening: no defect (group 1), mild thrombophilia (FVL heterozygous or PTM heterozygous = group 2) and severe thrombophilia (AT, PC, PS deficiencies, FVL homozygous, PTM homozygous, combined defects = group 3). A multivariate survival analysis using Cox's regression was performed from which a score was derived.

TABLE 1 Survival multivariate analysis. 1Body mass index. Reference groups used for estimating hazard ratio = No thrombophilia (group 1), F11 rs20369

	N (%)	Hazard Ratio (95% CI)	p-value		N (%)	HR (95% CI)	p-value
Mild thrombophilia (group 2)	793 (47.3)	2.29 (1.45-3.62)	0.0004	BMI1 30-35 kg.m-2	103 (6.1)	1.79 (1.16-2.77)	0.008
Severe thrombophilia (group 3)	184 (11.0)	5.45 (3.32-8.93)	<10-4	BMI ≥ 35 kg.m-2	34 (2.0)	2.69 (1.24-5.82)	0.01
F11 rs2036914 - CT/CC	1266 (75.5)	1.63 (1.06-2.51)	0.03	Current smoking	403 (24.0)	1.83 (1.25-2.67)	0.002
FGG rs2066865 - CT	616 (36.8)	1.67 (1.18-2.35)	0.004				
FGG rs2066865 - TT	133 (7.9)	2.04 (1.20-3.45)	0.008				
Blood group A or B	1026 (61.2)	1.37 (0.93-2.02)	0.11				
Blood group AB	94 (5.6)	2.68 (1.52-4.74)	0.0007				

A trend towards an increased incidence of VTE was observed according to the score: from 0 to 10.7 per 1000 PY ($p=2.3.10^{-8}$).

TABLE 2 VTE incidence according to the score derived from multivariate analysis

Score	Number of events	Follow-up (years)	Incidence (per 1000 person-years)	p-value
0	0	2046	0	
1	13	10769	1.21	
2	44	18365	2.40	
3	55	17068	3.22	
4	26	5879	4.42	
5	9	1406	6.40	
6-7	4	373	10.72	2.3.10-8

Of note this increase held in the different groups of thrombophilia severity. The incidence raised 31.2 per 1000 PY in group 3 relatives with a score of 6-7.

Results: 2214 relatives from 651 families were included among whom 246 (11%) had a personal VTE history. VTE incidence was 1.2, 2.9 and 5.4 per 1000 person.years (PY) in groups 1, 2 and 3 respectively ($p=9.7.10^{-12}$). Obesity, smoking, ABO blood group, F11_rs2036914 and FGG_rs2066865 were statistically associated with VTE and included in a score.

Conclusions: Taking into account common environmental and genetic risk factors appeared to improve VTE risk assessment in relatives from families with thrombophilia.

OC 48.2 | Coagulation Factor 12 and the Risk of Recurrent Venous Thromboembolism: A Prospective Cohort Study

L. Eischer, S. Eichinger, P. Kyrle

Medical University of Vienna, Hematology and Hemostasis, Vienna, Austria

Background: Factor 12 (F12) plays a major role in the activation of the contact system. Low F12 does not cause bleeding. High F12 confers an increased risk of ischemic stroke in young women, is protective against myocardial infarction in men, and is not related to first venous thromboembolism (VTE). F12 is considered a promising target for further anticoagulant strategies.

Aims: To assess the relationship between F12 and the risk of VTE in high risk patients, i.e. in patients with first, unprovoked VTE.

Methods: We followed patients with a first, unprovoked VTE after anticoagulation withdrawal for an average of 6 years. We excluded patients with major thrombophilia, cancer or requirement for indefinite anticoagulation for other reasons. Study endpoint was symptomatic recurrent VTE. We used cumulative incidence methods to estimate the VTE recurrence risk and uni- and multivariate Cox proportional-hazards models to analyze the association between F12 and recurrence risk.

TABLE 1 Relativerisk of recurrent VTE according to quartiles of F12

F XII (%)	Pt (n)	Rec (n)	HR (95% CI)	HR (95% CI) adjusted for age, sex, VTE site, F5 Leiden, F 2 G20210A
< 91	199	56	1.0 (ref)	1.0 (ref)
> 91-111	199	73	1.2 (0.8-1.2)	1.1 (0.7-1.5)
> 111-132	212	64	1.0 (0.7-1.1)	1.0 (0.7-1.4)
> 132	208	72	1.1 (0.8-1.2)	1.1 (0.7-1.5)

Results: We included 818 patients (66% men, mean age 53 years) with F12 between 24% and 212%. 265 patients (32%) had recurrence. The hazard ratio (HR) of recurrence was 1.0 (95% CI 0.99-1.01) for each 1% increase of F12 and was unchanged after adjustment for age, sex, VTE site, F5 Leiden and F2 G20210A. The cumulative incidence of recurrence was similar when patients were compared according to F12 quartiles (Figure 1). Compared to patients with lowest F12 (< 91%), those with higher levels did not have an increased recurrence risk (Table 1). The recurrence risk among patients with F12 >153% (90^{th} percentile) or < 73% (10^{th} percentile) was comparable to those with lower/higher F12 [HRs 0.9 (0.6-1.3) and 1.1 (0.7-1.7)].

Conclusions: F12 levels do not affect the recurrence risk in patients with a first, unprovoked VTE.

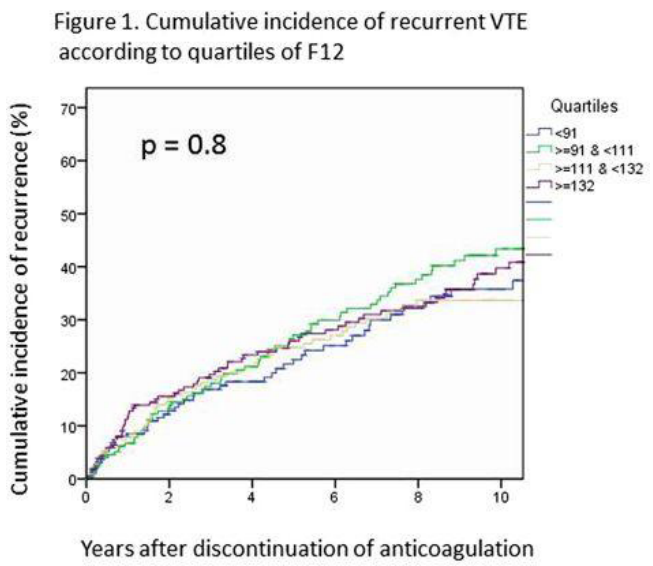

FIGURE 1 Cumulative incidence of recurrent VTE according to quartiles of F12

OC 48.3 | Indications and Outcomes after IVC Filter Insertion for Primary Prophylaxis of Pulmonary Embolism: A Population-based Cohort Study

M. Gurney[1], A. Ashrani[2], T.M. Petterson[3], D.J. Crusan[3], K.R. Bailey[3], J.A. Heit[4]

[1]Mayo Clinic, Internal Medicine, Rochester, United States, [2]Mayo Clinic, Hematology, Rochester, United States, [3]Mayo Clinic, Mayo Foundation for Medical Education and Research, Rochester, United States, [4]Mayo Clinic, Cardiovascular Diseases, Rochester, United States

Background: Inferior vena cava filter insertion (**filter**) for primary prevention of pulmonary embolism (**PE**) in patients without venous thromboembolism (**VTE**) is of unproven efficacy or safety.

Aims: To determine indications and estimate outcomes after a filter placement for primary VTE prophylaxis among Olmsted County (OC), MN residents, 1996-2015.

Methods: Using Rochester Epidemiology Project resources, we identified all OC residents with a filter, reviewed their complete medical records in the community and recorded demographic and clinical characteristics, type of filter placed and outcomes, including filter retrieval and complications, survival and cumulative VTE incidence. Age-, sex-specific VTE incident rates of the general OC population were used to calculate the expected number of VTE events and the standardized morbidity (i.e., VTE) ratio (95% CI).

Results: Over the 20-year period, 134 residents received a filter (85% retrievable) for primary VTE prophylaxis (**Figure**). Trauma (92%) was the most common indication (**Table**). Twenty-nine residents developed VTE (27 DVT; 2 PE). One-year survival and 3- and 12-month VTE cumulative incidence were 89%, 16%, and 21%, respectively. The standardized morbidity ratio for VTE was 47.1 (95% CI: 31.5, 67.6). Of 115 filters eligible for retrieval, 78 were removed, removal failed in 3, 9 transitioned to a permanent filter, 15 lacked documentation of removal, and 10 patients died or had persisting contraindications to anticoagulant use. Filter complications (n=2; 1% incidence at 3 months) included strut embolization with cardiac tamponade and duodenal perforation.

Conclusions: IVC filter insertion for primary prophylaxis was performed mainly post-trauma. Subsequent incident VTE was 47-fold higher than the general OC population of similar age and sex. Filter complications were rare but life-threatening. Conditional on surviving 14 days, 34% of potentially retrievable filters had not been removed at one year.

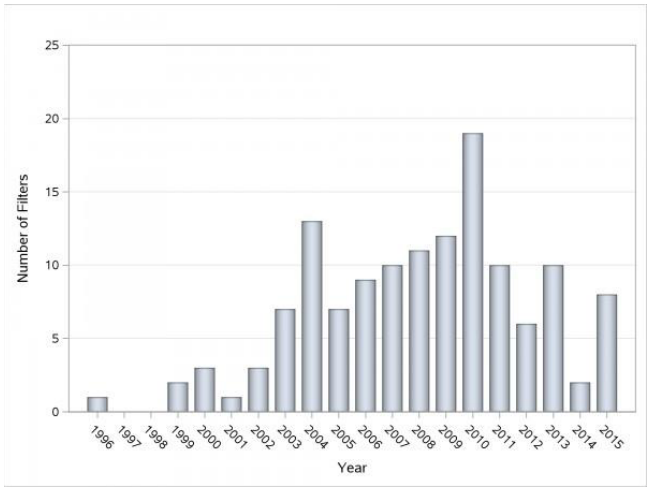

FIGURE Annual Number with IVC Filter Insertion for Primary VTE Prophylaxis Among Olmsted County, MN Residents, 1996-2015

TABLE Demographic and Baseline Clinical Characteristics of Olmsted County, MN Residents with IVC filter insertion for Primary Prophylaxis (n=134), 1996-2015

Patient age, mean ± SD (range)	45.1 ± 21.0 (16 - 89)
Male gender, n (%)	85 (63%)
BMI, kg/m2; median (range)	27.4 (17.8 - 52.3)
Trauma†	123 (92%)
Chronic cardiac disease, n (%)	22 (16%)
Chronic pulmonary disease, n (%)	16 (12%)
Active cancer, n (%)	5 (4%)
Therapeutic anticoagulation, n (%)	2 (2%)
Aspirin use, n (%)	21 (16%)

OC 48.4 | Derivation and Validation of a Prognostic Model for VTE Development in Outpatients Setting: A Nested Case-control Study

F. Dentali[1], A. Fontanella[2], G. Gussoni[3], M. Campanini[4], G. Agnelli[5], F. Lapi[6], FADOI-SIMG

[1]Insubria University, Clinical Medicine, Varese, Italy, [2]Ospedale Fatebenefratelli, Dept of Internal Medicine, Naples, Italy, [3]FADOI Foundation, Research Department, Milan, Italy, [4]AOU Maggiore della Carità, Department of Internal Medicine, Novara, Italy, [5]University of Perugia, Internal and Cardiovascular Medicine-Stroke Unit, Perugia, Italy, [6]Italian College of General Practitioners and Primary Care, Health Search, Firenze, Italy

Background: Consistent data have suggested that most episodes of venous thromboembolism (VTE) occurred in outpatients setting. Unfortunately, only a few studies have evaluated factors potentially associated with an increased risk of VTE in this setting and, to date, no score potentially able to identify the group of patients who may deserve an antithrombotic prophylaxis has been developed.

Aims: To assess potential risk factors for VTE in the outpatients setting.

Methods: Using the Health Search - IMS Health Longitudinal Patients Database, we followed a cohort of consecutive adult patients until the occurrence of one of these events, whichever came first: VTE (DVT and PE; event date), death from any cause, end of registration with GP, or end of the study period. The cohort was randomly divided into two cohorts containing approximately two-third (development) and one-third (validation) of patients, respectively; the presence of potential risk factor for VTE in cases and in controls was compared and a clinical score was developed and validated. Several sensitivity analysis were performed

Results: A total of 1,359,880 patients (53.4% women) met the study inclusion criteria. During follow-up, we identified 16317 cases of VET, yielding an overall incidence rate of 1.38 (95% CI: 5.0-6.4) per 1000 person-years. When the score was categorized in deciles and applied to the validation cohort, it was able to explain 27.9% of the variation for VTE occurrence. In terms of discrimination, AUC was 0.82 (95% CI: 0.82-0.83). The calibration measure revealed a margin of error lower than 10% in the 70% of the population. Results of sensitivity analyses substantially confirmed the finding of principal analysis.

Conclusions: Our clinical score, developed and validated, on a large population of outpatients demonstrated a good accuracy in predicting the risk of developing a VTE in this setting.

OC 48.5 | Increased Incidence of Venous Thromboembolism in Californians with Severe Asthma

A. Mahajan[1], A. Brunson[1], B. Kuhn[2], T. Keegan[1], T. Wun[1]

[1]University of California-Davis, Division of Hematology and Oncology, Sacramento, United States, [2]University of California-Davis, Division of Pulmonary and Critical Care, Sacramento, United States

Background: Chronic inflammatory diseases are associated with activation of coagulation and increased risk of venous thromboembolism (VTE). Asthma is a chronic inflammatory disease of the airways, marked by acute exacerbations. Severe asthma patients have a prothrombotic state as defined by higher biomarker levels of hemostasis and inflammation. There are limited population-based studies determining the association of asthma and VTE.

Aims: Determine the incidence of VTE in patients with asthma exacerbation requiring emergency department (ED) or in-patient care.

Methods: Using ICD-9 codes, we identified a cohort of adult patients (> 18 years) with a diagnosis of asthma during 2005-2013 in the California Patient Discharge Dataset and Emergency Department Utilization Dataset. We calculated incidence rates of VTE and used Cox proportional hazards regression to analyze factors associated with VTE and the association of VTE with mortality. Results are presented as adjusted hazard ratios (HR) and 95% confidence intervals (CIs).

Results: There were 387,860 asthma patients with 4,433 VTE events. The incidence rate of VTE was 226 per 100,000 person-years. Of the VTE events, 57.6% (n=2,553) were pulmonary emboli, 19.1% were proximal deep vein thromboses (DVT), 12.8% were distal DVT, and 10.5% were DVTs of the lower extremity not otherwise specified. Almost all (94.4%) of the VTE events were unprovoked. Compared to Non-Hispanic Whites, African Americans had a higher risk (HR=1.22, CI: 1.11-1.34) and Hispanics (HR=0.71, CI: 0.64-0.78) and Asians (HR=0.51, CI: 0.43-0.61) had a lower risk of VTE. VTE was associated with an increased risk of death (HR=2.26, CI 2.00-2.55).

Conclusions: In this large cohort of asthma patients, the incidence rate of VTE was twice as high as previously described in the general population. These data suggest adult asthma patients with acute exacerbations requiring ED or inpatient care are at a higher risk of VTE, which may increase their risk of mortality.

PEDIATRICS

OC 11.1 | Development of a Predictive Risk Model for Deep Vein Thrombosis in Pediatric Oncology Patients

L. Mitchell[1], F. Ruehle[2], L. Brandão[3], J. Halton[4], S. Israels[5], K. Dietrich[1], M. Spavor[1], M. Stoll[2], ABLE Investigators

[1]University of Alberta, Edmonton, Canada, [2]University of Muenster, Muenster, Germany, [3]Hospital for Sick Children, Toronto, Canada, [4]Children's Hospital of Eastern Ontario, Ottawa, Canada, [5]Winnipeg Children's Hospital, Winnipeg, Canada

Background: Pediatric oncology patients are at increased risk for deep vein thrombosis (DVT). Determining a predictive model to identify DVT risk is critical in order to target prophylactic interventions to children at risk.

Aims: To develop a predictive model for DVT in pediatric oncology patients using single nucleotide polymorphisms (SNPs) and clinical variables.

Methods: A population based nested case control study in 7 Canadian centers was conducted. SNPs were selected from candidate SNPs in 33 hemostasis-related genes and a concurrent genome wide association study (GWAS). To build a logistic risk model, the following clinical

variables were included: age, blood group, cancer diagnosis and type of chemotherapy received. In a first step, relevant predictors were determined by backward logistic regression in the initial sample set based on the minimized AIC (Akaike information criterion). Additionally, 10 SNPs were selected from the GWAS and candidate gene association analysis of DVT in pediatric oncology patients. Then, coded genotypes were added as predictors to the dataset, resulting in a combined dataset of 312 subjects (105 cases, 207 controls). Cross validated logistic regression was used for model training and backward feature selection in a training set, which was 70% of the subjects, as implemented in the ´caret´ R-package.

Results: The best model was selected with respect to AIC and contains the SNP genotypes of rs1800378, rs2028002, rs9332653, rs34631763, rs7837156 and rs10764406 as well as clinical variables. When applying the model to the remaining 30% of subjects in the test sample set, we determined an area under the ROC-curve (AUC) of 0.80 (0.74-0.86) and an accuracy of 0.7204 (for predictive risk threshold of 0.5). The model has a positive predictive value of 0.60 and negative predictive value of 0.75.

Conclusions: Using SNPs found to be associated with DVT in pediatric oncology patients, we propose a model for prediction of DVT risk in children undergoing chemotherapy.

OC 11.2 | External Validation of a Venous Thromboembolism Risk Prediction Tool for Critically Ill Children - The Cleveland Score

R. Talati[1], M. Tran[2], S.L. Shein[3], X. Ji[4], K. Chagin[4], H. Ding[5], S.P. Ahuja[1]

[1]Rainbow Babies and Childrens Hospital, Pediatric Hematology/Oncology, Cleveland, United States, [2]Willis Knighton Health Systems, Pediatric Critical Care Medicine, Shreveport, United States, [3]Rainbow Babies and Childrens Hospital, Pediatric Critical Care Medicine, Cleveland, United States, [4]Cleveland Clinic, Cleveland, United States, [5]Rady Children's Hospital San Diego, Pediatric Hematology/Oncology, San Diego, United States

Background: Pediatric venous thromboembolism (VTE) in critically ill children is associated with increased mortality, prolonged length of stay, and decreased ventilator-free days. We developed the "Cleveland Score" model to predict the risk of developing VTE in critically ill children with central venous catheters (CVCs). A validated bedside prediction tool may help improve outcomes through identification of patients benefiting from screening and prophylaxis.

Aims: To perform an external validation of the Cleveland Score using a cohort of critically ill children with central venous catheters.

Methods: With IRB approval, the Virtual Pediatric Systems, LLC database was interrogated for children < 18 years old admitted to pediatric intensive care units (PICU). All children had a CVC. VTE that were "active" but not "present on admission" were included. The "Cleveland Score" model was derived by logistic regression using data from 01/2009-09/2014. The major categories include age, sex, race, primary diagnosis, type of surgery, past medical history and CVC type. The model was validated using data from 10/2014-9/2016. Statistical measures included calculating the area under ROC curve, the concordance index and Brier score.

Results: The derivation cohort included 158,299 children of which 1623(1.0%) developed VTE. The validation cohort contained 57,976 patients of which 834(1.4%) patients developed VTE. Utilizing the validation cohort, this model had a concordance index of 0.782 (95% CI: 0.767, 0.798)(Fig. 1)

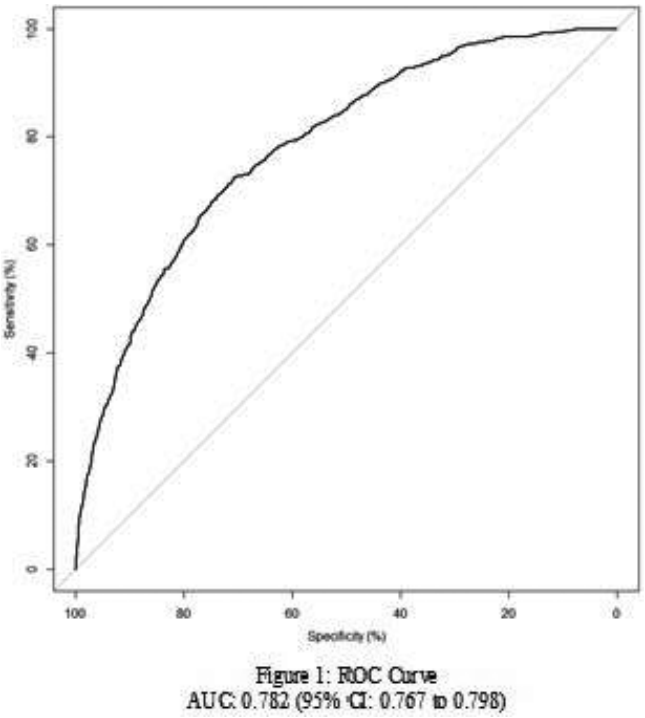

FIGURE 1 ROC Curve

and a Brier score of 0.0140. A score of 0 indicates a perfect association between the predicted and actual event. Predicted and actual VTE rates in the derivation and validation cohort are shown in Table 1.

TABLE 1

Risk Category	Predicted VTE risk	Derivation Cohort (n=158,299)		Validation Cohort(n=57,976)	
		n	Actual VTE(%)	n	Actual VTE (%)
Normal Risk	<0.3%	52973	73 (0.14%)	35411	179 (0.51%)
Moderate Risk	0.3%-0.7%	51788	204 (0.39%)	12886	200 (1.55%)
High Risk	>0.7%	53538	1346 (2.51%)	9679	455 (4.70%)
C-Statistic(95% CI)		0.826 (0.807-0.844)		0.782 (0.767-0.798)	

Analyzing specific groups within the dataset, the AUC of post-operative patients, cardiovascular diagnosis, and PICC lines, were 0.829, 0.865 and 0.745 respectively.

Conclusions: The Cleveland Score is externally validated and performs well to predict VTE in critically ill hospitalized children with CVCs.

OC 11.3 | External Validation of Risk Prediction Models for Catheter-associated Thrombosis in Critically Ill Children

J. Rutgers[1], S. Jones[2,3,4], P. Monagle[1,2,3], F. Newall[2,3,4], E.V. Faustino[5]

[1]Murdoch Research Childrens Institute, Haematology Research, Parkville, Australia, [2]The University of Melbourne, Department of Paediatrics, Parkville, Australia, [3]The Royal Children's Hospital, Department of Clinical Haematology, Parkville, Australia, [4]The University of Melbourne, Department of Nursing, Parkville, Australia, [5]Yale School of Medicine, Department of Pediatrics, New Haven, United States

Background: Risk prediction models for central venous catheter (CVC)-associated thrombosis in critically ill children were recently developed and internally validated using recursive partitioning (Model A) and logistic regression (Model B) methods with data from 3 centers in the United States (derivation cohort). The external validity of these models is unclear.

Aims: To externally validate the risk prediction models using data from critically ill children admitted to an Australian center.

Methods: Secondary analysis was performed in a prospective cohort study of critically ill children requiring a CVC (validation cohort). Predictive variables in the models (i.e., recent surgery, predicted risk of mortality, age, blood transfusion within 24H of CVC insertion and CVC location) were extracted from the study database. Discrimination and calibration of the models were expressed as areas under the receiver operating characteristic curves (AUROC) and Hosmer-Lemeshow chi-square test statistic, respectively.

Results: Data from 146 children (median age, 8 mo.) were used. A total of 32 children developed CVC-associated thrombosis. Both models had poor discrimination (AUROC-Model A: 0.44 [95% CI: 0.24-0.54]; Model B: 0.49 [95% CI: 0.37-0.61]). Model A (chi-square: 22.54, p< 0.001), but not Model B (chi-square: 14.01, p=0.12), had poor calibration. Stratification based on heart disease, suggested that Model B had better discrimination in those without heart disease (AUROC: 0.59 [95% CI: 0.40-0.79] vs. 0.40 [95% CI: 0.26-0.54]).

Conclusions: External validation should be performed to confirm the external validity of risk prediction models. The models for CVC-associated thrombosis performed poorly when validated in this Australian cohort, likely reflecting demographic variance between cohorts. Refining the risk prediction model using a larger cohort of children with a breadth of demographic variables is the next step in developing of a robust risk prediction model.

OC 11.4 | Thrombophilia in Children to Predict Recurrent Line-related Thrombosis: Time to Choose Wisely

M.L. Avila, N. Amiri, K. Barron, T. Vu, P. Krol, N. Yue, S. Williams, L.R. Brandão

The Hospital for Sick Children, Department of Paediatrics, Toronto, Canada

Background: The role of thrombophilia to predict recurrent line-related deep vein thrombosis (LR-DVT) with subsequent line placements after a first LR event in children remains unclear.

Aims: To investigate the association between thrombophilia and recurrent LR-DVT.

Methods: Children with a first episode of objectively confirmed LR-DVT from 1998 to 2014 and complete thrombophilia testing were included in the study. Recurrent (local or distant) LR-DVT with subsequent line placements was the main outcome. Thrombophilia was classified as minor (heterozygous FVL/PTG, high Lp(a), high FVIII levels), major (AT, PS, PC deficiency, ACLA/LAC+, homozygous FVL or PTG), or none. Analysis was conducted using logistic regression with a generalized estimating equation approach for correlated data. Ethics approval was obtained.

Results: 201 patients had 858 central venous lines (CVL, median 3 CVL/patient, range 1-23 lines) placed for a median of 4 days (range 1-1794 days); 59% were males. The most common underlying conditions were cardiac disease (35%), cancer (16%), and complex defects (14%). In 32% of the CVLs, patients did not receive anticoagulation (AC); in the remaining cases, patients received AC (either prophylaxis or treatment). 66% of the lines were temporary CVLs and 26% were PICCs. Whereas 78% of children had negative thrombophilia tests, 16% had minor and 6% had major thrombophilia.

24% of patients (49/201) had at least one recurrent LR-event (5% local, 17% distant, 2% both). Only time of line permanence was associated with recurrent LR-events (OR 1.01 for every 10 days of line permanence; 95% CI 1.00-1.02, p=0.04). Conversely, thrombophilia, age at the time of line insertion, sex, underlying condition, year of line insertion, type of line (PICC vs CVL) and AC (prophylaxis or treatment) were not.

Conclusions: Thrombophilia was not predictive of recurrent DVT during subsequent line insertions in this cohort of children with previous LR-DVT, suggesting that thrombophilia testing in these patients is not warranted.

OC 11.5 | Predictive Factors for Central Venous Catheter-related Thrombosis and Long Term Sequelae

S. Jones[1,2,3], J. Rutgers[4], W. Butt[1,5], F. Newall[1,2,3], P. Monagle[1,2,4]

[1]The University of Melbourne, Department of Paediatrics, Parkville, Australia, [2]The Royal Children's Hospital, Department of Clinical Haematology, Parkville, Australia, [3]The University of Melbourne, Department of Nursing, Parkville, Australia, [4]Murdoch Research Childrens Institute, Haematology Research, Parkville, Australia, [5]The Royal Children's Hospital, Paediatric Intensive Care Unit, Parkville, Australia

Background: Elevated D-dimer and Factor VIII levels are reported to predict poor outcomes, such as post thrombotic syndrome (PTS), in children with known thrombosis. Recently, an American cohort showed Factor VIII activity was predictive of asymptomatic central venous catheter (CVC)-related thrombosis in critically ill children.

Aims: To determine if D-dimer, Factor VIII levels and the probability of death score (pim2) are predictive of asymptomatic CVC-related thrombosis and PTS in critically ill children.

Methods: A prospective cohort study recruited children admitted to a paediatric intensive care unit (PICU) requiring a CVC. The study was approved by the hospital ethics committee and informed consent was obtained. Participants had a (blinded) ultrasound of the blood vessel in which the CVC was placed, plasma collection and clinical data was collected (phase I). PTS assessment and an ultrasound were performed approximately 24 months after CVC insertion (phase II).

Results: Neither Factor VIII, D-dimer or the pim2 score were predictive of CVC-related thrombosis in our cohort (Table 1). There was a statistically significant difference in Factor VIII and D-dimer levels between children with CVCs placed in their femoral veins compared to those with jugular CVCs (Table 2). No increased risk of clinically significant PTS was found related to D-dimer levels (p=0.2, OR 1.029 (0.66 - 1.57)) and pim2 scores (p=0.1).

TABLE 1 ^Mann Whitney U test; >Paediatric Index of Mortality 2

Factors	Normal	Thrombus	P value (2 tailed)	Odds ratio (95% CI)	P value for OR
Phase I					
Factor VIII	36	9	0.5^	0.99 (0.98 - 1.00)	0.2
D-dimer	111	32	0.2^	1.06 (0.9-1.26)	0.5
PIM2 score>	109	31	0.1^	1.02 (0.99-1.04)	0.09
Phase II					
Factor VIII	28	4	0.8^	1.0 (0.9-1.01)	0.9
D-dimer	101	15	0.1^	0.9 (0.58-1.4)	0.6
PIM2 score>	98	16	0.1^	1.02 (0.98-1.05)	0.4

TABLE 2 SD: standard deviation; *Mann Whitney U, >Paediatric Index of Mortality 2

	Jugular CVC		Femoral CVC		P value
	n	Median(range)/ Mean(SD)	n	Median(range)/ Mean(SD)	
D-dimer	150	0.59 (0.27-10.83)	35	2.35 (0.27-20.0)	<0.001*
Factor VIII	48	160.5 (59-516)	8	259 (116-399)	0.007*
PIM2 score> (%)	146	1.92 (0.14-100)	34	3.2 (0.30-90.6)	0.035*

Conclusions: This study shows D-dimer, Factor VIII and pim2 scores not predictive of acute CVC-related thrombosis or PTS in critically ill children. Children with femoral CVCs represented a subgroup with overall higher acuity shown by a significantly higher pim2 score, elevated D-dimers and factor VIII levels. These characteristics among children with femoral CVCs in PICU indicate a higher risk of mortality and could be useful in future studies identifying populations at risk of thrombosis.

OC 64.1 | Extracorporeal Membrane Oxigenation (ECMO) in Neonates and Children: Prospective Single Center Study of Argentina

C. Cervio, G. Sciuccati, M. Hepner, J.P. Frontroth, G. Pieroni, S.E. Annetta, A. Feliu Torres, M. Bonduel

Hospital de Pediatría ‚Prof. Dr. Juan P Garrahan', Servicio de Hematología y Oncología, Buenos Aires, Argentina

Background: ECMO is used in patients(pts) with severe respiratory(r) or cardiac(c) failure. Thrombotic and hemorrhagic complications are major causes of morbidity and mortality. The hemostasis disturbance assessment and antithrombotic therapy (ATT) are topics of debate.

Aims: To describe clinical characteristics, ATT and outcomes of a cohort of pts supported with ECMO at a tertiary care center.

Methods: From Jan 2010 to Dec 2016, consecutive pts < 18y old on rECMO or cECMO were studied. ATT was based on ELSO guidelines. Demographic, clinical and laboratory (lab) data, therapy and outcomes were prospectively registered. Data are expressed in median(range).

Results: 119pts with venoarterial ECMO were recruited. 4pts treated for < 12hours were excluded. rECMO:54pts (47%), 30males (56%), age:2d (7h-146d), 33pts (61%) had preoperative diaphragmatic hernia, days on ECMO :5 (1-26). Antithrombin replacement (ATR):41pts (76%). Unfractioned heparin (UFH)doses and lab data are shown in Table 1. aXa correlated with UFH doses (r=0.27, p=0.0008) whereas ACT did not (r=0.06, p=0.5052). Within therapeutic ranges, ACT/aXa were concordant 21.6% of times and ACT/APTT 2.8% of times. Intracranial hemorrhage (ICH) 16pts(30%), thrombosis18pts (33%). Survival 31pts (57%). cECMO: 61pts (53%),34males (56%),age7,6m (1d-174m),45pts (74%) had postoperative congenital heart disease, days on ECMO:4(1-12), ATR 33pts(53%), UFH dose and lab data are shown in Table 2. aXa correlated with UFH dose (r=0.42,p=< 0.001) whereas ACT did not (r=0.15, p=0.1398). Within therapeutic ranges, ACT/aXa were concordant 8.5% of times and ACT/APTT 11.2% of times. Major bleeding 29pts (48%),27/29 from surgical site; thrombosis 13pts (21%).Survival 33pts (54%).

TABLE 1 Respiratory ECMO: UFH doses and laboratory results in median (range)

	UFH doses (U/Kg/h)	Activated clotting time (ACT) (sec)	anti-Factor Xa activity level (aXa) (IU/mL)	Activated partial thromboplastin time (APTT) (sec)	Platelet count ($x10^9L^{-1}$)	Prothrombin time (%)	Fibrinogen (mg/dL)	Factor V (%)	Antithrombin (%)
Day 1 n=54	48 (5-90)	189 (165-575)	0,7 (<0,1-2,8)	240 (50->300)	110 (93-309)	40 (10-55)	175 (100-345)	36 (17-126)	34 (10-110)
Day 2 n=53	60 (20-87)	184 (165-240)	0,8 (0,2-2,0)	233 (84->300)	110 (50-183)	53 (10-84)	210 (139-608)	61 (19-136)	46 (23-101)
Day 3 n=48	55 (20-97)	182 (152-202)	0,7 (<0,1-1,9)	112 (57->300)	113 (35-211)	63 (24-92)	224 (157-409)	74 (24-217)	59 (33-100)

Day 5 n=27	45 (20-90)	186 (161-200)	0,7 (0,2-1,4)	180 (37->300)	97 (69-177)	65 (49-98)	252 (146-419)	80 (47-122)	60 (31-111)

TABLE 2 Cardiac ECMO: UFH doses and laboratory results in median (range)

	UFH doses (U/Kg/h)	Activated clotting time (ACT) (sec)	anti-Factor Xa activity level (aXa) (IU/mL)	Activated partial thromboplastin time (APTT) (sec)	Platelet count ($x10^9L^{-1}$)	Prothrombin time (%)	Fibrinogen (mg/dL)	Factor V (%)	Antithrombin (%)
Day 1 n=61	15 (5-72)	177 (135-229)	0,2 (<0,1-2,2)	102 (42->300)	105 (18-174)	39 (16-76)	201 (60-464)	35 (13-94)	39 (10-70)
Day 2 n=53	20 (5-51)	177 (101-250)	0,3 (<0,1-1,2)	100 (37->300)	97 (18-301)	50 (21-96)	240 (110-464)	50 (14-118)	41 (10-83)
Day 3 n=44	23 (8-72)	174 (125-250)	0,3 (<0,1-2,0)	109 (41->300)	87 (31-144)	58 (18-86)	264 (76-536)	67 (17-145)	48 (11-78)
Day 4 n=34	27 (5-45)	171 (149-200)	0,4 (<0,1-1,3)	122 (42->300)	77 (18-143)	62 (35-89)	275 (76-554)	76 (29-123)	54 (23-100)

Conclusions: In this cohort, most of the pts on ECMO survived. However, high rates of bleeding and thrombosis were observed. ICH and surgical site bleeding were the most frequent hemorrhagic complications in neonates on rECMO and in children on cECMO respectively. aXa assay was a superior correlate of heparin doses than APTT or ACT.

OC 64.2 | Can Coagulation Parameters Guide the Way in Neonatal and Pediatric Extracorporeal Membrane Oxygenation?

Ö. Erdem[1], J.W. Kuiper[1], R.J.M. Houmes[1], D. Tibboel[1], C.H. van Ommen[2], E.D. Wildschut[1]

[1]Erasmus Medical Center - Sophia Children's Hospital, Pediatric Surgery - Intensive Care Children, Rotterdam, The Netherlands, [2]Erasmus Medical Center - Sophia Children's Hospital, Pediatrics - Hematology, Rotterdam, The Netherlands

Background: Coagulation problems complicate extracorporeal membrane oxygenation (ECMO), a lifesaving procedure for severely respiratory or circulatory compromised children. There is no international evidence-based guideline for the management of coagulation during ECMO.

Aims: To outline the coagulation complications that arise during neonatal and pediatric ECMO in a high-volume ECMO center. Secondly, to analyze coagulation parameters with respect to complications and survival.

Methods: Analysis of prospectively collected data in 79 children treated with ECMO between September 2011-August 2015. In our protocol, anticoagulation with unfractionated heparin was monitored with APTT. Values of ACT, APTT, fibrinogen, d-dimers and platelet count and administered heparin and blood products during ECMO were collected. Complications were defined according to the Extracorporeal Life Support Organization. The Mann-Whitney U test was used to compare groups.

Results: Eighty ECMO runs were performed in 35 neonates and 44 children (0-16.8 yrs). The median duration of ECMO runs was 120.5 hours (IQR 190.0). As shown in table 1, clotting (CC) or hemorrhagic complications (HC) occurred in 43 (53.8%) of all patients with 40 CC in 30 ECMO runs and 44 HC in 33 ECMO runs. Neonates and children did not significantly differ. Ten patients died after ECMO-treatment was considered futile due to HC. Patients who developed CC or HC were on ECMO for a longer duration (p=0.0003). As presented in table 2, patients with CC received more platelet transfusions. There were no significant differences in coagulation parameters or heparin between patients with and without complications and between survivors and non-survivors.

TABLE 1 Coagulation complications during ECMO

Variable	n (% ECMO runs)	Survival to discharge (n (% of variable))	Died due to complication (n (% of variable))	Neonate (n (% ECMO runs))	Children (n (% ECMO runs))	p-value
ECMO runs	80	46 (58.3%)		35	45	
ECMO runs with coagulation complications	43 (53.8%)	19 (44.2%)		22 (62.9%)	21 (46.7%)	0.152
ECMO runs with clotting complication(s)	30 (37.5%)	14 (46.7%)	0 (0%)	15 (42.9%)	15 (33.3%)	0.386
Amount of clotting complications	40			20	20	
Clotting in patient	12					
Clotting in ECMO system	28					
ECMO runs with hemorrhagic complication(s)	33 (41.3%)	13 (39.4%)	10 (30.3%)	15 (42.9%)	18 (40.0%)	0.798
Amount of hemorrhagic complications	44			17	27	
ECMO runs with clotting and hemorrhagic complications	20 (25%)	8 (40%)		8 (22.9%)	12 (26.7%)	0.698

TABLE 2 Laboratory tests and administered heparin and blood products during ECMO]

Variable	Clot (n=30) (median (IQR)	No clot (n=50) (median (IQR)	p-value	Hemorrhage (n=33) (median (IQR)	No hemorrhage (n=49) (median (IQR)	p-value
ACT (s)	181.00 (30.50)	176.00 (26.25)	0.631	182.00 (45.75)	176.00 (18.50)	0.150
APTT (s)	84.50 (35.75)	86.25 (48.25)	0.925	88.00 (35.50)	81.00 (43.00)	0.688
Fibrinogen (g/L)	2.200 (2.595)	2.450 (1.825)	0.754	2.600 (2.065)	2.400 (2.0623)	0.551
Maximum D-dimers (mg/L)	14.52 (85.49)	23.10 (41.12)	0.055	35.20 (71.72)	25.41 (44.25)	0.105
Platelet count (10^9/L)	108.50 (39.25)	112.5 (54.38)	0.429	108.00 (35.00)	115.00 (59.00)	0.102
Heparin infusion rate (IU/kg/hr)	31.14 (18.30)	34.74 (17.03)	0.297	35.25 (19.93)	33.58 (14.43)	0.664
Red blood cell transfusion (ml/kg/day)	12.93 (31.33)	13.52 (12.29)	0.193	11.24 (14.11)	15.30 (12.96)	0.811
Fresh frozen plasma transfusion (ml/kg/day)	2.75 (8.09)	2.03 (4.49)	0.261	1.56 (6.31)	2.65 (4.74)	0.811
Platelet transfusion (ml/kg/day)	23.55 (30.17)	11.95 (16.14)	0.005*	16.69 (21.78)	13.60 (21.67)	0.534

Conclusions: Coagulation complications are associated with longer ECMO runs and can be fatal. No coagulation parameter differed in relation to complications and survival. Management of coagulation on ECMO remains challenging and requires intensive cooperation between intensivists and hematologists and multi-international evaluation.

OC 64.3 | Intraoperative ROTEM Predicts Excessive Bleeding in Infants on Cardiopulmonary Bypass

R. Bercovitz[1,2], E. Stuth[3], J. Scott[4], R. Niebler[5], P. Simpson[5,6,7], K. Yan[6], R. Woods[8], D. Newman[9]

[1]*BloodCenter of Wisconsin, Medical Sciences Institute, Milwaukee, United States,* [2]*Medical College of Wisconsin, Pathology and Pediatrics, Milwaukee, United States,* [3]*Medical College of Wisconsin, Anesthesiology, Milwaukee, United States,* [4]*Medical College of Wisconsin, Anesthesiology and Pediatrics, Milwaukee, United States,* [5]*Medical College of Wisconsin, Pediatrics, Milwaukee, United States,* [6]*Medical College of Wisconsin, Biostatistics, Milwaukee, United States,* [7]*Children's Research Institute, Milwaukee, United States,* [8]*Medical College of Wisconsin, Surgery, Milwaukee, United States,* [9]*BloodCenter of Wisconsin, Blood Research Institute, Milwaukee, United States*

Background: Excessive perioperative bleeding (EB) in infants undergoing cardiopulmonary bypass (CPB) is associated with significant morbidity and mortality. Early and accurate diagnosis of platelet defects is essential for timely and targeted therapy. Rotational thromboelastometry (ROTEM) is a rapid test of hemostasis. ROTEM-guided platelet transfusion protocols have safely reduced transfusions in adults but have not been implemented for infants due to a lack of data correlating ROTEM values with perioperative EB.

Aims: Test the hypothesis that intraoperative ROTEM values predict EB risk.

Methods: This IRB-approved observational study consented infants (< 365 days) undergoing cardiac surgery with CPB at Children's Hospital

of Wisconsin from 2013-2016. ROTEM was performed 1) pre-surgery, 2) pre-separation from CPB, 3) post-CPB, and 4) at CICU admission. Platelet contribution to clot formation as determined by ROTEM (PLTEM A10) was calculated as EXTEM A10 - FIBTEM A10. EB was defined as ≥6 mL/kg/h chest tube output (CTO) for 2 consecutive hours in the first 6 hours, >4 mL/kg/h average CTO for the first 24 hours, and/or reexploration for bleeding or tamponade in the first 24 hours after surgery. Most patients were transfused platelets between samples 2 and 3. Logistic regression models performed with SAS Studio.

Results: 66 subjects (43 neonates, 23 infants) were included in this analysis; 17 (25.6%) had EB. Preoperative mean platelet volume (MPV), number of CPB runs, and PLTEM A10 at Time 2 predicted EB risk (Table 1). In patients with PLTEM < 32mm at Time 2, a platelet count of < $60x10^9$/L was associated with higher odds of EB (Fig 1) despite platelet transfusion.

TABLE 1 Risk factors that predict excessive perioperative bleeding.

Effect	Odds Ratio Estimate (95% Confidence Interval)	P value
Pre-Operative MPV		
< 9.5 fL (normal or low)	referent	
> 9.5 fL (high)	19.7 (1.8 - 205.9)	0.0128
CPB runs		
1	referent	
≥2	8.5 (1.6 - 45.0)	0.0115
Pre-CPB separation PLTEM A10		
<32 mm	10.1 (1.07 - 94.7)	0.0427
≥32 mm	referent	

Conclusions: Risk factors for EB were high baseline MPV, ≥2 CPB runs, and intraoperative PLTEM < 32mm. Patients with PLTEM < 32mm and < $60x10^9$/L were at highest risk of EB. Studies of the safety of avoiding platelet transfusion in patients with PLTEM >32mm and efficacy of increasing platelet transfusion in patients with platelet count < $60x10^9$/L are needed.

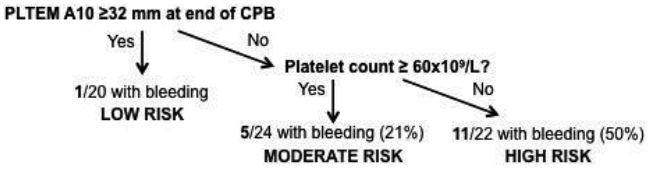

FIGURE 1 Risk of bleeding based on PLTEM A10 and platelet count prior to CPB discontinuation.

OC 64.4 | Antithrombotic Guideline for the PumpKIN Trial: Design and Rationale

M.P. Massicotte[1], D. Rosenthal[2], W. Mahle[3], R. Jaquiss[4], S. Siami[5], T. Baldwin[6,7], C. Almond[2]

[1]*University of Alberta/Stollery Childrens Hospital, Edmonton, Canada,* [2]*Stanford University, Pao Alto, United States,* [3]*Emory University, Atlanta, United States,* [4]*University of Texas Southwestern, Dallas, United States,* [5]*New England Research Institutes, Watertown, United States,* [6]*National Institute of Health, Bethesda, United States,* [7]*National Heart Lung Blood Institute, Bethesda, United States*

Background: The PumpKIN Trial will evaluate safety and probable benefit of the Jarvik 2015 continuous flow pediatric ventricular assist device (VAD) relative to the Berlin Heart EXCOR® pediatric pulsatile VAD, a device with a high early ischemic stroke risk.

Aims: To describe the antithrombotic (AT) guideline developed for the PumpKIN trial and its rationale.

Methods: Representatives from pediatric thrombosis, cardiology and cardiac surgery reviewed literature on pediatric VAD AT therapy and conducted a survey of 22 participating sites regarding local guidelines and laboratory practices. This information allowed development of a standard AT guideline to be used in each arm of the trial to minimize AT as a variable.

Results: Primary objectives were to develop a guideline that would be associated with few possible adverse events, reflect the most recent research, and be feasible for centers to implement. Challenges to guideline development included concern that the hemostatic "set point" of the original EXCOR® AT guideline was too low given the high stroke rate, uncertainty regarding thrombogenicity of the Jarvik 2015, Center variability in current EXCOR® AT practice, conflicting perceptions about the validity of using Platelet Mapping (PM) to guide platelet inhibition and inconsistent lab monitoring/availability across centers. Ultimately, the proposed guideline includes one anticoagulant plus dual high-dose antiplatelet therapy (with a third optional antiplatelet agent) with pre-specified antiplatelet dosing targets to supplement platelet-mapping data. Early surgical hemostasis is critical to enable timely up titration of AT therapy to address the early embolic stroke risk.

Conclusions: Despite uncertainty regarding the thrombogenicity of Jarvik 2015 pump, a higher-intensity antithrombotic guideline has been developed for the PumpKIN trial incorporating lessons learned from previous and emerging studies. Review of the guideline should be incorporated into routine data safety reviews as the clinical trial progresses.

OC 64.5 | Platelet Secretion Defects and Acquired von Willebrand Syndrome in Patients with Ventricular Assist Devices

U. Geisen[1], K. Brehm[2], G. Trummer[2], M. Berchtold-Herz[2], C. Heilmann[2,3], F. Beyersdorf[2], J. Schelling[4], A. Schlagenhauf[4,5], B. Zieger[4]

[1]*University Medical Center Freiburg/Institute for Clinical Chemistry and Laboratory Medicine, Freiburg, Germany,* [2]*University Heart Center Freiburg - Bad Krozingen, Department of Cardiovascular Surgery, Freiburg, Germany,* [3]*Saxon University of Cooperative Education, Plauen, Germany,* [4]*University of Freiburg; Faculty of Medicine, Department of Pediatrics and Adolescent Medicine, Division of Pediatric Hematology and Oncology, Freiburg, Germany,* [5]*Medical University of Graz, Department of Pediatrics and Adolescent Medicine, Graz, Austria*

Background: Acquired Von Willebrand syndrome (AVWS) is caused by increased shear stress resulting from the contact of blood with

foreign surfaces in the ventricular assist device (VAD). Impaired binding of Von Willebrand factor (VWF) to platelets and to collagen due to AVWS may increase bleeding tendencies in VAD patients who show bleeding as most frequent complication. Loss of HMW multimers is characteristic of AVWS. The HeartMate III (HM III) is a novel left-ventricular VAD (LVAD) featuring improvements over its predecessor, HeartMate II (HM II).

Aims: We investigated prevalence, onset and decline of AVWS in the largest cohort (n=185) of VAD-patients whose longitudinal data on AVWS have been collected and analyzed. We also investigated whether AVWS is less severe in HM III-patients than in HM II-patients. Further, platelet function was analyzed because platelet dysfunction can contribute to bleeding risk.

Methods: Observation started at 2006. Patients received a Thoratec HM II or HM III LVAD-system. Patients with LVAD combined with temporary right ventricular assist device (RVAD) or isolated biventricular assist device (Thoratec-BVAD) were also included in the study. As controls 84 patients with heart transplants were included. We determined the ratio of Von Willebrand factor collagen binding capacity (VWF:CB) to VWF antigen (VWF:Ag) (VWF:CB/VWF:Ag) and analyzed multimers and platelet function (especially secretion of α- and δ-granules).

Results: All 185 VAD-patients developed AVWS. After the VAD explantation AVWS disappeared within hours. AVWS was less severe in HM III-patients than in HM II-patients. HM III-patients suffered from fewer bleeding symptoms. All investigated VAD patients exhibited a platelet α- and δ-granule secretion defect.

Conclusions: AVWS develops in VAD patients and can increase the bleeding risk. The HM III device causes less serious AVWS. Platelet secretion defects should be investigated in VAD patients.

PLATELETS – BASIC

OC 03.1 | Platelet Activation by CLEC-2-Podoplanin Interaction is Essential for Lung Development

N. Tsukiji[1], O. Inoue[2], T. Shirai[1], S. Tamura[3], S. Otake[1], T. Sasaki[1], K. Satoh[1], Y. Ozaki[1], K. Suzuki-Inoue[1]

[1]University of Yamanashi, Faculty of Medicine, Department of Clinical and Laboratory Medicine, Chuo-shi, Japan, [2]University of Yamanashi Hospital, Faculty of Medicine, Infection Control Office, Chuo-shi, Japan, [3]Nagoya University Graduate School of Medicine, Department of Pathophysiological Laboratory Sciences, Nagoya, Japan

Background: We have previously identified CLEC-2 (*Clec1b*) as a platelet activation receptor and its endogenous ligand Podoplanin (*Pdpn*). Platelet CLEC-2 has a lot of physiological functions, such as blood-lymphatic vessel separation, inflammation and cancer metastasis. *Clec1b*$^{-/-}$ and *Pdpn*$^{-/-}$ mice die shortly after birth, but the mechanism has remained unclear. In the last ISTH congress, we reported that platelet CLEC-2 promotes alveolar myofibroblast (AMF) differentiation and normal alveolar formation.

Aims: The aim of this study is to elucidate how platelet CLEC-2 is involved in the AMF differentiation and to identify Pdpn-expressing cells required for lung development via binding to platelet CLEC-2.

Methods: Since AMFs are predominantly derived from lung mesothelial cells (LMCs), we histologically analyzed the LMC differentiation in *Clec1b*$^{-/-}$, *Syk*$^{-/-}$ and *Pdpn*$^{-/-}$ mice. We have found that Pdpn is expressed in LMCs, alveolar epithelial cells and lymphatic endothelial cells in the developing lung. We investigated AMF and PMC differentiation in those three tissue-specific *Pdpn*-deficient mice (*Wt1-Cre*, *Shh-Cre*, and *Tie2-Cre*, respectively). Neonatal lethality of all strains above was also examined. The effects of supernatants of activated platelets on AMF differentiation was examined in lung explant culture focusing on alpha-SMA expression.

Results: *Clec1b*$^{-/-}$, *Syk*$^{-/-}$, and *Pdpn*$^{-/-}$ mice showed overexpression of Wt1, a marker of LMC, hyperproliferation in LMCs and neonatal lethality. Of three tissue-specific *Pdpn*-deficient mice, only *Tie2-Cre*, *Pdpn*$^{fl/fl}$ mice exhibited similar phenotypes. In explant culture, the supernatants induced alpha-SMA expression in the interstitial cells of alveoli and the effect was canceled by TGF-beta antibody.

Conclusions: These results strongly suggest that TGF-beta released from activated platelets by interaction between CLEC-2 on platelets and Pdpn on lymphatic endothelial cells promotes AMF differentiation of LMCs, resulting in normal alveolar formation and acquisition of respiratory function.

OC 03.2 | Platelet Microparticles Infiltrating Solid Tumors Transfer miRNAs and Modulate Tumor Growth

L. Goldfinger[1], J. Michael[2], J. Wurtzel[1], G.F. Mao[1], A.K. Rao[1], D. Tomar[3], M. Muniswamy[3], M. Nieman[4], J. Rowley[5], A. Weyrich[5]

[1]Temple University, Sol Sherry Thrombosis Research Center, Philadelphia, United States, [2]Thomas Jefferson University, Center for Translational Medicine, Philadelphia, United States, [3]Temple University, Center for Translational Medicine, Philadelphia, United States, [4]Case Western Reserve University, University Hospitals, Pharmacology, Cleveland, United States, [5]University of Utah School of Medicine, Internal Medicine, Salt Lake City, United States

Background: Platelets, as well as other cells, release microparticles (microvesicles) into the plasma in response to receptor agonists and shear stress. The bulk of plasma-borne microparticles are platelet-derived microparticles (PMPs). PMPs are enriched in platelet-derived miRNA species, and can transfer platelet miRNAs to other cells including tumor cells following co-incubation *in vitro*. Tumor vasculature is highly permeable, allowing the possibility of PMP-tumor cell interaction.

Aims: The goal was to evaluate *in vivo* transfer of platelet-derived microRNAs (miRNAs) to tumor cells in solid tumors, via microparticles.

Methods: S.c. tumors.

Results: Here we report that PMPs infiltrate colon, lung, prostate, liver and breast solid tumors in humans, and PMPs infiltrated implanted tumors in mice. Infiltrating PMPs attached to tumor cells, and PMPs

transferred platelet-derived RNA, including microRNAs, to tumor cells *in vivo* and *in vitro*. MiR-24 was a major species in this transfer. We identified direct RNA targets of platelet-derived miR-24 in tumor cells, which included *mt-Nd2*, a mitochondrial mRNA, and *Snora75*, a non-coding small nucleolar RNA. These RNAs were depleted in PMP-treated lung and colon carcinoma cells, and PMP treatment resulted in mitochondrial dysfunction and tumor cell growth inhibition, in a miR-24-dependent manner. Tumor growth inhibition was the result of increased apoptosis but not blockade of cell cycle progression, *in vitro* and *in vivo*. PMP transfusion inhibited tumor growth in lung and colon carcinoma subcutaneous tumors, whereas blockade of miR-24 in tumor cells accelerated tumor growth *in vivo*, and prevented tumor growth inhibition by PMPs.

Conclusions: Thus, platelet-derived miRNAs transfer *in vivo* to tumor cells in solid tumors via infiltrating PMPs, regulate tumor cell gene expression, and modulate tumor progression. These findings shed novel insight onto mechanisms of horizontal RNA transfer and add multiple layers to the regulatory roles of miRNAs and PMPs in tumor progression.

OC 03.3 | Significance of Transforming Growth Factor-beta Signaling for Thrombofibrotic Remodeling in Murine Venous Thrombi and Human Chronic Thromboembolic Pulmonary Hypertension

M.L. Bochenek[1,2], C. Leidinger[1], N.S. Rosinus[1], M. Lankeit[2], E. Mayer[3], T. Münzel[1], S. Konstantinides[2], M. Bosmann[2], K. Schäfer[1]

[1]*University Medical Center Mainz, Cardiology I, Mainz, Germany,* [2]*University Medical Center Mainz, Center for Thrombosis and Hemostasis, Mainz, Germany,* [3]*Kerckhoff Klinik, Thoracic Surgery, Bad Nauheim, Germany*

Background: Chronic thromboembolic pulmonary hypertension (CTEPH) develops as a result of thrombofibrotic remodeling and major pulmonary artery obstruction. Defects of transforming growth factor-beta (TGFβ) pathway have been implicated in pulmonary arterial hypertension, whereas its role in CTEPH is unknown.

Aims: To investigate if TGFβ released from activated platelets promotes fibrosis in CTEPH via endothelial-to-mesenchymal transition (EndMT) and the endothelial TGFβ II receptor.

Methods: CTEPH specimens were processed for immunohistochemistry and quantitative *real time* PCR (qPCR). Endothelial cells outgrown from CTEPH specimens were subjected to immunofluorescence and microarray analyses. Murine venous thrombi were induced by *inferior Vena cava* (IVC) ligation.

Results: Dual immunofluorescence staining of CTEPH specimens demonstrated cells simultaneously expressing endothelial and mesenchymal markers suggesting the presence of EndMT. QPCR analysis confirmed these findings and also revealed upregulated expression of transcription factors involved in EndMT. Microarray, qPCR and immunohistochemical expression analysis confirmed the expression of TGFβ ligands (TGFβ-1, -2), receptors (TGFBRII, endoglin, BMPRII) and activated TGFβ signaling (phospho-SMAD2 and -SMAD5) in CTEPH tissue. Furthermore, mice with platelet-specific TGFβ1 deletion or inducible endothelial-specific deletion of TGFBRII were subjected to IVC ligation followed by ultrasound over 3 weeks. Venous thrombi were smaller in mice lacking TGFβ in platelets (n=10). Conversely, endothelial-specific deletion of TGFβRII was associated with an increase in thrombus size at all points examined (n=6). Confocal microscopy analysis demonstrated that EndMT was only detected in the presence of TGFβ and the accumulation of fibrotic material was also significantly increased.

Conclusions: Using this combined approach we found that TGFβ signaling in endothelial cells contributes to chronic fibrotic remodeling and involves EndMT.

OC 03.4 | Aspirin Therapy Reduces the Ability of Platelets to Promote Colon and Pancreatic Cancer Cell Proliferation: Implications for the Oncoprotein c-MYC

A. Mitrugno[1], J.L. Sylman[1], A.T.P. Ngo[1], J. Pang[1], R.C. Sears[2], C.D. Williams[3], O.J.T. McCarty[1]

[1]*Oregon Health & Science University, Biomedical Engineering, Portland, United States,* [2]*Oregon Health & Science University, Department of Molecular and Medical Genetics, Portland, United States,* [3]*Oregon State University, School of Pharmacy, Portland, United States*

Background: Aspirin, an anti-inflammatory and anti-thrombotic drug, has become the focus of research as a potential anti-cancer agent owing to its ability to reduce tumor proliferation *in vitro* and to prevent tumorigenesis in patients. Studies have found an anti-cancer effect of aspirin when used in low, anti-platelet doses. However, the mechanism(s) through which low dose aspirin works is poorly understood.

Aims: To characterize the molecular mechanisms underlying the anti-cancer effect of an anti-platelet dose of aspirin.

Methods: We used 2 colon cancer cell lines, SW480 and SW620, and a pancreatic cancer cell line, PANC-1 and combined each with platelets and their releasates in direct and transwell co-culture platforms to understand routes of platelet-cancer communications. Platelet-induced changes in cancer-relevant oncoproteins and cell proliferation were detected by western blotting and immunofluorescence imaging, respectively. Moreover, aspirin and inhibitors of c-MYC, phosphatidylinositol 3-kinase (PI3K), platelet derived growth factor receptor (PDGF-R) and platelet integrin αIIbβ3 were used to identify the molecular signals that trigger oncoprotein overexpression and drive proliferative responses in cancer cells in the presence of intact human platelets or platelet releasates.

Results: We demonstrate that platelet-derived signals stimulate the expression of the oncoprotein c-MYC and induce proliferation of colon and pancreatic cancer cells. We establish that the ability of platelets to upregulate c-MYC and trigger proliferative responses in cancer cells can be reversed by an anti-platelet dose of aspirin.

Conclusions: In this study, we unveil, for the first time, the ability of platelets and their releasates to regulate the expression of oncoproteins in cancer cells. Moreover, we propose a novel anti-cancer mechanism of action of low-dose aspirin, namely through the inhibition of platelet-induced molecular signals that cause aberrant expression of the c-MYC oncoprotein in cancers.

OC 03.5 | Platelet Releasate Promotes Breast Cancer Growth and Angiogenesis via VEGF-integrin Cooperative Signaling

L. Jiang[1,2], Y. Luan[3], X. Miao[1], C. Sun[3], K. Li[3], Z. Huang[1], D. Xu[4], M. Zhang[5], F. Kong[3], N. Li[1]

[1]Karolinska Institutet, Department of Medicine-Solna, Clinical Pharmacology, Stockholm, Sweden, [2]Ningbo University School of Medicine, Department of Pathology, Zhejiang Provincial Key Laboratory of Pathophysiology, Ningbo, China, [3]Shandong University Second Hospital, Central Laboratory, Jinan, China, [4]Karolinska Institutet, Department of Medicine-Solna, Hematology Lab, Stockholm, Sweden, [5]Shandong University Qilu Hospital, Key Laboratory of Cardiovascular Remodeling and Function Research, Jinan, China

Background: Platelets are an active player in angiogenesis. Selective platelet release of pro- or anti-angiogenic factors distinctly regulated angiogenesis.

Aims: To investigate if selective releases of platelet angiogenic factors differently regulate tumor growth.

Methods: *Breast cancer cell proliferation, cancer cell-induced endothelial tube formation in vitro, and tumor growth in vivo were studied in the presence of* protease-activated receptor 1-stimulated platelet releasate (PAR1-PR; rich in pro-angiogenic factors) or PAR4-PR (rich in anti-angiogenic factors).

Results: PAR1-PR and PAR4-PR supplementation (10%) similarly enhanced cell proliferation of MCF-7 and MDA-MB-231 breast cancer cells. Platelet releasates had, however, no influence on cancer cell apoptosis. MCF-7 and MDA-MB-231 cells triggered capillary-like tube formation of endothelial cells, and the effects were further enhanced by PAR1-PR, and tended to be enhanced by PAR4-PR. Further experiments showed that VEGF, but not SDF-1a blockade abolished PAR1-PR/PAR4-PR enhanced cell proliferation of both cancer cell lines, and that integrin blockade by RGDS had identical effects as VEGF inhibition. Intracellular signaling intervention of MCF-7 cells at Src and ERK diminished both PAR1-PR and PAR4-PR enhanced MCF-7 cell proliferation, while PI3K and PKC blockade inhibited platelet releasate-enhanced cell proliferation even more markedly. Similarly, the signaling blockade inhibited MDA-MB-231 cell proliferation. Using a model of subcutaneous implantation of MDA-MB-231 cells in nude mice, PAR1-PR demonstrated more marked enhancements on tumor growth than PAR4-PR. The exaggeration was linked to more profound tumor angiogenesis enhanced by PAR1-PR.

Conclusions: Platelet releasate increases breast cancer cell proliferation through VEGF-integrin cooperative signaling. Pro-angiogenic factor-rich platelet releasate enhances cancer cell-induced angiogenesis more markedly, and exaggerates tumor growth in vivo through promoting tumor angiogenesis.

OC 04.1 | Ultrastructural Characterization of the Cellular Contacts between Megakaryocytes and Endothelial Cells in the Bone Marrow

A. Eckly, J.-Y. Rinckel, F. Proamer, F. Lanza, H. de la Salle, C. Gachet

Université de Strasbourg, INSERM, EFS Grand Est, BPPS UMR-S 949, FMTS, Strasbourg, France

Background: The final steps of platelet production require that megakaryocyte (MK) fragments are released into the circulation after crossing the sinusoids. The cellular mechanisms involved in this passage remain unclear.

Aims: The aim of this study is to characterize the cellular events associated to the interaction of MKs with endothelial cells (ECs) of mice bone marrow sinuses.

Methods: *In situ* observations are performed using transmission electron microscopy and 3D imaging with the focused ion beam-scanning electron microscope (FIB-SEM).

Results: We observe at least four types of MK/EC interactions, including 1) planar contacts (46%), 2) short MK extensions (35%), 3) invasive MK protrusions penetrating deeply into endothelial invaginations (10%), and 4) transmigrating MK fragments (9%) (n=118 MKs). The protrusions resemble the MK marginal zone known to be rich in actomyosin. Protrusions provoke endothelial squeezing, resulting in the apposition of apical and basal membranes. In addition, pores appear to be formed at these particular MK/EC contacts. In the endothelium, local enrichment and fusion of vesicles are detected at sites of MK protrusion suggesting that they may play a role as local membrane suppliers necessary for pore formation. 3D imaging demonstrated that transmigrating MKs form large intravascular fragments corresponding for two-third of the total volume of MK. Remarkably, they differ from the thin elongated MK extensions called “proplatelets” and cross the ECs at sites distant from interendothelial cell junctions indicating trans-endothelial passage.

Conclusions: Collectively, these observations suggest a model in which MKs extended invasive protrusions which trigger endothelial surface invaginations and which could facilitate progressively formation of transcellular pores through the endothelium.

OC 04.2 | Loss of the Hematopoietic Adaptor Protein ADAP Impairs Megakaryocyte Polarization and Induces Ectopic Platelet Release

M. Spindler[1], J.M.M. van Eeuwijk[1], Y. Schurr[1], D. Stegner[1], B. Nieswandt[1], A. Reinhold[2], M. Bender[1]

[1]University Hospital and Rudolf Virchow Center, Department of Experimental Biomedicine, Würzburg, Germany, [2]University of Magdeburg, Institute of Molecular and Clinical Immunology, Magdeburg, Germany

Background: Bone marrow megakaryocytes (MKs) produce platelets by extending proplatelets into sinusoidal blood vessels. Defects in thrombopoiesis can lead to thrombocytopenia associated with increased bleeding tendency. Recently, the platelet disorder congenital

autosomal recessive small-platelet thrombocytopenia (CARST) was described which is caused by mutations in the *ADAP* (Adhesion and degranulation promoting adaptor protein) gene, and characterized by a microthrombocytopenia and bleeding symptoms.

Aims: The aim of this study was to investigate the role of ADAP in thrombopoiesis.

Methods: We capitalized on constitutive as well as conditional ADAP knockout mice, studied platelet biogenesis in *in vitro* and *in vivo* assays, and used multiple microscopic techniques (electron, confocal, two-photon microscopy).

Results: Constitutive ADAP deficient mice reproduced the microthrombocytopenia observed in CARST patients, and platelet counts could not be increased after splenectomy. *Adap*$^{-/-}$ platelets had a shorter life span than control platelets. Whole sternum 3D confocal imaging and two-photon microscopic analysis revealed altered morphology of ADAP deficient MKs with signs of fragmentation and ectopic release of platelet-like particles as well as proplatelets into the bone marrow compartment. In addition, cultured bone marrow-derived MKs lacking ADAP showed a reduced capacity to spread on collagen and form podosomes, but displayed defective polarization of the demarcation membrane system *in vitro*. MK-/platelet-specific ADAP deficient mice also produced less and smaller-sized platelets and released platelets ectopically. These data suggest that the abnormal platelet production in the mutant mice is a MK intrinsic defect.

Conclusions: Our results point to a so far unidentified role of ADAP in the process of MK polarization and platelet biogenesis. Thus, we suggest that the analysis of ADAP deficient mice may help to understand the platelet production defect in CARST patients.

OC 04.3 | Centrosome Destabilization through the Ubiquitin-proteasome Pathway Regulates Proplatelet Production

K. Machlus[1], P. Vijey[2], T. Soussou[2], J. Italiano[1]

[1]Harvard Medical School, Boston, United States, [2]Brigham and Women's Hospital, Boston, United States

Background: Proteasome inhibitors such as bortezomib, a chemotherapeutic used to treat multiple myeloma, induce thrombocytopenia within days of initiation because proteasome activity is essential for platelet formation. The major pathway of selective protein degradation uses ubiquitin as a marker that targets proteins for proteolysis by the proteasome. This pathway is previously unexplored in megakaryocytes (MKs).

Aims: We aimed to define how the ubiquitin-proteasome pathway affects platelet production.

Methods: Pharmacologic inhibition and proteomic and polysome profiling analyses were used.

Results: To characterize how proteasomal protein degradation was occurring, we probed distinct ubiquitin pathways. Inhibition of the ubiquitin-activating enzyme E1 significantly inhibited proplatelet formation up to 73%. In addition, inhibition of the deubiquitinases UCHL5 and USP14 significantly inhibited proplatelet formation up to 83%. These data suggest the ubiquitin pathway is necessary for proplatelet formation.

Proteomic and polysome analyses revealed a subset of proteins decreased in proplatelet-producing megakaryocytes, consistent with data showing that protein degradation is necessary for proplatelet formation. Specifically, the centrosome stabilizing proteins Aurora kinase (Aurk) A/B, Tpx2, Cdk1, and Plk1 were decreased in proplatelet-producing MKs. Furthermore, inhibition of AurkA and Plk1, but not Cdk1, significantly inhibited proplatelet formation in vitro over 86%.

Conclusions: We hypothesize that proplatelet formation is triggered by centrosome disassembly, and that the ubiquitin-proteasome pathway plays a crucial role in this transformation. Specifically, the AurkA/Plk1/Tpx2 pathway may be key in maintaining centrosome integrity and initiating proplatelet formation. Determination of the mechanism by which the ubiquitin-proteasome pathway regulates the centrosome and facilitates proplatelet formation will allow us to design better strategies to target thrombocytopenia.

OC 04.4 | Scalable Production of Human Platelets in a Bioreactor

L. Beaulieu[1], B. Dykstra[1,2,3], C. Peters[1], J. Italiano, Jr[1,2,3], J. Thon[1,2,3]

[1]Platelet BioGenesis, Boston, United States, [2]Brigham and Women's Hospital, Medicine, Boston, United States, [3]Harvard Medical School, Boston, United States

Background: A low platelet count resulting from conditions such as cancer treatment, transplantation, and surgery, require platelet transfusions to prevent mortality due to uncontrolled bleeding. Platelet transfusion units are exclusively obtained from human volunteer donors. They must be stored at room temperature to prevent irreversible activation, which limits the shelf life of a unit to 5 days. However, storage at room temperature increases the risk of contamination. After 2 days of contaminant testing and 1 day for transportation, blood centers typically do not have more than 1.5 days of platelet transfusion units available, which are even further depleted during emergencies.

Aims: To address this major unmet need, we have developed a scalable, microfluidic bioreactor that reproduces the key features of the bone marrow to trigger human platelet production from megakaryocytes.

Methods: To optimize the design and operation of the bioreactor, megakaryocytes derived from primary peripheral blood CD34^{+} cells are utilized as a physiologically relevant cell line to produce platelets. We have developed a computation fluid model to understand how pressure and shear independently affect platelet production. This allows us to visualize pressure, flow and shear stresses experienced by megakaryocytes in the bioreactor and to optimize the conditions to increase platelet production.

Results: Computational fluid modeling shows that the megakaryocytes can be targeted to experience flow rates of 0-5 cm/s and shear stresses ranging from 500-3000 mPa, while platelets can experience a flow rate of 0-8 cm/s and shear stresses of 1000-6000 mPa, which

encompassing the physiological shear stress range of 912-936 mPa These bioreactor-derived platelets are comparable in morphology and biomarker expression to human platelets.

Conclusions: We have developed a scalable microfluidic device that can produce platelets from human megakaryocytes *ex vivo* at clinically relevant yield.

OC 04.5 | Platelet Release from Infused Megakaryocytes is Largely Limited to the Pulmonary Vasculature

I. Johnston[1,2], D. Jarocha[1,3], V. Hayes[1,4], L. Rauova[1,5], M. Poncz[1,5]

[1]*Childrens Hospital of Philadelphia, Hematology, Philadelphia, United States,* [2]*University of Pennsylvania, Pharmacology, Philadelphia, United States,* [3]*Jagiellonian University, Department of Transplantation, Cracow, Poland,* [4]*Perelman School of Medicine, University of Pennsylvania, Department of Pathology and Clinical Laboratory Medicine, Philadelphia, United States,* [5]*Perelman School of Medicine, University of Pennsylvania, Department of Pediatrics, Philadelphia, United States*

Background: Factors that control platelet (Plt) shedding from megakaryocytes (MKs) have not been fully defined. We previously showed that intravenously (IV) infused mouse or human MKs are entrapped in the pulmonary vasculature and release particles physically and functionally similar to donor-derived Plts. Whether Plts are uniquely shed in the lung or MKs would shed Plts at the first vascular bed encountered is unknown.

Aims: To examine whether the pulmonary bed differs from other vascular beds for Plt shedding from infused MKs and to begin to visualize infused MKs shedding Plts.

Methods: CD34+-derived human MKs were infused into NSG-mice via tail vein or left carotid artery. Plt release was monitored via flow cytometry and organs were analyzed histologically for trapped MKs. Confocal in situ lung microscopy was done to visualize infused and endogenous Mks within the lung vasculature in real time.

Results: In vitro-grown MKs were studied in parallel mice one receiving an arterial and the other a venous MK infusion. Infusion of MKs resulted in a rise in circulating human Plts after venous, but not arterial infusion (Fig. 1).

Histologic examination 10 min and 4 hrs after infusion showed predominant pulmonary entrapment of IV infused MKs but only minimal MKs presence in any organ after intra-arterial infusion. In situ lung microscopy show the rapid extension of long (up to 200μ) proplatelets in the lungs after infusing MKs that was complete by 10 mins (Fig. 2). No spontaneous MKs were noted to be entrapped during several hrs of observation.

Conclusions: The pulmonary bed might offer a unique environment to entrap MKs and promote thrombopoiesis. These features can include the unique physical features of the pulmonary bed or its endothelial lining or the sharp oxygen gradient encountered. In addition, in the mouse, spontaneous MK entrapment and shedding was not observed, suggesting that in mice Plt shedding normally may not involve the pulmonary bed.

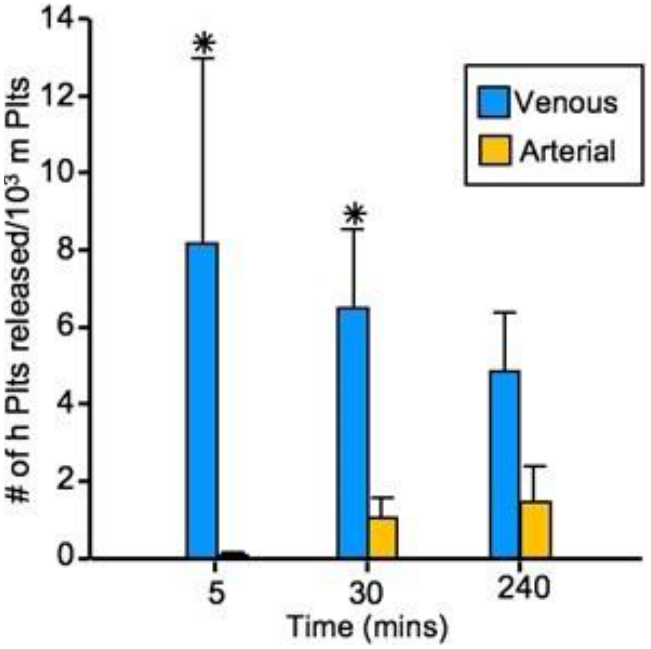

FIGURE 1 Arterial infused MKs produce significantly more plts than those infused venously (N=5; *=p<0.05)

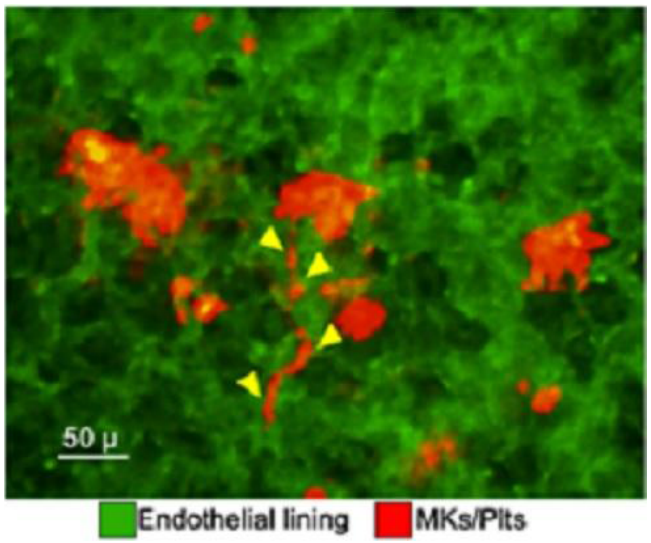

FIGURE 2 In situ lung microscopy shows calcein (red-orange) labeled human MK arrested in mouse lung with a sinuous extension after 8 mins.

OC 06.1 | Rap1A and Rap1B Functional Redundancy in Platelets and Megakaryocytes

L. Stefanini

Sapienza University of Rome, Rome, Italy

Background: RAP-GTPases are molecular switches that regulate various cellular functions, including integrin-mediated adhesion. Germline deletion of the RAP1B isoform causes elevated embryonic lethality in

mice. However, the platelet defects in the surviving *Rap1b-/-* mice are milder than in mice lacking the RAP activator, CalDAG-GEFI, suggesting that other RAP isoforms have important roles in platelet adhesion and hemostasis.

Aims: To determine the specific contribution of the most abundant RAP isoforms, RAP1A and RAP1B, to platelet activation and hemostasis.

Methods: Platelet functional responses were studied in mice where *Rap1a* and/or *Rap1b* were conditionally deleted in the megakaryocyte lineage (mKO). TALIN and integrin β3 colocalization was analysed by STORM imaging. Proplatelet formation was evaluated in bone marrow-derived megakaryocytes.

Results: *Rap1a/b-mKO* mice displayed a mild macrothrombocytopenia due to impaired proplatelet formation. *Rap1a-mKO* platelets had a significant and previously undetected defect in integrin activation, that was additive to that of *Rap1b-mKO platelets*. Combined deficiency in RAP1A and RAP1B impaired the ability of TALIN to colocalize with integrin β3 and led to an integrin activation defect comparable to that observed in *Tln1-mKO* mice. In contrast, granule secretion was only dependent on RAP1B. *In vivo, Rap1a/b-mKO mice, but not Rap1b-mKO or Rap1a-mKO* mice, were completely protected from arterial thrombosis and exhibited a severe defect in hemostasis after mechanical injury. Interestingly, at sites of inflammation, hemorrhage was observed in thrombocytopenic mice, but not in *Rap1a/b-mKO mice*.

Conclusions: Our studies demonstrate that RAP1A has a previously unrecognized role in platelet integrin activation, that the two RAP1 isoforms have both redundant and isoform-specific functions and that RAP1 signaling is critical for hemostatic plug formation, but not for other forms of hemostasis. Moreover, they provide the first direct evidence that RAP1 is important for platelet biogenesis.

OC 06.2 | The Kinase-phosphatase Pair Csk-CD148 is a Critical Regulator of Platelet Reactivity to Vascular Injury

J. Mori[1], Z. Nagy[1], R. Al Ghaithi[1], S. Heising[1], J.P. van Geffen[2], M.J.E. Kuijpers[2], J.W.M. Heemskerk[2], P. Harrison[3], A. Mazharian[1], Y.A. Senis[1]

[1]*University of Birmingham, Institute of Cardiovascular Sciences, Birmingham, United Kingdom,* [2]*University of Maastricht, Cardiovascular Research Institute Maastricht, Department of Biochemistry, Maastricht, The Netherlands,* [3]*University of Birmingham, Institute of Inflammation and Ageing, Birmingham, United Kingdom*

Background: Platelets contain high levels of Src family kinases (SFKs) that are essential for transmitting activation signals from a variety of receptors, including immunoreceptor tyrosine-based activation motif (ITAM)-containing receptors, integrins and G protein-coupled receptors. However, it remains unclear how SFKs are regulated in platelets.

Aims: To determine the role of the kinase-phosphatase pair C-terminal Src kinase (Csk) and CD148 in regulating SFK activity in platelets and their response to vascular injury.

Methods: *Csk* and *CD148* conditional double-knockout (DKO) mice were generated by crossing *Csk*- and *CD148-floxed* mice with *Pf4-Cre* transgenic mice. Platelet function was measured *in vitro* and *in vivo* using standard assays. Platelet receptor expression and signal transduction was measured by flow cytometry, western blotting and capillary-based immunoassay.

Results: Deletion of *Csk-CD148* in the megakaryocyte lineage in mice resulted in increased platelet SFK activity, but reduced platelet reactivity to collagen due to down-regulation of the ITAM-containing collagen receptor complex GPVI-FcR g-chain. Interestingly, the immunoreceptor tyrosine-based inhibition motif (ITIM)-containing receptor G6b-B and Csk-homologous kinase (Chk) were concomitantly up-regulated, contributing to the reduced platelet response. *In vitro*, whole-blood thrombus formation under non-coagulant conditions on multiple surfaces was markedly impaired; however, tissue factor-mediated thrombus formation on collagen under flow with high fibrin formation was normal. Consequently, DKO mice exhibited increased bleeding in the tail bleeding assay and thrombus instability following laser injury of arterioles in the cremaster muscle.

Conclusions: Findings from this study establish the kinase-phosphatase pair Csk-CD148 as a critical regulator of platelet SFK activity and reveal novel cell intrinsic negative feedback mechanisms that prevent pathological thrombosis from occurring.

OC 06.3 | Major Role for Rac/Cdc42 in PI3Kβ-driven Platelet Function

T. Durrant[1], T. Chessa[2], K. Anderson[2], L. Stephens[2], P. Hawkins[2], J. Downward[3], S. Moore[1], I. Hers[1]

[1]*University of Bristol, School of Physiology, Pharmacology & Neuroscience, Bristol, United Kingdom,* [2]*Babraham Institute, Cambridge, United Kingdom,* [3]*Francis Crick Institute, London, United Kingdom*

Background: Class I Phosphoinositide 3-kinase β (PI3Kβ) holds a key role in platelet activation and stable thrombus formation, attracting it considerable attention as a potential antithrombotic target. Despite this, the mechanisms underlying platelet PI3Kβ activation and it's predominance over the other Class I PI3K isoforms in these cells remain poorly understood.

Aims: Previous work in other cell types has defined a unique combination of activating inputs to PI3Kβ. These include the direct interaction of the Rho family GTPases Rac and Cdc42 with the ‚Ras-binding domain' (RBD) of the PI3Kβ catalytic subunit, p110β, and the association of p110β with the Gβγ subunits of activated heterotrimeric G proteins. We set out to define the importance of these inputs to PI3Kβ-driven platelet function.

Methods: We have used knock-in mice where p110β has been rendered unable to interact with Rac/Cdc42 (RBD mice) or with Gβγ subunits (GBG mice).

Results: Using RBD mice, we reveal that the Rac/Cdc42-binding domain of PI3Kβ is required for efficient agonist-induced platelet $\alpha_{IIb}\beta_3$ integrin activation and α-granule secretion. This was most notable

downstream of the collagen receptor glycoprotein VI (GPVI), with RBD mice also displaying a significant defect in GPVI-driven platelet aggregation and signalling to the PI3K effector, AKT. Strikingly, use of the PI3Kβ inhibitor AZD6482 suggests the Rac/Cdc42 input to p110β underlies much of PI3Kβ's role in these contexts. Surprisingly, results from the GBG mice suggest that Gβγ input to p110β does not hold a similar functional importance for PI3Kβ's role in platelet function.

Conclusions: This work identifies the Rac/Cdc42 input to p110β is an important requirement for PI3Kβ-driven platelet function, and provides important new mechanistic insights into PI3Kβ's dominant role in this cell type.

This work is funded by the British Heart Foundation.

OC 06.4 | CD40L Priming of Platelets and Activation of NF-κB are CD40-dependent

K. Kojok[1], S. El-Akoum[1], M. Mohsen[1], W. Mourad[2], M. Yahye[1,2]

[1]*Montreal Heart Institute, Research Department, Montreal, Canada,* [2]*Université de Montréal, Montreal, Canada*

Background: CD40 ligand (CD40L), a member of the Tumor Necrosis Factor superfamily, is released principally by activated platelets in the circulation and considered as a thrombo-inflammatory molecule that predicts cardiovascular events, related to enhanced platelet reactivity and thrombosis. We have shown that CD40L is a strong activator of NF-κB in platelets that primes and enhances platelet activation and aggregation in response to thrombotic stimuli. In addition to its main receptor CD40, platelets express two other CD40L receptors, αIIbβ3 and α5β1.

Aims: The present study was designed to identify the receptors of CD40L involved in platelet NF-κB activation and its implication in platelet aggregation.

Methods: Using washed human platelets, the presence of the different receptors of CD40L was determined by flow cytometry and WB. The release of CD40L was analyzed by ELISA. Activation of NF-κB was assessed by determining the phosphorylation of IκBα and P65 in human and mouse platelets. Platelet aggregation was measured optically.

Results: We showed that platelets release CD40L in response to thrombin and CD40L stimulation and express three CD40L receptors, CD40, αIIbβ3 and α5β1. CD40L, dose- and time- dependently, induced platelet NF-κB activation as revealed by IκBα and P65 phosphorylation. Activation of NF-κB by CD40L was absent in $CD40^{-/-}$ mouse platelets and inhibited by CD40 blockade in human platelets, but unaffected by αIIbβ3 or α5β1 blockade. CD40L alone had no effect on platelet aggregation but potentiated the aggregation response in the presence of priming doses of thrombin and collagen; an effect that was abolished by CD40 blockade.

Conclusions: This study demonstrates that CD40L triggers activation of NF-κB and primes platelets through the CD40 receptor, suggesting that CD40L is a platelet primer via signaling pathways involving CD40/NF-κB activation, which predisposes platelets to enhanced activation and aggregation in response to thrombotic stimuli.

OC 06.5 | Essential Role of GSK3α Phosphorylation in Restricting Platelet Activation and Thrombus Formation

I. Hers, J.A. Wersall, E.O. Agbani, R.W. Hunter, A.W. Poole, S.F. Moore

University of Bristol, School of Physiology, Pharmacology and Neuroscience, Bristol, United Kingdom

Background: Glycogen synthase kinase-3 (GSK3α) and GSK3β, are constituently active serine/threonine kinases whose activity is regulated by inhibitory phosphorylation at Ser21/Ser9 of GSK3α/β, respectively. Despite phosphorylation of GSK3α/β at Ser21/Ser9 being induced by a wide range of physiological platelet agonists, little is known about its role in platelet function and thrombosis.

Aims: To determine how loss of phosphorylation of GSK3α on Ser21 and GSK3β on Ser9 impacts on platelet function and thrombosis.

Methods: Platelet function and thrombosis was assessed using platelets from mice, where Ser21/9 of GSK3α/β is mutated to alanine. Rendering GSK3α (GSK3αKI) or GSK3β (GSK3βKI) or both GSK3α and β (GSK3α/βKI) resistant to inhibitory phosphorylation.

Results: Loss of GSK3β phosphorylation (GSK3βKI) resulted in reduced thrombin-mediated platelet aggregation and integrin $\alpha_{IIb}\beta_3$ activation, as well as reduced thrombin and CRP-mediated α-granule secretion, demonstrating that GSK3β phosphorylation contributes to both PAR and GPVI-mediated platelet function. Indeed, GSK3βKI mice showed a significant impairment of thrombus formation on a collagen-coated surface. In contrast, we found that loss of GSK3α phosphorylation had no effect on thrombin-mediated responses, but resulted in significantly enhanced responses to the GPVI agonist collagen-related peptide (CRP-XL). Integrin $\alpha_{IIb}\beta_3$ activation and P-selectin exposure were left-shifted with a decrease in the EC50 and a major increase in maximal binding. Furthermore, we show that GSK3α KI completely reversed the impaired thrombus formation observed in GSK3βKI mice, confirming that phosphorylation of these paralogs have opposing effects on thrombus formation. The enhanced platelet function in GSK3α KI platelets was blocked by wortmannin, suggesting that GSK3α phosphorylation may limit signalling through the PI3 kinase pathway.

Conclusions: Together these findings demonstrate that GSK3α phosphorylation restrains GPVI-mediated platelet activation and thrombosis.

OC 17.1 | Convection Denied: Platelet Packing Density is an Independent Regulator of the Hemostatic Response to Injury

S. Mirramezani[1], B. Herbig[2], T. Stalker[3], L. Nettey[2], M. Cooper[3], J. Weisel[4], S. Diamond[2], T. Sinno[5], S. Shadden[1], L. Brass[3], M. Tomaiuolo[3]

Philadelphia, United States, [5]University of Pennsylvania, Chemical Engineering, Philadelphia, United States

Background: The delivery and retention of coagulation factors and regulators is an important determinant of the hemostatic response to injury. Previous studies have suggested that the transport of thrombin and other platelet agonists can depend on the architecture of a nascent hemostatic thrombus and play a key role in determining its final size and the activation state of the platelets it contains.

Aims: Here we asked how the microenvironment within a hemostatic thrombus, including platelet packing density, affects the interplatelet plasma velocity and the thrombin concentration gradient in the gaps between platelets.

Methods: We have used a hybrid experimental and computational approach to reconstruct the microenvironment within a hemostatic thrombus, breaking the work into 3 stages. In the first, platelet aggregates formed under flow in a microfluidic chamber were analyzed using scanning electron microscopy to extract information about porosity and gap size distribution. In the second, a 3-dimensional model with single-platelet resolution was constructed with microenvironmental features matching the platelet aggregates formed *in vitro*. In the third, the 3D model was integrated with volume and morphology measurements of hemostatic thrombi formed *in vivo*.

Results: Our results show that over a broad range of thrombus sizes and gap sizes, the architecture of the hemostatic thrombus reduces interplatelet plasma velocity to near-stagnant levels. The internal environment of the thrombus is so sheltered that solute transport is governed by diffusion. This architecture helps to increase the local concentration of thrombin by preventing its escape.

Conclusions: Taken together, these findings demonstrate how the architectural features of the hemostatic thrombus microenvironment provide a basis to regulate chemical reactions by purely physical means.

OC 17.2 | Platelet Margination and Activation Are Essential for Thrombus Propagation in an in vitro Model of Venous Thrombosis

M. Lehmann[1], P. Krohl[1], K. Neeves[1,2]

[1]Colorado School of Mines, Chemical and Biological Engineering, Golden, United States, [2]University of Colorado, Department of Pediatrics, Aurora, United States

Background: Platelets are essential for thrombus growth in murine models of venous thrombosis (VT). Yet, these models do not capture the vortical flows and geometry that are characteristic of human venous valves where VT initiates.

Aims: To develop an in vitro flow model of VT that mimics the hemodynamics of human venous valves and to investigate the role of platelets on thrombus propagation in this model.

Methods: The flow chamber consists of a 150 X 150 µm channel that undergoes a 1:3 expansion with a varying undercut angle (90-150°) to mimic different positions of a valve leaflet (Fig. 1). Liposomal tissue factor (TF) was adsorbed in the valve sinus. Human whole blood was separated into platelet rich plasma (PRP) and red blood cells (RBC) and reconstituted to hematocrits of 0-0.6. Platelets were labeled with $DiOC_6$ prior to and/or with Annexin V after an experiment and exogenous Alexa 555-fibrinogen was added to visualize fibrin. Thrombus formation was measured by confocal microscopy as plasma, PRP, or reconstituted blood was perfused at flow rates that yield primary and secondary vortices similar to those measured in humans.

Results:

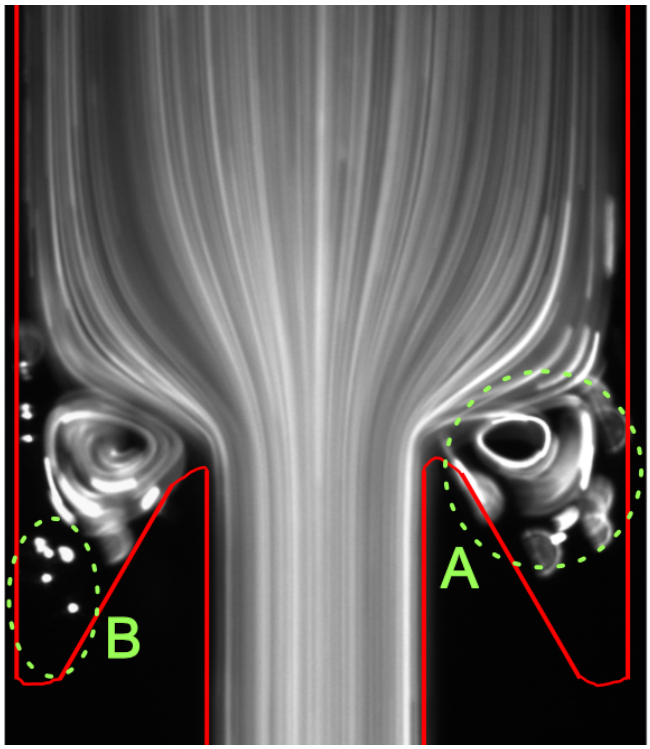

FIGURE 1 Particle tracing image of the model valve with a 150° undercut. A primary vortex (A) and a low flow zone (B) are created in the flow conditions

RBC were required for platelets to enter into the primary vortex suggesting the need for platelet margination. Platelets were required for the thrombus to grow out of the valve (Fig. 2). Plasma or RBC suspensions without platelets resulted in a fibrin gel that was confined to the deepest part of the pocket where flow is almost static. In reconstituted blood, platelets adhered to this initial fibrin gel, were activated and promoted coagulation as shown by Annexin V labeling, denser fibrin fibers, and robust thrombus growth.

Conclusions: We developed an in vitro model of VT that recreated essential features of hemodynamics in human valves. Thrombus propagation required RBC to marginate platelets so that they are delivered at a sufficient rate to adhere to fibrin and support further coagulation by PS exposure beyond TF-rich near wall regions.

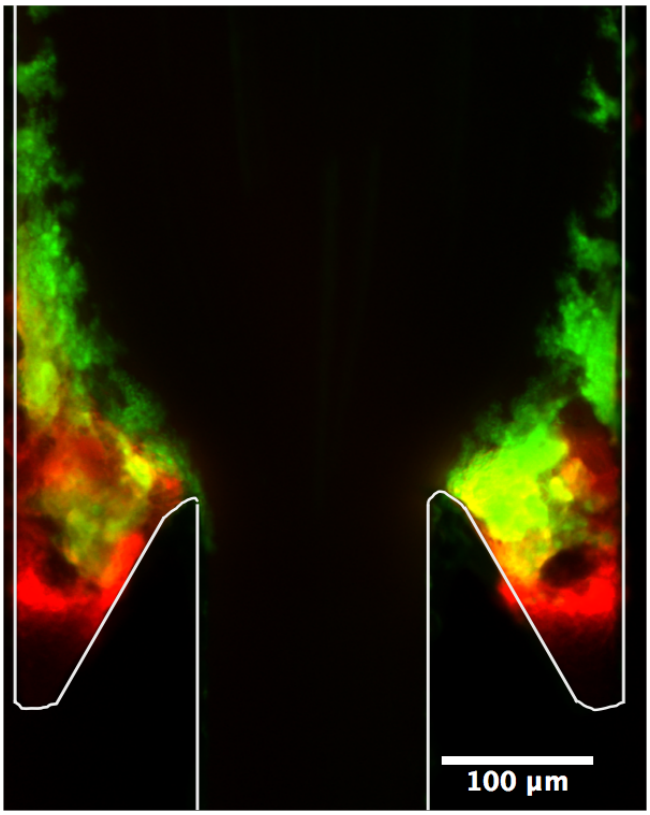

FIGURE 2 Thrombus formation in a model valve with a 150° undercut initiated by wall-bound TF after 25 min. Green: Platelets (DiOC6), Red: Fibrin(ogen)

OC 17.3 | Coactosin-like 1 is a Novel Regulator of Arterial Thrombosis and Hemostasis

I. Birkholz[1,2], S. Stritt[2,3], S. Beck[2,3], K.G. Heinze[4], G. Krohne[5], B. Nieswandt[2,3]

[1]*University Hospital Würzburg, Institute of Experimental Biomedicine - Department I, Würzburg, Germany,* [2]*University of Würzburg, Rudolf Virchow Center, Würzburg, Germany,* [3]*University Hospital Würzburg, Institute of Experimental Biomedicine-Department I, Würzburg, Germany,* [4]*University of Würzburg, Bio-Imaging Center, Würzburg, Germany,* [5]*University of Würzburg, Department of Cell and Developmental Biology, Würzburg, Germany*

Background: Cytoskeletal rearrangements play an important role in platelet activation by facilitating platelet shape change and the formation of filo- and lamellipodia that are critical for normal hemostasis. Coactosin-like 1 (Cotl1) is a small filamentous actin-binding protein that consists of a single actin-depolymerizing factor homology (ADF-H) domain. Cotl1 was shown to prevent cofilin-mediated depolymerization of actin filaments and to regulate the activity of 5-lipoxygenase that is implicated in leukotriene synthesis.

Aims: We investigated the role of Cotl1 in platelet production and function *in vitro* and *in vivo*.

Methods: We generated the first MK-/platelet-specific Cotl1-deficient (*Cotl1*$^{fl/fl\text{-}Pf4Cre}$) mouse line. Platelet morphology and function was assessed *in vitro* under static and dynamic conditions, as well as *in vivo*.

Results: *Cotl1*$^{fl/fl\text{-}Pf4Cre}$ mice displayed unaltered platelet counts and size compared with controls, suggesting unaltered thrombopoiesis. In addition, platelet activation and aggregation responses to various platelet agonists were normal in Cotl1-deficient mice. Surprisingly, despite the proposed inhibitory role of Cotl1 in actin dynamics, actin polymerization and cytoskeletal organization were unaltered in platelets lacking Cotl1 compared with controls. Strikingly, however, *Cotl1*$^{fl/fl\text{-}Pf4Cre}$ platelets showed a significantly reduced adhesion and aggregate formation on collagen I in a flow adhesion assay indicating impaired cellular activation under conditions of shear flow. *In vivo* this defect translated into slightly prolonged bleeding times and a profound protection from occlusive arterial thrombus formation.

Conclusions: In summary, we show for the first time that Cotl1 is dispensable for actin dynamics in platelets, but we identified a central regulatory role of Cotl1 in hemostasis and arterial thrombosis.

OC 17.4 | Clathrin-mediated Endocytosis is Required for Normal Platelet Hemostatic Function

S. Giannini[1,2], H.F.G. Heijnen[3], E. Legan[4], K.M. Hoffmeister[1,2,4], H. Falet[4,5]

[1]*Brigham and Women's Hospital, Division of Hematology, Boston, United States,* [2]*Harvard Medical School, Department of Medicine, Boston, United States,* [3]*University Medical Center Utrecht, Department of Clinical Chemistry and Hematology, Utrecht, The Netherlands,* [4]*Blood Research Institute, Milwaukee, United States,* [5]*Medical College of Wisconsin, Department of Cell Biology, Neurobiology, and Anatomy, Milwaukee, United States*

Background: Clathrin-mediated endocytosis (CME), the process by which cells internalize specific extracellular material and plasma membrane proteins, contributes to a wide range of cellular functions, including receptor signaling, cell adhesion, and migration. In platelets and megakaryocytes (MKs), CME mediates the uptake of fibrinogen into α-granules, and the internalization of thrombopoietin (TPO), thereby regulating hemostasis, megakaryopoiesis and thrombopoiesis. CME requires cargo receptor-dependent formation of clathrin-coated vesicles (CCVs), and their subsequent release into the cytosol by dynamin 2 (DNM2)-dependent membrane fission. *Dnm2*$^{fl/fl}$ *Pf4-Cre* (*Dnm2*$^{Plt-/-}$) mice specifically lacking DNM2 in the MK/platelet lineage develop severe macrothrombocytopenia. Further, *Dnm2*$^{Plt-/-}$ platelets fail to internalize TPO. Consequently, *Dnm2*$^{Plt-/-}$ mice develop myelofibrosis.

Aims: Here we investigated the role of CME in platelet hemostatic function.

Methods: In vivo and in vitro platelet activation parameters were determined in *Dnm2*$^{Plt-/-}$ mice.

Results: *Dnm2*$^{Plt-/-}$ mice had a severe bleeding diathesis with a tail bleeding time greater than 10 min, compared to 1.16 min in control mice. Consistent with impaired CME, *Dnm2*$^{Plt-/-}$ platelets were depleted of fibrinogen, but normally contained other α-granule proteins

such as von Willebrand factor and CD62P. *Dnm2*$^{Plt-/-}$ platelets were severely dysfunctional, as evidenced by poor α-granule release (CD62P expression) and αIIbβ3 activation (fibrinogen binding) in response to thrombin and the GPVI agonists, collagen-related peptide (CRP) and convulxin. *Dnm2*$^{Plt-/-}$ platelets failed to phosphorylate proteins on tyrosine, including phospholipase C-γ2, in response to CRP. Further, *Dnm2*$^{Plt-/-}$ platelets failed to spread in response to thrombin, and instead accumulated arrested CCVs and filamentous actin (F-actin) clusters.

Conclusions: Together, the data show that CME plays a critical role in normal platelet hemostatic function in vivo, and platelet receptor signaling and spreading in vitro.

OC 17.5 | Platelet-mediated Activation of FasR and Subsequent Phosphatidylserine Exposure of Red Blood Cells is Substantial for Thrombus Formation and Hemostasis

K.J. Krott[1], C. Klatt[1], S. Zey[1], N.S. Gowert[1], A. Oberhuber[2], M. Schaller[3], M. Kelm[4], H. Schelzig[2], M. Elvers[1]

[1]University Clinic of the Heinrich-Heine-University, Research Group Molecular Hemostasis, Duesseldorf, Germany, [2]University Hospital Düsseldorf, Department of Vascular and Endovascular Surgery, Düsseldorf, Germany, [3]University of Tübingen, Department of Dermatology, Tübingen, Germany, [4]Heinrich Heine University, Department of Cardiology, Pulmonology and Vascular Medicine, Düsseldorf, Germany

Background: A critical step in thrombus growth and stability is the contribution of platelets to coagulation and thrombin generation by providing a procoagulant surface. Recently, red blood cells (RBCs) were described to externalize phosphatidylserine (PS) on the membrane and might contribute to thrombin generation. First results point to a direct interaction of platelets and RBCs important for thrombin generation and stable thrombus formation suggesting an active role for RBCs in hemostasis and thrombosis beside their impact in rheology.

Aims: To analyze the impact of RBCs in platelet activation and stable thrombus formation.

Methods: Analysis of RBCs and RBC-platelet interactions upon thrombus formation were performed using platelets from different knock-out mice and patients.

Results: Platelet activation was enhanced by a small population of RBCs via direct cell-cell contact mediated by the FasL-FasR signaling pathway. Activated platelets externalized FasL on the membrane that activated FasR on RBCs leading to PS exposure on the RBC membrane. Accordingly, inhibition or genetic deletion of FasR on RBCs strongly reduced PS exposure followed by inhibition of three-dimensional thrombus formation *in vitro* and *in vivo*. Furthermore, decreased PS exposure of RBCs after treatment of platelets with ReoPro (Abciximab) suggests that integrin aIIbb3 serves as another ligand on the platelet membrane important for FasR activation on RBCs. Direct cell-cell contacts of platelets and RBCs have been observed in arterial thrombi derived from patients that underwent thrombectomy providing first evidence that FasL-FasR mediated cell contacts of platelets and RBCs reflect a pathophysiological mechanism as well.

Conclusions: RBCs play an active role in platelet thrombus formation. Thus, interfering with the interaction of platelets and RBCs by FasR inhibition might be a promising approach for a completely novel antithrombotic strategy.

OC 18.1 | Platelet GPIba Is Important for Liver Thrombopoietin (TPO) Production

M. Xu[1,2], G. Zhu[2], J. Li[1,2,3], N. Carrim[2,3], S. Kunishima[4], J. Ware[5], Z. Ruggeri[6], J. Freeman[1,2], H. Ni[1,2,3]

[1]University of Toronto, Toronto, Canada, [2]St Michael's Hospital, Toronto, Canada, [3]Canadian Blood Services, Toronto, Canada, [4]National Hospital Organization Nagoya Medical Center, Nagoya, Japan, [5]University of Arkansas for Medical Sciences, Little Rock, United States, [6]The Scripps Research Institute, La Jolla, United States

Background: TPO generation primarily occurs in liver parenchymal cells with minor amounts in other tissues. TPO clearance is mainly through platelets and megakaryocytes via c-Mpl-TPO interaction and its subsequent internalization and degradation. Although it was reported that platelets may play a role in TPO production, the mechanism and the key platelet receptor involved in this process are largely unknown.

Aims: To investigate the role of GPIbα in TPO generation.

Methods: Plasma TPO from wild type (WT), GPIbα$^{-/-}$ (KO), IL-4Rα/GPIbα transgenic (Tg) mice were measured with enzyme-linked immunosorbent assay. Clinical samples from Bernard Soulier Syndrome (BSS) patients were tested with chemiluminescentenzyme immunoassay.

Results: Interestingly, we observed a ~50% decrease in circulating TPO in KO mice compared with syngeneic WT and β3$^{-/-}$ mice. Similar results were also observed in GPIbα deficient BSS patients. We found TPO clearance was not enhanced but hepatic TPO mRNA was lower in KO mice compared to WT mice. Furthermore, transfusion of WT, but not KO platelets markedly increased TPO levels in circulation and mRNA transcription in the livers of KO mice. To determine whether the extracellular portion of GPIbα is required for platelet mediated TPO generation, we utilized Tg mice in which most of the extracellular domain of GPIbα is replaced by IL-4Rα. We found the TPO levels in these Tg mice were also low. Similarly, transfusion of Tg platelets did not affect TPO levels in KO, Tg or WT mice, but transfusion of WT but not KO or Tg platelets significantly improved TPO levels in Tg mice. In vitro studies further demonstrated that co-culturing GPIbα$^{-/-}$ platelets with hepatocytes resulted in less platelet uptake and lower mRNA transcription as compared to WT control platelets.

Conclusions: Our animal models and human studies clearly demonstrated that GPIbα is required for platelet mediated TPO generation from liver. These not only provide novel understandings of platelet homeostasis, but also the pathobiology of BSS.

OC 18.2 | Intravital Microscopy Reveals Key Role of Kupffer Cells in Clearance of Desialylated Platelets

C. Deppermann, P. Kubes

Snyder Institute for Chronic Diseases, Calgary, Canada

Background: The human body produces 10^{11} platelets every day by shedding from bone marrow megakaryocytes into the circulation. Platelets patrol the vasculature for about 10 days and at the end of their lifetime get cleared through a process that was shown to depend on the loss of sialic acid residues on the platelet surface receptor GPIb. Recent studies have shown that desialylation causes platelet clearance via the Ashwell-Morell receptor on hepatocytes. While there have been several advances in the field, it is still unclear how exactly platelets are cleared and how this process is regulated.

Aims: To investigate the process of platelet clearance *in vivo* using intravital microscopy of the liver.

Methods: Spinning-disk intravital confocal microscopy was performed on the liver of anesthetized mice. Mice were either treated with sialidase to induce *in vivo* desialylation of platelets or *ex vivo* desialylated platelets were labeled with CellTracker dye and transfused into mice. Kupffer cells and endogenous platelets were labeled using fluorescent anti-F4/80 and anti-CD49b antibodies, respectively.

Results: After application of sialidase, *in vivo* desialylated platelets accumulate on Kupffer cells within minutes. To rule out side-effects of *in vivo* administration of sialidase, *ex vivo* desialylated platelets were transfused into mice. *Ex vivo* desialylated platelets rapidly adhered to Kupffer cells and this adherence was specific for sialidase-treatment, since untreated transfused platelets continued circulating in the liver vasculature. Interestingly, the adhesion of desialylated platelets to Kupffer cells was independent of integrin alpha-M, since platelets adhered to the same extent in both wildtype and Mac-1-deficient mice. Of note, we did not observe uptake of platelets by hepatocytes.

Conclusions: Our data indicates that Kupffer cells play an important role in the clearance of desialylated platelets that is independent of integrin alpha-M.

OC 18.3 | Twinfilin 2a Is a Central Regulator of Platelet Reactivity and Turnover in Mice

I. Becker[1,2], S. Stritt[1,2,3], S. Beck[1,2], T. Vögtle[1,2], M. Hakala[4], K.G. Heinze[2], X. Du[5], M. Bender[1,2], A. Braun[1,2], P. Lappalainen[4], B. Nieswandt[1,2]

[1]*Institute of Experimental Biomedicine I, University Hospital, University of Würzburg, Wuerzburg, Germany,* [2]*Rudolf Virchow Center, University of Würzburg, Wuerzburg, Germany,* [3]*Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden,* [4]*Institute of Biotechnology, University of Helsinki, Helsinki, Finland,* [5]*Department of Pharmacology, University of Illinois, Chicago, United States*

Background: Controlled reorganization of the actin cytoskeleton is a prerequisite for proper platelet production and function and defects in actin-regulating proteins have been associated with platelet disorders in humans and mice. The small actin monomer-binding protein Twinfilin 2a (Twf2a) is thought to play an ambivalent role in actin dynamics. Twf2a inhibits actin filament assembly on barbed ends by capping and pointed end growth by sequestration of G-actin monomers. On the other hand, it favors filament assembly by localizing actin monomers to places of rapid actin turnover. Even though Twf2a has been implicated as a key molecule in actin dynamics, only little is known about its precise molecular function *in vivo*.

Aims: We aimed to elucidate the precise role of Twinfilins in platelet production and function.

Methods: Platelet production and function was studied in a broad range of *in vitro* assays and *in vivo* models of hemostasis and arterial thrombus formation.

Results: Here we report that constitutive Twf2a-deficient mice (*Twf2a*$^{-/-}$) display a mild macrothrombocytopenia due to a markedly reduced platelet half-life, and an increased number of proplatelet-forming megakaryocytes in the bone marrow. Twf2a-deficient platelets showed enhanced integrin activation and α-granule release in response to stimulation of (hem)ITAM and G-protein-coupled receptors, increased adhesion and aggregate formation on collagen I under flow and accelerated spreading on fibrinogen. In vivo, Twf2a deficiency resulted in shortened tail bleeding times and accelerated occlusive arterial thrombus formation. The hyper-reactivity of *Twf2a*$^{-/-}$ platelets was attributed to enhanced actin dynamics leading to sustained integrin activation, which collectively may explain the accelerated platelet turnover in *Twf2a*$^{-/-}$ mice.

Conclusions: In summary, our results demonstrate that Twf2a-controlled actin rearrangements dampen platelet activation responses and thereby indirectly regulate platelet survival in mice.

OC 18.4 | Investigating the Mechanisms of Clearance of Pre-activated Platelets in Mice Lacking Function of the Rap1 GAP Rasa3

R.H. Lee[1], C. Casari[1], D.S. Paul[1], L. Stefanini[2], L.L. Peters[3], W. Bergmeier[1,4]

[1]*University of North Carolina at Chapel Hill, McAllister Heart Institute, Chapel Hill, United States,* [2]*Sapienza University of Rome, Department of Internal Medicine and Medical Specialties, Rome, Italy,* [3]*The Jackson Laboratory, Bar Harbor, United States,* [4]*University of North Carolina at Chapel Hill, Department of Biochemistry and Biophysics, Chapel Hill, United States*

Background: Recently, our lab has shown that loss of the Rap GTPase-activating protein (GAP) Rasa3 (Rasa3$^{hlb/hlb}$, "hlb") leads to pre-activation and premature clearance of circulating platelets due to increased Rap1 activation. However, the mechanism of clearance of these platelets remains undetermined.

Aims: The objective of these studies was to determine the mechanism(s) underlying increased platelet clearance in hlb mice.

Methods: Mice used for these studies were at least 8 weeks old and were bred onto a C57BL/6 background. Platelet lifespan was determined by labeling platelets in vivo with an anti-GPIX antibody. Spleens and livers were perfusion fixed and frozen sections collected

for immunofluorescence using anti-GPIX and anti-F4/80 antibodies to stain platelets and macrophages in tissue, respectively.

Results: Mice lacking Rasa3 function (hlb) are thrombocytopenic primarily due to a markedly reduced platelet half-life in circulation. The increased clearance is intrinsic to platelets as hlb platelets transfused into wild-type mice are also rapidly cleared. While radioactive tracer studies identify the spleen and liver as sites of clearance, splenectomy and/or clodronate treatment had no significant effect on platelet counts in hlb mice. When we crossed hlb mice with mice lacking CalDAG-GEFI or the integrin adaptor Talin1, platelet survival and peripheral counts were significantly rescued, suggesting that enhanced platelet clearance in hlb mice is the result of uncontrolled Rap1-αIIbβ3 signaling. In ongoing work, we are using conventional immunohistochemistry approaches as well as intravital microscopy imaging of the liver microcirculation to identify mechanisms driving platelet clearance.

Conclusions: The Rap-GAP, Rasa3, is a critical inhibitor of Rap1-dependent platelet activation in circulation. Platelets lacking functional Rasa3 are seemingly cleared in a phagocyte-independent manner by a mechanism that involves talin-dependent integrin signaling.

OC 18.5 | TNF-α is an Important Factor for Platelet Hyperreactivity in Aging

P. Davizon-Castillo[1], S. Aguila[2], K. Higa[3], K.J. Ashworth[4], G. Hernandez[5], D. Bark[6], R.A. Campbell[7], M. Rondina[8], J. DeGregori[3], E.M. Pietras[5], J. Di Paola[4,9]

[1]University of Colorado, Pediatric Hematology, Denver, United States, [2]Royal College of Surgeons in Ireland, Irish Center for Vascular Biology, Dublin, Ireland, [3]University of Colorado, Department of Molecular Biology, Aurora, United States, [4]University of Colorado, Pediatric Hematology, Aurora, United States, [5]University of Colorado, School of Medicine, Division of Hematology, Aurora, United States, [6]Colorado State University, Department of Mechanical Engineering, Fort Collins, United States, [7]University of Utah School of Medicine, Molecular Medicine, Salt Lake City, United States, [8]University of Utah School of Medicine, Department of Medicine and George E. Wahlen VAMC GRECC, Salt Lake City, United States, [9]University of Colorado, Deparment of Genetics and Genomics Program, Aurora, United States

Background: Chronic inflammation due to elevated levels of IL-1β and TNF-α is a major component of the aging process. In addition, aging is an independent risk factor for thrombosis. The contribution of platelets to thrombosis during aging or states of inflammation and the mechanism promoting hyperreactivity needs to be further elucidated.

Aims: To investigate the mechanism(s) by which pro-inflammatory cytokines involved in aging may promote platelet hyperreactivity.

Methods: We analyzed megakaryocyte maturation, platelet number, and activation by FACS and functional assays using the following murine models of aging and inflammation: 1) aged C57BL/6J (>16 months old); 2) mice with constitutive expression of TNF-α ($TNF^{\Delta ARE}$) and; 3) C57BL/6J mice (2 months old) injected with IL-1β or TNF-α (1,5 or 20 days). In addition, to gain a better understanding of the molecular changes that occur in megakaryocytes and platelets during aging and inflammation, we sorted native megakaryocytes for transcriptome analysis by RNA-seq.

Results: Platelets from aged, $TNF^{\Delta ARE}$, and mice injected with TNF-α, have significantly higher phosphatidylserine exposure and active αIIbβ3 upon activation with thrombin. This hyperreactivity was also evident in a microfluidic assay when measuring platelet adhesion and aggregation on collagen surfaces. Interestingly, mice exposed to either IL-1β or TNF-α exhibited thrombocytosis and accelerated megakaryocyte maturation. However, only mice exposed to TNF-α developed the platelet hyperreactive phenotype.

Conclusions: Our data suggest that the platelet hyperreactive phenotype of aging could be directly associated with elevated TNF-α levels given that mice treated with IL-1β developed thrombocytosis but not the hyperreactive phenotype. We are undertaking transcriptome analysis of native megakaryocytes to provide significant insight into the molecular pathways governing platelet hyperreactivity, therefore, opening doors to possible new therapeutic interventions.

OC 29.1 | Platelet-dependent Leukocyte Adhesion and Fate in Whole Blood Thrombus Formation

M. Nagy[1], S. Montague[2], M.A.H. Feijge[1], T.G. Mastenbroek[1], K. Egan[3], F.N. Ainle[3,4], R.R. Koenen[1], S.P. Watson[2], J.M.E.M. Cosemans[1], J.W.M. Heemskerk[1]

[1]Maastricht University / Cardiovascular Research Institute Maastricht (CARIM), Department of Biochemistry, Maastricht, The Netherlands, [2]University of Birmingham, Institute of Cardiovascular Sciences, Birmingham, United Kingdom, [3]University College Dublin/School of Medicine and Medical Science, Dublin, Ireland, [4]University College Dublin/Conway Institute, Dublin, Ireland

Background: Leukocytes attract to platelet thrombi in late stages of thrombus formation. How this leads to leukocyte activation is unknown.

Aims: Characterization of leukocyte functions attracted to a thrombus.

Methods: Human platelet thrombi with increasing extent of platelet activation (type I< II< III) were formed by whole blood perfusion over collagen microspots. Leukocyte adhesion, differentiation and responses were assessed by multi-colour confocal microscopy. Interactions of activated platelets and neutrophils were confirmed in static systems and by flow cytometry.

Results: Type-III thrombi formed on collagen/tissue factor, supporting thrombin generation, were most attractive for leukocytes (>95% neutrophils CD15+). Platelets in type-III thrombi displayed highest secretion markers. Neutrophils attracted to these thrombi stayed attached for up to 6 h, and expressed the following functional markers/responses:

1. expressed CD66b and MPO;
2. production of reactive oxygen species (ROS);
3. repetitive, transient rises in cytosolic Ca^{2+} during movement at and between thrombi;
4. proteolytic degradation and endocytosis of collagen. Remarkably, the neutrophils were highly reluctant to form neutrophil extracellular traps (NETs) even after 16 h of incubation (citrulline histone H3; < 15%).

Post-silencing of platelets in thrombi with stable prostacyclin marked impaired neutrophil responsiveness, pointing to persistent platelet activity. Surface-located CCL5 (RANTES) stimulated neutrophil attachment. Blockage of CXCL7 (NAP2) but not of CXCL4 (PF4) silenced Ca^{2+} rises of those neutrophils nearby thrombi. Platelet silencing and CXCL7 blockage diminished the majority of neutrophil responses, but not ROS production.

Conclusions: Persistent secretion of chemokines CXCL7 and CCL5 from platelet thrombi attracts and activates neutrophils, induces Ca^{2+} rises, secretion and proteolytic collagen degradation, with no more than limited NETs formation. Thrombus silencing suppresses this neutrophil activation.

OC 29.2 | The Contribution of Platelet Adhesion Receptors to Vascular Integrity during Inflammation Is Stimulus and Organ Dependent

J. Rayes[1], S. Lax[1], A. Gros[2], S. Wichaiyo[1], S. Jadoui[2], V. Ollivier[2], J. Ware[3], B. Nieswandt[4], M. Jandrot-Perrus[2], S. Watson[1], B. Ho Tin Noé[2]

[1]Institute of Cardiovascular Sciences, College of Medical and Dental Sciences, University of Birmingham, Birmingham, United Kingdom, [2]INSERM U1148, Paris, France, [3]University of Arkansas for Medical Sciences, Little Rock, United States, [4]University Hospital and University of Würzburg, Würzburg, Germany

Background: Platelets maintain vascular integrity in various inflamed organs. Results from previous studies have indicated that platelet GPVI and CLEC-2 could be central to this function. Notably, GPVI was shown to support repairing of neutrophil-inflicted vascular injury in the inflamed skin. Whether the same mechanism also operates in other inflamed organs remains to be determined, as well as how CLEC-2 would contribute to it.

Aims: We investigated and compared the roles of GPVI, CLEC-2, and GPIb to the prevention of inflammatory bleeding in the inflamed skin and lungs.

Methods: The cutaneous reverse passive Arthus reaction (rpA) and intranasal lipopolysaccharide (LPS) instillation were induced in mice with a deficiency in CLEC-2 and/or GPVI, in IL4R-GPIbα transgenic mice, which lack the extracellular domain of GPIb, and in mice immunodepleted for platelets. Neutrophil recruitment and bleeding following rpa and LPS-induced lung inflammation were assessed by analysis of skin homogenates and of bronchoalveolar lavage fluid (BALF).

Results: Mice with deletion of CLEC-2 on platelets did not bleed in the rpa. This was in contrast to the cutaneous bleeding of $GPVI^{-/-}$ mice. RpA-induced bleeding in mice deficient in both GPVI and platelet CLEC-2 was more severe than in $GPVI^{-/-}$ mice, and approached that of thrombocytopenic mice. In LPS-inflamed lungs, neither GPVI- nor platelet CLEC-2-deficient mice bled, which was in contrast to the bleeding phenotype of IL4R-GPIbα-tg mice. Quantification of neutrophils in BALF indicated that the inflammatory reaction developed normally in both GPVI- and platelet CLEC-2-deficient mice.

Conclusions: GPVI plays the major role in preventing bleeding in the rpa, with CLEC-2 being involved only in the absence of GPVI. In contrast, neither receptor plays a prominent part in preventing bleeding in LPS-inflamed lungs, which relies on GPIb. Our results demonstrate that the contribution of platelet adhesion receptors to vascular integrity varies between vascular beds and inflammatory challenges.

OC 29.3 | Human Endoglin as a Potential New Partner Involved in Platelet-Endothelium Interactions

E. Rossi[1], M. Pericacho[2], C. Bachelot-Loza[1], D. Pidard[1], P. Gaussem[3], S. Poirault-Chassac[1], F.J. Blanco[4], C. Langa[4], C. Gonzalez-Manchon[4], J.M. Lopez-Novoa[2], D.M. Smadja[3], C. Bernabeu[4]

[1]Paris Descartes University - INSERM UMRS 1140, Paris, France, [2]University of Salamanca, Salamanca, Spain, [3]Paris Descartes University - INSERM UMRS 1140, AP-HP Hôpital Européen Georges Pompidou, Paris, France, [4]Centro de Investigaciones Biologicas (CIB) - CSIC, Madrid, Spain

Background: Hereditary hemorrhagic telangiectasia type 1 (HHT1) is characterized by a bleeding tendency that is postulated to be a consequence of telangiectasia fragility rather than a platelet defect. HHT1 patients present heterozygous mutations in the endoglin gene resulting in a loss of expression of membrane endoglin (Eng) on endothelial cells (EC).

Aims: We reported that endothelial Eng is involved in inflammation via its RGD motif, through integrin-mediated leukocyte adhesion and transmigration. These data prompted us to hypothesize that Eng may act as an adhesion molecule involved in the interaction between EC and platelets through integrin recognition.

Methods: Blood samples were obtained from healthy donors, HHT1 and Glanzmann´s thrombasthenia patients. Bleeding time in Eng-haplodeficient (Eng+/-) and wildtype (Eng+/+) mice was studied. Generation of stable cell transfectants in L6E9 rat myoblasts, expressing human Eng, and in Chinese hamster ovary (CHO) cells, expressing human αIIbβ3, were carry out. Microfluidic devices were used to evaluate shear-resistant platelet adhesion.

Results: We find that the extracellular domain of human Eng promotes platelet adhesion under static conditions and confers resistance of adherent platelets to detachment upon exposure to flow. Also, platelets adhere to confluent EC in an Eng-mediated process. CHO cells ectopically expressing the human αIIbβ3 integrin acquire the capacity to adhere to myoblast transfectants expressing human Eng, whereas platelets from Glanzmann´s thrombasthenia patients lacking the αIIbβ3 integrin are defective for Eng-dependent adhesion to EC. Furthermore, the bleeding time, but not the prothrombin time, is significantly prolonged in Eng+/- mice compared to Eng+/+ mice.

Conclusions: These results suggest a new and critical role for Eng in αIIbβ3 integrin-mediated adhesion of platelets to the endothelium and may provide a better understanding on the basic cellular mechanisms in thrombo-inflammatory events.

OC 29.4 | VWF-Mediated Platelet ´Priming´ Potentiates Novel Leukocyte Interactions under Flow

A. Constantinescu-Bercu, I.I. Salles-Crawley, K.J. Woollard, J.T.B. Crawley

Imperial College London, London, United Kingdom

Background: Platelet-leukocyte interactions are important in diverse conditions, such as atherogenesis, infection and DVT. All previously characterised interactions between platelets and leukocytes, require at least one of the cells to be fully activated before they can interact (e.g. via P-selectin,-PSGL, Mac1, CD40-CD40L). We hypothesised that the VWF-GPIbα interaction ‚primes' (but does not activate) platelets under flow leading to leukocyte binding.

Aims: To characterise novel platelet-leukocyte interactions under flow.

Methods: VWF A1 domain was purified and captured onto flow channels. Labelled whole or plasma-free blood was perfused at defined shear rates ($50s^{-1}$ to $1000s^{-1}$). Platelet and leukocyte binding were quantified.

Results: Binding of GPIbα to VWF A1 under flow ‚primed' platelets causing rapid and repeated release of intracellular Ca^{2+}, activation of Src kinase and activation of $\alpha_{IIb}\beta_3$ that promoted platelet aggregation. VWF-primed platelets captured neutrophils and T cells (but not monocytes or B cells) under low shear ($50s^{-1}$). Leukocyte binding was not influenced by blocking P-selectin, but was completely inhibited by $\alpha_{IIb}\beta_3$ blockade. Leukocyte binding was increased 3- to 5-fold in the absence of fibrinogen. Addition of fibrinogen to plasma-free blood induced a concentration-dependent decrease in leukocyte adhesion, suggesting that leukocytes and fibrinogen compete for binding activated $\alpha_{IIb}\beta_3$. In support of this, channels directly coated with activated $\alpha_{IIb}\beta_3$ captured neutrophils and T cells leading to phenotypic changes within neutrophils.

Conclusions: VWF A1-GPIbα binding under flow ‚primes' platelets, leading to the activation of $\alpha_{IIb}\beta_3$. For the first time, we show that $\alpha_{IIb}\beta_3$ can directly interact with neutrophils and T cells, providing a novel mechanism that drives platelet-leukocyte cross-talk. Work is now underway to identify $\alpha_{IIb}\beta_3$-binding receptors, and to characterise the functional response of leukocyte tethering to primed platelets.

OC 29.5 | Platelets Protect Cardiomyocytes from Ischaemic Damage

T. Walsh, A. Poole

University of Bristol, Physiology, Pharmacology & Neuroscience, Bristol, United Kingdom

Background: Upon activation, platelets secrete their granule cargo causing occlusive thrombosis and ischaemic injury, while also exerting heterogeneous effects on numerous cells in the vascular niche. It is unknown if this cargo can directly modulate ischaemic injury to cardiomyocytes.

Aims: To investigate if cargo secreted from activated platelets can exert protective or deleterious effects on cardiomyocytes during ischaemia.

Methods: Primary ventricular cardiomyocytes were isolated by Langendorff perfusion from hearts of adult mice and subjected to ischaemic injury using an *in vitro* pelleting method.

Results: Pretreating cardiomyocytes with releasates from collagen related peptide (CRP)-treated murine platelets delayed the rate of cardiomyocyte death during ischaemia. This cardioprotective effect was completely lost using platelets from *Unc13d*^{Jinx}mice, which have a major granule secretion defect. Similarly, the protective effect was abrogated when the releasate was separated into a < 3 kDa fraction, excluding a role for small molecules from platelet dense granules. Inhibitor studies targeting receptors for stromal cell-derived factor (SDF)-1α and transforming growth factor (TGF)-β1 on cardiomyocytes identified important roles for these α-granule-derived proteins in mediating cardioprotection. Mechanistically, platelet releasates enhanced protein kinase C (PKC) activity in cardiomyocytes during ischaemia, while inhibiting PKC activity in cardiomyocytes effectively blocked the protective signals from platelet cargo. Importantly, pretreating platelets with a $P2Y_{12}$ antagonist, but not the cyclooxygenase inhibitor aspirin, substantially attenuated the protective effect on cardiomyocytes.

Conclusions: These findings therefore reveal a paradoxically protective role for platelet activation during cardiac ischaemia, but also have important implications for the use of anti-platelet therapeutics in the management of myocardial infarction.

OC 30.1 | NOX2 as an Anti-thrombosis Target: Small Molecule Targeting of Rac1-p67phox Signaling Prevents NOX2 Mediated GPVI- and Non-GPVI Dependent ROS Generation and Platelet Activation

H. Akbar[1], X. Duan[2], S. Saleem[1], A.K. Davis[2], Y. Zheng[2]

[1]*Ohio University, Biomedical Sciences, Athens, United States,* [2]*Cincinnati Children's Hospital Medical Center, Division of Experimental Hematology and Cancer Biology, Cincinnati, United States*

Background: Platelets from mice deficient in NADPH oxidase isoform NOX2 exhibit diminished ROS generation and platelet activation (ATVB 36:846, 2016). Binding of Rac1 GTPase to $p67^{phox}$ plays a critical role in NOX2 activation by facilitating the assembly of the NOX2 enzyme complex (Physiol Rev 87:245, 2007).

Aims: In this study we tested our hypothesis that Rac1-$p67^{phox}$ interaction is critical for ROS generation by NOX2 and that small molecules interfering with this interaction may constitute anti-thrombosis agents.

Methods: We investigated the effects of Phox-I, a rationally designed small molecule inhibitor of Rac1-$P67^{phox}$ interaction (Chem & Biol

19:228, 2012), to determine if inhibition of Rac1-p67^{phox} interaction prevents ROS generation and platelet activation. ROS generation was determined by flow cytometry in dcf-da loaded washed platelets.

Results: Collagen-related peptide (CRP) or thrombin induced ROS generation in a time- and a dose-dependent manner. Treatment of platelets with Phox-I (1-10 μM) inhibited CRP induced:

(a) ROS generation;
(b) binding of PAC1 antibody to platelets;
(c) release of p-selectin;
(d) secretion of ATP; and
(e) Akt phosphorylation. Platelets from Rac1$^{-/-}$ mice or human platelets treated with NSC23766, a specific Rac inhibitor, produced significantly less ROS in response to CRP, but a combination of NSC23766 and Phox-I did not show an additive effect on ROS inhibition. Incubation of platelets with Phox-I inhibited thrombin induced:

(a) ROS generation;
(b) secretion of ATP;
(c) platelet aggregation;
(d) phosphorylation of Akt; and
(e) the rise in cytosolic calcium.

Conclusions: These data, taken together with earlier reports that Rac1 is required for thrombin induced ROS production (PloS One 11(9): e0163227, 2016) and NOX2 complex is genetically essential for thrombus formation (ATVB 36:846, 2016), suggest that small molecules targeting the Rac1-p67phox interaction may serve as anti-thrombosis agents by preventing GPVI- and non-GPVI mediated ROS generation and platelet activation.

OC 30.2 | Evidence from Protein Kinase C δ Y155F Knock-in Mice Reveal Positive Regulatory Role of Y155 in GPVI-mediated Platelet Activation

A. Patel, D. Bhavanasi, J. Kostyak, R. Turaga, R. Badolia, C. Dangelmaier, S. Kim, S. Kunapuli

Temple University School of Medicine, Philadelphia, United States

Background: Protein kinase C delta (PKCδ) is a serine/threonine kinase involved in a vast array of cellular functions and is differentially tyrosine phosphorylated depending on the agonist. In platelets, PKCδ positively and negatively regulates dense granule secretion in response to protease-activated receptors (PAR) and Glycoprotein VI (GPVI) agonists, respectively however how PKCδ regulates these functions is not understood. Hence, we speculate that the differential regulation by PKCδ in platelets is due to differences in its tyrosine phosphorylation state.

Aims: We investigated several phosphorylation sites on PKCδ and found that Y155 was phosphorylated in response to GPVI agonist but not PAR agonist. Hence, the focus of this study is to characterize the function of PKCδY155 in platelets.

Methods: We generated PKCδY155F mice to characterize the function of Y155 phosphorylation in platelets using *ex vivo* and *in vivo* methods.

Results: PKCδ Y311 and Y332 were phosphorylated in response to both convulxin (GPVI) and thrombin (PAR), however Y155 was only phosphorylated in response to convulxin (Figure 1A). AYPGKF (PAR4) stimulated PKCδY155F platelets did not show any difference in platelet aggregation and dense granule secretion. However, CRP (GPVI) stimulated PKCδY155F platelets showed decreased platelet aggregation and dense granule secretion (Figure 1 B & C) despite normal surface GPVI expression, suggesting that PKCδ Y155 phosphorylation is important for GPVI-mediated signaling. Whole blood from PKCδY155F mice perfused over collagen under arterial shear conditions showed decreased thrombus formation. Similarly, we observed that PKCδY155F mice survive longer than control following pulmonary embolism. Furthermore, PKCδY155F mice also exhibited longer time to occlusion using the ferric-chloride injury model. These data indicate that phosphorylation of Y155 on PKCδ is pro-thrombotic.

Conclusions: PKCδY155 is phosphorylated by GPVI agonist and Y155 phosphorylation positively regulates GPVI-mediated thrombus formation.

OC 30.3 | Implications of eNOS-signaling Heterogeneity within Human Platelets on Adhesion and Aggregation

G. Lesyk, A. Radziwon-Balicka, P. Jurasz

University of Alberta, Edmonton, Canada

Background: Despite a vast number of studies, molecular mechanisms regulating formation of platelet thrombus still remain poorly understood. In 1990 Radomski et al. proposed that human platelets have

endothelial nitric oxide synthase (eNOS)-signaling pathway present, providing an endogenous negative-feedback mechanism that prevents platelet adhesion and aggregation. Currently a great deal of controversy exists with regards to whether this pathway is actually present in platelets.

Aims: To investigate if platelet subpopulations exist based on the presence (eNOS+ve) and absence (eNOS-ve) of eNOS-signaling and whether this may contribute to platelet differential roles in hemostatic reactions.

Methods: Prostacyclin-washed human platelets were used to measure nitric oxide (NO) production by DAF-FM using flow-cytometry and fluorescence microscopy. Levels of eNOS, soluble guanylyl cyclase (sGC) and platelet aggregation-mediating receptor (GPIIb/IIIa) were measured using flow-cytometry. Platelet functionality was assessed using light-aggregometry and flow-chamber confocal microscopy.

Results: Based on DAF-FM fluorescence we identified a platelet subpopulation that produced no/low-levels of NO (17.9% ± 2.4%) and a platelet subpopulation which produced high-levels of NO (82.1%±2.4%). Intracellular flow-cytometry showed platelets that lacked eNOS (17.7%±5.0% Fig 1) and platelets that had eNOS present (82.3%±5.2% Fig 1.). Furthermore, eNOS+ve platelets had higher levels of sGC vs. eNOS-ve platelets (1.8±0.2 vs.1.2±0.1 MFI, P< 0.05, Fig 1). Additionally, eNOS-ve vs.eNOS+ve platelets activated a greater portion of their GPIIb/IIIa in response to collagen (78.0%±8.5% vs.21.4%±7.2%). Finally, under flow conditions, eNOS-ve platelets adhered to collagen prior to their eNOS+ve counterparts (Fig 2).

Conclusions: Human platelet subpopulations exist based on the presence or absence of a functional eNOS-PKG-signaling pathway. eNOS-ve platelets are less abundant and more reactive than eNOS+ve platelets and initiate thrombus formation.

OC 30.4 | Differential Roles of Paraoxonase-2 (PON2) and NADPH Oxidase-2 (NOX2) in Murine Platelets

V. Petermann[1,2,3], J. Ebert[1,2], K. Jurk[2], S. Horke[1], I. Witte[1], H. Kleinert[1]

[1]*University Medical Center Mainz, Department of Pharmacology, Mainz, Germany,* [2]*University Medical Center Mainz, Center for Thrombosis and Hemostasis, Mainz, Germany,* [3]*Johannes Gutenberg University, Department of Chemistry, Mainz, Germany*

Background: Paraoxonase-2 (PON2), an anti-oxidative protein with anti-inflammatory properties, has an emergent role in cardiovascular diseases, as it counter-acts atherosclerosis. As counterpart for anti-oxidative PON2, the NADPH oxidase 2 (NOX2) has been proposed as major pro-oxidative enzyme. Platelet activation is regulated by reactive oxygen species (ROS) and NOX2 has been suggested to modulate platelet activation via ROS generation.

Aims: To determine the effect of PON2 and NOX2 on platelet phenotype, activation and redox control using PON2- and NOX2-deficient mice.

Methods: PON2 was analyzed by immunoblotting and its localization by confocal microscopy. Platelet activation and ROS were measured by flow cytometry after stimulation with different concentrations of thrombin, convulxin, ADP or calcimycin. Platelet count and mean platelet volume were analyzed by an automated cell counter.

Results: Murine platelets expressed PON2 which was distributed in clusters intracellularly. PON2-deficient mice had unaltered

platelet count but significantly increased mean platelet volume whereas NOX2-deficient mice had slightly increased platelet count and decreased mean platelet volume compared to wildtypes. PON2 (-/-) platelets showed increased basal and agonist-induced ROS levels ex vivo. However, agonist-induced αIIbβ3 integrin activation and P-selectin surface expression were decreased in PON2 (-/-) mice. NOX2 (-/-) platelets showed decreased basal and agonist-induced ROS levels ex vivo as expected, but increased αIIbβ3 integrin activation and P-selectin activation in response to convulxin whereas thrombin stimulation resulted in unaltered responses.

Conclusions: Our data indicate that PON2 and NOX2 regulate platelet ROS generation and platelet activation differentially in a reverse dependent manner.

OC 30.5 | Alox12 Regulates Syk in FcγRIIA and Integrin αIIbβ3 Signaling in Platelets

S. Abraham[1], Y. Zhou[1], M. Whitley[1], J. Yeung[2], D.J. Maloney[3], T.R. Holman[4], M. Holinstat[2], S.E. McKenzie[1]

[1]Thomas Jefferson University, Medicine, Philadelphia, United States, [2]University of Michigan, Pharmacology, Ann Arbor, United States, [3]National Institutes of Health Chemical Genomics Center, National Center for Advancing Translational Sciences, Rockville, United States, [4]University of California Santa Cruz, Chemistry and Biochemistry, Santa Cruz, United States

Background: Heparin induced thrombocytopenia (HIT) is mediated by FcγRIIA and has a complex pathophysiology with high morbidity in affected individuals. We previously reported that Alox12 inhibitor-ML355 reduced FcγRIIA platelet activation but the signaling remains to be fully elucidated.

Aims: In the present study, we hypothesized that Alox12 regulated Syk activity upstream of PLCγ2 and also contributed to ‚outside-in' signaling.

Methods: Alox12 action was assessed in two ways:

1. Pharmacological intervention using ML355 in human and FcγRIIA transgenic mouse platelets, and

2. alox12 gene KO in mouse platelets expressing FcγRIIA. FcγRIIA stimulation (IV.3 antibody + goat-anti mouse) of washed platelets was done in the presence or absence of the inhibitor, and signaling was assessed. Platelet spreading on fibrinogen was evaluated for human platelets treated with ML355 and for alox12-null FcγRIIA transgenic mouse platelets.

Results: In the presence of ML355 or with alox12 KO, phosphorylation of Syk Y352/Y346 (mouse) decreased significantly within 30s post-stimulation of FcγRIIA. A reduction in phosphorylation of activation loop Tyr525/Y519 (m) within 30s was also observed. The phosphorylation of PLCγ2 was reduced within 30s of activation in mouse platelets, upon attenuation of Alox12 activity. Platelet spreading decreased by 62% in human platelets treated with ML355 and by 44% in alox12$^{-/-}$ FcγRIIA transgenic mouse platelets, on immobilized fibrinogen.

Conclusions: The results provide direct evidence of Alox12 activity in early activation of FcγRIIA signaling by regulating Syk tyrosine kinase. Alox12 activity is also required for ‚outside-in' signal transduction via integrin αIIbβ3 signaling, which involves FcγRIIA and Syk. Inhibition of platelet activation by the Alox12 inhibitor will impinge on both ‚inside-out' and ‚outside-in' signaling in thrombosis.

OC 44.1 | Thrombopoiesis is Spatially Regulated by the Bone Marrow Vasculature

D. Stegner[1], J.M.M. van Eeuwijk[1], O. Angay[2], M. Gorelashvili[1], J. Pinnecker[2], H. Schulze[1], B. Nieswandt[1,2], K.G. Heinze[2]

[1]University Hospital Würzburg, Institute of Experimental Biomedicine, Würzburg, Germany, [2]University of Würzburg, Rudolf Virchow Center, Würzburg, Germany

Background: Thrombopoietin acts on hematopoietic stem cells and induces their differentiation into the megakaryocytic lineage. During their maturation, megakaryocytes (MKs) are thought to migrate towards the vascular sinusoids in the bone marrow (BM) to release proplatelets into the bloodstream. The concept of blood precursor migration is less supported by direct evidence, but mostly based on evaluation of cell populations present at distinct spatiotemporal niches. Interestingly, contrary to this MK maturation model, two-photon intra-vital microscopy (2P-IVM) data indicated that MKs barely migrate and are mostly found in close proximity to blood vessels.

Aims: We aimed to reconcile the discrepancy between the current model of megakaryopoiesis and 2P-IVM data.

Methods: MK localization in intact BM of mice was studied by combining 2P-IVM and *in situ* light-sheet fluorescence microscopy (LSFM) supplemented by computational simulations.

Results: Using 3D reconstruction of murine femora or sterna, we show the vascularization of the entire BM and hence the absence of vessel-distant niches. Immunohistochemical analysis of cryo-sections and LSFM of intact bones revealed that MKs are homogeneously distributed within a dense vascular network. Likewise, two-photon intra-vital MK tracking under steady-state condition as well as under conditions of increased platelet-demand revealed that even vessel-distant MKs are essentially sessile. Using computational modeling based on ‚real' segmented BM structures, we tested whether MKs are randomly distributed. Indeed, while 79% of the MKs were found at the vessels, the remaining non-vessel associated MKs were randomly distributed, clearly arguing against MK migration.

Conclusions: Our data challenge the current thrombopoiesis model of MK migration and support a modified model where MKs at sinusoids are replenished by sinusoidal precursors rather than cells from a distant periostic niche.

OC 44.2 | Rap1a/b Isoforms Differentially Regulate Megakaryocyte Biology

D. Ghalloussi[1], E. O'Shaughnessy[2], D.S. Paul[1], K. Hahn[2], R. Piatt[1], L. Stefanini[3], R.H. Lee[1], K. Eto[4,5], W. Bergmeier[1]

[1]University of North Carolina, Mc Allister Heart Institute, Chapel Hill, United States, [2]University of North Carolina, Department of Pharmacology, Chapel Hill, United

States, [3]Sapienza University of Rome, Department of Internal Medicine and Medical Specialties, Rome, Italy, [4]Kyoto University, Department of Clinical Application, Kyoto, Japan, [5]University of Tokyo, Institute of Medical Science, Tokyo, Japan

Background: Thrombocytopenia, or low circulating platelet count, is often caused by a defect in megakaryocyte (MK) development. MKs reside primarily in the bone marrow, where they develop from undifferentiated multipotent cells into highly specialized, polyploidy cells that undergo the process of proplatelet formation (PPF). It is currently not clear if and how Rap1, a member of the Ras small GTPase superfamily, contributes to platelet generation.

Aims: We hypothesize that the two Rap1 isoforms, Rap1a and Rap1b, are critical in MK development and/or PPF.

Methods: We used two different cell models:

(1) primary murine MKs isolated from conditional knockout mice lacking Rap1a (Rap1a-mKO), Rap1b (Rap1b-mKO), or both isoforms (Rap1a,b-mKO) in megakaryocytes and platelets and

(2) an immortalized human MK cell line derived from pluripotent stem cells (imMKCLs). Flow cytometry, immunohistochemistry and confocal microscopy imaging were used to analyze MKs ex vivo, in situ, and in vitro.

Results: Rap1a-mKO mice exhibited a normal peripheral platelet count (PPC) but significantly increased MK numbers in the bone marrow and spleen. MKs from Rap1a-mKO mice were smaller and less differentiated than controls, and proplatelet extensions were shorter than in MKs isolated from control mice. Rap1b-mKO mice exhibited a mild macrothrombocytopenia and increased MK numbers. While MK maturation was only minimally affected, PPF was markedly altered (few but very large proplatelets). Consistently, Rap1a,b-mKO mice exhibited a marked macrothrombocytopenia, impaired MK endomitosis and a dramatic defect in PPF. Studies in imMKCL cells confirmed an important role for Rap1a and Rap1b in endomitosis and PPF, respectively.

Conclusions: These results provide the first definitive proof for a critical role of Rap1 GTPases in MK biology. Future studies will have to show whether some inherited or acquired thrombocytopenias are caused, at least in part, by altered Rap1 signaling in MKs.

OC 44.3 | A Cdc42/RhoA Regulatory Circuit Downstream of Glycoprotein Ib Guides Transendothelial Platelet Biogenesis

S. Dütting[1], I. Pleines[1], M. Popp[1], A. Antkowiak[2], J.M.M. van Eeuwijk[1], P. Nurden[1,3], S. Stritt[1], O. Angay[4], D. Cherpokova[1], N. Heinz[5], A.A. Baig[1], M. Gorelashvili[1], F. Gerner[1], K.G. Heinze[4], J. Ware[6], G. Krohne[7], D. Stegner[1], A.T. Nurden[3], H. Schulze[1], U. Modlich[5], F. Gaits-Iacovoni[8], C. Brakebusch[9], B. Nieswandt[1]

[1]Institute of Experimental Biomedicine, University Hospital and Rudolf Virchow Center, Würzburg, Germany, [2]BDM - Institut de Biologie du Développement de Marseille, Marseille, France, [3]Institut Hospitalo-Universitaire LIRYC PTIB, Hôpital Xavier Arnozan, Bordeaux, France, [4]University of Würzburg, Rudolf Virchow Center, Würzburg, Germany, [5]LOEWE Center for Cell and Gene Therapy Frankfurt/Main and Paul Ehrlich Institute, Langen, Germany, [6]University of Arkansas for Medical Sciences, Little Rock, United States, [7]University of Würzburg, Biocenter, Würzburg, Germany, [8]Institut des Maladies Métaboliques et Cardiovasculaires - I2MC, Université de Toulouse, Toulouse, France, [9]BRIC, Biomedical Institute, University of Copenhagen, Copenhagen, Denmark

Background: During the process of platelet biogenesis, megakaryocytes (MKs) extend long cytoplasmic protrusions (proplatelets) into bone marrow (BM) sinusoids from which platelets are released. The molecular cues that control MK polarization towards sinusoids and limit transendothelial passage to proplatelets remain incompletely understood.

Aims: We have previously shown that deficiency of the small GTPases RhoA or Cdc42 in MKs results in macrothrombocytopenia. Here, we investigated the roles of these GTPases in MK polarization-dependent platelet biogenesis.

Methods: Conditional Rho GTPase knock-out (KO) mice, GPIbα transgenic mice (*Gp1ba-Tg*), where the ectodomain of GPIbα is replaced by that of the human interleukin-4 receptor α, as well as inhibitors of MK/platelet signaling pathways were used in this study. MK localization was investigated by confocal immunofluorescence microscopy of native BM sections. MK demarcation membrane system (DMS) polarization was assessed in vitro and platelet biogenesis studied in vivo by two photon microscopy.

Results: We found a dramatic MK mislocalization in the BM of RhoA KO mice with a large population of whole MKs being present *inside* BM sinusoids. This led to perturbed platelet biogenesis in vivo, explaining the reduced platelet counts in RhoA KO animals. By contrast, in Cdc42 KO mice, no MKs were found in sinusoids and the number of MKs with direct contact to blood vessels was reduced. Our previous studies indicate that Cdc42 confers signaling downstream of GPIbα. Consistently, MKs also had less contact to sinusoids in the BM from *Gp1ba-Tg* mice exhibiting defective GPIbα ectodomain signaling. While *Gp1ba-Tg* MKs showed decreased Cdc42 activity and MK polarization, these processes were markedly increased in RhoA KO MKs. Finally, combined deficiency in RhoA and Cdc42 reverted the MK mislocalization seen in RhoA KO mice.

Conclusions: Our results reveal a Cdc42/RhoA regulatory circuit that controls GPIb-dependent transendothelial platelet biogenesis by mutual „go“/”stop” signals.

OC 44.4 | Megakaryocyte-Specific Sin1 Deficiency Leads to Thrombocytopenia and Defective Platelet Activation in Thrombosis and Myocardial Infarction

C. Xue, Y. Xu, L. Zhang, K. Wang, J. Liu

Shanghai Jiao Tong University School of Medicine, Shanghai, China

Background: Mammalian target of rapamycin complex 2 (mTORC2), consisting of mTOR, Sin1, Rictor and mLST8, has been proven to be present and intact in platelets. To date, it is still not clear whether loss of the integrity of mTORC2 complex has effects on platelet function.

Aims: The aims of this research were to identify the role and molecular mechanism of Sin1 in regulating platelet aggregation, spreading, clot retraction, thrombosis and myocardial infarction.

Methods: Platelet aggregation test; spreading; clot retraction; western blot; immunofluorescence; FecI3 artery thrombosis mouse model; LAD-ligation mouse model; flow cytometry.

Results: Here we reported that deficiency of Sin1, an essential component of mTORC2, caused a defect in platelet aggregation stimulated by thrombin, ADP, U46619 and collagen respectively. Interestingly, megakaryocyte/platelet-specific Sin1-deficient ($Sin1^{-/-}$) mice developed a severe thrombocytopenia, which was due to enhanced platelet apoptosis and decreased reticulated platelet count. Compared with wildtype platelets, Sin1 deficient platelets showed impaired clot retraction and incomplete platelet spreading on immobilized fibrinogen. Surprisingly, Sin1 deficiency resulted in significant decreased the phosphorylation and protein levels of Rictor and mTOR. Furthermore, ablation of Sin1 decreased the phosphorylation of AKT on Thr308, Ser473 and Thr450, which were all hyperphosphorylated in the platelets from myocardial infarction patients, indicating a potential role of Sin1 in myocardial infarction disease. Moreover, Sin1 was significantly phosphorylated on Thr86 in platelets treated with thrombin, and the levels of Sin1 Thr86 phosphorylation were correlated with the dose of thrombin. Importantly, Sin1 deficiency protected the heart against myocardial infarction-induced heart failure.

Conclusions: Together, our findings revealed that Sin1 deficiency caused a severe thrombocytopenia and defective platelet activation in thrombosis and myocardial infarction by ablating AKT phosphorylation.

OC 44.5 | CK2β Deficiency Results in Severe Macrothrombocytopenia due to Premature Megakaryocyte Fragmentation

P. Münzer[1], B. Walker-Allgaier[1], S. Geue[1], D. Eißler[1], D. Stegner[2], D. Semeniak[2,3], M. Chatterjee[1], L. Quintanilla-Martinez de Fend[4], D. Litchfield[5], F. Lang[6], B. Nieswandt[2], H. Schulze[2,3], M. Gawaz[1], O. Borst[1]

[1]*University of Tübingen, Cardiology and Cardiovascular Medicine, Tübingen, Germany,* [2]*University of Würzburg, Rudolf Virchow Center, Würzburg, Germany,* [3]*University of Würzburg, Experimental Haemostaseology, Würzburg, Germany,* [4]*University of Tübingen, Department of Pathology, Tübingen, Germany,* [5]*University of Western Ontario, Department of Biochemistry, London/Ontario, Canada,* [6]*University of Tübingen, Department of Physiology, Tübingen, Germany*

Background: Platelets are anucleated cells originated from polyploid megakaryocytes (MKs). MKs form proplatelets within the bone marrow (BM) and release platelets in BM sinusoids. The tetrameric serine/threonine kinase casein kinase 2 (CK2) is highly expressed in platelets. Although thrombopoiesis is strictly regulated by a wide variety of kinases less is known about the role of CK2 in the process of platelet biogenesis and proplatelet formation.

Aims: The present study explored the impact of the CK2 regulatory β-subunit on proplatelet formation and thrombopoiesis in MK/platelet-specific CK2β-deficient mice ($ck2\beta^{-/-}$).

Methods: megakaryocyte/platelet specific KO mice, flow cytometry, in vivo and in vitro proplatelet formation assay.

Results: As demonstrated by blood counts, CK2β deficiency resulted in a severe macrothrombocytopenia whereas platelet survival was only mildly affected. However, megakaryocytes from $ck2\beta^{-/-}$ mice exhibited increased plasma levels of thrombopoietin (TPO) and an increased extramedullar megakaryopoiesis correlating with enhanced ratio of premature platelets as shown by thiazole orange (TO) measurements. Megakaryocytes within BM of $ck2\beta^{-/-}$displayed drastic increased fragmentation resulting in significantly impaired proplatelet formation *in vitro* and *in vivo* as shown by means of multiphoton intravital microscopy. Interestingly, megakaryocyte fragmentation came along with decreased ploidy and less contact to bone marrow sinusoids in *ck2β*-deficient mice compared to wildtype littermates as investigated by flow cytometry or immunofluorescence stainings. At least in part, megakaryocyte fragmentation occurs due to abolished microtubule stability as megakaryocytes from $ck2\beta^{-/-}$ mice were unable to stabilize tubulin under taxol treatment leading to disrupted tubulin polymerization and incorrect distribution of microtubule-associated protein RP/EB family member 3 (EB3).

Conclusions: Finally, the present observations disclose CK2 as pivotal regulator in thrombopoiesis and proplatelet formation.

OC 45.1 | A Small Molecule Ligand for CLEC-2 Blocking Podoplanin Binding Inhibits Experimental Tumor Metastasis and Thrombus Formation in Mice

K. Suzuki-Inoue[1], H. Shinmori[2], M. Osada[3], T. Shirai[1], C. Mochizuki[2], S. Kojima[4], T. Saito[5], T. Sasaki[1], O. Inoue[6], Y. Ozaki[7]

[1]*University of Yamanashi, Faculty of Medicine, Department of Clinical and Laboratory Medicine, Chuo, Japan,* [2]*University of Yamanashi, Faculty of Life and Environmental Science, Chuo, Japan,* [3]*Gumma Paz University, Takasaki, Japan,* [4]*RIKEN Center for Life Science Technologies, Micro-Signaling Regulation Technology Unit, Wako, Japan,* [5]*RIKEN, Collaboration Promotion Unit, Global Research Cluster, Wako, Japan,* [6]*University of Yamanashi Hospital, Faculty of Medicine, Infection Control Unit, Chuo, Japan,* [7]*Fuefuki Central Hospital, Fuefuki, Japan*

Background: A platelet activation receptor, C-type lectin-like receptor 2 (CLEC-2) interacts with podoplanin, which expresses on the surface of certain types of tumor cells or lymphatic endothelial cells, and facilitates tumor metastasis and blood/lymphatic vessel separation during development. CLEC-2 stabilizes thrombus under flow condition by unidentified mechanisms. Since CLEC-2-dificient mice do not show a significant increase in bleeding tendency, CLEC-2 may be a good target for anti-metastasis or anti-thrombotic drug.

Aims: The aim of this study is to identify a small molecule ligand for CLEC-2 that inhibits podoplanin binding.

Methods: We screened 6720 small molecules for ability to inhibit CLEC-2/podoplanin binding using ELISA assay. Hit molecules by the 1st screening were analyzed its blocking ability using the CLEC-2-expressing cell line and recombinant podoplanin by flow cytometry.

Aggregation of human or mouse washed platelets was measured by Born's aggregometry. In vivo thrombus formation stimulated with FeCl3 was evaluated by femoral blood flow monitored using a Doppler blood flow velocimeter. For the hematogenous metastasis model, podoplanin-expressing melanoma cell line, B16F10 were injected intravenously into mouse tail veins. After 14 days, the weight of the lungs was measured.

Results: Sixty-three hit-molecules in the first screening were further screened for the ability to inhibit podoplanin binding to CLEC-2 expressing cells. The second screening resulted in 2 hit-molecules. We optimized one of the hit-molecules, X to make X complexed with cobalt (Co-X). Co-X specifically inhibited rhodocytin-induced platelet aggregation. Intravenous administration of Co-X to mice significantly inhibited hematogenous tumor metastasis to the lung and in vivo thrombus formation. On the other hand, Co-X did not significantly increase time of bleeding from the tail vein.

Conclusions: Co-X may be a good leading molecule for anti-metastatic and anti-platelet drug without bleeding tendency as an adverse event.

OC 45.2 | Pharmacological Characterization of the Functional Role of Calcium-activated Potassium Channels in Platelets

V. Back[1], G. Lesyk[1], F. Plane[2], P. Jurasz[1,2]

[1]*University of Alberta, Faculty of Pharmacy, Edmonton, Canada,* [2]*University of Alberta, Department of Pharmacology, Edmonton, Canada*

Background: In arteries, stimulation of endothelial cell small (SK_{Ca}) and intermediate (IK_{Ca}) conductance calcium-activated potassium channels provides a negative-feedback mechanism to limit agonist-induced vasoconstriction. Additionally, endothelial cell K_{Ca} channels in conjunction with nitric oxide (NO) mediate vasodilation in response to agonists and physical stimuli. Platelets, like endothelial cells, possess K_{Ca} channels and generate NO via endothelial nitric oxide synthase (eNOS). NO is known to limit platelet aggregation but the role of K_{Ca} channels in platelet function and NO-generation has not been explored. Our hypothesis was that activation of K_{Ca} channels would inhibit platelet aggregation and enhance platelet NO production.

Aims: Our objective was to pharmacologically characterize SK_{Ca} and IK_{Ca} channel function in platelets, and investigate their role in platelet NO production.

Methods: Platelets were isolated from the blood of healthy volunteers and aggregometry performed in the presence of SK_{Ca} (CyPPA) and IK_{Ca} (SKA-31) channel activators. Dense granule secretion was measured by ATP chemiluminesence. DAF-FM flow cytometry was used to measure NO generation.

Results: CyPPA and SKA-31 inhibited collagen-induced aggregation in a concentration dependent manner. IK_{Ca} selective channel blocker reversed the anti-aggregatory effects of 10μM SKA-31 but not CyPPA. SK_{Ca} channel-selective blocker did not reverse the effect of either CyPPA or SKA-31. CyPPA and SKA-31 inhibited NO generation back to basal resting platelet levels. CyPPA and SKA-31 demonstrated similar inhibitory effects on platelet dense granule secretion, whereas only SKA-31 significantly inhibited alpha granule secretion.

Conclusions: Activation of SK_{Ca} and IK_{Ca} channels inhibits both platelet aggregation and platelet NO generation. Furthermore, the use of selective blockers suggest that IK_{Ca} is the dominant K_{Ca} channel within platelets. These data indicate that K_{Ca} channels may provide novel targets for therapeutics to inhibit platelet aggregation.

OC 45.3 | Pharmacological Inhibition of the Class II PI3K, PI3KC2α, Provides Marked Anti-thrombotic Effects in Mice and Humans via a Unique Anti-platelet Mechanism

M. Selvadurai[1], M. Moon[1], S. Mountford[2], Z. Zheng[2], I. Jennings[2], P. Thompson[2], J. Hamilton[1]

[1]*Monash University, Australian Centre for Blood Diseases, Melbourne, Australia,* [2]*Monash University, Monash Institute of Pharmaceutical Sciences, Melbourne, Australia*

Background: The Class II PI3K, PI3KC2α, is a broadly expressed lipid kinase with few known roles. We recently used a mouse genetic approach to show that PI3KC2α is important for platelet function; PI3KC2α-deficient mice have a dysregulated open canalicular system structure and exhibit an impaired thrombotic response (Mountford, Nat Comm, 2015). These observations suggest PI3KC2α may represent a viable target for novel anti-platelet therapy. However, given the lack of PI3KC2α inhibitors, whether or not a similar function occurs in human platelets remains unknown.

Aims: To develop pharmacological inhibitors of PI3KC2α and use these to examine whether PI3KC2α similarly regulates the structure and function of human platelets as in PI3KC2α-deficient mouse platelets.

Methods: A rational drug design approach generated first generation PI3KC2α inhibitors. The effects of these inhibitors were examined on platelet structure (via SEM and TEM) and prothrombotic function (aggregation of isolated platelets, ex vivo thrombosis in human whole blood perfused over collagen-coated microslides, and in vivo thrombosis in mouse models).

Results: We developed X151, a competitive active site inhibitor of PI3KC2α with an IC_{50} of 13nM against purified enzyme. Pharmacological inhibition of PI3KC2α with X-151 closely mimicked the changes in platelet structure and function observed in PI3KC2α-deficient mice. Specifically, X151 (1 μM) dilated the open canalicular system of platelets isolated from both mice and humans to a similar extent to that observed in PI3KC2α-deficient mouse platelets (~40% increase in surface area). Furthermore, X151 nearly abolished thrombus formation in an ex vivo human whole blood model and two distinct in vivo mouse models.

Conclusions: These findings demonstrate PI3KC2α regulates human platelet structure and function and suggest that PI3KC2α may be a suitable target for novel anti-thrombotic drug therapies.

OC 45.4 | Quercetin and its Metabolites Inhibit Platelet Function and Thrombus Formation both in vitro and in vivo, and Combine with Aspirin to Increase Anti-platelet Effects

A. Stainer[1], L. Holbrook[1], P. Sasikumar[1], A. Bye[1], A. Unsworth[1], J. Lovegrove[2], M. Tindall[3], J. Gibbins[1]

[1]University of Reading, Institute for Cardiovascular and Metabolic Research, Reading, United Kingdom, [2]University of Reading, Hugh Sinclair Unit of Human Nutrition, Department of Food and Nutritional Sciences, Reading, United Kingdom, [3]University of Reading, Department of Mathematics and Statistics, Reading, United Kingdom

Background: Flavonoids, a class of plant secondary metabolites, are found in diets globally. Cohort studies have found one such flavonoid, quercetin, to possess anti-CVD (Cardiovascular Disease) effects. However, its extensive metabolism by the small intestine and liver has resulted in difficulty elucidating precise mechanisms of action.

Aims: To investigate the mechanisms through which quercetin and its methylated metabolites tamarixetin and isorhamnetin inhibit platelet function and thrombus formation *in vitro* and *in vivo*, and their interaction with the anti-platelet effect of aspirin.

Methods: Flavonoid:aspirin combinatorial effects on platelet aggregation were investigated using a 96-well aggregation assay. Inhibition of thrombus formation *in vitro* under physiological shear rate was investigated using microfluidic blood perfusion channels. A laser-injury model in C57/BL6 mice was used to assess thrombosis in mice.

Results: Quercetin, tamarixetin and isorhamnetin inhibited significantly thrombus formation *in vitro* at 10μM. Tamarixetin was most potent, indicating a 4´-methyl group in increased potency. Treatment of mice with isoquercetin over 48 and 72-hours resulted in significantly reduced thrombus size *in vivo*. The concentration of aspirin required for 50% inhibition of aggregation was lowered significantly by flavonoid administration, with higher (10μM) concentrations reducing IC_{50} values by an order of magnitude.

Conclusions: Thrombus formation is inhibited in whole blood at physiologically achievable concentrations, demonstrating the ability of flavonoids to inhibit platelet function despite high plasma-binding properties. This effect was maintained in a murine model of thrombosis. This may offer insight into the ability of a diet high in flavonoids, such as quercetin, to reduce CVD risk, and with their combinatorial effects with aspirin, offer potential to lower therapeutic aspirin doses and alleviate associated symptoms such as gastric bleeding.

OC 45.5 | Putative, Novel Mechanisms of Action for Citalopram-induced Platelet Inhibition

H.G. Roweth[1], N. Fowler[1], A. Chauhan[1], N. Habib[1], S.O. Sage[1], R.W. Farndale[2], G.E. Jarvis[1]

[1]University of Cambridge, Department of Physiology, Development and Neuroscience, Cambridge, United Kingdom, [2]University of Cambridge, Biochemistry, Cambridge, United Kingdom

Background: Citalopram, a selective serotonin reuptake inhibitor (SSRI), suppresses platelet function via a serotonin reuptake transporter (SERT)-independent mechanism. We report evidence for two putative, distinct mechanisms of action for citalopram-induced platelet inhibition.

Aims: To identify novel pharmacological mechanisms of action for citalopram-induced platelet inhibition.

Methods: Washed platelets (WP) were prepared from citrated blood from healthy volunteers and stimulated with either the GPVI agonist, collagen-related peptide (CRPXL, 0.5 μg/ml) or the thromboxane analogue, U46619 (0.2 μM). HPLC was used to quantify nucleotide release from platelet dense granules. Tyrosine phosphorylation of signalling proteins was determined by Western Blot. Rap1-GTP was isolated from platelet lysates using a GST-RalGDS-RBD fusion protein pull-down assay prior to Western Blot. Intracellular calcium ($[Ca^{2+}]_i$) mobilisation was measured in fura2/AM-loaded WPs.

Results: Citalopram inhibited CRPXL-induced dense granule release ($pIC_{50} \approx 4.5$), and tyrosine phosphorylation of FcRγ chain, Src-family kinases ($pIC_{50} \approx 4.2$), LAT ($pIC_{50} \approx 4.0$) and PLCγ2 ($pIC_{50} \approx 4.4$). Rap1 activation was also blocked by citalopram (200 μM) in both CRPXL- and U46619-stimulated platelets. CRPXL-induced $[Ca^{2+}]_i$ mobilisation was abolished by citalopram ($pIC_{50} \approx 4.4$). By contrast, U46619-induced $[Ca^{2+}]_i$ mobilisation was unaffected by citalopram up to 200 μM.

Conclusions: We have identified two putative distinct mechanisms of action for platelet inhibition by citalopram.

1) Citalopram suppressed protein phosphorylation proximally in the GPVI pathway, resulting in the inhibition of $[Ca^{2+}]_i$ mobilisation and dense granule release.

2) Despite blocking U46619-induced Rap1 activation, citalopram failed to inhibit $[Ca^{2+}]_i$ mobilisation induced by U46619. A likely target is the regulator of Rap1 activation, the Guanine Nucleotide Exchange Factor, CalDAG-GEFI.

OC 53.1 | Defective Arterial Thrombosis and Thrombo-inflammation in Mice Lacking Bridging Integrator 2 (Bin2)

J. Volz[1,2], M. Popp[1,2], D. Cherpokova[1,2], M.K. Schuhmann[3], T. Premsler[4], K. Wolf[1,2], S. Beck[1,2], D. Stegner[1,2], G. Stoll[3], A. Braun[1,2], B. Nieswandt[1,2]

[1]University Hospital Würzburg, Institute of Experimental Biomedicine I, Würzburg, Germany, [2]University of Würzburg, Rudolf Virchow Center, Würzburg, Germany, [3]University Hospital Würzburg, Department of Neurology, Würzburg, Germany, [4]Institute of Physiology, Cardiovascular Physiolog, Würzburg, Germany

Background: Store-operated calcium entry (SOCE) is the principal route of Ca^{2+} influx in platelets, critical for platelet activation. The calcium sensor molecule stromal interaction molecule 1 (STIM1) regulates SOCE by activation of the membrane calcium channel protein Orai1, but the exact mechanism of this interaction remains elusive. We used affinity chromatography to screen for STIM1 interacting

proteins in platelets and identified bridging integrator 2 (BIN2, mainly expressed in the hematopoietic system), a protein of the family of N-terminal Bin-Amphiphysin-Rvs (BAR) proteins.

Aims: We investigated the role of BIN2 in SOCE in platelets and its pathophysiological role in thrombotic and thrombo-inflammatory activity of the cells.

Methods: We generated a megakaryocyte-/ platelet-specific Bin2 KO mouse line (*Bin2*$^{fl/fl\text{-}Pf4Cre}$) and assessed platelet function *in vitro* using flow cytometry, biochemistry, calcium fluorimetry, aggregometry and flow adhesion assays. In addition, *in vivo* models of thrombosis and hemostasis, as well as the transient middle cerebral artery occlusion (tMCAO) model of ischemic stroke were performed.

Results: Bin2 KO platelets displayed markedly impaired SOCE in response to thapsigargin as well as CRP, convulxin and rhodocytin as well as thrombin, ADP and U46619, agonists acting on immunoreceptor tyrosine-based activation motif (ITAM) or G protein-coupled receptors, respectively. This SOCE defect resulted in impaired (hem) ITAM induced platelet activation, aggregate formation under flow and procoagulant activity, as assessed by measuring PS exposure. Similarly, mice lacking BIN2 in platelets were protected from occlusive arterial thrombus formation and thrombo-inflammatory cerebral infarct progression in a model of experimental stroke.

Conclusions: Our results show that the adapter protein BIN2 is an important regulator of SOCE in platelets, critically required for occlusive arterial thrombosis and thrombo-inflammatory brain infarction.

OC 53.2 | SNAP23 is Critical for Platelet Granule Secretion

C. Williams, A. Poole

University of Bristol, School of Physiology, Pharmacology and Neuroscience, Bristol, United Kingdom

Background: Secretion of platelet granule cargo is critical for efficient platelet function. Previous evidence from *in vitro* exocytosis assays using permeabilized platelets has suggested a role for SNAP23 in the regulation of granule secretion. A definitive assessment of its role in the regulation of all platelet granule types, in response to platelet agonists, and its role in mediating haemostasis and thrombosis *in vivo*, is currently lacking.

Aims: To characterize the role of SNAP23 in platelet secretion and function.

Methods: A SNAP23 conditional knockout was generated by crossing floxed allele mice with Cre-PF4. A range of functional assays *in vitro* and *in vivo* were used to determine the role of SNAP23.

Results: We have found that platelet-specific deletion of SNAP23 results in complete ablation of P-selectin surface exposure and PF4, ATP and beta hexaminidase release in response to thrombin or collagen-related peptide (CRP), indicating a complete absence of alpha granule, dense granule and lysosome secretion, respectively. Activation of the $\alpha_{IIb}\beta_3$ integrin was attenuated in these mice, but was rescued upon exogenous addition of ADP; however, exogenous addition of ADP did not rescue P-selectin exposure, demonstrating that the alpha granule defect observed is not due to absent dense granule release. Strikingly, these mice also presented as macrothrombocytopenic, with a 60% reduction in platelet count and 30% increase in mean platelet volume.

Conclusions: SNAP23 has long been suspected as playing a critical role in platelet secretion. Here we provide the first definitive evidence using a genetic approach that SNAP23 is essential for secretion from all granule types. Unexpectedly, we also observed a macrothrombocytopenia, which may indicate an additional role for SNAP23 in platelet biogenesis.

OC 53.3 | 14-3-3ζ Regulates the Mitochondrial Respiratory Reserve Linked to Platelet Phosphatidylserine Exposure and Procoagulant Function

R. Darbousset[1,2,3], S.M. Schoenwaelder[1,2,3], S.L. Cranmer[3], H.S. Ramshaw[4], S.L. Orive[3], S. Sturgeon[3], Y. Yuan[1,2,3], Y. Yao[3], J.R. Krycer[2,5], J. Woodcock[4], E.E. Gardiner[3], D.E. James[2,5,6], A.F. Lopez[4], S.P. Jackson[1,2,3]

[1]The Heart Research Institute, Thrombosis Group, Newtown, Australia, [2]Charles Perkins Centre, The University of Sydney, Camperdown, Australia, [3]Australian Centre for Blood Diseases, Monash University, Alfred Medical Research and Education (AMREP), Melbourne, Australia, [4]Centre for Cancer Biology, an Alliance between SA Pathology and The University of South Australia, Adelaide, Australia, [5]School of Molecular Bioscience, The University of Sydney, Camperdown, Australia, [6]Sydney Medical School, The University of Sydney, Camperdown, Australia

Background: The 14-3-3 family of adaptor proteins are ubiquitously expressed in eukaryotic cells and were the first identified phosphoserine-and phosphothreonine-binding proteins. They play a key role in regulating cell-cycle progression, apoptosis, metabolism, intracellular trafficking and regulating cell stress responses. Six 14-3-3 isoforms are present in human platelets including β, ε, ζ, γ, η and τ, with ζ and γ expressed at high levels. The first identified 14-3-3 binding partner in platelets was the VWF receptor GPIb/V/IX. 14-3-3 ζ binds to the cytoplasmic tails of GPIb α/β and numerous studies focussed on the relevance of this interaction for platelet activation and signalling, with varying views on its significance.

Aims: In the current study, we investigated the importance of 14-3-3ζ in regulating platelet function.

Methods: This was achieved by using mice genetically deficient in this specific 14-3-3ζ isoform.

Results: We demonstrated that mice specifically deficient in platelet 14-3-3ζ were protected against thrombosis, in the absence of a bleeding phenotype. Interestingly, the thrombotic defect in 14-3-3ζ$^{-/-}$ mice was not due to abnormal VWF-GPIb adhesive function, nor defective platelet activation induced by soluble platelet agonists. Instead, we identified an important role for 14-3-3ζ in regulating platelet phosphatidylserine (PS) exposure and procoagulant function associated with the generation of thrombin. We found evidence for a role for 14-3-3z in modulating levels of metabolic ATP and mitochondrial

respiratory reserve, potentially through the interaction of 14-3-3ζ with the mitochondrial F1-F0 ATP synthase.

Conclusions: Our studies have identified an important role for 14-3-3ζ in regulating platelet bioenergetics by modulating the mitochondrial respiratory reserve, leading to decreased platelet PS exposure and procoagulant function. Therapeutic targeting of 14-3-3ζ signalling may represent a new approach to reduce platelet procoagulant function and thrombosis without increasing bleeding.

OC 53.4 | Kinesin-1 Regulates Platelet Secretion and Thrombus Stability Through the Interaction with the Granular Slp4/Rab27b Effector Complex

F. Adam[1,2], A. Kauskot[1,2], M. Kurowska[3,4], N. Goudin[5], I. Munoz[3,4], J.-C. Bordet[6], J.-D. Huang[7], A. Fischer[3,4,8], D. Borgel[1,2,9], G. de Saint Basile[3,4], O. Christophe[1,2], G. Ménasché[3,4]

[1]INSERM, U 1176, Le Kremlin-Bicêtre, France, [2]Paris-Sud University, Université Paris-Saclay, Paris, France, [3]INSERM, U 1163, Paris, France, [4]Paris Descartes University, Sorbonne Paris Cité, Imagine Institute, Paris, France, [5]Cell Imaging Facility, Paris Descartes University - Sorbonne Paris Cité, Imagine Institute, Paris, France, [6]Laboratoire d'Hémostase, Hôpital Edouard Herriot, Lyon, France, [7]School of Biomedical Sciences, Li Ka Shing Faculty of Medicine, University of Hong Kong, Hong Kong, Hong Kong, [8]Immunology and Pediatric Hematology Department, Necker Children's Hospital, Assistance Publique Hôpitaux de Paris, Paris, France, [9]Assistance Publique Hôpitaux de Paris, Necker Children's Hospital, Biological Hematology Service, Paris, France

Background: Even if several regulators of fusion machinery for granule exocytosis have been identified in platelets, the exact molecular mechanisms regulating their trafficking on cytoskeleton are still poorly understood.

Aims: To define the role of the molecular motor, kinesin-1, in platelet secretion.

Methods: Using kinesin-1-deficient mice (cKO^{Kif5b}) in platelets, platelet functions were assessed (i) *in vivo* in a tail bleeding assay and in a thrombosis model, (ii) *in vitro* in thrombus formation under flow conditions and in platelet aggregation. Dense and α granule secretion were evaluated by measuring P-selectin exposure and ATP released. Rab27b, Slp4 and kinesin-1 interactions were studied by co-immunoprecipitation assays.

Results:

cKO^{Kif5b} mice display features of unstable hemostasis: in a tail clip-bleeding assay, a rebleeding tendency was observed (29% cKO^{Kif5b} mice versus 0% in WT mice). In a FeCl3-induced in vivo thrombosis model, thrombi formed normally; nevertheless they appeared less compact and stable over time. This instability was confirmed in vitro in a whole-blood perfusion assay. Aggregations induced by thrombin and collagen were impaired in cKO^{Kif5b} platelets. These results indicate that kinesin-1 plays a role in platelet functions and thrombus stability.

Kinesin-1 regulates dense and α granule secretion: ATP released and P-selectin exposure after thrombin stimulation were impaired in cKO^{Kif5b} platelets. As both granules appeared normal upon electron microscopy, total serotonin content was normal in dense granules and the defect of ATP release was overcome by high thrombin concentration, altogether, these results ruled out defects of granule cargo.

Kinesin-1-dependent transport machinery: We demonstrated that kinesin-1 links microtubules to α and dense granules through the molecular machinery composed of granule-associated Rab27b and the Slp4 adaptor protein.

Conclusions: Kinesin-1 regulates platelet granule secretion, and therefore thrombus stability, in collaboration with Rab27b and Slp4.

OC 53.5 | Secretory Granules and Molecular Interaction of DOCK7, VAC14 and SEC16A with NBEAL2

L. Mayer[1,2], M. Jasztal[1,2], J. Collins[1,2], S. Meacham[1,2], M. Pardo[3], J. Choudhary[3], W. Ouwehand[1,2,3], J. Guerrero[1,2]

[1]University of Cambridge, Haematology, Cambridge, United Kingdom, [2]National Health Service Blood and Transplant, Cambridge, United Kingdom, [3]Wellcome Trust Sanger Institute, Hinxton, United Kingdom

Background: Variants in *NBEAL2* are causal of Grey Platelet Syndrome (GPS), a rare bleeding disorder characterized by absence of alpha- and specific- granules in platelets and neutrophils, respectively. The role of the scaffolding multidomain NBEAL2 protein in cell biology and granule homeostasis is unknown.

Aims: To investigate the biochemical role of NBEAL2 in cell biology.

Methods: We have performed proteomics to identify NBEAL2's binding partners followed by different layers of validation including biochemical, cellular and functional analysis *in vitroand in vivo*.

Results: HEK293T cells overexpressing the Pleckstrin homology (PH), BEACH and the WD40 repeat domains of NBEAL2 fused with a Tandem Affinity Purification (TAP) tag were used. Baits were immune-purified and 164 proteins were identified by mass spectrometry but were unobserved in a control precipitation with a GFP-TAP tag. Reverse immunoprecipitation confirmed the binding of DOCK7 and VAC14 to NBEAL2's BEACH domain, while SEC16A specifically binds to the WD40 domain. Similar patterns of interactions were replicated in the megakaryocytic cells (CHRF) overexpressing PH-BEACH-WD40-TAP. Proximity ligation assays on endogenous proteins carried out in stem cell derived megakaryocytes (MKs) revealed significant interactions of NBEAL2 with DOCK7 and VAC14. Insertion of GPS-causing variants in the BEACH domain significantly impacted on its interaction with DOCK7 (P2100L, R2172H, G2290W) and VAC14 (M2080K, P2100L, G2290W), respectively. DOCK7 was significantly reduced in platelets from GPS mice and the phosphorylation pattern of coffilin and LIMK-2, effectors downstream the DOCK7 pathway, was also altered.

Conclusions: Our study shows the first NBEAL2 protein interactions and places DOCK7, SEC16A and VAC14 as binding partners of this uncharacterized multidomain protein. Further validation of new

proteins from the network will allow us to understand and define the biochemical and functional role of NBEAL2 in cell biology.

OC 57.1 | Blocking the b´x Domain of PDI Interferes with its Interaction with αIIbβ3 and Prevents Thrombus Formation

L. Lin, C. Garnier, J. Dilks, R. Bekendam, G. Merrill-Skoloff, R. Flaumenhaft

Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, United States

Background: Protein disulfide isomerase (PDI) serves an essential role in platelet activation and thrombus formation. αIIbβ3 has been proposed as an important substrate of PDI, but whether PDI mediates disulfide bond rearrangements in αIIbβ3 and contributes to the activation of the receptor is unknown.

Aims: To evaluate the mechanism by which PDI facilitates αIIbβ3 activation.

Methods: We identified PDI inhibitors using a high throughput approach. Several compounds with submicromolar potency were screened for their ability to inhibit platelet aggregation, identifying three structurally unrelated platelet antagonists (termed bepristats 3-5). We used these compounds to study how PDI influences αIIbβ3 activation.

Results: Studies using isolated PDI fragments showed that bepristats 3-5 all bound PDI at the substrate-binding domain (**b´x**) and did not block activity at the catalytic domains (**a** and **a´**). These compounds potently inhibited αIIbβ3 activation as determined by PAC-1 binding. Incubation of PDI with purified αIIbβ3 stimulated incorporation of maleimide polyglycol biotin (MPB) into αIIbβ3, demonstrating PDI-dependent exposure of free thiols. Unexpectedly, MPB was robustly incorporated into PDI upon exposure to αIIbβ3, indicating reciprocal disulfide exchange between αIIbβ3 and PDI. Activation of platelets with thrombin increased MPB incorporation into both endogenous αIIbβ3 and PDI. Thrombin-dependent disulfide exchange was inhibited by bepristat 4, showing involvement of the **b´x** domain of PDI. Conversely, the **b´xa´** fragment had substantially enhanced ability to reduce αIIbβ3 compared with the isolated **a´** domain. Comparison of different bepristats in a laser-induced model of thrombosis showed that bepristats that potently blocked PDI-αIIbβ3 interactions were better inhibitors of thrombosis than those that did not.

Conclusions: These studies show that **b´x** is required for disulfide exchange between PDI and αIIbβ3 and identifies improved strategies for developing antithrombotic PDI inhibitors.

OC 57.2 | Profilin 1 is a Central Regulator of Integrin Turnover and Function in Mouse Platelets

S. Beck[1,2], S. Stritt[1,2,3], S. Sorrentino[4], I. Birkholz[1,2], K.T. Sapra[4], H. Schulze[1], X. Du[5], J.H. Hartwig[6], M. Bender[1], A. Braun[1,2], O. Medalia[4,7], B. Nieswandt[1,2]

[1]Institute of Experimental Biomedicine I, University Hospital, University of Würzburg, Würzburg, Germany, [2]Rudolf Virchow Center, University of Würzburg, Würzburg, Germany, [3]Uppsala University, Department of Immunology, Genetics and Pathology, Uppsala, Sweden, [4]University of Zurich, Department of Biochemistry, Zurich, Switzerland, [5]University of Illinois, Department of Pharmacology, Chicago, United States, [6]Brigham and Women's Hospital, Harvard Medical School, Boston, Boston, United States, [7]Ben-Gurion University, Department of Life Sciences and the National Institute for Biotechnology in the Negev, Beer-Sheva, Israel

Background: Firm platelet adhesion at sites of vascular injury is mainly mediated by heterodimeric receptors of the β1- and β3-integrin families and is crucial to prevent excessive blood loss, but may also lead to thrombosis. Recruitment of talin-1 to β-integrin tails is essential for integrin activation and connects these adhesion receptors to the actin cytoskeleton. The small actin-binding protein Profilin 1 (Pfn1) is critical for actin rearrangements and platelet biogenesis. However, its role in platelet function and integrin activation is unknown.

Aims: We aimed to elucidate the precise role Pfn1 in platelet function and particularly integrin activation.

Methods: We generated mice with a platelet/ megakaryocyte-specific Pfn1-deficiency (*Pfn1*$^{fl/fl\ Pf4\text{-}cre}$). Platelet function was studied in a broad range of *in vitro* assays and *in vivo* models of hemostasis and arterial thrombus formation.

Results: Pfn1-deficient platelets showed a pronounced β1- and β3-integrin activation defect characterized by impaired platelet aggregation, adhesion to collagen under flow and clot retraction. *In vivo*, Pfn1 deficiency compromised hemostasis and resulted in a marked protection form arterial occlusive thrombus formation. The impaired integrin function in Pfn1-deficient platelets was characterized by an altered recruitment and localization of talin-1 and β3-integrins to the cell cortex of spreading platelets, as well as accelerated, calpain-mediated integrin inactivation.

Conclusions: These results reveal Pfn1 as a critical regulator of platelet integrin turnover with implications for hemostasis and thrombosis.

OC 57.3 | The Platelet Oxidoreductase ERp5 Modulates Fibrinogen Binding to A2bβ3 Integrin by Cleaving a βI Domain Disulphide Bond

F. Passam[1,2], J. Chiu[3], L. Ju[4], K. Kolsek[5], F. Graeter[5], P. Hogg[3,6]

[1]St George Clinical School, University of New South Wales, Sydney, Australia, [2]St George Hospital, Haematology, Sydney, Australia, [3]The Centenary Institute, University of Sydney, Sydney, Australia, [4]Heart Research Institute and Charles Perkins Centre, University of Sydney, Sydney, Australia, [5]Interdisciplinary Center for Scientific Computing, Heidelberg University, Heidelberg, Germany, [6]National Health and Medical Research Council Clinical Trials Centre, University of Sydney, Sydney, Australia

Background: The oxidoreductase, endoplasmic reticulum protein 5 (ERp5), is released at the site of thrombus formation in mice and ERp5 blocking antibodies (Passam et al. Blood, 2015) or morpholinos reduce platelet accumulation, fibrin generation and thrombus formation. ERp5 is secreted by platelets and endothelial cells and binds to surface

β3 integrin receptor. The ERp5 binding site has been localised to the βI domain of the β3 subunit of the major platelet integrin, α2bβ3. The oxidoreductase activity of ERp5 suggests that the enzyme cleaves one or more allosteric disulphide bonds in the integrin.

Aims: To determine the disulphide bonds in α2bβ3 targeted by ERp5 and the functional effect of their oxidoreduction.

Methods: Native α2bβ3 was incubated with RGD or RGE peptide in the presence or absence of reduced ERp5 or mutant inactive ERp5. The redox state of disulphide bonds in α2bβ3 was measured by differential cysteine alkylation and mass spectrometry. Molecular dynamics studies and atomic force microscopy were employed to determine the effect of reduction of disulphide bonds by ERp5 on α2bβ3 structure and ligand binding.

Results: We have measured the redox state of 31 of the 37 disulphide bonds in α2bβ3 integrin using differential cysteine alkylation and mass spectrometry. Incubation of RGD-extended α2bβ3 integrin with ERp5 resulted in significant cleavage of only one of the 31 disulphide bonds - the Cys177-Cys184 disulphide bond in the βI domain where ERp5 binds. The Cys177-Cys184 bond lies at the rim of the fibrinogen binding pocket of the integrin. Molecular dynamics studies reveal that cleavage of the βI domain Cys177-Cys184 bond changes the ligand binding pocket and the nature of the fibrinogen interaction. This has been confirmed in atomic force microscopy measurements of fibrinogen binding to α2bβ3 in the presence of ERp5.

Conclusions: Based on these findings, we suggest that ERp5 released during thrombus formation modulates fibrinogen binding to α2bβ integrin by changing the conformation of the binding site.

OC 57.4 | Synergistic Inside-out and Outside-in Activation of Integrin αIIbβ3

L. Ju[1,2,3], Y. Chen[4,5], C. Zhu[3,4,5]

[1]University of Sydney, Heart Research Institute, Charles Perkins Centre, Camperdown, Australia, [2]Heart Research Institute, Newtown, Australia, [3]Georgia Institute of Technology, Coulter Department of Biomedical Engineering, Atlanta, United States, [4]Georgia Institute of Technology, Woodruff School of Mechanical Engineering, Atlanta, United States, [5]Georgia Institute of Technology, Petit Institute for Bioengineering and Biosciences, Atlanta, United States

Background: Integrin $\alpha_{IIb}\beta_3$ can be activated by both inside-out and outside-in signaling. ADP and thrombin result in its chemical inside-out activation. Binding of GPIb to immobilized VWF under force gives rise to mechanical inside-out activation. Binding of $\alpha_{IIb}\beta_3$ to fibronectin (FN) triggers outside-in activation. It is unclear how these bi-directional signaling pathways cooperate to generate $\alpha_{IIb}\beta_3$ activation.

Aims: To elucidate the synergy among mechanical/chemical inside-out with mechanical outside-in activation of $\alpha_{IIb}\beta_3$.

Methods: We used a dual biomembrane force probe to sequentially stimulate/interrogate two receptors on a single platelet. To trigger mechanical inside-out activation, a micropipette aspirated platelet repeatedly contacted a VWF probe to exert force on GPIb, then switched to the FN probe to measure adhesion frequency. The above first step was replaced by inserting the platelet into a large micropipette pre-filled with ADP or thrombin to trigger chemical inside-out activation. For mechanical outside-in activation, the platelet was interrogated with the FN probe over a large number of repeated contacts to observe adhesion frequency change, with or without pre-conditioning by mechanical/chemical inside-out activation.

Results: GPIb-mediated mechanical inside-out activation activates $\alpha_{IIb}\beta_3$ to an intermediate level between the resting and ADP-activated states (Fig. 1A). Sequential stimulations by mechanical inside-out and outside-in activation activates $\alpha_{IIb}\beta_3$ to the level of the ADP-activated state (Fig. 1B). Mechanical outside-in activation further increases the affinity of ADP-activated $\alpha_{IIb}\beta_3$ by another 19-fold (Fig. 1C). Substituting ADP with low- but not high-dose thrombin resulted in a similar result (Fig. 1D). Without pre-conditioning by inside-out activation, mechanical outside-in activation was prevented (Fig. 1B).

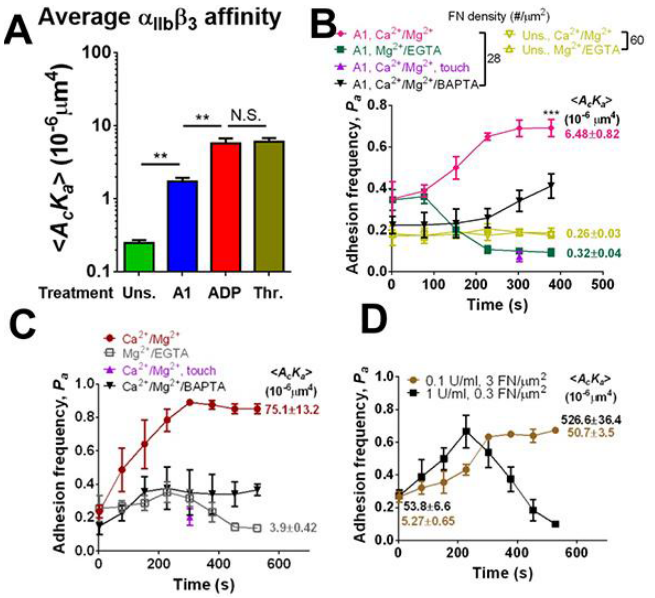

FIGURE 1 The discovery of two new states in integrin αIIbβ3, which has an intermediate and hyperactive affinity in binding to its ligand

Conclusions: Activation of $\alpha_{IIb}\beta_3$ is finely tuned by synergistic mechanical and chemical bi-directional signaling pathways.

OC 57.5 | IκB Kinase 2 impairs GPIIb/IIIa Activation in Platelets

M. Salzmann, M. Mussbacher, W.C. Schrottmaier, J.B. Kral-Pointner, B. Hoesel, A. Assinger, J.A. Schmid

Medical University of Vienna, Vascular Biology and Thrombosis Research, Vienna, Austria

Background: Megakaryocytes can sense inflammatory signals, but little is known how this might change platelet function. Most inflammatory signalling pathways converge at the kinase IKK2 (IκB kinase 2) activating the transcription factor NF-κB. Our aim was to determine the effect of chronic inflammation on platelets by using a conditional transgenic mouse model that alters NF-κB activity in megakaryocytes.

Aims: The aim of this study was to determine the effect of persistent inflammation on platelet function, by altering NF-κB activity in megakaryocytes with a constitutively active IKK2.

Methods: Mice with a megakaryocyte-specific constitutively active IKK2 were compared to littermate controls. Platelet count and lifespan was determined and function was tested *in vitro* by agonist-induced degranulation and aggregation and *in vivo* by tail bleeding and *intra vital* microscopy of ferric chloride induced thrombus formation.

Results: Platelet count and lifespan is unaltered, however GPIIb/IIIa activation was decreased in platelets with constitutively active IKK2 upon stimulation with ADP and PAR4 receptor agonist peptide. Consistently, *in vitro* platelet aggregation is reduced, *in vivo* thrombus formation delayed and bleeding time increased.

Conclusions: Platelets of mice with megakaryocyte-specific constitutive active IKK2 exhibit decreased GPIIb/IIIa activation and aggregation *in vitro*, while degranulation is only slightly affected. This specific reduction of GPIIb/IIIa activation is further supported *in vivo* by *intra vital* microscopy of ferric chloride induced thrombus formation, which is impaired in mice with constitutively active platelet IKK2, explaining the increased bleeding time. Taken together our data indicates that active IKK2 or NF-κB interferes with GPIIb/IIIa activation, either directly through kinase activity in platelets or via constitutively active NF-κB signaling in megakaryocytes.

OC 58.1 | Platelets Kill Bacteria after Bridging Innate and Adaptive Immunity via PF4 and FcγRIIA

R. Palankar[1], T.P. Kohler[2], K. Krauel[1], M. Medvidov[1], J. Wesche[1], S. Hammerschmidt[2], A. Greinacher[1]

[1]*Institute of Immunology and Transfusion Medicine, University Medicine Greifswald, Transfusion Medicine, Greifswald, Germany,* [2]*Interfaculty Institute for Genetics and Functional Genomics, University of Greifswald, Department Genetics of Microorganisms, Greifswald, Germany*

Background: Chemokine platelet factor 4 (PF4) bound to bacteria is recognized by anti-PF4/Heparin(H) IgG. Human platelets specifically interact with these opsonized bacteria through Fc gamma receptor 2A (FcγRIIA) resulting in bacterial killing.

Aims: (i) How platelets respond to PF4 and anti-PF4/H IgG complexes? (ii) What is the role of human platelet FcγRIIA PF4 anti-bacterial activity?

Methods: Platelet activation on planar and biomimetic bacteria-like micropatterns, or *E. coli* (wild type BW30270 and mutants expressing truncated LPS-KPM53 and KPM121 showing enhanced PF4 binding) coated with IgG, PF4, or anti-PF4/H IgG complexes was quantified by live imaging, in the presence/absence of platelet receptor/cytoskeletal function inhibitors. FcγRIIA and antibody-dependent bacterial killing by platelets was assessed by quantiative microscopy and co-culture experiments.

Results: Platelets adhered and spread on planar micropatterned arrays functionalized with IgG [% micropattern area covered 60.23% ±13.1 (mean ± SD)] and aggregated IgG [83.41%±11.36]. FcγRIIA blocking mab IV.3 reduced ($P < 0.0001$) platelet spreading on IgG [3.39% ±3.35] and aggregated IgG [11.41%±3.96], as did inhibitors of αIIbβ3, cytochalasin D and blebbistatin. Similar outcomes were obtained with biomimetic bacteria-like microbead arrays functionalized with IgG, aggregated IgG, PF4 or anti-PF4/H IgG complexes. In the presence of anti-PF4/H-IgG, platelets were able to kill *E. coli* strains within two hours, directly dependent on the bacterial PF4 binding capacity (up to 75.4 ±6.3% killing rate), which was inhibited by mab IV.3.

Conclusions: PF4 binds to polyanions on bacteria, enabling opsonization by anti-PF4/H IgG, and FcγRIIA mediated killing of *E.coli*. As PF4 binds to many gram positive and negative bacteria, preformed anti-PF4/H IgG rapidly recognizes even bacteria the organism has not seen before. Potentially, this IgG mediated innate immune defense mechanism is also relevant for control of Gram-positive bacteria such as staphylococci or pneumococci.

OC 58.2 | Aging-Associated Increases in Platelet Granzyme A Regulates Pro-inflammatory Gene Synthesis by Target Monocytes

R. Campbell[1], A. Bhatnagar[1], Z. Franks[2], J. Rowley[1,3], B. Manne[1], M. Supiano[4,5], H. Schwertz[1,6], A. Weyrich[1,3], M. Rondina[1,3,5]

[1]*University of Utah, Molecular Medicine, Salt Lake City, United States,* [2]*University of Arizona, Tucson, United States,* [3]*University of Utah, Internal Medicine, Salt Lake City, United States,* [4]*University of Utah, Division of Geriatrics and Center on Aging, Salt Lake City, United States,* [5]*George E. Wahlen VAMC GRECC, Salt Lake City, United States,* [6]*University of Utah, Division of Vascular Surgery, Salt Lake City, United States*

Background: Platelets govern signal-dependent inflammation by leukocytes. While dysregulated inflammation is common in older adults, platelet-leukocyte signaling events and inflammatory gene synthesis in aging is unknown.

Aims: We hypothesized that aging would alter the platelet molecular signature, leading to dysregulated platelet-leukocyte interactions and inflammatory cytokine synthesis.

Methods: Platelets and monocytes were isolated from healthy older (age>60, n=27) and younger (age< 45, n=36) adults. Inflammatory gene synthesis by monocytes in the presence or absence of activated platelets was examined. RNA-sequencing profiled the platelet transcriptome in older and younger adults. Differentially expressed candidates were validated (mRNA and protein), and inhibitors were used to identify putative receptors.

Results: Basal MCP-1 and IL-8 synthesis by monocytes alone did not differ in older and younger adults. However, when co-incubated with platelets, monocytes from older adults synthesized greater MCP-1 (867±150 vs. 216±36 ng/mL, $p< 0.0001$) and IL-8 (41±5 vs. 9±2 ng/mL, $p< 0.0001$) than younger adults. Switch experiments confirmed that aged platelets were sufficient for upregulating MCP-1 and IL-8. Platelet adhesion and signaling proteins that induce MCP-1 synthesis (p-selectin, RANTES) were not increased in aged platelets. Rather,

using RNA-seq followed by RT-PCR and immunoblot, we identified that granzyme A (GrmA), a serine protease not previously studied in human platelets, is significantly increased in aging (~9-fold vs. young). GrmA is secreted by aged platelets in signal-dependent fashion. Blocking GrmA inhibited MCP-1 and IL-8 synthesis through TLR4 and Caspase-1.

Conclusions: Inflammatory gene synthesis stimulated by platelet-leukocyte interactions is exaggerated in aging in a platelet-dependent manner. We identify a previously unrecognized protein in human platelets, GrmA, and demonstrate that increased platelet GrmA in aging contributes to exaggerated inflammation through TLR4 and Caspase-1.

OC 58.3 | Mature Murine Megakaryocytes Process and Present Both Exogenous and Endogenous Antigens to CD8+ T Cells and Transfer this Ability to Platelets

J.W. Semple[1,2,3], A. Zufferey[4], E.R. Speck[4], K.R. Machlus[5], R. Aslam[4], L. Guo[4], M.J. McVey[6,7], M. Kim[4], R. Kapur[4], E. Boilard[8], J.E. Italiano, Jr[5]

[1]Lund University and Skåne University Hospital,, Hematology and Transfusion Medicine, Lund, Sweden, [2]St. Michael's Hospital, University of Toronto, Pharmacology, Medicine, Laboratory Medicine and Pathobiology, Toronto, Canada, [3]Canadian Blood Services, Toronto, Canada, [4]Keenan Research Centre for Biomedical Science of St. Michael's Hospital, Toronto Platelet Immunobiology Group, Toronto, Canada, [5]Brigham and Women's Hospital, Harvard Medical School, Medicine, Boston, United States, [6]University of Toronto, Anesthesia and Physiology, Toronto, Canada, [7]St. Michael's Hospital, Toronto, Canada, [8]Université Laval, Centre de Recherche du Centre Hospitalier Universitaire de Québec, Microbiologie et Immunologie, Québec, Canada

Background: Megakaryocytes (MKs) are bone marrow cells that are responsible for releasing platelets into the blood circulation. Although MKs can express immune molecules such as Major Histocompatibility Complex (MHC) class I and II molecules along their differentiation pathway, little is known about their ability to interact with T cells.

Aims: We analyzed whether MKs can cross-present an exogenous Ovalbumin (OVA) antigen as well as endogenous GPIIIa antigens to activate CD8+ T cells and whether they can transfer this ability to platelets.

Methods: We used cultured murine MKs to analyze OVA endocytosis and test their capacity to cross-present antigens, i.e. proteolytically generate immunogenic peptide ligands which are presented on their surface with MHC class I molecules as well as their ability to transfer this process to platelets. Co-culture experiments with antigen-specific T cells and an in vivo murine model of immune thrombocytopenia (ITP) were used to test if the antigen-pulsed MKs could induce CD8+ T cell activation.

Results: Murine $CD34^-$ MHC class II^- $CD41^+$ MKs endocytosed exogenous OVA and processed it into its immunogenic peptide ligand that was loaded into the antigen binding groove of MHC class I molecules and re-expressed on the MKs surface. This re-expression event was correlated with activation of OVA-specific CD8+ T cells (OT-I) in vitro and when the OVA-pulsed MK were injected into in OT-I transgenic mice. Furthermore, these MK MHC/peptide complexes were packaged into α-granules and transferred to platelets during thrombopoiesis. MKs were also able to mediate GPIIIa-specific CD8+ T cell activation and thrombocytopenia in an in vivo murine model of T cell-mediated ITP.

Conclusions: These results suggest that bone MKs have the ability to interact with and activate CD8+
T cells in vitro and in vivo and transfer this ability to their platelet progeny. MKs also have the ability to present their endogenous protein antigens to T cells that then mediate thrombocytopenia in vivo.

OC 58.4 | Platelet Desialylation: Novel Mechanism of Immune Tolerance

J. Li[1,2,3], Y. Wang[1,2,3], Y. Yucel[1,3], J. Freedman[1,3], H. Ni[1,2,3]

[1]University of Toronto, Toronto, Canada, [2]Canadian Blood Services, Toronto, Canada, [3]St. Michael's Hospital, Toronto, Canada

Background: GPIbα and GPIIbIIIa are two abundant platelet (PLTs) surface receptors commonly targeted by auto- and allo-antiplatelet antibodies in thrombocytopenias. Interestingly, we found GPIbα was significantly less immunogenic than GPIIbIIIa, unless there is a co-infection.

Aims: Given that GPIbα is the most heavily sialylated protein, we hypothesized removal of charged terminal sialic residues will unmask and alter the glycosylation profile to enhance antigen presentation and antibody production.

Methods: N/A

Results: However, unexpectedly, we found desialylated platelets (dPLTs) led to suppressed antibody generation. This was true in both iso (WT (wild-type) PLTs into β3-/- or GPIbα-/- mice) and allo (C57BL/6 WT PLTs into BALB/c mice) anti-platelet responses. To assess whether dPLTs had immunomodulatory function beyond decreased immunogenicity, we transfused WT BALB/c mice with WT BALB/c dPLTs or PLTs during the course of immunization with allogeneic C57BL/6 WT PLTs. We found a significant decreased antibody response against alloantigen $H\text{-}2K^b$ in mice that were transfused with dPLTs but not WT PLTs. The suppressed antibody response was specific to platelet antigens, as there was no significant difference between the two groups following challenge with sheep red blood cells. Utilizing state-of-the-art non-invasive, in vivo Multispectral Optoacoustic Tomography imaging, we tracked, in real-time, increased pooling of ICG labeled dPLTs to the liver and surprisingly the gut in mice following transfusion. In contrast, ICG labeled PLTs remained in circulation. Correspondingly, intravital microscopy revealed increased adherence and arrest of dPLTs in mesenteric veins compared with PLTs.

Conclusions: Thus increased dPLTs sequestration and clearance in the liver/gut may be immunosuppressive against platelet associated antigens. These findings may be exploited as a therapeutic target to decrease alloantigenicity in transfusions/transplants (e.g. desialylated platelets carrying coagulation factors for hemophilia therapy).

OC 58.5 | Platelets Promote Monocyte Polarization to a M1 Phenotype upon LPS Stimulation

M. Schattner[1], A. Carestia[1], H.A. Mena[1], A.E. Errasti[2], S. Negrotto[1], E.A. Carrera Silva[1]

[1]*Institute of Experimental Medicine, CONICET-National Academy of Medicine, Laboratory of Experimental Thrombosis, Buenos Aires, Argentina,* [2]*Institute of Pharmacology, Faculty of Medicine, University of Buenos Aires, Buenos Aires, Argentina*

Background: Platelets and monocyte/macrophages interaction appears to play a relevant role in the pathophysiology of sepsis. However, it has been reported that platelets can positively or negatively regulate monocytes/macrophages responses. Although the reasons for these discrepancies are not clear, we hypothesize that LPS concentrations and stimulation times are critical determinants.

Aims: To clarify the role of platelets in the biology of monocytes/macrophages upon LPS challenge, we analyzed the monocyte inflammatory response at day 1 and 2 and their polarization at day 5 in the presence of platelets and broad range of LPS concentrations.

Methods: Human monocytes were purified by positive selection, incubated with autologous platelets and stimulated with LPS.

Results: LPS induced the release of pro (TNFα/IL-6)- and anti (IL-10/IL-4)-inflammatory cytokines (ELISA) in a LPS concentration-dependent manner after 1 and 2 days, respectively. Platelets decreased the release of all cytokines at all LPS concentrations (Fig.1).

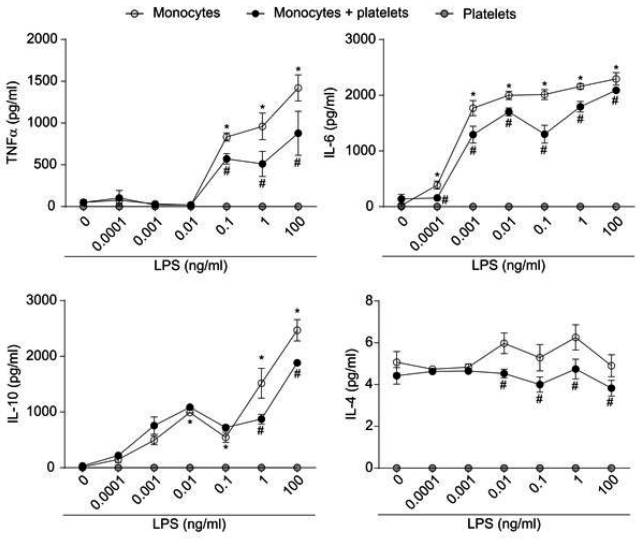

FIGURE 1 Cytokine release from platelet/monocytes co-cultures (n=5, ANOVA)

While low LPS concentrations differentiated monocytes into M2 macrophages by decreasing CD64 and augmenting CD206 and CD163 (flow cytometry), a more pro-inflammatory phenotype was observed with increasing LPS concentrations (Fig.2). Platelets polarized monocytes predominantly towards M1 phenotype at all LPS concentrations. Accordingly, macrophages derived from platelet/monocyte co-cultures had an increase capacity to produce TNFα and exerted a higher bacterial phagocytic activity (flow cytometry) (Fig.2). Moreover, endothelial cells presented a reduced capability of healing when incubated with supernatants from platelet/monocyte co-culture-derived macrophages (scratch assay) (Fig.2). The skewing effect of platelets on monocyte polarization was abrogated in a transwell assay.

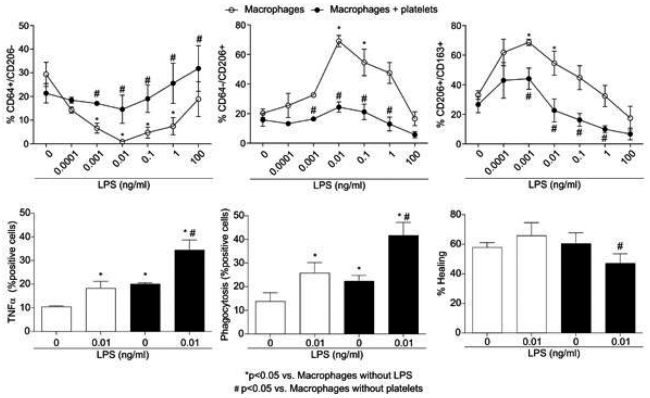

FIGURE 2 Phenotype and functionality of monocyte-derived macrophages in the presence of platelets and LPS stimulation (n=3, ANOVA)

Conclusions: Our results demonstrated that, upon LPS stimulation, platelets decrease the release of both pro and anti-inflammatory cytokines from monocytes but polarize them to M1 phenotype in a cell-contact dependent manner.

OC 66.1 | Platelet Collagen Receptor GPVI-dimer Binds to Fibrinogen D-fragment and D-dimer and May Contribute to Platelet Activation and Adhesion during Thrombus Formation

I. Induruwa[1], M. Moroi[2], A. Bonna[2], J.-D. Malcor[2], J.-M. Howes[2], E.A. Warburton[1], R. Farndale[2], S.M. Jung[2]

[1]*University of Cambridge, Clinical Neurosciences, Cambridge, United Kingdom,* [2]*University of Cambridge, Biochemistry, Cambridge, United Kingdom*

Background: Platelet collagen receptor GPVI-dimer initiates signalling leading to thrombus formation. Recently it has also been reported to stabilize thrombi through binding to fibrin.

Aims: Due to its possible emerging role as a fibrin receptor, we investigated the interaction between monomeric and dimeric GPVI with fibrinogen substrates to further explicate this interaction.

Methods: Binding of recombinant GPVI monomeric extracellular domain ($GPVI_{ex}$) or dimeric Fc fusion protein [$(GPVI\text{-}Fc)_2$] to immoblized fibrinogen derivatives was measured by ELISA (1G5 pan GPVI antibody)/IRDye®800CW anti-Mouse IgG; Licor Odyssey). Flow adhesion was performed with DiOC6 labelled normal or Glanzmann thrombasthenia (GT) platelets over fibrinogen substrate-coated slides.

Results: Under static conditions, $GPVI_{ex}$ did not bind fibrinogen D-fragment or D-dimer, but $(GPVI\text{-}Fc)_2$ exhibited specific, saturable

binding to both fragments. $(GPVI\text{-}Fc)_2$ showed only very low binding to fibrinogen, monomeric fibrin, and polymerized fibrin, contrary to published reports; $GPVI_{ex}$ bound none of them. Binding of $(GPVI\text{-}Fc)_2$ to D-fragment or D-dimer was abrogated by collagen type III, Horm collagen, or CRP-XL, suggesting proximity between the D-fragment-, D-dimer-, and collagen binding sites on GPVI-dimer. Neither $(GPVI\text{-}Fc)_2$ nor $GPVI_{ex}$ bound E-fragment. Under arterial shear rates, adhesion of normal platelets to fibrinogen, polymerized fibrin, D-fragment and D-dimer was inhibited by anti-GPVI-dimer mFab-F or Eptifibatide (inhibits αIIbβ3) used alone, and further inhibited when they were used in combination, suggesting that both receptors are involved in adhesion to these substrates under flow. GT platelets showed limited adhesion to fibrinogen substrates, which was further reduced by mFab-F, supporting involvement of GPVI-dimer in this interaction.

Conclusions: GPVI-dimers bind to fibrinogen D-fragment, suggesting that only GPVI-dimers contribute to platelet adhesion on fibrinogen and polymerized fibrin.

OC 66.2 | Gp6 Signaling is Compromised in Early Young Platelets in Mice

S. Gupta[1,2], D. Cherpokova[3], M. Morowski[3], M. Bender[3], B. Nieswandt[3]

[1]*Institute of Experimental Biomedicine I, University Hospital and Rudolf Virchow Center, University of Würzburg,, Würzburg, Germany,* [2]*University of Pennsylvania, Hematology/Oncology, Philadelphia, United States,* [3]*Institute of Experimental Biomedicine I,, University Hospital and Rudolf Virchow Center, University of Würzburg,, Würzburg, Germany*

Background: Platelets are derived from the cytoplasm of megakaryocytes (MKs) by extension of proplatelets into bone marrow sinusoids and ensuing release into the bloodstream. In humans, platelets circulate for 8-10 days before clearance by the reticuloendothelial system. It has been proposed that circulating young platelets are more reactive than aged platelets.

Aims: We investigated the reactivity of the circulating young platelets produced under high demand by using a mouse model of platelet recovery after induction of acute thrombocytopenia.

Methods: Mice were rendered thrombocytopenic by intravenous injection of polyclonal rat anti-mouse GPIba antibody and newly produced platelets in circulation were tested *in vivo* and *in vitro*.

Results: Newly produced circulating platelets on day 4-5 post-depletion showed an increased size and were called Early Young Platelets (EYPs). The surface expression on EYPs of major receptors including GPVI as well as integrins αIIb and β1 were largely unaltered. Remarkably, however, EYPs displayed a pronounced activation defect in response to GPVI agonists as detected by reduced aIIbb3 integrin activation and a-granule release. The GPVI defect in EYPs was linked to hypo-phosphorylation of downstream signaling proteins translating into reduced aggregation and thrombus formation in *in vitro* and *in vivo* platelet assays. A similar GPVI signaling defect was observed when mice were rendered thrombocytopenic using an anti-integrin aIIbb3 antibody, thus indicating that GPVI signaling is diminished in newly produced platelets independently of the exact mechanism underlying the preceding thrombocytopenia. The GPVI signaling defect was overcome with establishment of normal platelet counts in circulation.

Conclusions: Our results show for the first time that young platelets produced by MK rupture in response to acute thrombocytopenia display a severe and selective GPVI-ITAM signaling defect that is linked to hypo-phosphorylation of the GPVI signalosome.

OC 66.3 | Dissecting PAR1 Specific Signaling in Platelets Using Quantitative Mass Spectrometry Based Phosphoproteomics

S.B.G. Jansen[1], F.P.J. van Alphen[2], A.B. Meijer[1,2,3], M. van den Biggelaar[1]

[1]*Sanquin Research, Plasma Proteins, Amsterdam, The Netherlands,* [2]*Sanquin Research, Research Facilities, Amsterdam, The Netherlands,* [3]*Utrecht Institute for Pharmaceutical Sciences (UIPS), Utrecht University, Utrecht, The Netherlands*

Background: Protease-activated receptor 1 (PAR1) is a key platelet (PLT) receptor which is activated by thrombin and is a target for antiplatelet therapy. In clinical trials, PAR1 inhibitors are associated with increased risk of bleeding, likely due to PAR1's role in other cell types, notably the endothelium. Further understanding of PLT specific PAR1 signaling may help in the design of better antiplatelet therapies.

Aims: To unravel PLT specific PAR1 signaling and identify new targets for intervention.

Methods: PLT PAR1 signaling was assessed using mass spectrometry-based quantitative phosphoproteomics. Washed PLTs from transfusion-ready PLT pools were activated with PAR1 activating peptide ($SFLLRN\text{-}NH_2$) for 60s. PLT lysates were processed to peptides using trypsin digestion, and phosphopeptides enriched using TiO_2 beads and labelled using isobaric TMT labels. Phosphopeptides were identified and quantified on an Orbitrap Fusion Tribrid mass spectrometer.

Results: We reliably quantified >1600 phosphopeptides of which 110 changed upon PAR1 stimulation, corresponding to 98 proteins. Of the identified proteins, many have established roles in PLT biology but have not been previously associated with thrombin signaling (I.E. WIPF1, ITGA6, TLN1). A large proportion of the proteins are receptors or membrane bound (n=55), indicative of the formation of receptor complexes (I.E. PAR1 & PAR4). This is supported by STRING analysis, revealing that most regulated proteins form an interaction network, eluding to fast signal transduction at the PLT membrane.

Conclusions: This study provides novel phosphoproteomic data on PAR1 signaling in PLTs. Comparison with previously published phosphoproteomic studies on signaling of PAR1 in endothelial cells and ADP in PLTs revealed strong overlap with our dataset and identified shared but also specific PAR1/PLT signaling events, revealing potential new targets for antiplatelet therapy. These results pave the way for intimate understanding of converging and diverging platelet signaling pathways.

OC 66.4 | Perlecan: a Physiological Ligand for the Inhibitory Platelet Receptor G6b-B

T. Vögtle[1], S. Rajesh[2,3], M.R. Douglas[4,5,6], Y.A. Senis[1]

[1]University of Birmingham, Institute of Cardiovascular Sciences, Birmingham, United Kingdom, [2]Univeristy of Birmingham, Institute of Cancer and Genomic Sciences, Birmingham, United Kingdom, [3]GlaxoSmithKline, Protein Cell and Structural Sciences, Brentford, United Kingdom, [4]University of Birmingham, Institute of Inflammation and Ageing, Birmingham, United Kingdom, [5]Russells Hall Hospital, Dudley Group NHS Foundation Trust, Department of Neurology, Dudley, United Kingdom, [6]Aston University, School of Life and Health Sciences, Birmingham, United Kingdom

Background: The immunoreceptor tyrosine-based inhibition motif (ITIM)-containing receptor G6b-B is an essential regulator of platelet production and activation, loss of which results in severe macrothrombocytopenia and aberrant platelet function in mice and man.
Aims: To identify the physiological ligand of G6b-B and determine its biological effects on platelets.
Methods: Recombinant dimeric Fc-tagged mouse G6b-B ectodomain (mG6b-B-Fc) was used to identify tissues expressing the putative ligand of G6b-B by immunohistochemistry and to pull-down the ligand from tissue lysates. Following identification by mass spectrometry, the interaction between G6b-B and its binding partner was characterised *in vitro*. Effects of the ligand on platelets were assessed using standard functional and biochemical assays.
Results: The most abundant protein identified in mG6b-B-Fc pull-downs from vena cava lysates was the heparan sulfate (HS) proteoglycan perlecan. This result was confirmed by *in vitro* binding assays, where mG6b-B-Fc bound robustly to purified perlecan, but not to other extracellular matrix proteins. Heparinase III treatment of immobilised perlecan almost completely abolished its interaction with mG6b-B-Fc, strongly suggesting that G6b-B binds to the HS side-chains of perlecan. This was supported by surface plasmon resonance measurements, revealing binding affinities of mG6b-B-Fc to perlecan, HS and heparin in the low nanomolar range. Intriguingly, heparin induced G6b-B phosphorylation in washed human platelets. Adhesion of platelets to perlecan was observed only after removal of the HS side-chains, pointing to their inhibitory function. However, soluble HS and heparin enhanced aggregation of human platelets to subthreshold concentrations of collagen in platelet rich plasma.
Conclusions: Findings from this study establish the HS side-chains of perlecan as physiological ligands of G6b-B. Ongoing studies are aimed at determining the optimal binding sequence of HS and analysing the biological consequences of this interaction.

OC 66.5 | Structural Analysis of Protease Activated Receptor 4 (PAR4) with Histidine Hydrogen Deuterium Exchange

M. de la Fuente[1], M. Miyagi[2], M. Nieman[1]

[1]Case Western Reserve University, Pharmacology, Cleveland, United States, [2]Case Western Reserve University, Proteomics and Bioinformatics, Cleveland, United States

Background: Protease activated receptors (PARs) are GPCRs that have central roles in the cardiovascular system. The signaling pathways mediated by PARs are well-studied. However, the structural basis for PAR activation is unknown. PARs are activated by a tethered ligand that interacts with a binding pocket on the receptor. Since the ligand is attached to the receptor, there are likely substantial conformational changes that occur during PAR activation. We now describe the first biophysical studies examining this unique mode of activation using PAR4.
Aims: The goal of this study is to test the hypothesis proteolytic activation PAR4 results in a specific structural rearrangement of the receptor.
Methods: We have expressed and purified PAR4 from Sf9 cells for histidine-hydrogen deuterium exchange (His-HDX). The changes in overall stability of PAR4 were evaluated by proteolytic digestion.
Results: PAR4 has 9 histidine residues that are spaced throughout the protein allowing a global view of solvent accessible and non-accessible regions. Peptides containing each of the 9 His residues were used to determine the $t_{1/2}$ for each His residue in full length or thrombin cleaved PAR4. The thrombin cleaved PAR4 had a 2-fold increase ($p > 0.01$) in $t_{1/2}$ values observed for four histidine residues (His^{180}, His^{229}, His^{240}, and His^{380}) demonstrating that these regions have a decrease in solvent accessibility upon thrombin treatment. In agreement, thrombin cleaved PAR4 was resistant to thermolysis digestion. In contrast, activation with the PAR4 agonist peptide was digested at the same rate as uncleaved PAR4. Further analysis showed the C-terminus is protected in the thrombin cleaved PAR4 compared to uncleaved or agonist peptide treated PAR4.
Conclusions: The studies described here are the first to examine the tethered ligand activation mechanism for a PAR family member using biophysical approaches. These studies shed light on the overall conformational changes that follow activation of PARs by a protease.

OC 68.1 | Platelet Transcriptome Analysis of Mice with Altered Thrombin Regulation

S. Schubert[1], F. Marini[2], C. Santos[1], H. Binder[2], W. Ruf[1,3]

[1]Johannes Gutenberg-University Medical Center, Center for Thrombosis and Hemostasis, Mainz, Germany, [2]Johannes Gutenberg-University Medical Center, Institute for Medical Biostatistics, Epidemiology and Informatics, Mainz, Germany, [3]The Scripps Research Institute, La Jolla, United States

Background: Although mature platelets do not synthesize RNA, existing RNA can undergo splicing and translation. The RNA profile of platelets may also reflect changes in megakaryocyte development or alterations of the bone marrow (BM). Circulating platelets are therefore sentinels for pathological changes in BM niches, blood and acute or chronic diseases that could be detected by RNA profiling of platelets.

Aims: To identify platelet signatures associated with prothrombotic states.

Methods: We determined the platelet transcriptome in mice with altered thrombin regulation, specifically PAR4$^{-/-}$ mice and GP1ba-deficicent mice with defective platelet thrombin binding and TM$^{Pro/Pro}$ mice with diminished thrombin neutralization in the circulation. Total RNA of leukocyte-depleted platelets was sequenced yielding at least 35 Million reads per sample. Reads were mapped to GRCm38.76.

Results: GPIba-deficient, PAR4$^{-/-}$, and TM$^{Pro/Pro}$ mice showed highly reproducible NGS profiles with a distinct clustering of repeats from each receptor mutant in principle component analysis. Differential expression analysis identified transcripts that were changed selectively in TM$^{Pro/Pro}$ (190 transcripts), PAR4$^{-/-}$ (563) and GP1ba-deficient (609) platelets. Pathway analysis indicated distinct functional alterations for each strain. Furthermore, platelet transcript profiles were changed in opposite direction between TM$^{Pro/Pro}$ and PAR4$^{-/-}$ (323 transcripts) or GP1ba-deficient and PAR4$^{-/-}$ (574) mice, indicating that diminished thrombin neutralization by endothelial cell-expressed TM or by platelet-expressed GP1ba causes increased PAR4 signaling to alter platelet RNA profiles.

Conclusions: The transcriptome analysis provides insights into common and distinct pathways regulated by thrombin and its receptors expressed by the endothelium and platelets/megakaryocytes. These transcript profiles can be used to evaluate chronically elevated thrombin levels and coagulation activation in diverse clinical settings predisposing to thrombo-embolic complications.

OC 68.2 | Identification of eQTLs for Platelet and Hemostasis Related Genes in Platelets and Leukocytes within the Framingham Heart Study

J.E. Huffman[1], J.D. Eicher[1], C.J. O'Donnell[1,2], K. Tanriverdi[3], J.E. Freedman[3], A.D. Johnson[1]

[1]National Heart Lung Blood Institute, Population Sciences Branch, Framingham, United States, [2]Boston VA Healthcare System, Cardiology Section Administration, West Roxbury, United States, [3]University of Massachusetts Medical School, Department of Medicine, Worcester, United States

Background: Platelets and hemostatic factors are important in thrombosis, inflammation, and wound healing. Their functions and signaling pathways interact in the tight control of these processes. Consequently, platelets and hemostatic factor measures have been associated with cardiovascular disease, myocardial infarction, stroke, and venous thrombosis. Identifying key genetic regulators of platelets and hemostatic factors and their mechanisms are important to understanding their contribution to disease.

Aims: To identify expression quantitative trait loci (eQTLs) that influence the expression of key platelet and hemostatic factor associated genes.

Methods: We selected platelet and/or hemostasis related transcripts based on known biological function or past genetic associations in the literature. We then measured their RNA expression levels by qRT-PCR in leukocytes and platelets from ~1,600 Framingham Heart Study participants. We identified cis-eQTLs (±1 Mb of gene) and trans-eQTLs of expression levels corrected for age, sex, and other technical covariates. Conditional analyses were performed to identify independent loci and disease associations identified using GRASP and GWAS Catalog.

Results: We identified many *cis*- and *trans*-eQTLs in both leukocytes and platelets (Table 1). Of the *trans*-eQTLs, SNPs within the well-characterized *ARHGEF3* region were associated with expression of 14 transcripts (e.g. *VWF* and *FADS2*). Additionally, we observed intriguing associations of: 1) SNPs near *GP1BA*, a receptor for vWF, with platelet *CCL5* expression and 2) SNPs in *AP2B1*, a clathrin-dependent endocytotic factor associated with platelet count, with platelet *ITGA2B* expression.

TABLE 1 Summary of RNA Transcripts Investigated

	Leukocytes	Platelets	Overlapping
Total Number of Transcripts	84	140	79
Number with cis-eQTLs	39	67	22
Number with trans-eQTLs	8	41	6

Conclusions: We identified numerous *cis*- and *trans*-eQTLs of platelet and hemostatic factor related transcripts. Mapping these eQTLs enable the determination of whether genetic regulation of gene expression influences thrombosis, hemostasis, and ultimately human disease.

OC 68.3 | The First Quantitative Phosphoproteome after Selective cGMP/PKG Stimulation by Riociguat In Human Platelets and Comparison to the cAMP/PKA Phosphoproteome

O. Pagel[1], E. Walter[2], S. Makhoul[2], H. Gonczarowska-Jorge[1], A. Smolenski[3], S. Gambaryan[2,4], U. Walter[2], K. Jurk[2], R. Zahedi[1]

[1]Leibniz-Institut für Analytische Wissenschaften -ISAS-e.V., Protein Dynamics, Dortmund, Germany, [2]Universitätsklinikum der Johannes Gutenberg-Universität Mainz, Centrum für Thrombose und Hämostase (CTH), Mainz, Germany, [3]University College Dublin, UCD Conway Institute, UCD School of Medicine and Medical Science, Dublin, Ireland, [4]Sechenov Institute of Evolutionary Physiology and Biochemistry, Russian Academy of Sciences, St. Petersburg, Russian Federation

Background: Human platelets are tightly regulated by multiple vasoactive substances or drugs including endothelial-/drug-derived NO and prostacyclin (Iloprost). NO activates the soluble guanylyl cyclase (sGC)/cGMP pathway and inhibits platelets, often in synergy with prostacyclin. cGMP effects in platelets are poorly understood and sometimes controversial. Recently, we characterized the human platelet proteome (Burkhart et al. Blood 2012), and dynamic changes of the phosphoproteome upon Iloprost and ADP treatment (Beck et al. Blood 2014; Beck et al. Blood 2017).

Aims: Elucidation of the Riociguat/ sGC/ cGMP affected phosphoproteome in human platelets.

Methods: Human platelets were either stimulated with Iloprost (cAMP/PKA) or Riociguat, a robust, cAMP-independent cGMP-stimulator. Changes in protein phosphorylation were studied using established quantitative phosphoproteomics workflows.

Results: In total we quantified 8181 phosphorylation sites from 2249 proteins across three biological replicates. Riociguat increased (>1.5-fold up) and decreased (>1.5-fold down) phosphorylation levels in 345 and 94 proteins, respectively. These covered many platelet functions, including 24 protein kinases (e.g. MYLK, CAMKK1/2, CDK16/17/18, BRAF) with increased and 4 protein kinases (KALRN, KSR2, PAK2, WNK1) with reduced levels. Comparison of the Riociguat- and Iloprost phosphoproteomes showed a significant overlap but also specific Riociguat/cGMP effects. The top-list of Riociguat affected phosphoproteins includes known PKG substrates (e.g. VASP, ITPR1, MRVI1/IRAG) but also novel candidates including the PP2A inhibitor ENSA.

Conclusions: This first human platelet phosphoproteome of the Riociguat/sGC/cGMP pathway demonstrates an unexpected magnitude, diversity and involved protein kinase network. The Riociguat/sGC/cGMP and Iloprost/cAMP substrates show a remarkable overlap but also some specific events. Our data also provide a number of novel PKG substrates including the PP2A inhibitor ENSA which require further study.

OC 68.4 | Reversible Protein Lysine Acetylation as a Novel Regulatory Modality Orchestrating Platelet Function

J.E. Aslan[1], R.A. Rigg[2], A.T.P. Ngo[2], J.W. Nelson[1], J. Burchard[3], Ö. Babur[3], E. Demir[3], U. Shinde[4], L.L. David[4], O.J.T. McCarty[2]

[1]Oregon Health & Science University, Knight Cardiovascular Institute, Portland, United States, [2]Oregon Health & Science University, Biomedical Engineering, Portland, United States, [3]Oregon Health & Science University, Computational Biology, Portland, United States, [4]Oregon Health & Science University, Biochemistry, Portland, United States

Background: The reversible acetylation of protein lysine ε-amino groups - catalyzed by lysine acetyltransferases (KATs) and deacetylases (KDACs) - impacts diverse cellular and physiological activities. We recently demonstrated that KATs such as p300 regulate platelet cytoskeletal dynamics and platelet hemostatic function (Aslan et al., *JTH* 2015). To date, our proteomics efforts have identified >2,000 acetyllysine (acK) modifications on >1,000 platelet proteins that serve as potential nodes in the regulation of platelet function by lysine acetylation.

Aims: Here, we aim to determine mechanistic roles for protein lysine acetylation in platelet function.

Methods: We have developed a multi-dimensional targeted proteomics workflow using Tandem Mass Tags (TMT) and ultrahigh resolution mass spectrometry to quantify dynamic changes in protein lysine acetylation in the platelet activation program. Using a combination of bioinformatics, molecular modeling and cell physiological methods, we interrogate roles for protein lysine acetylation in platelet function.

Results: We find that >200 lysine residues on >100 platelet proteins undergo a >1.5 fold-change in site-specific acetylation following activation with the platelet glycoprotein GPVI agonist collagen-related peptide (CRP). A number of platelet cytoskeletal-associated proteins, including myosin IIA heavy chain (MYH9) show specific, several fold-change increases in lysine acetylation following stimulation with CRP. Molecular modeling, *in vitro* and functional studies point to MYH9 acetylation as a key regulatory step, similar to and concurrent with myosin light chain phosphorylation, critical to committing platelets to an activated state.

Conclusions: Our proteomics-based investigation supports specific roles for lysine acetylation in key molecular events of platelet activation and offers novel insights into potential molecular targets for the analysis and manipulation of platelet function in normal physiology and disease.

OC 68.5 | The Platelet Releasate is a ‚Barcode' for the Health Status of an Individual

P.B. Szklanna[1], M.E.M. Parsons[1], K. Wynne[2], H. O'Connor[3], K. Egan[1], F. Ni Ainle[1,3,4], P.B. Maguire[1]

[1]SPHERE Research Group, UCD Conway Institute, Belfield, D4, Dublin, Ireland, [2]UCD Conway Institute, Proteomics Core, University College Dublin, Dublin, Ireland, [3]Rotunda Hospital, Dublin, Ireland, [4]Mater Misericordiae University Hospital, Dublin, Ireland

Background: Upon activation, platelets release a multitude of soluble and vesicular signals, collectively termed the ‚platelet releasate' (PR). This PR plays an important role in haemostasis, wound healing and the inflammatory response. We and others have used qualitative/quantitative proteomic approaches to characterise the PR; however, with reports of marked inter-individual variability, confident and reliable insights have been hindered.

Aims:

1. Provide a reproducible and quantifiable proteomic analysis and establish a ‚core' human PR.
2. Assess the variability of the PR in healthy human pregnancy where increased platelet activation is observed.
3. Characterise the pathologic proinflammatory changes in patients with early-onset preeclampsia (EOP), a disease associated with potentially life-threatening consequences for both mother and baby.

Methods: PR from 32 healthy donors, 22 EOP patients (onset < 34 gestational weeks) and matched healthy pregnant controls, was obtained with informed consent. After trypsin/lys-C double digest, samples were subjected to label-free quantitative proteomic analysis.

Results: 897 proteins from thrombin-induced PRs were quantified across 32 healthy donors, with 278 proteins forming a ‚core' PR. The variability & origin of these proteins was assessed. In healthy pregnancy, 173 proteins were differentially found in PR, including proteins produced only in pregnancy such as pregnancy-specific glycoproteins

and CSH2. Moreover, an additional 36 PR proteins were modified in EOP, with 6/36 proteins previously associated with the pathogenesis of EOP. Strikingly, several platelet transmembrane and signalling proteins could differentiate between a moderate and severe maternal outcome in EOP.

Conclusions: The PR comprises a ‚core' set of proteins between healthy individuals. This dynamic proteome significantly changes in physiologic and pathologic conditions. Thus, the PR is a barcode for the health status of an individual at a given time.

PLATELETS – CLINICAL

OC 09.1 | Conformation of ADAMTS13 is Altered in Acquired TTP Patients

E. Roose[1], A.-S. Schelpe[1], B. Joly[2], A. Vandenbulcke[1], J. Caron[1], I. Pareyn[1], N. Vandeputte[1], M. Peetermans[3], P. Verhamme[3], H. Deckmyn[1], S.F. De Meyer[1], P. Coppo[4], A. Veyradier[2], K. Vanhoorelbeke[1]

[1]KU Leuven Campus Kulak Kortrijk, Laboratory for Thrombosis Research, Kortrijk, Belgium, [2]Hôpital Lariboisière, Service d'Hématologie Biologique, Paris, France, [3]KU Leuven, Center for Molecular and Vascular Biology, Leuven, Belgium, [4]Assistance Publique Hôpitaux de Paris, Université Pierre et Marie Curie, Département d'Hématologie Clinique, Paris, France

Background: Autoantibodies (autoAbs) targeting ADAMTS13 cause acquired thrombotic thrombocytopenic purpura (aTTP). ADAMTS13 has a ‚closed' conformation by interaction between its spacer and CUB domains. Disruption of this interaction by addition of VWF or an activating anti-CUB Ab changes the ADAMTS13 conformation, resulting in exposure of cryptic epitopes.

Aims: Determine if the conformation of ADAMTS13 is altered in aTTP patients compared to healthy donors (HD).

Methods: Abs recognizing cryptic epitopes in the cysteine/spacer (C/S) domain (hence recognizing ADAMTS13 with an altered conformation) were selected via ELISA. The conformation of ADAMTS13 in HD, acute aTTP patients and sepsis patients was determined via ELISA, in which plasma was added to the Ab that recognizes a cryptic epitope in ADAMTS13. As a control, plasma was also incubated with the activating anti-CUB Ab 17G2 which changes the conformation of ADAMTS13 and allows binding to the Ab recognizing a cryptic epitope.

Results: From our panel of Abs, we could identify one anti-C/S domain Ab (1C4) that recognizes a cryptic epitope in ADAMTS13. While Ab 1C4 could readily capture MDTCS, it only captured full length ADAMTS13 when its conformation was changed by addition of 17G2. Interestingly, ADAMTS13 in HD (n=33) adopts a closed conformation where the spacer and CUB domains interact and the epitope of 1C4 is inaccessible. In HD, changing the conformation of ADAMTS13 by addition of 17G2 did expose the cryptic epitope of 1C4. As expected, similar results were obtained for sepsis patients (n=60). Intriguingly, the conformation of ADAMTS13 is spontaneously altered in aTTP patients (n=57) as the cryptic epitope of 1C4 was readily available. Addition of 17G2 did not further change the conformation of ADAMTS13 in these aTTP patients.

Conclusions: The conformation of ADAMTS13 in aTTP patients is altered compared to the one in HD and sepsis patients. Exposure of cryptic epitopes in the C/S domain might induce immune responses and explain autoAb development in aTTP.

OC 09.2 | PAD4 Citrullination of ADAMTS13: A New Link between NETosis and Thrombosis

N. Sorvillo[1,2], K. Martinod[1,2], C. Staudinger[1], D. Wagner[2,3,4]

[1]Boston Children's Hospital, Program in Cellular and Molecular Medicine, Boston, United States, [2]Harvard Medical School, Department of Pediatrics, Boston, United States, [3]Boston Children's Hospital, Harvard Medical School, Boston, United States, [4]Boston Children's Hospital, Division of Hematology/Oncology, Boston, United States

Background: Neutrophils and neutrophil extracellular traps (NETs) are considered important for immunothrombosis and have been shown to promote coagulation. A driving force in NETosis is peptidyl arginine deiminase type IV (PAD4), an enzyme released with the decondensed chromatin, after it citrullinates arginine residues on histones. Citrullination of proteins is significant in many disorders. However, the effect in thrombosis is still unknown. ADAMTS13, cleaving VWF, is essential in regulating thrombosis and reduced activity or absence leads to microvascular thrombosis. Interestingly, plasmatic reduction of ADAMTS13 is observed in many thrombo-inflammatory disorders where NETs have also been associated, suggesting a link between NETs and reduction in ADAMTS13 activity.

Aims: ***To determine whether PAD4 interacts with and citrullinates ADAMTS13 and evaluate the effect of this post-translational modification on ADAMTS13 function.***

Methods: Recombinant human PAD4 (r-huPAD4) was incubated with recombinant human ADAMTS13 (r-huADAMTS13; provided by Shire), and citrullination of the protein was examined by western blot using an anti-citrulline antibody. Subsequently, we analyzed r-huADAMTS13 activity by VWF-FRETS assay and evaluated the function of citrullinated-r-huADAMTS13 upon injection into ADAMTS13$^{-/-}$ mice by intravital microscopy.

Results: We observed that r-huPAD4 citrullinated r-huADAMTS13 and that citrullination dramatically reduced its capacity to cleave VWF-substrate. This effect could be reversed by pre-incubating r-huPAD4 with a PAD inhibitor. Additionally, we observed in vivo, that VWF/platelet strings, seen on venules of ADAMTS13$^{-/-}$ mice, were cleared after infusion of r-huADAMTS13, while they remarkably persisted in vessels of mice treated with citrullinated-r-huADAMTS13.

Conclusions: Our results indicate that citrullination by PAD4 inactivates ADAMTS13 reducing its capacity to cleave VWF/platelet strings. This suggests a new way in which NETs are pro-thrombotic and support pathological thrombosis.

[ADAMTS13 was incubated with PAD4 with or without the PAD inhibitor Cl-Amidine. Then, ADAMTS13 activity was determined by VWF73-FRETS assay.]

OC 09.3 | The Role of ADAMTS13 Exosites in VWF Recognition and Proteolysis

A. Petri, R. de Groot, Y. Xu, J. Crawley

Imperial College London, Department of Medicine, Centre for Haematology, London, United Kingdom

Background: ADAMTS13 cleaves VWF with unprecedented specificity, owing to multiple exosite interactions between ADAMTS13 Spacer, Cysteine-rich (Cys), Disintegrin-like (Dis) and Metalloprotease (MP) domains, and binding sites in the unravelled VWF A2 domain.

Aims: To kinetically characterise the role of each ADAMTS13 exosite in coordinating VWF proteolysis.

Methods: A VWF A2 domain fragment (VWF96) was expressed and purified. VWF96 mutants, in which each exosite binding site was entirely ablated, were generated (Table 1). VWF96 variants were used as substrates in activity and binding assays with ADAMTS13.

TABLE 1

VWF A2 domain fragment	Sequence
VWF96	VWF1573-1668
VWF96-MP	VWF1573-1668 (L1603N, P3 residue)
VWF96-Dis	VWF1573-1668 (DIKRD1614/6/7/8/1622AQEET)
VWF96-Cys	VWF1573-1668 (IWAILI1642/4/7/9/1650/1QYSQQQ)
VWF96-Spacer	VWF1573-1668 (LVL1664/5/6TNQ)
VWF87ΔSpacer	VWF1573-1659

Results: VWF96 was proteolysed efficiently (k_{cat}/K_m=14x10^{5}M^{-1}s^{-1}). Deleting either the entire Spacer binding site (VWF87ΔSpacer) or mutating the 3 hydrophobic residues LVL1664-6 in that region (VWF96-Spacer) caused the same 17-fold reduction in proteolysis due to corresponding increases in K_m and K_D values. Mutating the Cys binding site (VWF96-Cys) reduced proteolysis 30-fold, again manifest through reduced substrate binding (higher K_m). Conversely, proteolysis of VWF96-MP was 130-fold reduced, characterised by normal substrate binding but reduced k_{cat} for proteolysis. Remarkably, mutation of the Dis binding site (VWF96-Dis) reduced proteolysis by 1000-fold, caused by a combination of reduced binding (26-fold higher K_m) and a 45-fold reduction in the k_{cat}.

Conclusions: We demonstrate the importance of VWF A2 domain residues LVL1664-6 in ADAMTS13 Spacer exosite binding. We also show that ADAMTS13 Spacer, Cys and Dis exosites form distinct interactions with VWF that influence the K_m for proteolysis. The low affinity interaction between ADAMTS13 MP and VWF P3 influences the k_{cat}, likely due to its proximity to the scissile bond. The ADAMTS13 Dis exosite interaction is the most important. The influence of this remote exosite on the k_{cat} suggests a potential allosteric mechanism that confers enzyme specificity.

OC 09.4 | Autoantibody Binding to 'Open' and 'Closed' ADAMTS13 in Patients with Acquired Immune Thrombotic Thrombocytopenic Purpura

M.I. Underwood[1], M.R. Thomas[2], M.A. Scully[2], J.T.B. Crawley[1]

[1]Imperial College London - Hammersmith Hospital Campus, Centre for Haematology, London, United Kingdom, [2]University College Hospital, Department of Haematology, London, United Kingdom

Background: Patients with an ADAMTS13-deficiency develop thrombotic thrombocytopenic purpura (TTP). Acquired, immune-mediated TTP (iTTP) accounts for ~95% of cases, with patients varying in terms of clinical severity. These patients develop anti-ADAMTS13 IgG autoantibodies that most frequently bind to the ADAMTS13 Spacer domain. ADAMTS13 can exist in two distinct conformations, a ‚closed' form in which the CUB domains fold back upon the Spacer domain, and a more extended ‚open' form.

Aims: To investigate whether iTTP patient autoantibody binding to ADAMTS13 is dependent upon ADAMTS13 conformation.

Methods: ELISAs were developed to specifically detect autoantibody binding to either ‚open' or ‚closed' forms of ADAMTS13 in 17 iTTP patients with medium/high titre anti-ADAMTS13 IgG. Recombinant ADAMTS13 was either coated directly onto ELISA wells (‚open') or captured via its 6xHis tag to the surface of Ni^{2+} coated plates (‚closed'). After iTTP plasma incubation, bound patient antibodies were detected using an anti-human antibody.

Results: For each patient there was higher autoantibody binding to ‚open' compared to ‚closed' ADAMTS13. In 3/17, autoantibody binding could only be detected towards the ‚open' form. In 11/17 5%-40% of those antibodies that bound ‚open' also bound ‚closed' ADAMTS13. Whereas in 3/17, 40-80% of those autoantibodies that could bind to the ‚open' form could also bind to ‚closed' ADAMTS13.

Conclusions: iTTP patient autoantibody binding to ADAMTS13 is highly dependent upon its conformation. Whilst ADAMTS13 is in its ‚closed' conformation, many frequently targeted epitopes recognised by autoantibodies are concealed, preventing antibody binding. It remains to be determined whether these differences effect how readily antibodies can bind to ADAMTS13 within the circulation and subsequently exert their pathogenicity either through inhibition and/or clearance of ADAMTS13.

OC 09.5 | Parallel Profiling of ADAMTS13-derived Peptide Repertoires on HLA-DR and HLA-DQ

J. Hrdinová[1], F. Verbij[1], P.H.P. Kaijen[1], R.B. Hartholt[1], F.P.J. van Alphen[2], N. Lardy[3], A. ten Brinke[4], K. Vanhoorelbeke[5], J. Voorberg[1,6], A.B. Meijer[2,7], I. Peyron[1]

[1]Sanquin Research and Landsteiner Laboratory, Academic Medical Center, University of Amsterdam, Department of Plasma Proteins, Amsterdam, The Netherlands, [2]Sanquin Research and Landsteiner Laboratory, Academic Medical Center, University of Amsterdam, Department of Research Facilities, Amsterdam, The Netherlands, [3]Sanquin, Department of Immunogenetics, Amsterdam, The Netherlands, [4]Sanquin Research and Landsteiner Laboratory, Academic

Medical Center, University of Amsterdam, Department of Immune Pathology, Amsterdam, The Netherlands, [5]KU Leuven Campus Kulak Kortrijk, Laboratory for Thrombosis Research, Kortrijk, Belgium, [6]Academic Medical Center, Department of Experimental Vascular Medicine, Amsterdam, The Netherlands, [7]Utrecht Institute for Pharmaceutical Sciences, Utrecht University, Department of Pharmaceutics, Amsterdam, The Netherlands

Background: Thrombotic thrombocytopenic purpura (TTP) is a severe life-threatening disorder resulting from the formation of autoantibodies against the von Willebrand Factor cleaving protease ADAMTS13. Several studies have identified HLA-DRB1*11, HLA-DQB1*03 and HLA-DQB1*02:02 as risk factors for acquired TTP. Previous research in our department identified ADAMTS13 CUB2 domain-derived peptides "FINVAPHAR" and "ASYILIRDTHSLR" to be presented on HLA-DRB1*11 and HLA-DRB1*03, respectively. We also showed that $CD4^+$ T cells reactive with these peptides were present in patients with acquired TTP.

Aims: We previously identified ADAMTS13-derived peptides presented on HLA-DR. The aim of this study was to identify peptides that are presented on HLA-DQ.

Methods: Monocyte-derived dendritic cells (DCs) of 11 HLA-typed healthy donors were pulsed with 100 nM of ADAMTS13. MHC-II:peptide complexes were purified using the HLA-DR specific antibody L243 and the HLA-DQ specific antibody SPV-L3. Peptides were separated by nanoscale C18 reverse phase chromatography connected to an Orbitrap Fusion Tribid mass spectrometer. All data was acquired with Xcalibur software.

Results: In 5 out of 11 donors ADAMTS13-derived peptides presented on HLA-DQ were identified. One peptide with the core sequence "CAVAIGRPL" derived from the CUB-1 domain was presented by DCs from 3 different HLA-DQB1*06 positive donors. Peptides "SFLDGTRCM" and "IRDTHSLRT" derived from the cysteine-rich and CUB-2 domain were presented by 2 different donors. Four HLA-DQ presented peptides were only identified on DCs derived from a single donor. In total, 7 different ADAMTS13-derived core peptides were identified on HLA-DQ; 4 core peptides were exclusively identified on HLA-DQ and not HLA-DR.

Conclusions: Our study shows that HLA-DQ contributes significantly to the MHC-II presentation of ADAMTS13 derived peptides. We propose that $CD4^+$ T cells recognizing these peptides may contribute to the onset of and/or relapses in acquired TTP.

OC 34.1 | Platelet Factor 4: von Willebrand Factor Complexes: An Important Antigenic Target in Heparin-induced Thrombocytopenia?

I. Johnston[1,2], J. Lopez[3,4], D. Cines[5], L. Rauova[1,6], M. Poncz[1,6]

[1]Children's Hospital of Philadelphia, Hematology, Philadelphia, United States, [2]Perelman School of Medicine, University of Pennsylvania, Department of Pharmacology, Philadelphia, United States, [3]Bloodworks Northwest, Seattle, United States, [4]University of Washington, Department of Medicine, Seattle, United States, [5]Perelman School of Medicine, University of Pennsylvania, Department of Pathology and Clinical Laboratory Medicine, Philadelphia, United States, [6]Perelman School of Medicine, University of Pennsylvania, Department of Pediatrics, Philadelphia, United States

Background: Heparin-induced thrombocytopenia (HIT) is driven by the binding of pathogenic HIT antibodies (Abs) to platelet factor 4 (PF4) complexed to cell surface glycosaminoglycans on vascular cells, including endothelial cells (ECs). However, in studies of HIT in an EC-lined microfluidic system, post hematoporphyrin-induced photochemical damage, we noted that infused PF4 bound specifically in the form of extended linear strands along the surface of ECs, a pattern described previously for von Willebrand Factor (vWF) under flow.

Aims: To evaluate the formation of HIT antigenic complexes of PF4 with extruded vWF and to explore their contribution to thrombosis in HIT.

Methods: Microfluidic channels coated with human umbilical vein ECs were exposed to blue light while cell media containing hematoporphyrin was infused. PF4, labeled HIT-like monoclonal Ab KKO, and labeled polyclonal anti-vWF Ab were then infused to identify HIT complexes. To examine if PF4-KKO-vWF complexes contribute to thrombosis, recalcified-human WB (WB) labeled with calcein AM was then flowed through the channels.

Results: PF4 co-localized with labeled vWF along the surface of injured EC (Fig. 1A). KKO bound PF4-vWF complexes (Fig. 1B).

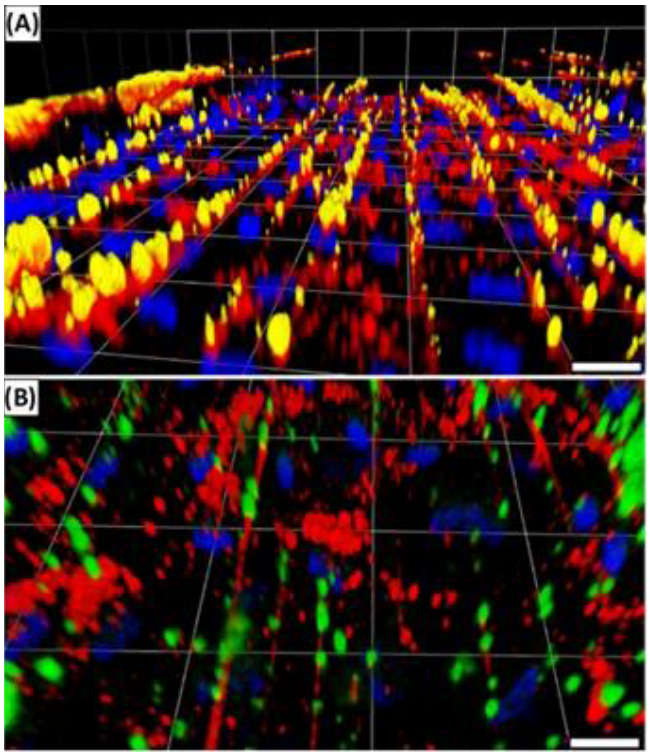

FIGURE 1 3D image (A) showing PF4 (yellow) bound along vWF (red) and KKO (green) binding in a similar linear fashion along vWF

When WB was flowed through channels containing PF4+KKO, large platelet aggregates developed within 10 mins along the extended strands of vWF which did not occur with KKO alone or PF4+ TRA, an isotype control. By 60 mins, aggregates in the PF4+KKO had grown significantly, but had largely disappeared in the other settings (Fig. 2).

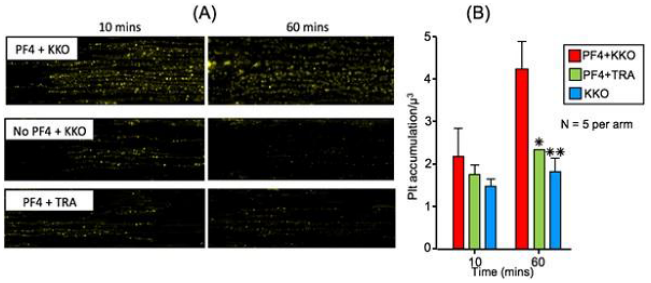

FIGURE 2 vWF-PF4-KKO are prothrombotic complexes that accumulate significantly more platelets than non-complexed vWF

Conclusions: These studies identify vWF as a PF4 binding site. PF4-vWF complexes bind a model HIT antibody. The ability of PF4-vWF-KKO complexes to form large platelets aggregates suggests that PF4-vWF complexes may contribute to thrombotic complications and provides a potential new therapeutic target. Studies to define the mechanistic details of PF4-vWF binding and its biological implications in HIT and other thrombotic disorders are underway.

OC 34.2 | A New Mechanism of Autoimmune HIT Caused by a Subset of Antibodies

T.-H. Nguyen, N. Medvedev, M. Delcea, A. Greinacher

University Medicine Greifswald, Institute for Immunology and Transfusion Medicine, Greifswald, Germany

Background: Antibodies recognizing complexes of the chemokine platelet factor 4 (PF4/CXCL4) and polyanions (P) cause the prothrombotic adverse drug reaction heparin-induced thrombocytopenia (HIT). In patients with autoimmune-HIT, antibodies activate platelets even in the absence of polyanions. The binding mechanism of these antibodies remains unclear.

Aims: We used multiple analytical techniques to elucidate the binding mechanism of these antibodies.

Methods: Multiple analytical techniques including ELISA, HIPA, single-molecule force spectroscopy, scanning electron microscopy, isothermal titration calorimetry, and dynamic light scattering were used.

Results: Antibodies with binding forces of ~60-100pN activate platelets in the presence of polyanions, while a subset of antibodies from patients with autoimmune-HIT with binding forces ≥100pN and low thermal off-rates self-clusters PF4 in the absence of polyanions. Their binding to PF4 releases more energy than heparin binding ($\Delta H = -3.5 \pm 0.86 \times 10^7$ cal/mol *vs* $\Delta H = -7.26 \pm 1.36 \times 10^3$ cal/mol). The PF4/antibody complexes subsequently allow binding of polyanion-dependent antibodies resulting of large immunocomplexes, which finally induce massive platelet activation.

Conclusions: We have discovered a new binding mechanism in autoimmune HIT caused by a subset of antibodies from patients with autoimmune-HIT. Antibody-mediated changes in endogenous proteins triggering binding of otherwise non-pathogenic (or cofactor-dependent) antibodies may also be relevant in other antibody-mediated autoimmune disorders.

OC 34.3 | A Standardized Functional Assay for Routine Reliable HIT Diagnosis: A Potential Alternative to the Serotonin Release Assay

B. Tardy-Poncet[1,2], A. Montmartin[2], M. Piot[1], F. Alkhalfioui[3], H. Maes[3], B. Tardy[1,2], GFHT-HIT Study Group

[1]*Université de Lyon, Inserm U 1059 SAINBIOSE, Saint-Etienne, France,* [2]*Inserm CIC 1408, FCRIN-INNOVTE, CHU Saint-Etienne, Saint-Etienne, France,* [3]*Emosis, Illkirch-Graffenstaden, France*

Background: Reliable diagnosis of HIT remains a major clinical concern. Screening tests are highly sensitive but lack specificity, while confirmatory tests lack standardization and are not widely available.

Aims: Our objective was to evaluate the performance of a novel functional flow cytometric assay (FCA) vs. clinical expert opinion and the serotonin release assay (SRA).

Methods: Plasmas of 228 patients included (after signing the informed consent) in a multicenter study „HIT Score" (NCT00748839) were randomly selected: 106 with a positive HIT diagnosis and 122 with a negative HIT diagnosis, as defined by the expert´ opinion adjudication. The experts expressing the opinions used in this study were blinded to SRA results. SRA and FCA were centrally performed. Here, we present a modified FCA based on a method previously described by B.Tardy-Poncet during 24th congress ISTH (2015), with a time to results of about 90 min, simplified reagent handling, and a standardized procedure for analyzing and interpreting the results.

Results: The FCA performed as well as the gold standard SRA when both tests were compared to clinical expert opinion. The sensitivity and specificity of the FCA vs. expert´ opinion were respectively 83% (95% CI: 75-90) and 97% (95% CI: 93-100). The sensitivity and specificity of the SRA vs. expert´ opinion were respectively 88% (95% CI: 81-94) and 97% (95% CI: 93-100). The sensitivity and specificity of the FCA vs. the SRA were respectively 85% (95% CI: 78-93) and 94 % (95% CI: 89-98).

Conclusions: This new FCA gave results similar to those of the SRA for HIT diagnosis, without requiring either radioactivity, or profound expertise in flow cytometry. Based on these results, the new FCA may be conveniently used in routine practice as a reliable test for HIT diagnosis.

OC 34.4 | Soluble Glycoprotein VI (sGPVI) Measurement Is a Useful Biomarker of Platelet Activation in Heparin-induced Thrombocytopenia (HIT) and Correlates with Thrombotic Events

C.W. Tan[1], E. Duncan[1], S. McRae[1], R.K. Andrews[2], E.E. Gardiner[3]

[1]*SA Pathology/ Royal Adelaide Hospital, Haematology, Adelaide, Australia,* [2]*Australian Centre for Blood Diseases, Monash University, Melbourne, Australia,* [3]*Australian National University, Cancer Biology and Therapeutics, Canberra, Australia*

Background: The receptor FcγRIIA plays a key role in the pathogenesis of HIT. The platelet-specific collagen receptor GPVI releases a soluble ectodomain fragment (sGPVI) in hypercoagulable states and by FcγRIIA-mediated signaling upon engagement by HIT (H-PF4) antibodies. Confirming HIT diagnosis is challenging. sGPVI could serve as a surrogate marker of pathological HIT antibodies and as a unique readout of patient platelet activation *in vivo*, in contrast to using donor platelets.

Aims: To assess the utility of measuring sGPVI in concert with standard HIT testing methods and a new automated test, and to correlate sGPVI with thrombotic events.

Methods: sGPVI measurements by ELISA were obtained from stored plasma of 65 patients with clinical suspicion of HIT from 2008-2014 who underwent assessment for HIT, including 4T score, ELISA for HIT H-PF4 antibodies(GTI IgG), serotonin release assay (SRA), platelet aggregation (PAT) and a new chemiluminescent test, HemosIL HIT-Ab assay (Acustar,Werfen).

Results: Patients with moderate/strong positivity for ELISA and positivity for PAT had higher sGPVI than patients with negative results ($p< 0.05$). sGPVI showed 90% agreement with negative PAT and Acustar with ELISA results. With SRA as the gold standard, NPV was 100% and PPV 76% with a combination of sGPVI and ELISA GTI IgG. Patients with thrombosis (scored 2 on the 4T score "thrombosis" parameter) had higher levels of both sGPVI and HIT antibody than patients who scored 0 ($p< 0.05$).

Conclusions: sGPVI testing is easy to perform, compares well with existing and new HIT testing, and is a useful tool in the assessment of patients with clinical suspicion of HIT. Patients negative for both sGPVI and ELISA for HIT antibodies are unlikely to have HIT and further testing can be avoided. Importantly, sGPVI levels are associated with the clinical outcome of thrombosis. These findings support the measurement of sGPVI in HIT, and provides novel insights into the mechanism of pathological platelet response to HIT antibodies *in vivo*.

OC 34.5 | Identification of Clinical Parameters for Heparin Induced Thrombocytopenia: An International Multicenter Prospective Study

B. Tardy[1], E. De Maistre[2], D. Lasne[3], C. Pouplard[4], M. Alhenc-Gelas[5], A. Serre-Sapin[6], C. Lavenu-Blombed[7], J. Perrin[8], F. Mullier[9], M.-H. Horellou[10], I. Elalamy[11], T. Lecompte[12], A. Greinacher[13], B. Tardy-Poncet[14], GFHT-HIT Study Group

[1]CHU de Saint-Etienne, CIC 1408, Saint Etienne, France, [2]CHU de Dijon, Hôpital du Bocage, Laboratoire d'Hématologie, Dijon, France, [3]APHP, Laboratoire d'Hématologie - Hôpital Necker, Paris, France, [4]CHU de Tours, Laboratoire d'Hématologie, Tours, France, [5]APHP, Laboratoire d'Hématologie - HEGP, Paris, France, [6]CHU Clermont-Ferrand, Laboratoire d'Hématologie, Clermont Ferrand, France, [7]APHP, Laboratoire d'Hématologie - Hôpital Bicètre, Paris, France, [8]CHU Nancy, Laboratoire d'Hématologie, Nancy, France, [9]UCL Namur, Laboratoire d'Hématologie, Namur, Belgium, [10]APHP, Laboratoire d'Hématologie - Hôpital Cochin, Paris, France, [11]APHP, Laboratoire d'Hématologie - Hôpital Tenon, Paris, France, [12]University Hospital Geneva, Hemostasis Unit, Geneva, Switzerland, [13]University Medicine Greifswald, Institute of Immunologie and Transfusion Medicine, Greifswald, Germany, [14]CHU de Saint-Etienne, CIC 1408, Saint-Etienne, France

Background: The accuracy of clinical scores currently proposed for the diagnosis of heparin-induced thrombocytopenia (HIT) varies greatly in clinical practice. In addition, their criteria were not established and/nor validated prospectively in a large group of patients.

Aims: To identify clinical and laboratory parameters associated with HIT in patients with suspected HIT included in a prospective multicenter study.

Methods: Consecutive patients with suspected HIT leading to an ELISA test were included in 31 centres in France, Belgium and Switzerland. Serotonin release assay (SRA) was centrally performed for each patient. The final diagnosis of HIT was reached by 2 independent experts (3 in case of discrepancy) based on all the clinical and laboratory data. To identify the parameters, 70 % of the total population was selected at random. Univariate analysis was performed to screen for potential variables associated with HIT diagnosis. Variables with a p value ≤0.15 were entered in the final multiple regression analysis.

Results: 1597 patients were selected among a total of 2280 included patients (HIT prevalence: 14.7%). The following parameters were identified as independent factors associated with HIT diagnosis (Hazard Ratio, 95% CI) : unfractionated heparin (1,53 [0,97-2,42]), therapeutic dose of heparin (1,6 [1,16-2,22]), cardiopulmonary bypass (2,09 [1,50-2,93]), platelet decrease occurring after 5 to 21 days (2,09 [1,50-2,93]), platelet decrease > 40 % occurring within the previous 6 days before suspicion (3,22 [1,89-5,50]), arterial thrombosis (3,62 [1,97-6,64]), venous thromboembolism (3,89 [2,45-6,20]), major trauma (3,66 [1,46-9,17]).

Conclusions: This study identifies clinical and laboratory parameters associated with HIT in a large cohort of patients. These parameters may improve identification of patients with a high likelihood for HIT. These parameters will be evaluated on the 30 % resting patients.

OC 59.1 | Phenotyping and Genotyping Inherited Platelet Disorders: The Iberian Peninsula Multicenter Project Experience

V. Palma-Barqueros[1], J.M. Bastida[2], K. Janusz[3], J.R. Gonzalez-Porras[2], J.M. Hernández-Rivas[2], V. Vicente[1], M.L. Lozano[1], J. Rivera[1,3]

[1]Servicio de Hematología y Oncología Médica, Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, CB15/00055-CIBERER, Murcia, Spain, [2]Servicio de Hematología, IBSAL-Hospital Universitario de Salamanca, Salamanca, Spain, [3]On behalf of Inherited Platelet Disorders Project, Hemorrhagic Diathesis Working Group, SETH, ., Spain

Background: Diagnosis of inherited platelet disorders (IPDs), rare genetic defects of platelet function/production associated to bleeding diathesis, is challenging due to a heterogeneous clinical and laboratory presentation, low specificity of platelet function tests and large number of possible genetic culprits. Multicentre projects on IPDs could help to overcome this drawback.

Aims: To establish a multicentric project facilitating specialized functional and molecular characterization of patients with suspicion of IPD.

Methods: In 8 years, we studied 139 patients (47 M, 92 F; median age 29yr;125 unrelated families; 69 thrombocytopenia; 70 thrombocytopathy), referred from different hospitals. Clinical records were reviewed and bleeding scored with ISTH-BAT (median 5[1-25]). Centralized platelet phenotyping was done in fresh or delivered (18-24h) blood samples from patients and healthy volunteers. Basic studies included: Blood count/film; PFA-100, platelet aggregation, GPs expression and granule secretion, ^{14}C-5HT uptake, protein immunoblotting, whole mount or full electron microscopy. Patients DNAs were analyzed by Sanger sequencing of target genes (37 cases), high-throughput sequencing (HTS) using a 71 gene panel (Lozano ML. Blood 2016)(102 cases) or whole exome sequencing (WES) (7 cases).

Results: Clinical information and centralized platelet phenotyping supported an IPD in 94% of cases. Molecular analysis identified a candidate gene leading to IPDs in 108 cases (77.7%). Three patients bear a possible harmful variant in a plasma coagulation protein. Sanger sequencing of selected candidate gene was successful in all but one case. HTS with our panel revealed candidate causative variants in 73% of the assessed cases. WES permitted molecular diagnosis in 3 out of 7 cases. The diagnosis of these patients is shown in Fig 1

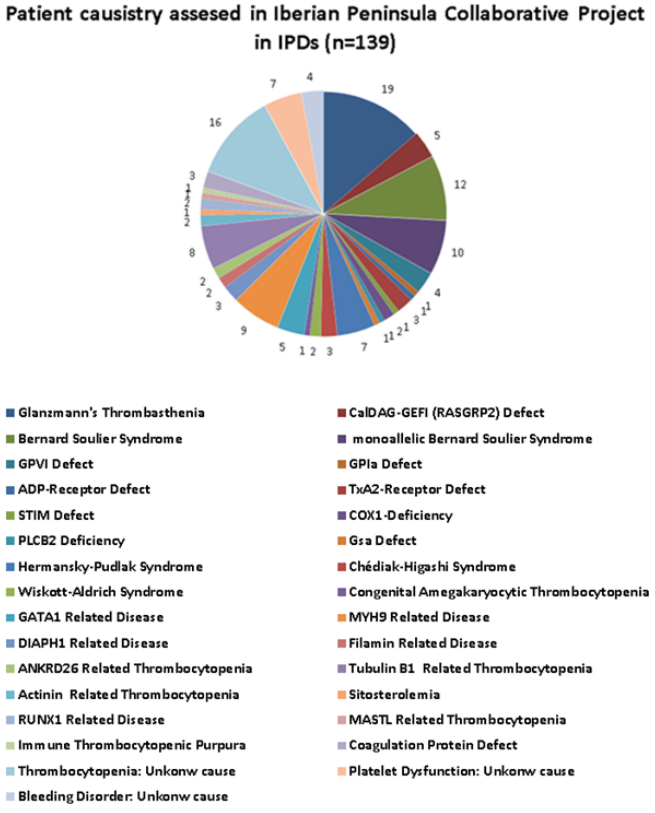

FIGURE 1 Patient causistry assessed in Iberian Peninsula Collaborative Project in IPDs (n=139)

Conclusions: A multicenter project has been consolidated that has assisted diagnose of the largest series of IPDs ever described in the Iberian Peninsula. (*ISCIII&Feder[PI14/01956,SETH&GRS 1370/A/16)*

OC 59.2 | Homozygous Frameshift in ABCC4 Causes a Novel Inherited Platelet Disorder Characterised by Increased cAMP Levels and Excessive Bleeding

T.K. Bariana[1,2,3], on behalf of the BRIDGE Consortium

[1]*Royal Free London NHS Foundation Trust, Katherine Dormandy Haemostasis and Thrombosis Unit, London, United Kingdom,* [2]*University College London, Haematology, London, United Kingdom,* [3]*NIHR Bioresource, Cambridge Biomedical Campus, Cambridge, United Kingdom*

Background: *Abcc4-/-* mice present with bleeding, altered platelet cAMP homeostasis and, in one study, reduced membrane expression of glycoprotein VI (GPVI). In humans *ABCC4* is highly expressed in megakaryocytes and platelets. In genome-wide association studies (GWAS) the minor allele of single nucleotide variant rs9524862 in *ABCC4* has been associated with a higher platelet count and higher transcript levels. Reduced ABCC4 protein expression has been observed in patients with storage pool disorder, without identification of causal genetic variants.

Aims: To determine the genetic cause of unexplained bleeding and platelet disorders we performed whole genome sequencing (WGS) for 896 patients recruited from 16 referral centres to the NIHR BioResource - Rare Diseases project.

Methods: In this study the analysis of WGS results was focussed on high impact variants in loci identified by GWAS to be associated with platelet traits. Functional phenotyping included platelet aggregometry, nucleotide and cAMP assays, electron microscopy (EM), GPVI expression by flow cytometry and sequencing of platelet RNA (RNA-seq).

Results: Two affected cases from a single pedigree carry a novel homozygous frameshift variant in *ABCC4* (13:95815456 CT>C, p.Ser743fs*2) that cosegregates with bleeding (Fig. 1). The variant is absent from 8,176 in-house controls and 60,706 individuals from the ExAC database.

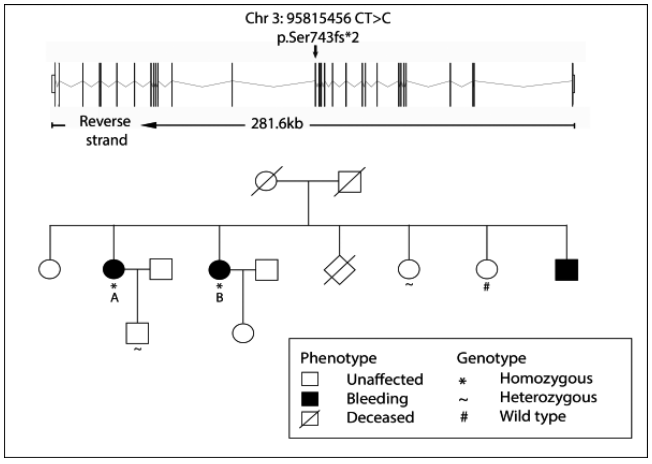

FIGURE 1 Phenotype and genotype relationship for the pedigree with a homozygous frameshift and premature stop codon at Chr 3: 95815456 CT>C, p.Ser743fs*

Presence of the premature stop codon was confirmed by RNA-seq. EM showed normal dense granules and GPVI expression was within the normal range. Platelet cAMP was significantly elevated compared to controls, including a wild-type sibling (p< 0.0001, Fig. 2).

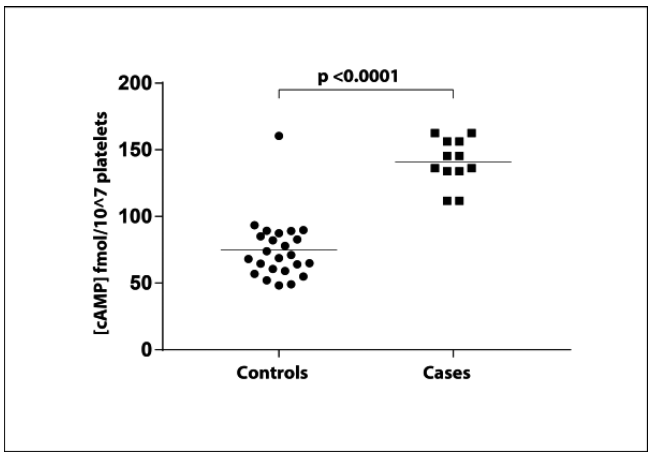

FIGURE 2 Platelet cAMP levels measured by ELISA in cases (labelled A and B in Fig. 1). Measurements were in triplicate on two occasions

Conclusions: This is the first report of a bleeding disorder associated with a variant in *ABCC4*. The variant is associated with increased intracellular cAMP levels resulting in reduced platelet responsiveness. Confirmatory studies are in progress, including platelet proteomics and phenotyping of megakaryocytes obtained by forward programming of patient-derived induced pluripotent stem cells.

OC 59.3 | A New Dominant Platelet P2RY12 Variant Affecting Receptor Function Identified in a Family with Severe Bleeding History

M.-C. Morel-Kopp[1,2], D. Rabbollini[1,2], S. Mundell[3], R. Aungraheeta[3], S. Gabrielli[1,2], Q. Chen[1,2], T. Kilo[4], J. Mackay[5], W. Stevenson[1,2], C. Ward[1,2]

[1]The University of Sydney, Northern Blood Research Centre - Kolling Institute, Sydney, Australia, [2]Royal North Shore Hospital, Department of Haematology and Transfusion Medicine, Sydney, Australia, [3]University of Bristol, School of Physiology,Pharmacology and Neuroscience, Bristol, United Kingdom, [4]Westmead Children's hospital, Haematology Department, Sydney, Australia, [5]The University of Sydney, School of Molecular Biosciences, Sydney, Australia

Background: Inherited bleeding disorders due to platelet defects are still underdiagnosed worldwide leading to inappropriate care.

Aims: To improve diagnosis, we developed a novel platelet candidate gene array for Next Generation Sequencing (NGS) targeting platelet surface receptors and transcription factors important for platelet production.

Methods: A Caucasian family was referred to us for a history of easy bruising and serious bleeding requiring blood transfusion following surgical procedures. Full blood count, blood film examination, platelet aggregometry, flow cytometry were performed before NGS. Informed consent was obtained and the study was approved by our local ethics committee.

Results: All affected individuals had markedly impaired ADP-induced platelet aggregation with primary wave only. Responses to collagen, TRAP and epinephrine were also reduced. A single nucleotide substitution in the *P2RY12* gene was identified in all affected individuals (NM_176876 exon2 c.G794C p.R265P). Platelet P2Y12 surface and total expression was normal as was ligand binding; however, receptor function was impaired. A hemagglutinin-tagged version of the R265P P2Y12 variant like the wild type expressed well at the cell surface of transfected CHO cells but produced minimal ADP-mediated inhibition of forskolin-induced adenylyl cyclase activity. R265 is located within the extracellular loop 3 (EL3), and has been identified as one of four amino acids important for the functional integrity of the receptor as it maintains the binding pocket conformation and allows rotation following ligand binding.

Conclusions: P2Y12, a member of the G protein-coupled receptor family, is one of the 2 platelet ADP receptors. P2Y12 defects are associated with increased bleeding risk. Only a small number of mutations have been reported so far with a majority of recessive transmission. Our study describes a new dominant mutation and confirms the important role of P2Y12 EL3 domain and of the R265 for the functional integrity of the receptor.

OC 59.4 | Characterisation of Two Novel FLI1 Variants Causing Substitution of Arginine 340 in the ETS Domain of FLI1 in Patients with Dense Granule Secretion Defects

M. Aldossary[1], V. Leo[1], M. Makris[1], C. Thornburg[2], D. Masser-Frye[3], N. Morgan[4], M. Daly[1]

[1]University of Sheffield, Department of Infection, Immunity and Cardiovascular Disease, Sheffield, United Kingdom, [2]Rady Children's Hospital San Diego, Division of Pediatric Hematology/Oncology, San Diego, United States, [3]Rady Children's Hospital San Diego, San Diego, United States, [4]Institute of Cardiovascular Sciences, College of Medical and Dental Sciences, University of Birmingham, Birmingham, United Kingdom

Background: FLI1 is a transcription factor which regulates genes expressed during megakaryocytopoiesis. We previously reported *FLI1* defects affecting residues 337 and 343 in the ETS domain of FLI1 in two families with a bleeding diathesis in which the predominant defect was a reduction in platelet dense granule secretion.

Aims: To characterise two novel *FLI1* variants affecting residue 340 in FLI1 which were identified in patients with platelet function disorders.

Methods: Whole exome sequencing (WES) was undertaken for two patients; Patient 1 (P1) was investigated following enrolment in the UK GAPP study with a history of bleeding, and reduced platelet dense granule secretion. Patient 2 (P2) and her two sons had a history of bleeding and a diagnosis of storage pool deficiency. P2 also suffered from recurrent infections and all three family members had a mild history of eczema. The ability of FLI1 variants to transactivate the *GP6* promoter and undergo nuclear translocation were assessed

in HEK293T and Dami cells using a dual luciferase reporter assay, and following their expression as GFP-fusion proteins respectively.

Results: Novel heterozygous *FLI1* alterations predicting p.R340C and p.R340H substitutions in the ETS domain of FLI1 were identified by WES of DNA from P1 and P2 respectively. Compared with cells expressing wild-type (WT) FLI1, both variants showed significant reductions in transactivation capacity in HEK293T (reduction: R340H 74%; R340C 88%) and Dami (reduction: R340H 39%; R340C 32%) cells ($p < 0.001$ for all comparisons). Both variants also showed reduced nuclear accumulation when compared with WT-FLI1 in HEK293T ($p < 0.0001$) and Dami ($p < 0.05$) cells.

Conclusions: We have identified novel *FLI1* variants in two patients with storage pool disease which reduce nuclear accumulation and transcriptional activity of FLI1 *in vitro*. Given the role of FLI1 in regulating megakaryocyte-specific genes, these variants may explain the bleeding tendency observed in the patients.

OC 59.5 | A Novel Splice-specific GFI1B-p32 Mutation in a Family with Recessive Macrothrombocytopenia

H. Schulze[1], A. Schlagenhauf[2], G. Manukjan[1], O. Andres[3], E. Klopocki[4], E.-M. König[4], S. Panzer[5], C. Beham-Schmid[2], K. Althaus[6], A. Greinacher[6], T. Bakchoul[6], M. Seidel[2]

[1]University Hospital Würzburg, Institute for Experimental Biomedicine, Würzburg, Germany, [2]University Hospital Graz, Graz, Austria, [3]University Hospital Würzburg, Würzburg, Germany, [4]University Würzburg, Würzburg, Germany, [5]Medical University of Vienna, Vienna, Austria, [6]University of Greifswald, Greifswald, Germany

Background: Growth Factor Independent 1B (GFI1B) is a transcription factor of the erythroid and megakaryocytic lineages. A shorter p32 splice-isoform lacking the first 2 of 6 zinc fingers. So far reported germline mutations cause autosomal-dominant macrothrombocytopenia with a grey-platelet syndrome phenotype.

Aims: We report a family whose affected members present with life-threatening bleedings. The index patient and her children had recurrent hematoma and petechiae since childhood with platelets less than 45/nL. Her brother also had low platelet counts and died age 33 due to spontaneous cerebral hemorrhage. Her parents, husband and the children of the deceased brother were clinically unaffected.

Methods: Blood smears were analyzed by immunofluorescence microscopy. Platelet function was tested by aggregometry and flow cytometry. We applied targeted next generation sequencing to screen DNA for variants in 59 genes reported to play a role in platelet biogenesis or function.

Results: Aggregometry with ADP or arachidonic acid was impaired. We found a novel homozygous single nucleotide insertion in GFI1B (NM_004188.5; c.551insG), expected to cause a premature stop-codon and which segregated with the phenotype. The unaffected mother, the husband and two nephews were heterozygous, confirming an autosomal-recessive trait. Dysplastic micromegakaryocytes and peripheral platelets were CD34-positive with reduced alpha-granule markers. Platelet RNA showed residual homozygous c.551_G insertion in the p37 transcript which was markedly reduced and an unexpected expression of p32.

Conclusions: Our findings imply that the first two zinc fingers of GFI1B are dispensable for human erythropoiesis, but essential for normal megakaryopoiesis and functional platelets. While previous mutations affect both isoforms, this insertion variant results in a premature stop-codon and affects only the p37 isoform. The transcriptional regulation of erythropoiesis is uncoupled from that of megakaryopoiesis through alternative splicing of GFI1B.

OC 63.1 | Childhood-onset Congenital Thrombotic Thrombocytopenic Purpura (Upshaw-Schulman syndrome): The French Reference Center for Thrombotic MicroAngiopathies Experience

B. Joly[1,2,3], P. Boisseau[4], A. Stepanian[1,2,3], C. Garrec[4], C. Desconclois[5], G. Deschênes[2,6], N. Biebuyck[7], C. Berger[8], L. Mansuy[9], J.-P. Vannier[10], S. Bezieau[4], P. Coppo[11,12], A. Veyradier[1,2,3], French Reference Center for Thrombotic MicroAngiopathies, Paris, France

[1]Hôpital Lariboisière, APHP, Service d'Hématologie Biologique, Paris, France, [2]Université Paris Diderot, Paris, France, [3]Institut Universitaire d'Hématologie, EA 3518, Hôpital Saint-Louis, Paris, France, [4]CHU Hôtel Dieu, Service de Génétique, Nantes, France, [5]Hôpital Antoine Béclère, APHP, Service d'Hématologie Biologique, Clamart, France, [6]Hôpital Robert Debré, APHP, Service de Néphrologie Pédiatrique, Paris, France, [7]Hôpital Necker, APHP, Service de Néphrologie Pédiatrique, Paris, France, [8]CHU Saint-Etienne, Service d'Immuno-Hématologie et Oncologie Pédiatrique, Saint Priest en Jarez, France, [9]CHU Nancy, Hôpital d'Enfants, Département d'Oncologie et d'Hématologie Pédiatriques, Thérapie Cellulaire, Vandoeuvre-lès-Nancy, France, [10]CHU de Rouen, Hôpital Charles Nicolle, Service d'Oncologie Pédiatrique, Rouen, France, [11]Hôpital Saint Antoine, APHP, Service d'Hématologie, Paris, France, [12]Université Pierre et Marie Curie, Paris, France

Background: Congenital thrombotic thrombocytopenic purpura (TTP) is a rare, inherited thrombotic microangiopathy (TMA), also named Upshaw-Schulman syndrome (USS). USS patients exhibit an ADAMTS13 activity < 10% linked to bi-allelic recessive mutations of the *ADAMTS13* gene. The first TTP episode may occur during childhood including the neonatal period.

Aims: Based on the experience of the French TMAs Reference Center, our work aimed to study the correlation between the phenotype and the genotype of ADAMTS13 deficiency in childhood-onset USS.

Methods: A cross-sectional analysis of the French TMAs Registry was performed from Jan 1st 1999 to Dec 31th 2016 to identify, among childhood-onset TMA patients, those exhibiting an inherited ADAMTS13 deficiency (USS). We measured plasmatic ADAMTS13 activity using ELISA Technozym® Chr-VWF73 kit (Technoclone), ADAMTS13 antigen, and we screened ADAMTS13 autoantibodies. Genomic DNA was screened for mutations by direct sequencing of *ADAMTS13* gene. An exhaustive analysis of clinical records was assessed.

Results: 27 patients from 24 families were enrolled (sex ratio: 1.3F/1M) and all of them had a severe ADAMTS13 deficiency (activity < 10%,

undetectable antigen), no ADAMTS13 autoantibodies and bi-allelic mutations of *ADAMTS13*. Two groups of patients were identified as a function of the presence of N-terminal mutation(s) of *ADAMTS13*: 10 patients had no N-terminal *ADAMTS13* mutation (group 1) while 17 had one or two N-terminal *ADAMTS13* mutation(s) (group 2). Group 1 was associated with an ADAMTS13 activity >1% [median 1.1%, IQR: 0.6-2.2], while group 2 was associated with an ADAMTS13 activity < 1% [median 0.6%, IQR: 0.4-0.9]. 21 patients developed the disease before 1 year-old, 16 of whom in the neonatal period. 23 patients needed prophylactic plasma infusions.

Conclusions: Childhood-onset congenital TTP is a very rare disease with a prevalence in France of 0.8 cases/ million children in 2016. N-terminal mutations of *ADAMTS13* may be associated with a more severe biologic phenotype.

OC 63.2 | Hereditary Thrombotic Thrombocytopenic Purpura - Incidence of Acute Events under Plasma Prophylaxis

J. Kremer Hovinga[1,2], Z. Cermakova[3], Y. Fujimura[4], K. Friedman[5], J. George[6], I. Hrachovinova[7], P. Knöbl[8], A.S. von Krogh[9], B. Lämmle[10], M. Matsumoto[4], R. Schneppenheim[11]

[1]Bern University Hospital, Department of Hematology and Central Hematology Laboratory, Bern, Switzerland, [2]University of Bern, Department of Clinical Research, Bern, Switzerland, [3]University of Ostrava, Department of Biomedical Sciences, Ostrava, Czech Republic, [4]Nara Medical University, Department of Blood Transfusion Medicine, Nara, Japan, [5]Blood Center of Wisconsin, Milwaukee, United States, [6]University of Oklahoma Health Sciences Center, Department of Medicine, Oklahoma City, United States, [7]Institute of Hematology and Blood Transfusion, Prague, Czech Republic, [8]Medical University of Vienna, Department of Medicine, Vienna, Austria, [9]Trondheim University Hospital, Department of Hematology, Trondheim, Norway, [10]University of Mainz, Center for Thrombosis and Hemostasis, Mainz, Germany, [11]University Medical Center Hamburg-Eppendorf, Department of Pediatric Hematology and Oncology, Hamburg-Eppendorf, Germany

Background: Hereditary TTP, Upshaw-Schulman syndrome (hTTP) is a rare, recessively inherited disorder and the result of congenital severe ADAMTS13 deficiency caused by *ADAMTS13* mutations. Acute TTP episodes can be prevented by regular plasma infusions.

Aims: Incidence rate of acute TTP events under documented plasma prophylaxis in hTTP.

Methods: Patients diagnosed with hTTP (having an ADAMTS13 < 10% in the absence of a functional ADAMTS13 inhibitor on at least two occasions > 1 month apart; a patient or family history with at least one TTP episode; two *ADAMTS13* mutations and/or a plasma infusion trial documenting full recovery and a half-life of infused ADAMTS13 of 2-3 days) enrolled in the hTTP registry (ClinicalTrials.gov NCT01257269) since 09/2012. Medical data are recorded retrospectively up to enrolment and then prospectively during annual follow-up or when an acute TTP episode occurs.

Results: As of December 31st 2016, 194 subjects had been enrolled into the study: 108 confirmed patients (of which 7 were lost to follow-up and 7 have died since enrollment) and 32 suspected patients (ADAMTS13 gene analysis pending) as well as 54 family members. Mean follow-up time was 2.8 years (IQR 1.6 - 4.9 years).

A total of 336 TTP events (including 47 prospective events) were documented in 77 hTTP patients. Twenty-four patients on regular plasma prophylaxis experienced 92 acute events during 473 person-years (incidence rate 0.19 [95% CI 0.16-0.24]). Number of subsequent TTP episodes in all patients with at least one documented prospective TTP episode was 0.4 episodes/year (IQR 0.1-1.05 episodes/year). Because of acute events 11 hTTP patients switched from a on demand treatment to plasma prophylaxis during the observation time.

Conclusions: The annual event rate is low under regular plasma prophylaxis in hTTP. The rate of subsequent events is higher once a prospective event has occurred and could help to identify patients, that will benefit from prophylactic treatment.

OC 63.3 | Clinical and Laboratory Characteristics of Patients Affected with Acquired Thrombotic Thrombocytopenic Purpura Enrolled in the Milan TTP Registry

Background: Thrombotic thrombocytopenic purpura (TTP) is a rare life-threatening thrombotic microangiopathy associated with the congenital or immune-mediated severe deficiency of ADAMTS13.

Aims: To report demographic and disease-related data of acquired TTP patients recorded in the Milan TTP registry.

TABLE 1 Demographic characteristics of patients included in the Milan TTP registry

Sex, %	Female	76.7
	Male	23.3
	White	98.2
Ethnicity, %	Black or African American	1.2
	Asian	0.3
	American Indian or Alaskan Native	0.3
Geographical origin, %	Europe/Italy	97.6/82.4
	Asia	0.7
	Africa	1
	South America	0.7

Methods: We performed a cross-sectional analysis of acquired TTP patients enrolled in the Milan TTP registry for an acute episode of TTP occurred between January 2002 and November 2015. Acquired TTP was defined as the occurrence of thrombocytopenia and microangiopathic hemolytic anemia, in absence of alternative causes.

Results: The Milan TTP registry included 416 acquired TTP patients, for a total of 837 acute events. Demographic and disease-related data are reported in Tables 1 and 2. Eighteen percent of patients had concomitant autoimmune disorders, mostly autoimmune thyroiditis (35%). Among potential triggers of acute episodes, infections were the most prevalent (26%), followed by assumption of estroprogestinics in women (4%). At presentation, systemic, bleeding and neurological signs and symptoms were the most prevalent. Clinical and laboratory parameters were less severe in relapses than first episodes. Almost all acute events were treated by plasma exchange and steroids, 12% by rituximab. ADAMTS13 activity at baseline was severely reduced (< 10%) in 88%, moderately reduced (10-45%) in 11% and normal in 1% of events. Anti-ADAMTS13 antibodies were positive in 95% of the cases. The TTP-related mortality in our population was 5%. The median time to remission was 13 days (IQR 724), shorter for relapses than first events (median difference 8 days, 95%CI 5-11). Of 348 survivors of the first TTP episode with at least 6 months of follow-up, 49% had a recurrence.
Conclusions: Acquired TTP is a rare, potentially fatal disease that may require a long hospitalization and recur in nearly half of the patients. A harmonized data collection system could be a powerful tool to improve our knowledge and management of acquired TTP.

TABLE 2 Clinical and laboratory characteristics of acute TTP events

		All events	First events	Relapses
Clinical signs and symptoms, %	None	6	0.3	13
	Systemic (fatigue, fever, abdominal pain, headache, jaundice, vomiting)	70	84	54
	Bleeding (hematuria, meno-metrorrhagia, mucosal bleeding, gastrointestinal bleeding, ecchymosis, purpura)	68	70	65
	Neurological (stroke, seizures, coma, personality change, focal neurological signs, transitory ischemic attack)	44	62	23
	Renal (acute renal failure, anuria, need for dialysis, creatinine >1.3 mg/dl)	19	24	14
	Cardiovascular (acute coronary syndrome, ECG ischemic abnormalities)	10	13	6
Laboratory data at presentation, median (IQR)	Platelet count, 10^9/l	18 (10-33)	14 (8-22)	27 (13-48)
	Hemoglobin, g/dl	9.3 (7.7-11.5)	8.0 (7.0-9.3)	11.5 (10.1-12.7)
	LDH, IU/l	1240 (656-1828)	1496 (955-2248)	784 (506-1356)

OC 63.4 | ML355, a Selective 12-LOX Inhibitor, Prevents Immune-mediated Thrombocytopenia and Thrombosis

J. Yeung[1,2,3], B. Tourdot[1], M. Jackson[1], R. Adili[1], S. Abraham[3], Y. Zhou[3], D. Maloney[4], T. Holman[2], M. Holinstat[1,5]

[1]*University of Michigan, Department of Pharmacology, Ann Arbor, United States,* [2]*University of California Santa Cruz, Department of Chemistry and Biochemistry, Santa Cruz, United States,* [3]*Thomas Jefferson University, Cardeza Foundation for Hematologic Research, Department of Medicine, Philadelphia, United States,* [4]*National Institutes of Health Chemical Genomics Center, National Center for Advancing Translational Sciences,, Rockville, United States,* [5]*University of Michigan, Department of Internal Medicine,Division of Cardiovascular Medicine, Ann Arbor, United States*

Background: FcgRIIa plays a central role in the pathogenesis of several immune-mediated thrombocytopenia and thrombosis (ITT) disorders, including heparin-induced thrombocytopenia and thrombosis (HITT). Devastating clinical manifestations of ITT or HITT are pulmonary thromboembolism and thrombocytopenia, which are associated with significant morbidity and mortality. Although we had

demonstrated that platelet 12-lipoxygenase (12-LOX) is important for FcgRIIa-mediated platelet activation *ex vivo*, it was not known whether 12-LOX intervention could prevent the development of thrombocytopenia or thrombosis *in vivo*.

Aims: To assess whether pharmacological inhibition or genetic ablation of 12-LOX prevents pulmonary thromboembolism and thrombocytopenia in mouse models of ITT.

Methods: Transgenic mice expressing human FcgRIIa on platelets with (hFcR/ALOX12$^{+/+}$) or without (hFcR/ALOX12$^{-/-}$) 12-LOX were retro-orbitally administered with IRDye 800CW a-GPIX antibody to induce ITT-like symptoms. HITT transgenic mice were orally gavaged with 7.5 mg/kg of ML355 or vehicle control prior to KKO (autoantibody derived from a HITT patient) and heparin administration for 7 days. Blood was collected from saphenous vein to measure platelet count at indicated time points. Lungs were harvested and imaged on Li-COR Odyssey for accumulation of a-GPIX labeled platelets.

Results: Following administration of a-GPIX, hFcR/ALOX$^{+/+}$ mice had significant reduction in platelet count compared to hFcR/ALOX$^{-/-}$ mice. In addition, pulmonary thrombosis was significantly reduced in hFcR/ALOX$^{-/-}$ compared to hFcR/ALOX$^{+/+}$. HITT transgenic mice treated with ML355 had a reduction in pulmonary thromboembolism and increase in platelet count compared to vehicle control treated HITT mice.

Conclusions: Targeting 12-LOX via genetic ablation or pharmacological inhibition with ML355 attenuated ITT and HITT *in vivo*, suggesting ML355 is a potential novel therapy to treat ITT syndromes.

OC 63.5 | Rituximab Use Is Associated with Longer Relapse Free Survival in Patients with Acquired Thrombotic Thrombocytopenic Purpura

Background: Rituximab is an effective drug to induce remission during the acute phase of thrombotic thrombocytopenic purpura (TTP) in refractory patients.

Aims: To study the effect of rituximab treatment during the acute phase (primary or relapse) of TTP on relapse rate of the disease in a cohort of patients affected by acquired TTP.

Methods: We analyzed the clinical data of 166 patients enrolled in the Milan TTP Registry referred for an acute episode of TTP from 2011 to 2015. After evaluation of inclusion criteria, 92 patients for a total of 109 acute episodes which reached remission were included. Patients have been followed until a new acute episode or the end of the observational period (censored data June 30th, 2016).

Results: All the 109 acute episodes were treated with plasma exchange (PEX) and steroids. Rituximab was used in 24 acute episodes (R+ group), while remaining 85 were treated without (R- group). The two groups did not differ in term of sex, age, and number of acute episodes. Autoimmune disorders were more prevalent in the R+ group (33.3% *vs* 22.4%). Hb levels, platelet count and LDH levels were also similar in the two groups. As expected, the median number of PEX to reach remission was higher in the R+ group (19, IQR 11-31) than in R- group (9, IQR 6-14). Median follow up was similar in the two groups (28 months for R+ and 33 months for R- group). Nineteen relapses out of 85 acute episodes were observed in the R- group and one out of 24 episodes in the R+ group, for a hazard ratio of 5.66 (95% C.I. 0.76-42.41). The efficacy of rituximab remained also restricting the analysis at the first two years of follow up, the period with the highest probability of relapse.

Conclusions: The administration of rituximab in acute phase of TTP appeared to be beneficial in reducing the relapse rate by 5 folds.

OC 69.1 | New Insights in Pathogenesis, Diagnosis and Phenotype of FLI1-associated Thrombocytopenia

P. Saultier[1], L. Vidal[1], M. Canault[1], D. Bernot[1], C. Falaise[2], K. Pouymayou[2], J.-C. Bordet[3], N. Saut[2], A. Rostan[2], V. Baccini[1], F. Peiretti[1], M. Favier[1], P. Lucca[4], P.E. Morange[1,2], C. Gachet[5], S. Fauré[1], A. Eckly[5], D.-A. Trégouët[4], M. Poggi[1], M.-C. Alessi[1,2]

[1]Aix Marseille Univ, INSERM, INRA, NORT, Marseille, France, [2]APHM, CHU Timone, French Reference Center on Inherited Platelet Disorders, Marseille, France, [3]Unité d'Hémostase Biologique, Bron, France, [4]Inserm, UMR_S 1166, Team Genomics and Pathophysiology of Cardiovascular Diseases, Paris, France, [5]UMR_S 949 INSERM, Strasbourg, France

Background: Congenital macrothrombocytopenias (CMTPs) are a family of rare diseases, of which a significant fraction remains to be characterized. Using two high-throughput sequencing strategies (308-gene panel or whole exome sequencing), we identified two families

carrying novel *FLI1* variants (p.R337Q and p.K345E) associated with CMTP.

Aims: To study the pathogenesis, phenotype and diagnosis of *FLI1*-associated CMTP.

Methods: We have studied $CD34^+$-derived megakaryocytes (MK) and used immunofluorescence and luciferase reporter system assay in transfected MSR cells. Platelet phenotype was studied using aggregation assay, flow cytometry, ATP release assay and mepacrine test. We used the innovative Focused Ion Beam / Scanning Electron Microscopy (FIB/SEM), which allowed the 3D ultrastructural analysis of platelets.

Results: The carriers had moderate thrombocytopenia (131-154 $x10^9$/l) with slightly increased mean platelet volume (10.7-13 fl; normal range 7-9 fl). The FLI1 variants nuclear accumulation and transcriptional activity properties were reduced. *In vitro* study of carriers' MK revealed a maturation defect and reduced proplatelet formation potential. The carriers' platelets exhibited dense granule abnormalities that may account for the observed bleeding diathesis. We observed defects in aggregation upon low dose ADP, collagen and TRAP, a defect in ATP secretion, a reduced mepacrine uptake and release and a reduced CD63 expression after stimulation. Remarkably, FIB/SEM revealed not only giant alpha-granules but also an almost absence of dense granules (Figure), likely due to a biogenesis defect. Furthermore, we developed the flow cytometry-based quantification of intraplatelet MYH10 (a biomarker of *FLI1* and *RUNX1* alteration), which could constitute a useful diagnostic tool.

Conclusions: Overall, this study provides new insights into the pathogenesis, phenotype and diagnosis of *FLI1*-associated CMTP, notably suggesting a role for FLI1 in dense granule biogenesis.

OC 69.2 | Identification of the DIAPH1 R1213* Variant in a Family with Macrothrombocytopenia and Hearing Loss

N. Mota-Pérez[1], V. Palma-Barqueros[1], J.M. Bastida[2], C. Martínez[1], J. Padilla[1], V. Vicente[1], B. Johnson[3], S.P. Watson[3], N. Morgan[3], M.L. Lozano[1], J. Rivera[1,4]

[1]Servicio de Hematología y Oncología Médica, Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, CB15/00055-CIBERER, Murcia, Spain, [2]Unidad de Trombosis y Hemostasia. H. Universitario de Salamanca-IBSAL, Salamanca, Spain, [3]Institute of Cardiovascular Sciences, College of Medical and Dental Sciences, University of Birmingham, Birmingham, United Kingdom, [4]On behalf of "Inherited Platelet Disorders Project", Hemorrhagic Diathesis Working Group, SETH, Murcia, Spain

Background: Recently, the R1213X variant in *DIAPH1* has been identified as a causative mutation for congenital macrothrombocytopenia (MTP) and sensorineural hearing loss in 2 unrelated pedigrees (Stritt S, Blood 2016).

Aims: Functional and molecular characterization of three patients from the same pedigree presenting with MTP and sensorineural hearing loss.

Methods: The index cases were a Spanish man, his daughter and son (43, 15 & 7 yr), all presenting with sensorineural hearing loss detected in the first 5 yrs of life. DNA was analyzed by whole exome sequencing (WES) and/or Sanger sequencing. Phenotyping included: blood cell count/film, platelet aggregation, platelet adhesion in cone and plate test, glycoproteins (GPs) expression and platelet activation by flow cytometry, immunofluorescence and immunoblotting of selected proteins.

Results: Patients developed moderate MTP (52-84$x10^9$/L) and neutropenia (1.1-1.6$x10^9$/l) in the first 5 yrs of life. WES identified the *DIAPH1* R1213* variant in both the father and the daughter, and Sanger sequencing confirmed the variant in the three relatives. Platelet studies showed moderately increased GPs expression (αIIbβ3, GPIb/IX, αIIbβ1) and no abnormalities in shear-induced adhesion, aggregation to distinct agonists or granule secretion. Western blot revealed normal platelet expression levels of DIAPH1, actin and β1-Tubulin. Platelet immunofluorescence exhibited no obvious alteration in DIAPH1 localization pattern. However, α-tubulin staining showed normal microtubular coils but aberrant microtubules distributed throughout the cytoplasm in patient platelets.

Conclusions: We report the third unrelated family with MTP and hearing loss resulting from *DIAPH1* R1213* variant. While no platelet adhesion, aggregation and secretion defects were observed, our findings support the relevant role of *DIAPH1* in the regulation of platelet cytoskeletal organization. *(ISCIII & Feder [PI14/01956], SETH & GRS 1370/A/16)*

OC 69.3 | Genotype-phenotype Correlation in Wiskott-Aldrich Syndrome: Four Novel Mutations in WAS Gene

S.S. Medina[1], L.H. Siqueira[1], M.P. Colella[1], M.M.S. Vilela[2], M.C. Ozelo[1,3]

[1]IHTC 'Claudio L.P. Correa', INCT do Sangue Hemocentro UNICAMP, Campinas, Brazil, [2]University of Campinas, Department of Pediatrics, Campinas, Brazil, [3]University of Campinas, Department of Internal Medicine, Campinas, Brazil

Background: Wiskott-Aldrich syndrome (WAS) is an X-linked primary immunodeficiency characterized by thrombocytopenia, small platelets, eczema, recurrent infections and increased risk of autoimmune diseases and cancer. It is caused by mutations in the gene coding for the Wiskott-Aldrich syndrome protein (WASP). Some mutations in *WAS* gene may be associated with milder manifestations, such as X-linked thrombocytopenia (XLT).

Aims: To determine the disease-related genotype, to quantify the level of WASP expression in hematopoietic cells, and to correlate these data with clinical manifestations in WAS patients.

Methods: We performed genomic DNA extraction from peripheral blood leukocytes, sequenced *WAS* gene and quantified the level of WASP expression in leukocytes by flow cytometry in WAS patients.

TABLE 1 Characterization of the mutations found in the WAS gene

Patient ID	Diagnosis	Clinical score	Mother as a carrier	Site of mutation	Type of mutation	Nucleotide change	Mutation	Novel mutation	Level of WAS expression
HSD and BSD (siblings)	WAS	4	Yes	exon 1	Nonsense	c.155C>T	p.Arg41X	No	Not determined
DLCS	WAS	3	Yes	exon 1	Nonsense	c.140_143 DelTT	p.Phe36X	No	Reduced
JCM MFB	XLT____ XLT	2____ 1	Yes	exon 2 exon 2	Missense Missense	c.168C>T c.207C>T	p.Thr45Met p.Pro58Leu	No___ Yes	Reduced Reduced
JPMP	WAS	3	Not determined	exon 2	Deletion	c.233delC	p.Asn78 AsnfsX48	Yes	Not determined
JCF	WAS	4	Yes	exon 4	Missense	c.431G>A	p.Glu133Lys	No	Not determined
LSMN	WAS	4	Yes	exon 6	Splice	Not determined	Not determined	Not determined	Not determined
GVSR	WAS	4	Yes	exon 7	Deletion	c.743_746 delAT	p.Asp237 AspfsX21	Yes	Not determined
BGS	WAS	4	Yes	intron 8	Splice	IVS8 as -2A>G	p.Asp259 fsX69	No	Reduced
PLSV	WAS	3	Yes	exon 10	Deletion	c.1040delA	p.Lys336 ArgfsX108	Yes	Reduced

Results: We included 16 patients from 15 distinct families with clinical suspicion of WAS or XLT. The diagnosis was confirmed in 11 patients (9 WAS and 2 XLT). WASP expression was evaluated in 5 patients, and was shown to be reduced in peripheral blood leukocytes from all tested samples (3 WAS and 2 XLT) when compared to normal control. A total of 10 mutations in the *WAS* gene were identified, including four novel mutations (p.Lys336ArgfsX108, p.Asp237AspfsX21 and p.Asn78AsnfsX48 associated with WAS, and p.Pro58Leu associated with XLT), which are shown in table 1.

Both patients with XLT presented missense mutations located in the upstream portion of the *WAS* gene (exon 2). Among the 9 patients with WAS, four of them showed nonsense mutations in the upstream region of the WAS gene, while the other five patients had missense, nonsense and splice site mutations located in the downstream portion of the WAS gene (from exon 4 and beyond).

Conclusions: Our findings support the hypothesis that milder forms of WAS are associated with missense mutations in exons 1 and 2 of *WAS* gene (upstream region), while the most severe manifestations are caused by missense and splice site mutations located in the downstream region or nonsense mutations.

OC 69.4 | Identification of Two Novel Mutations in RASGRP2 Affecting Platelet CalDAG-GEFI Expression and Function in Patients with Bleeding Diathesis

T. Sevivas[1], J.M. Bastida[2], D.S. Paul[3], E. Caparros-Pérez[4], V. Palma-Barqueros[4], M. Coucelo[1], D. Marques[1], F. Ferrer-Marín[4], J.R. González-Porras[2], V. Vicente[4], J.M. Hernández-Rivas[2], S.P. Watson[5], M.L. Lozano[4], W. Bergmeier[3], J. Rivera[4], On behalf of "Inherited Platelet Disorders Project", Hemorrhagic Diathesis Working Group, SETH, Murcia, Spain

[1]Serviço de Hematologia Clínica do Centro Hospitalar e Universitário do Centro Hospitalar de Coimbra, EPE, Coimbra, Portugal, [2]Servicio de Hematología, IBSAL-Hospital Universitario de Salamanca, Salamanca, Spain, [3]University of North Carolina at Chapel Hill, Department of Biochemistry and Biophysics, and McAllister Heart Institute, Chapel Hill, United States, [4]Servicio de Hematología y Oncología Médica, Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, CB15/00055-CIBERER, Murcia, Spain, [5]College of Medical and Dental Sciences, University of Birmingham, Institute of Cardiovascular Sciences, Birmingham, United Kingdom

Background: The *RASGRP2* gene encodes the Ca^{2+} and DAG-regulated guanine nucleotide exchange factor I (CalDAG-GEFI), which plays a key role in integrin activation in platelets and neutrophils. To date, few *RASGRP2* variants have associated to platelet dysfunction and bleeding in patients.

Aims: To assess the platelet phenotype in two patients with lifelong mucocutaneous bleeding and to unravel their genetic defect by high-throughput sequencing (HTS).

Methods: Blood cell counts and platelet function were assessed in two unrelated Portuguese children. Platelet aggregation, flow cytometry, clot retraction and spreading assays were done. Integrin expression and function in neutrophils were also studied. DNA was analyzed by HTS using a 71 gene panel (Lozano ML. Blood 2016). Platelet CalDAG-GEFI level was quantified by immunoblotting.

Results: The patients had normal platelet and neutrophil counts and morphology. Platelet phenotyping showed: prolonged PFA-100 closure times; normal expression of major GPs receptors; severely reduced platelet aggregation response to ADP and collagen (both patients); aggregation response to PAR1 and arachidonic acid markedly impaired in one patient; PMA-induced aggregation unaffected;

platelet secretion, clot retraction and spreading minimally affected. HTS analysis showed two new homozygous variants in *RASGRP2*: c.706C>T (p.Q236X) and c.887G>A (p.C296Y). In both patients, CalDAG-GEFI protein was hardly detected in platelet lysates, and platelet αIIbβ3 activation, as assessed by fibrinogen binding, was greatly impaired in response to all agonists except PMA. Patient neutrophils showed normal integrin expression, but impaired Mn^{2+} induced fibrinogen binding.

Conclusions: We report two unrelated patients with bleeding diathesis, new homozygous mutations in *RASGRP2*, sharply reduced CalDAG-GEFI platelet expression, and defective activation of αIIbβ3 in platelets and β2 in neutrophils. *RASGRP2* mutations are an increasing form of inherited platelet disorder. (*ISCIII&Feder-PI14/01956,SETH&GRS 1370/A/16)*

OC 69.5 | Phenotyping of Platelets of Patients with Inherited Platelet Disorders on Blood Smears by Immunofluorescence Microscopy - Experience of the Greifswald Laboratory

K. Althaus[1], C. Blumentritt[1], U. Strobel[1], T. Bakchoul[2], A. Greinacher[1]

[1]Universitätsmedizin Greifswald, Institut für Immunologie und Transfusionsmedizin, Greifswald, Germany, [2]Universitätsklinikum Tübingen, Zentrum für Klinische Transfusionsmedizin Tübingen (ZKT), Tübingen, Germany

Background: Diagnostic evaluation of hereditary platelets disorders is still challenging. High-throughput sequencing identified many genes with their pathogenic variants. But it is still difficult to correlate the many variants within the genome to the phenotypes of inherited platelet disorders. Specialized laboratory testing for detailed phenotyping is only available in few centers. Furthermore the need for relatively large blood volumes for functional testing precludes testing in children. Together with A. Pecci, C. Balduini, Pavia; S. Kunishima, Nagoya, P. Nurden, Bordeaux, we developed a method to identify characteristic changes in the distribution of specific platelet proteins on blood smears.

Aims: Identification of characteristic changes in platelet proteins on blood smears

Methods: We use standard blood smears, prepared by the treating physician and shipped by regular mail to the laboratory. After fixation and permeabilization, staining with specific antibodies, allows to "phenotype" platelets by microscopy using characteristic changes of the distribution of certain proteins as markers for hereditary platelet disorders.

Results: Assessing blood smears of 1250 patients referred to our laboratory with unclear platelet disorders, we achieved the diagnosis in 282 (23%) patients: *MYH9*-disorders (147), Bernard Soulier syndrome (BSS) (25), gray platelet syndrome (2), *GFI-1b* mutation (3), ß1-tubulin defects (19), Wiscott-Aldrich syndrome (WAS) (1), Glanzmann thrombasthenia (16), alpha storage pool defects (32), delta storage pool defects (37). Diagnostic sensitivity and specificity of the method was high for *MYH9*-disorders, biallelic BSS, Glanzmann thrombasthenia, and gray platelet syndrome.

Conclusions: Immunofluorescence microscopy offers a diagnostic approach requiring minimal blood volume for patients with unknown inherited platelet disorders who lack access to specialized laboratories and thereby supports interpretation of results of high-throughput methods for platelet disorders.

OC 74.1 | Low-dose Decitabine Improves Platelet Recovery in Patients with Isolated Thrombocytopenia Following SCT

Y. Han, Y. Tang, Y. Zhao, M. Huang, J. Qi, J. Chen, X. Wu, X. Ma, F. Chen, X. Feng, D. Wu, C. Ruan

The First Affiliated Hospital of Soochow University, Jiangsu Institute of Haematology, Suzhou, China

Background: Isolated thrombocytopenia is a common complication of stem-cell transplantation (SCT), which was defined as consistent low platelet counts with recovery of the other two cell lines after transplantation. Previous studies have demonstrated that decitabine, a hypomethylating agent, may increase platelet counts by promoting megakaryocyte maturation and platelet release in mouse model. Here, we conduct a clinical trial to validate this effect in post-SCT setting.

Aims: We performed a prospective open-label study to evaluate the treatment of low-dose decitabine in patients with hematological malignancies who received allogeneic SCT and suffered from isolated thrombocytopenia.

Methods: The inclusion criteria were:

(1) Platelet count ≤ 30 × 109/L persistently at day 60 post-SCT or later;

(2) Recovered neutrophil and hemoglobin;

(3) Full donor chimerism; and

(4) No response to conventional treatments for a duration of at least 4 weeks.

From July 2013 to July 2016, 38 patients were randomly assigned into either the control group to receive conventional treatment only, or the test group to receive additional decitabine (15mg/m^2, intravenously daily for 3 consecutive days).

Results: Major response was observed in 16 out of 19 patients (84.2%) in decitabine group, with a median time of 22 days to achieve platelet transfusion-independence. In contrast, 3 out of 19 patients in the control group (15.8%) showed a major response.

For bone marrw morpholocial analysis, all 38 patients showed low levels of megakaryocytes at week 0. However, the megakaryocyte counts in decitabine group were significantly increased at week 4, while no significant difference was recorded in control group. However, reactive oxygen species (ROS) and megakaryocyte counts increased in the test group.

Conclusions: Our data showed an encouraging efficacy of decitabine in patients after SCT suffering from isolated thrombocytopenia owing

to remarkably increased megakaryocyte counts via regulating ROS and megakaryocyte reconstitution.

OC 74.2 | Circulating Histone-associated Thrombocytopenia Has a Significant Adverse Impact on Outcome in Critically Ill Patients

Y. Alhamdi[1], S. Abrams[1], I. Welters[2], G. Wang[1], C.-H. Toh[1,3]

[1]University of Liverpool, Institute of Infection and Global Health, Liverpool, United Kingdom, [2]University of Liverpool, Institute of Aging and Chronic Disease, Liverpool, United Kingdom, [3]Royal Liverpool University Hospital, Roald Dahl Haemostasis and Thrombosis Centre, Liverpool, United Kingdom

Background: Thrombocytopenia is frequently encountered in the intensive care unit (ICU) and associated with adverse outcomes. Circulating histones have been reported to associate with significant thrombocytopenia in a small case-control study.

Aims: To determine the clinical relevance of circulating histones on thrombocytopenia development in a large ICU cohort.

Methods: A longitudinal retrospective cohort study of 470 ICU patients admitted between February 2008 and June 2013 to the ICU of the Royal Liverpool University Hospital were followed for the first 96 hours of ICU admission. 68 patients were excluded due to identifiable causes of thrombocytopenia. Daily circulating histone levels were measured in the remaining 402 patients.

Results: Circulating histones were detectable in 150/157 (~95.5%) of thrombocytopenic patients as compared to 103/245 (~42%) of non-thrombocytopenic patients (p< 0.001). Daily histone levels were significantly higher in thrombocytopenic patients as compared to non-thrombocytopenic patients. Highest admission levels were in moderate (platelets 50-99x10^9/L) and severely (platelets< 50x10^9/L) thrombocytopenic patients. Admission histone levels robustly predicted the development of moderate-severe thrombocytopenia [AUC 0.844 (95% CI 0.810-0.877)]. Among 157 thrombocytopenic patients, 67 had DIC as defined by ISTH criteria. However, the remaining 90 thrombocytopenic patients did not have DIC. When these were stratified by admission histone levels, those with levels ≥30 μg/ml (60/90 patients) were significantly associated with more severe thrombocytopenia, longer ICU stay, longer cardiovascular and ventilation support and higher 28-day mortality than those with levels< 30 μg/ml (30/90 patients).

Conclusions: Circulating histones are significantly associated with moderate-severe thrombocytopenia in the ICU and adverse clinical outcome, even in the absence of DIC.

OC 74.3 | Lack of Effect of Inhaled Nitric Oxide on Platelet Function or Bioenergetics in Patients with Acute Submassive Pulmonary Embolism: Results of a Randomized, Placebo-controlled Trial

J. Kline[1], M. Puskarich[2], A. Jones[2], R. Mastouri[1], T. Lahm[1], E. Gundert[3], C. Hall[1]

[1]Indiana University School of Medicine, Indianapolis, United States, [2]University of Mississipi Medical Center, Jackson, United States, [3]University of Texas Southwestern Medical Center, Dallas, United States

Background: Prior work has shown platelet hyperactivation with acute pulmonary embolism (PE), and **nitric oxide (**NO**)** signaling attenuates platelet activation.

Aims: Test if adminis**tration of inhaled NO+**O2 to subjects with submassive PE will attenuate platelet hyper-reactivity more than O2 alone.

Methods: Phase II, (NCT01939301), 3-center, randomized, double blind, controlled trial. **Patients** had CT proven acute PE, were normotensive, and had RV dysfunction using explicit criteria. Subjects were randomized to either 50 ppm NO+O2 (treatment) or O2 only (placebo), delivered by nasal cannula and identical equipment for 24 h with blood sampling before and after treatment to assess whole-blood thromboelastography (TEG, Haemoscope 5000®, including platelet mapping); O2 consumption was measured in isolated platelets using high fidelity respirometry (Oroboros®) under basal and maximal (uncoupled) conditions. Plasma [NO3-] **was** confirmed by HPLC.

Results: We enrolled 76 patients with complete data**,** randomized to groups (N=38 each) that were well-matched for **PE severity**, comorbidities as well as TEG parameters (R **time**, angle and **maximum amplitude** without and with **heparin, arachidonateor** ADP) and platelet O2 consumption. After 24 hours of NO2+O2 or placebo, no TEG nor O2 consumption parameter was significantly different between groups. However, with NO+O2, plasma **NO3-** concentrations (μM) increased from a median of 11.7 (IQR 8.5,16.1) at enrollment to 26.9 (IQR 22.3, 38.9, P< 0.001) at 24 hours, and with placebo, plasma nitrate was unchanged from 14.9 (9.5, 19.1) at enrollment to 15.7 (11.4, 20.2).

Conclusions: Inhaled NO, delivered by nasal cannula at 50 ppm does not change TEG parameters without or with thrombin, arachindonate or ADP stimulation, nor did NO change platelet O2 consumption. The increased plasma NO3- concentrations indicate adequate drug delivery. Inhaled NO is therefore unlikely to produce clinically important changes in platelet function or bioenergetics during acute PE.

OC 74.4 | The Hypercoagulable State in Patients with Immune Thrombocytopenia (ITP) and its Association with Bleeding Symptoms

T. Chiasakul, B. Akkawat, P. Rojnuckarin

Chulalongkorn University and King Chulalongkorn Memorial Hospital, Division of Hematology, Department of Medicine, Bangkok, Thailand

Background: In immune thrombocytopenia (ITP), major bleeding is uncommon even when platelet counts are very low. Additionally, the severities of bleeding symptoms vary widely among patients at similar platelet counts. We proposed that the different degrees of hemostatic compensation from coagulation system are responsible for these phenomena. Thrombin generation test (TGT) is a new assay designed to measure the hyper-function of the whole coagulation system.

Aims: This cross-sectional study was aimed to explore the TGT variables in primary ITP patients and their associations with bleeding symptoms.

Methods: Primary ITP patients aged ≥18 years with platelet count of < 50 x 10^9/L were enrolled. Bleeding symptoms were evaluated using WHO bleeding scale (WHO BS) and ITP bleeding score (ITP BS). Moderate/severe bleeding was defined as WHO BS ≥2. TGT was measured in platelet-poor plasma triggered by 1 pM recombinant tissue factor and 1 µM phospholipid, with and without addition of thrombomodulin (TM).

Results: Of 27 patients enrolled, 23 (85%) were female. The mean age was 46 years (range, 17-88). Compared to healthy control (N =90), ITP patients had significantly higher mean endogenous thrombin potential (ETP, 1402 ±267 *vs.* 1213 ±257 nMxmin, p=.001), peak height (197 ±63 *vs.* 106 ±35 nM, p< .001), and velocity index (57.3 ±33.4 *vs.* 18.7 ±1.4 nM/min, p< .001). The mean ratio of ETP with TM to ETP without TM was higher in ITP patients (76 ±12 *vs.* 52 ±12, p< .001), suggesting a defect of the protein C pathway. Five ITP patients (18%) had moderate/severe bleeding. Mean ETP was significantly lower in this group (1165 ±273 *vs.*1456 ±240nM x min, p=.02). In addition, there was a negative correlation between ETP value and ITP BS in ITP patients (r=-.40, p=.04).

Conclusions: ITP patients show increased thrombin generation that is negatively correlated with bleeding severity. TGT may be used as an adjunctive measure to assess an individual's tendency to bleed.

OC 74.5 | Effects of the Btk Inhibitor Ibrutinib on Platelet Function during Inflammation and in Primary Hemostasis

R.H. Lee[1], R. Piatt[1], P.B. Conley[2], W. Bergmeier[1,3]

[1]University of North Carolina at Chapel Hill, McAllister Heart Institute, Chapel Hill, United States, [2]Portola Pharmaceuticals, Inc., South San Francisco, United States, [3]University of North Carolina at Chapel Hill, Department of Biochemistry and Biophysics, Chapel Hill, United States

Background: Ibrutinib is an inhibitor of Bruton's tyrosine kinase (Btk) used to treat hematological malignancies, including chronic lymphocytic leukemia. Bleeding is observed in up to 50% of ibrutinib-treated patients, but the origin of bleeding remains unclear. Platelets are critical for forming hemostatic plugs at sites of mechanical vascular injury. They also play a role in vascular integrity at sites of inflammation. Immunoreceptor tyrosine-based activation motif (ITAM) signaling in platelets is necessary to protect against inflammatory hemorrhage and Btk signals downstream of ITAM receptor activation.

Aims: The objective of this study was to investigate potential mechanisms of ibrutinib-associated bleeding during inflammation and in primary hemostasis.

Methods: We used two inflammatory models - the skin reverse passive Arthus reaction (rpA) and LPS-induced lung inflammation. To selectively inhibit Btk in platelets, thrombocytopenic mice were reconstituted with ibrutinib- or vehicle-treated wild-type (wt) platelets. To study primary hemostasis, platelet plug formation and bleeding was analyzed at sites of laser-induced injury to the saphenous vein.

Results: Ibrutinib dose-dependently inhibited platelet aggregation in response to GPVI or CLEC-2 agonists. In both inflammatory models, thrombocytopenic mice showed robust hemorrhage. Interestingly, transfusion of ibrutinib-treated platelets prevented hemorrhage to the same extent as vehicle-treated platelets. In our hemostasis model, ibrutinib did not prolong bleeding in wt mice. However, ibrutinib treatment significantly impaired hemostasis in P2Y12-deficient mice compared to vehicle treatment.

Conclusions: Our findings demonstrate that ibrutinib alone does not impair platelet-driven hemostasis at sites of inflammation or mechanical injury in wt mice but increases bleeding in P2Y12-deficient mice. This suggests bleeding in ibrutinib-treated patients may be due to a combination of factors inhibiting platelet function.

VASCULAR BIOLOGY & ANGIOGENESIS

OC 67.1 | Endothelial Cells Are Important Players in the Pathogenesis of Thrombosis in Myeloproliferative Neoplasms

A. Guy[1,2], V. Gourdou-Latyszenok[1,2], N. Le-Lay[3], J. Vieira Dias[1,2], B. Kilani[1,2], C. Peghaire[1,2], C. Duplaa[1,2], C. Denis[4], J.-L. Villeval[5], M. Jandrot-Perrus[3], T. Couffinhal[1,2], C. James[1,2,6]

[1]University of Bordeaux, Bordeaux, France, [2]INSERM, UMR 1034, Pessac, France, [3]INSERM, UMR_S1148, University of Paris Diderot LVTS, Paris, France, [4]INSERM U1176, Univ. Paris-Sud, Université Paris-Saclay, Le Kremlin-Bicêtre, France, [5]INSERM, U1009, Gustave Roussy Institute, Villejuif, France, [6]Laboratory of Hematology, University Hospital Center of Bordeaux, Pessac, France

Background: Thrombosis is the most frequent complication during evolution of myeloproliferative neoplasms (MPN) but the events causing these clotting abnormalities remain unclear. Recent studies have demonstrated the presence of $JAK2^{V617F}$ in endothelial cells (EC) in some patients with thrombotic complications.

Aims: To assess whether $JAK2^{V617F}$ ECs promote a prothrombotic phenotype and participate to thrombus formation.

Methods: We performed two complementary approaches.

(i) Human Umbilical Venous Endothelial Cells (HUVEC) were stably transfected with human $JAK2^{V617F}$ or $JAK2^{WT}$ as control.

(ii) For *in vivo* study, we used an inducible Cre-Lox mice model which allows expression of $JAK2^{V617F}$ in endothelial cells: *Pdgfb-iCreERT2;JAK2V617F/WT* mice.

Results: We showed that

1. expression of JAKV617F in HUVEC promotes adhesion of mononuclear cells (MNC) and neutrophils,
2. leukocyte rolling and adhesion are increased in mesenteric venules of *Pdgfb-iCreERT2;*$JAK2^{V617F/WT}$ mice
3. P-Selectin and vWF expression is increased at the surface of JAK2V617F HUVEC,

4. P-Selectin plasma concentration and endothelial cell expression are increased in *Pdgfb-iCreERT2;JAK2*$^{V617F/WT}$ mice,
5. blocking of P-Selectin decreases leukocyte adhesion on JAK2V717 HUVECs *in vitro* and leukocyte rolling and adhesion *in vivo*,
6. pulmonary thrombus formation is increased in *Pdgfb-iCreERT2;JAK2*$^{V617F/WT}$ mice,
7. blocking P-Selectin protect *Pdgfb-iCreERT2;JAK2*$^{V617F/WT}$ mice against thrombosis,
8. hydroxyurea (HU) diminishes leukocyte rolling and adhesion *in vivo* and *in vitro*, and *in vivo* thrombosis.

Conclusions: This study demonstrates that JAK2V617F ECs have a proadhesive phenotype due to P-Selectin overexpression. More, JAK2^{V617F} EC promotes thrombus formation. Finally, we show that HU decreases the pro-adhesive phenotype of JAK2V617F ECs. In summary, our results show that JAK2V617F endothelial cells contribute to thrombotic complications in MPN.

OC 67.2 | Modification of the VEGF165 C-terminus by Activated Thrombin-activatable Fibrinolysis Inhibitor (TAFIa) Inhibits Neuropilin-1 (Nrp1)-dependent Induction of Angiogenesis in vitro and in vivo

T.L. Wyseure[1], R.K. Sinha[1], P.J. Declerck[2], J.C.M. Meijers[3], A. von Dryglaski[1,4], L.O. Mosnier[1]

[1]*The Scripps Research Institute, Molecular Medicine, La Jolla, United States,* [2]*University of Leuven, Pharmaceutical and Pharmacological Sciences, Leuven, Belgium,* [3]*Sanquin Research, Amsterdam, The Netherlands,* [4]*University of California, Division of Hematology/Oncology, Medicine, San Diego, United States*

Background: Vascular endothelial growth factor 165 (VEGF165) contains a C-terminal (CT) Arg-Arg that is required for binding to Nrp1 and enhancing angiogenesis by Nrp1-mediated activation of the VEGF receptor 2 (VEGFR2). CT Arg's are subject to cleavage by carboxypeptidase B-like enzymes such as TAFIa.

Aims: To characterize the CT Arg removal of VEGF165 by TAFIa and determine the effects of TAFIa-generated des-Arg-VEGF165 forms on Nrp1 binding and induction of angiogenesis in vitro and in vivo.

Methods: TAFIa-mediated cleavage of VEGF165 was determined by HPLC. Nrp1 binding was measured by Octet-Red, ELISA and on mCherry-Nrp1 expressing HEK293 cells. Nrp1-mediated VEGFR2 signaling was determined on endothelial cells (EC). EC migration was evaluated in a transwell migration assay, and angiogenesis in vivo by Directed In Vivo Angiogenesis Assay (DIVAA).

Results: TAFIa rapidly removed Arg165 from synthetic VEGF CT peptides, but did not remove Arg164. Binding to soluble or cellular Nrp1 of TAFIa-generated or recombinant des-Arg-VEGF165 was reduced to ~42%, but binding to VEGFR1 and VEGFR2 was normal. Des-Arg-VEGF165 failed to induce EC ERK1/2 signaling and TAFIa reduced VEGF165-mediated EC migration to baseline ($p < 0.01$). To evaluate angiogenesis in vivo (DIVAA), angioreactors containing growth-factor-reduced Matrigel pre-mixed with VEGF165 were implanted in WT or TAFI$^{-/-}$ mice. After 12 days, visual inspection of angioreactors from TAFI$^{-/-}$ mice revealed increased vessel ingrowth. Accordingly, hemoglobin and lactate dehydrogenase activity were increased in angioreactors from TAFI$^{-/-}$ compared to WT mice ($p < 0.01$), indicating that TAFI deficiency promoted VEGF165-driven vessel ingrowth.

Conclusions: TAFIa significantly diminished VEGF165 binding to Nrp1, thereby attenuating VEGF165-driven angiogenesis by removing its CT Arg165. The CT-Arg-Arg is a common motif among most VEGF-A isoforms suggesting that the anti-angiogenic properties of TAFIa may play an important role in the regulation of revascularization in injured tissue.

OC 67.3 | Deficiency of Androgen Dependent TFPI-Regulating Protein (ADTRP) Promotes Vascular Malformations via Wnt-mediated up-regulation of Metalloproteases

C. Lupu[1], M.M. Patel[1,2], A. Behar[1], R.S. Keshari[1], R. Silasi[1], G. Regmi[1], F. Lupu[1,2]

[1]*Oklahoma Medical Research Foundation, Cardiovascular Biology, Oklahoma City, United States,* [2]*Oklahoma Health Sciences Center, Cell Biology, Oklahoma City, United States*

Background: ADTRP is a novel protein that co-regulates with, and supports the function of tissue factor pathway inhibitor (TFPI) (Blood 2011;118:4463). We also found that ADTRP is a negative regulator of Wnt signaling and that its deficiency affects vascular development (Blood 2016;128:556).

Aims: We investigated the role of ADTRP in vascular homeostasis and the mechanisms underlying vascular defects due to ADTRP loss of function.

Methods: We used in vitro cell based assays and mouse and zebrafish models to investigate vascular defects induced by ADTRP deficiency.

Results: Genetic inhibition of ADTRP in zebrafish and mice leads to vascular malformations including abnormal dilations, tortuosity and branching, increased permeability, ruptures and micro-hemorrhages. These defects resemble phenotypes observed in mice with over-activation of Wnt, supporting our hypothesis that ADTRP is a negative regulator of Wnt signaling in vascular cells. We observed that ADTRP deficiency associates with increased expression of two Wnt-regulated matrix metalloproteases, MPM2 and MMP9. Silencing ADTRP in cultured endothelial cells increased MMP9 in a Wnt-dependent manner. ADTRP knockdown in zebrafish increased MMP9 mRNA by over 8 fold. In situ hybridization showed enhanced expression of MMP9 in cells surrounding the defective vessels. Gel zymography revealed increased gelatinolytic activity in ADTRP-morpholino knockdown vs. scrambled morpholino in zebrafish. Similarly, MMP9 protein was increased in the endothelial cells, macrophages and mast cells surrounding vascular malformations in the skin of ADTRP knockout mice. Treatment with the Wnt inhibitor IWR1 reversed MMP9 expression in

ADTRP null mouse fibroblasts and in zebrafish embryos, demonstrating that MMP9 expression induced by ADTRP deficiency is downstream Wnt signaling.

Conclusions: ADTRP deficiency leads to increased Wnt signaling and subsequent up-regulation of metalloproteases that degrade the perivascular matrix and destabilize the vessel wall.

OC 67.4 | The von Willebrand Factor-binding Protein Bridges the Bacterial Cell Wall via Clumping Factor A and Endothelial von Willebrand Factor Allowing Shear-resistant Binding of Staphylococcus aureus to Inflamed or Damaged Endothelium

J. Claes[1], L. Liesenborghs[1], M. Peetermans[1], T.R. Veloso[1], D. Missiakas[2], O. Schneewind[2], S. Mancini[3], J.M. Entenza[3], M.F. Hoylaerts[1], R. Heying[1], P. Verhamme[1], T. Vanassche[1]

[1]University of Leuven, Department of Cardiovascular Sciences, Leuven, Belgium, [2]University of Chicago, Department of Microbiology, Chicago, United States, [3]University of Lausanne, Department of Fundamental Microbiology, Lausanne, Switzerland

Background: When establishing endovascular infections, *Staphylococcus aureus* (*S. aureus*) overcomes shear forces of flowing blood by binding to von Willebrand factor (VWF). Staphylococcal von Willebrand factor-binding protein (vWbp) interacts with the A1-domain of VWF, enabling bacterial adhesion to endothelial cells (ECs) and subendothelial matrix. However, it is unknown how this secreted protein binds to the bacterial cell wall. Surface proteins of *S. aureus* are linked to the bacterial cell wall by sortase A (SrtA). A mutation in this gene leads to an anchoring defect of about 20 *S. aureus* surface proteins.

Aims: We hypothesized that vWbp interacts with a staphylococcal surface protein, mediating the adhesion of *S. aureus* to VWF and vascular endothelium under shear stress.

Methods: We studied the binding of *S. aureus* to vWbp, VWF and ECs in a micro-parallel plate flow chamber using various mutants deficient in SrtA and SrtA-dependent surface proteins, and *Lactococcus lactis* expressing single staphylococcal surface proteins. *In vivo* adhesion of bacteria was evaluated in the murine mesenteric circulation using real-time intravital vascular microscopy.

Results: Absence of SrtA and Clumping factor A (ClfA) reduced adhesion of *S. aureus* to vWbp, VWF and activated ECs. ADAMTS13 (a disintegrin and metalloproteinase with thrombospondin type 1 motif, member 13) and an anti-VWF A1 domain antibody, when combined reduced *S. aureus* adhesion to activated ECs by 90%. Selective overexpression of ClfA in the membrane of *Lactococcus lactis* enabled these bacteria to bind to VWF and activated ECs but only in the presence of vWbp. Absence of ClfA abolished bacterial adhesion to the activated murine vessel wall.

Conclusions: vWbp interacts with the A1-domain of VWF and with the SrtA-dependent staphylococcal surface protein ClfA. The complex formed by endothelial VWF, secreted vWbp and bacterial ClfA anchors *S. aureus* to vascular endothelium under shear stress.

OC 67.5 | Cadherin 6 (cdh6) is Required for Thrombus Formation in vivo

E. Bouck[1], M. de la Fuente[1], W. Li[2], M. Mumaw[3], M. Nieman[1]

[1]Case Western Reserve University, Pharmacology, Cleveland, United States, [2]Cleveland Clinic, Cleveland, United States, [3]Case Western Reserve University, Hematology-Oncology, Cleveland, United States

Background: The regulation of hemostasis and thrombus formation is a tightly controlled event that has catastrophic consequences when it is deregulated. Adhesion molecules have a critical role in hemostasis and thrombosis by mediating multiple cell-cell interactions. We now evaluate the role of the cell adhesion protein, cadherin-6 (cdh6) in vivo using cdh6$^{-/-}$ mice.

Aims: The goal of this study was to determine the contribution of cdh6 to hemostasis and thrombosis in vivo.

Methods: The role of cdh6 in hemostasis and arterial thrombosis in vivo was evaluated using cdh6$^{-/-}$ mice in both the Rose Bengal and ferric chloride ($FeCl_3$) models. The function of platelets from cdh6$^{-/-}$ mice were evaluated with aggregometry and flow cytometry.

Results: The cdh6$^{-/-}$ mice were prolonged in the Rose Bengal thrombosis model to 52±11 min from 35±5 min in wild type mice (p=0.019). Similarly, the cdh6$^{-/-}$ mice were prolonged in the $FeCl_3$ model. Five of eight mice did not occlude by the conclusion of the experiment at 30 min. In contrast, wild type mice occluded at 10±2 min (n=8). In tail bleeding assays, there was no difference between wild type and cdh6$^{-/-}$ mice (119±38 vs 159±61 s, p=0.11) We next evaluated the response of platelets from cdh6$^{-/-}$ to ADP, PAR4 agonist, or convulsion. There was no difference in aggregation, GPIIbIIIa activation, or P-selectin expression. These data suggest that cdh6 is mediating thrombosis via platelet interactions with other cells. Finally, we tested if targeting cdh6 with a blocking antibody interred with thrombosis in C57Bl6 mice. The time to occlusion was prolonged in both thrombosis assays.

Conclusions: These combined studies show that cdh6 forms a complex with the necessary proteins required to mediate adhesion in platelets. Our results demonstrate that cdh6 has a physiologically important role during thrombus formation in vivo, but does not impact hemostasis as measured by tail bleeding time. Finally, our studies show that cdh6 is a targetable receptor in thrombosis.

NURSES FORUM

NUR 04.5 | Knowledge and Awareness of Pharmacists about Venous Thromboembolism and Anti Coagulation in Pakistan

S. Khan[1], S. Ahsan[2], A. Zehra[1], D.B. Moiz[3], S.S. Raza[1]

[1]Aga Khan University Hospital, Pharmacy, Karachi, Pakistan, [2]Shifa International Hospital, Pharmacy, Islamabad, Pakistan, [3]Aga Khan University Hospital, Hematology, Karachi, Pakistan

Background: Venous thromboembolism (VTE) is considered to be the most common preventable cause of hospital-related deaths.

Hospitalized patients undergoing major surgeries and those with acute medical illness are at an increased risk of VTE. Since management of VTE is multidisciplinary, it is critical that pharmacists should have adequate understanding of the anti coagulation.

Aims: The purpose of this study was to investigate pharmacists' awareness and knowledge of VTE, thromboprophylaxis and perioperative management of anti-coagulated patients in a hospital.

Methods: Cross-sectional survey design was shared between two tertiary care hospitals, The Aga Khan university hospital Karachi and shifa international Islamabad. Pharmacists working as clinical, operational and ambulatory care were enrolled in the study. A questionnaire was made with multiple choice questions and was distributed for responses.

Results: 60 pharmacists were requested to participate in the study and 41responded with a response rate of 68.33%. The responses were as follow: All pharmacists agreed that VTE prophylaxis is clinically important, 75% pharmacists were aware of institutional policy for thromboprophylaxis, 95% agreed that their institute should have peri-operative guidelines available for safe care, 100% agreed that pharmacists can play important role in VTE guideline development in their institutes, only 33% pharmacists were aware of perioperative management of heparin, only 52% were aware of appropriate use of DVT prophylaxis in hospitalized patients, 53.66% knew that patients can develop DVT after discharge, only 34.15% aware of VTE occurrence within 90 days of hospitalization in majority of hospitalized patients.

Conclusions: Pharmacist knowledge about VTE in hospital setting requires improvement.in Pakistan . Focusing the need of pharmacists and providing them with learning opportunities through discussions and lectures may improve the current situation.

NUR 05.1 | Delays in the Presentation of Chemotherapy Induced Venous Thromboembolism: Scope of the Problem and Potential Solutions

S. Noble[1], N. Pease[2]

[1]*Cardiff University, Palliative and Supportive Care, Newport, United Kingdom,* [2]*Velindre Cancer Centre, Palliative Medicine, Cardiff, United Kingdom*

Background: Thrombosis is the commonest cause of chemotherapy related mortality. Currently, the data does not support routine pharmacological prophylaxis for all patients and good practice recommends patients are warned of the signs and symptoms of venous thromboembolism (VTE) which would necessitate medical review. Qualitative data suggests patients receive adequate timely information pertaining to febrile neutropenia but not for cancer associated thrombosis. This could lead to delays in the diagnosis and treatment of VTE that has been precipitated by chemotherapy.

Aims: To evaluate the behaviors and understanding of chemotherapy patients who develop VTE.

Methods: Prospective observational cohort study of cancer patients attending a regional cancer associated thrombosis clinic. Data was collected on patients with a history of chemotherapy within the previous six weeks and symptomatic VTE. Length of time from development of symptoms to presentation to healthcare professionals was noted along with their recollection of information they had been given pertaining to VTE.

Results: Data was collected on 40 patients with VTE, presenting with deep vein thrombosis (DVT) (n=23), pulmonary embolism PE (n=16), DVT and PE (n=1). Patients with DVT experienced leg swelling (n=17), leg pain (n=4) or both (n=2). Patients with PE experienced dyspnea (n=8), chest pain (n=5) or both (n=3). Time to presentation ranged from 4 hours to 40 days (mean 18 days, median 8 days, mode 4 days). 28 patients had no recollection of receiving information about the risk of VTE. All patients were knowledgeable about febrile neutropenia.

Conclusions: Patients receiving chemotherapy do not to appear recall information regarding the risks and symptoms of VTE leading to delayed presentation and treatment. Their knowledge of febrile neutropenia suggests important information can be retained by patients and that oncology services need to consider ways to prioritise the knowledge transfer pertaining to chemotherapy induced VTE.

NUR 05.2 | Significant Reduction in Hospital Acquired Thrombosis: Impact of a National Risk Assessment Target & Local Real-time Reporting

H. Rowswell, T. Nokes

Plymouth Hospitals NHS Trust, Haematology, Plymouth, United Kingdom

Background: Since 2010 National Health Service (NHS) hospitals in England have been incentivised to risk assess for venous thromboembolism (VTE) all patients admitted, using a national tool, together with guidance on appropriate thromboprophylaxis (TP).

Aims: The impact of this initiative in reducing hospital-acquired thrombosis (HAT) is reviewed over 7 years within a large hospital. Similarly, those HAT events associated with inadequate TP are assessed.

Methods: This was an observational cohort study reviewing all cases of HAT diagnosed between January 2010 and December 2016 obtained in real-time from radiology records. Crude incident rates (CIR) are determined by comparison against patients admitted, expressed as events per 1,000 patients. HAT cases associated with inadequate or inappropriate TP are also assessed over the same period. This data is obtained from hospital notes and drug charts.

Results: In 2010 there were 217 HAT events from 103845 admissions (CIR 2.09 per 1000 admissions, 95% CI 1.81 - 2.37). By 2016 this has reduced to 176 HAT events from 119128 admissions (CIR 1.47 per 1000 admissions 95% CI 1.28-1.71) relative risk (RR) 0.718 (95% CI 0.589 to 0.875; p = 0.001). Over the same period, 50 of the 217 HAT events were associated with inadequate TP, falling to 7/176 in 2016 RR 0.140 (95% CI 0.0653 to 0.3002; p= 0.0001).

Conclusions: National guidance on VTE prevention and mandatory risk assessment are associated with significant reductions, both in total HAT events and those associated with inadequate TP. Locally, real-time feedback on HAT events to senior clinicians, has very likely contributed to the improvements in HAT metrics.

NUR 05.3 | Impact of a Thrombosis Pharmacist in Optimizing Anticoagulation Management in Paediatric Patients

E. Chung[1], C. Chan[1], M. Ho[2], J. Fung[1], L. Brandão[3], W. Seto[1]

[1]The Hospital for Sick Children, Pharmacy, Toronto, Canada, [2]The Hospital for Sick Children, Complex Care Program, Toronto, Canada, [3]The Hospital for Sick Children, Haematology and Oncology, Toronto, Canada

Background: Thromboembolic disease is a new epidemic in tertiary paediatric centres. These thrombotic complications are prevented and treated with anticoagulants. However, anticoagulants are high-alert medications associated with major patient safety incidents. Pharmacists specialized in managing anticoagulation have shown improved clinical outcomes in adult patients. To our knowledge, this thrombosis pharmacist pilot program, is the first for a paediatric hospital in Canada.

Aims: We evaluated the impact of this program on clinical outcomes, assessed family/patient satisfaction and knowledge on low molecular weight heparin (LMWH) post-discharge, obtained staff feedback, and determined net cost benefit.

Methods: A thrombosis pharmacist pilot program was implemented on February 29, 2016 and ended on June 3, 2016 to optimize LMWH and warfarin use in the inpatient setting. This project compared health outcomes against a pre-implementation period (August 1 to November 30, 2015). Surveys were conducted on telephone for patients and families, and conducted online for staff.

Results: Data from 94 and 64 patients during the pre- and post-pilot periods respectively demonstrated an increase in clot resolutions by 23.65%, reduction in bleeding events by 2.26% and length of stay by 320 patient days (during pilot period), an improvement in family/patient satisfaction and LMWH knowledge by 15.63%, and an increase in anticoagulation control (for LMWH and warfarin) during the pilot period. Staff highly recommended the thrombosis pharmacist position to continue. The net cost benefit was $348 806.

Conclusions: A paediatric thrombosis pharmacist can provide substantial improvement to anticoagulation management and may lead to significant cost avoidance to healthcare payers.

NUR 05.4 | St. Joseph's Healthcare Hamilton Perioperative Anticoagulation Clinic Quality Improvement Project

L. Sardo, J. Bayadinova

St. Joseph's Healthcare Hamilton, Hemostasis & Thrombosis, Hamilton, Canada

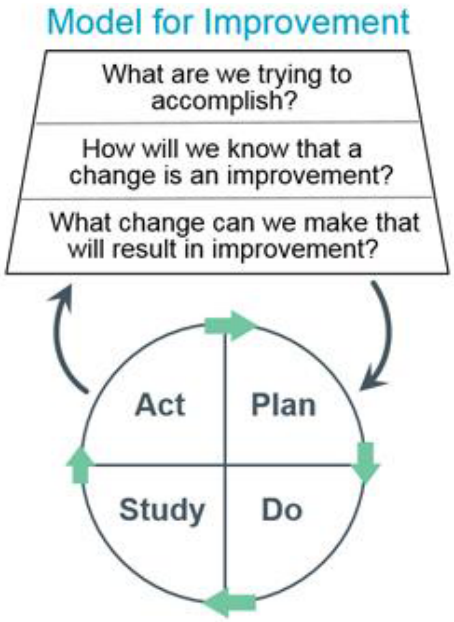

FIGURE 1 Model for Improvement by Institute for Healthcare Improvement

Background: Nurse practitioners (NPs) were introduced to the Thrombosis service at St. Joseph's Healthcare, Hamilton in December, 2014. Multiple quality improvement (QI) initiatives were undertaken to increase efficiencies of the perioperative anticoagulation clinic.

Aims: The aims of the QI project were fourfold:

1. Maximize clinic capacity (increase number of patients seen, decrease no show rate, eliminate wait list);
2. Improve patient care (Reminder phone calls, minimize unnecessary laboratory testing, minimize patient anxiety, decrease wait times, minimize delayed/cancelled procedures);
3. Achieve economic savings (maximize scope of NP practice, laboratory savings); and
4. Ensure physician satisfaction.

Methods: The Institute for Healthcare Improvement's Model for Improvement (Figure 1) was used to identify and implement changes.

Results: Multiple steps were undertaken to improve efficiency of the Perioperative Clinic. The expanded scope of NP practice resulted in increased appointment efficiency (assessment of appropriateness of anticoagulation agent, patient education); overall clinic time increased by 20 percent. Together, these steps increased clinic capacity by 160%. Implementation of reminder phone calls reduced the no show rate by 85% (17.5% to < 2%). All changes led to elimination of the wait list. Laboratory testing was reduced by 80.9%, resulting in decreased patient wait time with estimated economic savings of $1423.41/month in lab testing alone; no increase in peri/postoperative bleeding events noted. Finally, a Thrombosis physician survey revealed physician were 'very satisfied' with NP quality of care.

Conclusions: Since December 2014, multiple QI strategies were implemented by NPs in the perioperative anticoagulation clinic. These led to increased efficiencies including increased clinic capacity, elimination of wait list, economic savings and physician satisfaction.

NUR 05.5 | National Quality Improvement for Transition from Pediatric to Adult Care: Evaluation of a Pilot Program

F. Ann[1], R. Malouin[2], L. Palmer[3], C. Thornburg[4], S. Dunn[5], L. Casto[6], J. Hill[7], B. Koval[8], D. Oldfield[9], V.L. Foster-Johnson[10]

[1]ATHN, Inc, Riverwoods, United States, [2]Michigan State University, Lansing, United States, [3]Hemophilia Outreach Center, Green Bay, United States, [4]Rady Children's Hospital San Diego, SanDiego, United States, [5]Center for Inherited Bleeding and Coagulation Disorders,, Orange, United States, [6]Natioanwide Childrens Hospital, Cincinnati, United States, [7]Emory University, Atlanta, United States, [8]Emory University, Atanta, United States, [9]Gulf States Hemophilia and Thrombophilia Cener, Houston, United States, [10]Dartmouth College, Lebanon, United States

Background: In 2016, the National Hemophilia Program Coordinating Center (NHPCC), The Dartmouth Institute Microsystems Academy (TDIMA) and 10 Hemophilia Treatment Centers (HTCs) participated in the first US pilot National QI Program on TBD. The national transition QI framework has three interactive aspects: outcome measure (Healthy People 2020 transition measure); utilization of tools and evidence based practices ("Got Transition" and HTC developed tools) and; QI management. HTCs used standard QI assessment methodology to identify specific aims to improve TBD.

Aims:

1. To utilize focus groups to gather recommendations for improvement of future programs.
2. To determine feasibility of using the standardized QI methodology for future dispersion.

Methods: Evaluators from the Center for Program Design and Evaluation at Dartmouth College and Michigan State University conducted 3 focus groups with participants of the pilot program using a semi-structured interview guide. The quantitative data were analyzed using grounded theory methods to evaluate QI program and determine the feasibility of using this model for future dispersion.

Results: Forty-five out of 72 (63%) participated in focus groups conducted by external evaluators. 77% of respondents indicated they would definitely or probably recommend the program to colleagues an 75% indicated they were satisfied with program. Barriers to implementing QI initiative included competing priorities (49%); time management (42%); team dynamics 20%) and date collection (13%).

Conclusions: This was the first US national pilot program focused on quality improvement for transition from pediatric to adolescent care. Most of the staff indicated that the NHPCC/TDIMA program is a feasible model to implement at other HTCs. Areas of suggested program improvement include adjusting workload to align with clinical demands, clarification of program expectations and additional didactic training.

NUR 05.6 | Nurse as Change Agent for Improved Nurse Safety and Patient Satisfaction

M. Blumenstein[1], C. Law[2], J. Whittle[3]

[1]Children's Hospital of Philadelphia, Hematology, Philadelphia, United States, [2]Children's Hospital of Philadelphia, Pharmacy, Philadelphia, United States, [3]Children's Hospital of Philadelphia, Cardiology Nursing, Philadelphia, United States

Background: Low molecular weight heparins (LMWH) are the anticoagulants of choice in pediatrics except in patients with mechanical heart valves. Enoxaparin, a LMWH administered by subcutaneous injection twice daily, is used off-label in pediatrics. It is supplied as prefilled safety syringes with a 27g, 1/2" fixed needle and in multidose vials. Needle/syringe choices vary when using vials. Thick needle gauges cause more injection-related trauma/pain and long needles risk accidental intramuscular injection. Using pre-filleds can lead to dosing errors and drug waste, especially in children. Needles without safety devices risk nurse injury. At our hospital, about 27,000 enoxaparin doses were dispensed for inpatients in 2016.

Aims: To improve nurse safety & patient satisfaction through nurse-initiated change.

Methods: Assessed practices for enoxaparin administration

- Patient c/o bruising/pain at injection sites
- Doses < 20 mg needed dilution to read dose
- Needle-stick risk with non-safety needles
- Safety needle/syringe search revealed desired syringe was not available in US

Planned quality improvement

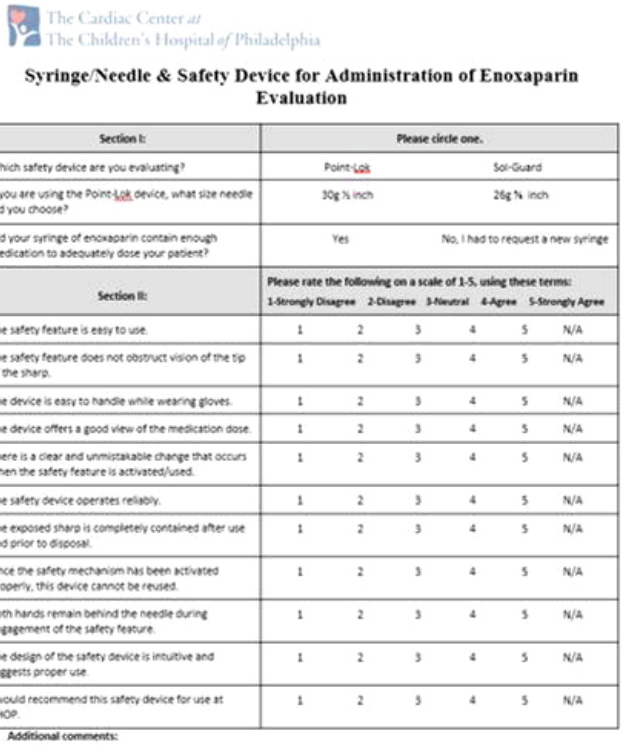
- Followed institutional processes for new product and safety approvals
- Identified a manufacturer to make a fine gauge/short, fixed-needle safety syringe
- Developed pilot program trialing newly manufactured syringes

Implement

- Developed nursing & pharmacy education
- Pilot roll-out on Cardiac units only

Evaluate

- Nurses completed pre and post implementation questionnaire



The Cardiac Center at The Children's Hospital of Philadelphia

Syringe/Needle & Safety Device for Administration of Enoxaparin Evaluation

Section I:	Please circle one.					
Which safety device are you evaluating?	Point-Lok			Sol-Guard		
If you are using the Point-Lok device, what size needle did you choose?	30g ½ inch			26g ⅝ inch		
Did your syringe of enoxaparin contain enough medication to adequately dose your patient?	Yes			No, I had to request a new syringe		
Section II:	**Please rate the following on a scale of 1-5, using these terms:** **1-Strongly Disagree 2-Disagree 3-Neutral 4-Agree 5-Strongly Agree**					
The safety feature is easy to use.	1	2	3	4	5	N/A
The safety feature does not obstruct vision of the tip of the sharp.	1	2	3	4	5	N/A
The device is easy to handle while wearing gloves.	1	2	3	4	5	N/A
The device offers a good view of the medication dose.	1	2	3	4	5	N/A
There is a clear and unmistakable change that occurs when the safety feature is activated/used.	1	2	3	4	5	N/A
The safety device operates reliably.	1	2	3	4	5	N/A
The exposed sharp is completely contained after use and prior to disposal.	1	2	3	4	5	N/A
Once the safety mechanism has been activated properly, this device cannot be reused.	1	2	3	4	5	N/A
Both hands remain behind the needle during engagement of the safety feature.	1	2	3	4	5	N/A
The design of the safety device is intuitive and suggests proper use.	1	2	3	4	5	N/A
I would recommend this safety device for use at CHOP.	1	2	3	4	5	N/A

Additional comments:

FIGURE 1 Blank pre/post evaluation questionnaire

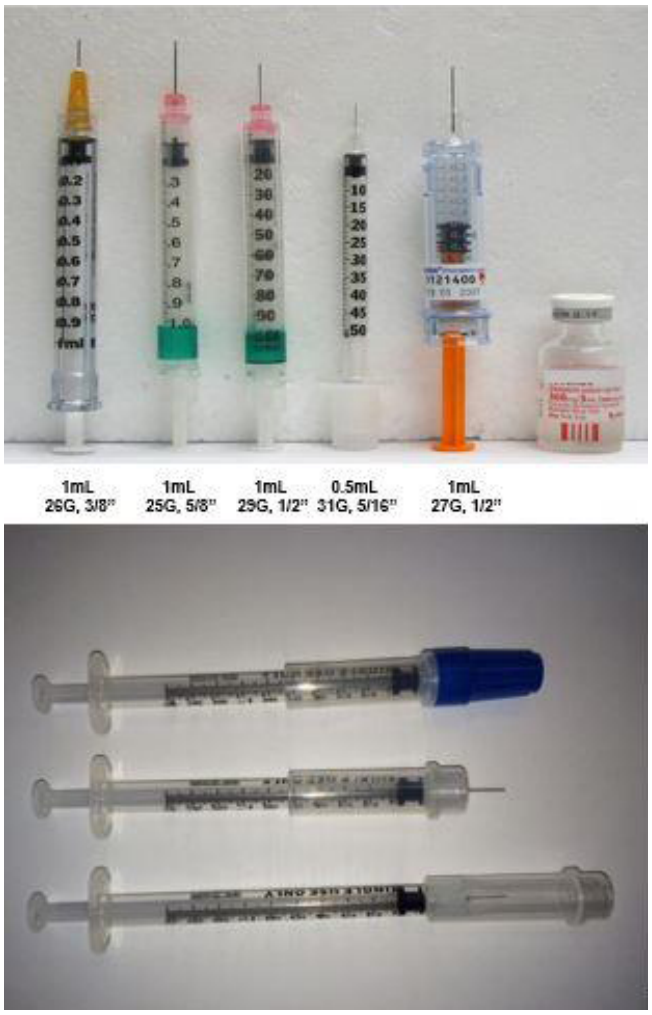


FIGURE 2 Images of syringe/needle types

- Monitored: staff needle-stick injuries,patient harm reports, pharmacy dose/fill errors
- Interviewed patients/families

Re-assess administration practice of enoxaparin

Results: Supported use of new syringe. Expanded needle use for enoxaparin hospital-wide

- Increased patient & nursing satisfaction (Fig. 1 & Fig. 2)
- New syringe caused work-flow challenges for pharmacy

Conclusions: Nurses are educated and positioned for success in:

- Identifying opportunities to improve nurse & patient safety
- Developing & executing actions yielding system-wide change
- Improving patient satisfaction.

NUR 05.7 | Lung Function, Functional Capacity and Heart Rate Recovery at Discharge in Patients with Acute Pulmonary Embolism

J.S. Danielsbacka[1], M. Fagevik Olsén[1], P.-O. Hansson[2], K. Mannerkorpi[3]

[1]*Sahlgrenska University Hospital, Physiotherapy Department, Göteborg, Sweden,*
[2]*Sahlgrenska University Hospital, Department of Medicine, Göteborg, Sweden,*
[3]*University of Gothenburg, Department of Health and Rehabilitation, Göteborg, Sweden*

Background: Acute pulmonary embolism (PE) is a cardiovascular disease with symptoms as dyspnea and hypoxemia as a consequence of haemodynamic disturbances. No previous studies exist focusing on lung function, functional capacity and heart rate recovery (HHR2) at discharge after PE.

Aims: The aims was to examine and describe lung function, functional capacity and HRR2 at discharge in patients with PE and compare to reference values for spirometry and six minute walk test (6MWT).

Methods: Thirty-one patients with first time PE admitted to the Acute Medical Unit, Sahlgrenska University Hospital were included. The patients had no earlier heart- or lung disease. Size of PE was calculated by Qanadli score (QS) percentage (mean QS 45.9 % (SD 5.2). Forced vital capacity and forced expiratory volume in one second were registered (n=30) and 6MWT performed (n=28) at the day of discharge. HRR2 was calculated after the 6MWT. Spirometry and 6MWT results were compared to reference values.

Results: This study shows that patients with PE have significantly reduced lung function ($p < 0.05$) and functional capacity ($p < 0.001$) at discharge compared to reference values. HRR2 was abnormal in 50% of all included patients. When excluding patients with beta blocker (n=7) 39% of the patients had an abnormal HRR2.

Conclusions: This study indicates that patients with PE have a reduced lung function, reduced functional capacity and abnormal HRR2 in up to 50% of the patients. Further studies is needed concerning long term follow-up of lung function, functional capacity and HRR2 after PE.

NUR 05.8 | Long-term Mental Well-being of Adolescents and Young Adults Diagnosed with Venous Thromboembolism. A Multistage Mixed Methods Study

A.A. Højen[1], P.S. Dreyer[2], E.E. Sørensen[3,4], T.B. Larsen[1]

[1]*Aalborg Thrombosis Research Unit, Department of Clinical Medicine, Aalborg University, Aalborg, Denmark,* [2]*Aarhus University, Institute of Public Health, Section of Nursing, Aarhus, Denmark,* [3]*Aalborg University Hospital, Clinical Nursing Research Unit, Aalborg, Denmark,* [4]*Aalborg University, Department of Clinical Medicine, Aalborg, Denmark*

Background: Critical and chronic illness in youth can lead to impaired mental well-being. Although, venous thromboembolism (VTE) is a potentially traumatic and life-threatening condition, the long-term mental well-being of adolescents and young adults (AYAS) with VTE is unclear.

Aims: To investigate the long-term mental well-being of AYAS (13-33 years) with VTE.

Methods: This multistage mixed methods study included 3 sub-studies:

1) a Danish nationwide registry-based study investigating the mental well-being of AYAS with incident VTE using psychotropic drug purchase as proxy,

2) a qualitative study with 12 semi-structured interviews exploring AYAS's lived experiences following VTE, and

3) a Danish nationwide registry-based cohort study of the mental well-being of AYAS with VTE vs. AYAS with insulin dependent diabetes mellitus (IDDM) using psychotropic drug purchase as a proxy.

An integrated mixed methods interpretation of findings from the 3

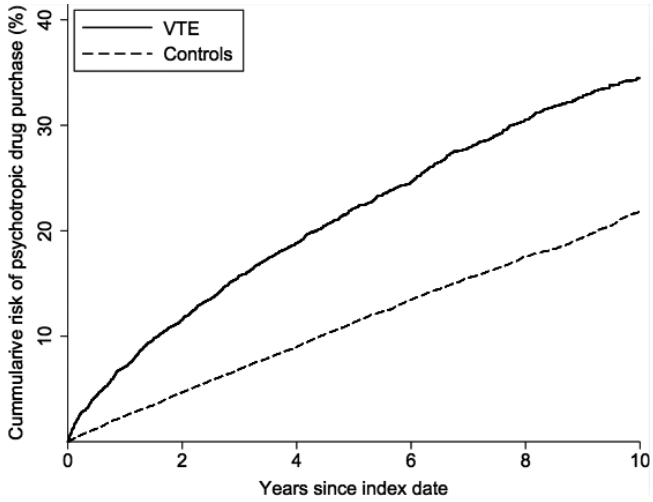

FIGURE 1 Cumulative risk of psychotropic drug purchase in 5,027 AYAS with a first VTE diagnosis versus 19,292 sex- and age matched population controls]

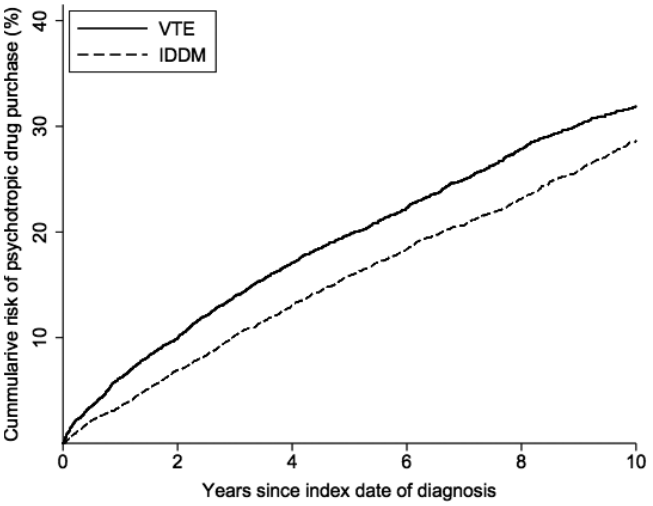

FIGURE 2 Cumulative risk of psychotropic drug purchase in 4,552 AYAS with a first VTE diagnosis compared with 5,189 AYAS with IDDM

sub-studies were conducted through narrative weaving and joint displays.

Results: The integrated mixed methods interpretation showed that the mental well-being of AYAS with VTE had a chronic perspective, with a persistently higher risk of psychotropic drug purchase among AYAS with VTE compared with sex and age matched population controls(Figure 1) and AYAS with IDDM (Figure 2). Impaired mental well-being was largely connected to fear of recurrence and concomitant uncertainty. Thus, to navigate uncertainty was important for the long-term mental well-being. Perceived health threat played a more profound role for the long-term mental well-being than illness severity, as the potential life-threat was the pivot pointing both back to the initial VTE and forward to the perception of future health-threat and the potential risk of dying of a recurrent event.

Conclusions: Our findings show that VTE has a negative impact on the long-term mental well-being of adolescents and young adults and highlight these patients' need for adequate support.

NUR 05.9 | Prevention of Hospital-acquired Venous Thromboembolism: The Project of Effective Quality Improvement

G. Saharov[1], Y.N. Nadir[1], I. Tzoran[1], A. Jabareen[1], G. Heims[2], B. Brenner[1], Orit Gur

[1]Rambam Health Care Campus, Haematology, Haifa, Israel, [2]Rambam Health Care Campus, Nursing Administration, Haifa, Israel

Background: Venous thromboembolism (VTE) is the most common preventable cause of hospital death. Several pharmacological and mechanical methods are available to prevent VTE in hospitalized patients. Yet, despite the awareness of the medical staff that the majority of hospitalized medical and surgical patients have multiple risk factors for VTE and despite the existence of evidence-based guidelines, preventive methods are quite underused. An established institutional protocol, including systemic VTE risk assessment and electronic alert of high risk patients could promote VTE prophylaxis.

Aims: To improve the use of personalized VTE prophylaxis in hospitalized patients.

Methods:

1. Creating a model of quality improvement steps.
2. Adoption of the Padua risk assessment scale (RAS) and its computerization.
3. Development of educational program on VTE risk assessment and prevention methods for nurses, physicians and hospital administration.
4. Recruitment of nurses dedicated to the project in each hospital department.
5. Development of evidence-based institutional guidance to improve the management of high-risk VTE inpatients.

Results: The project has been continued for 8 years. In 2009, 2674 (17.5%) of 15315 patients were assessed for VTE risk. In 2016, 14803(99.5%) of all patients hospitalized at Rambam are evaluated for VTE risk factors using the Padua RAS. Over the 8-year follow-up, the thromboprophylaxis rate for high risk patients has increased from 957(62.2%) in 2009 to 5479(75.0%) in 2016. The total improvement in prevalence of VTE prophylaxis is 20%.

Conclusions: The project of Effective Quality Improvement has led to a rise in VTE risk assessment of hospitalized patients and to an upward trend in prescription of VTE prophylaxis.

We intend to examine the actual influence of the results obtained on VTE prevalence among inpatients.

NUR 05.10 | A Unique National Plan for Prevention of Severe Familial Hemophilia

D. Bashari[1], V. Shemer[1], R. Dardik[1], B. Feldman[2], T. Brutman Barazani[1], D. Eli[1], G. Kenet[1]

[1]*Sheba Medical Center affiliated to Sackler School of Medicine, Tel Aviv University, Israeli National Hemophilia Center, Ramat Gan, Israel,* [2]*Sheba Medical Center affiliated to Sackler School of Medicine, Tel Aviv University, Human Genetics, Ramat Gan, Israel*

Background: Hemophilia (H) has an estimated incidence of 1/5000 male births. The Israeli national comprehensive care hemophilia center treats over 650 hemophilia patients.

Aims: A unique hemophilia prevention program has been running since 2009 aiming to decrease the incidence of familial hemophilia.

Methods: The National Hemophilia prevention program was led by a multidisciplinary team. Hemophilia patients and their families were interviewed and potential carriers were screened. Carriers were provided with genetic consultation and prenatal diagnosis and Preimplantation Genetic Diagnosis (PGD) was offered.

Results: Since the plan was implemented in 2009, 353 families were approached, 417 potential carries were tested and 249 carriers were diagnosed. 117 prenatal diagnostic procedures were performed. Out of 35 pregnancies diagnosed with H, 31 were terminated. PGD was offered to 108 carries. 64 women underwent a total of 158 IVF cycles that yielded 126 embroyonal returns and a total of 43 healthy babies were born. Notably, the numbers of carriers referred for IVF and PGD gradually increased with time (5-29 cases in 2009 and 2016 respectively) .Since 2009, 25 children with severe H were born despite preventive measures.

Conclusions: Our national prevention programs leads to a decreased incidence of new familial cases with severe hemophilia. The aim of this program is to reduce the burden on affected families and the health care system.

NUR 05.11 | Responding to Patient's Needs: Presenting a Framework of Support for Psychological Distress Following VTE

R. Hunter[1], P. Bennett[2], S. Lewis[3], S. Noble[4]

[1]*Swansea University, Psychology, Swansea, United Kingdom,* [2]*Swansea University, Swansea, United Kingdom,* [3]*Aneurin Bevan University Health Board, Abergavenny, United Kingdom,* [4]*Cardiff University, School of Medicine, Cardiff, United Kingdom*

Background: High levels of anxiety, trauma and uncertainty are common following Venous Thromboembolism (VTE). Findings from qualitative and quantitative study have also highlighted the emotional support needs of patients who have experienced VTE (Noble et al, 2014; Hunter et al, 2016) and point to a need for intervention to improve patient wellbeing and wider health outcomes.

Aims: The aim of this research was to develop a cost-effective intervention and/or support tools which could improve patients psychological wellbeing following VTE.

Methods: Evidence based psychological and self-help interventions were identified and a corresponding intervention pack (Coping with VTE; COVET) was developed to support VTE patients. The LENS framework was developed to assist health professionals in identifying psychological distress and providing targeted intervention.

Results: The COVET and LENS framework will be presented. The COVET intervention provides psychoeducation and is sensitive to anxieties and uncertainties commonly reported following VTE. These include:

Psychoeducation about VTE and its treatment
- Anxiety management techniques
- Support for coping with symptoms of trauma
- Information about coping with uncertainty

The COVET may be delivered as a stand-alone intervention or within the context of the proposed LENS framework.

Conclusions: The presented COVET intervention and the LENS framework aim to provide much needed tools for health professionals to support VTE patients and reduce distress following VTE. The tools presented are flexible, cost-effective and have the potential to be delivered live (i.e. nurse-led, face-to-face) or in distal settings (i.e. self-help, online). Clinical implications are discussed.

NUR 05.12 | Effect of Comprehensive Hemophilia Education Programme (CHEP) for Children and Youth on Knowledge and Quality of Life - A Pilot Project

A. Dsouza[1], D. Nayak[2], A. Kurien[3]

[1]*Manipal College of Nursing, Manipal University, Child Health Nursing, Udupi, India,* [2]*Manipal University, Dr. T. M. A. Pai Hospital, Udupi, India,* [3]*Melaka Manipal Medical College,Manipal university, Manipal, India*

Background: Many children and youth are newly diagnosed to have hemophilia in developing country like India. When newly diagnosed it is common that parents are apprehensive and if properly educated many of the problems can be solved.

Aims: The aim of the study was to evaluate the effectiveness of comprehensive hemophilia education programme on knowledge and quality of life among children and youth with hemophilia.

Methods: An evaluative study was conducted at two centres (intervention and control)of hemophilia comprising 10 children in each group. Children (5-12yrs) and youth (13-24yrs) were selected by convenient sampling. Data were collected by using demographic proforma , knowledge questionnaire, Hemo QoL and A36 Hemofilia-QoL. Content validity was done based on expert opinion. Ethical committee approval was obtained before the commencement of the study and a written consent from parents was obtained.

The education programme (included five sessions on hemophilia and its management ,video on bleeds and its management,a booklet on hemophilia, a log book to record bleeds and factor replacement therapy)was given on two days when parents were attending a camp. Knowledge and quality of life was assessed before the intervention and six months after the intervention.

Results: Paired t test value for knowledge was 2.68 and the p value is 0.031, so it was found significant that education programme was effective in improving knowledge. In the age group of 8-12yrs and 13-16yrs the obtained t value for qol was 3.29 and 5.78 which was significant at 0.05 level, so the intervention was effective in improving quality of life. In the age group of 17-21 yrs the obtained t value was 1.44 and the p value is 0.38 which is not significant.

Conclusions: The study concludes that educational programme is effective in improving knowledge of mothers and it also improves the quality of life.

NUR 05.13 | Implementation of the Nurse Practitioner Role in the Thrombosis Service at St. Joseph's Healthcare, Hamilton

L. Sardo, J. Bayadinova

St. Joseph's Healthcare Hamilton, Hemostasis & Thrombosis, Hamilton, Canada

Background: Nurse practitioners (NPs) were introduced to the Thrombosis service at St. Joseph's Healthcare, Hamilton in December, 2014; this represented a role change from clinical registered nurses.

Aims: The rationale for implementation of the NP role was threefold: NPs could

1. Independently assess, diagnose and treat
2. Manage atypical consults and
3. Ensure timely discharge with prescriptive authority.

Methods: The new role was evaluated using a Canadian Framework of Advanced Practice Nursing (APN) identifying four domains of practice (clinical, research, leadership, consultation and collaboration). A Thrombosis physician (MD) survey was administered to endorse NP competencies.

Results: 100% response rate for MD survey.

Clinical competencies identified include use of best practice guidelines and acting as independent practitioner and patient educator. MD survey results: 4.89/5 for NP knowledge and skill in patient care decisions; 5/5 for quality of care provided.

Research competencies include incorporating most recent research evidence into practice, NP led research and initiating regional thrombosis and knowledge translation journal clubs.

Leadership competencies include initiation of nursing staff/student thrombosis orientation, participation in national thrombosis networks and nursing practice committees. Quality improvement initiatives include 160% increase in outpatient clinic capacity with >80% reduction in lab work.

Consultation and collaboration competencies: MD survey results: 4.89/5 concur consultation with physician when appropriate, 5/5 NPs value nursing and medical aspects of care.

Conclusions: Since introduction of the NP role, achievement in each of the core competencies has been validated. Competency achievement is supported by physician colleague survey. Future goals identified include an NP led clinic for defined diagnoses and patient education initiatives.

NUR 05.14 | Nurse Practitioner-led Quality Improvement Project on Inferior Vena Cava Filter Placement and Retrieval: A Patient Focused Approach

L. Sardo[1], J. Bayadinova[1], W. Lim[2]

[1]*St. Joseph's Healthcare Hamilton, Hemostasis & Thrombosis, Hamilton, Canada,* [2]*McMaster University, Hematology, Hamilton, Canada*

Background: In July 2016, Health Canada issued an alert regarding inferior vena cava (IVC) filters and their associated risk of serious complications. Recommendations included ensuring appropriate indication for filter insertion, timely follow-up and retrieval. Following this alert, our tertiary university-affiliated hospital initiated a strategy to incorporate recommendations into current practice.

Aims: To determine the indications for IVC filter insertion (compared to published guidelines), rates of IVC filter retrieval and consistency of patient follow-up prior to initiation of the IVC filter retrieval strategy. The second objective was to develop patient-centered educational material based on a patient needs assessment.

Methods: Retrospective chart review of patients with IVC filters placed at our institution from January to December 2016. REB approval was obtained. Data was extracted including date and type of filter inserted, indication for insertion and details of retrieval. A patient needs assessment was conducted via telephone to measure patient awareness and understanding of IVC filter placement, including satisfaction with education received at time of filter insertion.

Results: A total of 16 IVC filters were placed during this time; 9 were retrieved. Final results not available at this time. Complete analysis pending.

Conclusions: In addition to providing information about current practice with respect to IVC filters at a tertiary care, university-affiliated hospital, this QI project will aid in the development of a formal patient education program based on a needs assessment.

NUR 05.15 | Providing Leadership in Thrombosis - A National Network for Nurses, Midwives and AHPs

E. Gee[1], L. Bonner[2], on behalf of the VTE National Nursing and Midwifery Network

[1]*King's College Hospital NHS Foundation Trust, Haematology, London, United Kingdom,* [2]*King's College Hospital NHS Foundation Trust, London, United Kingdom*

Background: To support the National drive to implement a systematic approach to improving VTE prevention for hospitalized patients, an Exemplar Centre Network was established in 2010. Exemplar status was awarded to organisations demonstrating pre-specified quality VTE prevention care standards. This gave organisations an opportunity to showcase their work and a responsibility to provide leadership to other providers.

Aims: The VTE National Nursing and Midwifery Network (VTE NNMN) was created as a sub group of the Exemplar Centre Network

to provide support and leadership to nurses, midwives and allied health professionals working in the field. It aimed to work in alignment with the National VTE Prevention Programme in England to encourage innovation and collaborative working.

Methods: Senior nursing and midwifery support at a national level was gained. Lead nurses and midwives became members once their organisations gained exemplar status. Nurses, midwives, allied health professionals and patient representatives were invited to biannual meetings. Terms of reference were agreed and work streams set up.

Results: The network has successfully provided national leadership in VTE evidenced by the numerous clinical queries the network answers, ongoing dedication of it's members, sustained growth in new exemplar centres and it's national presence in the form of publications, social media and educational opportunities, with the aim of driving high quality care. The Network has succeeded in finding and growing talent by providing support and platforms to present and disseminate work. Resources are centralised and shared to expedite the spread of quality evidence based practice. Members report that the network has a positive impact on their professional practice.

Conclusions: A national network enables networking amongst clinicians, collaborative working and resource sharing to promote an evidence based, consistent approach to patient centred thrombosis care.

NUR 05.16 | Living with the Unpredictability of an Inhibitor as an Adolescent - Results of the SO-HEROIC Study

K. Khair[1,2], L. Wollard[3], M. Holland[3]

[1]Great Ormond St Hospital NHS Trust, London, United Kingdom, [2]London South Bank University, London, United Kingdom, [3]Haemnet, London, United Kingdom

Background: Haemophilia results in bleeding, predominantly into the weight bearing joints. British children with severe haemophilia are treated with factor prophylaxis. Around 1/3 will develop inhibitors making treatment complex. Tolerance is induced in many; when it fails treatment options are limited. There are no guidelines on how to treat this cohort of adolescents/young adults and clinical approaches vary widely between centres.

Aims: There is little data from a patient perspective on how living with a long-term inhibitor impacts on peoples' and families' lives. The SO-HEROIC study aims to understand the needs of these individuals, through focus groups and questionnaires.

Methods: Questionnaires were sent to participants to ask about inhibitor management, impact on lifestyles and if they would meet others for further discussions. Telephone and face-to-face interviews were conducted which were transcribed and analysed.

Results: 6 boys, with haemophilia A and a long-standing inhibitor, responded to our survey. ITT had failed in 4/6; 2/6 had not received ITT. All described limitations on physical activity and noted that they had more bleeds that took longer to resolve due to their inhibitor. 5/6 were keen to share their experiences. further 4 boys and 1 girl were identified opportunistically and agreed to in-depth interviews. All described frustrations with current treatment, the unpredictability of bleeding, and school absences. Nevertheless, some developed coping strategies and continued education to graduate levels.

Conclusions: Living with a long-standing inhibitor places extra limitations on physical and everyday activities, compounded by the unpredictability of bleeding episodes. The effect of recurrent bleeds and length of recovery for the person and family is profound. By giving greater attention to these physical and psychosocial concerns, we can promote access to and provide the necessary healthcare to ensure equal opportunity and the best possible outcomes.

NUR 07.2 | Identifying the Principles Guiding the Development and Delivery of Patient Education in Thrombosis and Hemostasis Disorders: A Literature Review

J. Hews-Girard[1], C. Guelcher[2], J. Meldau[3], E. McDonald[4], F. Newell[5]

[1]University of Calgary, Foothills Hospital, Southern Alberta Rare Blood and Bleeding Disorder Comprehensive Care Program, Calgary, Canada, [2]Center for Cancer and Blood Disorders, Children's National Health System, Hemostasis and Thrombosis Program, Washington, United States, [3]Children's National Medical Center, Washington, United States, [4]McMaster University/Hamilton General Hospital, Critical Care Research, Hamilton, Canada, [5]University of Melbourne/The Royal Children's Hospital Melbourne, Department of Nursing and Paediatrics, Melbourne, Australia

Background: Prior work in the area of patient education has identified the importance of using learning theory and educational models to develop and deliver content that will result in improved patient outcomes. Current literature appears to focus on implementation and evaluation of teaching strategies without identifying underlying educational principles.

Aims: To identify principles of education being used to plan and deliver patient education in the field of hemostatic and thrombotic disorders.

Methods: PubMed and CINHAL were searched using the terms 'patient education' and 'hemostasis OR thrombosis'. Articles published in English from 2007-2015 were sought; 46 citations were found. Eight citations were excluded due to duplication, lack of abstract, inapplicable content; six did not meet inclusion criteria. The remaining articles were reviewed; information regarding educational principles used, disorder and learners was extracted.

Results: 26 articles evaluated the impact of educational interventions or information delivery on patient adherence, knowledge, and skills without identifying specific educational theories or models. Of these, 10 evaluated the effect of patient-directed educational interventions on patient-related outcomes; nine reported improvement. Three articles referenced educational theory/models in their development of patient education; however, they lacked the evaluation component. Only one article was specific to the population of interest.

Conclusions: While literature discussing the impact of specific educational strategies and interventions on patient outcomes is prevalent, discussion tying the use of educational theory and principles to changes

in these outcomes is lacking. Also lacking is literature connecting specific educational principles to the development and delivery of patient education in disorders of hemostasis and thrombosis. Further research is needed to identify the most effective theoretical framework for developing, delivering and evaluating patient education in this field.

POSTERS

ATHEROTHROMBOSIS & STROKE

PB 001 | ErbB Signaling Gene EGFR Centric Network Plays an Important Role in Coronary Artery Disease

M. Ghatge[1], J. Nair[2], A. Sharma[3], R.K. Vangala[4]

[1]Manipal Univeristy/Thrombosis Research Institute, Proteomics and Coagulation Unit, Bangalore, India, [2]Thrombosis Research Institute, Mary and Gary Weston Functional Genomics Unit, Bangalore, India, [3]Manipal University/Thrombosis Research Institute, Proteomics and Coagulation Unit, Bangalore, India, [4]Thrombosis Research Institute, Proteomics and Coagulation Unit, Bangalore, India

Background: Coronary Artery Disease (CAD) is a major cause of death in India and more so in young people. Combinatorial and integrative approaches to evaluate pathways and genes to gain a better understanding and potential biomarkers for risk assessment are the need of the hour.

Aims: This study aims at identifying candidate proteins associated with coronary artery disease (CAD) based on network approach.

Methods: CAD related genes were selected from CADgene database and were used for identifying common gene ontology terms across the CAD functional categories. The genes that are part of common gene ontology (GO) and disease ontology (DO) formed the seed gene for network construction. The network constructed was analyzed based on topological parameters to finally come up with backbone network and the hub molecules. Finally, pathway enrichment analysis and validation in laboratory settings on samples were carried out. The hub gene was validated on (n= 682 samples).

Results: The 608 genes from the CADgene database version 2.0 classified into 12 functional classes representing the atherosclerotic disease process were analyzed. GO homology analysis resulted into 8 GO terms. 29 CAD genes obtained after GO and DO analysis were used as a seed set for the network construction using STRING v9.1. Based on node degree, betweenness centrality and eigenvector, we identified EGFR gene as the central hub. Logistic regression analysis suggested that increased EGFR levels have 3 fold higher risk of CAD (OR 3.51(95%CI 1.96-6.28); p< 0.001), upon adjustment with hypertension, diabetes, and smoking. Furthermore, a unit increase in EGFR levels increased the risk by 2 fold for stable angina (OR 2.58 [95%CI 1.25-5.33]; p=0.01) and 3.8 fold for myocardial infarction (OR 3.82 (95%CI 1.94-7.52); p=0.001) after adjustment.

Conclusions: Our integrative analysis using gene ontologies homology across different functional classes and network analysis can help in understanding disease pathways and identify biomarkers of complex diseases.

PB 002 | Immunization with Recombinant Atherosclerosis Vaccine Candidate (AHhHmR) Does Not Promote Melanoma Lung Metastasis in B6;129S-Ldlrtm1herApobtm2sgy/J Mice

M. Xia[1], V. Endresz[2], I. Lantos[2], K. Buzas[3], X. Lu[1]

[1]Thrombosis Research Institute, London, United Kingdom, [2]University of Szeged, Szeged, Hungary, [3]Biological Research Centre, Szeged, Hungary

Background: Tregs play an important role in the progress and metastasis of lung cancer and are considered as biomarkers for prediction and recurrence of lung cancer. On the other hand, Tregs have a protective role in the progression of atherosclerosis through their expansion induced by immunization with an atheroprotective antigen. Whether immunization with such antigen has a promoting effect on melanoma metastases in the lungs remains unclear.

Aims: To assess whether immunization with an atherosclerosis vaccine candidate, recombinant antigen AH^hH^mR containing epitopes derived from Apolipoprotein B (ApoB), heat shock protein 60 (HSP60) s, and complement component 5a receptor (C5aR) has an effect to promote lung metastases of melanoma cells (B16F1) in B6;129S-*Ldlr*^{tm1Her}*Apob*^{tm2Sgy}/J mice.

Methods: 5-6-week old B6;129S-*Ldlr*^{tm1Her}*Apob*^{tm2Sgy}/J mice were immunized with AH^hH^mR recombinant antigen containing epitopes derived from ApoB (AA688-707) designated as epitope A, human HSP60 (AA303-312) as H^h, mycobacterium HSP60 (AA253-268) as H^m and human C5aR (AA1-31) as R which were incorporated into a dendroaspin (den) scaffold. Melanoma cells (B16F1, $1x10^6$ in 100 µl PBS) were inoculated intravenously (tail vein) 8 weeks after the initiation of immunization. Lungs were dissected on day 12 after melanoma cell inoculation. Photos of lungs were taken, and the number of metastases was counted.

Results: The number of metastases detected in the lungs of AH^hH^mR-immunized mice was 54 ± 25 when compared to that in either AGD-den (scaffold antigen)-immunized control (63 ± 18) or in non-immunized control (93 ± 13) mice.

Conclusions: Our *in-vivo* study suggests that immunization of mice with the antigen (AH^hH^mR) did not promote the development of melanoma cell metastasis in the lung, therefore, the paradigm that Tregs are disadvantageous for the control of malignancies remains under investigation.

PB 003 | Pro-inflammatory and Pro-thrombotic Phenotype of Spontaneously Differentiated Human Monocyte-derived Macrophages in Coronary Heart Disease Patients: Implications for Plaque Morphology and Activity

S. Eligini[1], N. Cosentino[1], S. Fiorelli[1], F. Fabbiocchi[1], G. Niccoli[2], H. Refaat[2], M. Camera[1,3], G. Calligaris[1], S. De Martini[1], A. Bonomi[1], F. Veglia[1], F. Fracassi[2], F. Crea[2], G. Marenzi[1], E. Tremoli[1]

[1]Centro Cardiologico Monzino IRCCS, Milano, Italy, [2]Institute of Cardiology, Catholic University of the Sacred Heart, Rome, Italy, [3]Università degli Studi di Milano, Dipartimento di Scienze Farmacologiche e Biomolecolari, Milano, Italy

Background: The behavior of the *in vitro* differentiation of human monocyte-derived macrophages (MDMs), a representative model of macrophage infiltrating tissue, has not been explored in coronary artery disease (CAD) patients yet.

Aims: To compare the morpho-phenotype of MDMs obtained from CAD patients and healthy subjects and to assess the association between MDM profile and coronary plaque features evaluated by intravascular optical coherence tomography (OCT).

Methods: 90 CAD patients undergoing coronary angiography (stable angina or acute myocardial infarction, NSTEMI and STEMI) and 25 healthy subjects were enrolled. In 50 CAD patients OCT assessment was also performed. MDMs were obtained after differentiation (7 d, 10% autologous serum) of monocytes isolated from peripheral blood.

Results: The morphological analysis of MDMs showed a higher prevalence of round MDMs compared to spindle MDMs in CAD patients (43.94%±14.16 vs 27.22%±12.69, p< 0.001), while in healthy subjects the prevalence of these two morphotypes was similar (38.36%±6.6 vs 36.36%±7.12). MDMs of CAD patients showed higher tissue factor (TF) levels (p< 0.05), with a peak in NSTEMI and STEMI. Accordingly, MDMs of CAD patients showed a reduction in the lag time and in the time to peak, with respect to healthy subjects, with no change on endogenous thrombin potential. MDMs of CAD patients showed lower efferocytosis and lower transglutaminase-2 levels. At OCT, patients with a higher round MDMs prevalence exhibited more frequently a lipid rich plaque (p< 0.002), a thin cap fibroatheroma (p< 0.0005), a greater intra-plaque macrophage accumulation (p< 0.02), and a ruptured plaque (p< 0.0005). TF levels in round and spindle MDMs correlated with the presence of ruptured plaque, thrombus, and intra-plaque macrophages.

Conclusions: MDMs from CAD patients show a morpho-phenotypic heterogeneity with a prevalence of round MDMs displaying pro-thrombotic and pro-inflammatory properties. The MDM profile might help in predicting plaque composition and activity.

PB 004 | Regression of Atherosclerosis in ApoE Null Mice through Targeting Coagulation Factor Xa

J.J. Posthuma[1], J.J.N. Posma[1], R. van Gorp[2], A. Jaminon[2], R. van Oerle[1], S. Heitmeier[3], L.J. Schurgers[2], H. ten Cate[1], H.M.H. Spronk[1]

[1]*Cardiovascular Research Institute Maastricht, Maastricht University, Laboratory for Clinical Thrombosis and Haemostasis, Maastricht, The Netherlands,* [2]*Cardiovascular Research Institute Maastricht, Maastricht University, Biochemistry, Maastricht, The Netherlands,* [3]*Bayer Pharmaceutics, Drug Discovery, Wuppertal, Germany*

Background: Coagulation proteases such as thrombin and factor Xa (FXa) may regulate pro-atherosclerotic mechanisms mediated through protease-activated receptors (PARs). Whereas experimental thrombin or factor Xa inhibition reduced atherosclerosis, the effects of targeting FXa on pre-existing atherosclerotic plaques are unknown.

Aims: We investigated the effects of direct FXa inhibition by rivaroxaban on pre-existing atherosclerotic plaques in ApoE$^{-/-}$ mice

Methods: Female ApoE$^{-/-}$ mice (age: 8-9 weeks, n=10/group) received western type diet (WTD) for 14 weeks, followed by either continuation with either WTD or WTD supplemented with rivaroxaban (1.2mg/g) for 6 weeks. Quantitative and qualitative analysis of the aortic arch was performed by immunohistochemical stainings. Data were analyzed using a Mann-Whitney U test. A 2-tailed p< 0.05 was considered as statistically significant.

Results: Treatment with rivaroxaban induced a regression of pre-existing plaques in the aortic arch (-17%, p< 0.05). Moreover, plaque vulnerability upon FXa inhibition was reduced, as reflected by reduced macrophage infiltration (-39%, p< 0.05), enhanced collagen (+38%, p< 0.05) and diminished necrotic core (-31%, p< 0.05). These findings were accompanied by increased number of vascular smooth muscle cells (+22%, p=0.02) and reduced levels of MMP9 (-35%, p=0.03) and MMP13 (-50%, p=0.0009). In addition, expression of PARs and their activators, thrombin and FXa was diminished.

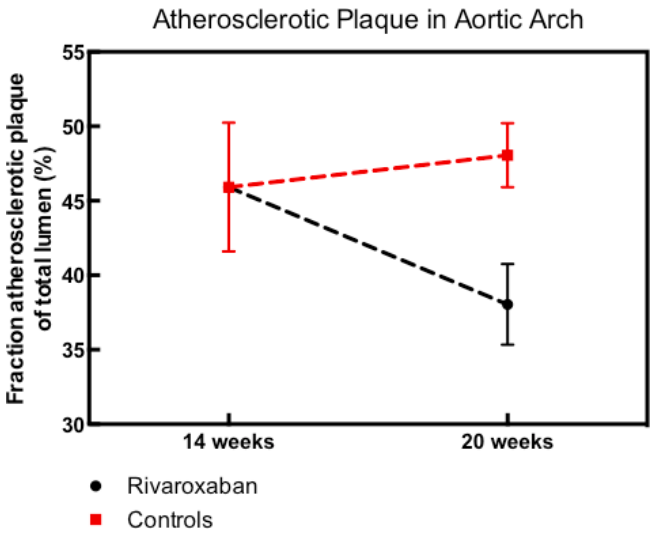

FIGURE 1 Regression of pre-existing atherosclerotic plaques in the aortic arch of ApoE null mice

Conclusions: Pharmacological inhibition of FXa induced regression of pre-existing atherosclerotic lesions and enhanced plaque stability in ApoE$^{-/-}$ mice. These findings are possibly mediated through reduced activation of PARs. Whether direct inhibition of FXa might be a promising treatment of atherosclerosis in humans needs to be elucidated in further studies.

PB 005 | The Effect of Factor XIII on the Proliferation and Migration of Vascular Smooth Muscle Cells

R. Bogáti[1], É. Katona[1], A.H. Shemirani[1], E. Balogh[2], V. Jeney[2], L. Muszbek[1]

[1]*University of Debrecen, Division of Clinical Laboratory Science, Department of Laboratory Medicine, Debrecen, Hungary,* [2]*University of Debrecen, Department of Internal Medicine, Debrecen, Hungary*

Background: Plasma factor XIII (pFXIII) is a heterotetramer of FXIII-A and FXIII-B subunits. The cellular form (cFXIII), present in platelets,

monocytes, macrophages, osteoblasts and chondrocytes, is a dimer of FXIII-A. pFXIII plays an important role in blood coagulation, wound healing and maintaining pregnancy. cFXIII has been implicated in phagocytosis, cell differentiation, and extracellular matrix formation. Its role in mineralization has also been suggested. In atherosclerotic plaque vascular smooth muscle cells go through osteoblastic transformation.

Aims: 1/ To investigate if cFXIII is expressed in human aorta derived smooth muscle cells (HAoSMC) during osteoblastic transformation. 2/ To investigate the effect of extracellular FXIII on HAoSMC.

Methods: Osteoblastic transformation of HAoSMC was induced by Pi and Ca^{2+}. FXIII-A in cell lysate was measured by ELISA and Western Blot. Cell proliferation and migration were measured by EZ4U or CCK-8 cell proliferation assay kits and CytoSelect 24-Well Wound Healing Assay, respectively. Cell migration was monitored by Juli Stage Real Time Cell History Recorder. Thrombospondin-1 levels in the medium and in the cell lysate were measured by ELISA, its mRNA level was estimated by RT-qPCR.

Results: FXIII-A could not be detected in differentiated HAoSMCs. Activated recombinant cFXIII (rFXIIIa), but not the non-activated form, increased cell proliferation in concentration dependent manner. Its effect in the wound healing assay was even more considerable. The time to reach 30% and 80% confluence was decreased to less than 1/7 and 1/3 by the addition of 20 µg/mL cFXIIIa. In parallel a highly significant (67%) decreases in thrombospondin-1 concentration in the medium and a 2.5-fold increase in the cells were observed. Thrombospondin-1 mRNA did not change significantly.

Conclusions: During the course of plaque hemorrhage FXIII can be activated and exert its effect on vascular smooth muscle cells. This effect might be important in the pathogenesis of atherosclerotic plaques.

PB 006 | Insights Into the Genetic Architecture of Coronary Artery Disease in Asian Indians

J. Nair, J. Shanker

Thrombosis Research Institute, Bangalore, India

Background: Genetic approaches have identified numerous loci associated with coronary artery disease (CAD). However, most of these studies have been carried out on Caucasian population with very little information available about their association in Asian Indians. With the background of Asian Indians being high predisposed to CAD at relatively younger age refers to certain uniqueness in the genetic architecture.

Aims: The study aims at understating the genetic association of most widely studied variants in Asian Indian cohort.

Methods: The 82 potential SNPs that showed association with CAD based on literature evidence were selected for genotyping by Taqman assay in 500 CAD cases and 500 age and gender matched controls. The significant physical interaction among proteins encoded by the genes in these loci was analysed with the help of DAPPLE (Disease Association Protein-Protein Link Evaluator) algorithm. Enrichment analysis to identify the overrepresented pathways was carried out using ClueGO.

Results: The most significant associationed SNPs in Asian Indians belonged to the well-established CAD risk locus on the 9p21.3 region, KIF6, CNNM2 and the CELSR2-PSRC1-SORT1 gene cluster. The network generated by DAPPLE revealed 9 genes to be highly connected and formed two main clusters. These gene clusters mainly included lipid associated genes and cell-cycle regulating genes. The enrichment analysis using ClueGO also revealed ‚positive regulation of response to external stimuli' and ‚regulation of plasma lipids and lipoproteins' to be highly represented.

Conclusions: This analysis showed highly replicated loci, 9p21.3 to be associated with CAD in Asian Indians too. In addition SNPs belonging to KIF6 (rs20455), CNNM2 (rs12413409) and the CELSR2-PSRC1-SORT1 gene cluster (rs599839) also showed association with CAD.

PB 007 | Oral Anticoagulants as Modulators of Arterial Calcification

R. van Gorp[1,2], A. Jaminon[3], M. Bauwens[4], J. Bucerius[4], V. Brandenburg[5], W. Jahnen-Dechent[6], H.M.H. Spronk[7], C.P. Reutelingsperger[7], L.J. Schurgers[7]

[1]Maastricht University / Cardiovascular Research Institute Maastricht (CARIM), Biochemistry, Maastricht, The Netherlands, [2]Nattopharma ASA, Hovik, Norway, [3]Maastricht University / Cardivascular Research Institute Maastricht (CARIM), Maastricht, The Netherlands, [4]Maastricht University / Cardivascular Research Institute Maastricht (CARIM), Radiology and Nuclear Medicine, Maastricht, The Netherlands, [5]University Hospital of the RWTH Aachen, Cardiology, Aachen, Germany, [6]Helmholtz-Institute, RWTH Aachen, Aachen, Germany, [7]Maastricht University / Cardivascular Research Institute Maastricht (CARIM), Biochemistry, Maastricht, The Netherlands

Background: Vitamin K antagonists (VKA) have the undesired side effect to accelerate atherosclerotic plaque calcification. Dabigatran-etexilate (DE) is an oral anticoagulant and alternative for VKA by directly inhibiting thrombin. However, effects of DE on plaque calcification remain unknown.

Aims: The aim of this study is to compare effects of warfarin and DE on intimal calcification in an $apoE^{-/-}$ mouse model of atherosclerosis. Additionally, the prospective of vitamin K (MK7) supplementation was investigated.

Methods: Female $apoE^{-/-}$ mice received Western Type Diet (WTD; control) or WTD supplemented with either warfarin (3mg/g) or DE (7,5mg/g) for 20 weeks. Additionally, mice received the first 6 weeks WTD supplemented with warfarin followed by 14 weeks of WTD alone or supplemented with MK7 (0,1 mg/g), DE or DE with MK7. Some mice received intravenous NaF^{18} and after 30 minutes were imaged using PET and CT-scan. After 20 weeks, mice were sacrificed and aortic arches dissected, paraformaldehyde-fixed and analyzed by µCT and immunohistochemistry.

Results: Long-term warfarin treatment exacerbates atherogenesis by increased plaque size and calcification compared to DE. Moreover,

warfarin promotes micro-calcification (in 66% of mice) compared to DE (in 16% of mice). Plaque calcification was accompanied by loss of active matrix Gla protein, a pivotal vitamin K-dependent calcification inhibitor, and increased osteochondrogenic differentiation. Furthermore, supplementation of WTD or DE with MK7 reduced active calcification of the atherosclerotic plaque.

Conclusions: In contrast to DE, long-term warfarin treatment aggravates atherogenesis and intimal calcification caused by loss of calcification inhibition. Furthermore, MK7 supplementation reduced active calcification in atherosclerotic plaques. Combining DE with MK7 might be beneficial by decreasing thrombosis tendency and improving vascular vitamin K status and subsequent inhibition of vascular calcification.

PB 008 | Involvement of PAR Signaling in Thrombin Generation on Vascular Smooth Muscle Cells from Abdominal Aortic Aneurysms

M. Didelot[1], J.B. Michel[2], P. Lacolley[1], V. Regnault[1]

[1]UMRS 1116, DCAC, Vandoeuvre les Nancy, France, [2]UMRS 1148, LVTS, Paris, France

Background: In contrast to abdominal aortic aneurysm (AAA), aneurysms of the thoracic ascending aorta (TAA) are not associated with a mural thrombus. However, we have previously shown the presence of prothrombin in the media of TAA (Touat et al, ATVB 2009).

Aims: To determine (i) whether thrombin generation at the surface of VSMCs is increased in AAA, (ii) its dependence with respect to the etiology of the aneurysm, and (iii) the contribution of $a_v b_3$ integrins as a receptor for prothrombin and PAR activation to thrombin generation and thrombin-induced proliferation.

Methods: Primary cultures of SMCs seeded on fibronectin were prepared from human biopsies of TAA (n=6) and AAA (n=6). Thrombin generation was measured by thrombography in the presence of healthy plasma or plasma deficient in prothrombin, factor X or factor VII.

Results: In the presence of prothrombin deficient plasma, similar low levels of thrombin are formed on the 3 types of VSMCs indicating the presence of prothrombin within the media. There is no formation of thrombin in plasma deficient for factor VII or X. The synthesis of endogenous prothrombin has been confirmed by Western blot. There was no difference in $a_v b_3$ integrin expression between the different VSMCs. In presence of healthy plasmas, thrombin generation was significantly higher (30% increase) on VSMCs from AAA compared with VSMCs from TAA. Inhibition of thrombin generation by an antagonist of PAR-1 was more pronounced in VSMCs from AAA than from TAA without significant difference in the expression of PAR-1. This effect was associated with an increased proliferation of VSMCs from AAA in response to thrombin.

Conclusions: These results demonstrate an increase in thrombin generation on VSMCs from AAA only in the presence of plasma, which is likely mediated by PAR signaling. This new contribution of PAR in thrombin generation is also supported by an increased proliferative index.

PB 009 | Commensal Microbiota Contribute to Atherosclerotic Plaque Formation and Thrombogenicity in the Carotid Artery of Ldlr-/- Mice

S. Jäckel[1,2], K. Kiouptsi[1], E. van der Vorst[3], C. Neideck[3], M. Kuijpers[4], K. Jurk[1], S. Ascher[1], S. Subramaniam[1], D. Tsiantoulas[5], J. Heemskerk[4], C.J. Binder[5,6], C. Weber[3,7], Y. Döring[3,7], C. Reinhardt[1,2]

[1]Center for Thrombosis and Hemostasis (CTH), University Medical Center Mainz, Mainz, Germany, [2]German Center for Cardiovascular Research (DZHK), Partner Site RheinMain, Mainz, Germany, [3]Institute of Cardiovascular Prevention, Department of Medicine, Ludwig-Maximilians-University Munich, Munich, Germany, [4]Cardiovascular Research Institute Maastricht, Maastricht University, Department of Biochemistry, Maastricht, The Netherlands, [5]Department of Laboratory Medicine, Medical University of Vienna, Vienna, Austria, [6]Center for Molecular Medicine, Austrian Academy of Sciences, Vienna, Austria, [7]German Center for Cardiovascular Research (DZHK), Partner Site Munich Heart Alliance, Munich, Germany

Background: Atherosclerotic plaque development depends on chronic inflammation in the artery wall, fueled by innate immune signaling pathways. The commensal microbiota is promoting low-grade inflammation and was recently linked to cardiovascular disease risk. Although implicated in atherogenesis, the role of the commensal microbiota in atherosclerosis and atherothrombosis is unexplored.

Aims: To analyze the role of commensal microbiota in atherosclerosis and plaque thrombogenicity.

Methods: We kept Ldlr-/- mice for 16 weeks on an atherogenic Western diet under germ-free isolator conditions (GF) and under SPF conditions (CONV-R). Blood cell counts, lipoprotein profile, cholesterol levels, plasma cytokines, and plasma microvesicles were determined. Plaque area of GF and CONV-R Ldlr-/- mice was histologically determined in the aortic arch, the aortic root, and the carotid artery. Thrombus formation following ultrasound-induced plaque rupture was quantified by intravital microscopy.

Results: Atherogenic Western diet fed GF Ldlr-/- mice showed significantly less atherosclerotic plaque area in the aortic arch and the common carotid artery compared with CONV-R Ldlr-/- controls. Similar to Ldlr-/- mice that were fed a normal chow diet, white blood cell counts were reduced in the GF state, while platelet numbers were unaltered. In GF Ldlr-/- mice, a reduction in the quantity of microvesicles and VLDL was observed, but total plasma cholesterol was not different. The plasma cytokine profile showed reduced levels of pro-inflammatory CCL7 and CXCL1 in GF Ldlr-/- mice, whereas T-cell related IL9 and IL27 were elevated. Following ultrasound-induced rupture of the common carotid artery plaque, the thrombus area was significantly reduced in GF Ldlr-/- relative to CONV-R Ldlr-/- mice.

Conclusions: Our results identify the commensal microbiota as an environmental factor that not only increases inflammatory markers and plaque size, but also augments thrombogenicity of ruptured plaques in atherosclerotic Ldlr-/- mice.

PB 010 | C3-Complement Activation is Found in Human Severe Atherosclerotic Plaques

T. Padro, M. Garcia-Arguinzonis, A. Deya, L. Badimon

Cardiovascular Research Center (CSIC-ICCC) and Biomedical Research Institute Sant Pau (IIB-Sant Pau), Barcelona, Spain

Background: Innate-immunity is a major component in the atherothrombotic process and non-structural components of the vascular extracellular matrix (ECM) are thought to regulate progression of the atherosclerotic lesions. The C3-System of the complement (C3-S) is an inflammatory pathway that has been found increased at the onset of acute myocardial infarction. The C3-S is the trigger of a cascade regulated by components as the Factor-H / CFHR family.
Aims: To investigate whether C3-S changes are found in the ECM of human atherosclerotic plaques of different severity.
Methods: Segments of human aorta with advanced atherosclerotic lesions (AAT) and without atherosclerosis (nAT) were sequentially extracted to obtain the ECM protein-fraction. The proteomic profile was analyzed by 2D-electrophoresis and mass-spectrometry. Protein and mRNA levels were analyzed by western-blot and RT-PCR. Human vascular smooth muscle cells (hVSMC) in culture were also investigated.
Results: The ECM of human aortas is enriched in active components of the C3-S with a significantly different proteomic-signature in ATT. C3 signal was more abundant in ECM of ATT-arteries and western blot analysis demonstrated a 3-fold increase in its active cleaved product C3b ($p< 0.05$) compared with nAT-ECM. C3 is expressed in hVSMC as demonstrated by RT-PCR and significantly upregulated (1.7-fold) in cells exposed to aggregated-LDL (100 µg/ml). In addition, CFHR1 and CFHR5 increased 2.5- and 3.8-fold, respectively in ATT-arteries. In contrast, Factor-H consistently detected in ECM, did not differ between ATT and nAT.
Conclusions: Our results demonstrated for the first time the presence and differential abundance of active products of C3-System in the ECM of advanced plaques, suggesting the C3-complement pathway as a novel player in vascular remodeling and in the progression of advanced human atherosclerotic lesions.

PB 011 | Relationship of Elevated Levels of Visfatin with Insulin Resistance and Prothrombotic State in Coronary Artery Disease

O. Korzh, E. Lavrova, O. Pavlova

Kharkiv Medical Academy of Postgraduate Education, Kharkiv, Ukraine

Background: Recent data suggest that various adipocytokines are dysregulated in coronary artery disease and might be of pathophysiological and prognostic significance in cardiovascular complications. Visfatin has been linked to obesity, type 2 diabetes mellitus, inflammation and atherosclerosis.
Aims: The purpose of this study was to examine the relationship between visfatin and prothrombotic factors in patients with coronary artery disease.
Methods: We consecutively evaluated 223 patients, who presented with coronary artery disease. We measured anthropometric and biochemical variables including renal function, plasma lipid profile, fasting glucose, insulin and C-peptide, PAI-1, prothrombin fragment 1+2 (F1+2), and D-dimer as markers of a prothrombotic state, and C-reactive protein (CRP) as a marker of proinflammatory state. The Homeostatic Model Assessment (HOMA) index was calculated as an index of sensitivity to insulin.
Results: Coronary artery disease patients had significantly higher levels of visfatin, D-dimer, PAI-1, F1+2 compared with healthy men. On univariate regression analysis, visfatin was directly related with PAI-1 ($r = 0.173$, $P< 0.05$) and duration of diabetes ($r = 0.141$, $P< 0.05$), BMI ($r = 0.214$, $P < 0.01$), HOMA index ($r = 0.347$, $P < 0.001$), CRP ($r = 0.375$, $P < 0.001$), triglycerides ($r = 0.193$, $P< 0.01$) and LDL-cholesterol ($r = 0.190$, $P < 0.01$), and inversely related with HDL-cholesterol ($r = -0.179$, $P< 0.01$). A multivariate analysis indicated that visfatin levels are independently related with D-dimer
(β=0.203, $P< 0.01$), PAI-1 and duration of disease (respectively: β=0.195 and β=0.157, both $P< 0.05$), LDL cholesterol ($\beta = 0.164$, $P< 0.05$), HOMA index ($\beta = 0.236$, $P< 0.001$), and CRP (β=0.278, $P< 0.001$).
Conclusions: These results indicate that a prothrombotic state is associated with elevated visfatin level and duration of disease, insulin resistance and a proinflammatory status in coronary artery disease. Intriguingly, high plasma level of adipokine seem to modulate platelet activation.

PB 012 | Parameters of Complete Blood Count Do Not Predict On-treatment Platelet Reactivity in Acute Coronary Syndrome Patients

L. Bonello[1], M. Laine[1], V. Baccini[2], C. Frere[2]

[1]Assistance Publique-Hôpitaux de Marseille, Department of Cardiology, Marseille, France, [2]Assistance Publique-Hôpitaux de Marseille, Department of Haematology, Marseille, France

Background: A large body of evidence clearly demonstrated that persistent high on-treatment platelet reactivity (HTPR) is associated with a higher risk for adverse cardiovascular events in acute coronary syndrome (ACS) patients. Several parameters of complete blood count (CBC) including the mean platelet volume (MPV), the platelet-lymphocyte ratio (PLR) and the neutrophil-lymphocyte ratio (NLR) were also demonstrated to correlate with clinical outcomes in ACS patients.
Aims: To investigate whether CBC parameters correlate with HTPR and could independently predict HTPR as compared with the well established vasodilator stimulated phosphoprotein platelet reactivity index (VASP-PRI) in ACS patients treated with P2Y12 receptor antagonists.
Methods: We retrospectively reviewed patients who underwent percutaneous coronary intervention (PCI) for the treatment of an ACS and who were treated with dual antiplatelet therapy between January 2014 and August 2016.
Results: Among patients that underwent PCI during this period, 565 patients had a pre procedural CBC and were further included in the analysis. Among these 565 patients, 426 (75.4 %) were men and 139 (26.6%) were women. The median age was 65 years. One hundred twenty four out of 565 patients (21.9%) presented a HTPR. Neither MPV, nor PLR, nor NLR were correlated with the VASP-PRI (r=0.029, p=ns; r=0.025, p=ns; r=-0.35, p=ns respectively). ROC curve of MPV, PLR and NLR for

predicting HTPR found areas under the curve close to 0.5 (0.528; 95%CI, 0.486-0.570 for MPV; 0.542; 95%CI, 0.500-0.584 for PLR; 0.516; 95%CI, 0.474 -0.558 for NLR) representing a worthless test for predicting HTPR. The patients were further divided into quartiles based on MPV, PLR and NLR. Rates of patients with HTPR were determined in all the quartiles, and we found no difference in rates of patients with HTPR between quartiles of MPV, PLR or NLR for any of these CBC parameters.

Conclusions: In our study, MPV, PLR and NLR do not predict HTPR in ACS patients undergoing PCI.

PB 013 | Impairment of Weight Gain and Lipoprotein Lipase Mediated-triglyceride Clearance in Integrin β3 (CD61) Deficient Mice

B. Xiao[1,2], J. Mao[1], W. Zhang[1], Z. Ruan[1], X. Shi[1,3], X. Xi[1]

[1]*Ruijin Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, State Key Laboratory of Medical Genomics, Shanghai Institute of Hematology, Collaborative Innovation Center of Hematology, Shanghai, China,* [2]*Shanghai Jiao Tong University, School of Life Science and Biotechnology, Shanghai, China,* [3]*Affiliated Hospital of Jiangsu University, Department of Hematology, Zhenjiang, China*

Background: CD61-involved platelet function is implicated in atherosclerosis. CD61 deficiency causes platelet dysfunction and promotes atherosclerosis for which hyperlipidemia is an independent risk factor. Previous studies showed that the CD61 polymorphisms were associated with the plasma triglyceride (TG) level, and the CD51/61 blockade inhibited adipogenesis. However, the regulatory mechanisms for CD61 in lipid metabolism have yet to be established.

Aims: To better understand the mechanisms underlying the pro-atherogenic potential of CD61 gene expression focusing on the lipid metabolism in the CD61-deficient (CD61KO) mice.

Methods: The mouse body weight, tissues weight, body composition and physiological parameters were measured on chow diet. Plasma and hepatic TG levels, and the tissue and plasma lipoprotein lipase (LPL) expression and activity were assayed with established protocols. Statistical significance was determined using an unpaired two-tailed Student *t* test. The animal protocols were reviewed and approved by the local authorities to comply with the Declaration of Helsinki.

Results: The CD61KO mice exibited a weight loss (Fig. 1A) and less fat mass (Fig. 1B-C) together with an increased energy expenditure (Fig. 1D-E) and unaltered food consumption. Notably, plasma TG was significantly elevated (Fig. 2A), probably ascribable to an impaired TG clearance (Fig. 2B-D). An abnormal distribution of LPL (Fig. 2E-F, 2H) further suggested that plasma TG trafficking into peripheral tissues might be interrupted. On the other hand, the mRNA expression (Fig. 2G) and activity of LPL were found in the normal range (Fig. 2I-J).

Conclusions: The impaired TG clearance in CD61KO mice might be responsible for weight loss, reduction of the adipose tissues and elevated plasma TG level. The enhanced LPL expression in adipose tissues might provide a plausible explanation for this phenotype. Data indicate that CD61 contributes to the development of atherosclerosis most likely through regulating the key pathways of lipid metabolism.

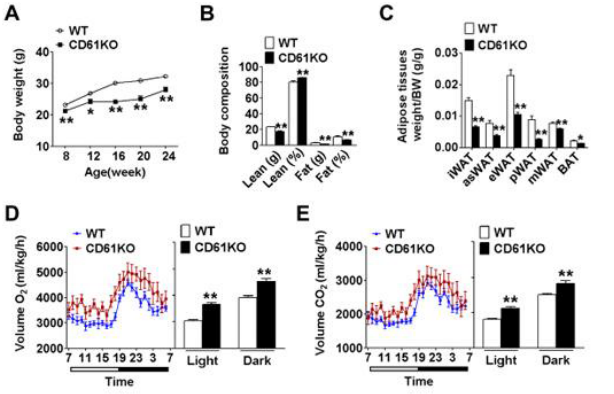

Figure 1. CD61KO results in body weight and fat mass loss, and increase of energy expenditure on normal chow diet (NCD).

(A) Body weight curves of age-matched male WT and CD61KO mice.

(B) Absorptiometry for fat and lean masses of male WT and CD61KO.

(C) Weight of different adipose tissues (iWAT (inguinal adipose tissue), asWAT (anterior subcutaneous adipose tissue), eWAT (Epididymis adipose tissue), pWAT (perirenal adipose tissue), BAT (brown adipose tissue)) after 24 weeks of NCD.

(D-E) Oxygen (O_2) consumption (D) and carbon dioxide (CO_2) release (E) during light (left) and dark phases (right) of mice with NCD for 16 weeks.

Data are presented as means ± SEM (n=8～10). $^*P < 0.05$, $^{**}P < 0.01$ *vs* WT.

FIGURE 1 CD61KO results in body weight and fat mass loss, and increase of energy expenditure on normal chow diet (NCD)

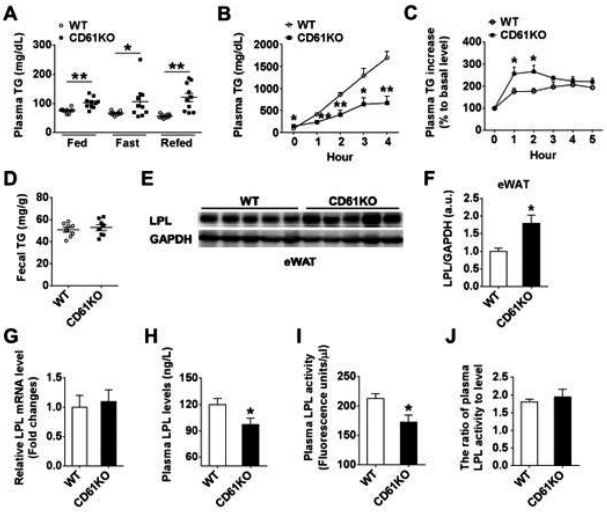

Figure 2. CD61 deficiency impairs plasma TG clearance owing to the abnormal distribution of LPL.

(A) Plasma TG level in NCD fed mice starting at the age of 10 weeks. (Fed, NCD; Fast, fasted overnight; Refed, refed NCD for 3 hour after an overnight fast).

(B) Hepatic VLDL-TG production. Plasma TG was measured after administration of poloxamer407 in mice fasted overnight.

(C) Intragastric lipid loading test. Plasma TG level at indicated time after a 15ml/kg olive oil gavage in overnight-fasted mice.

(D) Fecal TG contents were measured in NCD feeding mice.

(E-F) Representative immunobloting (E) and quantitative (F) data of LPL in eWAT of mice fed with NCD for 24 weeks.

(G) Relative LPL mRNA levels by qPCR normalized to GAPDH in eWAT of mice fed with NCD for 24 weeks.

(H-J) Plasma LPL levels (H), activity (I) and the activity over protein levels (J) were measured in mice after fasted overnight starting at 20 weeks age.

Data are represented as means ± SEM (n=5～10) . $^*P < 0.05$, $^{**}P < 0.01$, *vs* WT.

PB 014 | Platelet Acetyl-CoA Carboxylase Phosphorylation: A Potential Marker for Atherothrombotic Coronary Artery Disease

S. Kautbally[1], S. Lepropre[1], A. Lerigoleur[1], B. Gerber[1], J. Kefer[1], D. Castanares[1], S. Eeckhoudt[2], C. Oury[3], J.-L. Vanoverschelde[1], L. Bertrand[1], S. Horman[1], C. Beauloye[1]

[1]*Université Catholique de Louvain, Pole of Cardiovascular Research, Brussels, Belgium,* [2]*Cliniques Universitaires Saint Luc, Laboratory of Hematology, Brussels, Belgium,* [3]*University of Liège, GIGA-Cardiovascular Sciences, Liege, Belgium*

Background: In human platelets, Acetyl-CoA Carboxylase (ACC), the downstream specific substrate of the AMP-activated protein kinase, is mainly phosphorylated in response to thrombin compared to other platelet agonists. In clinical situation, such as coronary artery disease (CAD), associated with thrombin generation, ACC phosphorylation (P-ACC) can be an interesting marker of thrombin action on platelets.

Aims: In the current prospective clinical trial (ACCTHEROMA), we investigate platelet P-ACC as a marker of atherothrombotic CAD.

Methods: A total of 188 consecutive patients admitted for coronary angiogram were included from March 2015 to February 2016. Blood samples were drawn immediately after sheath insertion at the cath lab. Platelets were isolated and protein extracts were analysed by immunoblotting and electrochemiluminescence (ECLIA). CAD was assessed in all patients by coronary angiogram. Global atherosclerotic burden was evaluated by coronary (CAC Agatston score) and extra-coronary (Aortic- AoC score) calcification score on thoraco-abdominal scanner with prospective ECG-gating in a randomly selected subgroup of patients(n=68).

Results: Patients with demonstrated CAD (CAC Agatston score >100 and/or at least 1 vessel disease on the angiogram) have higher platelet P-ACC compared to non-CAD (p< 0,001). Quartile analysis of platelet P-ACC revealed a significantly higher proportion of patients (45%) with unstable CAD (acute coronary syndrome) in the 4th quartile (p=0, 01). More importantly, after adjusting for established cardiovascular risks factors, platelet P-ACC was an independent predictor of unstable CAD

(OR: 7.03, p=0,001). Likewise, ECLIA test shows significant correlation with immunobloting for platelet P-ACC analysis (p< 0,001).

Conclusions: Platelet P-ACC is a potential marker for screening patients with CAD at high ischemic risk. Optimizing ECLIA test for platelet P-ACC analysis seems to be a promising tool for future clinical studies. (ACCTHEROMA, NCT03034148).

PB 015 | Recombinant Atherosclerosis Vaccine Candidate Antigen (AHhHmR)-induced Tregs in B6;129S-Ldlrtm1herApobtm2sgy/J Mice Do Not Promote Melanoma Cell (MC) Proliferation

M. Xia[1], V. Endresz[2], I. Lantos[2], X. Lu[1]

[1]*Thrombosis Research Institute, London, United Kingdom,* [2]*University of Szeged, Szeged, Hungary*

Background: Atherosclerosis is an inflammatory disease in which plaque builds up inside the arteries. Natural regulatory T (nTreg) cells have a protective role in the progression of atherosclerosis. Atheroprotective antigen-induced specific regulatory T (iTreg) cells seem to provide more protection than nTreg. On the other hand, Treg can interfere with the function of anti-tumour immune effectors. However, whether the iTregs have a promoting effect on cancer cell growth remains unclear.

Aims: To assess whether atheroprotective antigen-induced Treg cells have an effect to promote MC proliferation when immunization with this antigen reduces atherosclerotic lesion through Treg expansion in B6;129S-*Ldlr*^{tm1her}*Apob*^{tm2sgy}/J mice.

Methods: Mice were immunized with atheroprotective antigen (AH^{h}H^{m}R) containing epitopes derived from Apolipoprotein B (A), human heat shock protein (HSP)60 (H^{h}), mycobacterium HSP60 (H^{m}) and complement component 5a receptor (R) which were incorporated into a dendroaspin (den) scaffold. Treg cells were isolated from the spleen of the immunized mice at the end of week 12 after being fed a high-fat diet and co-cultured with MCs for different time periods. The cell proliferation experiment was performed using Quick Cell Proliferation Assay Kit II (Abcam, Cambridge, UK), according to manufacturer's protocol.

Results: When the MCs were co-cultured with Treg cells, no effect on MC proliferation was detected in the presence of Treg cells either from control (non-immunized or AGD-den-immunized mice) or antigen-immunized mice. In addition, no significant difference expressed as OD values was observed when MCs were co-cultured with AH^{h}H^{m}R or AGD-den or with PBS as stimulators in a serum-free medium.

Conclusions: The results showed that Treg cells either from non-immunized or antigen-immunized mice have no direct proliferation promoting effect on the MCs in co-culture experiment, indicating that the notification of Tregs as disadvantageous for the control of malignancies should remain under investigation.

PB 016 | Peripheral Immune Changes and Persistence of Tolerance to Atherosclerosis by Immune Modulation with Multi-antigenic Construct in Apobtm2Sgy Ldlrtm1Her/J Mice

L.N.R. Thota[1], L. Mundkur[1], T. Ponnusamy[1], M. Ghatge[2], R.K. Vangala[2]

[1]*Thrombosis Research Institute, Molecular Immunology, Bangalore, India,* [2]*Thrombosis Research Institute, Proteomics & Coagulation, Bangalore, India*

Background: Inflammatory pathogenic T-cell response to self-antigens like LDL and heat shock proteins (HSP) as well as exogenous antigens from pathogens has been implicated in the initiation of an autoimmune response during atherogenesis. We have shown that oral administration of a multiantigen molecule expressing peptides derived from ApoB100, human HSP60 and outer membrane protein of Chlamydia pneumonia induces tolerance to peptides and controls the disease development.

Aims: To study the longevity of the tolerance by AHC molecule and changes in spleen cell population in response to immune therapy and its association with disease progression.

Methods: Apobtm2Sgy Ldlrtm1Her/J knockout mice (5-6 weeks) were given five oral doses of AHC molecule on alternate days to induce immune tolerance and fed on a high-fat diet (HFD) for 0,6,12,18,24 and 30 weeks with HFD (21.5%) alone fed mice as a control.

Results: Histological analysis revealed reduction in plaque at 6 (62%, p=0.002), 12 weeks (46%, p=0.001), 18 (23%, p=0.001) but later at 24 and 30 weeks confounds to 20% (p=0.001). We observed a significant increase in regulatory T cells in the spleen at 0 (60%, p=0.02), 6 (50%, p=0.02) and 12 weeks (43%, p=0.02) in corroboration with adaptive immunity to native LDL and Ox-LDL. We also observed lower levels of IFN-γ at 6 (42%, p=0.009), 12 (31%, p=0.015), 18 (33%, p=0.007) and 24 weeks (24%, p=0.015) and inflammatory Ly6C monocytes 21% at 6 week (p=0.02) and 70% at 12 week (p=0.005). The CD11b+CD11c+ were higher at 0 (46%, p=0.02), 6 (63%, p=0.028) and 12 weeks (64%, p=0.04) while $CD11c^{+}CD103^{+}$ cells were 26.5% higher at 0 week (p=0.02) and 55% at 6 week (p=0.02).

Conclusions: Our results suggest that oral treatment with multi-antigenic molecule can control the progression of atherosclerosis efficiently in early stages by inducing regulatory T cells and tolerogenic dendrites. The effect of tolerance reduced at later stages of the disease. Optimizing immune tolerance could induce long-term protection against the disease.

PB 017 | Association of vWF Antigen/ADAMTS13 Activity Ratio with Gensini Score in Type 2 Diabetes Mellitus

S. Lasom[1,2], N. Komanasin[2,3], N. Settasatian[2,4], C. Settasatian[2,5], U. Kukongviriyapan[2,6], P. Intharapetch[2,7], V. Senthong[2,8]

[1]Khon Kaen University, Biomedical Sciences, Graduate School, Khon Kaen, Thailand, [2]Cardiovascular Research Group, Khon Kaen University, Khon Kaen, Thailand, [3]Khon Kaen University, Faculty of Associated Medical Sciences, Department of Clinical Microscopy, Khon Kaen, Thailand, [4]Khon Kaen University, Faculty of Associated Medical Sciences, Department of Clinical Chemistry, Khon Kaen, Thailand, [5]Khon Kaen University, Faculty of Medicine, Department of Pathology, Khon Kaen, Thailand, [6]Khon Kaen University, Faculty of Medicine, Department of Physiology, Khon Kaen, Thailand, [7]Queen Sirikit Heart Center of the Northeast, Khon Kaen University, Khon Kaen, Thailand, [8]Khon Kaen University, Faculty of Medicine, Department of Medicine, Khon Kaen, Thailand

Background: High levels of von Willebrand factor (vWF) and low levels of a disintegrin and metalloproteinase with a thrombospondin type 1 motif, member 13 (ADAMTS13) were associated with risk of coronary artery disease (CAD) and development of atherosclerosis. Moreover, elevated vWF was also associated with diabetes mellitus (DM).

Aims: This study aimed to assess the association of ADAMTS13 activity and vWF levels with severity of coronary stenosis in DM patients.

Methods: Type 2 DM with CAD patients (n = 62) and non-DM without CAD subjects (control group, n = 84) were recruited. Severity of coronary stenosis was considered by using Gensini score and the DM with CAD subjects were divided into 2 groups; high (Gensini score ≥ 20, n = 46) and low-medium score (Gensini score < 20, n = 16). vWF antigen and activity were measured by in-house ELISA and collagen binding assay (CBA), while ADAMTS13 activity was determined by residual-CBA.

Results: vWF antigen/ADAMTS13 activity (vWF/ADAMTS13) ratio was likely to increase in DM with CAD patients compared to control group (p for trend = 0.046). However, no significant differences of other parameters were observed between both groups. DM patients with high Gensini score showed elevated ADAMTS13 activity and tendency of decreased vWF/ADAMTS13 ratio compared to those with low-medium score [(73.4±17.2% vs 59.5±22.5%, p = 0.037) and (1.1±0.6 vs 1.5±1.3, p for trend = 0.024), respectively]. Furthermore, multivariate regression analysis showed that after adjustment for hypertension and HDL-C, DM with high vWF/ADAMTS13 ratio were significantly associated with low-medium Gensini score [OR (95% CI) = 5.4 (1.1, 26.9)].

Conclusions: This study suggested that high vWF/ADAMTS13 ratio was associated with low-medium Gensini score, which may indicate the association of ADAMTS13 and vWF levels with early atherosclerosis in DM patients. However, further study with larger sample size is needed to confirm the association.

PB 018 | Activated Protein C Protects against Accelerated Atherosclerosis in Diabetes by Epigenetically Restricting p66Shc Expression in Macrophages

K. Shahzad[1,2], I. Gadi[3], S. Nazir[3], M. Aldabet[3], S. Kohli[3], S. Ranjan[3], B. Isermann[3]

[1]University of Health Sciences, Lahore, Pakistan, [2]Magdeburg University Hospital, Magdeburg, Germany, [3]University Clinic Magdeburg, Magdeburg, Germany

Background: Atherosclerosis is two- to four-fold increased in diabetic patients. The mechanisms of accelerated atherosclerosis in diabetes remain poorly defined.

Aims: As plasma levels of activated protein C (aPC) a protease known for its cytoprotective effects, are reduced in diabetes we hypothesized that aPC protects against diabetes induced atherosclerosis.

Methods: ApoE-/- mice were made diabetic or fed HFD for 20 weeks. Subgroup of mice were either fed chow diet or were given SGLT2 inhibitor to reduce blood lipid and blood glucose level. Atherosclerotic plaques macrophages and SMC were isolated by laser capture dissection microscopy.

Results: Diabetic ApoE-/- mice displayed smaller but less stable plaques with more macrophages and less smooth muscle cells (immunohistochemical analyses) compared to HFD ApoE-/- mice. Expression of $p66^{Shc}$ and CD36 was increased in macrophages, but not in SMCs isolated by laser dissection from plaques of DM ApoE-/- mice as compared to HFD ApoE-/- mice. Likewise, $p66^{Shc}$ expression was increased in human atherosclerotic lesion from diabetic patient compared to non-diabetic patient. Bone marrow transplantation from

p66^{Shc}-/- into ApoE-/- revealed complete protection from glucose induced atherosclerosis. HFD induced atherosclerotic plaques regressed after normalizing blood lipid levels, while hyperglycaemia induced atherosclerotic plaques did not regress despite restoring normoglycemia, suggesting epigenetic regulation of atherosclerotic plaque in diabetic mice. *In vitro* glucose induces p66^{Shc} and CD36 expression in macrophages. Glucose induced p66^{Shc} expression remained high even when normoglycemia is restored, indicating epigenetic control of p66^{Shc}. Treatment with aPC reduced p66^{Shc} expression, strongly induces expression of DNMT-1 and decreases plaque size.

Conclusions: These data shows that aPC reverses hyperglycemia induced and epigenetically sustained expression of p66^{Shc} and CD36 in atherosclerotic plagues macrophages, providing new insight into aPC dependent vascular protection.

PB 019 | Restoration of Blood Flow Contributes to the Regression of Atherosclerosis Plaque in Mice

L. Ren[1], Y. Liu[1], Y. Wang[1], Y. Cao[1], F. Wu[1], L. Wang[1], T. You[1], L. Zhu[1], C. Tang[2]

[1]*Soochow University, Suzhou, China,* [2]*Cyrus Tang Hematology Center, Soochow University, Suzhou, China*

Background: Disturbed flow (d-flow) is being unveiled as an equal essential player as lipid in the initiation and progression of atherosclerotic plaques. Both mouse models and clinical statin treatment were in certain extent proved to induce plaque regression by lowering of LDL level. However, the role of blood flow in atherosclerosis regression has not been illustrated.

Aims: We aimed to establish a practical method to study the effects of blood flow on atherosclerosis regression based on hemodynamic regulation.

Methods: A single slipknot was applied to three branches of the left carotid artery (LCA) in ApoE$^{-/-}$ mice. After 2 weeks on HFD, the blood flow in LCA was reconstructed by knot release. Ultrasonography was used to verify successful induction of d-flow and the restoration of the blood flow. Atherosclerotic plaques in carotid arteries were stained with Sudan IV.

Results: After the release of the knots, an abrupt increase in flow velocity indicated a successful restoration of blood flow from the LCA to its branches. At this point, the restored flow in ligated LCA was still lower compared to the untied right carotid artery (RCA). After the procedure, mice were given chew diet for additional 4 weeks and blood flow was re-accessed using carotid ultrasonography. Results showed no significant difference of blood flow between LCA and RCA, indicating nearly complete regression of carotid atherosclerosis. The blood flow of LCA in the control group maintained low and d-flow even after 4 weeks with chew diet. The *en face* staining with Sudan IV clearly showed regression of carotid atherosclerosis. Meanwhile, the vascular lumen of the LCA became larger and the infiltration of monocytes decreased in the atherosclerotic plaque.

Conclusions: The results give us the first proof of the influence of blood flow on the regression of atherosclerotic plaque. Moreover, the results revealed a practical tool for a study model of the atherosclerosis regression and the evaluation of anti-atherosclerotic drugs.

PB 020 | Nanoliposomes for Transfection Of CD39 mRNA: A Step towards Nanotheranostics for Delivery of Anti-inflammatory Therapeutics against Thrombosis

M.-K. Abraham[1,2], K. Peter[2,3], T. Michel[1], H.P. Wendel[1], S. Krajewski[1], X. Wang[2,3]

[1]*Clinical Reserach Laboratory, Thoracic, Cardiac and Vascular Surgery, Tuebingen, Germany,* [2]*Baker Heart and Diabetes Institute, Atherothrombosis and Vascular Biology, Melbourne, Australia,* [3]*Monash University, Department of Medicine, Melbourne, Australia*

Background: Genetic therapy using modified mRNA for specific therapeutic protein expression for disease treatment and vaccination displays a new field of therapeutic and diagnostic medicine in cardiovascular research. Non-viral vectors transfection using biocompatible nanoliposomes enables safe and efficient delivery of the CD39 mRNA. CD39 is an ecto-nucleoside triphosphate diphosphohydrolase which degrades adenosine 5'-diphosphate (ADP), a major player of the platelet activation cascade, therefore provides a promising anti-thrombotic strategy.

Aims: Generation of cell-favorable cationic nanoliposomes as nanotheranostic agents to successfully deliver therapeutic CD39 mRNA for anti-thrombotic therapy.

Methods: Cationic nanoliposomes (DC-Cholesterol/DOPE-1,2-dioleoyl-sn-glycero-3-phosphoethanolamine) were generated as transfection vehicles for either eGFP mRNA, or the therapeutic anti-inflammatory, CD39 mRNA.

Results: We observed no toxicity using these nanoplexes and noted good cell viability after transfection. Nanoplexes for the transfection of eGFP mRNA showed an increase in fluorescence signals on microscopy as compared to mRNA control after 24 hours in chinese hamster ovary (CHO) cells. Nanoplexes for the transfection of CD39 mRNA showed increase CD39 expression signals on flow cytometry as compared to mRNA control after 24 hours using CHO cells. We have also demonstrated efficient transfection across several cell lines (CHO, HEK293 and A549), as well as long-term protein expression (120 h and 168 h) using these nanoplexes.

Conclusions: A non-toxic, safe and efficient nanoliposome for the delivery of therapeutic mRNA for gene therapy is useful for diseases such as inflammation and thrombosis. This approach supplies the primary basis to use CD39 mRNA as an anti-inflammatory therapeutics for future nanotheranostics approach.

PB 021 | Association of Plasma Soluble Thrombomodulin and HDL-C with Coronary Artery Stenosis

N. Komanasin[1,2], N. Sittidedpachone[3], N. Settasatian[2,4], C. Settasatian[2,5], U. Kukongwiriyapan[2,6], P. Intharapetch[2,7], V. Senthong[2,8]

[1]Khon Kaen University, Faculty of Associated Medical Sciences, Department of Clinical Microscopy, Khon Kaen, Thailand, [2]Cardiovascular Research Group, Khon Kaen University, Khon Kaen, Thailand, [3]Khon Kaen University, Faculty of Associated Medical Sciences, Khon Kaen, Thailand, [4]Khon Kaen University, Faculty of Associated Medical Sciences, Department of Clinical Chemistry, Khon Kaen, Thailand, [5]Khon Kaen University, Faculty of Medicine, Department of Pathoogy, Khon Kaen, Thailand, [6]Khon Kaen University, Faculty of Medicine, Department of Physiology, Khon Kaen, Thailand, [7]Khon Kaen University, Queen Sirikit Heart Center of the Northeast Hospital, Khon Kaen, Thailand, [8]Khon Kaen University, Faculty of Medicine, Department of Medicine, Khon Kaen, Thailand

Background: Arterial wall damage is the early stage of atherosclerosis which is a major underlying cause of coronary artery stenosis. Thus, biomarkers of endothelial injury are considerable interest in predicting the severity of coronary artery disease (CAD). Thrombomodulin can be released from damage endothelial cells and it has been shown that the soluble form of this protein (soluble thrombomodulin; sTM) is a specific marker of endothelial injury.
Aims: This study aimed to determine the association between sTM and CAD risk factors with coronary artery stenosis in Thai women.
Methods: A total of 135 Thai females at the age of 61.8+8.2 years were recruited in the study. Based on coronary angiography, the subjects were classified into 3 groups; 75 females without a significant stenosis vessel, 18 females with a single stenosis vessel and 42 females with multiple stenosis vessels. Levels of sTM were measured by using an enzyme-linked immunosorbent assay (ELISA) technique.
Results: Plasma sTM levels among 3 groups of subjects were significantly different (3.1±1.3, 3.3±1.6 and 3.7±1.6 ng/ml, respectively, p=0.041). In addition, the significant differences of plasma HDL-C concentrations were found among those subject groups (48.3+14.5, 42.6+10.2 and 38.4+10.1 mg/dl, respectively, p< 0.001). Inverse correlation between the levels of plasma sTM and HDL-C was demonstrated in this population (r=-0.254, p=0.003). Binary logistic regression analysis revealed that high sTM levels and low HDL-C concentration were independently associated with vascular stenosis [adjusted OR (95% CI) = 3.2 (1.0, 10.0) and 2.5 (1.2, 5.2) respectively].
Conclusions: These findings suggested that raised plasma sTM concentration released from endothelial damage during the plaque progression as well as low levels of HDL-C which involved in disposal of blood cholesterol were likely to be used for predicting coronary stenosis.

PB 022 | Protective Auto Antibodies and their Inverse Correlation with Antigen Levels in Indian Patients with Acute Coronary Syndrome

T. Ponnusamy[1], L. Mundkur[1], S.K. Venkatachala[2], R.K. Vangala[3]

[1]Thrombosis Research Institute, Molecular Immunology, Bangalore, India, [2]Narayana Institute of Cardiac Sciences, Cardiology, Bangalore, India, [3]Thrombosis Research Institute, Proteomics and Coagulation, Bangalore, India

Background: Auto antigens and their antibodies in peripheral circulation have been shown to be associated with atherosclerosis. Several studies support the dual activity of these auto antibodies either playing a causative or protective role in atherosclerosis. Sudden cardiac death is highly prevalent in Indian subcontinent.
Aims: To assess level of circulating athergenic autoantigens and auto antibodies in acute coronary syndrome patients from India.
Methods: Peripheral blood was collected and plasma was isolated from patients (N= 195) admitted after myocardial infarction and equal number of age and gender matched controls without any prior history of cardiac disease. IgG and IgM antibodies for APO B 100, HSP 60, Ox-LDL and LDL were assessed using ELISA. All the plate carried a common control for normalizing the titre. The level antigens in circulation for HSP 60 and Ox-LDL were measured following manufacture guidelines.
Results: The auto antibodies were found to be less in circulation in MI patients for APO B 100 ((IgG (1.87±0.02 vs 1.62±0.02, p< 0.001) and IgM (0.68±0.02 vs 0.57±0.03, p< 0.01)), HSP 60 ((IgG (2.12±0.01 vs 1.91±0.02, p< 0.01) and IgM (0.79±0.02 vs 0.68±0.02, p< 0.01)), Ox-LDL ((IgG (0.96±0.02 vs 0.88±0.02, p< 0.05) and IgM (0.41±0.02 vs 0.34±0.02, p< 0.001)) and LDL ((IgG (1.63±0.01 vs 1.46±0.02, p< 0.001) and IgM (0.63±0.02 vs 0.55±0.02, p< 0.01)) compared to the controls. The level of HSP 60 antigen (34.63±3.66 vs 48.54±3.52, p=0.01) and their ratio to their respective antibody (16.8±2.04 vs 26.67±2.53, p< 0.01) was high in patients compared to controls. There was a negative correlation between IgM auto antibodies to Ox-LDL (r=-0.11, p=0.04), LDL (r=-0.15, p< 0.01) and number of diseased vessels.
Conclusions: The study suggests that auto antibodies may play a protective role in our population by antigen removal by auto antibodies in circulation there by reducing the antigen load.

PB 024 | Role of RhoA/Rho Kinase Pathway Activation in Cocaine-induced Leukocyte Transendothelial Migration

J. Pereira, C.G. Sáez, M. Palominos, G. Valenzuela, A. Pastore, I. Solar-Costabal, D. Mezzano

Pontificia Universidad Catolica de Chile Universidad Católica de Chile, Hematology-Oncology, Santiago, Chile

Background: Cocaine use increases the risk for serious cardiac and cerebrovascular events. The pathogenic mechanisms are not fully understood although accelerated atherosclerosis and thrombus formation are prominent findings. Leukocyte transendothelial migration (TEM) is one of the crucial steps in the development of atherosclerosis (AE) and, RhoA/Rho kinase (ROCK) pathway plays a key role in pathogenesis of AE. We hypothesized that cocaine enhances leukocyte TEM associated to activation of endothelial ROCK.

Aims: To assess the effect of cocaine on leukocyte TEM and the contribution of ROCK activation to this phenomenon.

Methods: In cultured Human Aortic Endothelial Cells (HAEC) exposed to cocaine (10μM) or vehicle, ROCK activity was determined by western blot (phosphorylated versus total myosin light chain phosphatase 1 levels) and, E and P-selectin exposure by immunofluorescence. For TEM assays, HAEC were grown onto transwell filters and co-cultured with leukocytes for 90 minutes. Migrated leukocytes were quantified in the lower chamber and the cells on the grids were stained for VE-cadherin and CD45. All the experiments were conducted in the presence or absence of Y-27632 (10 μM), which targets the catalytic domain of ROCK.

Results: HAEC exposed to cocaine expressed significantly higher amount of E- and P-selectin and showed increased activation of ROCK (p: 0.038). These phenomena were inhibited by Y-27632 (p: < 0.05). Intercellular gaps and VE-cadherin junction dissociation were observed in HAEC treated with cocaine which was associated with a 2.6-fold increase in leukocyte TEM. Treatment with Y-27632 preserved the monolayer architecture and intercellular VE-cadherin localization and reduced dramatically the leukocyte TEM (p: 0.004).

Conclusions: We showed that activation of RhoA/ROCK pathway plays a key role in cocaine-induced leukocyte TEM. Its inhibition (e.g. with statins) may provide a novel target in the management of cocaine-associated vascular complications.

PB 025 | High Circulatory Level of Inflammatory Cells and their Relation to Recurrent Cardiac Events tn Indian Population

T. Ponnusamy[1], L. Mundkur[1], S.K. Venkatachala[2], R.K. Vangala[3]

[1]*Thrombosis Research Institute, Molecular Immunology, Bangalore, India,* [2]*Narayana Institute of Cardiac Sciences, Cardiology, Bangalore, India,* [3]*Thrombosis Research Institute, Proteomics and Coagulation, Bangalore, India*

Background: Inflammatory and regulatory response play key role in immune regulation. We reported imbalance between peripheral inflammatory and regulatory subsets in myocardial infarction (MI) in our previous study.

Aims: To study the imbalance between the inflammatory and regulatory subsets in patients with MI, clinically recovered MI, patients with recurrent cardiac event and patients with history of CAD.

Methods: Peripheral blood was collected from the patients admitted after first MI, clinically recovered patients 6-18 months after the first event, patients with history of CAD, patients with recurrent event, age and gender matched controls without any prior history to CAD. All the patients were followed up for 2 years. The inflammatory (Th17 and Tc17) and regulatory Tcells ($CD4^+CD25^{High}$ and Tregs) were assessed by flowcytometry. Statistical analysis was performed in SPSS version 17.0.

Results: Immune imbalance observed in MI was recovered in clinically recovered MI with reduced peripheral inflammatory cells Th17 (4.45±0.36 vs 3.09±0.37, p< 0.01), increased regulatory subsets $CD4^+CD25^{High}$ (3.69±0.45 vs 5.30±0.33, p< 0.01), Tregs (3.07±0.47 vs 4.23±0.43, p< 0.05) and decrease in inflammatory to regulatory Tcell ratio (Th17/Tregs (1.71±0.16 vs 0.784±0.06, p< 0.01 and Th17/$CD4^+CD25^{High}$ (1.43±0.13 vs 0.604±0.04, p< 0.01)) compared to their first sample. The Th17 cells was high in the patients with the history of CAD (4.45±0.36 vs 5.22±0.22, p< 0.01) and patients who had incident of recurrent cardiac event later (4.45±0.36 vs 4.76±0.49, p=0.67) compared to MI patients without any previous history of CAD or future events during follow up.

Conclusions: Our results suggest that immune imbalance could be one of the causative for MI and high circulatory level of inflammatory cells could be a cause of recurrent cardiac events.

PB 026 | Lipoprotein a [Lp(a)] and Hemostatic Variables in Young and Post Menopausal Women: Are their Levels Affected by Hormones Use?

M.G. Carvalho[1], D.B. Serenini[1], C.N. Ferreira[2], E. Reis[3], I.F. Silva[1]

[1]*Faculty of Pharmacy - Federal University of Minas Gerais, Belo Horizonte, Brazil,* [2]*Technical College of Federal University of Minas Gerais, Belo Horizonte, Brazil,* [3]*Department of Statistics - Institute of Exact Sciences - Federal University of Minas Gerais, Belo Horizonte, Brazil*

Background: Lipoprotein (a) [Lp(a)] is a risk factor for atherogenesis and due to its structural homology with plasminogen may contribute to thrombogenesis by reducing fibrinolysis. Use of oral contraceptives (OC) and hormone replacement therapy (HRT) may favor hypercoagulability and, consequently, add clinical significance to elevated levels of Lp (a).

Aims: To evaluate the lipid profile focused on Lp (a) and some hemostatic variables and investigate whether the use of hormones can affect their plasma levels in young (OC) and postmenopausal women (HRT).

Methods: A total of 82 women were distributed into four groups: young people in use of OC (YP n = 20), or not (YN n = 20) and menopausal people in use of HRT (MP n = 17) or not (MN n = 25). Levels of Lp(a) were determined by turbidimetry while the lipidic profile for conventional methods. Plasma levels of plasminogen activator inhibitor type 1 (PAI-1), 1+2 prothrombin fragment (F1+2) and plasminogen were determined by ELISA and D-Dimer (D-Di) by ELFA. Mann-Whitney test was used to compare the medians of the pairs of groups: YNxYP, MNxMP and YNxMN. Informed consent was obtained from all partipants.

Results: Lp(a) levels were not significantly different among all groups. Increased levels of TC, F+2 and DDi were observed in OC users while no change in lipidic and hemostatic profiles was found, except reduction in TC and LDL levels in HRT users. Comparative analysis between YN x MN showed increased levels of TC, LDL, PAI-1, F1+2 and DDi, and reduced levels of HDL (Tables 1 and 2).

TABLE 1 Hemostatic variables (median and 25th and 75th percentile). PAI-1 in ng/mL; F1+2 in pmol/L; D-Di in ng/mL; Plasminogen in µg/mL

Group (n)	PAI-1	P -value	F1+2	P -value	D-Di	P -value
YN (20)	33.55 (17.05-42.33)	0.3438	218.30 (176.40-278.00)	0.0009	156.10 (128.80-282.60)	0.0679
YP (20)	21.90 (15.95-37.88)		385.50 (283.80-628.40)		234.60 (188.70-311.80)

Conclusions: Use of hormones or aging did not affect the levels of Lp(a). However, use of oral contraceptive (OC) seems to be atherogenic and thrombogenic, while the use of HRT seems to protect against atherogenesis but did not significantly influence thrombogenesis. Aging by itself contributed significantly to the atherogenic and thrombogenic potentials, as expected. Supported by CAPES, CNPq and FAPEMIG - BRAZIL.

PB 027 | Selected Factors of Haemostasis and Some Clinical Parameters in Patients with Peripheral Arterial Disease with Regard to Atherosclerosis

R. Wieczór[1], D. Rość[1], K. Stankowska[1], A.M. Wieczór[1], B. Ruszkowska-Ciastek[1], J. Fabisiak[2], K. Suppan[2], J. Budzyński[2], G. Pulkowski[2]

[1]*Department of Pathophysiology, Faculty of Pharmacy, Nicolaus Copernicus University in Toruń, Ludwik Rydygier Collegium Medicum, Bydgoszcz, Poland,* [2]*Clinic of Vascular and Internal Medicine, Dr Jan Biziel University Hospital No. 2, Bydgoszcz, Poland*

Background: A hypercoagulable state is found in the blood of patients with atherosclerosis leading to thrombotic events such as cardiac infarction, cerebral stroke or peripheral arterial disease.

Aims: The objective of this study was the evaluation of selected haemostasis factors depending on the clinical parameters in the patients with symptomatic PAD.

Methods: The study group consisted of 80 patients with symptomatic PAD (M/F 53/27) at an average age of 63.5 ± 9 years, and the control group members were healthy volunteers (M/F 20/10) at an average age of 56 ± 6 years. The testing involved determining the concentrations of tissue factor (TF), tissue plasminogen activator antigen (t-PA Ag), type-1 tissue plasminogen activator inhibitor (PAI-1 Ag), fibrinogen, D-dimers and platelet count (PLT) in citrated venous blood. The obtained results were subjected to analysis depending on the age of the patients, the levels of ABI, IC distance, BMI levels, the concentration of low-density lipoproteins (LDL) and triglycerides (TG), in smokers with regard to the period of cigarette smoking (the number of pack-years).

Results: Increased concentrations of all the haemostatic parameters were fund in the blood of the patients involved in the study. There

was observed a positive correlation between D-dimers levels and the age, a negative correlation was revealed between D-dimers levels and ABI value, a negative correlation was between the PLT count and ABI value, a negative correlation was between fibrinogen concentration and IC distance, a negative correlation was observed between PLT and IC and a positive correlation was between t-PA Ag and BMI as well as between PAI-1 Ag and BMI.

Conclusions: A shortened intermittent claudication distance and decreased ankle-brachial index value (PAD progression indices) correlated positively with increased fibrinogen concentration level and platelet count and D-dimers concentration which suggested the coexistence of hypercoagulability and secondary fibrinolysis and inflammatory process.

PB 028 | MicroRNA Target Prioritization to Identify Potential Therapeutic Candidate in Cardiovascular Disease

V. Deshpande[1], A. Sharma[2], L.N. Thota[3], R. Vangala[4]

[1]Thrombosis Research Institute, Transcriptomics and Immunohistochemistry, Bangalore, India, [2]Thrombosis Research Institute, Bioinformatics and Biostatistics, Bangalore, India, [3]Thrombosis Research Institute, Immunology, Bangalore, India, [4]Thrombosis Research Institute, Bangalore, India

Background: Micro RNA profiling can often reveal several hundreds of genes getting regulated for a particular biological system of interest. Multiple algorithm based target prediction tools are now available that ranks the potential targets on the basis of the complimentarity and the degree of conservation between mi RNA and 3'UTR target sequence across species. However, in cases where the number of target genes of interest is in the order of hundreds and thousands, a gene by-gene approach becomes impractical.

Aims: To prioritize potential micro RNAs at each stage of cardiovascular disease development and to explore the therapeutic potential of these miRNAs in treatment of cardiovascular disease.

Methods: Atherosclerosis was induced in groups of Apob^{tm2Sgy} Ldlr^{tm1Her}/J mice by feeding them with diet rich in cholesterol. Micro RNA profiling was performed with RNA extracted from ascending aorta at 6, 18 and 30-week time points. The disease specific correlation of our data and parent ontology ranking helped us to identify potential mirnas at each stage of cardiovascular disease development.

Results: We demonstrated a novel algorithm based approach (miRrank) which ranks the targets on the basis of functional ontology. Totally, 25 miRNAs were enriched across the disease development and the expression levels were experimentally verified using mice aorta samples. According to the AHA drug classification and cytoscape analysis we observed that the targets of mmu-mir-497-5p and mmu-mir-185-5p belong to calcium channel blocker category and these mirnas potentially be used as a therapeutic candidate in treatment of cardiovascular disease. Thus, calcium channel blockers play a very essential role to control the entry of calcium ions into the cells.

Conclusions: We believe that our method will significantly add biological value to the existing tools and identify bio markers with potential use in therapy as shown above.

PB 029 | Plasminogen Deficiency Attenuates Atherosclerosis in a Murine Model of Type II a Familial Hypercholesterolemia

C. Miyajima[1], T. Iwaki[1], V.A. Ploplis[2], K. Umemura[1], F.J. Castellino[2]

[1]Hamamatsu University School of Medicine, Hamamatsu, Japan, [2]University of Notre Dame, Notre Dame, Armenia

Background: Due to atherosclerosis is asymptomatic nature, it is difficult to investigate the progression of this disease in humans. Animals, especially mice with select genetic alterations, are very useful to investigate this disease. Mice with a double deficiency of LDLr and Apobec1 (*Ldlr$^{-/-}$/Apobec1$^{-/-}$*) show high levels of plasma total cholesterol on a normal chow diet, most of which is distributed in the LDL fraction. Consequently, spontaneous atherosclerotic plaques form in the aorta, a situation that is similar to human familial hypercholesterolemia.

Aims: Many studies have defined a relationship between atherosclerosis and the fibrinolytic system. So, we examined the role of plasminogen in atherosclerosis with *Ldlr$^{-/-}$/Apobec1$^{-/-}$* mice.

Methods: We established *Ldlr$^{-/-}$/Apobec1$^{-/-}$/Plasminogen$^{-/-}$*(*Ldlr$^{-/-}$/Apobec1$^{-/-}$/Plg$^{-/-}$*) triple deficient mice from *Ldlr$^{-/-}$/Apobec1$^{-/-}$* mice and *Plg$^{-/-}$* mice. In triple-deficient mice, we investigated the levels of total cholesterol (total-C), LDL-C and HDL-C and the size of plaques in the aortic sinus.

Results: We have found that total cholesterol levels were significantly higher in *Ldlr$^{-/-}$/Apobec1$^{-/-}$/Plg$^{-/-}$* mice than in *Ldlr$^{-/-}$/Apobec1$^{-/-}$* mice. Furthermore, almost all of the cholesterol accumulated in the LDL fraction, and the HDL cholesterol level was not different between both groups. Although the cholesterol levels are very high in this murine model, these mice showed much smaller plaques in the aortic sinus. These results suggest that a Plg deficiency in a *Ldlr$^{-/-}$/Apobec1$^{-/-}$* background might restrict uptake of oxidized (Ox)-LDL in monocyte/macrophages as well as other cell types.

Conclusions: In the *Ldlr$^{-/-}$* background, not only Ox-LDL but native LDL should also be cleared by scavenger receptors. Hence, we examined continuously whether Plg affects the expression of various scavenger receptors in macrophage of *Ldlr$^{-/-}$/Apobec1$^{-/-}$* mice in order to reveal important roles of Plg in atherosclerosis in a model of familial hypercholesterolemia.

PB 030 | Integrated microRNA and mRNA Expression Profiling to Identify mRNA Targets of Dysregulated miRNAs in Coronary Artery Disease Condition

J. Nair, J. Shanker

Thrombosis Research Institute, Bangalore, India

Background: The interplay between miRNA and their mRNA has been proposed to play an important role in biological and pathological process of many diseases. We have constructed and explored the interactive molecular networks impacted by predicted mRNA targets of differentially expressed miRNAs in patients with coronary artery disease.

Aims: To identify mRNA targets of dysregulated miRNAs through the integrated analysis of miRNA and mRNA expression profiling in patients with and without Coronary artery disease.

Methods: The miRNA and mRNA expression profiling was carried out on 20 subjects, Including 10 CAD patients and 10 healthy controls on the Agilent platform. Data was analysed with Gene SpringGx12.5 and integrated network analysis using Ingenuity Pathway Analysis (IPA. The expression pairing was applied to identify the anti-correlated miRNA-mRNA changes. The connections with in the IPA interaction network were visualised and analysed based on their topological parameters in Cytoscape.

Results: The integrated analysis of miRNA and mRNA expression data identified 6 miRNAs that were up regulated and one miRNA that was down regulated. We identified RUNX1as key target based on anti-correlated miRNA-mRNA interaction. The core analysis results revealed dis-regulation of key pathways, such as Cytokine signaling, Cell cycle regulation and Circadian rhythm. The interaction network analysis based on the topological parameters confirmed the top hub miRNA node in the network to play a key role in regulation RUNX1.

Conclusions: Using this integrated approach, we identified RUNX1 a novel target gene of dysregulated miRNAs, that could have potential role in cardiovascular disease development.

PB 032 | Predictive Value of Neutrophil to Lymphocyte Ratio in Long-term Outcomes of Left Main and/or Three-Vessel Disease in Patients with Acute Myocardial Infarction

N. Xu, X.-F. Tang, Y. Yao, J.-J. Xu, Y. Song, L. Jiang, P. Jiang, R. Liu, J.-Q. Yuan, R.-L. Gao

Beijing Fuwai Hospital, Beijing, China

Background: Patients with acute coronary syndrome due to left main and/or three-vessel disease (LM/3VD) are at the highest risk of adverse cardiovascular events. Neutrophil to lymphocyte ratio (NLR) has been proposed as a marker of cardiovascular risk.

Aims: We sought to evaluate the independent predictive value of NLR for LM/3VD in AMI patients.

Methods: Patients (n=806) admitted with LM/3VD in AMI and who underwent PCI between January 2013 and December 2013 were followed up for 2 years. NLR was calculated as the ratio of neutrophil to lymphocyte based on the laboratory data on admission. We used Cox regression models to examine the relation between NLR and clinical outcomes.

Results: In this cohort, median NLR in the entire study population was 2.60 (interquartile range, 1.86-4.04). By receiver operating characteristics curve analysis, the optimal cut-off value of admission NLR to predict 2-year all-cause mortality was 3.39 (area under the curve 0.753, sensitivity 77%, specificity 70%). NLR was divided into two sub-groups based on an optimal cut off value of 3.39. Of the 806 patients, 255 patients (31.6%) had NLR≥3.39. The high NLR group had higher prevalence of prior myocardial infarction, prior PCI and Intra-aortic balloon pump (IABP). During the follow-up period, the high NLR group was associated with a significantly higher rate of long-term all-cause death (6.7% vs 0.9%, p< 0.001), cardiac death (5.5% vs 0.9%, p< 0.001) and MACCE (24.7% vs 15.8%, p=0.002) compared to the low NLR group. In multivariate analysis, after adjusting for risk factors, NLR≥3.39 was determined as an independent predictor of 2-year all-cause mortality (hazard ratio[HR] 3.08, 95% confidence interval [CI] 1.06 to 8.97, p=0.039) and MACCE (hazard ratio 1.44, 95% CI 1.01 to 2.05, p=0.046) for LM/3VD. The NLR was significantly and positively correlated with hsCRP levels (r=0.231, p< 0.001).

Conclusions: Our study demonstrates that admission NLR≥3.39 is an independent predictor of LM/3VD in patients with AMI after PCI.

PB 034 | Myocardial Infarction is a Risk Factor for Venous Thromboembolism (VTE) Recurrence in Women with a First VTE

N. Arshad[1], W. Lijfering[2], S. Cannegieter[2], J.B. Hansen[1,3], F. Rosendaal[1,2], S.K. Braekkan[1,3]

[1]UiT The Arctic University of Norway, K.G.Jebsen Thrombosis Research and Expertise Center (TREC), Department of Clinical Medicine, Tromsø, Norway, [2]Leiden University Medical Center, Department of Clinical Epidemiology, Leiden, The Netherlands, [3]University Hospital of North Norway, Division of Internal Medicine, Tromsø, Norway

Background: Previous reports suggest that myocardial infarction (MI) is a transient risk factor for incident venous thromboembolism (VTE). Whether patients with a history of MI and VTE have an increased risk of VTE recurrence (reVTE) remains unsettled.

Aims: To assess whether a history of MI is associated with risk of reVTE in a cohort of patients with incident VTE.

Methods: A total of 5494 VTE patients were recruited from the Tromsø Study and the MEGA study and followed from the date of their first VTE until the date of recurrence, death, or the last date they were known to be recurrence free. Cox regression models were used to calculate hazard ratios (HR) with 95% confidence intervals (CI) of reVTE according to MI status adjusted for age and body mass index, and stratified by sex since men have a higher recurrence risk than women.

Results: During a median follow-up of 11.3 years, 792 patients experienced a reVTE. Women with a history of MI before the first VTE

had a 2.4-fold higher risk of reVTE (HR 2.44; 95%CI 1.27-4.69) than those without a history of MI. No association was observed in men (HR 1.20, 95%CI 0.71-1.94). When competing risk by death was taken into account, the corresponding subdistribution hazard ratios were 2.14 (95%CI 1.08-4.24) in women, and 0.99 (95%CI 0.60-1.66) in men. Similar risk estimates were observed when MIs that occurred during follow-up were modeled as intermediate exposures using a time-varying Cox-model.

Conclusions: Women with a history of MI had an increased risk of recurrence after a first VTE. Although the risk of a first VTE is highest during the first months following an MI, our findings suggests that MI is a persistent rather than transient risk factor for venous thrombosis, especially in women.

PB 035 | Lack of Tissue Factor Cytoplasmic Tail Attenuates Cardiac Injury after Myocardial Infarction

V.S. Garlapati[1], M. Brandt[2], S. Kossmann[1], J. Lagrange[1], W.-S. Rudi[1], W. Ruf[1,3], P. Wenzel[2]

[1]Center for Thrombosis and Hemostasis (CTH), Mainz, Germany, [2]Center for Thrombosis and Hemostasis (CTH), Center for Cardiology - Cardiology 1, University Medical Center of the Johannes Gutenberg University, Mainz, Germany, [3]The Scripps Research Institute, La Jolla, CA, United States

Background: The interplay of immune cells has an important role in driving both acute inflammatory as well as regenerative responses post myocardial infarction (MI). The phosphorylation of tissue factor (TF) at its cytoplasmic tail (CT) influences inflammatory response, angiogenesis and tumor development. However, the role of TF CT in infarct healing and cardiac remodeling is still unknown.

Aims: The main aim of this study was to elucidate whether, phosphorylation of CT of TF affects infarct healing and remodelling.

Methods: LAD ligation is an established method to study post-MI tri-phasic immune cell response. MI was induced in 9 to 12 weeks old male C57BL/6J and mice specifically lacking CT of TF ($TF^{\Delta ct}$) by permanent ligation of the left anterior descending (LAD) coronary artery. We assessed left ventricular function at specific time points (1,7,14,21,28 days) after MI by high frequency ultrasound. Infiltration of immune cells was investigated by performing flow cytometry analysis after enzymatic digestion of the myocardium.

Results: Determination of the ejection fraction by ultrasound showed that $TF^{\Delta ct}$ had preserved left ventricular function compared to C57BL/6 controls at d1, d7, and d21 post MI, respectively. Flow cytometric analysis revealed a significant influx of $CD45.2^+$ leukocytes as well as $CD45.2^+$ /$CD3^-$/$CD11b^+$/$Ly\text{-}6G^+$ neutrophils into infarcted areas at d1 post MI in C57BL/6, which was augmented in $TF^{\Delta ct}$ (n=7-8, $p< 0.05$). Interestingly, initially increased influx was followed by dampened inflammatory response at d7 post MI in $TF^{\Delta ct}$ compared to C57BL/6 controls (n=8-9, $p< 0.01$). Importantly, post infarct survival after 28d post MI was significantly higher in $TF^{\Delta ct}$ compared to B6J mice (n=17, $p< 0.05$).

Conclusions: We show here that deletion of the cytoplasmic tail of TF is protective in acute as well as chronic MI by preserving LV function and increasing survival. In subsequent studies we will investigate whether phosphorylation of TF-CT in inflammatory cells is one of the key mechanisms in cardiac injury.

PB 036 | Free Ubiquitin Promotes Cardiomyocytes Proliferation and Survival In vitro and In vivo via CXCR4 Pathway

J. Yao, K. Lv, Q. Zhang, M. Tong, W. Chen

Suzhou Municipal Hospital Affiliated to Nanjing Medical University, Department of Cardiology, Suzhou, China

Background: Ubiquitin (UB) is one of the most highly conserved low molecular weight (8.5 kDa) protein. Supplementation of free ubiquitin (extracellular ubiquitin) has been shown to limit inflammation and attenuate tissue injury in several diseases. However, the biological effect of ubiquitin on cardiomyocyte (CM) has not been defined.

Aims: To examine the ability of free ubiquitin to promote CM proliferation and enhance cardiac function after MI.

Methods: In the present study, we investigate the effect of free UB on the proliferation and apoptosis of cardiomyocytes under hypoxia and the potential relationship of free UB/CXCR4 to Akt, YAP pathways. Mouse models of acute myocardial infaction (AMI) were established. Free UB was injected into the myocardium. Cardiomyocyte apoptosis, infarct size and cardiac function were analyzed.

Results: Improved CM survival was found in ubiquitin treatment compared with controls after hypoxia. Knock-down of ubiquitin by mixed shRNAs targeting its coding genes ubiquitin B (*UBB*) and ubiquitin C (*UBC*) reduced the growth of CM by inducing apoptosis and modulating the cell cycle progression. Moreover, injection of free ubiquitin after MI significantly improved survival, cardiac function, and reduced infarct area 4 weeks after MI. Expression of proliferation activator (cyclin D1, E1, p-AKT) were increased and negative cell-cycle and apoptotic regulators (p21, caspase-3) were decreased under hypoxia and MI conditions. Ubiquitin activates various proliferation pathways, including Akt and YAP through ubiquitin/CXCR4 axis.

Conclusions: Our results demonstrate the critical role of ubiquitin in CM proliferation and survival after MI. Targeting ubiquitin may serve as a potentially novel approach for MI prevention and therapy.

PB 037 | Development of a Novel Flow Cytometric Immunobead Array to Quantify von Willebrand Factor Antigen and Ristocetin Cofactor Activity and its Application in Acute Myocardial Infarction

Y. Zhao

The First Affiliated Hospital of Soochow University, Jiangsu Institute of Hematology, Suzhou, China

Background: Both von Willebrand disease (VWD) and acute myocardial infarction (AMI) generate quantitative and qualitative changes of von Willebrand factor (VWF).

Aims: To develop a rapid, and precise flow cytometric immunobead array (FCIA) to quantify VWF antigen (VWF:Ag) and risrocetin cofactor activity (VWF:Rco), and to apply it in AMI.

Methods: Microbeads coated with anti-VWF mAb SZ29 were incubated with diluted plasma for VWF:Ag assay, and microbeads coated with anti-GP Ibα mAb SZ151 were bonded with recombinant fragment GPIbα, then incubated with diluted plasma and ristocetin simultaneously for VWF:Rco assay. Finally, both binding VWF microbeads were detected with FITC conjugated sheep-anti-human VWF IgG antibody by flow cytometry, respectively. 21 VWD patients, 105 controls (CTL) and 146 AMI patients were analyzed. VWF:Ag and VWF:Rco were measured by FCIA l. VWF:CB was tested by ELISA. ADAMTS13 activity was measured by FRETS-VWF73. VWF multimer assay was implemented by SDS-PAGE.

Results: Both VWF:Ag and VWF:Rco by FCIA had a good linear regression (R^2 = 0.9941 and R^2 = 0.9876). The intra-assay and inter-assay coefficient variations were 9.2% and 12.6% for VWF:Ag-FCIA, 7.7% and 13.5% for VWF:Rco-FCIA. The specificity and accuracy for VWF:Rco-FCIA (98.1% and 97.62%) were higher compared with VWF:Rco-ELISA (92.38% and 92.86%, P < 0.05). Plasma VWF:Ag, VWF:Rco and VWF:CB in AMI (mean ± SD, 299.4% ± 16.8, 242.0% ± 17.3 and 309.2% ± 19.9) were significantly higher than those in controls (73.5% ± 4.1, 65.5% ± 3.4 and 75.6% ± 6.0, all P < 0.0001), while ADAMTS13 and ADAMTS13/VWF:Ag in AMI (44.9% ± 0.8 and 0.25% ± 0.02) was significantly lower than those in controls (48.8% ± 1.2, P < 0.01 and 1.04% ± 0.10, P < 0.0001). The plasma ultra-large VWF level was dramatically increased in AMI.

Conclusions: We have developed a novel FCIA quantifying VWF:Ag and VWF:Rco quickly with specific and accurate results. The FCIA can not only be utilized for screening VWD, but also has clinical value in monitoring AMI patients.

PB 039 | Post-infarct Survival and Cardiac Remodeling Depends on the Interplay of Neutrophils, Monocytes and Interferon Gamma in a Mouse Model of Myocardial Infarction

S. Finger[1], M. Knorr[2], S. Kossmann[1], R. Schüler[1], M. Molitor[2], S. Karbach[2], T. Münzel[2], P. Wenzel[2]

[1]Center for Thrombosis and Hemostasis (CTH), Mainz, Germany, [2]Center for Thrombosis and Hemostasis (CTH), Center for Cardiology - Cardiology 1, University Medical Center of the Johannes Gutenberg University, Mainz, Germany

Background: Myelomonocytic cells are involved in the initial injury as well as in the later healing mechanisms of myocardial infarction (MI). The exact interaction of inflammatory myeloid cells and prominent cytokines remains only partly understood.

Aims: The cardio protective or in part adverse role of lysozyme M positive ($LysM^+$) and granulocyte-receptor 1 positive ($Gr\text{-}1^+$) immune cells on cardiac injury and healing in a murine model of MI should be investigated.

Methods: MI was induced in 8 to 12 week-old male mice (C57BL/6 background) by permanent ligation of the left anterior descending coronary artery (LAD).

Results: Compared to LysMCre controls, $LysM^+$ cell depleted $LysM^{iDTR}$ transgenic mice (depletion 3d prior MI by diphtheria toxin application, 25 ng/g body weight) displayed a reduced influx of $Gr\text{-}1^{high}$ neutrophils into infarcted myocardium 1d post MI (measured by FACS). Additionally, cardiac mRNA expression levels of the cytokines interferon gamma and tumor necrosis factor alpha were decreased 7d post MI. Mortality after MI was significantly increased in LysM-depleted mice within 28d post MI. To estimate the role of neutrophils, we depleted C57BL/6 mice with a monoclonal anti-Gr-1 antibody and found increased mortality early after MI as well as a decrease in INFg mRNA expression. MCP-1 and CCR2 mRNA were decreased 3d after MI according to reduced amount of $Ly6C^{high}$ inflammatory monocytes in the infarcted myocardium of anti-Gr-1 treated mice. LAD ligated $INFg^{-/-}$ mice and $TNF\alpha^{-/-}$ mice displayed a significantly decreased post-infarct survival, worsening of left ventricular function and an impaired inflammatory cell infiltration.

Conclusions: We provide evidence that neutrophils, monocytes and INFg play an essential role in survival and cardiac remodeling following MI. Our data indicate that neutrophils are required for monocyte chemotaxis. We argue that therapeutic strategies to oppose the inflammatory injury in MI must consider a potentially beneficial effect of early neutrophil influx into infarcted myocardium.

PB 040 | Control of Thrombosis and Inflammation by Platelet p38α in Acute Myocardial Infarction

P. Shi, X. Fan, Y. Xu, X. Chen, L. Zhang, K. Wang, J. Liu

Shanghai Jiao Tong University School of Medicine, Shanghai, China

Background: Mitogen-activated protein kinases (MAPKs), especially P38 play detrimental roles in cardiac hypertrophy, atherosclerosis, vascular restenosis and cardiac remodeling post-myocardial infarction (MI), which have established the foundation of recent P38 inhibitors cardioprotection clinical trial activities.

Aims: To study the activation and function of MAPKs in coronary thrombosis process in vivo and its relationship with clinical outcomes.

Methods: The relative phosphorylation levels of MAPKs in human platelets between STEMI patients and healthy subjects were assayed and analyzed by GraphPad prism. A LAD coronary artery ligation MI model was carried out to elucidate the roles of P38 in distal microvascular embolization, inflammatory response, ventricular remodeling and cardiac function post MI.

Results: The results indicated that MAPKs, especially P38 were highly and frequently phosphorylated in the STEMI patients platelets, and the phosphorylation levels of P38 in platelet was probably correlated

to no-reflow. Further results showed that P38α was the major isoform expressing in human and mouse platelets. Platelet specific P38α deficient mice presented impaired ability of thrombosis and homeostasis, but had improved cardiac function, smaller infarct size, decreased inflammatory response and microthrombus in a left anterior descending artery ligation mouse model. Signaling analysis revealed that P38 activation was one of the earliest events in platelet under the treatment of receptor agonists or hydrogen peroxide. P38α/MK2/HSP27 and P38α/cPLA2 were major pathways in regulation of platelet activation receptors-mediatedor reactive oxygen species (ROS)-induced in ischemic environment. Moreover, the distinct roles of ERK1/2 in receptors- or ROS-induced P38 activation were elucidated.

Conclusions: P38α acts as a critical regulator of platelet activation in response to injured endothelium and ischemic environment. Inhibition of platelet P38α may improve clinical outcomes in subjects with acute STEMI.

PB 041 | Identification of a Plasma microRNAs Profile Related to Arterial Thrombosis

L. Martos[1], A. Fernández-Pardo[1], D. Hervás[2], L.A. Ramón[1], J. Oto[1], E. Plana[1,3], J. Rueda[4], E. Zorio[4], P. Medina[1], F. España[1], S. Navarro[1]

[1]Medical Research Center IIS La Fe, Research Group in Haemostasis, Thrombosis, Atherosclerosis and Vascular Biology, Valencia, Spain, [2]Medical Research Center IIS La Fe, Bioestatistics Unit, Valencia, Spain, [3]University and Polytechnic La Fe Hospital, Service of Angiology and Vascular Surgery, Valencia, Spain, [4]University and Polytechnic La Fe Hospital, Service of Cardiology, Valencia, Spain

Background: MicroRNAs (miRNAs) regulate protein expression and are present in biological fluids. Circulating microRNAs (miRNAs) have been described as promising and non-invasive clinical biomarkers for cardiovascular diseases.

Aims: To validate a miRNAs plasma profile characteristic of patients with chronic ischemic heart disease (MI).

Methods: Optimized method for plasma miRNA isolation was used. We measured miRNA expression with the GeneChip miRNA 3.0 Array (Affymetrix) in plasma from 6 stable patients with a history of MI and 6 healthy subjects, age and sex matched. The results were analyzed with the PARTEK Genomic Suite software. The array showed a different miRNA expression profile between MI and controls. We selected 15 miRNAs differently expressed (P< 0.05; fold-change>1.5) for validation by RT-qPCR in plasma from 30 stable MI and 37 controls, age and sex matched. The results were analyzed using an elastic net penalized logistic regression model (R version 3.3.1).

Results: Statistical analysis of the RT-qPCR validation results showed that there is a list of 6 miRNAs able to distinguishing between patients and control [fold-changes ranging from -1.75 to 3.68]. We obtained a good prediction of the risk of MI applying a predictive model using these 6 miRNAs, achieving an area under the ROC curve (AUC) = 0.81 [95% CI=0.70-0.92; *P*< 0.001]. In addition, computational prediction of miRNA targets (miRWalk) on the 3´UTR region showed that they may interact with proteins involved in coagulation and complement, endothelium, and lipid transport or metabolism pathways (*P*< 0.05).

Conclusions: This study identifies a plasma miRNA profile characteristic of MI with good prediction of the risk of MI in our patients. Although these results need to be replicated in larger series, this miRNA profile may potentially be useful for MI discrimination. ISCIII-FEDER (PI14/00512; PI12/00027; RD12/0042/0029; PI14/00079; FI14/00269; CPII15/00002), GVA (PROMETEOII/2015/017), IIS La Fe.

PB 042 | Platelet Serotonin Aggravates Myocardial Reperfusion Injury via Degranulation

M. Mauler[1,2], N. Herr[2], C. Schoenichen[2], T. Witsch[2], T. Marchini[2], C. Haerdtner[2], C. Koentges[2], M. Schell[2], L. Dorner[2], D. Stallmann[2], H. Bugger[2], P. Walther[3], D. Wolf[2,4], I. Ahrens[2], K. Ley[4], C. Bode[2], I. Hilgendorf[2], D. Duerschmied[2]

[1]University of Freiburg, Faculty of Biology, Freiburg, Germany, [2]University Heart Center Freiburg - Bad Krozingen, Freiburg, Germany, [3]University of Ulm, Central Facility for Electron Microscopy, Ulm, Germany, [4]La Jolla Institute for Allergy and Immunology, San Diego, United States

Background: Inflammation during reperfusion injury after acute myocardial infarction (MI) comes with a burst of neutrophils migration. The peripheral hormone serotonin is synthesized by tryptophan hydroxylase 1 (TPH1) and mediates neutrophil recruitment during acute phase inflammation.

Aims: To assess the contribution of platelet derived serotonin on inflammation during myocardial reperfusion injury.

Methods: MI was induced for 30 minutes, followed by 24 hours of reperfusion. Heart function and infarct size was evaluated. Heart tissue was analyzed for cytokine expression and migrated inflammatory cells. Integrins were analyzed on circulating cells using flow cytometry. *Ex vivo* heart function was analyzed using the isolated working heart assay.

Results: Serotonin peaked 24 hours after MI in WT mice (150 ng/mL) and reached normal levels after 2 days (90 ng/mL). Heart function in SSRI treated and *Tph1*$^{-/-}$ mice compared to WT was improved and infarct size was reduced (40 in SSRI; 35 in *Tph1*$^{-/-}$; 53 in WT; % area at risk (AAR)). This effect was absent *ex vivo*. WT mice revealed increased MPO levels in the heart and neutrophil content in the AAR was reduced in *Tph1*$^{-/-}$ mice (14 vs. 28 in WT per mm^2 tissue). Depletion of neutrophils reduced infarct size to 37 %AAR in WT mice. Neutrophils had decreased expression of CD11b in SSRI (70%) treated and *Tph1*$^{-/-}$ mice (30%) compared to WT. *In vitro* stimulation with serotonin induced degranulation of neutrophils and increased CD11b expression, which was reversable by addition of a protein transport inhibitor.
Human neutrophils revealed the same phenotype and ACS patients showed a correlation of plasma 5-HT and neutrophil CD11b (R^2=0,72).

Conclusions: Serotonin directly mediates neutrophil migration during myocardial reperfusion injury by inducing degranulation and subsequent upregulation of CD11b. Intervening in serotonin-neutrophil crosstalk might provide novel anti-thromboinflammatory treatment strategies.

PB 043 | Smoking and Fibrinogen Levels Modify the Risk of MI due to FXIII V34L: Results from the MAMI Study

J. Debattista[1], R. Attard[1], C. Tabone[1], T. Lisman[2], K. Cassar[3], C.J.M. Doggen[4], S. Bezzina Wettinger[1], R. Farrugia[1]

[1]University of Malta, Department of Applied Biomedical Science, Msida, Malta, [2]University of Groningen, Surgical Research Laboratory, Department of Surgery, University Medical Centre, Groningen, The Netherlands, [3]University of Malta, Faculty of Medicine and Surgery, Msida, Malta, [4]University of Twente, Health Technology and Services Research, MIRA, Enschede, The Netherlands

Background: Coagulation factor XIII (FXIII), after activation by thrombin cleavage in the final step of the coagulation cascade, participates in cross-linking fibrin to form a stable clot. The Leu34 form of the common FXIII V34L polymorphism (rs5985) accelerates the rate by which thrombin activates FXIII during coagulation.

Aims: To determine the risk of Myocardial Infarction (MI) due to FXIII V34L in combination with smoking status and fibrinogen levels.

Methods: Data on 394 cases and 465 controls was obtained through an interviewer-led questionnaire as part of the Maltese Acute Myocardial Infarction (MAMI) Study. FXIII activity (%) was measured using a microtitre assay with fibrinogen and 5-(biotinamido)pentylamine as substrates. Fibrinogen was quantified using the Clauss assay. FXIII V34L was genotyped by PCR-RFLP with Hhal. Differences between median FXIII activity were evaluated using the Mann Whitney and Kruskal-Wallis tests. Age and gender adjusted odds ratios (OR) with 95% confidence interval (CI) were determined.

Results: In controls, median FXIII activity was markedly higher in individuals with the FXIII Leu34 allele (V/V 76.1%, V/L 125.8% and L/L 180.3%; $P < 0.001$). FXIII activity was almost identical in cases (84.5%) and controls (88.5%; P=0.42) and FXIII V34L does not appear to change the risk of MI ($OR_{V/L}$ 1.3; 95% CI 0.6-2.5, $OR_{L/L}$1.3; 95% CI 0.9-1.7). However, in smokers, risk increases with increasing number of Leu34 alleles ($OR_{V/L}$ 4.2; 95% CI 2.4-7.6, $OR_{L/L}$ 5.0; 95% CI 1.2-21.0) when compared to wild-type non-smokers. Also, men in the highest fibrinogen tertile carrying one or two Leu34 alleles had an increased risk of MI (OR 2.2; 95% CI 1.1-4.4) when compared to wild-type men in the lowest fibrinogen tertile.

Conclusions: On its own, FXIII V34L does not appear to alter the risk of MI; but in the presence of the Leu34 allele, risk is increased >4-fold in smokers and doubles in men with fibrinogen levels in the highest tertile.

PB 044 | Levels of Beta-thromboglobulin and Platelet Factor 4 Are Different between NSTEMI and STEMI: Results from the MAMI Study

J. Bonaci[1], R. Attard[1], P. Dingli[1], T. Lisman[2], K. Cassar[3], C.J.M. Doggen[4], S. Bezzina Wettinger[1], R. Farrugia[1]

[1]University of Malta, Department of Applied Biomedical Science, Msida, Malta, [2]University of Groningen, Surgical Research Laboratory, Department of Surgery, University Medical Centre, Groningen, The Netherlands, [3]University of Malta, Faculty of Medicine and Surgery, Msida, Malta, [4]University of Twente, Health Technology and Services Research, MIRA, Enschede, The Netherlands

Background: Platelet factor 4 (PF4) and Beta-Thromboglobulin (β-TG; NAP2) are both released from platelet α-granules during platelet activation. The simultaneous measurement of both proteins in plasma may be a useful marker of platelet activation.

Aims: To determine the association, if any, of these two platelet-specific proteins with ST elevation myocardial infarction (STEMI) and non-STEMI (NSTEMI).

Methods: The Maltese Acute Myocardial Infarction (MAMI) collection is composed of 394 cases with a first myocardial infarction (MI) and 465 gender and frequency matched controls. Type of MI was determined from electrocardiogram (ECG). All participants completed an interviewer-led questionnaire. Platelet poor plasma obtained from citrated blood samples was stored at -80°C. PF4 and β-TG were quantified by ELISA. The Kruskall-Wallis test was used to determine differences in median levels whilst correlation between both proteins was assessed using Spearman's rho.

Results: Levels of PF4 and β-TG are correlated (r_s 0.92; $P< 0.01$). Both PF4 and β-TG levels were lower in men when compared to women (PF4: 117.17pg/ml *vs* 134.08pg/ml; $P< =0.05$; β-TG: 119.02pg/ml *vs* 145.87pg/ml; $P<0.01$). Both decreased slightly with age whilst smoking did not have an effect. Levels of PF4 and β-TG were lower in cases when compared to controls (PF4: 97.23pg/ml *vs* 121.41pg/ml;

$P< 0.01$; β-TG: 99.51pg/ml *vs* 127.81pg/ml; $P< 0.01$). Levels were higher in patients with NSTEMI compared to those with STEMI (PF4: 104.42pg/ml *vs* 89.76pg/ml; $P< 0.01$; β-TG: 104.09pg/ml *vs* 90.13pg/ml; $P< 0.05$).

Conclusions: Our findings were different when compared to other studies which concluded that PF4 and β-TG are higher in cases than controls. Higher levels in NSTEMI may suggest ongoing platelet activation which may result in increased risk of a second event.

PB 045 | CD41 Distribution within Platelet-Monocyte Complexes in Patients with Acute Myocardial Infarction

M. Loguinova[1], N. Pinegina[1], M. Vagida[1], A. Shpektor[2], L.B. Margolis[3], E. Vasilieva[1]

[1]Moscow State University of Medicine and Dentistry, Laboratory of Atherothrombosis, Moscow, Russian Federation, [2]Moscow State University of Medicine and Dentistry, Department of Cardiology, Moscow, Russian Federation, [3]NICHD, NIH, Program in Physical Biology, Bethesda, United States

Background: The amount of circulating platelet-monocyte complexes (PMCs) is an early marker of immunoactivation and atherothrombosis. The elevated level of PMC is detected in patients with acute coronary syndrome (ACS), although the composition of such complexes has never been revealed. Participation of platelet-derived extracellular vesicles (PEVs) in formation of PMCs may be of particular interest in ACS.

Aims: To compare the amount and composition of PMCs in the whole blood of healthy donors and patients with ACS and stable angina.

Methods: The study included 28 patients with acute myocardial infarction (MI), 21 patients with unstable angina (UA), 27 patients with stable coronary artery disease (SA) and 20 healthy volunteers. Patients with ACS received standard therapy, including aspirin and P2Y12 inhibitors and subjected to PCI. Whole venous blood was sampled at admission and immediately fixed with 0,25% formaldehyde. Then 30 µL of fixed blood was immunolabeled with CD45-eFluor450, CD14-PerCP Cy5.5 and CD41a-APC and subjected to flow cytometry. PMCs were defined by simultaneous expression of all three markers. Data are presented as mean±SEM or ±SD when applicable.

Results: The percent of monocytes complexed with platelets is elevated in MI patients, compared to the group of healthy volunteers 8,98±7,33% vs. 3,55±0,81% (p< 0,00001) (Fig1). Flow cytometry revealed three populations of PMCs based on CD41 expression (Fig2A). Percent of PMCs with low CD41 MFI (type 1) increases significantly between MI and Control groups (32,8±9,3% vs. 40,7±14,4%, p*=0,03), while PMC with medium CD41 expression (type 2) tend to decrease (67,2±9,9 vs. 58,9±13,3, p=0,05) (Fig 2B).

Conclusions: PMC level is elevated in MI patients. Based on CD41 expression PMCs form three populations with dominant type 2. In MI patients compared to Control group there is a significant increase of CD41 low (type 1) PMC population, which is presumably formed with platelet-derived vesicles, but the nature of these complexes needs to be further clarified.

PB 046 | Cardiomyocyte Extracellular Vesicles Increase after Experimental Myocardial Infarction and Promote Endothelial Dysfunction in vitro

C. Roncal[1], J.A. Rodriguez[1], J. Orbe[1], G. Abizanda[2], F. Prosper[2], J.A. Paramo[3]

[1]CIMA-University of Navarra, CIBER Cardiovascular (CIBERCV), Instituto de Salud Carlos III, Program of Cardiovascular Diseases, Pamplona, Spain, [2]Clínica Universidad de Navarra-University of Navarra, Hematology Service, Pamplona, Spain, [3]Clínica Universidad de Navarra-University of Navarra, CIBER Cardiovascular (CIBERCV), Instituto de Salud Carlos III, Hematology Service, Pamplona, Spain

Background: In acute myocardial infarction (AMI), damaged cardiac cells produce extracellular vesicles (EVs) capable of transferring biological information from the cell or organ of origin. Likewise, EVs have been shown to predict future risk of cardiovascular events in some patients, although the dynamics of their release and clearance are still unclear.

Aims: to determine changes in EV numbers and cellular origin at different time points after myocardial infarction (MI) in WT mice, and to assess in vitro whether cardiomyocyte derived EVs modify endothelial function.

Methods: Mice were subjected to MI by the ligation of left-descending coronary artery. Platelet poor plasma (PPP) was obtained by double centrifugation at baseline, day 3, 15 and 30 post-MI. EV numbers and cell origin were measured in PPP by FACs using antibodies against CD41 (platelets), CD62E (endothelial cells), CD11b (leukocytes), TER119 (erythrocytes) and connexin-43 (cardiomyocytes). In vitro, endothelial function (proliferation, migration, tube formation) was determined after stimulation with cardiomyocyte (HL-1 line) derived EVs.

Results: EV numbers were similar at baseline (806±12 EVs/mL) and after MI (EVs/mL: 741±108 Day 3, 670±84 Day 15, 704±84 Day 30). No changes were observed in those derived from leukocytes, endothelial cells, platelets or erythrocytes. Cardiac EVs increased by 35 % early after infarction, remain high 15 days post-ischemia (216±16 EVs/mL, p=0.037 vs baseline) and start to decrease at day 30 (200±13 EVs/mL). In vitro, cardiomyocyte derived EVs were internalized by endothelial cells, induced their proliferation and migration, and impaired tube formation capacity.

Conclusions: Changes in circulating cardiac EVs after MI indicate a dynamic release of vesicles according to organ damage. Those heart-derived EVs could further promote endothelial dysfunction after myocardial infarction.

PB 047 | T Lymphocyte Microparticles Are the Major Determinant of Acute Coronary Syndrome

S. Howhan[1,2], N. Komanasin[2,3], A. Jumnainsong[4,5], B. Pussadhamma[6], V. Senthong[2,6], P. Makarawate[2,6], K. Anutarapongpan[7], D. Kaewkes[7]

[1]Khon Kaen University, Ph.D. Candidate in Biomedical Sciences, Graduate School, Khon Kaen, Thailand, [2]Cardiovascular Research Group, Khon Kaen University, Khon Kaen, Thailand, [3]Khon Kaen University, Faculty of Associated Medical Sciences, Department of Clinical Microscopy, Khon Kaen, Thailand, [4]Khon Kaen University, Faculty of Associated Medical Sciences, Department of Clinical Immunology and Transfusion Sciences, Khon Kaen, Thailand, [5]Khon Kaen University, Faculty of Associated Medical Sciences, The Centre for Research and Development of Medical Diagnostic Laboratories (CMDL), Khon Kaen, Thailand, [6]Khon Kaen University, Faculty of Medicine, Department of Medicine, Khon Kaen, Thailand, [7]Queen Sirikit Heart Center of the Northeast, Khon Kaen University, Khon Kaen, Thailand

Background: Microparticles (MPs) are vesicles released from various cell origins following activation or apoptosis. Cell activation and apoptosis occur during atherosclerosis development and progression. MPs have been considered as markers and contributors to the inflammatory process of atherosclerosis. Each type of MPs plays different role in the pathogenesis.

Aims: This study aimed to assess the distribution of MPs from various cell origins in patients with the occurrence of acute coronary syndrome (ACS)

Methods: Thirty two ACS patients and 30 age-matched control subjects were recruited in the study. Platelet free plasma was separated from citrated blood and MPs were measured by flow cytometry. Endothelial MPs (EMPs), platelet MPs (PMPs), monocyte MPs (MMPs), neutrophil MPs (NMPs) and T lymphocyte MPs (TMPs) were determined using specific monoclonal antibodies. Phosphatidylserine positive (PS+) and phosphatidylserine negative (PS-) MPs were also classified.

Results: Proportion of male gender, dyslipidemia and smoking as well as level of fasting blood sugar were significantly increased in ACS compared to control group. Patients with ACS revealed significantly

higher levels of EMPs, PMPs, TMPs, PS+EMPs, PS+PMPs, PS+MMPs, PS+NMPs, PS+TMPs, PS-PMPs and PS-TMPs than those in control subjects. Binary logistic regression analysis revealed the association of TMPs, PS+PMPs, PS+MMPs, PS+NMPs, PS+TMPs and PS-TMPs with ACS. However, after adjustment for male gender, dyslipidemia, smoking and fasting blood sugar, only the association of TMPs, PS+TMPs and PS-TMPs with ACS still existed [OR (95% CI) = 6.53 (1.39, 30.67)].
Conclusions: This study suggested that among MPs from various cell origins, TMPs were the major determinant of ACS.

PB 049 | Specificity of Various Haemostatic Markers in Young and Elderly Patients with Myocardial Infarction

N. Antonijevic[1,2], L. Jovanovic[1], I. Veljic[1], D. Matic[1], S. Obradovic[3], J. Dubljanin[1], J. Perunicic[1], D. Vucelic[4], D. Vukosavljevic[5], A. Beletic[5]

[1]Clinical Center of Serbia, Clinic of Cardiology, Belgrade, Serbia, [2]Shool of Medicine, Belgrade, Serbia, [3]Military Medical Academy, Belgrade, Serbia, [4]Clinical Center of Serbia, Clinic for Digestive Surgery, Belgrade, Serbia, [5]Clinical Center of Serbia, Center of Medical Biochemistry, Belgrade, Serbia

Background: Numerous haemostatic factors may induce formation of various pathogenetic substrates of atherothrombosis, further contributing to the occurrence of different forms of myocardial infarction in both young and elderly patients.
Aims: To determine the difference in the values of haemostatic markers (antithrombin, protein C, fibrinogen, FVII , FVIII , vWF, FX, FXII, homocysteine, PAI-1, CRP) in patients with myocardial infarction younger than 45 years and the group of patients with myocardial infarction older than 65 years.
Methods: In a prospective study, 143 patients were examined, i.e. 80 patients with myocardial infarction younger than 45 years and 63 patients with myocardial infarction older than 65 years.
Results: Patients with myocardial infarction of older age group compared with younger patients had statistically lower values of antithrombin (p = 0.000) (87.2±12.6 vs 105.5 ±12.4 %) and protein C (p = 0.001) (104.8±17.2 vs 117.9±18%) as well as statistically higher values of fibrinogen (p = 0.000) (5.0 ± 1.9 vs 3.8 ± 1.6 g / L) and statistically significant (p = 0.005) higher CRP concentration (32.8 ± 52.2 vs 15.0 ± 25.2 mg / L). Coagulation factor VII activity was statistically insignificantly higher (p = 0.061) in younger patients with myocardial infarction than in older patients (109.3 ± 21.8 vs 101 ± 22.8%).Compared with younger patients with myocardial infarction older patients had statistically significantly higher (p = 0.004) levels of FVIII activity (198.2 ± 92.4 vs 129.1 ± 89.8%) and statistically significantly higher (p = 0.000) values of vWF activity (183.7 ± 86.5 vs 111.9 ± 47.1%).
Conclusions: The obtained significant differences in haemostatic markers indicate their possible impact on myocardial infarction in young and elderly patients, though further research is still required to fully clarify them.

PB 050 | Soluble P-selectin Levels Are higher in Patients with NSTEMI vs STEMI

C. Agius[1], R. Attard[1], P. Dingli[1], T. Lisman[2], K. Cassar[3], C.J.M. Doggen[4], S. Bezzina Wettinger[1], R. Farrugia[1]

[1]University of Malta, Department of Applied Biomedical Science, Msida, Malta, [2]University of Groningen, Surgical Research Laboratory, Department of Surgery, University Medical Center, Groningen, The Netherlands, [3]University of Malta, Faculty of Medicine and Surgery, Msida, Malta, [4]University of Twente, Health Technology and Services Research, MIRA, Enschede, The Netherlands

Background: P-selectin is stored in the α-granules of platelets and the Weibel-Palade bodies of endothelial cells. Upon activation, it is redistributed to the plasma membrane where it participates in binding to its receptor, P-selectin glycoprotein ligand-1, present on the surface of activated leukocytes. Soluble P-selectin (sP-sel) is a cleaved form detected in plasma and is a marker of platelet activation and endothelial dysfunction.
Aims: To investigate factors that influence levels of sP-sel and to determine whether sP-sel levels are different between controls and cases with myocardial infarction (MI).
Methods: Data on 394 cases and 465 controls was obtained through an interviewer-led questionnaire as part of the Maltese Acute Myocardial Infarction (MAMI) Study. Levels of sP-sel were determined in citrated plasma using specific ELISA. Blood samples were collected from cases at least 6 months after MI. Hypercholesterolaemia and diabetic status were determined using self-reporting and biochemical measurements (lipid profile and HbA1c respectively). Differences between medians were evaluated using the Mann Whitney test.
Results: Amongst controls, median sP-sel levels were higher in men (28.4ng/ml) than in women (26.5ng/ml, $P< 0.01$). In women, sP-sel levels increased with age (< 40y=22.2ng/ml, ≥40y=27.2ng/ml, $P< 0.001$). Smoking also increased sP-sel levels (29.3ng/ml *vs* 27.4ng/ml, $P< 0.05$). Individuals with elevated HbA1c (above 6.5%) had increased median sP-sel levels when compared to non-diabetics (30.5ng/ml *vs* 27.4ng/ml, $P=0.06$), whilst cholesterol levels did not have an effect. sP-sel levels were higher in cases with non-ST elevation MI (NSTEMI) relative to cases with STEMI (29.4ng/ml *vs* 27.6ng/ml, $P< 0.01$).
Conclusions: Levels of sP-sel are affected by gender, smoking and age. sP-sel levels are higher in cases with NSTEMI where thrombi tend to be smaller, are fibrin-poor but contain numerous platelet aggregates.

PB 051 | On-treatment Platelet Reactivity in Peripheral and Coronary Blood in Patients Undergoing Primary PCI for ST-segment Elevation Myocardial Infarction (STEMI)

L. Spiezia, A. Al Mamary, E. Campello, D. Piazza, S. Maggiolo, F. Dalla Valle, M. Napodano, P. Simioni

University of Padova, Padova, Italy

Background: Dual oral antiplatelet therapy is widely used in the setting of primary percutaneous coronary intervention (p-PCI) for ST-segment

elevation myocardial infarction (STEMI). Platelet function analysis in these patients revealed a variable level of efficacy of these treatments.

Aims: Our goal was to evaluate the on-treatment platelet reactivity in peripheral and coronary blood in patients with STEMI.

Methods: One hundred and nine patients who consecutively underwent p-PCI at Cardiology Unit of Padua University Hospital from June 2014 to June 2015 were enrolled. Before the procedure, all patients received: unfractionated heparin; intravenous aspirin 250 mg; oral clopidogrel 600 mg or prasugrel 60 mg or ticagrelor 180 mg. Samples were collected from a peripheral vein and from the culprit coronary artery. Classic coagulation parameters and impedance aggregometry were measured.

Results: ASPI-test and ADP-test in peripheral blood (23±26 and 43±29 U, respectively) were higher than in coronary blood (17±23 and 39±29 U, respectively) but the differences weren't statistically significant (p >0.05). In peripheral blood, fourteen (13%) patients had ASPI-test above a predetermined (41 U) cut-off level and thirty-one (29%) patients had ADP-test above the cut-off value of 44 U. Considering clopidogrel, prasugrel and ticagrelor, the prevalence of patients above the ADP-test cut-off level was 23%, 31%, 28% respectively. Similar results were observed in coronary blood.

Conclusions: Patients undergoing p-PCI for STEMI showed an overall platelet function slightly lower in coronary than in peripheral blood. The clinical significance of peripheral and coronary on-aspirin/thienopyridines platelet reactivity remains to be clarified.

PB 052 | Ultrasound Elastography: A New Technique to Distinguish between Acute and Chronic Deep Vein Thrombosis

F. Dentali[1], N. Mumoli[2], R. Pesavento[3], M. Mochi[4], W. Ageno[1]

[1]Insubria University, Varese, Italy, [2]Department of Internal Medicine, Livorno, Italy, [3]Padua University, Padova, Italy, [4]GE Healthcare Italia SPA, Milano, Italy

Background: Ultrasound Elastography (UE) imaging is a novel ultrasound technique for relative quantification of tissue elasticity. Its applicability to venous thromboembolic events has not been established. In particular, it is not clear if this technique may be useful to determine the age of deep venous thrombosis (DVT).

Aims: The aim of this study was to assess the role of UE in distinguishing acute from chronic DVT.

Methods: Consecutive patients with unprovoked acute and chronic (≥ three month) DVT were analyzed with a 6-15 MHz matrix array linear probe during continuous freehand manual compression of the anatomic site. UE shows the spatial distribution of tissue elasticity properties in a Region of Interest (ROI) by estimating the strain before and after the distorsion caused by external and internal forces. The mean strain values of acute and chronic popliteal and femoral vein thrombosis were compared. Furthermore, we assessed the accuracy of strain in distinguishing between acute and chronic DVT.

Results: 80 patients (mean age 65.6 years, SD 14.2; 41 males) with acute and chronic DVT were included; 116 femoral and popliteal DVT were analyzed. Mean strain value of acute femoral DVT was significantly higher than chronic femoral DVT (4.92 vs 2.62 $p < 0.001$) and mean strain value of acute popliteal DVT was significantly higher than chronic popliteal DVT (4.82 vs 2.60 $p < 0.001$). Age, sex and thrombus location did not significantly affect the strain value (data not shown). A strain value > 4 had a sensitivity of 97.6% (95% CI 85.9, 99.8), a specificity of 94.6% (95% CI 86.0, 98.2), a positive predictive value of 91.1% (95% CI 77.9, 97.1), a negative predictive value of 98.6% (95% CI 91.3, 99.9), and a positive likelihood ratio of 18.06 (95% CI 6.95, 46.9), and a negative likelihood ratio of 0.025 (95% CI 0.003, 0.175).

Conclusions: UE appeared a promising technique to distinguish between acute and chronic DVT.

ClinicalTrials.gov Identifier: NCT02809638

PB 053 | General Practitioner-performed Compression Ultrasound for Deep Vein Thrombosis (Practicus Study): A Prospective, Multicenter Cohort Study

F. Dentali[1], D. Mastroiacovo[2], M. Giorgi-Pierfranceschi[3], R. Tulino[4], N. Mumoli[5]

[1]Insubria University, Varese, Italy, [2]Angiology Unit, Avezzano, Italy, [3]Emergency Department, Piacenza, Italy, [4]Primary Care, Grosseto, Italy, [5]Department of Internal Medicine, Livorno, Italy

Background: Currently, compression ultrasonography (CUS) is universally recognized as the procedure of choice for the diagnosis of suspected deep vein thrombosis (DVT) of the lower limb.

Aims: The aim of this study was to assess the diagnostic accuracy of CUS performed by General Practitioners (GP) in primary care setting for symptomatic proximal DVT of the lower limb.

Methods: We prospectively evaluated, in a multicenter cohort study, all the consecutive outpatients referred for suspected DVT from May 2014 to May 2016; all patients underwent bilateral proximal lower limb CUS first by GP and then by physicians expert in vascular ultrasonography, every group blinded with respect to each other. This test was repeat after 5-7 days in all negative or unclear exams. Inter-observer agreement and accuracy were calculated.

Results: We enrolled 1107 patients; DVT was diagnosed by expert ultrasound physicians in 200 patients with an overall prevalence of 18.1% (95% CI 15.8, 20.3). GP agreement with the physician in DVT diagnosis was excellent (Cohen's k 0.86, 95% CI 0.84, 0.88). GP-performed CUS had a sensitivity of 90.0% (95% CI 88.2, 91.8) and a specificity of 97.1% (95% CI 96.2, 98.1) with a diagnostic accuracy of 95.8% (95% CI 94.7, 97).

Conclusions: Our results suggest that GP-performed CUS may be a potential useful alternative in the diagnosis of DVT, with a good accuracy. However, sensibility of GP-performed CUS appeared sub-optimal and future studies should incorporate in the evaluation of this technique other pre-test tools that may increase its accuracy.

ClinicalTrials.gov Identifier: NCT02114983

PB 054 | Targeted MiR126 Therapy of Abdominal Aortic Aneurysm

X. Wang, A.K. Searle, Y.C. Chen, A. Liu, K. Peter

Baker Heart and Diabetes Institute, Melbourne, Australia

Background: Abdominal aortic aneurysm (AAA) is a major health concern, carrying an astonishingly high acute mortality rate. Current condition monitoring for high-risk patients is ultrasound imaging, without secondary prevention therapies available. Limited high-risk surgical interventions are available for severe cases.

Aims: Targeted microbubbles for the delivery of microRNA-126 (miR_{126}) mimics downregulate vascular cell adhesion molecule-1 (VCAM-1) expression, rectify endothelial inflammation and ameliorate the development of abdominal aortic aneurysm.

Methods: Single-chain antibodies against VCAM-1 were conjugated onto ultrasound enhancing microbubbles, and coated with miR_{126} for targeted delivery.

Results: Using the angiotensin II induced model of murine AAA, we observed that targeted delivery of mimic-miR_{126} hinder the dilation of the abdominal aorta both before (1.12 ± 0.11 vs. 1.36 ± 0.12; mm mean ± SD; p>0.05; N=5-9) and after (0.88 ± 0.06 vs. 1.05 ± 0.05; p>0.001; N=5-9) the renal arteries. Further confirmation using 3D ultrasound vessel reconstructions, immunohistological examination, and gene expression analyses (p>0.01; N=5-9) confer an overall decrease in VCAM-1 expression and aneurysm severity.

Conclusions: We describe a novel theranostic approach towards effective reestablishment of intravascular endothelial homeostasis under pro-inflammatory conditions. This technology holds immense potential for a safe, non-invasive, targeted treatment towards conditions driven by inflammation of the endothelial, including AAA.

PB 056 | Risk Prediction Model for Peripheral Arterial Disease Patients Undergoing Revascularization within Two Years of Diagnosis

R. Olie[1,2,3], S. Petersohn[4,5], B. Ramaekers[4,5], S. van Kuijk[4,5], A.J. ten Cate-Hoek[6,7], M.-C. Kleinegris[7], M. Joore[4,5], H. ten Cate[6,7,8]

[1]Maastricht University Medical Centre+, Internal Medicine, Maastricht, The Netherlands, [2]Maastricht University Medical Centre+, Thrombosis Expertise Center, Maastricht, The Netherlands, [3]Maastricht University / Cardiovascular Research Institute Maastricht (CARIM), Laboratory for Clinical Thrombosis and Haemostasis, Maastricht, The Netherlands, [4]Maastricht University Medical Center +, Department of Clinical Epidemiology and Medical Technology Assessment (KEMTA), Maastricht, The Netherlands, [5]Maastricht Unversity, School for Public Health and Primary Care (CAPHRI), Maastricht, The Netherlands, [6]Maastricht University Medical Center +, Thrombosis Expertise Center, Maastricht, The Netherlands, [7]Maastricht University / Cardivascular Research Institute Maastricht (CARIM), Laboratory for Clinical Thrombosis and Haemostasis, Maastricht, The Netherlands, [8]Maastricht University Medical Center +, Internal Medicine, Maastricht, The Netherlands

Background: Despite standard conservative management of patients with peripheral arterial disease (PAD), about 40% will undergo revascularization procedures within 2 years. Predicting the risk for progression more accurately at time of diagnosis would provide physicians with a means to stratify patients in low and high risk subjects and to tailor treatment accordingly. Stricter monitoring of high-risk patients, leading to a more timely decision to switch from conservative treatment to invasive therapy, can prevent further progression with associated quality of life decline.

TABLE 1 Multivariate model for prediction of revascularization within two years following diagnosis

	Regression coefficient (crude)	Regression coefficient (adjusted[a])	Odds ratio (OR)(80% confidence-interval)		Regression coefficient (crude)	Regression coefficient (adjusted[a])	Odds ratio (OR)(80% confidence-interval)
Hypertension	-0.045	-0.031	0.956 (0.669-1.366)	Fontaine stage IIb-IV	0.623	0.462	1.865 (1.292-2.694)
History of myocardial infarction	-0.189	-0.139	0.828 (0.478-1.436)	Age	-0.043	-0.032	0.958 (0.937-0.979)
Cholesterol lowering drugs	-0.057	-0.043	0.944 (0.607-1.469)	Male gender	0.010	0.010	1.010 (0.699-1.460)
Diabetes	-0.197	-0.142	0.821 (0.519-1.298)	Impaired kidney function (GFR<60ml/min)	-0.607	-0.448	0.545 (0.340-0.874)
Physical function	-0.017	-0.013	0.983 (0.975-0.991)	Elevated age-adjusted D-Dimer	0.415	0.296	1.514 (1.033-2.218)
Ankle-brachial index	-1.246	-0.930	0.288 (0.108-0.763)	Constant	3.985	2.902	

[a]Regression coefficients adjusted for over-fitting with shrinkage factor = 0.74, intercept is re-estimated. To calculate the absolute probability of revascularization within 2 years of PAD diagnosis: P(revascularization) = $1/(1+e^{-Regression})*100\%$. Regression = (-0.032 x age) + (0.010 x male gender) - (0.930 x ABI) - (0.139 x MI) - (0.142 x Diabetes) - (0.031 x Hypertension) - (0.043 x Cholesterol-lowering drugs) - (0.013 x Physical Function) + (0.462 x Fontaine severe) - (0.448 x Impaired kidney function) + (0.296 x Elevated D-Dimer) + 2.902.

Aims: To develop and internally validate a prediction model for revascularization within two years following diagnosis, to assist in personalizing treatment of PAD-patients.

Methods: In a cohort of 280 newly diagnosed PAD-patients data regarding medical history, cardiovascular risk profile, D-dimer, medication use and patient-reported quality of life were collected at baseline. Primary endpoint was defined as a revascularization procedure within two years after diagnosis. A set of predictors was selected from a literature review and expert consultation, subsequently a prediction rule was developed using multivariable logistic regression and internally validated using bootstrapping techniques.

Results: In total, 108 patients (38.6%) underwent revascularization within two years of diagnosis. Predictors included into the model were hypertension, history of myocardial infarction, cholesterol-lowering drug use, diabetes, physical function, ankle-brachial index, Fontaine stage, age, gender, renal function and increased age-adjusted D-Dimer. The area under the receiver operating characteristic curve of the internally validated model was 65% (95%CI 63.7-76.3%) with good calibration.

Conclusions: We successfully developed a practical prediction model to stratify newly diagnosed PAD-patients in low and high risk for revascularization to assist physicians in optimizing individual patient management.

PB 057 | Repetitive Intravenous Thrombin Injections Result in Pulmonary Arterial Endothelial Dysfunction in a Mouse Model of Sublethal Acute Pulmonary Embolism

V.S. Garlapati[1], M. Brandt[2], E. Giokoglu[1], T. Schoenfelder[1], S. Kossmann[1], M. Knorr[2], T. Muenzel[3], P. Wenzel[2]

[1]Center for Thrombosis and Hemostasis (CTH), Mainz, Germany, [2]Center for Thrombosis and Hemostasis (CTH), Center for Cardiology - Cardiology I, University Medical Center of the Johannes Gutenberg University, Mainz, Germany, [3]Center for Cardiology – Cardiology I, University Medical Center of the Johannes Gutenberg-University Mainz, Mainz, Germany

Background: Acute pulmonary embolisms (APEs), resulting from deep vein thromboses (DVT), undergo a total or near-total resolution. Caused by yet unidentified mechanisms, a process of remodeling ultimately resulting chronic thromboembolic pulmonary hypertension (CTEPH) is initiated. The mechanisms that underlie the chronification of emboli and ultimately the development of CTEPH remain uncertain.

Aims: The main aim is to investigate the effect of single or repetitive sublethal experimental pulmonary embolism on the pulmonary vasculature, further comparing it to the IVC (inferior caval vein)-stenosis model.

Methods: C57BL/6J mice were anaesthetized and APEs were induced by i.v. injection of thrombin 2.5-5 Units (U) by retro-orbital injection. Repetitive thrombin doses were administered after recovery. For IVC-ligation the IVC was exposed and permanently ligated with space holder. PA vasoconstriction as well as endothelial dependent and independent relaxation was analyzed by exposure to increasing concentrations to phenylephrine, acetylcholine and glyceryl trinitrate under physiologic conditions. ROS-burden was evaluated and dihydroethidium (DHE) staining of PA cryosections.

Results: Pulmonary embolisms after injection of thrombin were confirmed by a sudden bradycardia and an increase in PA-pressure as observed by echocardiography. 12 h after repetitive (triple) pulmonary embolisms, isometric tension studies revealed a significant endothelial dysfunction in PAs explanted from embolized animals as compared untreated animals. Importantly, no APE and no PA endothelial dysfunction were detected after IVC-ligation. Further, the levels of superoxide were significantly increased in PAs from triple-embolized mice as compared to PAs from control mice or after IVC-ligation.

Conclusions: Subtotal IVC-ligation is not a subsequent model for APEs, the most important complication of DVT. Repetitive APEs by triple injection of thrombin results in PA endothelial dysfunction, which could initiate remodeling cascade resulting in CTEPH.

PB 058 | Lack of Association between Candidate Gene Polymorphisms and Ischemic Events in Patients with Peripheral Arterial Disease

V. Boc[1], M. Bozic Mijovski[1], M. Pohar Perme[2], A. Blinc[1]

[1]University Medical Centre Ljubljana, Department of Vascular Diseases, Ljubljana, Slovenia, [2]Medical Faculty, University of Ljubljana, Institute of Bomedical Informatics, Ljubljana, Slovenia

Background: Genetic basis of peripheral arterial disease (PAD) is incompletely understood.

Aims: We tested whether selected single nucleotide polymorphisms (SNPs) were associated with PAD and whether they affected cardiovascular adverse events in comparison to diabetes and smoking.

Methods: 710 patients with PAD and 650 age- and sex-matched control subjects, both groups aged 65±9 years at inclusion, were subjected to yearly physical and laboratory investigations and were managed for 5 years according to the European guidelines on cardiovascular disease prevention (ClinicalTrials.gov number NCT00761969). The occurrence of death, non-fatal myocardial infarction or ischemic stroke (major events) and revascularization procedures (minor events) was recorded. SNPs of Nurr1 gene, associated with regulation of inflammation (rs1466408, rs13428968 and rs12803), IL6 gene, encoding the inflammatory cytokine and being associated to susceptibility to diabetes mellitus (rs10499563), PECAM 1 gene, involved in leukocyte migration, angiogenesis and integrin activation (rs668 and rs12953), and Chr12 gene, associated with coronary events (rs10861032) were determined.

Results: The distribution of selected SNPs did not differ between patients with PAD and control subjects, and neither between subjects with ischemic events (n = 275) and those without events. In contrast with the negative findings of genetic testing, diabetes and smoking strongly affected survival. The hazard ratio for cardiovascular death in PAD patients with diabetes was 2.14 (CI 1.21-3.76) in comparison to patients without diabetes (p = 0.008). The 5-year survival of active

smokers with PAD was 0.80 (CI 0.75-0.62), of former smokers 0.83 (CI 0.79-0.88), and of never-smokers 0.89 (CI 0.86-0.93), (p = 0.024).
Conclusions: SNPs of Nurr1, IL6, PECAM1 and Chr12 were not associated with PAD or with ischemic events. However, diabetes and smoking were associated with worse survival.

PB 059 | Restenosis is a Predictor of Poor Outcome in Patients Undergoing Endovascular Intervention for Peripheral Arterial Disease

M. Sartori[1], A. Pacelli[2], E. Favaretto[1], E. Conti[1], B. Cosmi[1]

[1]*Azienda Ospedaliera di Bologna Policlinico Sant'Orsola Malpighi, Angiology and Haemostasis Unit, Bologna, Italy,* [2]*Ospedale ICOT di Latina, Sapienza Universita' di Roma, UO Medicina Interna, Rome, Italy*

Background: Few data are available on clinical outcome in patients who underwent percutaneous transluminal angioplasty (PTA) for peripheral arterial disease (PAD). We speculated that restenosis after PTA is a predictor of poor outcome, being restenosis a marker of a more aggressive atherothrombosis.
Aims: To ascertain if restenosis after PTA was associated with higher risk of cardiovascular events in patients with PAD.
Methods: A longitudinal study of 310 patients who underwent PTA for PAD (Fontaine's stages: II through IV; aged 70 ±11 years, male/female 182/126). Major adverse cardiovascular events (MACE) were the composite end-point. The study started after the PTA. Each patient was seen after one month, six months, one year and every year thereafter. At each visit, clinical examination, ABI measurement and duplex sonography (DUS) were performed. Primary patency was maintained until restenosis defined by a peak systolic velocity (PSV) ratio >2.4 and >70% diameter reduction was documented by DUS. Patients were followed-up for an average time of 4050±885 days.
Results: 117 (37.7%) patients developed restenosis. Age, sex, and ABI before PTA were similar among patients with restenosis vs. those without. Diabetes was more frequent in patients with restenosis vs. those without (33.3 vs. 20.9%, p=0.017). During the follow-up, MACEs (n=146) were more frequent in the patients with restenosis versus those without (79.5 vs. 30.1% log-rank p< 0.001). According to Cox regression analysis, age, diabetes, critical limb ischemia before PTA, and restenosis (RR 3.2 95%CI 2.3-4.5, p< 0.001) were predictors of MACE.
Conclusions: The presence of restenosis at DUS in patients who underwent PTA for PAD is associated with increased risk of arterial thrombotic events. Intervention trials are required to show the benefit of different therapeutic approaches in such patients at high risk of clinical deterioration.

PB 061 | Venous Thromboembolism Following Hantaviral Infection

A.-M. Connolly-Andersen[1], H. Whitaker[2], J. Klingström[3], C. Ahlm[1]

[1]*Umeå University, Dept. of Clinical Microbiology, Umeå, Sweden,* [2]*Open University, Dept. of Mathematics and Statistics, Milton Keynes, United Kingdom,* [3]*Karolinska Institutet, Center for Infectious Medicine, Huddinge, Sweden*

Background: The hallmark characteristics for viral hemorrhagic fevers are thrombocytopenia, vascular dysfunction and disseminated intravascular coagulation. Previously, we have shown that Puumala hantavirus, an etiologic agent for hemorrhagic fever with renal syndrome (HFRS) constitutes a significant risk factor for acute myocardial infarction and stroke (Connolly-Andersen et al., 2014, Circulation). However, there is no information available regarding whether the risk for venous thromboembolism (VTE) increases during HFRS.
Aims: Determine whether HFRS is a risk factor for VTE.
Methods: HFRS in Sweden is a notifiable disease. The personal identification numbers from all HFRS patients since 1997 were cross-linked with the Swedish National Patient Register. We used the self-controlled case series method to calculate the incidence rate ratio (IRR) for VTE during HFRS.
Results: 7244 HFRS patients were included in the study and of these 146 had a first deep vein thrombosis (DVT) or pulmonary embolism (PE). The age-adjusted IRR for a first VTE in the first two weeks following HFRS was 64.3 (95% CI 36.3-113.9). When divided into a first DVT or PE, the age-adjusted IRR was 45.9 (18-116.9) and 76.8 (37.1-158.9), respectively. The risk for a VTE remained significantly higher up to 3 months following HFRS.
Conclusions: HFRS is a risk factor for venous thromboembolic events. Although HFRS is considered a mild viral hemorrhagic fever, our studies highlight the increased risk for thromboembolic complications. Our findings support the notion that preventive measures, especially for patients with additional risk factors, might be beneficial. However, this warrants further studies.

PB 062 | Abdominal Aortic Calcification in Patients with Peripheral Arterial Disease: Hemostasis Changes in Relation to Calcinosis Grade

V. Zelinskiy, A. Svetlikov, V. Andreev

L.G. Sokolov Memorial Hospital №122, Trombosis Center, Vascular Surgery Department, Saint Petersburg, Russian Federation

Background: Peripheral arterial disease (PAD) has often assosieted with abdominal aortic calcification (AAC) and hypercoagulable states.
Aims: The objective of our research work was to determine the specific haemostatic features in patients with PAD in relation to different grade of an AAC.
Methods: A total of a 94 symptomatic PAD patients with objective signs of AAC were enrolled into the study cohort. PAD was defined as an ABI < 0.9. The exclusion criteria of our study were diabetes mellitus, abdominal aortic aneurism, previous vascular intervention and chronic renal insufficiency. AAC was verified by CT-imaging. Adopted Agatston score (As) was used for evaluating of an AAC severity. The study cohort was divided into three groups according to As: group I (mild calcification) - 30 patients, group II (moderate calcification) - 32 patients, group III (severe calcification) - 32 patients. Activity of VIII and von Willebrand factors (vWF), fibrinogen concentration, antithrombin activity and Hagemann-dependent lysis were evaluated.

Results: Three groups of patients were similar according to age, gender and other risk factors for PAD. We have not found any statistically significant differences in activity of VII factors and the Hageman-dependent lysis between groups (p>0.05 for all compared variants). The concentration of antithrombin activity was inversely correlated with the grade of aortic calcification (p< 0.01). The mean concentration of fibrinogen (4.1±1.2 g/l vs. 8.6±0.8 g/l vs. 6.7±0.6 g/l, respectively (p< 0.01 for all compared variants)) and the mean activity of vWF (136.2±12.7% vs. 188.1±15.2% vs. 161.6±11.8%, respectively (p< 0.01 for all compared variants)) were highest in patients with moderate aortic calcification.

Conclusions: Our findings have shown that an AAC may influence to haemostatic system in patients with PAD. Interestingly, that haemostasis was correlated with the grade of abdominal aortic wall calcification and, severe coagulation disorders were related to a moderate grade of calcification.

PB 063 | Thrombophilic and Cardiovascular Risk Factors for Retinal Vein Occlusion

P. Bucciarelli, S.M. Passamonti, F. Gianniello, A. Artoni, F. Peyvandi, I. Martinelli

Fondazione IRCCS Ca' Granda - Ospedale Maggiore Policlinico, A. Bianchi Bonomi Hemophilia and Thrombosis Centre, Milan, Italy

Background: The role of thrombophilic and cardiovascular risk factors in different manifestations of retinal vein occlusion (RVO), i.e., central or branch RVO, and at different ages is still debated.

Aims: To evaluate the association between thrombophilic and cardiovascular risk factors and the risk of RVO (overall, separately for central and branch RVO, and at different ages).

Methods: Case-control study on 313 patients with a first objectively-confirmed RVO (52% females, median age 54 yrs, 216 central and 97 branch RVO) consecutively referred at our Thrombosis Center for a thrombophilia work-up, and 415 healthy individuals (71% females, median age 41 yrs). Cardiovascular risk factors (hypertension, hyperlipidemia, diabetes and cigarette smoking) were recorded. In a multivariable logistic regression model, the risk of RVO in carriers relative to non-carriers of a particular risk factor was estimated as odds ratio (OR) and 95% confidence intervals (CI), adjusting for age, sex and the other risk factors.

Results: Antithrombin, protein C or protein S deficiency (adjusted odds ratio [95%CI]: 15.60 [2.01-121]), hyperhomocysteinemia (HHCy: 3.22 [1.38-7.49]), high factor VIII (FVIII) levels (3.08 [1.20-7.89]), factor V Leiden (2.93 [0.97-8.86]) and the presence of at least one cardiovascular risk factor (1.79 [1.00-3.23]) were associated with an increased risk of branch RVO. The association was weaker for central RVO, and limited to HHCy (2.15 [1.09-4.24]) and high FVIII (1.99 [0.90-4.42]). For HHCy, high FVIII and cardiovascular risk factors the association with the risk of RVO was stronger at an age >50 yrs (3.41 [1.29-8.99], 2.57 [1.00-6.68] and 2.03 [1.16-3.56], respectively) than ≤50 yrs (1.93 [0.85-4.36], 1.67 [0.54-5.12] and 1.22 [0.73-2.03], respectively).

Conclusions: Thrombophilic and cardiovascular risk factors are associated with RVO, particularly branch RVO. The risk of RVO associated with HHCy, high FVIII and cardiovascular risk factors is higher at an older age.

PB 064 | Patients with Cryptogenic Acute Limb Ischemia Have High Recurrence Rates Off Anticoagulation: Results of a Single Institution Retrospective Cohort Study

D. Mart, J. Shatzel, T. Deloughery

Oregon Health & Science University, Hematology, Portland, United States

Background: Acute limb ischemia (ALI) is often secondary to emboli, or progression of peripheral vascular disease (PVD). Rarely, ALI occurs in the absence of known PVD, or obvious cause. Rarer still, occasionally the cause of ALI remains truly cryptogenic. (cALI) While precipitated ALI (pALI) is well-described, cALI is a population that has not been studied, and whose management is not established.

Aims: To describe the population that develops ALI without PVD, and cALI, and recurrence rates based on therapeutic choices.

Methods: Retrospective review of patients treated from Jan, 2002 - present at our facility. We included adults seen for ALI with at least 3 months of follow up. Patients with known PVD, trauma, critical illness, or recent vascular access were excluded. We examined documentation to determine a root cause in each case. Patients with no identifiable cause for their ALI were labeled as cALI. We compared patients with pALI and cALI, evaluating rates and mean time to recurrence, and circumstances surrounding recurrence.

Results: Out of 608 patients analyzed, 39 had ALI without PVD. 30 were found to have a precipitating cause and were labeled as pALI. 9 (23%) had no identifiable cause, and were labeled as cALI. The demographics of the two groups were similar. In total, 8 patients recurred (20%) 5 with pALI (15%) and 3 with cALI (33%). Median time to recurrence was 16.5 months in the pALI group, and 23.3 months in the cALI group. Of those who recurred, a similar proportion did so off anticoagulation in both groups (60 and 66% of patients off anticoagulation, respectively).

Conclusions: Over 20% of patients presenting with ALI without PVD did not have an identifiable cause and remained cryptogenic. Recurrence rates in patients with pALI and cALI are similar, occuring in nearly 60% of patients who are not anticoagulated. This suggests that the etiology of ALI may be less important in patients without PVD, and that indefinite anticoagulation may be warranted in both precipitated and cryptogenic ALI.

PB 065 | Gene-sodium Interaction on the Developing of Hypertension: A Cohort-based Case-control Study

M.-L. Chen[1], T.-P. Huang[2], B.-F. Hwang[3]

[1]Hungkung University, Taichung, Taiwan, Republic of China, [2]National Chung Hsing University, Taichung, Taiwan, Republic of China, [3]China Medical University, Occupational Safety and Health, Taichung, Taiwan, Republic of China

Background: There are few studies concerning gene-sodium interaction between G-protein beta3 subunit (GNB3) C825T (rs5443) and dietary sodium intake on the risk of hypertension, i.e. BP salt sensitivity.
Aims: The study aims to evaluate the joint influence of GNB3 polymorphisms and sodium consumption on the occurrence of hypertension.
Methods: A cohort-based case-control study was conducted in 2014. There are 233 participants with new hypertension in the case group and 233 participants in the sex-matched the control group. The primary outcome is the occurrence of hypertension over a 10-year period. The determinants of hypertension were 3 genotypes of SNP in GNB3 (TT; CT and CC) and two dietary salt categories on the basis of the level of sodium consumption representing high (> 4800 mg/day), and low-sodium (< 2400 mg/day) diets.
Results: The occurrence of hypertension was increased with participants carrying TT genotype and high-sodium diets comparing with those carrying TC or CC genotype with low-sodium diets (adjusted OR 4.13, 95% CI 1.53-10.95) (Rothman synergy index=1.49).
Conclusions: The study suggests that GNB3 C825T polymorphism may influence the response of the renin-angiotensin system to high-sodium diet. It imply that participants carrying TT variant allele and dietary high-sodium are more likely to occurrence of hypertension.

PB 066 | Drug Induced Venous Thrombosis

F. Saïd[1,2], M.S. Hamdi[1,2], M. Khedher[1,2], I. Ben Ghorbel[1,2], M. Lamloum[1,2], T. Ben Salem[1,2], M. Smiti[1,2], M.H. Houman[1,2]

[1]*University Hospital La Rabta, Department of Internal Medicine, Tunis, Tunisia,*
[2]*University Tunis El Manar, University of Medicine of Tunis, Tunis, Tunisia*

Background: Deep vein thrombosis and pulmonary embolism are major cause of morbidity. It has been recognized that drugs may play an important role in development of thrombosis whether it is chemotherapy or a vastly prescribed therapy such as oral contraceptive.
Aims: To investigate the epidemiological and clinical characteristics of patient presenting drug induced thrombosis.
Methods: Retrospective study including 1055 patients admitted in internal medicine department of La Rabta hospital in Tunisia, researching patients with drug usage prior to thrombosis.
Results: Among the 1055 patients hospitalized for venous thrombosis, 421 were already on drugs. Of these patients, intake of thrombosis inducing drug was noted in 46 cases (10.9%). Sex-ratio was 1.19. Mean age of our patients was 51 years. Elderly patients represented 34.8%. Smoking was observed in 28% of patients. The other factors, contributing to thrombosis formation are presented in table 1.
Venous thrombosis was at the lower limbs in 95.7%. It was a proximal venous thrombosis in 76% of cases. Inferior vena cava thrombosis was noted in 3 cases.
Among the incriminated drugs, we noted chemotherapy (4 cases), Thalidomide (2 cases), estroprogestative (13 cases), Androcur® (2 cases) and Carbamazepine (12 cases). Complications observed consisted in pulmonary embolism (11.2%) and post-phlebitis syndrome (15%). On treatment no thrombosis extension was observed. Treatment was based on LMWH relayed by oral anticoagulant with eviction of suspected drug whenever possible. The average duration of VKA treatment in our patients was 35 months. Recurrence of thrombosis was noted in 13% of cases.
Conclusions: Drug-induced thrombotic event are usually venous thrombosis, however arterial thrombotic event have also been reported. Better understanding of the mechanisms by which drugs exert thrombosis may facilitate their safe use in patients, especially those with predisposing risk factors.

PB 067 | Retinal Vascular Occlusions: A Retrospective Study

F. Saïd[1,2], S. Hamrouni[1,2], Z. Meddeb[1,2], M. Lamloum[1,2], I. Ben Ghorbel[1,2], T. Ben Salem[1,2], M. Khanfir[1,2], M.H. Houman[1,2]

[1]*University Hospital La Rabta, Department of Internal Medicine, Tunis, Tunisia,*
[2]*University Tunis El Manar, University of Medicine of Tunis, Tunis, Tunisia*

Background: Retinal vascular thrombosis (RVT) are an important cause of vision loss. Some of them may result of loco-regional ocular causes. They more often occur in patients with cardiovascular pathologies or risk factors, or sometimes other systemic diseases that need to be recognized for a proper treatment.
Aims: to study clinical, etiologic and evolutive characteristics of RVT.
Methods: This retrospective study included patients hospitalized in our department between 2005 and 2016 for RVT.
Results: Ten cases of RVT were observed. It was venous thrombosis (4 cases), arterial thrombosis (4 cases) and mixed thrombosis (arterial and venous) (2 cases). The sex ratio was 1. 4 men had retinal venous thrombosis (RVeT), 3 women had retinal arterial thrombosis (RAT) and 2 women had mixed thrombosis (MT). The average age was 50 years. Patients in the RVeT group had unilateral involvement in 50% of cases affecting the central retinal vein in all cases. These RVeT were ischemic (2 cases), oedematous (1 cases) and mixed (1 case). The symptoms during RVeT were marked by progressive reduced visual acuity in 75% of the cases with a visual acuity less than 1/10 in the both patients with ischemic involvement. The etiologies found in this group are presented in table 1.RAT affected the central artery of the retina in all cases and was symptomatic of amputation of the visual field. Theetiologies of this group are presented in table 2.
MT was observed in 2 patients. It affected the retinal ciliary artery and was responsible for a reduction in visual acuity.
All patients received platelet anti-aggregation with specific treatment of background pathology.
Conclusions: A diagnosis of RVT represents a challenge for both ophthalmologists and internists. Collaboration is required to properly investigate and manage these patients. In spite of the current knowledge, there is a clear need for future studies evaluating medical interventions for this condition.

PB 068 | Thrombosis Events in Antiphospholipid Syndrome

F. Saïd[1,2], M. Khedher[1,2], M.S. Hamdi[1,2], I. Ben Ghorbel[1,2], M. Lamloum[1,2], T. Ben Salem[1,2], M. Khanfir[1,2], M.H. Houman[1,2]

[1]University Hospital La Rabta, Department of Internal Medicine, Tunis, Tunisia, [2]University Tunis El Manar, University of Medicine of Tunis, Tunis, Tunisia

Background: Anti-phospholipid syndrome (APS) is an autoimmune disease characterized by the occurrence of thrombo-embolic manifestations or obstetric complications.

Aims: to report the epidemiological, clinical and evolutionary characteristics of venous thrombosis during the APS.

Methods: A retrospective study including records of patients hospitalized between 2010 and 2015 for venous thrombosis which was related to antiphospholipid syndrome.

Results: Between 1055 cases of venous thrombosis, 80 patients had an antiphospholipid syndrome. The latter was associated with systemic lupus erythematosus in 4 patients and Sjogren syndrome in one patient. . Female predominance was observed in 77.8% of patients. The risk factors for MVTE observed were: age over 50 years (27.8%), obesity (33%), venous insufficiency (5.6%), varicose veins (11.1%), bed rest Prolonged (16.7), trauma (5.6%) and surgery (16.7%). Thrombosis of the lower limbs was found in 66.7% of the cases. An unusual localization was reported in 27.8% of the patients. It was proximal in 38.9% of the cases and distal in 27.8% of the cases. A post-phlebitic syndrome was objectified in 16.7%. Six cases of recurrence were found.

Conclusions: Antiphospholipid syndorme is an important aetiology of venous thrombosis which must be searched when thrombosis occured in young patient, thrombosis have unusual localization or is reccurent.

PB 069 | Mean Platelet Volume (MPV) as a Predictor of Venous Thromboembolism (VTE) in Colorectal Cancer

C. Wilasrusmee[1], B. Siribumrungwong[2], N. Poprom[1]

[1]Faculty of Medicine Ramathibodi Hospital, Mahidol University, Surgery, Bangkok, Thailand, [2]Faculty of Medicine, Thammasat University Hospital, Surgery, Bangkok, Thailand

Background: Platelet activity is a major devilish in atherothrombotic events and cancer. Mean platelet volume (MPV), which is widely available as a routine parameter of the complete blood count, is a potentially useful biomarker of platelet activity in the setting of venous thrombosis. Recent studies showed that high-MPV levels associated with a increase VTE risk in cancer patients.

Aims: To investigate the role of MPV in VTE and colorectal-cancer.

Methods: A retrospective study was performed to analyze differences of MPV between patients with VTE, VTE and colorectal-cancer, and control. Two reviewers independently extracted data for meta-analysis. Differences in MPV were expressed as unstandardized mean difference.

Results: Among 170 patients, 58-control, 54-VTE, and 58-VTE with colorectal-cancer, MPV was significantly higher in VTE groups. From 403 articles, 10 studies(5 cohorts and 5 case-controls) comprising 2,265 patients. MPV was significantly higher in those with VTE (mean difference 0.61 fL,95%CI 0.34-0.88,P< 0.001). Elevated MPV increased the relative risk of VTE (RR 1.319,1.061-1.641,I2=82.5%).

Conclusions: Our evidence suggests that elevated MPV is associated with VTE and VTE with colorectal-cancer. A mechanistic study and RCT are required in order to use antiplatelet therapy.

PB 772 | Regular Physical Activity and Risk of Incident Venous Thromboembolism in the General Population

L.H. Evensen[1,2], T. Isaksen[1,2], S.K. Braekkan[1,2], J.B. Hansen[1,2]

[1]UiT - The Arctic University of Norway, K.G. Jebsen - Thrombosis Research and Expertise Center (TREC), Tromsø, Norway, [2]University Hospital of North Norway, Division of Internal Medicine, Tromsø, Norway

Background: Despite extensive health benefits of regular physical activity (PA), most cohort studies investigating the association between PA and risk of incident venous thromboembolism (VTE) have failed to show a favorable effect. The lack of effect may reflect an underestimation of the true association due to fluctuations in PA during a long follow-up (regression dilution bias).

Aims: To investigate whether regular PA of moderate and high intensity during leisure time was associated with incident VTE in a population-based cohort with repeated assessments of PA.

Methods: A total of 30 046 subjects with data on PA participating in one or more surveys of the Tromsø Study (1994-95, 2001-02, 2007-08) were included, and incident VTE was registered up to 31.12.12. Self-reported weekly duration of moderate and high intensity PA was categorized (no PA, < 1h, 1-3h and >3h), and hazard ratios (HRs) adjusted for sex and BMI were calculated using time-varying Cox-regression models with age as timescale. The lowest PA category was set as reference.

Results: There were 457 VTE events during follow-up (incidence rate 1.5 per 1000). PA was not associated with risk of incident VTE in the general population (HR for upper PA category: 0.92; 95% CI 0.63-1.32). However, in elderly (≥65 years), a moderate amount of PA (1-3h/week) was associated with 38% lower risk of VTE (HR 0.62; 95% CI 0.41-0.95), 63% lower risk of provoked VTE (HR 0.37; 95% CI 0.19-0.71) and 47% lower risk of deep vein thrombosis (DVT) (HR 0.53; 95% CI 0.30-0.95). No significant effect of PA was observed for pulmonary embolism (PE) (HR 0.76; 95% CI 0.41-1.42). The risk estimates were attenuated when subjects with previous cancer or who developed cancer during follow-up were censored.

Conclusions: By applying time-varying analyses, we found that moderate amounts of PA lowered the risk of provoked VTE, and DVT in particular, in the elderly. The beneficial effect may be partially mediated by a lower incidence of cancer-related VTE among elderly who exercise regularly.

PB 773 | Impact of Regular Physical Activity on the Risk of Recurrent Venous Thromboembolism and All-cause Mortality

L.H. Evensen[1,2], T. Isaksen[1,2], S.K. Braekkan[1,2], J.B. Hansen[1,2]

[1]UiT - The Arctic University of Norway, K.G. Jebsen - Thrombosis Research and Expertise Center (TREC), Tromsø, Norway, [2]University Hospital of North Norway, Division of Internal Medicine, Tromsø, Norway

Background: Venous thromboembolism (VTE) recurs frequently and is associated with an increased risk of mortality. Current evidence indicates that physical activity (PA) may reduce the risk of incident VTE, but the effect on recurrence and all-cause mortality is unknown.

Aims: To investigate the impact of moderate and high intensity PA, assessed prior to the incident VTE, on the risk of recurrence and all-cause mortality in a cohort of VTE-patients recruited from the general population.

Methods: A total of 733 patients with incident VTE and data on PA derived from the Tromsø Study surveys 4-6 were included, and recurrent VTE and all-cause mortality were registered up to December 31, 2012. The most recently reported weekly level of moderate and high intensity PA before the incident VTE was dichotomized (none vs. any), or categorized according to weekly duration (no PA, < 1h, 1-3h and >3h per week). Hazard ratios (HRs), adjusted for sex and BMI, were calculated using Cox regression models with age as timescale.

Results: There were 115 recurrences and 342 deaths during a median follow-up of 2.5 years. PA was associated with a non-significant lower risk of VTE recurrence (HR none vs. any PA 0.73; 95% CI 0.48-1.10). The impact of PA was driven by the effect in patients with incident deep vein thrombosis (DVT) (HR 0.63; 95% CI 0.38-1.03), with no effect in pulmonary embolism (PE) (HR 1.06; 95% CI 0.50-2.25). PA was associated with 39% lower risk of all-cause mortality (HR 0.61; 95% CI 0.47-0.79), which tended to be more pronounced in men than in women (HR 0.56; 95% CI 0.39-0.79 vs. HR 0.74; 95% CI 0.49-1.09). The beneficial effect of PA on all-cause mortality was restricted to patients with incident DVT and showed a dose-response effect with the weekly duration of PA (p for trend 0.01).

Conclusions: Our results suggest that a sedentary lifestyle is associated with higher risk of recurrence and mortality after incident VTE, and that PA displays a stronger protective effect on mortality with increasing weekly duration.

PB 775 | Associations between Serum Levels of Calcium, Parathyroid Hormone and Future Risk of Venous Thromboembolism - The Tromsø Study

G. Lerstad[1], E.E. Brodin[1,2], J. Svartberg[3,4], R. Jorde[3,4], J. Brox[1,5], S.K. Braekkan[1,4], J.-B. Hansen[1,4]

[1]K.G. Jebsen Thrombosis Research and Expertise Center, University of Tromso, Tromso, Norway, [2]Division of Internal Medicine, Akershus University Hospital, Lorenskog, Norway, [3]Endocrine Research Group, Department of Clinical Medicine, University of Tromso, Tromso, Norway, [4]Division of Internal Medicine, University Hospital of North Norway, Tromso, Norway, [5]University Hospital of North Norway, Department of Laboratory Medicine, Tromso, Norway

Background: Population-based cohorts have demonstrated that serum calcium and parathyroid hormone (PTH) are risk factors for arterial cardiovascular disease and mortality. The relationship between serum levels of calcium, PTH and risk of venous thromboembolism (VTE), however, has not been addressed in population-based cohorts.

Aims: To investigate the associations between serum levels of calcium and PTH and future risk of VTE in a general adult population.

Methods: A total of 27,712 subjects (25-87 years) who participated in the Tromsø 4 (1994-95) and Tromsø 5 (2001-02) surveys were included. Total calcium and PTH were measured in 27,685 and 8,547 subjects, respectively. Incident VTE was recorded through December 31, 2012. Cox-regression models with quartiles of calcium and PTH as time-varying exposures were used to calculate hazard ratios (HR) of VTE. Quartiles of calcium and PTH were also combined in order to assess the effect of discordants of both PTH and calcium (e.g. highest and lowest quartiles of both calcium and PTH) on VTE risk using the middle two quartiles as reference.

Results: There were 712 VTEs during a median of 15.0 years of follow-up. Serum levels of calcium and PTH were not associated with risk of VTE. However, subjects with discordant high serum levels of both calcium and PTH (calcium ≥2.45mmol/L and PTH ≥4.0pmol/L) had increased risk of VTE compared to subjects with normal calcium and PTH (multivariable HR 1.78, 95% CI 1.12-2.84). This association was not mediated by cancer or arterial CVD.

Conclusions: Serum levels of calcium and PTH separately were not associated with future risk of VTE, but subjects with high levels of both calcium and PTH had increased risk of VTE compared to subjects with normal levels.

PB 776 | Repeated Measures of Fish Consumption, n-3 PUFA Intake and Future Risk of Incident VTE

T. Isaksen[1,2], H. Kristian[3], E. Line Holtet[3], B. Sigrid[2,3], H. John-Bjarne[2,3]

[1]K.G. Jebsen Thrombosis Research and Expertise Center (TREC), Department of Clinical Medicine, Tromsø, Norway, [2]University Hospital of North Norway, Division of Internal Medicine, Tromsø, Norway, [3]K. G. Jebsen Thrombosis Research and Expertise Center (TREC), Department of Clinical Medicine, Tromsø, Norway

Background: Strong evidence supports that polyunsaturated fatty acids (n-3 PUFAs) have beneficial effects on key pathways in the pathogenesis of thrombosis. However, studies on the association between fish intake and venous thromboembolism (VTE) show diverging results, and few studies have investigated the relationship between n-3 PUFA intake and VTE.

Aims: To investigate the association between weekly fish consumption and n-3 PUFA intake on the risk of incident VTE in a population-based cohort with repeated measurements of fish- and fish-oil consumption.

Methods: 29,547 subjects, aged 25-97 years, were recruited from the fourth (1994-95) and sixth (2007-08) surveys of the Tromsø study.

Information on fish consumption and fish-oil supplements was assessed by self-reported questionnaires at baseline, and updated when a subject re-entered the next survey. Incident VTEs were validated and recorded up to Dec 31, 2012. Total n-3 PUFA concentration was estimated based on the reported intake of fat and lean fish, fish as bread spread and fish-oil supplements, using standardized schemes. Quartiles of fish consumption (Q1:≤400, Q2:400-599, Q3:600-849, Q4≥850 g/week) and n-3 PUFA intake (Q1:< 7.79, Q2:7.79-20.74, Q3:20.75-33.34, Q4:≥33.35 g/week) were created. Cox-regression models with age as timescale, and fish- and n-3 PUFA consumption as time-varying covariates, were used to calculate hazard ratios (HR) of VTE adjusted for sex and BMI. The first quartile (Q1) was used as reference.

Results: There were 660 VTE events during a median of 17.8 years of follow-up. There was no association between fish intake and risk of VTE (HR Q4 vs. Q1: 1.03, 95% CI: 0.82-1.31, p for trend across quartiles: 0.8). Moreover, there was no association between n-3 PUFA intake and VTE risk (HR Q4 vs. Q1: 0.88, 95% CI: 0.70-1.109 p for trend: 0.15). Similar results were observed in subgroup analyses of unprovoked and provoked VTE.

Conclusions: Neither weekly fish consumption nor intake of n-3 PUFAs was associated with risk of VTE.

PB 777 | Residual Vein Thrombosis in Subjects with Proximal DVT: An Association with Subclinical Atherosclerosis. The VERITAS Study

P. Prandoni[1], M. Ciammaichella[2], N. Mumoli[3], N. Zanatta[4], A. Visonà[5], G. Avruscio[6], E. Bucherini[7], C. Bova[8], D. Imberti[9], V. Rossetto[10], G. Camporese[6], F. Noventa[1], M. Milan[1]

[1]Vascular Medicine Unit/University of Padua, Dept of Cardiovascular Sciences, Padua, Italy, [2]Emergency Unit, A.O. San Giovanni-Addolorata Roma, Roma, Italy, [3]Dept of Internal Medicine, Livorno Hospital, Livorno, Italy, [4]Angiology Medical Centre, Conegliano, Conegliano, Italy, [5]Angiology Unit, Hospital of Castelfranco Veneto, Castelfranco Veneto, Italy, [6]Dept of Cardiovascular Sciences, Angiology Unit, University of Padua, Padova, Italy, [7]Faenza Hospital, Faenza, Italy, [8]Dept of Medicine, University Hospital of Cosenza, Cosenza, Italy, [9]Haemostasis and Thrombosis Centre, Dept of Internal Medicine, Hospital of Piacenza, Piacenza, Italy, [10]Internal Medicine, San Daniele del Friuli, Italy

Background: Following the demonstration that there is a link between venous and arterial thrombotic disorders, the ultrasound detection of residual vein thrombosis (RVT) has recently been shown to be a powerful and independent predictor of subsequent symptomatic atherosclerotic events.

Aims: We sought to assess whether in patients with proximal deep vein thrombosis (DVT) the ultrasound persistence of RVT is associated with the presence of subclinical atherosclerosis.

Methods: An Italian multicentre cross-sectional study was conducted between 2014 and 2016. Consecutive subjects older than 40 with an episode of proximal DVT were eligible, provided that they had not experienced atherosclerotic disorders or ipsilateral DVT. Subjects were investigated at three months after the qualifying DVT by two "blind to each other" assessors. The former investigated the presence of RVT (persistence of a thrombotic burden of at least 4 mm in the transverse section under maximum compressibility); the latter evaluated the presence of intima-media tickness (IMT) (> 0.9 mm) or carotid plaques (according to NASCET classification). For each patient detailed information on risk factors for vein and arterial thrombosis was collected.

Results: We recruited 252 patients (see table 1 for population characteristics).

TABLE 1 Population characteristics

	Study population N 252
Age	67.2±12.8
Male Sex (%)	133 (52.8)
Type of event (%) DVT DVT+PE	130 (51.6) 122 (48.4)
Unprovoked DVT (%) Provoked DVT	194 (77.0) 58 (23)
Inherited thrombophilia (%)	16 (10.5)
BMI > 30 (%)	58 (23)
Hypertension (%)	117 (46.4)
Diabetes mellitus (%)	38 (15.1)
Dyslipidemia (%)	78 (31)

Subjects with RVT (139, 55.2%) had more frequently an unprovoked DVT , a DVT associated with PE and a lower prevalence of inherited thrombophilia. Persistence of RVT was significantly related to presence of IMT and of carotid plaques as shown in table 2.

TABLE 2 RVT and subclinical atherosclerosis

	3rd month RVT Absent 113	3rd month RVT Present 139	p
Age	66.3±13.1	67.9±12.5	0.524
Thrombophilia (%)	10/54 (18.5)	5/99 (5.1)	0.011
Idiopathic VTE (%)	83 (73.5)	119 (86.2)	0.011
Event type (%) TVP TVP+EP	82 (72.6) 31 (27.4)	56 (40.3) 83 (59.7)	<0.001
Hypertension (%)	52 (46.0)	65 (46.8)	0.906
Dyslipidemia (%)	30 (26.8)	48 (34.5)	0.187
Diabetes Mellitus (%)	13 (11.5)	25 (18.0)	0.153
IMT (%)	35 (31)	76 (54.7)	<0.001
Carotid plaques (%)	36 (31.9)	80 (57.6)	<0.001

Overall, the persistence of RVT was associated with an increased risk of asymptomatic atherosclerosis with an odds ratio of 2.71 (95% CI 1.61-4.55).

Conclusions: The persistence of RVT three months after an episode of proximal DVT has the potential to identify a subgroup of patients with a higher prevalence of subclinical atherosclerosis and, as such, exposed to a higher risk of subsequent arterial cardiovascular disorders.

PB 778 | Elevated Circulating CD40-L in Atrial Fibrillation and its Modulation by Ablation

A. Otto, J. Fareed, S. Statz, J. Liles, A. Walborn, D. Hoppensteadt, T. Rowe, S. Jabati, M. Syed

Loyola University Medical Center, Pathology, Maywood, United States

Background: Atrial fibrillation (AF) is currently the most common cardiac arrhythmia and is a major cause of morbidity and mortality. Inflammation plays a crucial role in the progression of atrial fibrillation. CD40-Ligand (CD40-L) is a cellular mediator that is elevated in inflammatory processes. CD40-L can be expressed on platelets, leading to the release of cytokines during inflammation.

Aims: The purpose of this study is to characterize and quantify the levels of CD40-L to evaluate its relevance to AF both pre- and post-ablation.

Methods: In a prospective study, plasma samples were collected from 55 AF patients at baseline prior to ablation, and at 1 and 3-month follow-up post-ablation. Normal human plasma samples (n=50) were supplied by George King Biomedical Inc. (Overland Park, KS). ELISA kits were obtained to profile CD40-Ligand (R&D Systems, Minnesota USA). Statistical analysis was performed using non-parametric Mann-Whitney t-tests.

Results: There was a significant increase in CD40-L at pre-ablation baseline in patients with AF compared to normal (401.0 pg/mL vs. 53.62 pg/mL, p=0.0034). CD40-L levels post-ablation significantly decreased. At 1 month follow up, CD40-L levels dropped (401.01 pg/mL vs. 40.59 pg/mL, p=< 0.0001). At 3 months, the levels of CD40-L remained decreased (43.28 pg/mL, p=< 0.0001). There was no significant change between levels at 1 month and 3 months (p=0.8573). There was also no significant increase in post-ablation levels of CD40-L compared to normal human plasma levels (p=0.2095).

Conclusions: Inflammation plays an important role in the pathogenesis of atrial fibrillation. In this study, patients with AF have highly elevated levels of CD40-L compared with normals. Contrary to previous reports, our study suggests that elevated levels of CD40L may play an important role in the pathogenesis of AF. It is also noted that the levels of this inflammatory mediator are modulated by atrial ablation as a medical treatment for AF.

PB 779 | Elevated Cellular Fibronectin is a Modifier of Clot Properties in Type 2 Diabetes: Association with Cardiovascular Disease

A.H. Bryk[1,2], M. Konieczyńska[1], K.P. Malinowski[3], K. Draga[4], A. Undas[1,2]

[1]John Paul II Hospital, Cracow, Poland, [2]Institute of Cardiology, Jagiellonian University Medical College, Cracow, Poland, [3]Faculty of Health Science, Jagiellonian University Medical College, Cracow, Poland, [4]INC Research LLC, Central Nervous System Department, Cracow, Poland

Background: Type 2 diabetes is associated with faster formation of poorly lysable, denser fibrin clots and elevated cellular fibronectin (cFn), a marker of vascular injury.

Aims: We investigated whether cFn affects clot properties in type 2 diabetes.

Methods: In 200 consecutive patients with type 2 diabetes and 100 control subjects matched for age and sex, we determined plasma cFn along with clot formation and degradation using turbidimetric and permeability assays. The study was conducted in compliance with Declaration of Helsinki. The local ethics committee approved the study. All enrolled subjects provided written, informed consent.

Results: cFn positively correlated with age, body mass index, glucose, fibrinogen, and triglicerydes (all p< 0.05). Diabetic patients had elevated cFn (median, 3.99 [interquartile range, 2.87-4.81] µg/ml]), increased clot density ($MaxAbs_C$) and prolonged lysis time (Lys_T) compared with those without type 2 diabetes (all p< 0.01). Diabetic patients with documented cardiovascular disease (CVD, n=127, 63.5%) had increased cFn (4.53 [3.68-4.95] µg/ml), decreased clot permeability (K_s) and increased $MaxAbs_C$ compared with those without CVD (all p< 0.001). Diabetic patients with cFn in the top quartile (>4.81 µg/ml) were 2 times more likely to have CVD compared with those in the lowest quartile (odds ratio 1.80, 95% confidence interval 1.41-2.46, p< 0.001). No differences in cFn were observed in relation to microvascular complications. After adjustment for potential confounders, cFn accounted for 10.2% of variance in K_s, 18.2% of variance in clot density and 10.2 % of variance in AUC in diabetic patients.

Conclusions: This study shows that elevated cFn unfavorably modifies clot properties in type 2 diabetes, especially with CVD, which indicates novel links between vascular injury and prothrombotic alterations in diabetes.

PB 780 | Thrombin Generation Potential is Increased in Anabolic Androgenic Steroid Abuse Years after Cessation

S. Chang[1], J. Rasmussen[2], M. Frandsen[2], M. Schou[3], J. Faber[2], J.J. Sidelmann[1], C. Kistorp[2]

[1]Unit for Thrombosis Research, Department of Public Health, University of Southern Denmark and Department of Clinical Biochemistry, Hospital of South West Denmark, Esbjerg, Denmark, [2]Center of Endocrinology and Metabolism, Department of Internal Medicine, Copenhagen University Hospital, Herlev, Denmark, [3]Copenhagen University Hospital, Department of Cardiology, Herlev, Denmark

Background: Abuse of anabolic androgenic steroids (AAS) is suspected to increase cardiovascular morbidity and mortality. However, the effects of AAS abuse on the haemostatic balance are poorly understood and especially little is known about the long-term effects.

Aims: We assessed the effect of AAS abuse on thrombin generation and inhibitors of coagulation.

Methods: Young men 18-50 years of age and either current AAS abusers, former AAS abuser or controls were included for this cross-sectional study. Morning blood samples were collected after overnight fasting and 30 minutes rest in the supine position. Thrombin generation (lag time, time to peak, peak height and endogenous thrombin potential (ETP)) was determined in citrated plasma samples after addition of 5 pM tissue factor. Also, antithrombin, protein C, free protein S and CRP were assessed. Groups were compared by ANOVA or

Kruskal-Wallis test corrected for mass significance. Associations were evaluated by ANCOVA.

Results: ETP was increased among both current (n=37) and former AAS abusers (n=33; mean (95 % CI) duration since cessation 2.5 (1.7-3.7) years) compared with controls (n=30) (p< 0.001) (Table 1). Lag time, time to peak, protein C activity and free protein S were increased among current AAS abusers compared with former AAS abusers and controls (p< 0.001). Also, antithrombin activity was increased among current AAS abusers compared with controls (p=0.012). CRP was increased among current AAS abusers compared with both former AAS abusers and controls (p< 0.01). Among current AAS abusers, CRP was strongly associated with the ETP (β=57.5; p=0.005).

Conclusions: Current AAS abuse increases ETP and prolongs lag time and time to peak. The pro-coagulant effect of AAS appears to dominate the increase of inhibitors sustaining a pro-thrombotic condition. In current AAS abusers low-grade inflammation seems to support the phenotype. Importantly, the ETP is persistently increased more than two years after AAS cessation.

TABLE 1 Thrombin generation, coagulation inhibitors and CRP. Results are given as mean ± SD or median (25th - 75th percentiles)

	Controls (n=30)	Current AAS abusers (n=37)	Former AAS abusers (n=33)	P-value
Lag time (min)	3.04 (3.00 - 3.50)	4.00 (3.45 - 4.67)	3.33 (2.71 - 4.00)	<0.001*
Peak (nmol/l)	223 ± 45	224 ± 42	246 ± 39	0.053
Time to peak (min)	6.80 (6.17 - 8.17)	8.50 (8.13 - 10.2)	7.67 (6.33 - 8.75)	<0.001*
ETP (µmol/l x min)	1.59 ± 0.28	1.85 ± 0.23	1.81 ± 0.30	<0.001**
Antithrombin activity (IU/ml)	0.89 (0.83 - 0.93)	0.98 (0.89 - 1.10)	0.90 (0.84 - 0.98)	0.012***
Protein C activity (IU/ml	0.97 (0.88 - 1.07)	1.30 (1.07 - 2.20)	1.02 (0.96 - 1.22)	<0.001*
Free protein S (IU/ml)	0.90 ± 0.15	1.13 ± 0.21	1.00 ± 0.21	<0.001*
CRP (mg/l)	0.40 (0.22 - 0.80)	1.15 (0.67-2.24)	0.52 (0.33 - 0.89)	<0.01*

*Significant difference between current AAS abusers and controls, as well as current AAS abusers and former abusers.
**Significant difference between current AAS abusers and controls, as well as former AAS abusers as controls.
***Significant difference between current AAS abusers and controls.

PB 781 | The CHA2DS2-VASc Score Predicts Bleeding Risk in a Cohort with Implantable Cardiac Monitoring Devices without Atrial Fibrillation

F. Shamoun[1], C. Parson[2], S. Cha[3], A. Tseng[2], F. Al-Saffar[4], H. Esser[5], F. Mookadam[4]

[1]Mayo Clinic in Arizona, Cardiovascular Diseases, Scottsdale, United States, [2]Mayo Clinic in Arizona, Internal Medicine, Scottsdale, United States, [3]Mayo Clinic in Arizona, Biostatistics, Scottsdale, United States, [4]Mayo Clinic in Arizona, Cardiovascular Disease, Scottsdale, United States, [5]Mayo Clinic in Arizona, Cardiovascular Medicine, Scottsdale, United States

Background: Our team demonstrated in published work that the CHA2DS2-VASc score is a useful and simple tool to predict the risk of stroke and cardiovascular mortality in a population without atrial fibrillation. We investigated whether CHA2DS2-VASc score can predict bleeding risk in this cohort.

Aims: To evaluate if CHA2DS2-VASc score predicts bleeding incidence in a cohort of patients with implantable cardiac devices without atrial fibrillation.

Methods: We used the Rochester Epidemiology Project from 1/10/04 - 3/7/16 to evaluate if CHA2DS2-VASc score predicted the risk of bleeding. An implantable device was required to discern the absence of atrial fibrillation. Baseline cardiovascular risk factors (age, gender, heart failure, thromboembolism, vascular disease, and diabetes) were assessed. Log-Rank test was used for comparisons. Multivariate analysis was conducted. We applied the validated ATRIA bleeding score in the same cohort.

Results: The population (n=1,606) had mean age of 69.8 years and median follow-up of 4.8 years. CHA2DS2-VASc score was divided into 3 tertiles. Bleeding was defined as GI or other hemorrhage requiring hospitalization. The highest tertile patients were older and had more comorbidity. Those with CHA2DS2-VASc score of 2-5 and 6-9 had a bleeding hazard ratio of 2.1 (P< 0.0001) and 3.02 (P< 0.001) respectively. In a multivariate modeling age, male gender and history of CHF were associated with the highest risk of bleeding (HR 1.01, P< 0.001; and 1.6, P< 0.001, 1.2 p< 0.06) respectively. Females had lower risk of bleeding (HR 0.64 P< 0.0001). There was a linear association between CHA2DS2-VASc and the risk of bleeding (HR 1.18 per score increment, p< 0.001, or 6% increase on bleeding event at end of 5th year per score increase, p< 0.001).

Conclusions: CHA2DS2-VASc predicted bleeding risk in patients with implantable cardiac monitoring device and no evidence of atrial fibrillation. Clinicians can to use the CHA2DS2-VASc score to predict the risk of bleeding in patients with multiple comorbidities.

PB 782 | PCSK9 Promotes Arterial Thrombosis in Mice

J. Wu, Y. Liu, M. Ren, N. Chen

Southwest Medical University, Luzhou, China

Background: Proprotein convertase subtilisin/kexin type 9 (PCSK9) promotes the degradation of the LDLR thereby elevating plasma low-density lipoprotein cholesterol levels and the risk of coronary heart disease. Recent study has reported that plasma PCSK9 levels are elevated with acute myocardial infarction. However, the contribution of elevated plasma PCSK9 level in arterial thrombosis remains unexplored.

Aims: The authors assessed whether PCSK9 was associated with an induction of prothrombotic effect in FeCl3 carotid artery injury model. Using pcsk9 deficient mice, the authors evaluated the roles of PCSK9 in regulation of arterial thrombosis and platelet activation.

Methods: Mice were subjected to FeCl3 carotid artery injury, and the time required to form an occlusive thrombus was measured. To study the contribution of PCSK9 in arterial thrombosis, we used *Pcsk9* deficient mice and recombinant PCSK9 protein to examine occlusion time after injury. Platelet aggregation was also measured.

Results: *Pcsk9* deficient mice exhibited slow thrombotic occlusion of the carotid artery after injury. In contrast, infusion of recombinant PCSK6 protein into C57BL mice shortened the prolonged time to carotid artery occlusion. Binding assay revealed that PCSK9 can bind directly to the LDLR in platelets. Platelet aggregation and flow cytometry analysis revealed that PCSK9 protein significantly induced platelet aggregation, and surface P-selectin exposure.

Conclusions: These findings show that PCSK6, a component of cholesterol metabolism, plays a role in hemostasis and thrombosis.

PB 783 | Plasma Lipoprotein(a) Predicts Bleeding and Long-term Adverse Events in Patients with Chronic Kidney Disease who Underwent Percutaneous Coronary Intervention

N. Xu, Y. Yao, X.-F. Tang, J.-J. Xu, Y. Song, L. Jiang, R. Liu, P. Jiang, J.-Q. Yuan, R.-L. Gao

Beijing Fuwai Hospital, Beijing, China

Background: Chronic kidney disease (CKD) is associated with increased risk for cardiovascular disease. Elevated serum levels of Lp(a) are associated with an increased risk of major adverse cardiac events in patients with CAD after PCI.

Aims: We aimed to determine the role of Lp(a) on long-term clinical outcomes in patients with CKD after PCI.

Methods: Consecutive patients with CKD who underwent percutaneous coronary intervention at our institution from January 2013 to December 2013 were included in this cohort study. We divided patients into 2 groups [high (n = 214) or low (n = 213)] according to median levels of Lp(a). Outcomes included 2-year risk of major adverse cardiovascular and cerebrovascular events (MACCE) and bleeding according to Bleeding Academic Research Consortium (BARC) definitions.

Results: A total of 427 patients (41.2% women, mean age 69.6±9.1 years) were recruited. In this cohort, the prevalence of prior PCI, the level of BMI, total cholesterol, LDL-C and the level of hsCRP were higher in the group with high Lp(a) than with low Lp(a). After 2-year follow up, no significant differences were observed between the two groups in all-cause mortality, unplanned revascularization and stroke. Event rate of cardiac death (5.6% vs 1.4%, p=0.018), stent thrombosis (5.6% vs 1.4%, p=0.018) and myocardial infarction (9.4% vs 2.8%, p=0.004) were significantly higher in the high Lp(a) than in the low Lp(a) group. Unadjusted cumulative incidence of 2-year MACCE was statistically different between the two groups (23.0% vs 15.4%, p=0.047). Group with high Lp(a) had higher risk of BARC bleeding (8.9% vs 4.2%, p=0.049). Differences persisted after adjustment (hazard ratio [HR] 1.64, 95% confidence interval [CI] 1.04-2.58 for MACCE and HR 2.29, 95% CI 1.51-5.15 for bleeding).

Conclusions: Our study demonstrates that a high Lp(a) level is an independent predictor of bleeding and long-term adverse events. A high Lp(a) value is associated with a poor prognosis after PCI for patients with CKD.

PB 784 | Effects of HAART on Fibrinogen, D-dimer and Protein C Levels in Patients with HIV at the University of Benin Teaching Hospital Benin City, Nigeria

O. Awodu[1], A. Onunu[2], E. Chukwuka[3]

[1]University of Benin Teaching Hospital, Department of Haematology, Benin City, Nigeria, [2]University of Benin Teaching Hospital, Department of Medicine, Benin City, Nigeria, [3]University of Benin Teaching HospitalTeaching Hospital, Haematology and Blood Transfusion, Benin City, Nigeria

Background: Changes in haemostatic parameters are associated with HIV infection and its therapy, which could contribute to atherothrombosis and cardiovascular diseases. However, the underlying mechanism is yet to be fully understood, particularly in the Nigerian setting.

Aims: To determine the plasma fibrinogen, d-dimer and protein C levels in HIV infected patients and to evaluate the effect of HAART on these parameters.

Methods: This is a cross-sectional study. Participants were divided into three study groups; HIV seronegative control subjects, HIV seropositive subjects therapy naïve and HIV seropositive subjects on HAART. Fibrinogen levels were assessed using Clauss modified method (GIESSA). D-dimer levels were assessed using ELISA test kits (Imunoclon). Protein C activities were assessed using chromogenic methods (Technochrom).

Results: A total of 210 participants were recruited into the study comprising of 70 HIV seronegative control subjects,70 HIV seropositive subjects therapy naïve and 70 HIV seropositive subjects on HAART. The mean plasma fibrinogen in the control, HAART naïve and HAART experienced groups were 5.0 ± 1.5g/L, 6.9 ± 2.9g/L and 6.3 ± 2.3g/L respectively. There was a significant difference between means of control and HAART naïve ($p < 0.001$). The mean d-dimer level for therapy naïve was 168 ± 41mg/L and 168 ± 17mg/L for the HAART experienced, the mean difference were statistically significant when compared with the controls (92 ± 11mg/L) $p < 0.001$. The mean

protein C level for the seropositive therapy naïve and HAART experienced subjects were 0.618 ± 0.446IU/ml and 0.34 ± 0.226IU/ml respectively (p< 0.001).

Conclusions: Fibrinogen and d-dimer levels were significantly higher in HIV infected subjects and these elevations persisted despite HAART. HIV seropositive group on HAART had a much lower protein C level compared to the other two groups. Haemostasis is grossly altered in HIV infection and HAART therapy did not correct these changes.

PB 785 | Persistent Thrombin Generation at 24 Months after Acute Coronary Syndrome

C. Yip[1], A. Seneviratna[2], S.H. Tan[2], S.C. Poh[2], Z.L. Teo[3], J.P.Y. Loh[2], E.S. Yap[1,4], M. Richards[2,3], M. Chan[2,3], C.M. Gibson[5], E.M. Ohman[6]

[1]National University Hospital, Department of Lab Medicine, Division of Haematology, Singapore, [2]National University Heart Centre, Cardiac Department, National University Hospital, Singapore, [3]National University of Singapore, Department of Medicine, Yong Loo Lin School of Medicine, Singapore, [4]National University Hospital, Department of Hematology Oncology, Singapore, Singapore, [5]Beth Israel Deaconess Hospital, Boston, United States, [6]Duke Clinical Research Institute, Durham, United States

Background: Acute coronary syndrome (ACS) is triggered by thrombosis after rupture or erosion of an atherosclerotic plaque. Thrombin generated at the site of vascular injury plays a key role in regulating thrombus formation and serves as a potent platelet activator. Antiplatelet therapy has been the cornerstone for preventing recurrent ACS.

Aims: We monitored longitudinal changes of thrombin generation (TG) indices up to 24 months in ACS patients on dual antiplatelet therapy (DAPT).

Methods: Citrated blood was obtained 48-72 hours after percutaneous coronary intervention (PCI) from ACS patients (n = 110). The 3 thrombin generation indices: rate of thrombin generation or velocity index (VI), endogenous thrombin potential (ETP) and Peak thrombin (PT) concentration were measured using Calibrated Automated Thrombography (CAT). Age-matched controls (n=25) were selected from healthy blood donors. TG measurements were repeated in ACS patients at 6, 12 and 24-month.

Results: Baseline characteristics of patients and controls are summarized in table 1. All the patients were on aspirin and a P2Y12 antagonist (Prasugrel 74.5%, Ticagrelor 14.5%, Clopidogrel 10.9%) for 1 year after the ACS event and subsequently on single antiplatelet therapy. All TG indices were significantly elevated in ACS patients when compared to controls at baseline. At 6, 12 and 24 months, the VI and PT were lower than at baseline but indices remained persistently elevated when compared to controls (figure 1). Surprisingly, ETP declined faster than VI and PT.

Conclusions: Despite treatment with new generation P2Y12 antagonists, patients with recent ACS have persistent elevation of two indices of thrombin generation at 24 months after ACS. Further studies should investigate the role of TG in guiding antithrombotic therapy after ACS.

PB 786 | A Chemical Screen for Small Molecule Modulators of Fibrinogen Production

R. Vilar[1], M. Neerman-Arbez[1,2], R.J. Fish[1]

[1]University of Geneva, Faculty of Medicine, Department of Genetic Medicine and Development, Geneva, Switzerland, [2]Institute of Genetics and Genomics in Geneva, Geneva, Switzerland

Background: Plasma fibrinogen levels associate with the risk of cardiovascular disease (CVD) endpoints. Despite the expectation that high fibrinogen concentrations affect fibrin clot formation, there is no direct evidence for a clinical cause-effect relationship between high plasma fibrinogen and CVD events. As agents have not been developed to decrease plasma fibrinogen levels it has not been possible to assess a possible protective effect of lowering fibrinogen on CVD endpoints.

Aims: By screening a library of defined off-patent pharmacological agents we aim to identify compounds that can lower fibrinogen production in cell culture prior to testing in vivo.

Methods: 1280 compounds were tested for their ability to alter fibrinogen production by hepatocellular carcinoma-derived HepG2 cells. Secreted fibrinogen was measured by enzyme-linked immunosorbent assay in cell-conditioned medium and normalized to total protein in cell lysates. The screen was completed three times, with technical triplicate values measured in each of the three biological replicates. Data were adjusted for medium alone on all assay plates and effects of compounds compared to vehicle (DMSO).

Results: A left-skewed frequency distribution was observed when plotting fibrinogen level (fibrinogen/total protein ratio) as the variable and normalizing to DMSO. 59 compounds reduced fibrinogen by at least 25% without reducing total protein by more than 10% (fibrinogen range -26% to -68%). Nominal p-values for fibrinogen level in compound-treated versus DMSO using paired t-tests were < 0.05 for 33 of these (n=3). These molecules will be tested for dose-response efficacy, and a selection assessed for fibrinogen modulation in zebrafish.

Conclusions: By screening components of approved off-patent medicines, we identified modulators of fibrinogen production. Such molecules could be developed for assessing a potential protective effect of lowering plasma fibrinogen in cardiovascular disease.

PB 787 | The Novel 2MACE Score Predicts Cardiovascular Events in Atrial Fibrillation Patients

J.M. Rivera-Caravaca[1], F. Marín[2], M.A. Esteve-Pastor[2], M. Valdés[2], V. Vicente[1], G.Y.H. Lip[3,4], V. Roldán[1]

[1]Hospital General Universitario Morales Meseguer, Instituto Murciano de Investigación Biosanitaria (IMIB-Arrixaca), Department of Hematology and Clinical Oncology, Murcia, Spain, [2]Hospital Clínico Universitario Virgen de la Arrixaca, Instituto Murciano de Investigación Biosanitaria (IMIB-Arrixaca), Department of Cardiology, Murcia, Spain, [3]University of Birmingham, Institute of Cardiovascular

Sciences, City Hospital, Birmingham, United Kingdom, [4]Aalborg Thrombosis Research Unit, Department of Clinical Medicine, Aalborg University, Aalborg, Denmark

Background: Atrial fibrillation (AF) increases the risk for stroke and mortality, but also for non-embolic cardiovascular events such as acute coronary syndrome or heart failure (HF).

Aims: To investigate the incidence of non-embolic adverse events in a ‚real world' cohort of AF patients and to validate the 2MACE score [2 points (metabolic syndrome, age ≥75); 1 point (history of myocardial infarction (MI)/revascularization, congestive HF and stroke/TIA/thromboembolism)] as predictor of major adverse cardiovascular events (MACEs).

Methods: 693 consecutive AF patients were recruited and the 2MACE score was calculated. All non-embolic adverse events and MACEs (nonfatal MI/revascularization, HF and cardiovascular death) were recorded during a median of 7.2 (IQR 6.2-7.9) years. ROC curves comparison, reclassification and discriminatory analyses and decision curve analysis, were performed in order to compare predictive ability of the 2MACE score and its clinical usefulness against CHA_2DS_2-VASc. The study protocol was approved by the Ethics Committee from our institution and performed in accordance with the Declaration of Helsinki. All patients gave informed consent.

Results: Median 2MACE score was 2 (IQR 1-3). During follow-up, there were 113 MACEs (2.26% per year). Annual event rate was higher in the medium/high risk group (i.e. 2MACE score ≥3) (3.33%/year *vs*. 1.45%/year, p< 0.001). The 2MACE score ≥3 was significantly associated with MACE (HR = 2.80, 95% CI 1.90-4.10, p< 0.001). The predictive performance of 2MACE according to the ROC curve was 0.67, and was significantly higher from that of CHA_2DS_2-VASc (0.67; 95% CI 0.63-0.70 *vs*. 0.62; 95% CI 0.58-0.66, p< 0.001). Decision curve analysis demonstrates improved clinical usefulness of the 2MACE compared to the CHA_2DS_2-VASc score.

TABLE 1 Comparison of the ROC curves, IDI and NRI of the CHA2DS2-VASc and 2MACE scores

	C-index	95% CI	p*	IDI	p	NRI	p
2MACE vs. CHA2DS2-VASc	0.67 vs. 0.62	0.63-0.70 0.58-0.66	<0.001	0.02	0.002	0.22	<0.001

CI = Confidence Interval; IDI = integrated discriminatory improvement; NRI = net reclassification index. *for c-index comparison

Conclusions: In ‚real world' AF patients, the 2MACE score is a good predictor of MACE. A score ≥3 should be used to categorize patients at ‚high risk', in identifying patients at risk of MACE.

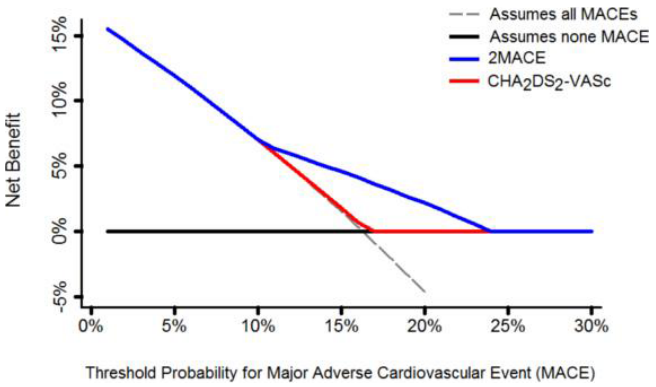

FIGURE 1 Decision curves for the 2MACE and CHA2DS2-VASc scores

PB 788 | Altered Platelet Lipidome Influences Thrombotic Disposition: Implications in Acute Coronary Syndrome and Modulation by the CXCL12-CXCR4-CXCR7 Axis

M. Chatterjee[1], D. Rath[1], J. Schlotterbeck[2], J. Rheinlaender[3], B. Walker-Allgaier[1], T.E. Schäffer[3], M. Lämmerhofer[2], T. Geisler[1], M. Gawaz[1]

[1]University Clinic Tübingen, Cardiology and Cardiovascular Medicine, Tübingen, Germany, [2]Eberhard Karls University Tübingen, Institute of Pharmaceutical Sciences, Tübingen, Germany, [3]Eberhard Karls University Tübingen, Institute of Applied Physics, Tübingen, Germany

Background: Hyperlipidaemia propagates thrombosis, while acute coronary syndrome (ACS) patients show increased platelet oxLDL binding, correlating with activation status. Besides, elevated platelet CXCR7 surface expression and altered plasma CXCL12 levels in ACS, have significant prognostic impact. Activation also influences intraplatelet lipid metabolism.

Aims: To characterize the dynamics of platelet lipidome in coronary artery disease (CAD) patients and explore the influence of CXCL12-CXCR4/CXCR7 axis on pro-thrombotic platelet-lipid association.

Methods: Flowcytometry, untargeted lipidomics analysis, confocal microscopy, impedance aggregometry, live imaging-scanning ion conductance microscopy, thrombinoscopy, *ex/in vivo* thrombosis assay.

Results: Enhanced platelet-oxLDL in CAD correlated positively with platelet CXCR7 surface expression, but inversely with CXCR4, and was further elevated in ACS with intracoronary thrombi showing oxLDL deposition in platelet-rich areas.LDL/oxLDL enhanced reactive oxygen species generation,lipid peroxidation, whereby platelets executed intracellular (per)oxidative lipid modifications. Lipidomic analysis revealed enhanced-intraplatelet oxidized phospholipids denoting redox stress, cholesteryl-esters, triglycerides despite normal plasma levels, sphingomyelin-ceramides denoting increased sphingolipid me tabolism,acylcarnitine,PLA2(lysoPC), PLC(diacyglycerol) metabolites in ACS(STEMI). LDL/oxLDL induced degranulation, $\alpha_{IIb}\beta_3$-integrin activation, aggregation, apoptosis, thrombin generation, dynamic shape change, also thrombus formation *ex vivo* and *in vivo*. LDL-oxLDL

enhanced CXCL12 release, decreased CXCR4, while enhanced CXCR7 expression. CXCL12-CXCR4-CXCR7 prompted LDL/oxLDL uptake by enhancing availability of scavenger receptors, also synergistically augmented LDL/oxLDL-induced oxidative and thrombogenic functions.

Conclusions: Pro-oxidative platelet lipidome favours thrombotic disposition, potentially modulated by CXCL12-CXCR4-CXCR7 axis to influence progression and prognosis in CAD.

PB 789 | A Time-course Analysis of Activated Factor VII-antithrombin Complex Plasma Concentration in the Follow-up of Patients with Angiographically-demonstrated Coronary Artery Disease

F. Stefanoni[1], A. Castagna[1], M. Baroni[2], F. Tosi[1], G. Poli[3], B. Lunghi[2], S. Gaino[3], B. Woodhams[4], G. Lippi[3], D. Girelli[1], O. Olivieri[1], F. Bernardi[2], N. Martinelli[1]

[1]University of Verona, Department of Medicine, Verona, Italy, [2]University of Ferrara, Department of Life Sciences and Biotechnology, Ferrara, Italy, [3]University of Verona, Section of Clinical Biochemistry, Verona, Italy, [4]Haemacon Ltd, Bromley, Kent, United Kingdom

Background: activated factor VII-antithrombin (FVIIa-AT) complex reflects tissue factor exposure to the blood, thus being a biomarker of prothrombotic diathesis, and has been associated with mortality in patients with coronary artery disease (CAD).

Aims: to evaluate FVIIa-AT plasma concentration in CAD patients in a two-points (baseline and during the follow-up) time-course analysis.

Methods: within the original prospective study showing baseline levels of FVIIa-AT as a predictor of cardiovascular mortality, in 178 survived CAD patients (85.4% males, mean age 58.2±8.5 years) a second blood drawn for FVIIa-AT evaluation was performed in occasion of an ambulatory visit (after a median follow-up of 63 months). FVIIa-AT plasma levels were measured by ELISA.

Results: during the follow-up 58 subjects reported angina symptoms, 7 had myocardial infarction (MI), and 35 underwent new coronary revascularization. FVIIa-AT levels at second control were significantly correlated with those at baseline (R=0.262, P< 0.001) and were significantly higher than those at baseline (P< 0.001), except for patients having begun anticoagulant therapy with warfarin. Neither baseline nor second control FVIIa-AT levels were associated with angina, MI, or coronary revascularization. On the other hand, subjects with angina had a higher increase of FVIIa-AT levels from baseline to the second control (50.1±55.9 *versus* 31.4±54.4 pM, P=0.035), as well as subjects with MI (79.4±52.2 *versus* 35.8±55.1 pM, P=0.040), while no significant difference was found for coronary revascularization (49.9±48.8 *versus* 34.4±56.6 pM, P=0.139). Subjects with an increase higher than the median value (>36.4 pM) had an about two-fold increased risk of angina/MI after adjustment for sex, age, time of follow-up, and warfarin therapy (OR 2.05 with 95%CI 1.05-4.02).

Conclusions: in the setting of secondary prevention of CAD a larger time-related increase of FVIIa-AT levels during follow-up is associated with angina and non-fatal MI.

PB 791 | Up-Regulation of HO-1 by CORM-2 Attenuates Thrombin-Induced COX-2 Expression and Hypertrophy in Human Cardiomyocytes

C.-M. Yang

Chang Gung University, Pharmacology, Tao-Yuan, Taiwan, Republic of China

Background: Heme oxygenase (HO)-1 and exerts anti-inflammatory action in various models. However, the detailed mechanisms underlying CO-induced HO-1 expression in primary human cardiomyocytes remain largely unidentified.

Aims: We used primary human cardiomyocytes as a model and applied CO releasing molecule (CORM)-2 to investigate the relationship of CO and HO-1 expression and its protecting effects.

Methods: COX-2 and HO-1 expression were determined by Western blotting, real time-PCR, and promoter analyses. The signaling molecules were investigated by pretreatment with respective pharmacological inhibitors or transfection with siRNAs. The interaction between COX-2 promoter and transcription factors was determined by chromatin immunoprecipitation (ChIP) assay. Finally, the effect of CORM-2 on COX-2 expression and PGE_2 synthesis induced by thrombin was determined by Western blot and EIA to investigate the role of HO-1 expression protecting against thrombin-mediated responses.

Results: We found that thrombin-induced COX-2 expression, PGE_2 release and cardiomyocyte hypertrophy markers (increase in ANF/BNP, α-actin expression and cell surface area) was attenuated by pretreatment with CORM-2 which was partially reversed by hemoglobin (Hb) or ZnPP (an inhibitor of HO-1 activity), suggesting that HO-1/CO system may be of clinical importance to ameliorate heart failure through inhibition of inflammatory responses. CORM-2-induced HO-1 protein expression, mRNA and promoter was attenuated by pretreatment with the inhibitors of Pyk2 (PF431396), PDGFR (AG1296), PI3K (LY294002), Akt (SH-5), p38 (SB202530), JNK1/2 (SP600125), FoxO1 (AS1842856) and Sp1 (mithramycin A). The involvement of these signaling components was further confirmed by transfection with respective siRNAs, consistent with those of pharmacological inhibitors.

Conclusions: These results suggested that CORM-2-induced HO-1 expression is mediated through a Pyk2/PDGFR/PI3K/Akt/FoxO1/Sp1-dependent manner and exerts a cytoprotective effect in human cardiomyocytes.

PB 792 | High Antithrombin Levels in Women Are Associated with a Lower Risk of Recurrent Arterial Thromboembolism or Death. Results from the Observational ATTAC-Study

F.N. Croles, M.P.M. De Maat, F. Leebeek

Erasmus MC, Department of Hematology, Rotterdam, The Netherlands

Background: Inherited thrombophilia is associated with venous and arterial thromboembolism (ATE). Antithrombin deficiency is a strong risk

factor for venous thromboembolism, but data on antithrombin levels and the risk of ATE are sparse. An association is not clearly established. A role of antithrombin levels in recurrent ATE is largely unknown.

Aims: First we aimed to investigate if antithrombin levels are associated with first ATE-events at a young age. The second aim was to investigate if antithrombin levels are associated with recurrent ATE or death.

Methods: In a case-control study, 620 patients with a recent premature first event of coronary heart disease, cerebrovascular disease or peripheral artery disease and 461 community controls were included. Antithrombin activity levels were measured. 323 subjects of this study that had presented with a cardiac event in the case-control study participated in a prospective cohort study. Time to a recurrent ATE or death was recorded.

Results: No differences in antithrombin levels were found between the cases and controls. Only after correction for all for classical risk factors for ATE risk factors logistic regression showed a relationship between antithrombin levels and ATE (HR 1.35, 95%CI 1.01-1.81). When comparing the three subgroups and controls also no differences were found. In the follow-up study no increased risk for recurrent ATE or death was found in subjects with low versus high antithrombin levels overall. However women with lower antithrombin levels had a higher risk (HR4.53, 95%CI 1.25-16.34) than women with levels above median antithrombin levels. In men, no such difference was found, and the risk was similar to the risk in women with low antithrombin levels.

Conclusions: Antithrombin levels are not clearly associated with first ATE at a young age. Women with high antithrombin levels have a lower risk of recurrent ATE or death than women with low antithrombin levels, whereas in men antithrombin levels do not influence risk of recurrent ATE or death.

PB 793 | The Role of Fasting Glucose Levels and Self-reported Diabetes in the Risk of a First Event of Venous Thrombosis: The MEGA Case-control Study

R. Li-Gao[1], V.M. Morelli[1], W.M. Lijfering[1,2], S.C. Cannegieter[1,2], F.R. Rosendaal[1,2], A. van Hylckama Vlieg[1]

[1]*Leiden University Medical Center, Clinical Epidemiology, Leiden, The Netherlands,* [2]*Leiden University Medical Center, Einthoven Laboratory for Experimental Vascular Medicine, Leiden, The Netherlands*

Background: Conflicting results have been reported on the risk of venous thrombosis (VT) for diabetes mellitus (DM) and whether individuals with hyperglycaemia in the non-diabetic population are at an increased risk of a first event of VT.

Aims: To assess whether self-reported DM and hyperglycaemia in a non-diabetic population are associated with an increased risk of a first event of VT.

Methods: Analyses were performed in the Multiple Environmental and Genetic Assessment of Risk Factors for Venous Thrombosis (MEGA) case-control study. Pregnant women and individuals with malignancy were excluded. In the analysis of glucose levels and the risk of VT, participants with self-reported DM (n=145) were further excluded. Fasting glucose levels were categorized based on the World Health Organization (WHO) criteria (< 6.1 mmol/L [reference], 6.1-7.0 mmol/L, ≥7.0 mmol/L) as well as using the fasting glucose distribution of the control subjects. Logistic regression models were performed, after adjusting for age, sex, body mass index, statin use, estrogen use, and C-reactive protein levels.

Results: In the analysis of fasting glucose and the risk of VT, 1,888 patients (median age, 49 years; 51% women) and 2,531 controls (median age, 50 years; 50% women) were included. Using the lowest category of the WHO classification as the reference, the odds ratios for VT in the second and third categories of fasting glucose levels were 0.98 [95% CI 0.69-1.37] and 0.97 [95% CI 0.58-1.63]. Similar results were observed from the classification by glucose distribution in the controls. In the analysis of self-reported DM and the risk of VT, 1,930 patients (147 self-reported diabetes cases) and 3,331 controls (184 self-reported diabetes cases) were included. The odds ratio for VT in the diabetic population compared with the non-diabetic population was 1.10 [95% CI 0.78-1.56].

Conclusions: Neither increased levels of fasting glucose in non-diabetic individuals nor self-reported diabetes was associated with risk of a first event of VT.

PB 794 | Urinary 11-dehydrothromboxane B2 Measurement Assays and their Clinical Correlation

U. Tantry[1], R. Chaudhary[1], L. Lopez[2], K. Bliden[1], P. Gurbel[1]

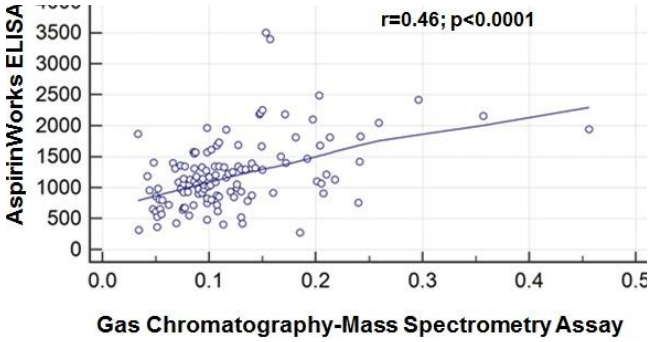
[1]*Inova Heart and Vascular Institute, Falls Church, United States,* [2]*Corgenix, Broomfield, United States*

Background: High urinary 11-dehydrothromboxane B_2 (UTB) is linked with adverse outcomes in cardiovascular (CV) disease patients on aspirin therapy. We correlated UTB levels determined by AspirinWorks ELISA and gas chromatography-mass spectrometry (GC/MS) and determined their association with CV risk factors; hypercoagulability (HC), high platelet reactivity (HPR), and inflammation.

Aims: To compare UTB levels measured by AspirinWorks ELISA and gas chromatography-mass spectrometry (GC/MS) and to determine their relation to CV risk factors.

Methods: Blood and Urinary samples (n=122) were collected multiple times from Type 2 diabetes patients (n=37) on 81-325mg aspirin. HC was defined as >69mm platelet-fibrin clot strength by TEG. HPR was defined as any 2: 2mM AA-induced aggregation ≥ 10%, 4mg/ml collagen-induced aggregation ≥ 70%, AU*min ≥ 30 by Multiplate Aspitest, and aspirin reaction units (ARU) ≥550 by VerifyNow. Inflammation was defined as hs-CRP >3 mg/L.

Results: UTB levels measured by ELISA weakly correlated with GS/MS (r=0.46, p< 0.0001) Figure).



FIGURE

HC patients (41%) had higher UTB by ELISA (p=0.013) and GS/MS (p=0.041). Patients with HPR (51%) had higher UTB by ELISA (p< 0.05) but not for GS/MS (p≥0.05 for all). Patients with inflammation (54%) had higher UTB by ELISA (p=0.014). By INOVA, UTB increased in a stepwise fashion with the number of risk factors more closely by ELISA (p< 0.001) than GS/MS (p=0.041).

Conclusions: Identification of hypercoagulability, high platelet reactivity, and inflammation by UTB is dependent on the assay with better identification by ELISA. Our findings are relevant for future investigations of UTB as a high cardiovascular risk marker.

PB 795 | The Value of sPESI for Risk Stratification in Patients with Pulmonary Embolism

P. Wells[1], W.F. Peacock[2], G.J. Fermann[3], C.I. Coleman[4], L. Wang[5], O. Baser[6,7], J. Schein[8], C. Crivera[8]

[1]University of Ottawa and the Ottawa Hospital Research Institute, Ottawa, Canada, [2]Baylor College of Medicine, Houston, United States, [3]University of Cincinatti, Cincinnati, United States, [4]University of Connecticut, Hartford, United States, [5]STATinMED Research, Analytic Research, Plano, United States, [6]Columbia University, Innovation & Outcomes Research, Department of Surgery, New York, United States, [7]STATinMED Research, Health Economics & Outcomes Research, New York, United States, [8]Janssen Scientific Affairs, LLC, Raritan, United States

Background: Various risk stratification methods exists for patients with pulmonary embolism (PE).

Aims: Use the simplified Pulmonary Embolism Severity Index (sPESI) as a risk stratification method to understand the PE population within the Veterans Health Administration (VHA).

Methods: Retrospective review using VHA dataset. Entry criteria were age > 18 with ≥1 inpatient diagnosis for PE (index date) between October 2011- June 2015, continuous enrollment for ≥12 months pre- and 3 months post-index date. We defined a sPESI score of 0 as low risk, and all others as high risk. Hospital-acquired complications (HACs), 90-day follow-up PE-related outcomes, and health care utilization and costs were compared between high-risk (HRPE) and low-risk (LRPE) patients.

Results: Of 6,746 PE patients, 95.4% were men, 67.7% were white, 22.0% were African American; LRPE occurred in 28.4%, and HRPE 71.6%. Versus HRPE, LRPE patients had lower Charlson Comorbidity Index scores and other baseline comorbidities, fewer HACs (11.37% vs 19.97%, p< 0.0001), less bacterial pneumonia (10.58% vs 22.33%, p< 0.0001), and shorter inpatient length of stay (8.77 vs 11.15 days, p=0.0050) during the index hospitalization. During follow-up, LRPE patients had fewer PE-related outcomes of recurrent venous thromboembolism (4.38% vs 6.03%, p=0.0077), major bleeding (1.20% vs 1.93%, p=0.0382), death (3.70% vs 16.16%, p< 0.0001). LRPE also had fewer inpatient, outpatient, and pharmacy visits per patient, and lower total health care costs ($12,021 vs $16,911, p< 0.0001) (Figure 1).

Conclusions: Using the sPESI score identifies a PE cohort with a lower clinical and economic burden.

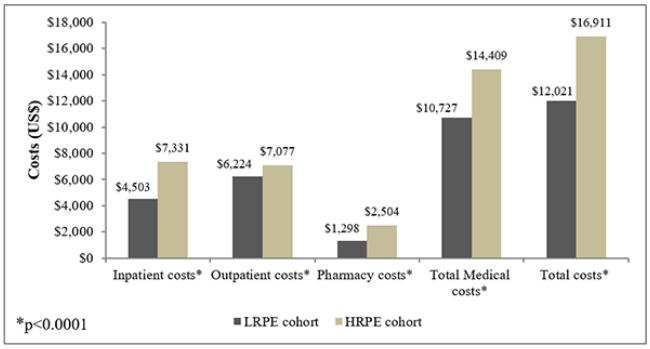


FIGURE 1 Health Care Costs among LRPE vs. HRPE Patients

PB 796 | D-Dimer but Not Platelet Function Testing Improves Risk Stratification in Patients Treated with Elective PCI

A. Komarov[1], E. Guskova[1], E. Novikova[1], A. Samko[1], A. Deev[2], A. Dobrovolsky[1], E. Panchenko[3]

[1]Russian Cardiology Research and Production Complex, Moscow, Russian Federation, [2]National Research Center for Preventive Medicine, Moscow, Russian Federation, [3]Russian Cardiology Research and Production Complex, Atherothrombosis, Moscow, Russian Federation

Background: Integration of anatomical and clinical variables enhanced risk stratification following PCI.

Aims: Aim of the study was to assess the potential role of D-Dimer and platelet reactivity (PR) for improvement of conventional scoring algorithms in all-comer patients treated with elective PCI.

Methods: Single center data from 188 consecutive patients (76% males, age 61±10,7 yrs) undergoing successful PCI with new-generation drug-eluting stent implantation and receiving 1 year dual antiplatelet therapy were prospectively collected. Baseline D-Dimer level and on-treatment PR (VerifyNow P2Y12) were assessed in addition to conventional MACE scores (SYNTAX, clinical SYNTAX, SYNTAX Score-II (SS-II), ACEF).

Results: The frequency of major adverse cardiac events (MACE : vascular death, acute coronary syndrome, stroke/transient ischemic attack) at a median time of 3.2 years was 15,4% (4,8/100 patient years). Among all scores only SS-II was predictive of MACE. Age and sex adjusted Cox relative risk (RR) for high SS-II (cutoff ≥40) was 3.9 (95% CI 1.7-9.1, p=0.001). D-Dimer and PR were tended to be higher in upper

vs lower quintiles of SS-II distribution: 777,1±100,7 vs 379±48,1 ng/ml and 178,7±14,6 vs 159±11,9 PRU respectively. PR has no prognostic impact. D-Dimer (cutoff ≥783 ng/ml) per se has weak association with MACE: age and sex adjusted RR = 2.2; 95% CI 0.76-6.58, p=0,1. Adding D-Dimer improves the prognostic capacity of the SS-II. Frequency of MACE in pts with simultaneous elevations of both variables was 27,3% compared with 10,6% in pts with low SS-II and low D-Dimer (RR = 5.9, 95% CI 1.7-19.7, p=0.004).

Conclusions: D-Dimer may be considered as a valuable prognostic biomarker to improve the prediction of MACE in addition to well-known scoring systems in patients after elective PCI.

PB 797 | Increased Extracellular Nucleosome Levels, Biomarkers of Cell Death, in Atrial Fibrillation Patients Compared to the Normal Population

D. Hoppensteadt, S. Jabati, T. Phan, J. Liles, T. Rowe, J. Fareed, M. Syed

Loyola University Medical Center, Pathology, Maywood, United States

Background: Atrial fibrillation (AF) is currently the most common cardiac arrhythmia encountered in clinical practice and a major cause of morbidity and mortality among adults. Extracellular plasma nucleosomes (PNs) are complexes of DNA and histones that are released during cell death. Histones have been shown to function as DAMPs when they are translocated from the nucleus to the extracellular space. These nucleosomes mediate inflammatory and thrombotic responses and could serve as biomarkers in atrial fibrillation.

Aims: The primary aim of this study was to demonstrate that PN levels are increased in atrial fibrillation and may contribute to the pathogenesis of this syndrome.

Methods: The concentration of PNs in plasma samples of atrial fibrillation patients (n=43), aged normals (n=35), and young normals (n=29) were measured using the Cell Death Detection ELISA PLUS assay (Roche Diagnostics, Mannheim, Germany). For this study, the baseline plasma samples of atrial fibrillation patients were analyzed.

Results: In comparison to the plasma from aged normals (11.42 ± 9.15 Arbitrary Units (AU)) and young normals (6.42 ± 0.87 AU; p < 0.0001), the plasma collected from atrial fibrillation patients (19.42 ± 20.5 AU; P = 0.0015) demonstrated much higher levels of PNs. When comparing the concentration of nucleosomes in plasma, the atrial fibrillation patients (306.1 ± 328.86 µg/mL) had much higher levels than the aged normals (177.9 ± 146.7 µg/mL; p = 0.0015).

Conclusions: PNs were elevated in atrial fibrillation when compared to both aged and young normals, indicating an increased release of nucleosomes, suggesting increased cell death. Due to the involvement of inflammation and thrombosis in the pathology of atrial fibrillation, the increased circulating nucleosome level in patients with atrial fibrillation implies that PNs may activate multiple pathogenic responses including immunologic, thrombotic and vascular responses.These results also suggest that PNs may provide a new biomarker for atrial fibrillation.

PB 798 | vWF Thr789Ala Genetic Variants Correlates with the Type of Myocardial Ischemia in Egyptian Patients

N. Osman[1], R. Yaseen[2]

[1]Menoufia University, Clinical Pathology, Shebin Elkom, Egypt, [2]Menoufia University, Cardiology, Shebin Elkom, Egypt

Background: von Willbrand factor antigen (vWF: Ag) levels were shown to contribute to the risk cardiovascular disease. Single nucleotide polymorphism (SNP) at codon 789 results in replacement of amino acid threonine by alanine (Thr789Ala) and is thought to affect factor level and activity.

Aims: The aim was to adress the impact of vWF Thr789Ala gene polymorphism on the risk of critical myocardial ischemia.

Methods: The study included 112 patients, 31 unstable angina (UA) and 81 myocardial infarction (MI), and 118 healthy controls. vWF :Ag level was measured by ELISA (Diapharma, West Chester, USA). The gene analysis was carried out by polymerase chain reaction using restriction fragment length polymorphism (RFLP-PCR) principles (Bioline, Toronto, Canada).

Results: There was significant correlation between the vWF genetic variant and the type of ischemia as Ala789 homozygous was seen in 25 patients with UA (80.6%), in 28 MI patients (34.6%) compared to 56 controls (47.5%). Thr789Ala heterozygous was seen in 39 MI patients (48.1%) and in only 2 (6.5%) of those with UA compared to 39 of the controls (33.1%). The genotype distribution was significantly different among the 3 groups, p < 0.001, and between the groups with UA and MI, p < 0.001. Our data showed the AA genotype to be an independent risk factor for UA with an estimated risk of 3.7 per minor allele (p < 0.001). Interestingly, T/A genotype was associated with 13.46 folds estimated risk of MI compared to UA (p < 0.001). vWF :Ag levels were significantly higher in patients compared to controls (111.29 ± 24.43 Vs 71.13 ± 13.72 respectively, p < 0.0001).

Conclusions: vWF Thr789Ala genotype is independent risk factor for UA and has significant impact on disease phenotype in Egyptian patients with myocardial ischemia. It should be incorporated in a risk assessment model to identify individual patient risk and guide the management plan.

PB 799 | The Incidence and Prognosis of Venous Thromboembolism (VTE) and Arterial Thromboembolism (ATE) Associated with Oral Contraceptives by Age Groups in Japan

K. Sugiura[1], T. Kobayashi[2], T. Ojima[3], T. Urano[4]

[1]Nagoya City University Graduate School of Nursing, Department of Reproductive Health Nursing/Midwifery, Nagoya, Japan, [2]Hamamatsu Medical Center, Hamamatsu, Japan, [3]Hamamatsu University School of Medicine, Department of Community Health and Preventive Medicine, Hamamatsu, Japan, [4]Hamamatsu University School of Medicine, Department of Medical Physiology, Hamamatsu, Japan

Background: Thromboembolism is an unavoidable adverse event of combined oral contraceptives (COCs), and the reported events increased year by year in Japan.

Aims: We analyzed the incidence and prognosis of thromboembolism associated with COCs by age groups in Japan.

Methods: 394 venous thromboembolism (VTE) events and 154 arterial thromboembolism (ATE) events associated with COCs were analyzed from the Pharmaceuticals and Medical Devices Agency database from 2004 to 2013. In a statistical analysis, a good-prognosis group included recovery cases and a poor-prognosis group involved unrecovered cases with some sequela or fatal cases definitely caused by thromboembolism. The significant difference between both groups was calculated by Pearson´s chi-square test, and the age-specific tendency was examined by Cochran-Armitage test. Statistical analysis was done using SPSS version 20. The study was approved by the Ethics Committee of Hamamatsu University School of Medicine.

Results: 548 events involved DVT only, cerebral infarction, PE with DVT, PE only, cerebral vein thromboses, other venous thromboses, coronary heart diseases, and other arterial thromboses in that order. Thromboembolic events occurred mostly in the 40s, followed by the 30s, 20s, 50s and teens by age. Judging from whole VTE and ATE events by age, the VTE rate decreased whereas the ATE rate significantly increased with advancing age (p=0.0041). Recovery cases were the most common, followed by unrecovered cases and fatal cases. In VTE and ATE, recovery cases were 86.4% and 70.9%; unrecovered cases were 10.1% and 28.2%; and fatal cases were 3.6% and 0.9%, respectively. All ATE cases had a significantly much poorer prognosis in comparison with all VTE cases (p< 0.0001).

Conclusions: Thromboembolic events were the most frequent in the 40s, followed by the 30s. The VTE rate decreased whereas the ATE rate significantly increased with advancing age. All ATE cases had a significantly much poorer prognosis in comparison with all VTE cases.

PB 800 | Implementation of CHA2DS2-VASc and HAS-BLED Scoring E-tool for Aatrial Ffibrillation Patients into Routine Clinical Practice in North Estonia Medical Centre

J. Arjakse[1], R. Berner[2], H. Ilumets[3], S. Kaarna[2], J. Kostjuk[3], M. Märk[3], T. Marandi[4,5]

[1]North Estonia Medical Centre, Hospital Pharmacy, Tallinn, Estonia, [2]North Estonia Medical Centre, IT Department, Tallinn, Estonia, [3]North Estonia Medical Centre, Emergency Internal Medicine Department, Tallinn, Estonia, [4]North Estonia Medical Centre, Therapy Quality Division, Tallinn, Estonia, [5]University of Tartu, Heart Clinic, Tartu, Estonia

Background: European Society of Cardiology (ESC) guidelines recommend to estimate stroke and bleeding risk for all atrial fibrillation (AF) patients (1). Simple and clinically applicable stroke risk score CHA2DS2-VASc and bleeding risk score HAS-BLED are recommended tools for selecting AF patients who would benefit from oral anticoagulation and in whom usage of anticoagulants is inappropriate because of the high risk of bleeding. Earlier in our hospital these scores were possible to calculate manually and then results were reported in patients' records. However, due to inconvenience of scoring, it was frequently not performed and could lead to incorrect treatment decisions. Since January 1st 2017 a new e-tool for risk scoring and reporting was implemented into e-record of the North Estonia Medical Centre (NEMC) and made mandatory for all patients with AF.

(1) European Heart Journal (2016) 37, 2893-2962

Aims: Aim for this study was to describe first results of implementing e-tool for CHA2DS2-VASc and HAS-BLED scoring of AF patients.

Methods: All patients (incl patients discharged from hospital or treated as outpatients) with diagnosis of AF were selected from the hospital database from January 1st 2016 to January 30th 2017. Data about age, gender, risk scores reporting, physician and departments/clinics were collected. Data analysis was performed by MS Excel 2010.

Results: There were total 12386 cases of AF during the period studied. Baseline characteristics of patients are listed in table 1 and risk scores reporting in table 2.

TABLE 1 Baseline characteristics of the patients

	2016	January 2017
Patients (n)	11659	727
Female sex (n) (%)	5865 (50.3)	365 (50.2)
Male sex (n) (%)	5794 (49.7)	362 (49.8)
Age- years (SD)	71,8 (11.7)	73,3 (11.6)
Female age- years (SD)	75,4 (9.7)	77,3 (9.5)
Male age- years (SD)	68,2 (12.5)	69,2 (12.0)

TABLE 2 Risk scores reporting in AF patients

	2016		January 2017	
	Patients (n)	Risk scores reported (n) (%)	Patients (n)	Risk scores reported (n) (%)
Anaesthesiology clinic	3042	70 (2.3)	225	12 (5.3)
Internal medicine clinic	7337	1564 (21.3)	448	369 (82.4)
Other clinics	1280	29 (2.3)	54	40 (74.1)
Total	11659	1663 (14.3)	727	421 (57.9)

Conclusions: The e-tool increases the rate of reporting risk scores and could improve patient management among the population of patients with AF. However, recognising of AF diagnosis, scoring and reporting in non-internal medicine clinics should be further evaluated, too.

PB 801 | Heightened Thrombogenicity in Women with Myocardial Infraction No Obstructive Coronary Artery Disease: The Difference between the Sexes

P. Gurbel, R. Chaudhary, H. Tran, K. Bliden, A. Fitzgerald, U. Tantry

Inova Heart and Vascular Institute, Falls Church, United States

Background: Sex differences exist in the prevalence and severity of myocardial infraction no obstructive coronary artery disease (MINOCA). Symptomatic women are less likely to have obstructive CAD than men with similar symptoms, and tend to have a significantly increased risk of heart attack or death.

Aims: The aim of the study is to compare thrombogenicity, lipid profile, and urinary 11-dehydrothromboxane B_2 ($dTxB_2$) among men and women with MINOCA

Methods: Consecutive patients (n=139) undergoing elective cardiac catheterization with ANOCA were analyzed. Patients with prior percutaneous coronary intervention and coronary artery bypass grafting were excluded. Blood and urine samples for thromboelastography, lipid profile, $dTxB_2$ and oxidized-LDL were obtained prior to cardiac catheterization.

Results: Women with MINOCA (n=76) had a higher prevalence of hypertension, and higher total cholesterol, total LDL, LDL subtypes1 and 2 , total HDL, HDL subtypes 2 and 3, and ApoA1 compared to men with MINOCA ($p < 0.05$ for all). Women also had greater thrombin-induced platelet fibrin strength (TIP-FCS), greater fibrinogen activity, and clotting index (Table 1). On linear regression, only TIP-FCS remained significantly higher in women (p=0.0002). Urinary $dTxB_2$ and oxidized-LDL were similar between the two groups.

TABLE 1

	Men (n=63)	Women (n=76)	p value
TIP-FCS (mm)	64.6+/-6.2	67.9+/-4.5	0.001
Clotting Time, R (min)	7.3+/-2.4	7.1+/-2.1	0.64
Clotting Index, CI	-0.62+/-2.71	0.30+/-2.22	0.05
Fibrinogen activity (degrees)	63.2+/-7.4	66.7+/-7.1	0.01

Conclusions: Heightened thrombogenicity with a greater platelet response to thrombin may play an important mechanistic role in the poorer clinical outcomes observed in women with angina and ANOCA compared to men. Further larger translational studies potentially targeting the thrombin pathway are warranted.

PB 802 | Role of Matrix Metalloproteinase-2 and Correlation with the Anticoagulant System in Diabetes

K. Nishihama[1], T. Yasuma[2], A. Takeshita[1], T. Totoki[3], Y. Takahashi[4], K. Fujiwara[4], C.N. D'Alessandro-Gabazza[2], M. Toda[2], T. Kobayashi[4], Y. Yano[1], E.C. Gabazza[2]

[1]Mie University Graduated School, Diabetes, Metabolism and Endocrinology, Tsu, Japan, [2]Mie University Graduated School, Immunology, Tsu, Japan, [3]Mie University Graduated School, Gastroenterology and Hepatology, Tsu, Japan, [4]Mie University Graduated School, Pulmonary and Critical Care Medicine, Tsu, Japan

Background: Diabetes mellitus is a metabolic disorder frequently associated with vascular complications that worsen the life expectancy and quality of life of many patients worldwide. Matrix metalloproteinase-2 (MMP-2) is a gelatinase with multiple functions including proteolysis, tissue remodeling, angiogenesis and cell-cycle control. Circulating MMP-2 is increased in diabetes but its relationship with the anticoagulant system is unknown.

Aims: To evaluate the role of MMP-2 in diabetes mellitus and its relationship with the anticoagulant system.

Methods: Experimental model of diabetes mellitus was developed by injection of streptozotocin in transgenic mice overexpressing MMP-2 and in wild type mice. Blood glucose and insulin levels were measured after induction of diabetes. The grade of pancreatic β-cell apoptosis was evaluated. The mechanistic action of MMP-2 was evaluated using MIN6 β cells. Blood samples from 30 patients with type 2 diabetes and 37 healthy volunteers were available to measure circulating MMP-2 and total protein S. All subjects gave written informed consent, the study was approved by the Institutional Ethics Committee and performed following the Helsinki declaration.

Results: Compared with wild type mice with diabetes, the blood glucose level was significantly decreased and the grade of insulin secretion was significantly enhanced in hMMP-2 transgenic mice with diabetes. The number of insulin-positive cells in pancreatic islet was significantly preserved in diabetic hMMP-2 transgenic mice compared to their wild type counterparts.

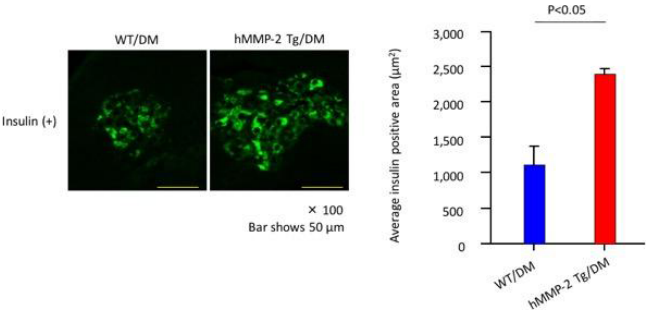

FIGURE 1 The number of insulin-positive cells in pancreatic islet was significantly preserved in diabetic hMMP-2 transgenic mice compared to controls

MMP-2 showed apoptotic activity by stimulating the activation of the AKT pathway in pancreatic cells. Circulating MMP-2 was significantly increased in diabetic patients compared to healthy controls and showed a strong tendency (p=0.05) to correlate with circulating protein S.

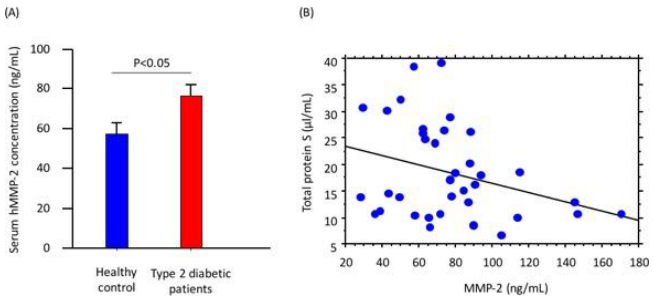

FIGURE 2 (A) Circulating MMP-2 levels in diabetic patients and healthy controls. (B) Correlation between MMP-2 and protein S in diabetic patients

Conclusions: Human MMP-2 is protective in experimental diabetes by activating the AKT pathway and correlates with protein S in diabetic patients.

PB 804 | Extracellular Nucleosomes, Markers of Cell Death, are Elevated in End-Stage Renal Disease Independent of Circulating Microparticle-associated Tissue Factor

T. Phan[1], R. Mcmillan[1], A. Walborn[2], D. Hoppensteadt[1], J. Fareed[1], V. Bansal[3]

[1]Loyola University Medical Center, Pathology, Maywood, United States, [2]Loyola University Medical Center, Pharmacology, Maywood, United States, [3]Loyola University Medical Center, Nephrology, Maywood, United States

Background: Extracellular nucleosomes in plasma (PNs) are complexes of DNA and histones that are released during cell death. In acute kidney injury, there is an increased release of nucleosomes with decreased nucleosome clearance. Microparticle-associated tissue factor (MP-TF) are released during cell death and mediate thrombotic responses.

Aims: The objective of this study is to determine the interdependance of nucleosomes and microparticles in ESRD.

Methods: The concentrations of PNs in ESRD patients (n = 90) and healthy volunteers (n = 50) were measured using the Cell Death Detection ELISA PLUS assay (Roche Diagnostics, Mannheim, Germany). MP-TF levels were measured using the ZYMUPHEN MP-TF kit (Hyphen BioMed, Neuville-sur-Oise, France).Th elevels of both PNs and MP-TF were also correlated with WBCs, RBCs and platelets to determine the origin of measured PNs.

Results: In comparison to the plasma from healthy volunteers (6.74 ± 13.7 Arbitrary Units (AU)), the levels of PNs in ESRD patients were higher (15.5 ± 14.1 AU; $p < 0.0001$). Similarly, MP-TF levels were elevated in ESRD patients (3.00 ± 1.42 pg/mL; $p < 0.0001$) compared to normal (0.363 ± 0.263 pg/mL). There was no correlation between PNs and MP-TF in ESRD patients ($r = 0.077$; $p = 0.501$). Moreover, there was no correlation between PNs and platelets ($r = 0.067$; $p = 0.543$) and RBCs ($r = 0.083$;
$p = 0.447$). However, the PNs showed a positive correlation with WBCs ($r = 0.223$; $p = 0.042$). There was no correlation between MP-TF and WBCs ($r = -0.057$; $p = 0.632$) and RBCs ($r = -0.042$; $p = 0.722$), but a positive correlation was observed between MP-TF and platelets ($r = 0.237$; $p = 0.042$).

Conclusions: PNs were elevated in ESRD patients, suggesting increased cell death. The observed correlation between PNs and WBCs suggests that the detected PNs are derived from WBCs. A lack of correlation between PNs and MP-TF suggests that the MP-TF increase is independent of the pathophysiologic processes responsible for abnormal PN generation in ESRD patients.

PB 805 | Stroke Prevalence in Patients with Different Patterns of Atrial Fibrillation: Cross-sectional Study of Moscow Registry

A. Melekhov, G. Gendlin, E. Dadashova, E. Alekseeva, I. Zaigraev, I. Nikitin

Russian National Research Medical University, Internal Diseases, 2, Moscow, Russian Federation

Background: 2016 ESC guidelines for the atrial fibrillation (AF) patients management states that stroke risk is equal in all AF patterns, paroxysmal, persistent or permanent. But some recent studies´ve shown weak evidence, that AF pattern may influence stroke risk.

Aims: To estimate the prevalence of stroke in patients with different patterns of AF.

Methods: Cross-sectional study of Moscow AF registry data, 1624 adult patients of 2 hospitals and 3 out-patient clinics, observed at 2009-2015.

Results: Median age was 73,0 (64,0-79,0), women prevailed (61,4%). 39,1% of patients had permanent, 31,4% - paroxysmal and 29,4% - persistent AF. The age of patients with permanent AF was significantly higher (75 (66,9-81,0) years), than with non-sustained forms (71 (62,5-78) years), as well as CHA_2DS_2-Vasc (6 (4-7) vs 4 (3-5)) and HAS-BLED scores (3 (2-3) vs 2 (2-3)), $P < 0,05$ for all comparisons.
29,2% of the registry patients had a stroke or a transient ischemic attack (TIA) (21,7% - one, 7,4% - repeated). The patients, who had stroke, were significantly older, than the patients without stroke. 29,9% of patients with permanent AF had a stroke, 11,7% - repeated strokes. In patients with paroxysmal or persistent AF these rates comprised 21,4; 7,7% and 11,6; 6,6% respectively ($P < 0,05$, X^2 method).
Warfarin use rates in out-patients with permanent AF was 8,4%, with paroxysmal - 4,9%, with persistent - 13,0%. In hospital these rates increased to 28; 17,3 and 68,9% respectively. New oral anticoagulants (NOAC) use rates was very low: 0,8; 0,6; 9,6% vs 6,4; 3,9; 23,1% respectively. The patients, who had stroke, especially repeated, were prescribed both warfarin and NOAC less likely.

Conclusions: Permanent AF was associated with higher prevalence of stroke, that can be considered while making a decision of anticoagulants prescription to the patients with intermediate risk (CHA_2DS_2-Vasc=1).

PB 806 | Validation of a Patient-completed Caprini Risk Assessment Tool in a Spanish-speaking Population

H. Fuentes[1], L. Paz[1], D. Oramas[2], C. Acob[1], X. Andrade[1], A. Tafur[3], J. Caprini[3]

[1]John Stroger Hospital Cook County, Internal Medicine, Chicago, United States, [2]University of Illinois, Chicago, United States, [3]NorthShore University HealthSystem (University of Chicago Pritzker School of Medicine), Evanston, United States

Background: Personalized risk assessment for venous thromboembolism (VTE) using the Caprini risk score (CRS) coupled with targeted prophylaxis based on the score is effective in reducing the post-operative VTE. Critics contend that the tool is time-consuming for healthcare providers and is limited to the English language.

Aims: To develop and validate a patient-completed CRS for Spanish-speaking (SS) population.

Methods: A focus group was held with family members and patients to determine areas of misunderstanding in the original score. Based on these interviews a patient-friendly form was created and completed by hospitalized patients. A CRS trained, blinded SS physician scored 33 patients during the pilot study. Patients found it challenging to calculate BMI,

which we excluded from the final Patient-CRS form due low agreement in the interim analysis. The study was approved by our local Institutional Review Board. We calculated the sample size to be 37 assuming power of 80% and an alpha of 0.05. We calculated the individuals' questions and categorized scores using SPSS version 23 to estimate Kappa, linear correlation and Bland Altman test. A kappa value over 0.8 was defined as "almost perfect agreement", 0.61-0.79 was "substantial agreement".

Results: We recruited 50 native SS patients (average age (47yo), men (56%), less than college education (77.5%)). Of the 30 individual questions 1 had substantial agreement and the rest had almost perfect agreement comparing physician and patient results. We report a high correlation (r= 0.99) for the overall score and the Bland Altman plot did not show any trend for extreme values.

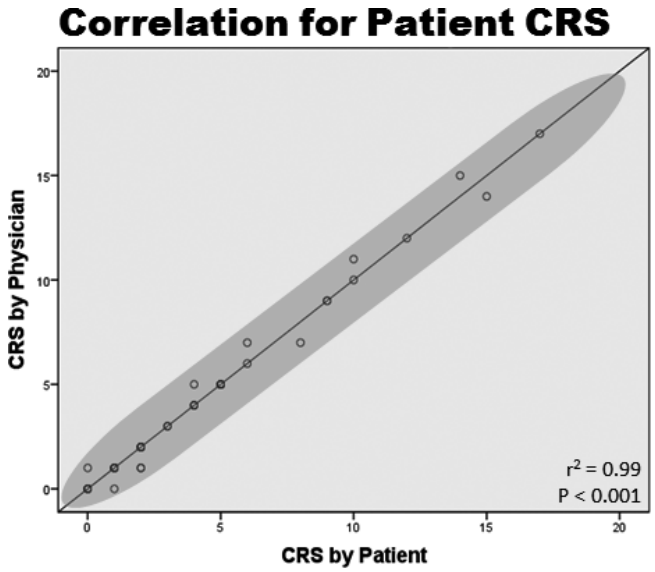

FIGURE 1 Correlation of Patient CRS

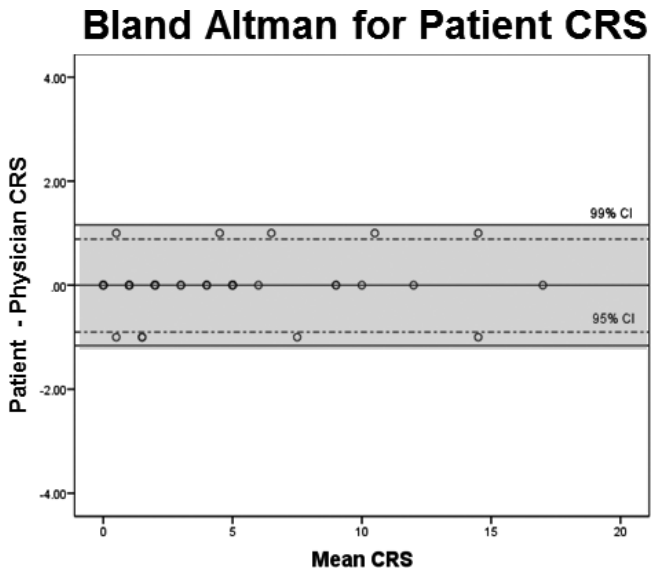

FIGURE 2 Bland Altman for Patient CRS

Conclusions: We created and validated a self-reported CRS form to assess peri-operative thrombotic risk in SS patients. The new version has an almost perfect agreement between patient and physician completed scores and substantial agreement for immobilization during the past 2 days. Based on these results, the physician only needs to calculate the BMI. Completing the form was not time-consuming.

PB 807 | The Procoagulant Contribution of Tissue Factor Expressing Platelets in Hypertension

M. Brambilla[1], L. Rossetti[1], L. Lodi[1], P. Canzano[1], E. Tremoli[1], M. Camera[1,2]

[1]*Centro Cardiologico Monzino IRCCS, Milan, Italy,* [2]*Università degli Studi di Milano, Department of Pharmacological and Biomolecular Sciences, Milan, Italy*

Background: Platelets (PLT) express Tissue factor (TF), the main activator of the blood coagulation cascade. Cardiovascular risk factors, such as hypertension and diabetes, affect TF expression both in human and in rat PLT. However, the relative contribution of TF+ PLT, compared to that of the other circulating TF-expressing cells, in thrombin-generating events has not been addressed.

Aims: To analyze the procoagulant potential of TF+ PLT compared to that of TF+ monocytes (Mo) and microvesicles (MV).

Methods: Hypertension was induced by stenosis of renal artery in Wistar Kyoto rats (Hyp; n=7). Sham operated rats were used as normotensive controls (Norm, n=4). Blood was drawn into CTI tubes and intracellular TF expression was evaluated by flow cytometry in PLT, Mo and MV. Their thrombin generation (TG) capacity was measured by CAT assay, taking into account their relative number in 1µl blood volume.

Results: Compared to Norm, Hyp had an increased number of TF+ PLT and Mo (PLT: 7.5±3.2% vs 11.1±2.9%; p=0.035; Mo: 10.3±9.4% vs 34.8±30%; p=0.04) as well as of TF+/Ann+ MV (157±86 /µl vs 428±24 /µl; p=0.04). However, the amount of TF+ PLT in 1µl blood volume was more than 500- and 100-fold higher compared to that of Mo and MV, both in Norm and Hyp. CAT assay indicated that while PLT from Hyp had a higher kinetic rate of TG compared to Norm (Lag Time: 8.6±3.1 vs 10±0.7 min; p=0.036) and generated greater amount of thrombin (Peak: 32.5±21 vs 23.1±6.6 nM, p=0.04), no differences between Norm and Hyp were found in the TG of Mo and MV. Moreover, a double amount of thrombin was generated by PLT compared to that of Mo and MV. After preincubation of samples with a neutralizing anti-TF antibody, a significant delay in the TG was observed only for PLT.

Conclusions: Despite in hypertension an increase of the amount of TF+ PLT, Mo and MV occurs, the number of TF+ PLT, in one unit of blood, far exceeds that of Mo and MV and results in a significantly higher TF-dependent TG, thus supporting a role for TF+ PLT as coagulation trigger.

PB 808 | Patients with Multiple Cardiovascular Risk Factors Show a Characteristic Decrease in Circulating MAIT Cells

S. Fujii[1], K. Akasaka[2], K. Ito[2], K. Ohtsuka[2], E. Ito[2], Y. Kawahara[2], H. Takahashi[2], K. Saito[2], Y. Tomoda[2], I. Kawabata[2], T. Takeuchi[3], N. Hasebe[3]

[1]*Asahikawa Medical University, Laboratory Medicine, Asahikawa, Japan,* [2]*Asahikawa Medical University Hospital, Medical Laboratory, Asahikawa, Japan,* [3]*Asahikawa Medical University, Cardiovascular Medicine, Asahikawa, Japan*

Background: Mucosal-associated invariant T (MAIT) cells regulate natural immunity and exhibit antimicrobial activities in infectious diseases. Inflammation is involved in the development of atherosclerosis and thrombosis. However, little is known about cardiovascular risk factor-related changes in circulating MAIT cell level in healthy Japanese subjects.
Aims: We aimed to determine the level of circulating MAIT cells in plasma in healthy adults and the potential relationships between cardiovascular risk factors and circulating MAIT cell levels.
Methods: Healthy subjects were enrolled (n = 20, age 20 - 60 years). MAIT cells were measured by flow cytometry.
Results: Circulating MAIT cell levels extensively varied (0.4% to 9.5%) among subjects. A linear regression analysis revealed that circulating MAIT cell levels declined significantly with aging (R = -0.86, P < 0.01). No significant difference was found in the circulating MAIT cell levels between male and female subjects (P = 0.43). MAIT cell levels were significantly lower in obese subjects (BMI > 25) than in non-obese subjects (BMI < 25, P < 0.01). In addition, the number of representative cardiovascular risk factors (male gender, age over 55 years, history of smoking, obesity, family history of cardiovascular diseases, hypertension, dyslipidemia, hyperuricemia) closely correlated with the decrease in circulating MAIT cells (P < 0.05), suggesting a close link between MAIT cells and progression of early atherosclerosis.
Conclusions: Our data strongly suggest that aging and accumulation of cardiovascular risk factors are closely associated with a reduction in circulating MAIT cells in Asians. The precise roles of circulating MAIT cells as biomarker of early atherosclerosis need further investigation.

PB 809 | Protein Z Deficiency: A Reliable Risk Factor for Acute Coronary Syndrome

D.S. Eissa[1], M.F. Ghozlan[1], A.A.E.-H. Mohamed[1], H.S. Eldawy[2]

[1]*Faculty of Medicine, Ain Shams University, Clinical Pathology, Cairo, Egypt,* [2]*Faculty of Medicine, Ain Shams University, Cardiology, Cairo, Egypt*

Background: Acute coronary syndrome (ACS) comprises a range of life-threatening thrombotic coronary artery diseases. Understanding the pathophysiology and identifying the risk factors are crucial for prevention of ACS. The protein Z (PZ)/PZ-dependent protease inhibitor (ZPI) is a natural anticoagulant system, with a presumptive role for PZ deficiency in the pathogenesis of ACS.
Aims: We aimed at investigating the role of plasma PZ level as a risk factor for ACS.
Methods: Hundred patients with history of ACS and 60 matched healthy controls were enrolled. Patients with recent ACS, on oral anticoagulants or with liver diseases were excluded. ACS patients were subdivided into 3 clinical subgroups [ST-segment elevation myocardial infarction (STEMI), non-STEMI (NSTEMI) and unstable angina (UA)], and 2 age subgroups (Group A ≤55 years and Group B >55 years). Plasma PZ levels were assayed using enzyme linked immunosorbent assay.
Results: PZ levels were lower in ACS patients' group and clinical subgroups (STEMI, NSTEMI, UA) compared to controls (p< 0.01), however; showed no difference among the ACS clinical subgroups (p= 0.783). PZ levels decreased with increasing age (r= -0.739, p< 0.01) and were lower in female versus male patients (p< 0.05). Lower PZ levels were found in hypertensive ACS patients in both age groups (p< 0.05). Smokers and patients with family history of ACS in Group A showed lower PZ levels (p< 0.05), while Group B patients showed lower PZ levels among diabetics (p< 0.05). In Group A, the more the number of ACS conventional risk factors, the lower the PZ levels (p< 0.01). Receiver operating characteristic (ROC) curve assigned the PZ level 3.7 µg/mL as the best cut-off value for predicting ACS. Uni/multi-variate logistic regression analyses denoted PZ level as an independent risk factor for ACS (p< 0.01).
Conclusions: PZ deficiency is a reliable risk factor for ACS. Assay of PZ level, especially in older age, female patients, and in the subset of patients lacking ACS conventional risk factors, is worthwhile.

PB 810 | Cardiac and Inflammatory Biomarkers and their Role in the Pathogenesis of Heart Failure in End-Stage Renal Disease

R. Mcmillan[1], V. Bansal[2], D. Hoppensteadt[1], J. Fareed[1]

[1]*Loyola University Medical Center, Pathology, Maywood, United States,* [2]*Loyola University Medical Center, Nephrology, Maywood, United States*

Background: Heart failure (HF) is highly prevalent in patients with End-Stage Renal Disease with a presence of approximately 40 %. The purpose of this study was to determine the role of cardiac and inflammatory biomarkers in the pathogenesis of HF in ESRD patients.
Aims: The primary aim of this study is to investigate the role of inflammatory mediators in heart failure.
Methods: Ninety blood samples from maintenance hemodialysis patients were retrospectively collected and stored at -70° C. Twenty-five male and twenty-five female plasma samples from healthy individuals were purchased from a biobank as a control. The samples were used to profile KIM-1, NT-pro BNP, NGAL, IL-18, PDGF, Vitamin D, PTH, Endothelin, Endocan, MPTF, Heparin anti Xa, Lp(a) using commercial sandwich and competitive ELISA kits and assays.
Results: All plasma biomarkers, except PDGF, Endothelin and Vitamin D, were statistically increased in patients with ESRD compared to normal (P < 0.05). HF patients with ESRD, as compared to non-HF patients with ESRD, had significantly elevated NT-pro-BNP (P = 0.0194 | % change = 52.9) and KIM-1 (P = 0.0485 | % change = 58.5%). There were no statistical differences found between age groupings, except < 60 y.o KIM-1 vs 60-69 y.o KIM-1. NT-pro-BNP in ESRD patients with HF was found to correlate

with K+ (P = 0.023 | R = -0.39), Ca+ (P = 0.029| R = -0.38), and Heparin anti Xa (P = 0.045 | R = 0.35). KIM-1 in ESRD patients with HF was found to correlate with Creatinine (P = 0.0175 | R = -.41), EGFR (P = 0.008 | R = 0.45), Phosphate (P = 0.002 | R = -0.51), Intact PTH (P = 0.043 | R = -0.36), Calcium Phosphate Product (P = 0.002 | R = -0.52), and Vitamin D (P = 0.037 | R = 0.36).

Conclusions: Elevated plasma NT-pro-BNP and KIM-1 in all of the ESRD patients and ESRD patients with HF suggest that natriuretic peptides and KIM-1 may contribute to the pathogenesis of HF in ESRD patients. Elevated NT-pro-BNP further supports previous studies demonstrating NT-pro-BNP's potential diagnostic and prognostic utility.

PB 811 | Risk Factors for Recurrent Venous Thromboembolism in the Elderly

H. Alshammari[1], M. Al Subieg[2], F. Al-Eidan[2,3]

[1]Arar Central Hospital, Clinical Pharmacy, Arar, Saudi Arabia, [2]King Abdulaziz Medical City, Riyadh, Saudi Arabia, [3]King Saud bin Abdulaziz University for Health Sciences, Riyadh, Saudi Arabia

Background: Although recurrent venous thromboembolism (VTE) is an important cause of morbidity and mortality among the elderly, limited data written about risk factors predisposing to recurrent VTE in the elderly.

Aims: To identify the risk factors associated with recurrent VTE in the elderly. Incidence of recurrence rate was also assessed.

Methods: A retrospective cohort observational study was conducted between January 2014 and December 2016. A cohort of 458 VTE elderly patients aged 65 and above who were referred to VTE clinic were included. Univariate and multivariate Cox proportional hazards model were used to calculate the hazard ratios for the recurrence of VTE.

Results: A total of 72 elderly patients (16%) developed a recurrent VTE over the study period. The annual rate of recurrence was 1.0% in patients with trauma, 2.0% in patients with active cancer and 3.2% in patients with primary unprovoked VTE. Hazards ratio (HR) for recurrence was 0.34 (95% CI 0.21-0.62) in elderly with VTE provoked by trauma while elderly with active cancer associated VTE had a HR of 0.60 (95% CI 0.39-1.15) compared to elderly with unprovoked VTE.

Conclusions: Our findings suggest elderly patients had lower risk of developing recurrent VTE. Elderly with active cancer associated VTE had a lower risk of recurrence than elderly with unprovoked VTE, but not as low as trauma provoked VTE.

PB 812 | Increased von Willebrand Factor Platelet Interactions in Patients with Chronic Pain

I. Scharrer, M. Hoffmann

University Medical Center Mainz, Haematology, Mainz, Germany

Background: Von Willebrand factor and factor VIII are acute phase proteins. Besides, they are associated with arterial thrombosis in coronary heart diseases and ischemic stroke (Sonneveld M.A.H. et al. 2014).

Aims: To solve the crucial question whether patients with chronic pain show elevated levels of Von Willebrand factor, factor VIII and low ADAMTS 13 activity which may contribute to arterial thrombosis.

Methods: Our clinical study was carried out in the departments of anaesthesiology and hemostaseology. It was approved by a recognized ethic committee. A blood sample was taken from all participants in order to determine the Von Willebrand factor, factor VIII and the Von Willebrand factor cleaving protease ADAMTS 13. In addition, the blood groups of the participants were identified.

Results: 52 patients, mean age 52,1 years, with chronic pain (57,7% suffering for > 5 years; 26,9% for 2-5 years; 11,5% for 1-2 years; 3,8% for ½-1 year) and 53 pain-free probands, mean age 51,96 years, were included after an informed consent. Patients with chronic pain had significant higher levels of Von Willebrand factor activity and by trend higher levels of Factor VIII and lower levels of ADAMTS13 compared to pain free probands matching by age and sex.

Conclusions: According to our survey, patients with chronic pain may be a risk group for arteriosclerotic diseases, particularly due to the permanent higher levels of Von Willebrand factor and factor VIII and the lower levels of ADAMTS13. However, our results cannot be explained with the age or blood group of the patients. The influence of AB0-system was adjusted in our testing methods.

PB 813 | Routine Care Data in Prediction Research

S. van Doorn, T. Brakenhoff, G.-J. Geersing, A.W. Hoes, K.G.M. Moons

University Medical Center Utrecht, Julius Center for Health Sciences and Primary Care, Utrecht, The Netherlands

Background: Data from routine care is becoming increasingly available, also in the field of thrombosis research. While having great potential, their use for research inherently has its limitations. For instance, misclassification of both risk factors and the outcome under study may strongly affect inferences, though to what extent is currently unclear.

Aims: To quantify the amount of misclassification in routine care data and its influence on studies evaluating risk prediction models.

Methods: In a prospective cohort in general practice in the Netherlands, we used routinely collected data from the electronic medical records of patients with known atrial fibrillation (AF) and compared these to data collected after manually scrutinizing all complete medical files. As an example, we used the CHA2DS2-VASc clinical decision rule to predict the outcome, all-cause mortality. Using our manually obtained data as a reference standard, we assessed misclassification of individual predictors and compared hazard ratios (HR) and predictive performance from Cox survival analyses using either routine care data or manually collected data.

Results: In total 2363 AF patients were included. After a median follow-up of 2.7 years (IQR 2.3 - 3.0 years), all-cause mortality occurred in 368 patients (incidence rate 6.2 deaths per 100 person-years). Misclassification in individual predictors ranged from substantial (Cohen's kappa 0.56 for heart failure) to minor (kappa 0.90 for diabetes), as did differences in HRs in the Cox models (univariate HRs for heart failure 2.1 using routine care data versus 1.7 in

manually collected data; HRs for diabetes 0.81 versus 0.83, respectively). However, overall model performance was not affected by misclassification (c-statistic for CHA2DS2-VASc as a continuous score of 0.684 for routine care data vs. 0.681 for manually collected data, predicted probabilities were similar).

Conclusions: While misclassification was substantial in several variables, this did not influence apparent overall model performance.

PB 814 | Markers of Plasma and Platelet Hemostasis Function as the Risk Factors for Leg Amputation in Patients with Critical Limbs Ischemia

J. Budzyński[1], D. Rość[2], R. Wieczór[2], A.M. Wieczór[2], K. Stankowska[2], B. Ruszkowska-Ciastek[2], J. Kubiak[1], J. Fabisiak[1], K. Suppan[1], G. Pulkowski[1]

[1]Clinic of Vascular and Internal Medicine, Dr Jan Biziel University Hospital No. 2, Bydgoszcz, Poland, [2]Department of Pathophysiology, Faculty of Pharmacy, Nicolaus Copernicus University in Toruń, Ludwik Rydygier Collegium Medicum, Bydgoszcz, Poland

Background: Identification of factors linking the risk of failure of endovascular treatment might help in better patients qualification and individualization of pharmacotherapy and in decrease in risk of amputation.

Aims: The aim of the study was to determine the importance of chosen hemostatic factors in prediction of leg amputation after endovascular procedure.

Methods: One hundred twenty five patients treated endovascularly due to critical limbs ischemia were enclosed to the analysis, 39 patients in whom leg amputation was performed 192 ± 257 days after procedure, and 86 patients with salvaged extremities.

Results: Patients with leg amputation, in comparison to patients with rescued limb, had: greater INR (1.14 ± 0.2 vs. 1.03 ± 0.11, p=0.003) and platelet count (356.4 ± 143.5 vs. 272.9 ± 110 G/l, p=0.001). In progressive stepwise regression method the time duration between the first revascularization procedure and the amputation was significantly determined by many various factors, including clinical (e.g. age, history of atrial fibrillation, stroke, hypertension, diabetes mellitus), periprocedural (e.g. number of implanted stents), angiographical (e.g. atherosclerotic lesion advancement, inflow, outflow in relation to target lesion), biochemical (LDL cholesterol, leukocytes count, C-reactive protein), and hemostatic (number of platelets, mean platelets volume, INR, aPTT).

Conclusions: Simple hemostatic tests were the ones of independent factors affecting the risk of leg amputation after endovascular procedure. The further studies are needed to determine their predictive values and confirm their clinical usefulness.

PB 815 | Validation of a Patient-completed Caprini Risk Assessment Tool

H. Fuentes[1], L. Paz[1], A. Al-Ogaili[1], D. Oramas[2], C. Acob[1], A. Tafur[3], J. Caprini[3]

[1]John Stroger Hospital Cook County, Internal Medicine, Chicago, United States, [2]University of Illinois, Chicago, United States, [3]NorthShore University HealthSystem (University of Chicago Pritzker School of Medicine), Evanston, United States

Background: Individual risk assessment for Venous Thromboembolism (VTE) using the Caprini Risk Score (CRS) coupled with targeted prophylaxis based on the score is effective in reducing the post-operative VTE. Critics contend that the tool is time-consuming for healthcare providers.

Aims: To compare scores calculated by a patient to scores in the same patient calculated by a blinded physician.

Methods: A focus group interview was held with family members and patients to determine areas of misunderstanding in the original CRS. Based on these interviews a patient-friendly form was created and completed by hospitalized patients. A CRS trained, blinded physician scored 20 patients during the pilot study. Patients found it challenging to calculate BMI, which we excluded from the final Patient-CRS form due to low agreement in interim analysis. The study was approved by our local Institutional Review Board. We calculated the sample size to be 37 assuming power of 80% and an alpha of 0.05. We calculated the individuals' questions and categorized scores using SPSS version 23 to estimate Kappa, linear correlation and Bland Altman test. A Kappa value over 0.8 was defined as "almost perfect agreement."

Results: We recruited 42 patients (average age (55yo), female (45%), less than college education (62%)) who completed the CRS form. There was almost perfect agreement both for individual questions and for the overall score comparing physician and patient results. We report a high correlation (r=0.97) and the Bland Altman did not show any trend for extreme values.

Conclusions: We created and validated a self-reported CRS form to assess peri-operative thrombotic risk. The new version has an almost perfect agreement between patient and physician completed scores except for BMI. Based on these results, the physician only needs to calculate the BMI. Completing the form was not time-consuming.

PB 816 | Patients with Diabetes Mellitus 2 on Treatment, with or without Previous Cardiovascular Events, Have Delayed Clot Lysis, but Not Hyperactive Platelets Nor Increased Thrombin Generation

O. Panes[1], L. Quiñiñir[2], J. Pereira[1], R. Corbalán[2], D. Mezzano[1]

[1]*School of Medicine, P. Catholic University of Chile, Hematology-Oncology, Santiago, Chile,* [2]*School of Medicine, P. Catholic University of Chile, Cardiology, Santiago, Chile*

Background: The increased cardiovascular risk (CVR) in patients with diabetes mellitus 2 (DM-2) is well known (65-80% of deaths). Glycemic control has not decreased significantly the CVR in 3 Clinical Trials. Thus, other factors must play a role in it, such as the prothrombotic abnormalities described in DM-2.

Aims: We studied hemostasis variables in 2 groups of 20 DM-2 patients with (CV+) and without (CV-) previous CV events, and compared them with 20 age and sex-matched Controls (Co), all of them without aspirin.

Methods: Both patient groups had increased BMI (means of 29 and 28 vs 26 Kg/m^2 in Co), glycosylated hemoglobin (8.0 and 7.6 vs 5.6%) and triglycerides (187 and 149 vs 130 mg/dL). Most DM-2 patients received statins and had total and LDL cholesterol lower than Co ($p< 0.01$). Blood pressure, creatinine and smoking habits were similar in the 3 groups. We also measured sCRP, advanced oxidation protein products (AOPP) and VWF. Clot Lysis Time (CLT) in ristocetin stimulated PRP was also measured (Panes et al Platelets 2012).

Results: Basal P-selectin exposure was slightlyly higher in CV+ patients than in Co ($p=0.03$). CV+ patients had less aggregation and 5-HT secretion to sub-threshold 0.5µM ADP (but not to epinephrine) concentration than CV- and Co ($p< 0.01$). Platelet tissue factor-dependent FXa generation was similar in all groups. Thrombin generation in PPP and PRP, and plasma F_{1+2} and TAT complexes in CV+, CV- and Co, as well as inflammatory, oxidative stress and endothelial dysfunction markers did not differ significantly in all the groups. However, PAI-1 was lower in Co compared with CV+ ($p=0.003$) and CV- ($p< 0.05$); and CLT-PRP was significantly prolonged in CV+ ($p< 0.001$) and CV- ($p< 0.001$) patients compared with Co.

Conclusions: We did not confirm platelet hyperfunction (aggregation, secretion and procoagulant activity) nor increased thrombin generation potential in our DM-2 cohorts. Hypofifrinolysis may be major contributor of CVR in DM-2, but the mechanisms involved need to be studied.

PB 817 | Haemorrheologic and Fibrinolytic Activities in Diabetic Patient with Hypertension in Calabar, Nigeria

M.S. Edem[1], D.C. Okpokam[2], A.O. Emeribe[2]

[1]*University of Calabar Teaching Hospital, Haematology, Calabar, Nigeria,* [2]*University of Calabar, Medical Laboratory Science (Haematology Unit), Calabar, Nigeria*

Background: Cardiovascular disease is the leading cause of morbidity and mortality among persons with diabetes with smoking, hypertension, poor glycaemic control etc. as risk factors.

Aims: This study is aimed at determining the plasma viscosity, euglobulin lysis time, and fibrinogen levels in diabetics and diabetics patients with hypertension.

Methods: A total of fifty (50) diabetic subjects aged between 35-75 years attending the diabetic clinic of University of Calabar Teaching Hospital, and fifty age-matched non-diabetic apparently healthy volunteers (controls) were selected for the study. Diabetes and hypertension in this study was defined according to WHO 1999 guidelines. 7ml of venous blood was collected from each subject. It was dispersed to the appropriate bottles for analysis. Standard methods of Haugie, (1986), Reid and Ugwu, (1987), Ingram's and Hills (1976) and Nelson (1944) were employed for the determination of euglobulin lysis time, relative plasma viscosity, plasma fibrinogen concentration and fasting blood sugar levels in duplicates respectively. The results were expressed as mean ± standard deviation and students't test for paired means was used for statistical comparison.

Results: The fasting blood sugar of diabetic patients, RPV, PFC and ELT (10.23mmol/l, 1.65, 5.22g/L and 268.4mins) was significantly higher than that of the control subjects. There was no statistical difference in RPV, PFC and ELT ($P>0.05$) for both diabetic subjects and the controls based age and gender. Fibrinogen levels (6.27g/l) showed significant increase ($P< 0.05$) in diabetics with hypertension when compared with those who had no hypertension while no statistical difference was observed in RPV and ELT.

Conclusions: This study shows values of RPV, PFC and ELT in diabetics, control subjects and diabetics with hypertension in this locality. it indicate that the subjects are prone to developing thrombosis. For better management of diabetic patients in this locality, it may be necessary to include RPV, PFC and ELT as routine tests.

PB 1638 | Platelet α-granule Deficiency Protects Local and Distal Organs in Intestinal Ischemia Reperfusion Injury

K. Ashworth[1], P. Davizon-Castillo[1], L. Johnson[2], B. Branchford[1], D. Bark[1,3], J. DiPaola[1]

[1]*University of Colorado, Anschutz Medical Campus, Hematology & Oncology - Pediatrics, Aurora, United States,* [2]*University of Colorado, Anschutz Medical Campus, Department of Pathology, Aurora, United States,* [3]*Colorado State University, Mechanical Engineering, Fort Collins, United States*

Background: Intestinal I/R has been associated with distal organ injury, in particular the lungs. A deficiency of α-granules in *Nbeal2*^{KO} platelets has been previously reported to reduce brain infarct size in transient cerebral ischemia. A functional role for platelets and their α-granules in tissue damage after intestinal I/R injury remains unknown.

Aims: Investigate the role of platelet α-granules in the pathological process of intestinal ischemia reperfusion injury.

Methods: *Nbeal2*^{KO} and *Nbeal2*^{WT} mice were subjected to 1 hour of intestinal ischemia by clamping of the superior mesenteric artery using a small arterial clip. The arterial clip was removed, followed with a 3-hour period of reperfusion. During the reperfusion period, platelets and neutrophils in the mouse mesentery were monitored in real time by fluorescent microscopy. At the end of reperfusion, mice were euthanized and their tissue was harvested.

Morphological changes in the small intestine and lungs were determined by H&E staining. Histopathology of the small intestine and lungs was assessed by randomly selecting 8 images per mouse/ tissue section and scored in individual categories.

Results: During reperfusion, platelet-leukocyte aggregates in the mesentery were significantly decreased in the *Nbeal2*^{KO} mice. Intestinal I/R in *Nbeal2*^{WT} mice caused severe damage, including distortion and shortening of villi, disruption of villi epithelium, infiltration of leukocyte cells and hemorrhage. Similarly, in *Nbeal2*^{WT} mice, lung injury was characterized by the congestion of lung vessels, thickening of the alveolar wall, mild atelectasis, leukocyte cell infiltration and hemorrhage in the air space. *Nbeal2*^{KO} mice displayed statistically significant less severe morphological changes in their intestinal mucosa and lung architecture.

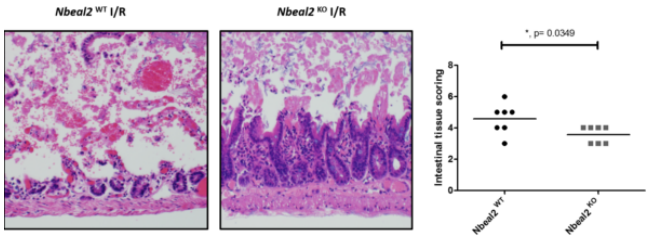

FIGURE 1 Representative images of H&E stained sections of small intestine after 1hr ischemia and 3hrs reperfusion and tissue injury scoring

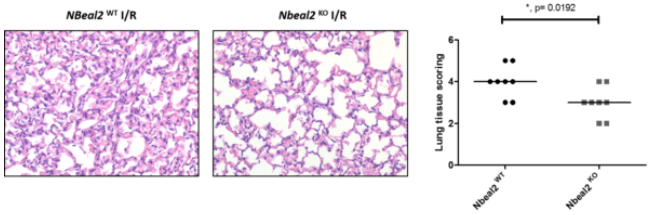

FIGURE 2 Representative images of H&E stained sections of mouse lung after 1hr ischemia and 3hrs reperfusion and lung tissue injury scoring

Conclusions: Local intestinal and distal lung tissue damage was reduced in *Nbeal2*^{KO} mice after intestinal ischemia reperfusion underscoring the role of platelet α-granules in thromboinflammation and tissue injury.

PB 1639 | Structure-function Relationships of Krait Natriuretic Peptide: Design of Natriuretic Peptide Analogues with Vasodilatory or Renal Activities for Personalized Care of Heart Failure Patients

S. Sridharan, M. Kini

National University of Singapore, Dept of Biological Sciences, Faculty of Science, Singapore, Singapore

Background: Heart failure (HF) or congestive heart failure is a common, costly, and frequently fatal condition. Current treatments for acute decompensated HF, including combinations of renin-angiotensin-aldosterone system inhibitors, diuretics, vasodilators, inotropes, opiates and ion channel blockers, are effective in short-term restoration of function but are associated with higher readmission rates. HF patients, classified as „dry/wet“ and “cold/warm” depending on their hemodynamic status based on perfusion vs. congestion, need specific treatments.

Aims: To understand the structure-function relationships of ‚ring' of krait natriuretic peptide (K-Ring) and to design distinct classes of natriuretic peptide analogues (NPAs) with exclusive vasodilatory or diuretic effects.

Methods: We designed and synthesized a number of analogues of K-Ring and human ANP and evaluated their hemodynamic and diuretic properties in anesthetized rats.

Results: By systematic mutations and functional studies of various mutants, we identified residues in K-Ring responsible for vasodilatory and/or diuretic functions of NPs. In the process, we also identified the residues affecting heart rate and pulse pressure, sustained effect on vasodilatory function, vasodilatory-diuresis balance and forceful diuresis switches. Based on the results, we designed human ANP analogues with predominant vasodilatory effects without diuresis and others with exclusive diuretic effects without vasodilation.

Conclusions: Through systematic evaluation of K-Ring and human ANP, we have delineated the key molecular switches responsible for vasodilatory or diuretic effects of NPs and further design NPAs with exclusive functions. Thus, this study has led to the development of a unique set of ligands that alter blood pressure-volume status independently, thereby creating a platform for personalised care of heart failure patients.

PB 1640 | Development of a Novel Strategy to Target CD39 Antithrombotic Activity to the Endothelial-platelet Microenvironment in Kidney Ischemia-reperfusion Injury

M. Sashindranath[1], K. Dwyer[2], S. Dezfouli[3], C. Selan[1], S. Crikis[3], B. Lu[3], Y. Yuan[1], M. Hickey[4], K. Peter[5], S.C. Robson[6], P. Cowan[3], H. Nandurkar[1]

[1]Monash University, Australian Centre For Blood Diseases, Melbourne, Australia, [2]Deakin University, Medicine, Geelong, Australia, [3]St. Vincent's Hospital, Immunology Research Centre, Fitzroy, Australia, [4]Monash University, Department of Medicine, Clayton, Australia, [5]Baker Heart and Diabetes Institute, Melbourne, Australia, [6]Harvard University, Boston, United States

Background: Kidney ischemia-reperfusion injury (IRI) is characterised by inflammation and thrombosis. P-selectin and its ligand PSGL-1 control leukocyte-endothelial and leukocyte-platelet interactions under inflammatory conditions. CD39 is the dominant vascular nucleotidase that facilitates adenosine generation via extracellular ATP/ADP-phosphohydrolysis. Adenosine signalling is protective in renal IRI, but CD39 catalytic activity is lost with exposure to oxidant stress. We designed a new therapeutic targeting CD39 to P-selectin to improve renal IRI.

Aims: To improve outcomes from renal IRI with a novel therapeutic rsol.CD39-PSGL-1

Methods: Production of rsol.CD39-PSGL-1: Production in CHO cells that stably express core 2 O-linked B1-6-N-acetylglucosaminyltransferase (C2GnT) and α1-3 fucosyltransferase activity (FucTVII), followed by concentration by immunoaffinity with anti-FLAG antibody.

P-selectin ELISA, aggregometry, flow cytometry, tail bleeding time, NTPDsase activity, serum urea and creatinine: conventional techniques

Warm renal IRI model: Unilateral kidney IRI with nephrectomy of the second kidney with varying doses of rsol.CD39-PSGL-1, or clopidogrel, 30 min before IRI.

Renal Histology and Scoring: Kidney tissue sections were stained with hematoxylin-eosin and a semi-quantitative scale was used to evaluate the degree of tubular necrosis.

Results: The rsol.CD39-PSGL-1 displayed ADPase activity and inhibited platelet aggregation ex vivo, as well as bound with high specificity to soluble P-selectin and platelet surface P-selectin. Importantly, mice injected with rsol.CD39-PSGL-1 and subject to renal IRI showed significantly less kidney damage both biochemically and histologically, compared to those injected with untagged solCD39. Furthermore, the equivalent dose of rsol.CD39-PSGL-1 had no effect on tail template bleeding times.

Conclusions: Targeting CD39 to the injured vessel wall resulted in substantial preservation of renal function and morphology after IRI without toxicity.

PB 1641 | Trif-deficiency Impairs Leukocyte Adhesion and Netosis in Mesenteric Ischemia-reperfusion

S. Ascher[1], E. Wilms[1], K. Schwierczek[1], K. Jurk[1], C. Reinhardt[1,2]

[1]University Medical Center of the Johannes Gutenberg University, Center for Thrombosis and Hemostasis (CTH), Mainz, Germany, [2]German Center for Cardiovascular Research (DZHK), Partner Site Rhein-Main, Mainz, Germany

Background: Vascular responses to injury depend on Toll-like receptor (TLR) signaling that requires the adapter molecules myeloid differentiation primary response gene 88 (MyD88) and TIR-domain-containing adapter-inducing interferon-β (TRIF).

Aims: To analyze the role of MyD88 and TRIF for leukocyte and platelet adhesion to mesenteric venules and the formation of neutrophil extracellular traps (NETs) in ischemia-reperfusion injury, as it occurs during mesenteric infarction.

Methods: By clamping the *A. mesenterica superior*, WT, *Myd88* $^{-/-}$, and *Trif* $^{-/-}$ mice were subjected to 1 hour of ischemia. Then, reperfusion of the small intestine was allowed and the number of rolling leukocytes, firmly adherent leukocytes, and platelet-leukocyte conjugates per viewing field was quantified in mesenteric venules by fluorescence intravital microscopy. NETs were stained with SYTOX orange and the number of NETs per viewing field was quantified prior to and directly after the onset of mesenteric ischemia-reperfusion injury. Ex vivo, LPS-induced formation of NETs from cultured bone marrow neutrophils was compared.

Results: In contrast to WT and *Myd88* $^{-/-}$ mice, *Trif* $^{-/-}$ mice were protected against the ischemia-induced increase in leukocyte rolling, adhesion, and conjugate formation in mesenteric venules. In contrast, platelet adhesion to mesenteric venules was diminished in *Myd88* $^{-/-}$ mice. Neutrophil extracellular traps (NETs) in mesenteric venules could be detected prior to ischemia induction, with reduced numbers in *Myd88* $^{-/-}$ mice. Interestingly, the ischemia-induced increase in NETosis was not observed in mesenteric venules of *Trif* $^{-/-}$ mice. In isolated bone marrow derived neutrophils, LPS-induced NETosis of *Myd88* $^{-/-}$ or *Trif* $^{-/-}$ neutrophils was unchanged relative to WT.

Conclusions: Our results demonstrate the involvement of TLR adaptors in balancing heterotypic cell interactions and NET formation in the post-ischemic mesenteric microvasculature.

PB 1642 | Inhibition of Coagulation Factor Xa Attenuates Myocardial Ischemia Reperfusion Injury in Mice

J.J.N. Posma[1], J.J. Posthuma[2], R. Van Oerle[2], S. Heitmeier[3], H. Ten Cate[2], H.M.H. Spronk[2]

[1]Maastricht University / Cardiovascular Research Institute Maastricht (CARIM), Biochemistry and Internal Medicine, Maastricht, The Netherlands, [2]Maastricht University / Cardivascular Research Institute Maastricht (CARIM), Biochemistry and Internal Medicine, Maastricht, The Netherlands, [3]Bayer Pharmaceutics, Wuppertal, Germany

Background: Ischemic/reperfusion (I/R) injury affects the outcome of myocardial infarction (MI). Current reperfusion therapy does not sufficiently prevent microvascular thrombo-inflammatatory injury. Coagulation proteases mediate inflammation via protease activated receptors (PARs).

Aims: We aim to elucidate FXa's role in I/R injury after MI by inhibiting FXa with rivaroxaban.

Methods: Male WT BL/6 mice underwent surgical ligation of the left anterior descending coronary artery 7days pre-experimentation. Next, the ligature was tightened for 1h to induce ischemia and loosened either for 4h (early), or 4 weeks (late), to allow reperfusion. The intervention consisted of 2 rivaroxaban (1.6 mg/kg) i.v.-injections or placebo (0.9%NaCl) after 15min ischemia and 5min reperfusion. In the early model the area at risk (AAR) was visualized with Evans blue and differentiated from the area of infarction (AOI) through triphenyl tetrazolium chloride. Plasma cardiovascular markers were quantified using Luminex Multiplex. In the late model, left ventricle ejection fraction (LVEF) was measured 10min pre-ischemia and 4 weeks' post-reperfusion.

Results: The rivaroxaban treatment group showed attenuated myocardial damage indicated by reduced AOI/AAR (41%[IQR34-48]) vs. control (62%[IQR52-67]) (Fig1). This was supported by preliminary data indicating a better preserved LVEF after 4 weeks' reperfusion in the treatment group (25%[IQR19-31]) vs. control (16%[IQR12-21]) (Fig2). Plasma E-Selectin, PECAM-1, PAI-1, proMMP9, and thrombomodulin levels tended to be increased upon rivaroxaban treatment.

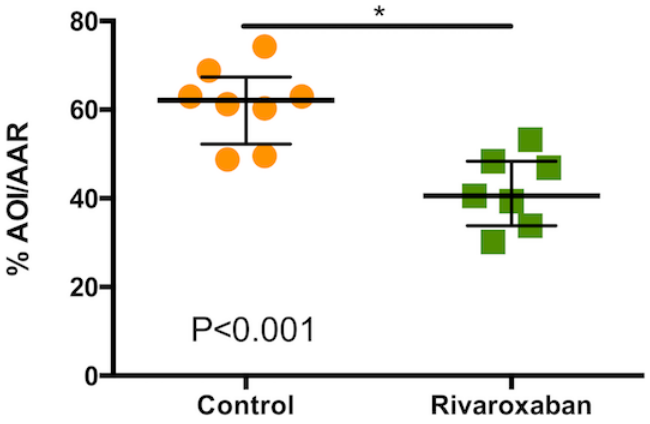

FIGURE 1 Area of Infarction. Median infarction area was reduced in the rivaroxaban treated group (n=7) vs. control (n=8)

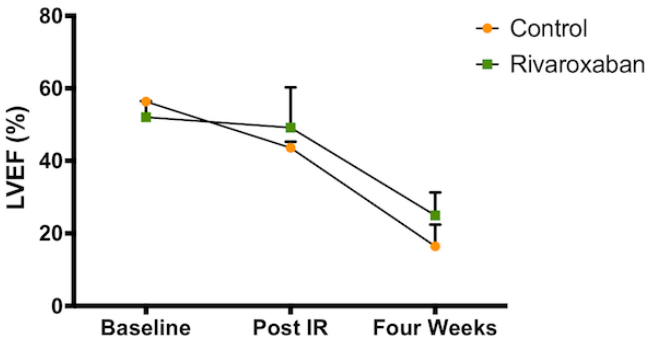

FIGURE 2 Left Ventricle Ejection Fraction. Median left ventricle ejection fraction of control mice (n=2) vs. rivaroxaban treated mice (n=4) NS

Conclusions: FXa inhibition by rivaroxaban reduces myocardial I/R injury in mice and may provide long term preservation of LVEF. Raised cardiovascular markers suggest increased tissue remodeling and phenotypical alteration of endothelial cells after rivaroxaban treatment. These results suggest that coagulation proteases play a role in I/R injury during MI, most likely by activating PARs.

PB 1643 | Biomarkers of Oxidative Stress in Venezuelan Sickle Cell Patients: Association with the Clinical Severity

D. Higuera[1], A. Salazar[1], E. Hergueta[2], N. Estepa[2], E. Salazar[1], K. Perez[1], C. Ibarra[1], B. Guerrero[1]

[1]*Venezuelan Institute of Scientific Research, Pathophysiology of Coagulation, Caracas, Venezuela,* [2]*Venezuelan Central University, School of Bioanalysis, Caracas, Venezuela*

Background: Sickle cell Disease (SCD) includes a group of hemolytic anemia associated to the presence of hemoglobin S, which is characterized by acute pain episodes and progressive damage of different organs. In Venezuela SCD frequency ranges between 0 and 7%. The overproduction of reactive oxygen species (ROS) and reactive nitrogen species (RNS) are part of the pathophysiology and induce a state of oxidative stress that is associated with endothelial dysfunction and tissue damage in SCD.

Aims: This study evaluated biomarkers of oxidative stress in Venezuelan sickle cell patients and their association with the clinical severity.

Methods: The present study was conducted in 22 Venezuelan sickle cell patients that were classified according to their genotype (Hb SS, Hb SC and Hb Sβtal) and phenotype (Mild, Moderate and Severe) and 23 apparently healthy individual. Biomarkers related to oxidative stress (serum nitrites, conjugated dienes, thiobarbituric acid reactive substances (TBARS) and serum homocysteine) were evaluated and their associated with the clinical severity.

Results: In reference to the lipid peroxidation markers, a significant increase of TBARS was observed in patients with Hb SS and Severe phenotype ($p < 0.05$).Also was exhibited a significant increase of conjugated dienes in Hb SC patients with Mild and Severe phenotype ($p < 0.05$). Homocysteine levels were significantly lower in patients with Hb SS and Moderate and Severe phenotypes ($p < 0.05$). Nitrite values did not showed statistically significant changes.

Conclusions: Our results evidence an increase in biomarkers related to oxidative stress in Venezuelan sickle cell patients with Hb SS and SC genotypes, especially in severe phenotypes. This study suggests the importance of evaluating different oxidative stress biomarkers in patients with SCD, in order to prevent endothelial damage and complications of the disease.

PB 1644 | Contribution of Neutrophil Extracellular Trap (NET) Components to the Structure of Thrombi from Therapeutic Intervention in Ischemic Coronary, Peripheral and Cerebral Artery Disease

Á.Z. Farkas[1], V.J. Farkas[1], K. Bálint[1], I. Gubucz[2], I. Szikora[2], A. Nagy[3], P. Sótonyi[3], L. Hidi[3], B. Merkely[3], K. Kolev[1]

[1]*Semmelweis University, Department of Medical Biochemistry, Budapest, Hungary,* [2]*National Institute of Clinical Neurosciences, Department of Neurointervention, Budapest, Hungary,* [3]*Semmelweis University Heart and Vascular Center, Budapest, Hungary*

Background: The ultrastructure and cellular composition of thrombi profoundly affect the therapeutic outcome in myocardial infarction (AMI), stroke and peripheral artery disease (PAD). In thrombi, citrullination of histones in activated white blood cells (WBC) initiates the release of NETs composed primarily of DNA and histones that modify the stability and lysibility of fibrin.

Aims: To investigate the interrelations of structural properties of thrombi and routinely available clinical data.

Methods: Thrombi extracted from AMI (n=65), PAD (n=64) or stroke (n=78) patients were processed for scanning electron microscopy, (immune)stained for fibrin, citrullinated histone H3 (cH3) and extracellular DNA. Fibrin fiber diameter, relative occupancy of fibrin, cellular components, DNA and cH3 were measured. Correlations between these structural features and clinical parameters were analyzed.

Results: The relative occupancy of platelets is generally higher in AMI and stroke compared to PAD thrombi. The presence of certain comorbidities, risk factors (atherosclerosis, thrombophilia, cancer and smoking) usually lowered the platelet content of thrombi (Table 1). In stroke thrombi, the diameter of fibrin fibers shows an inverse correlation with the plasma level of C-reactive protein in the range of 0-8 mg/L, but this trend is reversed in more severe inflammation. There is no significant difference in the fibrin/cH3 (FHr) and fibrin/DNA ratio (FDr) between samples from the three localizations. In AMI, FDr correlates inversely with plasma fibrinogen level and WBC count (up to 10 G/L). FHr correlates positively with WBC count, but in malignancy the relationship is reversed despite elevated fibrinogen levels.

TABLE 1 The relative occupancy of platelets (median, lower and upper quartile, %) in thrombi in different subgroups (*: p<0.05, n.a., not applicable)

Subgroup		AMI	PAD	Stroke
All		3.1 (0.7-8.75)	2.2 (0.8-6.025)*	3.9 (1.5-9.6)
Athero-sclerosis	No	3.15 (0.625-8.4)	3 (1.05-6.325)	5.25 (1.975-13.2)
	Yes	2.3 (0.9-9.35)*	2 (0.7-5.7)	2.7 (1.3-7.525)*
Smoking	No	3.6 (1.15-9.625)	3.2 (1.3-6.9)	5 (1.65-12.83)
	Yes	1.6 (0.5-7.1)*	1.6 (0.6-4.3)*	2.4 (0.9-10.6)
Thromb-ophilia	No	3.2 (0.8-8.9)	n.a.	3.85 (1.5-9.675)
	Yes	0.6 (0.275-2.75)*	n.a.	5.4 (1.4-9.6)
Malignancy	No	2.5 (0.625-8.25)	2 (0.7-5.7)	4.4 (1.7-10.4)
	Yes	3.9 (1.2-10.1)	3.4 (1.6-10)	1.9 (0.8-6.5)*

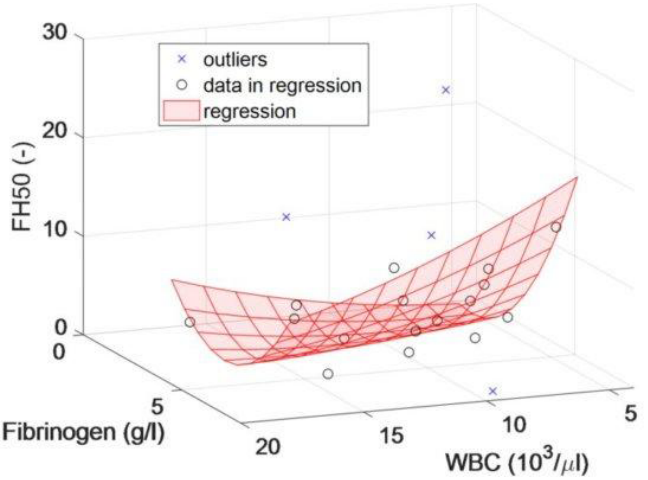

FIGURE 1 Joint impact of WBC and fibrinogen on fibrin/histone ratio (FH50) of thrombi in patients with malignancy

Conclusions: Structural variations (fibrin composition, cellular and NET content) of thrombi from different locations are related to systemic signs of inflammation and comorbidities. The established relationships could help to optimize interventional therapy using routinely available laboratory and clinical data.

PB 1645 | A Novel Easy-to-Perform Thromboembolic Stroke Model in Mice: Application to the Study of the Thrombolytic Effect of N-acetylcysteine

M. Gauberti[1,2], S. Martinez de Lizarrondo[1], M. Rubio[1], S. Goursaud[1,3], D. Vivien[1,4], C. Gakuba[1,3]

[1]*INSERM UMR-S U 1237, Caen, France,* [2]*Caen University Hospital, Department of Diagnostic Imaging and Interventional Radiology, Caen, France,* [3]*Caen University Hospital, Department of Anesthesiology and Critical Care Medicine, Caen, France,* [4]*Caen University Hospital, Department of Cell Biology, Caen, France*

Background: Several experimental models of ischemic stroke are currently available. Among the most clinically relevant, models involving occlusion of a cerebral artery by a blood clot allow investigation of thrombolytic and combined strategies. However, most of these models are technically challenging, limiting their large adoption.

Aims: To developed an original model of thromboembolic stroke in mice mimicking large vessel atherothrombotic stroke in humans.

Methods: Stroke was induced by intracranial embolization of an endogenous thrombus formed on the surface of the common

carotid artery using topical application of ferric chloride. We characterized this model using 7 Tesla magnetic resonance imaging, immunohistology and behavioral testing. Then, using this model, we performed a double-blinded randomized and controlled trial of N-acetylcysteine
(NAC, a von Willebrand Factor targeted thrombolytic drug) combined with non-peptidic anti-GpIIb/IIIa inhibitor (GR).

Results: This model led to occlusion of intracranial arteries by platelet-rich thrombi formed under high shear rates. Interestingly, it showed all the common features of human stroke: a thromboembolic nature, a diffusion-perfusion mismatch, a low mortality rate (< 10%) and significant neurological deficits. Importantly, this model is straightforward to perform, do not require expensive reagents/material and can be performed in less than 20 minutes. In the randomized trial involving 25 animals per group, we observed a beneficial effect of NAC+GR on stroke outcome (lesion size, recanalization rate, neurological outcome) without significant increase in the risk of hemorrhagic transformation.

Conclusions: We developed a new thromboembolic stroke model in mice with potential for a large diffusion in laboratories interested in brain ischemia. Using this model, we demonstrated the efficacy of NAC combined with an anti-GpIIb/IIIa inhibitor as a treatment for acute ischemic stroke.

PB 1646 | Human Platelet Alloantigens and P-Selectin Gene Polymorphisms in Pediatric Arterial Ischemic Stroke

D. Coen Herak[1], M. Pavic[2], A. Ceri[3], J. Lenicek Krleza[4], V. Djuranovic[5], N. Barisic[6], R. Zadro[1,3]

[1]University Hospital Centre Zagreb, Department of Laboratory Diagnostics, Zagreb, Croatia, [2]Medical School University Hospital ´Sestre Milosrdnice´, Clinical Institute of Chemistry, Department for Laboratory Diagnostics in Traumatology and Orthopaedics, Zagreb, Croatia, [3]Faculty of Pharmacy and Biochemistry, University of Zagreb, Department of Medical Biochemistry and Hematology, Zagreb, Croatia, [4]Children's Hospital Zagreb, Department of Laboratory Diagnostics, Zagreb, Croatia, [5]Children's Hospital Zagreb, Departrment of Neuropediatrics, Zagreb, Croatia, [6]University Hospital Centre Zagreb, Department of Pediatrics, Division of Neuropediatrics, Zagreb, Croatia

Background: Pediatric arterial ischemic stroke (AIS) is a heterogeneous multifactorial disorder, with a wide range of identified inherited and acquired risk factors. Genetic risk factors are incompletely characterized with only FV Leiden being consistently associated with pediatric AIS. We have also demonstrated that inherited genetic risk factors for perinatal and childhood AIS are not the same (Coen Herak et al *in press*).

Aims: The study aimed to find out if individual gene polymorphisms or haplotypes of: a) human platelet alloantigens (HPA) and b) P-selectin (P-SEL) gene alone and combined with FV Leiden are risk factors for perinatal and childhood AIS.

Methods: Study group comprised 110 children with childhood (N=61) and perinatal AIS (N=49), and 100 age- and sex-matched controls. Genotyping of HPA-1, -2, -3 and PSEL-S290N, -N562D, -V599L, -T715P were performed using allele-specific PCR.

Results: Carriers of at least one HPA-3b allele had a 2-fold lower risk of AIS (OR: 0.48, 95% CI: 0.26-0.89, P=0.018) and perinatal AIS (OR: 0.45, 95% CI: 0.21-0.97, P=0.041), but not of childhood AIS (P=0.074). Increased risk for AIS was not found for any single P-SEL gene polymorphism, but carriers of PSEL-562DD genotype had a 2.37-fold (95% CI: 1.07-5.23, P=0.034) increased risk for perinatal AIS. The presence of P-SEL-599LL genotype was significantly associated with childhood AIS (P=0.048). Haplotype ANDVT (FV Leiden/P-SEL-S290N/N562D/V599L/T715P) was identified more frequently in perinatal AIS (0.053) compared to controls (0.005), but the difference was not statistically significant (P=0.075). On contrary, lower, although nonsignificant HPA-1a/2a/3b haplotype frequency (P=0.078) was found in childhood AIS (0.242) compared to controls (0.365).

Conclusions: Identified association of HPA-3b allele with perinatal AIS and different P-SEL polymorphisms with perinatal and childhood AIS corroborate our previous finding that perinatal and childhood AIS do not share the same genetic risk factors.

PB 1647 | MicroCT Imaging of Cerebral Thromboemboli *In vivo*: The Effects of Tissue Plasminogen Activator

D.-E. Kim

Dongguk University College of Medicine, Goyang, Korea, Republic of

Background: Since tPA was first introduced in 1996, no study has quantitatively assessed a detailed spatial and temporal evolution of cerebral thromboemboli before, during, and after tissue plasminogen activator (tPA) treatment.

Aims: To quantify the evolution of cerebral thromboemboli using fibrin-targeted gold nanoparticles (fib-GC-AuNPs) and micro-computed tomography (mCT), with/without tPA-therapy.

Methods: We injected thrombi into the distal internal carotid artery in mice (n=50). Fifty-five minutes later, we injected fib-GC-AuNPs, and five minutes after that, treated animals with tPA or not (25mg/kg). We acquired serial mCT images for 24 hours post-treatment.

Results: Thrombus-burden at baseline was $784\pm59\times10^3\mu m^2$ for the tPA-group (n=42) and $655\pm103\times10^3\mu m^2$ for the saline-group (n=8, P=0.37). Thrombus shrinkage began at 0.5-1 hour after tPA-therapy, with a maximum initial Rate-of-Change (RoC) at $4603\pm957\mu m^2$/minute. The RoC lowered to ~61% level of the initial in hours 1-2, followed by ~29% and ~1% in hours 2-3 and 3-24, respectively. Thus, 85% of total thrombolysis over 24 hours (about $500\mu m^2$, equivalent to 64% of the baseline thrombus-burden) occurred within the first 3-hours of treatment. Thrombus-burden at 24 hours could be predicted at around 1.5-2 hours. Saline treatment was not associated with significant changes in the thrombus-burden. Infarct size was smaller in the tPA-group vs. saline-group ($18.1\pm2.3mm^2$ vs. $45.8\pm3.3mm^2$, P< 0.01). Infarct size correlated to final thrombus-burden (r=0.71, P< 0.01). Time to thrombolysis, completeness of thrombolysis, and tPA-therapy were independent predictors of infarct size.

Conclusions: Thromboembolic burden and the efficacy of tPA-therapy can be assessed serially, non-invasively, and quantitatively using high-resolution mCT and a fibrin-binding nanoparticle imaging-agent.

PB 1648 | Incidence Rates and Case Fatality Rates of Cerebral Vein Thrombosis: A Population-based Study

F. Dentali[1], V. Gessi[1], F. Pomero[2], A. Squizzato[1], M. Bonzini[3], W. Ageno[1]

[1]*Insubria University, Clinical Medicine, Varese, Italy,* [2]*Cuneo Hospital, Clinical Medicine, Cuneo, Italy,* [3]*University of Milan, Department of Clinical Science, Milan, Italy*

Background: The incidence of cerebral vein thrombosis (CVT) is estimated at 0.2- 0.5/100000/year. These data derived from autopsy studies performedl decades ago. Little is known about mortality rates in patients with CVT during the acute phase of the disease.

Aims: To estimate, in a large epidemiologic study on hospital admissions in Northwestern Italy, the contemporary incidence of hospital admissions for pyogenic (PCVT) and non pyogenic CVT (NPCVT) in Italy, to assess in-hospital mortality rates and factors associated with mortality, and to assess trends in the incidence of this disease from 2002 to 2012.

Methods: Primary and secondary discharge diagnoses of PCVT and NPCVT were identified using ICD-9 codes in Lombardy and Piedmont. Recurrent events were excluded. Age, gender, vital status at discharge, duration of hospitalization, up to 5 secondary discharge diagnoses and concomitant intracranial hemorrhage (ICH) were registered. Comorbidity was evaluated using the Charlson comorbidity index (CCI).

Results: 1718 patients were hospitalized for CVT (1147 females, 66.7%; 810 PCVT and 908 NPCVT), 134 patients (7.8%) had a concomitant ICH. The overall gender-specific incidence rates for CVT were 17.3 (95% CI 16.3, 18.4)/1000000 in females and 8.3 (95% CI 7.6, 9.1)/1000000 in males. The incidence was highest in women aged 45-50 years (27 cases/1000000) and increased in women from 2002 to 2012. In-hospital case fatality rate (CFR) was significantly higher in patients with concomitant ICH (7.46% vs 2.65%; p< 0.001) and progressively increased with CCI (2.27% in CCI=0, 14.29% in CCI>1; p< 0.001). Age and CCI were independently associated with in-hospital mortality after stepwise regression analysis.

Conclusions: Incidence of CVT is higher than previously reported. The incidence appeared to increase in women during the period of observation. In-hospital CFR was not negligible in patients presenting with a concomitant ICH.

PB 1649 | Biomarkers for the Symptomatic Carotid Atheroma

M.J. Iglesias[1], L. Perisic[2], M. Vesterlund[3], M. Lengquist[2], M.-G. Hong[4], L. Sanchez-Rivera[1], M. Berg[5], M. Kronqvist[2], P. Gillgren[6,7], F. Ponten[8], M. Uhlén[4], J.M. Schwenk[4], G.K. Hansson[5], G. Paulsson-Berne[5], J. Lehtiö[3], U. Hedin[2], J. Odeberg[1,5,9]

Background: Unstable carotid plaque is an important source of extracranial atheroembolism and stroke. Current guidelines for stroke-preventive carotid endarterectomy are based on surrogate markers for stroke risk and no precise diagnostic tools are available for identification of either individuals or lesions at risk.

Aims: Our aim is to identify biomarkers for the unstable atheroma, which could offer new diagnostic tools to improve selection of patient for intervention.

Methods: We analyzed transcriptional profile of plaques from patients treated for symptomatic (S) and asymptomatic (AS) carotid stenosis, collected within the Biobank of Karolinska Endarterectomies (BiKE) using microarrays. Proteomic profiling of peripheral and ‚local' plasma, obtained during carotid clamping prior to arteriotomy, was performed by suspension antibody-bead assays using over 10,000 antibodies as part of the Human Protein Atlas project.

Results: Plasma analysis identified 150 candidates with p< 0.05 based on comparisons in local vs. peripheral plasma, as well S vs. AS patients in both plasma sources. Among the identified candidates, Biliverdin reductase B (BLVRB) was significantly enriched in local plasma and plaque tissue. Upregulation of BLVRB in plasma was validated by dual binder assay in both the discovery and an extended validation sample set. Moreover, transcriptomic levels of BLVRB in plaques from S patients were verified by qPCR and BLVRB was localized in CD68+ macrophages by immunohistochemistry.

Conclusions: The high-throughput analysis of plasma and tissue samples from patients undergoing carotid surgery permitted identification of BLVRB as a potential biomarker for unstable carotid atherosclerosis. Further validation in independent, extended cohorts of patients is necessary in order to determine predictive power of BLVRB for the identification of individuals at risk or development of targeted bioimaging for lesion detection.

PB 1650 | Neutrophil Extracellular Traps (NETs) in Patients with Acute Stroke Are Associated with Stroke Severity and Progression

A. Moscardó[1], M.T. Santos[1], A. Lago[2], A.M. Latorre[1], J.I. Tembl[2], J. Salom[3], C. Nieves[2], S. Bonanad[4], J. Vallés[1]

[1]*Health Research Institute La Fe, Hemostasis, Thrombosis, Atherosclerosis, and Vascular Biology, Valencia, Spain,* [2]*University and Polytechnic Hospital La Fe, Department of Neurology, Valencia, Spain,* [3]*Health Research Institute La Fe, Cerebrovascular Research Joint Unit, Valencia, Spain,* [4]*University and Polytechnic*

Hospital La Fe, Department of Hemostasis and Thrombosis, Valencia, Spain

Background: NETs are considered a link between immunity, inflammation and thrombosis. Data on arterial thrombosis is scarce, particularly in patients with acute stroke, and there is no data on the NET-specific marker, citrullinated histone 3 (CitH3) in stroke.
Aims: To study NETs in the plasma of patients with acute stroke, and their potential association with stroke severity, risk factors, and clinical outcomes at one-year.
Methods: Patients (n=243) had suffered stroke < 24h before admission to hospital and treated according to stroke guidelines. The study was approved by the ethical Committee of the Hospital La Fe. All patients or their proxy gave their written informed consent. Clinical and demographic data were registered, including scores of neurological severity (NIHSS, mRs) at the onset and at discharge. Patients were followed-up for one-year. A control group of normal subjects was used for comparison. Cell free DNA (cfDNA), nucleosomes and CitH3 were determined in plasma as markers of NETs.
Results: All the NET markers were significantly elevated in patients as compared with controls, and positively associated with the clinical scores of stroke severity at entrance and discharge. CitH3 was elevated particularly in older patients (> 65 years of age), patients with higher fasting glucose, and in patients with history of atrial fibrillation (AF). In multivariate analysis including risk factors, medications and NIHSS, elevated CitH3, the most specific marker of NETs, was independently associated with AF and all-cause mortality at one-year follow-up.
Conclusions: Conclusions. NETs participate in the pathopysiology of ischemic stroke and are associated with the stroke severity and mortality. NETs could be a potential therapeutic target in patients with acute stroke, and especially CitH3 may be of prognostic value in those patients. Grants. FIS13/00016. ACIF/2016/465. PB 1651 | Case-fatality after Venous Thromboembolism and Ischemic Stroke in Subjects without and with Atrial Fibrillation. The Tromsø Study

E.M. Hald[1,2], L.B. Rinde[3], M.-L. Løchen[4], E.B. Mathiesen[3,5], T. Wilsgaard[4], I. Njølstad[3,4], S.K. Braekkan[2,3], J.-B. Hansen[2,3]

[1]K.G. Jebsen TREC - Thrombosis Research and Expertise Center, Dept. of Clinical Medicine, UiT, Tromsø, Norway, [2]Division of Internal Medicine, The University Hospital of North Norway, Tromsø, Norway, [3]K. G. Jebsen TREC - Thrombosis Research and Expertise Center, Dept. of Clinical Medicine, UiT, Tromsø, Norway, [4]Epidemiology of Chronic Diseases Research Group, Dept. of Community Medicine, UiT, Tromsø, Norway, [5]Brain and Circulation Research Group, Dept. of Clinical Medicine, UiT, Tromsø, Norway

Background: Atrial fibrillation (AF) is associated with increased risk of ischemic stroke (IS) and stroke severity. Recent studies have also demonstrated that patients with AF have increased risk of venous thromboembolism (VTE), but data on VTE-related mortality in AF is lacking.
Aims: To investigate the impact of atrial fibrillation on mortality rates after incident VTE and ischemic stroke in a population-based cohort.
Methods: Patients with a first, objectively confirmed VTE (n=735) or IS (n=1250) were recruited among participants in the Tromsø study (1994-2008) and deaths were recorded up to the end of 2012. Information on prevalent AF and potential confounders was obtained at baseline. Crude mortality rates (per 100 person-years) according to AF status were calculated among patients with VTE and IS, respectively, and Cox proportional hazards regression models were used to obtain hazard ratios (HR) for death with 95 % confidence intervals (CI).
Results: There were 337 (45.9%) deaths among the VTE patients and 682 (54.6%) deaths among the IS patients during a mean follow-up of 4.6 years. In VTE patients, the mortality rate was 20.6 (95% CI 15.9-26.7) in those with AF and 9.0 (95% CI 8.0-10.2) in those without AF. In IS patients, the corresponding rates were 19.8 (95% CI 17.1-23.1) and 10.1 (95% CI 9.3-11.1), respectively. AF was associated with a 1.7-fold (HR 1.73, 95% CI 1.29-2.30) increased risk of death after VTE, and a 1.5-fold risk of death after IS (HR 1.45, 95% CI 1.22-1.73) in analyses adjusted for age and sex. Multivariable adjustment for cardiovascular risk factors (BMI, hypertension, total cholesterol, smoking, diabetes and a history of myocardial infarction) barely altered the risk estimates.
Conclusions: We found that atrial fibrillation aggravated the mortality rate to a similar extent in patients with VTE and stroke. Our findings suggest that special medical attention should be given to VTE and stroke patients with AF.

PB 1652 | Role of ARHGEF10 in Platelet Function and Thrombosis

D.-H. Lu[1], T.-F. Huang[1], H.-C. Liu[1], S.S.-F. Gau[2], W.-M. Fu[1]

[1]National Taiwan University, Pharmacological Institute, College of Medicine, Taipei, Taiwan, Republic of China, [2]National Taiwan University Hospital, Department of Psychiatry, Taipei, Taiwan, Republic of China

Background: ARHGEF10, a member of Rho guanine nucleotide exchange factor (GEF) family, stimulates the Rho GTPases. Rho GTPases have been reported to regulate a variety of cellular behaviors such as cell polarity, cytoskeletal organization, and gene transcription. GEFs are responsible for the activation of Rho GTPase and ARHGEF10 is especially for RhoA.
Aims: ARHGEF10 is expressed in several tissues in human and murine, however, its role and impact on platelet function are not well understood.
Methods: We generated ARHGEF10 knockout mice and examined the in vitro and in vivo effect of ARHGEF10 knockout on the platelet function and thrombosis formation.
Results: ARHGEF10 knockout mice had normal platelet counts but displayed altered aggregation in response to collagen, ADP, PAR4 peptide and U46619 stimulation. Knockout of ARHGEF10 influenced platelets spreading on fibrinogen - coated surface and formed less lamellipodia-like extension than wild-type platelets. ARHGEF10 knockout also inhibited platelet clot retraction induced by thrombin stimulation. Knockout of ARHGEF10 resulted in prolonged tail bleeding time and

inhibited the stable thrombus formation induced by $FeCl_3$ in the carotid artery. Furthermore, the ischemia/reperfusion-induced infarct volume was markedly reduced in ARHGEF10 knockout mice.

Conclusions: These results demonstrate the role of ARHGEF10 in platelet function in homeostasis and thrombosis.

PB 1653 | The Efficacy and Safety of a Laser Thrombolytic System in Animal Thrombosis Models

Y. Matsumoto[1], K. Hokamura[1], D. Yamashita[2], Y. Shimizu[2], Y. Takata[2], T. Kosugi[2], Y. Tamaoki[2], T. Kawashima[2], Y. Yamashita[2], H. Okada[2], T. Nakayama[3], K. Umemura[1]

[1]Hamamatsu University School of Medicine, Department of Pharmacology, Hamamatsu City, Japan, [2]Hamamatsu Photonics K.K., Hamamatsu CIty, Japan, [3]Hamamatsu Medical Center, Department of Neurosurgery, Hamamatsu CIty, Japan

Background: Currently, the thrombolytic agent rt-PA is used for treating acute cerebral infarction in the world. However, the risks of cerebral bleeding and other side effects result in the limited application. In addition, endovascular interventions (e.g., Merci retriever, Penumbra system and Solitaire FR) are also applied to treating acute cerebral infarction. Yet, those devices are not completely free from clinical problems, e.g., risk of vessel injury, indicating the need for safer, quicker, and more reliable recanalization approaches. We therefore developed a laser thrombolytic system with the second harmonic generation of microsecond Nd:YAG laser.

Aims: We investigated its effectiveness, safety and mechanisms in animal thrombosis models.

Methods: The dynamics of laser-induced thrombolysis in a gelatin phantom model was investigated with a high-speed camera. In vivo thrombolytic efficacy was investigated using several animal thrombosis models. Thrombi in the vena cava inferior of rats or in the carotid artery of rabbits were induced by an application of ferric chloride ($FeCl_3$). Laser irradiation was then carried out through an optical fiber inserted from the femoral vein or artery.

Results: The dynamic observation revealed that laser irradiation generated a bubble in the gelatin phantom. Laser irradiation induced significant thrombolysis in the rat thrombosis model. Laser irradiation also resulted in recanalization in the rabbit thrombosis model. One day after the recanalization, neurological disorders, cerebral ischemia and cerebral hemorrhage were not observed. No vascular endothelial damage evaluated by Evans blue staining after laser irradiation was observed.

Conclusions: The irradiation of the pulsed green laser can induce bubbles that fragment thrombi without vessel or brain damage. Recently, we have started investigator-initiated clinical trials in Japan.

PB 1654 | Thrombi Retrieved from Patients Suffering Acute Ischemic Stroke Show both Active and Mechanical Interaction between Stent Retrievers and Thrombus, and is Associated with Specific Thrombus Surface Characteristics

A.S.A. Autar[1,2], H. Hund[1,3,4], S.A. Ramlal[1], D. Hansen[1], M. de Maat[2], A. van der Lugt[3], D. Dippel[4], A.C.G.M. van Es[3], H.M.M. van Beusekom[1]

[1]Erasmus MC, Cardiology, Rotterdam, The Netherlands, [2]Erasmus MC, Hematology, Rotterdam, The Netherlands, [3]Erasmus MC, Radiology, Rotterdam, The Netherlands, [4]Erasmus MC, Neurology, Rotterdam, The Netherlands

Background: Multiple randomized controlled trials have confirmed the positive effects of intra-arterial treatment (IAT) by means of retrievable stent based thrombectomy on clinical outcome for patients suffering acute ischemic cerebral stroke (AIS). Although a pure mechanical interaction between clot and stent-retriever is suspected, no study has focused on the direct interaction between stent-retriever and thrombus.

Aims: To study the interaction between stent and thrombus following thrombectomy for AIS.

Methods: From the MR CLEAN registry, seven stents were collected directly after IAT. The stent-retriever with thrombus was carefully rinsed in non-heparinized saline and fixed in buffered formaldehyde-glutaraldehyde in preparation for micro CT, scanning electron - and light microscopy (SEM, LM). All stent-thrombus interactions and associated thrombus surfaces were studied by SEM. In total 85 interactions were identified by two independent raters. Then, specimens were prepared for LM (methacrylate embedding), sectioned and stained using Hematoxylin-Eosin as an overview stain, Resorcin-Fuchsin as an elastin stain, and Okajima as a hemoglobin stain.

Results: Retrieved thrombi were heterogeneous in composition as determined by LM, consisting of erythrocyte rich and fibrin rich areas. Atheromatous plaque was not observed. Stent-thrombus interaction as determined by SEM consisted of mechanical interaction in 47% of interaction sites, showing thrombus wrapped around wires. Active adhesion was observed in 53% of interaction sites, showing mostly thrombus coalescing around the wires. While mechanical interaction did not show an association with a specific thrombus surface, active interaction between thrombus and stent retriever was characterized by a dense thrombus surface, p=0.003 (Chi-square)).

Conclusions: The interaction between stent retrievers and thrombus as revealed by SEM identifies both active and mechanical interaction, with active adhesion being associated with specific surface characteristics.

PB 1655 | The Effect of Recanalization on Long-term Neurologic Outcome after Cerebral Vein Thrombosis

F. Dentali[1], I. Martinelli[2], E. Rezoagli[1], D. Poli[3], S.M. Passamonti[2], W. Ageno[1]

[1]Insubria University, Clinical Medicine, Varese, Italy, [2]Ospedale Maggiore Policlinico, A.Bianchi Bonomi Hemophilia and Thrombosis Center, Milan, Italy, [3]Azienda Ospedaliero Universitaria Caregg, Firenze, Italy

Background: Only few studies with small sample sizes have investigated the long-term recanalization rates after cerebral venous thrombosis (CVT) and their association with neurologic outcome.

Aims: To evaluate the recanalization rate in a large population of patients with CVT and to assess the prognostic role of recanalization on the long-term neurologic outcome in these patients.

Methods: Patients with an acute first episode of CVT with at least one available imaging test during follow-up were included. Patency status of the vessels was categorized as completely, partially or not recanalized. Neurologic outcome was defined using the modified Rankin Scale (mRS) as excellent by a score of 0-1 or poor by a score of 2-6. Predictors of recanalization and residual disability were assessed with a follow-up of up to three years.

Results: Five-hundred and sixteen patients (median (IQR) age, 39 (28.5-49) years; 74% female) were included. Complete or partial recanalization was detected in 81.2% of patients at scans performed between 28 days and 3 months; in 75.2% of patients at scans performed between 3 and 6 months; in 80.4% of patients at 6-12 months; 74.5 of patients at 1-3 years (p=0.452). At multivariate analysis, single site involvement (OR 1.78, 95% CI 1.27-2.50) and pregnancy or puerperium at the time of index event (OR 2.16, 95% CI 1.23-3.77) were associated with recanalization, whereas age>39 years was associated with no recanalization (OR 0.54, 95% CI 0.38-0.77). mRS at the time of follow-up imaging was available in 491 patients; 454 of them (92.5%) had a mRS of 0-1. CVT recanalization (OR 2.30, 95% CI 1.47-3.60), cancer (OR 0.28, 95% CI 0.09-0.84), and personal history of venous thromboembolism (OR 0.36, 95% CI 0.14-0.91) were independently associated with a favourable outcome at follow-up.

Conclusions: Most patients with a first CVT had complete or partial recanalization at follow-up. Recanalization was independently associated with a good neurologic outcome.

PB 1656 | Hyperglycemia Precipitates Infarct Growth and Hemorrhagic Transformation in Ischemic Stroke Though Exacerbation of Thromboinflammation

J.-P. Desilles, V. Syvannarath, V. Ollivier, C. Journé, C. Ducroux, W. Boisseau, S. Loyau, M. Jandrot-Perrus, J.-B. Michel, M. Mazighi, B. Ho-Tin-Noé

INSERM U1148, Paris, France

Background: Admission hyperglycemia is associated with a poor outcome in acute ischemic stroke (AIS). How hyperglycemia impacts the pathophysiology of AIS remains largely unknown.

Aims: We investigated how preexisting hyperglycemia increases ischemia/reperfusion cerebral injury.

Methods: Normoglycemic (NG) and streptozotocin-treated hyperglycemic (HG) rats were subjected to transient middle cerebral artery occlusion (tMCAO). Infarct growth and brain perfusion were assessed by perfusion/diffusion MRI sequences. Markers of platelet, coagulation, and neutrophil activation were measured in plasma samples and in brain homogenates. tMCAO-associated thromboinflammation was investigated by intravital microscopy.

Results: HG rats had an increased infarct volume with an increased blood-brain barrier (BBB) disruption and hemorrhagic transformation rate compared to NG rats. MRI scans during occlusion and after recanalization revealed that hyperglycemia enhanced and accelerated diffusion lesion growth, and was associated with hemorrhagic transformation (HT) originating from non-reperfused downstream territories. Intravital microscopy showed that downstream microvascular thromboinflammation (DMT) was initiated immediately after MCA occlusion and was exacerbated by hyperglycemia. Analysis of plasma samples indicated that neutrophils and platelets were primed in HG rats. Neutrophils from HG diabetic patients showed increased adhesion to endothelial cells as compared to neutrophils from NG control donors in flow chamber experiments.

Conclusions: We show that hyperglycemia primes the inflammatory cascade, thus amplifying MCAO-induced DMT. DMT exacerbation in HG rats impaired reperfusion and precipitated neurovascular damage, BBB disruption and hemorrhagic transformation. Importantly, we show that HT occurred in non-reperfused areas, thus challenging the current paradigm that HT is a consequence of reperfusion. Our results designate DMT as a possible target for reduction of the deleterious impact of hyperglycemia in AIS.

PB 1657 | The Association between Ring Finger Protein213 (RNF213) Polymorphisms and Ischemic Stroke Risk in Korean Patients

H.W. Kim[1,2], J.O. Kim[1,2], H.J. An[1,2], K.A. Kim[1,2], E.S. Kim[1,2], J.H. Sakong[1,2], H.A. Lee[1,2], C.S. Ryu[1,2], D. Oh[3], O.J. Kim[4], Y.S. Park[5], N.K. Kim[1,2]

[1]CHA University, Department of Biomedical Science, College of Life Science, Seongnam, Korea, Republic of, [2]CHA University, Institute for Clinical Research, CHA Bundang Medical Center, Seongnam, Korea, Republic of, [3]CHA University, Department of Internal Medicine, School of Medicine, Seongnam, Korea, Republic of, [4]CHA University, Department of Neurology, CHA Bundang Medical Center, College of Medicine, Seongnam, Korea, Republic of, [5]Chungbuk National University, Department of Neurosurgery, College of Medicine, Cheongju, Korea, Republic of

Background: Ring finger protein 213 (RNF 213) encodes RNF motif that functions as an E3 ubiquitin involved in angiogenesis. Therefore, RNF213 may be relevant to vascular disorder of intracranial arteries including ischemic stroke and moyamoya disease.

Aims: Aim of this study was four RNF213 polymorphisms that RNF213 4448G>A, 4810G>A, 4863G>A, and 4950G>A association with ischemic stroke susceptibility.

Methods: We analyzed the associations with RNF213 polymorphisms in 529 ischemic stroke patients and 424 controls. DNA was extracted from leukocytes using a G-DEX™ II Genomic DNA Extraction kit (Intron Biotechnology, Seongnam, Korea) according to the manufacturer's instructions. Genotyping was performed with polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) analysis.

Results: The RNF213 4950G>A (GA: AOR, 1.547; 95% CI, 1.025-2.335, P=0.038; GA+AA: AOR, 1.637; 95% CI, 1.089-2.461, P=0.018) was significantly associated with ischemic stroke. Also, the genotype combination analysis of RNF213 was shown that RNF213 4448GG/4950GA (AOR, 5.327; 95% CI, 2.482-11.434, P< 0.001), RNF213 4448GA/4950GG (AOR, 1.769; 95% CI, 1.028-3.047; P=0.040) combined genotypes were increased risk of ischemic stroke. Whereas RNF213 4448GA/ 4950GA (AOR, 0.216, 95% CI, 0.091-0.514, P=0.001) was decreased ischemic stroke risk.

Conclusions: Our data demonstrated that RNF213 4950G>A polymorphism associated with ischemic stroke susceptibility.

PB 1658 | Effects of Phosphodiesterase 3A Modulation on Murine Cerebral Microhemorrhages

R. Sumbria[1,2], V. Vasilevko[2], M.M. Grigoryan[3], A. Paganini-Hill[2], R. Kim[3], K. Kilday[2], T. Ngo[3], N. Chan[3], G. Pannu[3], K. Nguyen[3], A. Jafari[3], D. Cribbs[2], M. Fisher[4]

[1]Keck Graduate Institute, Claremont, United States, [2]UC Irvine, Irvine, United States, [3]UC Irvine, Orange, United States, [4]UC Irvine, Neurology, Anatomy & Neurobiology, Pathology & Laboratory Medicine, Irvine, United States

Background: Cerebral microbleeds are MRI-demonstrable cerebral microhemorrhages (CMH), which commonly coexist with ischemic stroke. A strategy that simultaneously protects the vessel wall and provides anti-thrombotic activity is an attractive potential therapeutic approach. Phosphodiesterase 3A (PDE3A) inhibition is known to have vasculoprotective and anti-thrombotic effects.

Aims: To test the hypothesis that inhibition of the PDE3A pathway is protective against CMH development.

Methods: PDE3A pathway inhibition was studied in the inflammation-induced mouse model of CMH. 3mg/kg lipopolysaccharide (LPS) was given intraperitoneally (IP) at 0, 6, and 24 hours, and brains are harvested at 48 hours. The PDE3A pathway was examined using PDE3A knockout mice (KO) (9/15 LPS-treated) and wildtype (WT) littermates (16/20 LPS-treated), and effects on hematoxylin & eosin (H&E)-positive CMH development; BBB function (IgG, claudin-5, and fibrinogen); inflammation of brain endothelium (ICAM-1), astrocytes (GFAP), and microglia (Iba-1); and serum TNF-α were investigated.

Results: Robust development of CMH was observed following LPS treatment. LPS induced significant increases in all markers of BBB dysfunction and inflammation. Deletion of the PDE3A gene did not alter CMH number or size. Compared to WT littermates, PDE3A KO mice had significantly reduced markers of endothelial and astrocyte activation and peak TNF-α levels following LPS treatment. Indices of BBB function and microglial activation did not significantly differ between PDE3A KO and WT littermates.

Conclusions: Genetic deletion of PDE3A does not alter CMH development in an inflammation-induced mouse model of CMH. Comparison of PDE3A KO versus WT mice using this model showed that microglial activation was associated with CMH development and BBB dysfunction. The role of microglial activation in CMH development warrants further investigation.

PB 1659 | Coding Variants in ADAMTS Genes Derived from Next Generation Sequencing Associated with Pediatric Stroke

F. Rühle[1], A. Witten[1], A. Barysenka[1], C. Strauss[1], M. Hiersche[1], A. Arning[1], U. Nowak-Göttl[2], M. Stoll[1]

[1]University of Münster, Institute for Human Genetics, Genetic Epidemiology, Münster, Germany, [2]University Hospital Schleswig-Holstein, Institute of Clinical Chemistry, Thrombosis & Hemostasis Treatment Center, Kiel, Germany

Background: Extracellular matrix components like members of the ADAMTS gene family in combination with misbalanced coagulation signals appear to play an important role in pediatric stroke etiology after postnatal vascular injuries. Recently, we have reported results of a family-based genome wide association study (GWAS) pointing our attention to ADAMTS2 and ADAMTS12.

Aims: Identification of coding variants in ADAMTS genes contributing to risk for pediatric stroke.

Methods: ADAMTS2 and ADAMTS12 were sequenced in 48 affected children and 48 unaffected siblings to identify putative causative variants using next generation sequencing (NGS). Sequencing reads (>50x coverage) were mapped by using BWA and analyzed by GATK. We identified 8 non-synonymous single nucleotide polymorphisms (SNPs) in ADAMTS2 and 6 in ADAMTS12 potentially influencing the respective protein function. Promising variants were genotyped within a cohort of 270 affected offspring trios using Taqman genotyping assays. Association with pediatric stroke was calculated using the Transmission Disequilibrium Test (TDT) as implement in PLINK. No adjustment for covariates was applied.

Results: While no significant association was found for variants residing in ADAMTS2, we observe the ADAMTS12 variant rs77581578 to be significantly under-transmitted (p = 6.26E-3) to pediatric stroke patients. This variant resides within a thrombospondin 1 domain of ADAMTS12 and leads to replacement of proline by threonine at amino acid position 1329 (NP_001311441). This change is predicted as damaging to the protein according to the respective SIFT score of 0.029 and potentially influences the protein's function and adhesion properties.

Conclusions: A protective variant in ADAMTS12 likely influences the function of ADAMTS12 protein and thereby decreases the risk for pediatric stroke. To validate this result, future studies in independent replication cohorts as well as functional studies to assess its biological properties are warranted.

PB 1660 | Long-term Stroke Risk Prediction in 'Real World' Atrial Fibrillation Patients: A Comparison of the ABC-stroke and CHA_2DS_2-VASc Scores

J.M. Rivera-Caravaca[1], V. Roldán[1], M.A. Esteve-Pastor[2], M. Valdés[2], V. Vicente[1], G.Y.H. Lip[3,4], F. Marín[2]

[1]Hospital General Universitario Morales Meseguer, Instituto Murciano de Investigación Biosanitaria (IMIB-Arrixaca), Department of Hematology and Clinical Oncology, Murcia, Spain, [2]Hospital Clínico Universitario Virgen de la Arrixaca, Instituto Murciano de Investigación Biosanitaria (IMIB-Arrixaca), Department of Cardiology, Murcia, Spain, [3]University of Birmingham, Institute of Cardiovascular Sciences, City Hospital, University of Birmingham, Birmingham, United Kingdom, [4]Aalborg Thrombosis Research Unit, Department of Clinical Medicine, Aalborg University, Aalborg, Denmark

Background: The ABC-stroke score (age [A], cardiac biomarkers (N-terminal fragment B-type natriuretic peptide, troponins high-sensitivity) [B], and clinical history (prior stroke/transient ischaemic attack) [C])

has recently been proposed to predict stroke in atrial fibrillation (AF). This score was derived and validated in two clinical trial cohorts, where AF patients are often highly selected and carefully followed-up. ‚Real world' patients tend to be older, with associated comorbidities and polypharmacy.

Aims: Given that the ABC-stroke score was derived from a trial cohort with a median follow-up of 1.9 years, we aimed to investigate its long-term predictive performance in comparison with CHA_2DS_2-VASc.

Methods: We recruited 1125 consecutive AF patients stables on Vitamin K Antagonists (INR 2.0-3.0) and followed-up for a median of 6.5 years. We calculated ABC-stroke and CHA_2DS_2-VASc scores. All ischaemic strokes were recorded.

Results: The median CHA_2DS_2-VASc and ABC-stroke scores were 4 (IQR 3-5) and 9.1 (IQR 7.3-11.3), respectively. There were 58 ischaemic strokes (1.50%/year) at 3.5 years (IQR 3.1-3.6) and 114 (1.55%/year) at 6.5 years (IQR 4.3-7.9). The c-index of ABC-stroke at 3.5 years was significantly higher than CHA_2DS_2-VASc (0.66 vs. 0.60, p=0.046) but at 6.5 years the c-indexes of ABC-stroke and CHA_2DS_2-VASc were similar (both approx. 0.6), with no difference in their predictive performances.

IDI showed a small improvement (< 2%) in sensitivity at 3.5 and 6.5 years with ABC-stroke. NRI demonstrated a non-significant positive reclassification at 3.5 years and a negative reclassification at 6.5 years of the ABC-stroke compared with CHA_2DS_2-VASc. Decision curves analyses did not show a substantial improvement in clinical usefulness of the ABC-stroke over CHA_2DS_2-VASc.

TABLE 1 C-indexes, IDI and NRI of the ABC-stroke score in comparison with CHA2DS2-VASc score for predicting ischaemic stroke

	C-index	95% CI	p	IDI	p	NRI	p
At 3.5 years							
ABC-stroke score vs. CHA2DS2-VASc	0.600 vs 0.663	0.567-0.625 0.634-0.690	<0.001 <0.001	0.019	0.002	0.002	0.903
At 6.5 years							
ABC-stroke score vs. CHA2DS2-VASc	0.620 vs 0.662	0.590-0.648 0.633-0.690	<0.001 <0.001	0.019	0.002	-0.053	<0.001

CI = confidence interval; IDI = integrated discriminatory improvement; NRI = net reclassification index

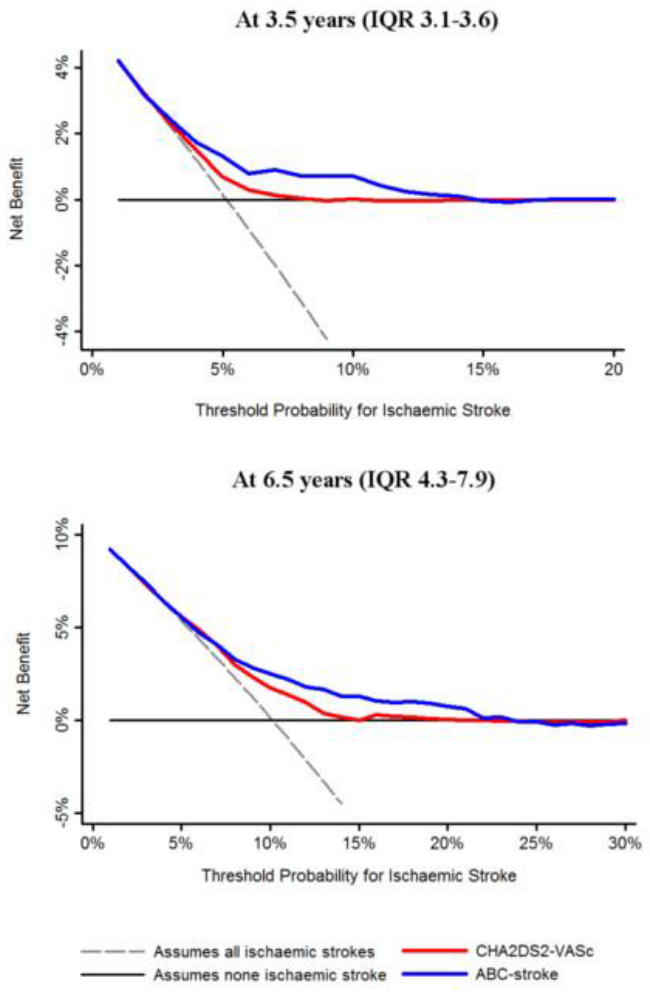

FIGURE 1 Decision curves for the ABC-stroke and CHA2DS2-VASc scores.

Conclusions: In 'real world' anticoagulated AF patients followed-up over a long-term period, the novel ABC-stroke score has not better predictive performance compared to the CHA_2DS_2-VASc score.

PB 1661 | Time-restricted Feeding Disturbs Circadian Expression of Thrombomodulin in the Mouse through Peripheral Clock Molecules

S. Horie[1], K. Oishi[2]

[1]*Kagawa Nutrition University, Clin. Biochem., Sakado, Japan,* [2]*Natl Inst. Adv. Ind. Sci. Tech., Inst. Biol. Res. Func., Tsukuba, Japan*

Background: Cardiovascular diseases are closely related to circadian rhythm, which is under the control of the internal biological clock, and it has been shown that most of cardiovascular diseases including stroke occurred in the morning to late morning. A biological clock exists not only in the hypothalamus but also in peripheral tissues and desynchronization between the central and peripheral clocks by altered timing of food intake can induce development of cancer, metabolic syndrome, and obesity.

Aims: However, whether the timing of food intake influences the thrombin formation is obscure. In this study, we measured the expression of thrombomodulin (TM), an important regulator of thrombin production on the endothelium, in the mice fed on normal or high-fat diets under the regular and/or time-restricted feeding patterns.

Methods: Under the condition of constant light-dark cycle, male mice were received a normal or a high-fat diet containing 1% cholesterol in the night- or day-time for 2 to 30 weeks, and measured mRNA and antigen levels of TM in lung which is abundant in microendothelium. To examine interaction of TM protein with the promoter region of the gene, cultured human cells were used.

Results: A circadian variation of TM mRNA level as well as that of the circadian clock gene *per2*, in the lung of mice fed a normal diet was observed, though the expression rhythms were obviously damped in *clock* mutant mice. The mRNA and antigen levels of TM were reduced by feeding of a high-fat diet containing 1% cholesterol, and the circadian oscillation of the TM expression was shifted by temporal restriction feeding of the both diets.

Conclusions: These results demonstrate that the peripheral clocks in vascular endothelial cells modulate TM gene expression and that the regularly eating of breakfast is quite important to prevent thrombosis formation through maintaining the daily normal oscillation of TM expression.

PB 1662 | Reduced ADAMTS13 Levels in Patients with Acute and Chronic Cerebrovascular Disease

F. Denorme[1], P. Kraft[2], I. Pareyn[1], C. Drechsler[3], H. Deckmyn[1], K. Vanhoorelbeke[1], C. Kleinschnitz[4], S.F. De Meyer[1]

[1]KU Leuven Campus Kulak Kortrijk, Laboratory for Thrombosis Research, Kortrijk, Belgium, [2]University Hospital of Würzburg, Department of Neurology, Würzburg, Germany, [3]University Hospital of Würzburg, Department of Internal Medicine, Würzburg, Germany, [4]University Hospital Essen, Departement of Neurology, Essen, Germany

Background: Von Willebrand Factor (VWF) plays a major role in thrombosis and hemostasis and its thrombogenicity is controlled by ADAMTS13. Whereas increasing evidence shows a clear association between VWF levels and acute ischemic stroke, less is known about a correlation with ADAMTS13.

Aims: To compare plasma levels of ADAMTS13 between acute ischemic stroke patients, patients with a chronic cerebrovascular disorder (CCD) and healthy volunteers (HV).

Methods: In this case-control study, ADAMTS13 antigen levels from 104 ischemic stroke patients, 112 patients with CCD and 85 HV were measured by ELISA. VWF levels, measured previously, were used to calculate VWF:ADAMTS13 ratios. ADAMTS13 levels and VWF:ADAMTS13 ratios were correlated with key demographic and clinical parameters.

Results: Acute stroke patients had significantly reduced ADAMTS13 levels (82.6% ± 21.0%) compared with HV (110.6% ± 26.9%; $p < 0.0001$). Interestingly, also CCD patients had significantly lower ADAMTS13 levels compared with HV (99.6% ± 24.5%; $p < 0.03$), however this was still higher compared with the acute stroke patients ($p < 0.0001$). In particular, the combination of high amounts of VWF with low levels of ADAMTS13 could be harmful. We therefore also assessed the VWF:ADAMTS13 ratio in our cohorts. A significantly higher VWF:ADAMTS13 ratio was found in stroke patients (2.7 ± 1.9) compared with HV (1.1 ± 0.5; $p < 0.0001$) and patients with chronic cerebrovascular disease (1.7 ± 0.7; $p < 0.0001$). Interestingly, the VWF:ADAMTS13 ratio was significantly associated with stroke severity (NIHSS: $p = 0.048$; mRS: $p = 0.015$ and BI: $p = 0.004$) and stroke modality (AIS or TIA; $p = 0.023$).

Conclusions: In both acute and chronic cerebrovascular disease patients, ADAMTS13 levels were significantly decreased, with the lowest ADAMTS13 levels found in acute stroke patients. This difference was even more distinct when the ratio of VWF:ADAMTS13 was considered. These results demonstrate the possible important involvement of the VWF/ADAMTS13 axis in ischemic stroke.

PB 1663 | High Level of von Willebrand Factor Ristocetin Cofactor Activity is Associated with Poor 2-years' Prognosis in Cerebral Infarction

W. Shen

The First Affiliated Hospital of Soochow University, Jiangsu Institute of Hematology, Suzhou, China

Background: Cerebral infarction (CI) is the most common type of stroke, and it also generates quantitative and qualitative changes of von Willebrand factor (VWF).

Aims: To investigate the clinical value of VWF ristocetin cofactor activity (VWF:Rco) in predicting the 2-years' prognosis of CI patients.

Methods: 61 CI patients and 104 controls (CTL) were measured for VWF antigen (VWF:Ag) and VWF:Rco by ELISA. CI patients were divided into three subgroups: < 40, 40-60 and > 60 years old. The modified Barthel index and Rankin score were used to evaluate the followed up 2-years' prognosis of activities of daily life and neurological recovery.

Results: Plasma VWF:Ag and VWF:Rco in CI patients (mean ± SD, 172.5% ± 10.4 and 225.0% ± 14.6) were significantly higher than those in controls (72.8% ± 4.1 and 65.4% ± 3.4, all $P < 0.0001$), and VWF:Rco in CI patients was positively correlated with VWF:Ag (Figure 1A, $r = 0.996$, $P < 0.0001$). VWF:Rco in CI patients was increased with age, and had significant differences in the three subgroups (162.3% ± 29.5, 214.4% ± 17.6 and 315.6% ± 25.5, $P < 0.01$). There were no significant differences between incipient and relapsed CI patients for VWF:Ag and VWF:Rco. VWF:Rco in CI patients was positively correlated with both high-sensitivity C-reactive protein (Figure 1B, $r = 0.382$, $P < 0.01$) and the 2-years' recovery of neurological function (Figure 1D, $r = 0.269$, $P < 0.05$) in the firstly diagnosed CI patients, however, VWF:Rco in CI patients was negatively correlated with 2-years' activities of daily life (Figure 1C, $r = -0.293$, $P < 0.05$). The plasma ultra-large VWF was increased in CI patients.

Conclusions: CI patients on admission had significantly higher VWF:Ag and VWF:Rco than those in controls. VWF:Rco level was associated with the severity of CI, and high VWF:Rco level was associated with poor 2-years' prognosis in CI patients. VWF:Rco may be used as a marker to predict the prognosis of CI.

PB 1664 | Evaluation of the Thrombolytic Potential of N-acetyl Cysteine in a Mouse Model of Thrombotic Stroke

F. Denorme, H. Deckmyn, K. Vanhoorelbeke, S.F. De Meyer

KU Leuven Campus Kulak Kortrijk, Laboratory for Thrombosis Research, Kortrijk, Belgium

Background: The mainstay of ischemic stroke treatment is aimed at achieving fast restoration of blood flow. We recently demonstrated a

thrombolytic effect of ADAMTS13 on von Willebrand Factor (VWF)-rich thrombi that were resistant to t-PA mediated thrombolysis. N-Acetylcysteine (NAC) is a mucolytic drug that was shown to also disassemble large VWF multimers.

Aims: The aim of this study was to assess the effect of NAC in stroke, with a particular focus on its thrombolytic potential.

Methods: The therapeutic potential of NAC was assessed in a mouse model of $FeCl_3$-induced thrombotic stroke, characterized by a VWF-rich occlusive thrombus, and a mouse model of transient middle cerebral artery occlusion (tMCAO). Cerebral blood flow was monitored, and twenty-four hours after stroke mice were neurologically scored and brain infarct sizes were calculated.

Results: When NAC was administered 5 min before vessel wall injury, occlusive thrombus formation was significantly delayed or did not occur within the experimental timeframe of 40 min ($p< 0.01$). As expected, this effect of NAC on thrombus formation was associated with a reduced stroke brain damage ($p< 0.001$). However, when NAC was administered 5 min after thrombotic occlusion of the MCA, NAC was unable to restore blood vessel patency, and infarct sizes were similar in vehicle and NAC treated animals. Despite the lack of a thrombolytic effect, the anti-thrombotic properties of NAC could be beneficial in the reperfusion phase after ischemic stroke. Indeed, in a model of cerebral ischemia/reperfusion injury, NAC reduced cerebral infarct sizes when administered immediately after reperfusion was allowed ($p< 0.01$).

Conclusions: We have shown that NAC is protective when given before thrombotic stroke and during cerebral reperfusion injury. However, NAC was unable to dissolve an already formed VWF-rich thrombus when treatment was initiated after occlusion. These results implicate distinctive effects of NAC on circulating VWF and VWF incorporated in a thrombus.

PB 1665 | Is There a Difference in Inherited Prothrombotic Polymorphisms between Arterial Ischemic Stroke and Cerebral Sinus Venous Thrombosis in Children?

A. Ceri[1], D. Coen Herak[2], A. Grzunov[3], J. Lenicek Krleza[3], V. Djuranovic[4], N. Barisic[5], R. Zadro[1,2]

[1]Faculty of Pharmacy and Biochemistry, University of Zagreb, Department of Medical Biochemistry and Hematology, Zagreb, Croatia, [2]University Hospital Centre Zagreb, Department of Laboratory Diagnostics, Zagreb, Croatia, [3]Children's Hospital Zagreb, Department of Laboratory Diagnostics, Zagreb, Croatia, [4]Children's Hospital Zagreb, Departrment of Neuropediatrics, Zagreb, Croatia, [5]University Hospital Centre Zagreb, Department of Pediatrics, Division of Neuropediatrics, Zagreb, Croatia

Background: Cerebral sinus venous thrombosis (CSVT) in children is a rare, but serious multifactorial disorder, associated with significant morbidity and mortality. The etiology of CSVT is not completely clarified. The role of inherited prothrombotic risk factors remains to be elucidated. To date, no difference in investigated inherited prothrombotic polymorphisms between arterial ischemic stroke (AIS) and CSVT in children was demonstrated.

Aims: The aim was to investigate whether CSVT and AIS in children share the same inherited prothrombotic polymorphisms.

Methods: The study included 14 children with CSVT (7 boys and 7 girls) and 41 children with AIS (20 boys and 21 girls). Sixteen polymorphisms (FV Leiden, FV HR2, FII G20210A, MTHFR C677T, MTHFR A1298C, FXIII-A Val34Leu, PAI-1 4G/5G, EPCR haplotype, eNOS -786T>C, eNOS G894T, LTA C804A, ACE I/D, HPA-1, β-fibrinogen -455G>A, and apoE ε2-4 were genotyped using a multilocus CVD Strip assay (ViennaLab, Austria).

Results: Similar genotype distribution frequencies for majority of investigated polymorphisms (FV Leiden, FV HR2, FII G20210A, MTHFR C677T, FXIII-A Val34Leu, PAI-1 4G/5G, eNOS -786 T>C, eNOS G894T, ACE I/D, β-fibrinogen -455G>A and apoE ε2-4) were found in both patient groups. Higher frequencies of MTHFR 1298CC genotype, although nonsignificant (P=0.270), were identified in CSVT (0.14) compared to AIS (0.05). On contrary, LTA 804AA genotype (4/41) and EPCR A3 haplotype (7/41) were found only in children with AIS, but the associations were not significant (P=0.120 and P=0.172, respectively). Statistically signicant difference of genotype distributions were obtained for HPA-1 (P=0.009), resulting in a 5.50-fold increased risk for CSVT (95% CI: 1.48-20.39).

Conclusions: Although a relatively small number of children with CSVT was investigated, obtained results indicate that AIS and CSVT mostly share the same inherited prothrombotic polymorphisms. Results suggest that HPA-1, not yet identified as risk factor, could be involved in the etiology of CSVT in children.

PB 1666 | Alpha-2-antiplasmin Arg407Lys Polymorphism and Cryptogenic Ischemic Cerebrovascular Events: Association with Neurological Deficit

J. Wzorek[1], M. Karpinski[2], E. Wypasek[3], A. Undas[4]

[1]The Center for Research and Medical Technology, John Paul II Hospital, Cracow, Poland, [2]John Paul II Hospital, Cracow, Poland, [3]Institute of Cardiology, Jagiellonian University School of Medicine, John Paul II Hospital, Cracow, Poland, [4]Institute of Cardiology, Jagiellonian University School of Medicine, The Center for Research and Medical Technology, John Paul II Hospital, Cracow, Poland

Background: Studies on the genetic background of ischemic stroke (IS) and transient ischemic attack (TIA) have yielded inconsistent results. Alpha-2-antiplasmin (α2AP) Arg407Lys polymorphism has been previously examined in patients with abdominal aortic aneurysm (AAA) and showed a different distribution in AAA patients compared with healthy controls (Arg/Arg: 71% vs. 65%; Arg/Lys: 27% vs. 33%; Lys/Lys: 2% vs. 2%, respectively).

Aims: We investigated associations of α2AP Arg407Lys polymorphism with the occurrence of IS and TIA and neurological deficits during follow-up.

Methods: We studied 199 Caucasian patients aged below 70 years who experienced cryptogenic IS (n=149) or TIA (n=50). Neurological outcomes were assessed using the modified Rankin Scale (mRS) as

the excellent recovery (mRS score 0-1) or poor outcome (mRS score 2-6) on admission in the acute phase of IS and then at 8 (6-12) months after the index episode. Patients were genotyped for α2AP Arg407Lys polymorphism (rs1057335) using real time PCR technique.

Results: The genotypes distribution of Arg407Lys polymorphism was as follows: Arg/Arg: 136 (68%), Arg/Lys: 57 (29%), Lys/Lys: 6 (3%). Interestingly, 407Lys allele was more frequent in TIA patients compared to the IS group (0.29 vs. 0.13, p=0.004). Moreover, in the whole group, as well as in IS and TIA patients analyzed separately, possession of the Arg/Arg genotype was associated with worse outcomes during follow-up (p=0.04), but at not in the acute phase of ischemic events. Possession of Arg/Lys genotype was associated with excellent outcomes a few months after the event (p< 0.001).

Conclusions: We found that the presence of 407Lys allele in cerebral ischemia patients is associated with better prognosis in both IS and TIA patients. The α2AP Arg407Lys polymorphism could be involved in the pathogenesis of cerebrovascular events and contribute to neurological outcomes within months since the episode, which highlights a role of α2AP in cerebral ischemia.

PB 1667 | Association between Ring Finger Protein213 Polymorphisms (*RNF213* 4448 G>A, 4810G>A, 4863G>A, 4950G>A) and Moyamoya Disease (MMD) in Koreans

C.S. Ryu[1], J.O. Kim[1], H.J. An[1], K.A. Kim[1], E.S. Kim[1], J.H. SaKong[1], H.A. Lee[1], H.W. Kim[1], D. Oh[2], O.J. Kim[2], Y.S. Park[3], N.K. Kim[1]

[1]CHA University, Department of Biomedical Science, College of Life Science, Seongnam, Korea, Republic of, [2]CHA University, Department of Neurology, CHA Bundang Medical Center, College of Medicine, Seongnam, Korea, Republic of, [3]Chungbuk National University, Department of Neurosurgery, College of Medicine, Cheongju, Korea, Republic of

Background: Moyamoya disease (MMD) is a chronic occlusive cerebrovascular disease characterized by progressive stenosis at the terminal portion of the internal carotid artery and an abnormal vascular network at the base of the brain. Although its etiology is unknown, recent genetic studies have identified *RNF213* in the 17q25-ter region as an important susceptibility gene of MMD among East Asian populations. Ring finger protein 213 (RNF 213) encodes RNF motif that functions as an E3 ubiquitin involved in angiogenesis. Therefore, RNF213 may be relevant to vascular disorder of intracranial arteries including moyamoya disease.

Aims: The aim of this study was four RNF213 polymorphisms that *RNF213* (4448G>A, 4810G>A, 4863G>A, and 4950G>A) association with moyamoya disease (MMD) susceptibility.

Methods: We analyzed the associations with RNF213 polymorphisms in 117 moyamoya disease (MMD) patients and 310 controls. Genotyping was performed by polymerase chain reaction (PCR) - restriction fragment length polymorphism (RFLP) method.

Results: Consequently, the *RNF213* 4810GA type (AOR: 92.84, P< 0.001) and dominant type (AOR: 93.61, P< 0.001) was significantly associated with moyamoya disease. The *RNF213* 4950GA type (AOR: 2.440, P=0.003) and dominant type (AOR: 2.440, P=0.003) was significantly associated with moyamoya disease. Also, the GA/GG (*RNF213* 4810/4950; AOR: 87.91, P< 0.001) and the GA/GA (*RNF213* 4810/4950; AOR: 260.9, P< 0.001) were significantly increased risk of moyamoya disease in combined genotype analysis.

Conclusions: In conclusion, our study demonstrated that *RNF213* 4810G>A and *RNF213* 4950G>A polymorphisms were associated with moyamoya disease susceptibility.

PB 1669 | Early Plasma Fibrinogen Level after Thrombolytic Therapy in Acute Ischemic Stroke Patients Cannot Predict Intracranial Hemorrhage

T. Ruchutrakool, Y. Nakkinkun, Y. Nilanon

Faculty of Medicine Siriraj Hospital, Mahidol University, Department of Medicine, Bangkok, Thailand

Background: Thrombolytic therapy (ThLy) in acute ischemic stroke (AIS) makes impressive outcome, however intracranial hemorrhage (ICH) as a serious complication is of concern.The prevalence of ICH is 2-10%. Intra-luminal fibrin clot as well as plasma fibrinogen are dissolved by thrombolytic agents.Whether plasma fibrinogen level during ThLy predicts ICH is not known.

Aims: We aimed to study the prevalence of ICH and predictive factors of ICH after recombinant tissue-plasminogen activator (rt-PA) administration in AIS patients.

Methods: During July 2014 to June 2016, AIS patients with the onset of ≤ 4.5 hours (hr) and without contraindication of rt-PA were enrolled prospectively. Repeated CTscan of brain was performed in every patient after ThLy for one day or immediately if ICH was suspected. Demographic data, NIH stroke scale (NIHSS), and plasma fibrinogen level at 0, 6 and 24 hr after rt-PA administration were recorded. The clinical and laboratory data were compared between ICH and non-ICH group.

Results: A total of 102 patients had a median age of 67 years old (range 24-88). Median duration from the onset of AIS to rt-PA administration (time to injection, TTI) was 90 minutes (range 10-270 minutes). Seven patients (6.8%) developed ICH. No significant difference of age, sex, concomitant use of anticoagulants or antiplatelets, systolic and diastolic blood pressure, blood sugar and NIHSS were found between two groups. The TTI of ICH group was significantly shorter than that of non-ICH group (60 VS. 120 minutes, p=0.04). Mean plasma fibrinogen at 0 hr of ICH group did not differ from that of non-ICH group (292±79 VS. 318±85 mg/dL, p=0.4). Mean plasma fibrinogen level of ICH and non-ICH group at 6 hr was 148±110 and 189±91 mg/dL, respectively (p=0.3). 22/102 patients (21.5%) had plasma fibrinogen level lower than 100 mg/dL but only three patients (13.6%) developed ICH.

Conclusions: The prevalence of ICH after thrombolysis was 6.8%. Plasma fibrinogen level at 6 hr did not predict ICH.

PB 1670 | Prediction of Venous Thromboembolism and Ischemic Stroke by Modified CHA_2DS_2-VASc Score in Patients with Atrial Fibrillation. The Tromsø Study

E.M. Hald[1,2], L.B. Rinde[3], M.-L. Løchen[4], E.B. Mathiesen[3,5], T. Wilsgaard[4], I. Njølstad[3,4], S.K. Braekkan[2,3], J.-B. Hansen[2,3]

[1]K.G. Jebsen TREC - Thrombosis Research and Expertise Center, Dept. of Clinical Medicine, UiT, Tromsø, Norway, [2]Division of Internal Medicine, The University Hospital of North Norway, Tromsø, Norway, [3]K. G. Jebsen TREC - Thrombosis Research and Expertise Center, Dept. of Clinical Medicine, UiT, Tromsø, Norway, [4]Epidemiology of Chronic Diseases Research Group, Dept. of Community Medicine, UiT, Tromsø, Norway, [5]Brain and Circulation Research Group, Dept. of Clinical Medicine, UiT, Tromsø, Norway

Background: Recent studies have demonstrated that patients with atrial fibrillation (AF) have increased risk of venous thromboembolism (VTE). While the CHA_2DS_2-VASc score is an established risk stratification scheme for ischemic stroke (IS) in AF patients, data on its predictive ability for VTE is scarce.

Aims: To investigate the association between modified CHA_2DS_2-VASc scores and risk of first-ever VTE and IS in subjects with AF recruited from a general population.

Methods: Patients with confirmed AF (n=1668) were recruited among participants in the Tromsø study (1994-2008), and incident VTE and IS events were recorded to the end of 2012. Information on the CHA2DS2-VASc score components (congestive heart failure (CHF), hypertension, age ≥75 (doubled), diabetes, stroke (doubled), vascular disease, age 65-74 and sex category (female)) was registered at baseline. As CHF data was only available for a subset of the study population, the CHA2DS2-VASc score was modified by omitting CHF from the model. Incidence rates (per 1000 person-years (PY)) for VTE and IS were calculated, and Cox proportional hazards regression models were used to obtain hazard ratios (HR) for VTE and IS by CHA2DS2-VASc score categories with 95% confidence intervals (CI).

Results: The mean age of the AF patients was 73 (range 28-99) years. There were 75 VTEs (IR 7.7 (95% CI 6.1-9.6) per 1000 PY) and 229 IS (IR 24.8 (95% CI 21.8-28.2) per 1000 PY) during a mean follow-up of 5.7 years. Increasing CHA_2DS_2-VASc score was associated with both VTE (HR per 1-point increase 1.24, 95% CI 1.05-1.47) and IS (HR per 1-point increase 1.54, 95% CI 1.39-1.70). When grouping patients by CHA_2DS_2-VASc score, a CHA_2DS_2-VASc score >1 increased VTE risk 2.7-fold (HR 2.70, 95% CI 1.38-5.28) and IS risk 3.1-fold (HR 3.10, 95% CI 2.10-4.56).

Conclusions: Increasing modified CHA_2DS_2-VASc score was associated with both VTE and IS. The utility of the score for VTE prediction in AF patients merits further study in larger cohorts.

PB 1671 | Safety of Aspirin for Secondary Stroke Prevention: POoled Data Reanalysis of Aspirin for CErebraL InfArction PreventIoN: PORCELAIN Study

T. Nagao

Nippon Medical School Tama-Nagayama Hospital, Department of Neurology, Tokyo, Japan

Background: Although aspirin is globally known as a first-line drug for secondary stroke prevention, differences of its safety among patients are not well established.

Aims: To clarify the individual risk for aspirin therapy, we combined and reanalyzed the aspirin treatment arms from three large scale randomized double-blinded antiplatelet trials conducted in Japan.

Methods: S-ACCESS study (2008; aspirin vs sarpogrelate), CSPS 2 study (2010; aspirin vs cilostazol) and JASAP study (2011; aspirin vs Aggrenox) were included in this analysis. All trials are randomized double-blinded prospective studies and enrolled only patients with non-cardioembolic stroke. The dosage of aspirin was 81mg/day. The patients' profiles from aspirin arms of each trial are combined and compared between patients with intracranial hemorrhage or intracerebral hemorrhage and those without.

Results: Total 2726 patients (752, 1315, 639, respectively; mean age 64.5 y/o, 28.5% female) were included. The average follow-up period was 715 days. The average aspirin initiation was 60 days from initial stroke onset. The intracranial hemorrhage and intracerebral hemorrhage occurred in 56 and 46 patients (1.05 and 0.86 %/patient-year) respectively. No pre-specified clinical background profile was identified as a risk factor for intracranial hemorrhage whereas the lacunar stroke was the significant risk factor for intracerebral hemorrhage (2.12% vs 0.85*%; p=0.046).

Conclusions: For secondary non-cardioembolic stroke prevention, the intracerebral hemorrhage risk of aspirin is prominent in patients with lacunar stroke.

PB 1672 | Abnormal Red Cell Indices and the Risk of Arterial Ischemic Stroke in Children

N. Sirachainan[1], W. Sasakakul[1], P. Kadegasem[1], P. Wongwerawattanakoon[2], C. Khongkhatithum[1], A. Chuansumrit[1]

[1]Faculty of Medicine, Ramathibodi Hospital, Pediatrics, Bangkok, Thailand, [2]Faculty of Medicine, Ramathibodi Hospital, Nursing, Bangkok, Thailand

Background: High red cell distribution width (RDW) and low hemoglobin (Hb) levels have been reported to increase risk of cardiovascular diseases, arterial ischemic stroke (AIS) and venous thromboembolism (VTE) mainly in case controlled studies, mostly in adults. The mechanisms related to the diseases were unknown.

Aims: To determine the risk of abnormal red cell indices and AIS in children and demonstrate the correlation of red cell indices with the endothelial and coagulation markers.

Methods: Children age 1-18 years with AIS and children without underlying medical illnesses were informed to enroll to the study. Blood from healthy controls was collected and tested for complete blood count, thrombomodulin (TM), E-selectin (CD62E), prothrombin fragment (F1+2), thrombin-antithrombin complex (TAT), and D-dimer levels. The red cell indices in patients were recorded. The Chi-square, Wilcoxon-Mann-Witney tests and Pearson's correlation coefficient were used for statistical analysis.

Results: A total of 240 subjects, 97 were AIS patients and 143 were controls. The mean (SD) for ages in patients and controls was 9 (4.2) and 11.4 (1.8) years respectively. Mean corpuscular volume (MCV), mean corpuscular hemoglobin (MCH), Hb, and RDW showed significant correlation with TM level (r, -0.36, 0.37, 0.2, and -0.24, $p< 0.001$, < 0.001, 0.03 and 0.04 respectively). RDW level had significant correlation with D-dimer level (r 0.2, $p= 0.01$). Hb < 11 g/dL, RDW >15% and MCV < 80 fL had higher levels of TM when compared to those with Hb ≥ 11 g/dL, RDW ≤ 15% and MCV ≥ 80 fL, p =0.007, 0.004 and < 0.001 respectively. Patients with Hb < 11 g/dL, RDW >15% and MCV < 80 fL increased ORs for AIS at 4.8 (95% CI 2.3-10.0), $p< 0.001$, 3.8 (95% CI 2.0-7.4), $p< 0.001$ and 3.6 (95% CI 2.0-6.3), $p< 0.001$ respectively.

Conclusions: Low Hb and MCV, and high RDW levels may cause endothelial activation and increased risk of AIS in children. High RDW level may contribute to the coagulation stimulation.

PB 1673 | Remote Platelet Function Testing Using Platelet-bound P-selectin as a Marker of Platelet Activation. Findings in Patients with Stroke or TIA Treated with Clopidogrel

N. Dovlatova, S. Heptinstall, J. May, P. Bath

University of Nottingham, Clinical Neuroscience, Nottingham, United Kingdom

Background: Remote assessment of platelet activation is available and involves quantification of surface expression of P-selectin. Other platelet assays have suggested that ‚resistance' to clopidogrel may be common, e.g. in 30-40% of patients.

Aims: To study platelet function in patients studied 4 weeks after acute stroke or TIA receiving a standard daily dose of clopidogrel.

Methods: Kits to assess the effects of aspirin and clopidogrel on platelet activation were obtained from Platelet Solutions Ltd (Nottingham, UK). Patients with recent non-cardioembolic ischaemic stroke or TIA were enrolled. Only clopidogrel was prescribed. Activating agents included arachidonic acid (AA) to assess effect of aspirin), adenosine diphosphate (ADP) to assess effects of clopidogrel), and thrombin receptor activating peptide (TRAP) to assess overall platelet reactivity. Data are number (%) or mean Median Fluorescence (MF, standard deviation); aspirin non-response was defined as mf >=500, and clopidogrel non-response as mf >=860, levels used in previous studies.

Results: Data were analysed from the first 50 patients enrolled (24 males) with stroke (29) or TIA (21), mean age 64 (13), range 40-88. Platelet testing was performed at least one month after starting clopidogrel. The mean MF for the Aspirin Test was 627 (335, range 82-1462); 30 (60%) of patients had a level exceeding 500. The mean MF for the Clopidogrel Test was 457 (238, range 138-1083); 3 (6%) patients exceeded 860. Significant correlations were observed: aspirin and clopidogrel (r=0.329, 2p=0.020), aspirin and TRAP (r=0.412, 2p=0.003).

Conclusions: Remote measurement of platelet function assessed by platelet surface expression of P-selectin is feasible. Few patients taking clopidogrel showed resistance. 40% of patients demonstrating suppressed levels in the Aspirin Test; this may reflect non-prescribed aspirin use or the effects of other drugs or foods. Assessment of thrombotic outcomes in this patient group is warranted.

PB 1674 | Mechanical Endovascular Therapy Plus Intravenous Tissue Plasminogen Activator versus Intravenous Tissue Plasminogen Activator Alone for the Management of Acute Ischemic Stroke: An Adjusted Indirect Treatment Comparison Meta-analysis

J. Caranfa[1,2], W. Baker[3], R. Ali[4], I. Francis[4], E. Bosco[3], A. Zichichi[3], C. Coleman[2,3], C. Kohn[2,4]

[1]University of Connecticut School of Medicine, Farmington, United States, [2]UConn/Hartford Hospital Evidence-based Practice Center, Hartford, United States, [3]University of Connecticut, School of Pharmacy, Storrs, United States, [4]University of Saint Joseph, School of Pharmacy, Hartford, United States

Background: Randomized controlled trials (RCTs) have compared mechanical endovascular therapy (MET) in addition to intravenous tissue plasminogen activator (IVtPA) to IVtPA alone for the management of acute ischemic stroke (AIS). Direct comparative studies between individual METs+IVtPA vs. IVtPA alone are not available.

Aims: To perform an adjusted indirect treatment comparison (ITC) meta-analysis to assess the efficacy and safety of different METs+IVtPA vs. IVtPA alone in AIS patients.

Methods: A systematic literature search was conducted in MEDLINE and CENTRAL from 1/2005-10/2016 for RCTs in AIS patients comparing a single MET+IVtPA to IVtPA alone and reporting shift in ordinal modified Rankin Scale (mRS) score at 90 days. Secondary endpoints included 90 day mortality and early symptomatic intracerebral hemorrhage (sICH). Endpoints were pooled using traditional random effects meta-analysis methods, producing odds ratios and 95% confidence intervals. Adjusted ITCs using pooled estimates were then performed.

Results: Three studies (SWIFT PRIME, EXTEND-IA, THERAPY) were included; 2 evaluating the Solitaire stent retriever and 1 the Penumbra system.

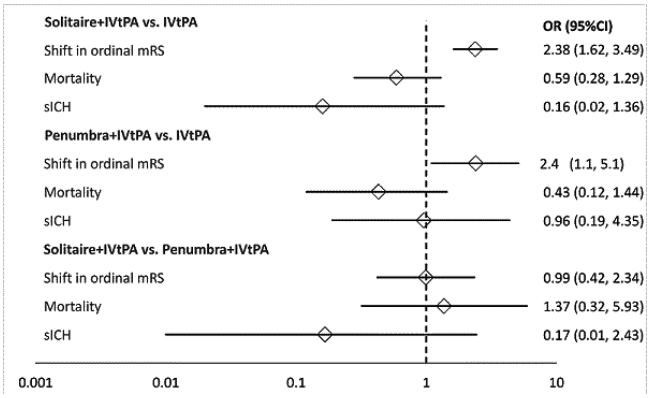

FIGURE 1 PRISMA Diagram for Traditional and Indirect Treatment Comparison Meta-Analyses]

Traditional meta-analysis demonstrated each MET+IVtPA resulted in an increased odds of improving ordinal mRS score vs. IVtPA alone, but did not alter the odds of death or sICH. Adjusted ITC showed no significant difference between the METs for any outcome.

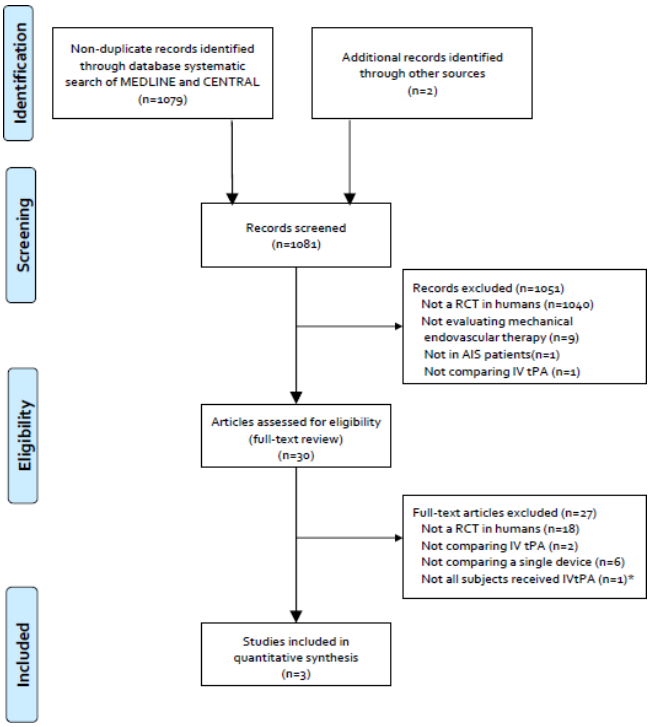

FIGURE 2 Results of Traditional and Indirect Treatment Comparison Meta-Analyses

Conclusions: No significant difference in efficacy or safety between the Solitaire and Penumbra devices were observed.

PB 1676 | Unhelpful Use of Hereditary Thrombophilia Tests in Young Patients with Ischemic Stroke. Final Results of the AISYF's Trial

J.M. Ceresetto[1], C. Duboscq[1], P. Bonardo[2], L. Leon Cejas[2], V. Genoud[3], S. Palmer[1], G. Stemmelin[1], R. Reisin[2]

[1]Hospital Británico de Buenos Aires, Hematologia, Buenos Aires, Argentina, [2]Hospital Británico de Buenos Aires, Neurologia, Buenos Aires, Argentina, [3]Facultad de Ciencias Exactas, Bioquimica, Buenos Aires, Argentina

Background: Between 5-10% of ischemic strokes occur in young patients (pts). A hereditary thrombophilia (HTF) panel is frequently performed, but the value of such screening is still controversial. AISYF is a national, prospective, multicenter study for detection of Fabry disease in Argentina. It enlisted 293 pts between 18-55 years old that had ischemic or hemorrhagic stroke in the previous 180 days. All patients signed informed consent.

Aims: To investigate HTF in a prospective young population with ischemic stroke.

Methods: We evaluated 236 pts with ischemic stroke confirmed by images that participated in the AISYF study. Cardioembolic pts (n=20) were excluded. Antithrombin (AT) and Protein C were performed by chromogenic assay, Free Protein S (FPS) by immunoturbidimethric method, Anticardiolipin Antibodies IgG-IgM by ELISA. Lupus Anticoagulant according ISTH recommendations. Factor V Leiden (FVL), Prothrombin G20210A (P20210) and PAI 4G/5G gene mutation by PCR.

Results: mean age 43 years (53% male). Molecular TF tests were performed in 161 of 236 pts (68%). Just 7 pts were FVL positive (one Homozygous, 2 combined). P20210 was found only combined (one AT deficiency, one antiphospholipid syndrome (AFLS). Tree pts had a confirmed inhibitor deficit: PC (24%), FPS (40%) and AT (28%). The PAI polymorphism was 19% homozygotes 4G/4G and 46% heterozygotes 4G/5G which was similar to the average frequency in Argentine population (21% 4G/4G and 43% 4G/5G). Only one patient had Fabry disease. On the other hand 9 pts (4%) had AFLS, 2 combined with other TF. Only the AFLS and the AT deficient patient were anticoagulated.

Conclusions:

a) Our study showed alterations in HTF studies in 12/161 (7%) pts; 3 of them were combined with other TF.
b) HTF seems to be unhelpful as part of the screening work up in young patients with stroke, even in patients with an idiopathic event, since only a few required anticoagulation.
c) AFLS remains the most frequent TF in this population.

PB 1677 | Association of PAI-1 4G/5G Polymorphism with Ischemic Stroke in Young Indians

M. Akhter[1,2], A. Biswas[3], S. Abdullah[4], M. Behari[5], R. Saxena[2]

[1]College of Applied Medical Sciences, MLT, Jizan, Saudi Arabia, [2]All India Institute of Medical Sciences, Haematology, New Delhi, India, [3]Institute of Experimental Hematology and Transfusion Medicine, University Clinic Bonn, New York City, Germany, [4]College of Applied Medical Sciences, Jizan, Saudi Arabia, [5]All India Institute of Medical Sciences, New Delhi, India

Background: A serine protease inhibitor that has an important role in the regulation of fibrinolytic system is Plasminogen activator inhibitor-1 (PAI-1). PAI-1 is crucial in the regulation of the conversion of plasminogen into plasmin by inhibiting the action of tissues plasminogen activator (tPA) and urokinase plasminogen activator (uPA). Diverse role of PAI-1 is known to be in metabolic and vascular diseases. It has a role in the progression of brain damage and recuperation after stroke; and also modulates the activity of tPA and uPA. Also both clinical and experimental studies have clearly suggested an increased risk for thrombosis with high PAI-1 levels while deficiencies are associated with accelerated fibrinolysis and bleeding.

Aims: To find the association of higher PAI-1 plasma levels and the prevalence of the 4G/5G polymorphism in PAI-1 gene promoter region in young Ischemic stroke (IS) patients.

Methods: Our study included subjects of young age from 18-45 years. Seventy patients with ischemic stroke and equal number of age- and

sex-matched controls were studied. We genotyped 4G/5G polymorphism in the study population through allele specific PCR. Commercial Kit was used to evaluate plasma PAI-1 levels.

Results: We observed that Pai-1 levels were significantly higher in patients as compared to controls. (p=0.04).The variant 4 G allele for the PAI-I 4G/5G polymorphism showed both genotypic (p = 0.02, Chi-square = 8.32; O.R = 2.60) and allelic association (p = 0.004, Chi-square = 10.54; O.R = 1.80) with ischemic stroke. The homozygous variant 4G/4G was also found to be associated with the higher PAI-1 levels. (0.001).

Conclusions: There is an association of the variant allele 4G with higher PAI-1 levels as well as with ischemic stroke. We thereby suggest in the light of our findings that PAI-1 gene polymorphism may be a risk factor for ischemic stroke in young Asian Indians.

PB 1678 | Serotonin and von Willebrand Factor Serum Content under Ischemic Stroke with or without Type 2 Diabetes Mellitus

O. Kravchenko, T. Tsarenko, O. Savchuk, L. Ostapchenko

Taras Shevchenko National University of Kyiv, Kyiv, Ukraine

Background: The incidence of stroke among patients with diabetes of the 2 type can be 3 times higher, comparing to the general population. Besides it is known that platelets in patients with the 2 type of diabetes adhere and aggregate more frequently than the ones of healthy people so activated platelets release serotonin and therefore, changes of serotonin levels and enzymes activity responding of serotonin metabolism (i.e. monoamine oxidases) in blood could be a signalling biomarker of the risk of cerebrovascular occurrences in the future under diabetes mellitus.

Aims: Thus to examine of coagulation von Willebrand (vW) factor, serotonin and tryptophan contents, monoamine oxidase (MAO) activity in ischemic stroke (IS) patient blood with or without 2 type diabetes were the aim of the present study.

Methods: The experimental group consisted of 65 IS individuals including 34 persons with type 2 diabetes. All patients or their relatives gave written agreement to participate. Von Willebrandt factor was determined by Elisa. Serum tryptophan and serotonin content assay included ion-exchange chromatography with fluorescence spectrophotometry. Determination of monoamine-oxidase serum activity was spectophotometry.

Results: The investigation showed an increase of tryptophan, serotonin and vW factor blood content in both group of IS patients independently from diabetes present comparing with the healthy donors values. Moreover, a larger deviation of serotonin - 65% from the control was observed in the blood of patients with IS alone, meanwhile the higher serum concentrations of tryptophan and von Willebrandt factor were determined of IS patients with diabetes. The monoamine-oxidase activity was reduced in diabetes patients' blood against to the values of the healthy donors and ischemic stroke alone patients.

Conclusions: These obtained data suggested a significant imbalance of different elements of hemostasis under the ischemic stroke and amplification of negative changes in case the 2 type diabetes present under the stroke.

PB 1679 | Incidence and Outcome of Childhood Stroke in Thailand

P. Komvilaisak[1], S. Tiamkao[2], S. Sutra[1], N. Sirachainan[3], K.T. Thepsuthammarat[4]

[1]Khon Kaen University, Department of Pediatrics, Faculty of Medicine, Muang, Thailand, [2]Khon Kaen University, Department of Medicine, Muang, Thailand, [3]Mahidol University, Department of Pediatrics, Faculty of Medicine Ramathibodi Hospital, Bangkok, Thailand, [4]Khon Kaen University, Clinical Epidemiology Unit, Muang, Thailand

Background: Since the development of Stroke fast track in Thailand in 2008, the incidence rate of stroke in adult group is increasing. Incidence of stroke in Thai children has not yet been reported. In addition, there is still lack of information of the outcome.

Aims: A retrospective descriptive study was to identify the incidence rate of stroke in the Pediatric group.

Methods: Neonates and children age less than 18-year diagnosed with stroke during 2004-2015 were identified through the National Health Security Office (NHSO) using International Classification of Diseases for codes G08 (cerebral sinovenous thrombosis;CSVT), codes I60-I69 (arterial ischemic strok;AIS). The first diagnosis of either AIS or CVST was recruited as subjects. The NHSO data was limited only patients under health insurance gold card that includes 75% of all patients' data in Thailand. Data of patients those parents work for government was not included in NHSO data which accounted for 25% of patients' data.

Results: The number of children with CSVT is 11 [M:F=3:8] with age < 1 year =2, 1-5 years =3 and >10 years =6. The number of children with AIS was 1499 [M:F=768:731] with age of diagnosis < 1 year =186, 1-5 years =335, 6-10 years =241 and >10 years =737. Incidence rate of CSVT was 0.006/100,000 children-yr. Trends of incidence rate of AIS between 2004- 2015 increased from 0.5 to 0.9/100,000 children-yr. The most common condition associated with stroke is obesity followed by heart diseases, sepsis, autoimmune diseases, and hematologic disorders. Among of 478 subjects died from AIS, death at < 30 days was 196, 31-90 days: 62, 91-180 days: 44, 181-1 year: 40 and > 1 year: 140 subjects.

Conclusions: Incidence of AIS and CSVT in Pediatric group was lower than the incidence reported from China, Europe and North America. Trend of diagnosis has been increasing since 2007 to date. The mortality rate of AIS was high, as a result, the improvement of education to medical personnel should be provided to early diagnosis and appropriate treatment.

PB 1681 | Another Indication to DOACs

A.M. Pizzini[1], D. Galimberti[2], G. Malferrari[3], M.C. Leone[4], D. Arioli[4], A. Ghirarduzzi[4]

[1]Azienda Ospedaliera Santa Maria Nuova, Medicine, Reggio Emilia, Italy, [2]Arcispedale Santa Maria Nuova, Medicina Interna, Reggio Emilia, Italy, [3]Arcispedale Santa Maria Nuova, Neurology Stroke Unit, Reggio Emilia, Italy, [4]Arcispedale Santa Maria Nuova, Internal Medicine, Reggio Emilia, Italy

Background: Carotid and vertebral artery dissection (CAD) is an important cause of stroke in the young, up to 25% in patients below 45 years. Antiplatelets or anticoagulants are the conventional treatment, but the superiority of either approach has not yet been estabilished.
Aims: Anticoagulants represent the treatment of choice expecially in severe stenotic or occluded vessels and in case of luminal thrombosis or cerebral microembolism. Given the safety profile of direct oral anticoagulants (DOACs) and their efficacy in stroke prevention, we evaluated their use in young patients with CAD.
Methods: We treated with Rivaroxaban 20 mg daily three young patients (mean age 42 years). Oral anticaogulation was preferred to antiplatelets for the dissection features: cerebral embolization in two and severe vertebral stenosis in one. The choice of DOACs over Warfarin was justified by the difficult monitoring of Warfrain and by the patients compliance.
Results: After 60 days from DOAC start Doppler Sonography (TSA e TCCD) and brain MR documented signs of recanalization.The clinical symptoms improved as well and no major bleeding or clinically significant event was reported, a part from a slight metrorrhagia.
Conclusions: Althought there are only few retrospective case reports on the use of DOACs in CAD, these drugs, easier to use and with a fastest and predictable action, could represent a suitable alternative to conventional anticoagulation, expecially in young patients with an active life.

COAGULANT & ANTICOAGULANT MECHANISMS

PB 071 | The Chimeric Monoclonal Antibody MHCSZ-123 against Human von Willebrand Factor A3 Domain Inhibits High Shear Arterial Thrombosis Model in Rhesus Monkeys

S. Ji[1,2], M. Jiang[1,2], F. Shen[1,2], Y. Zhao[1,2], C. Ruan[1,2]

[1]Jiangsu Institute of Hematology, Key Laboratory of Thrombosis and Hemostasis, Ministry of Health, First Affiliated Hospital, Soochow University, Suzhou, China, [2]Collaborative Innovation Center of Hematology, Soochow University, Suzhou, China

Background: SZ-123, a murine monoclonal antibody targeting the human von Willebrand factor (VWF) A3 domain and blocking the binding of collagen, is a powerful antithrombotic. In Rhesus monkeys, this was without side effects such as bleeding or thrombocytopenia. Recently, we developed a mouse/human chimeric version of SZ-123, MHCSZ-123, which maintains its inhibitory capacities *in vitro* and *ex vivo* after injection in monkeys. We selected CHO-S cells stably expressing MHCSZ-123 with G418 and adapted cell clones to serum-free suspension culture.
Aims: To investigate the antithrombotic properties, the effect on bleeding time and blood loss and initial pharmacokinetics of MHCSZ-123 in monkeys.
Methods: The antithrombotic effect of MHCSZ-123 on acute platelet-mediated thrombosis was studied in Rhesus monkeys. The thrombus formation is induced at an injured and stenosed site of the femoral artery, allowing for cyclic flow reductions (CFRs) which were measured in the femoral artery of anesthetized monkeys before and after intravenous administration of MHCSZ-123. *Ex vivo* VWF binding to collagen, platelet agglutination, platelet count, and template bleeding time were used as measurements of antithrombotic activity. In addition, plasma VWF and VWF occupancy were measured by ELISA. Statistical analysis was performed using GraphPad Prism 5 (San Diego, CA) using Student's *t* test (paired) and one-factor ANOVA followed by Fisher's test. $P < 0.05$ was considered significant.
Results: Injection of 0.1, 0.3, and 0.6 mg/kg MHCSZ-123 significantly reduced the CFRs by 29.4%, 57.9%, and 73.1%, respectively. When 0.3 and 0.6 mg/kg MHCSZ-123 were administered, 46.6% - 65.8% inhibitions of ristocetin-induced platelet agglutination were observed from 15 min to 30 min. Finally, minimal effects on bleeding time and blood loss, no spontaneous bleeding and no thrombocytopenia were observed.
Conclusions: We conclude that the VWF-A3 inhibitor MHCSZ-123 significantly reduced thrombosis in Rhesus monkeys and appeared to be safe and well tolerated.

PB 072 | Effects of Two Plant Protein Inhibitors on Haemostasis and Thrombosis

M.L. Vilela Oliva[1], B. Salu[1], S.C. Pando[2], M. Vilela de Brito[1], F. Odei-Addo[3], C. Frost[3], R. Johannes Naude[3], J. Emsley[4], M. Uemura Sampaio[1], F. Humberto de Abreu Maffei[5]

[1]Federal University of São Paulo, Biochemistry, São Paulo, Brazil, [2]Federal University of Amazonas, Department Physiological Sciences, Manaus, Brazil, [3]Nelson Mandela Metropolitan University, Port Elizabeth, South Africa, [4]University of Nottingham, Nothing, Brazil, [5]São Paulo State University, Botucatu, Brazil

Background: The purpose of antithrombotic therapy is the prevention of thrombus formation and/or its extension with a minimum risk of bleeding. The inhibition of a variety of proteolytic processes, especially those of the coagulation cascade, has been reported as a property of plant protease inhibitors.
Aims: In the present study, the role of DrTI and AsTI, from *Delonix regia* and *Acacia schweinfurthii*, respectively, being members of the Kunitz family of protease inhibitors, inhibiting trypsin in the nM range, were investigated in blood coagulation.
Methods: The inhibitory activity of DrTI and AsTI with bovine trypsin, human plasma kallikrein (huPK), and factors XIIa and XIa (FXIIa and FXIa, respectively) was analysed against specific chromogenic and fluorogenic substrates. The effect of DrTI and AsTI on prothrombin time (PT) and activated prothrombin time (aPTT) was determined. The

in vivo and *ex vivo* effect of the protein inhibitors on haemostasis and arterial thrombus formation was investigated.

Results: DrTI and AsTI increased the aPTT in human plasma due to the inhibition of huPK. DrTI differs from AsTI by inhibiting FXIa, with a K_{iapp} of 1.3 nM, indicating the dynamic nature of their reactive sites. DrTI and AsTI inhibited ex-*vivo* mice platelet aggregation induced by ADP and significantly prolonged the time for total carotid artery occlusion in mice compared to the NaCl control. In contrast to heparin, the bleeding time in mice treated with the two inhibitors did not differ from that of the control group.

Conclusions: DrTI and AsTI effectively prevented arterial thrombus formation in mice without increasing the bleeding time, possibly by interfering with the activity of the huPK and FXIa blood coagulating contact factors associated with platelet inhibition. Support by Coordenação de Aperfeiçoamento de Pessoal de Nível Superior (CAPES) [grant number 23038.0077762/2014-32, AUPE 140/2015].

PB 073 | Slounase, a Modified Snake Venom Hemocoagulase Combined with FXa, Enhances Hemostasis and Limits Bleeding in Both Normal and Hypocoagulant Conditions

R. Adili[1], X. Dai[2], B.X. Li[3], M. Holinstat[1]

[1]*University of Michigan, Department of Pharmacology, Ann Arbor, United States,* [2]*Zhaoke Pharmaceutical (Heifei) Co. Limited, Hefei, China,* [3]*Lee's Pharmaceutical (Hong Kong) Limited, Shatin, China*

Background: Uncontrolled post-traumatic bleeding is the leading cause of preventable death. Hemocoagulase, a thrombin-like serine protease from snake venom, converts fibrinogen to fibrin and thus may reduce blood loss in hemorrhagic medical conditions. A modified hemocoagulase combined with activated factor X (FXa), may potentially improve the hemostatic effect of hemocoagulase. However, the *in vivo* hemostatic effect of these reagents is not well characterized due to lack of reliable *in vivo* hemostasis models.

Aims: To determine the efficacy of slounase *and* hemocoagulase on hemostatic clot formation and bleeding at the site of vascular injury i*n vivo*.

Methods: Effect of slounase, hemocoagulase, and FXa on human platelet function was assessed *in vitro*. *In vivo* hemostatic efficacy was determined in mice using intravital microscopy laser ablation hemostasis models and liver puncture hemostasis model.

Results: Both slounase and FXa, but not hemocoagulase, enhanced human platelet aggregation induced by thrombin. As expected intravenous injection of 25U of heparin into WT mice prevented the hemostatic clot formation at the site of vascular injury and FXa treatment did not restore clot formation *in vivo*. Hemocoagulase treatment in heparin-treated hypocoagulant mice resulted in detectable fibrin formation but no notable change in platelet recruitment in the clot. Interestingly, slounase treatment resulted in a significant enhancement of both fibrin and platelet content in control WT mice and restored the clot formation in heparin-treated hypocoagulant mice. Similar results were also observed in laser-ablated saphenous vein hemostasis model. The bleeding time was shorter in slounase-treated hypocoagulant mice both in vascular injury models and using liver pricking injury model.

Conclusions: Slounase enhances hemostasis in normal mice and restores hemostasis in hypocoagulant conditions via both enhancing fibrin formation and platelet activation while hemocoagulase only enhances fibrin formation *in vivo*.

PB 074 | Platelet Defects Upon Surgical Liver Disease Models iin Mice

F. Reusswig[1], N.S. Gowert[1], M. Klier[1], M. Reich[2], L. Donner[1], V. Keitel[2], D. Häussinger[2], M. Elvers[1]

[1]*University Clinic of the Heinrich-Heine University, Research Group Molecular Hemostasis, Duesseldorf, Germany,* [2]*Heinrich-Heine-University, Clinic for Gastroenterology, Hepatology and Infectiology, Duesseldorf, Germany*

Background: Acute and chronic liver diseases are characterized by alterations in primary hemostasis including thrombocytopenia and platelet function defects. Moreover, different studies show that hypercoagulability play a prominent role in liver diseases. However, the consequences of liver failure on platelet function are not well defined.

Aims: Functional analysis of platelet activity, thrombus formation and hemostasis in liver injury models.

Methods: *In vitro* and *in vivo* experiments using Bile Duct Ligation (BDL) and Partial Hepatectomy (PHx) in mice.

Results: 24 h and 3 days after BDL a moderate decrease of platelet counts occurred, whereas the platelet counts increased to normal levels after 7 and 21 days. Platelet counts after PHx were slightly reduced after 3 days and fully recovered at later time points. However, intrinsic platelet activation was strongly reduced upon CRP activation at early time points in both BDL and PHx operated mice compared to sham controls. 7 days after BDL platelets displayed a complete activation defect with all agonists tested, whereas in the PHx model acute platelet activation defects were measured in the first 3 days. This activation defects resulted in strongly reduced thrombus formation under flow in both models as well as reduced platelet adhesion to fibrinogen. In vivo platelet defects resulted into bleeding complications, predominantly in BDL mice as measured by tail bleeding experiments. The analysis of platelet activation defects revealed a contribution of altered glycoprotein expression to defective signal transduction. Moreover, high plasma levels of NO, PG-E and bile acids increased endogenous levels of VASP phosphorylation resulting in almost non-functional platelets after liver injury.

Conclusions: These results indicate that liver diseases affect intrinsic platelet activation and impair thrombus formation that might contribute to bleeding complications in patients with acute or chronic hepatic failure and resection.

PB 075 | D-Insight - An Integrated Animal and Cell Model System to Interrogate the Expression and Secretion Dynamics of F2 Real-time *in vivo*

S. Khokhar[1,2], L.K. Schott[1,2], K. Mühlbach[1,2], S. Tolakov[1,2], S. Danckwardt[1,2]

[1]*Johannes Gutenberg University Medical Center, Center for Thrombosis and Hemostasis (CTH), Mainz, Germany,* [2]*Johannes Gutenberg University Medical Center, Institute for Clinical Chemistry and Laboratory Medicine, Mainz, Germany*

Background: The coordinated dynamics of F2 gene expression and protein secretion determine the well-balanced equilibrium between coagulation and blood loss, and ensure proper execution of numerous other F2a-mediated functions beyond blood coagulation.
Aims: Here, we report on a genetic model that allows to interrogate and define regulatory principles controlling F2 gene expression and secretion in a spatiotemporal manner.
Methods: By applying a multimodal genetic tagging strategy, we generated a novel constitutive knock-in mouse model based on fluorescence and luminescence reporters separated by P2A peptides for tailored multicistronic expression. This mouse model, termed D-Insight, allows the "visualization" of regulated F2 gene expression and protein secretion in its natural context, and the coupling between these processes real-time *in vivo* by the use of non-invasive optical imaging. Complementary, we generated primary hepatic cell lines derived from this mouse model. This cell line permits the deconvolution of F2 gene expression-, protein biosynthesis- and secretion dynamics in high resolution and in a scalable high-throughput format *ex vivo* with bioluminometry and fluorescence microscopy.
Results: We confirm that this model faithfully recapitulates established (patho)physiologically relevant modifiers of F2 expression, and thereby show that the complementarity of this experimental setup may help to foster the reverse and forward translation of conditions impinging on F2-modulating circuits.
Conclusions: This experimental model thus represents a versatile tool to identify physiologically relevant rheostats involved in the cross-talk between F2 gene expression and protein biosynthesis and secretion. It will also help deciphering underlying mechanisms of disordered hemostasis e.g. in response to pathophysiological cues and other (environmental) perturbations.

PB 076 | Role of Disruptive Hydrodynamic Forces in Determining Occlusive and Non-occlusive Arterial Thrombosis Scenarios

A. Yakusheva[1,2,3], N. Receveur[3], D. Nechipurenko[1,4], A. Eckly[3], F. Ataullakhanov[1,2,4], C. Gachet[3], P. Mangin[3], M. Panteleev[1,2,4]

[1]*Lomonosov Moscow State University, Faculty of Physics, Moscow, Russian Federation,* [2]*Center for Theoretical Problems of Physicochemical Pharmacology, Russian Academy of Sciences, Moscow, Russian Federation,* [3]*Universite de Strasbourg, INSERM, EFS Grand Est, BPPS UMR-S 949, FMTS, Strasbourg, France,* [4]*Federal Research and Clinical Centre of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation*

Background: The mechanisms responsible for difference between occlusive and non-occlusive thrombosis scenarios are not clear. Disruption of thrombus by flow (locally accelerated because of vessel lumen narrowing) was previously suggested to be important.
Aims: To investigate flow pattern changes and parameters of thrombi induced by paper patches of different length in FeCl3-induced model of murine arterial thrombosis.
Methods: Real-time videomicroscopy was used to monitor thrombus formation. Doppler flow probe was applied to validate occlusion. End-point thrombi were analyzed with scanning electron microscopy and confocal microscopy. Computational fluid dynamics was used to investigate the relationship between thrombus formation and flow parameters.
Results: Occlusion occurred in 1 case out of 6 for the damage size 1 mm long (versus 5 cases of 6 for 3 mm). Non-occlusive thrombosis was always a two-phase process, with initial formation of a large thrombus followed by its disruption and stabilization. This stabilization always occurred at a thrombus height less than 40% of the vessel diameter (90±15 microns for 1 mm, 211±50 microns for 3 mm). The structure of occlusive thrombus was non-homogeneous, with large regions composed of erythrocytes compressed into tightly packed polyhedrals. Computational flow dynamics confirmed that the vessel with thrombus functioned as a constant differential pressure system. This resulted in local acceleration of blood flow near thrombus and disruption of unstable thrombi, which could prevent occlusion. Chances of this were higher for small damage size because such thrombi did not increase overall vessel hydrodynamic resistance greatly.
Conclusions: Transition between non-occlusive arterial thrombosis and vessel occlusion is determined by disruption of thrombi by hydrodynamic forces during the phase when thrombus is not yet strong enough. Thrombus geometry determines local flow forces and is a critical factor in this process.

PB 077 | Sickle Cell Red Blood Cells Alter Properties of Mouse and Human Clot

C. Faes[1], E.M. Sparkenbaugh[1], S. Wang[1], K.I. Ataga[2], A.S. Wolberg[1,3], N.S. Key[1,2], R. Pawlinski[1,2]

[1]*McAllister Heart Institute, University of North Carolina, Chapel Hill, United States,* [2]*University of North Carolina at Chapel Hill, Division of Hematology/Oncology, Chapel Hill, United States,* [3]*University of North Carolina at Chapel Hill, Department of Pathology and Laboratory Medicine, Chapel Hill, United States*

Background: Sickle cell disease (SCD) is associated with increased risk of venous thromboembolism. It has been proposed that clot contraction-mediated packaging of red blood cells (RBC) is significantly altered in SCD and may affect clot stability.
Aims: We investigated the cellular mechanism of clot retraction in SCD.
Methods: *Ex vivo* clot retraction was performed using blood from sickle cell (SS) Townes mice and SS patients. The number of RBC extruded from the clot into serum was expressed as a % of initial RBC in whole blood.

Results: In mice, dramatically less RBC were extruded into the serum from SS clots than control (AA) (0.8±0.8% vs 19.4±0.8%, n=3, p< 0.0001). A similar result was observed in human blood. FXIIIa inhibition with T101 increased the release of AA (by 64%, n=6, p< 0.05) but not SS RBC from mouse clots. Mixing the platelet poor plasma (PPP) and cellular fraction of AA and SS mouse blood revealed that entrapment of SS RBC is mediated by the cellular fraction of blood (AA blood 6.9±3.6%; SS blood 0.4±0.4%; AA cells/SS PPP 6.7±6.4%; SS cells/AA PPP 0.1±0.2%, n=3 per group). Mixing the platelet free plasma (PFP), platelets and RBC of AA and SS mice demonstrated that the entrapment of SS RBC within the clot is entirely mediated by yet unknown properties of SS RBC (n=3).

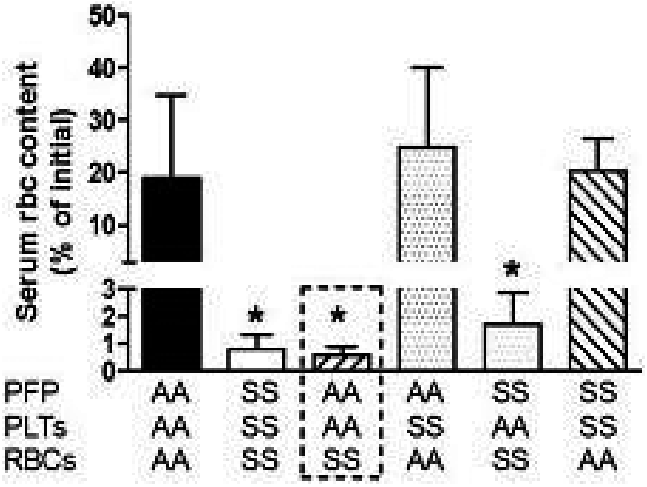

FIGURE 1 Effets of cellular compartments on the entrapment of AA and SS RBCs within the clot

Lowering hematocrit (HCT) of AA mouse blood reduced RBC extrusion from the clots. However, increasing HCT of SS mouse blood to that of AA blood did not increase the number of SS RBC extruded from the clot, suggesting that the entrapment of SS RBCs within the clot is not simply caused by lower RBC number in SCD. Electron microscopy analysis of the clots demonstrated that mouse and human SS RBC underwent sickling and formed "spicule-like" processes intertwined with fibrin fibers that prevented formation of tight polyhedral shapes observed in AA clots.

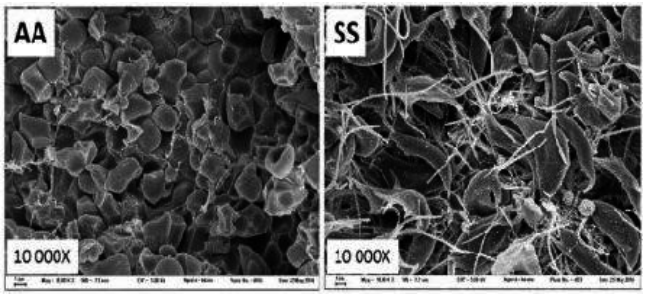

FIGURE 2 Scanning electron microscopy of AA and SS blood clots formed ex vivo

Conclusions: Sickling of SS RBC alters the process of clot retraction and changes clot structure. In vivo consequences of these observations are currently under investigation.

PB 078 | Porcine Model of Methicillin-resistant Staphylococcus Aureus (MRSA) Sepsis-induced Disseminated Intravascular Coagulation (DIC) and Multiple Organ Dysfunction Syndrome (MODS)

T. Nguyen[1,2], J. Marini[1,3], B. Guillory[2,4], C. Valladolid[2,4], D. Cohen[2,5], Q. Da[2,4], S. Cirlos[2,4], M. Martinez-Vargas[2,4], F. Lam[1,2], Y. Yuan[1,3], B. Stoll[1,3], D. Bashir[1,2], M. Desai[1], E. Mason[1], S. Kaplan[1], J. Vallejo[1], L. Lamberth[1], K. Hulten[1], V. Vijayan[2,4], M. Cruz[2,4]

[1]Baylor College of Medicine/Texas Childrens Hospital, Pediatrics, Houston, United States, [2]Center for Translational Research on Inflammatory Diseases (CTRID), Michael E. DeBakey VA Medical Center, Houston, United States, [3]USDA/Agricultural Research Service, Children's Nutrition Research Center, Houston, United States, [4]Baylor College of Medicine, Medicine, Houston, United States, [5]Baylor College of Medicine, Pathology, Houston, United States

Background: Sepsis-induced DIC is associated with a high mortality with no existing therapy except for supportive care. MRSA infections are increasingly becoming a significant healthcare burden. Currently there is a paucity of published MRSA sepsis models. Large animal models are now recommended prior to human clinical trials.

Aims: Our aim is to validate a published model (Soerensen et al 2013) and establish a hemodynamically relevant porcine model of MRSA sepsis-induced DIC.

Figure 1. Platelet Counts, Prothrombin Time, Activated Partial thromboplastin Time D-dimer, and Fibrinogen levels in sham and Methicillin-Resistant Staphylococcus Aureus (MRSA) septic pigs at 0, 24h, 48h, 60h, and 70h post-MRSA injection.

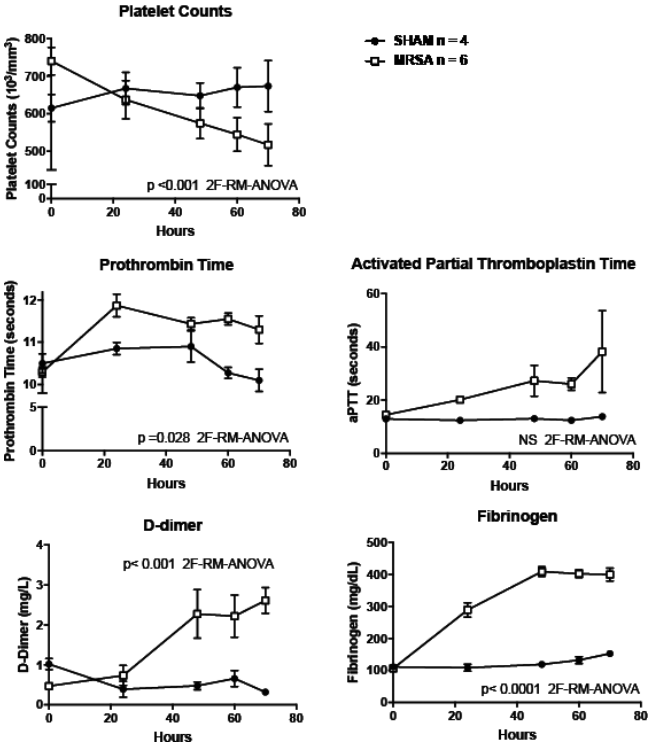

FIGURE 1 Platelet counts, PT, aPTT, D-dimer, and fibrinogen levels in sham and MRSA septic pigs.

Methods: Ten four-week old pigs (8 kg) were implanted with jugular and carotid catheters and a telemetry device in a femoral artery

for continuous hemodynamic monitoring. Four days later 6 pigs were injected intravenously with MRSA (USA300, TCH 1516 strain) dose of $1x10^9$ CFU/kg and 4 pigs (Sham) were injected with saline. Fluid resuscitation was given for heart rate > 50% or mean arterial blood pressure < 30% from baseline. Point-of-care complete blood count, prothrombin time (PT), activated thromboplastin time (aPTT), D-dimer, and fibrinogen were done at 0, 24, 48, 60 and 70h post-MRSA injection. Factors V and VII, protein C, and antithrombin activities were also measured. Pigs were euthanized and necropsies performed.

Results: Platelet counts decreased and PT, D-dimer, and fibrinogen increased significantly in septic compared to sham pigs over time ($p< 0.05$; 2FRM-ANOVA). Factors V and VII, and protein C activities significantly decreased in septic pigs by 24h post-MRSA injection. Antithrombin activity significantly decreased in septic pigs by 48h post-MRSA injection. Histopathologic examination shows microvascular thrombi, necrosis, hemorrhage, infarction and infection in the kidney, liver, and lung of septic pigs.

Conclusions: Our 70h porcine model of MRSA-sepsis induced DIC showed consumptive coagulopathy, organ injuries, and vascular thromboses. Characterization of this model is ongoing with the aim of having a pathologically and hemodynamically relevant large animal model to study DIC and evaluate potential therapeutic targets.

Figure 2. Factor V, Factor VII, Protein C and Antithrombin activites in sham pigs at 0h and 70h and in Methicillin-Resistant Staphylococcus Aureus (MRSA) septic pigs at 0, 24h, 48h, 60h, and 70h post MRSA injection.

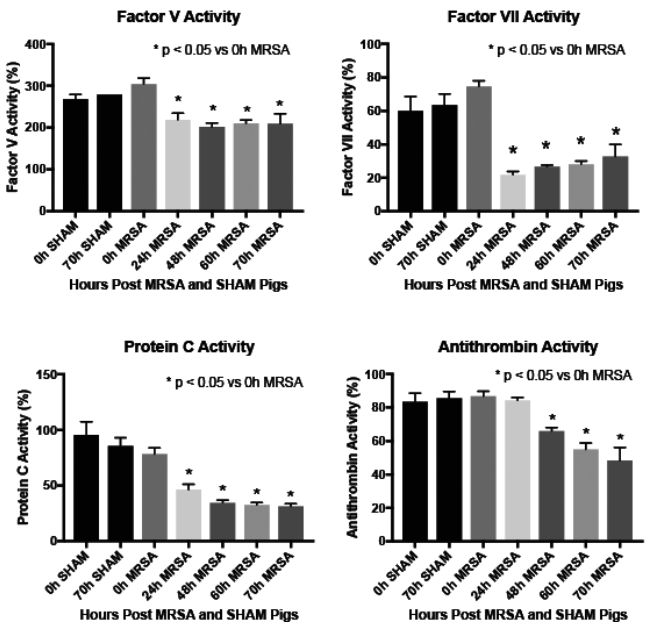

FIGURE 2 Factors V, VII, protein C and antithrombin activities in sham and MRSA septic pigs

PB 079 | Role of bone morphogenetic protein receptor type II in vascular remodeling during thrombosis

S. Sharma, A. Alimohammadi, A. Panzenboeck, I.M. Lang

Medical University of Vienna, Internal Medicine II, Cardiology, Vienna, Austria

Background: Several lines of evidence have implicated the role of inheritance and genetics in pathogenesis of pulmonary arterial hypertension (PAH). Mutations in the bone morphogenetic protein type II receptor (BMPR2), a member of the TGF-β superfamily, have been identified as a risk factor for pulmonary arterial hypertension. Fibrotic vascular occlusion is a feature of PAH and chronic thromboembolic pulmonary hypertension (CTEPH), therefore we wanted to study the role of BMPR2 in murine model of chronic venous thrombosis.

Aims: In the present study we investigated the role of BMPR2 deficiency in fibrotic vascular remodeling following thrombosis. Additionally, we aim to study the cellular composition of chronic thrombotic material excised during pulmonary endarterectomy (PEA) surgery.

Methods: We utilized a mouse model of stagnant flow venous thrombosis to study the effect of BMPR2 deficiency on thrombus formation/resolution. Wild type mice and transgenic mice, bearing a heterozygous knock-in allele of human BMPR2 mutation, R899X, were subjected to subtotal ligation of the inferior vena cava (IVC). Thrombus was harvested at different time points (days 1, 3, 7 and 14 after IVC ligation) and histological and molecular analysis were performed. Trichrome stain was performed to assess the accumulation of matrix components.

Results: We observed a significant increase of thrombus cross-sectional areas and volumes on days 1, 3 and 7 in transgenic mice. During early time points (days 1, 3 and 7) mice with BMPR2 deficiency showed more fibrin in their thrombi than wild type controls. By day 14, transgenic mouse thrombi seem to have more accumulation of extracellular matrix components like collagen.

Conclusions: These results indicate a role of BMPR2 during early thrombosis, impacting fibrotic remodeling thereafter.

PB 080 | In Vivo Neutralization of Unfractionated Heparin (UFH) and a Bioengineered Heparin Dodecasccharide (12-mer) by Protamine Sulfate in a Primate Model

A. Kouta[1], R. Duff[2], D. Hoppensteadt[3], W. Jeske[4], S. Abro[3], J. Fareed[3]

[1]Loyola University Medical Center, Pharmacology, Maywood, United States, [2]Loyola University Medical Center, Comparative Medicine, Maywood, United States, [3]Loyola University Medical Center, Pathology, Maywood, United States, [4]Loyola University Medical Center, Thoracic and Cardiovascular Surgery, Maywood, United States

Background: Heparin, a sulfated natural glycosaminoglycan (GAG) which is widely used. Chemoenzymatic methods provide an alternate approach to synthesize heparin-related GAGs. A dodechasaccharide represents a homogeneous oligosaccharide with high affinity to antithrombin and exhibits anti-Xa activity with weak anti-IIa actions.

Aims: This study was aimed to investigate the neutralization of UFH and dodechasaccharide by protamine sulfate (PS) following intravenous administration to non-human primates.

Methods: Porcine UFH and PS were commercially obtained. The 12-mer was synthesized by a chemo-enzymatic method. In vivo studies

were carried out in individual groups of primate (n=4). Blood samples were obtained at baseline from dodechasaccharide or UFH treated groups after a 500 ug/kg IV administration to an individual group of primates (n=4). An additional sample was drawn at 5 minutes after drug administration and followed by IV PS administration at 1.0 mg/kg. Subsequent blood samples were drawn at 5 and 30 minutes post PS administration. These samples were analyzed in the APTT, anti-Xa, anti-IIa and TFPI assays.

Results: Administration of UFH increased the aPTT (>300 sec) whereas dodechasaccharide had a marginal effect. Both UFH and dodechasaccharide strongly inhibited the Xa assay (>90%) 5 mins after administration. PS neutralized the anticoagulant effect of UFH and partially neutralized the IIa and Xa activities. PS had minimal effect on the activities of dodechasacharide. While PS markedly decreased TFPI levels in UFH treated primates it had minimal effect on dodechasaccharide treated animals.

Conclusions: Unlike UFH dodechasaccharide exhibited minimal anticoagulant and anti-IIa activities, yet markedly higher anti-Xa activity. In the UFH group PS almost completely neutralized the anticoagulant effects as measured by APTTs and significantly reduced the anti-Xa effects. In contrast, PS was not effective in neutralizing the effects of dodechasaccharide in all assays.

PB 081 | Hemostatic Profile in Mouse Models of Advanced Chronic Liver Disease

N.C. Dewarrat[1,2], C. Quarroz[1,2], J. Jankovic[1,2], M.D. Reina Caro[1,2], R. Prince[1,2], A. De Gottardi[3], S. Calzavarini[1,2], A. Angelillo-Scherrer[1,2]

[1]Inselspital, Bern University Hospital, University of Bern, Department of Hematology and Central Hematology Laboratory, Bern, Switzerland, [2]University of Bern, Department of Clinical Research, Bern, Switzerland, [3]Inselspital, Bern University Hospital, University of Bern, Department of Visceral Surgery and Medicine, Bern, Switzerland

Background: Advanced chronic liver disease (ACLD), a condition including cirrhosis and fibrosis, is characterized by changes in the coagulation system that embrace both hypo- and hypercoagulability. In this rebalanced situation, hypercoagulability can contribute to fibrosis progression and cirrhosis complications.

Aims: To create ACLD murine models and evaluate hemostatic changes.

Methods: 20 adult male mice received i.p. 200mg/kg thioacetamide (TAA) 3x/week for 12 weeks or i.p. 1ml/kg carbon tetrachloride (CCl_4) and p.o. 0.3g/L phenobarbital (PB), 2x/week for 11 weeks. At the end of the treatment mice were sacrificed; blood and organs were collected.

Results: We observed a slight increase in body weight in both CCL_4/PB (28.0±2.7 vs 24.5±3.9g, P< 0.0001) and TAA (22.8±3.1 vs 21.6±3.3g, P=0.01) groups compatible with ascites development while mortality rate was higher in the CCL_4/PB than in the TAA group (32% vs 7%). In the CCL_4/PB group, liver histology displayed extensive fibrosis with both portal-to-portal and portal-to-central bridging. Albeit present, fibrosis in the TAA treated group was less extensive. Interestingly, occlusive centrilobular vein thrombosis was more prominent in the TAA than in the CCL_4/PB group, where we observed also partial periportal thrombosis. Coagulation investigation showed a slight decrease of fibrinogen in both CCL_4/PB and TAA groups compared to controls (1.4±0.1 vs 1.7±0.1g/L, P=0.04 and 1.3±0.1 vs 1.7±0.1g/L, P=0.01) and prolonged PT in both CCL_4/PB and TAA groups compared to controls (9.3±0.1 vs 8.9±0.03sec, P=0.01 and 9.8±0.2 vs 8.9±0.03sec, P=0.007). Factor VIII was highly increased in the CCL_4/PB group compared to controls (350±17 vs 194±35%, P=0.002) but not in the TAA group (278±66 vs 194±35%, P=ns).

Conclusions: These data provide the first evaluation of hemostatic profile in mice with ACLD. Evaluation of thrombin generation potential is ongoing to further characterize the bleeding and thrombotic tendency linked to murine ACLD.

PB 082 | A Dual Antiplatelet (AP) and Anticoagulant (AC) Compound - APAC - Inhibits Collagen-induced Platelet Aggregation in Mice and Protects against Arterial Thrombosis

N.R. Bonetti[1], A. Jouppila[2], S. Gobbato[1], S. Stivala[1], G.G. Camici[1], R. Lassila[3], J.H. Beer[1,4]

[1]University of Zurich, Center for Molecular Cardiology, Schlieren, Switzerland, [2]Helsinki University Hospital Research Institute, Helsinki, Finland, [3]Helsinki University Hospital, Coagulation Medicine, Helsinki, Finland, [4]Cantonal Hospital Baden, Internal Medicine, Baden, Switzerland

Background: Antithrombotic treatments are key for preventing complications in vascular disease. APAC mimics natural heparin proteoglycans and has dual antiplatelet (AP) and anticoagulant (AC) actions *in vitro* and at vascular injury sites *in vivo*. Upon local intraluminal application, APAC preserved vascular integrity in a rat femoral anastomosis model. APAC IV protected against renal ischemia/reperfusion injury in rats.

Aims: We aimed to test APACs anti-platelet effects in mice as well as its antithrombotic potential in a mouse model of arterial thrombosis (AT).

Methods: For platelet studies, we used male C57BL/6 wildtypes aged 12 w. Light transmission aggregometry was performed on citrated PRP. PRP was pretreated with either APAC or PBS at a dose of 5 µg/ml for 15 min. The agonist was collagen, concentrated 2 µg/ml.

For AT, we used a mouse model of laser-induced injury of the common carotid artery (CCA). Briefly, after IV injection of rose bengal, the CCA was targeted by a 1.5 mW green laser and the time to thrombotic occlusion measured by Doppler flow probe.

Mice were IV treated with either PBS, UFH or APAC at a dose of 0.3 mg/kg, 15 min before onset of laser injury.

Results: Collagen-induced platelet aggregation was significantly inhibited in APAC vs PBS treated PRP (Fig.1)

In line with this, *in vivo* APAC treated mice took double the time to thrombotic occlusion (97 s vs 47 s & 49 s) compared to PBS and UFH treated animals (Fig.2)

Conclusions: APAC inhibits murine collagen-induced platelet aggregation *in vitro*.

IV application of APAC but not UFH or PBS significantly delays thrombotic occlusion *in vivo*. This implies APAC's anti-thrombotic effect even after systemic application, suggesting a mechanism of self-targeting to the site of vascular injury. The compound's attractiveness, i.e. local effectiveness with less systemic side effects, is thus underlined.
Further studies will address APACs local distribution at the site of vascular injury and other mechanisms including local tissue factor expression and activity.

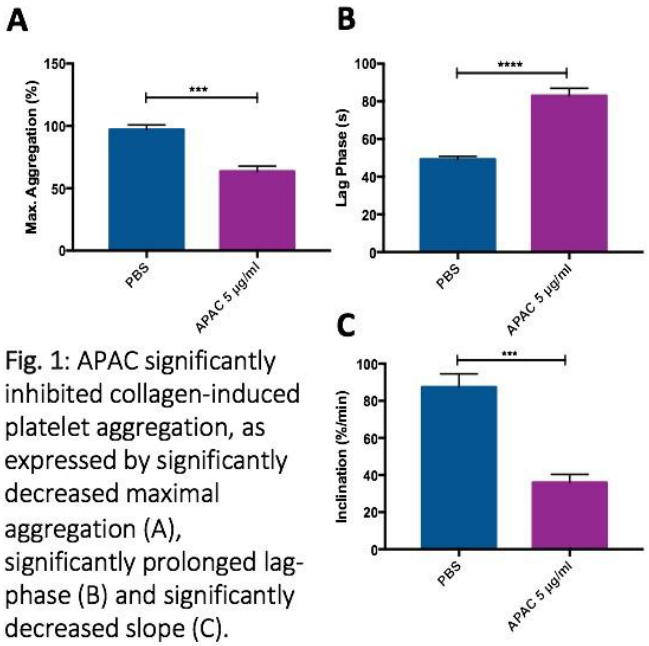

Fig. 1: APAC significantly inhibited collagen-induced platelet aggregation, as expressed by significantly decreased maximal aggregation (A), significantly prolonged lag-phase (B) and significantly decreased slope (C).

FIGURE 1 Platelet aggregation studies in mice treated with APAC

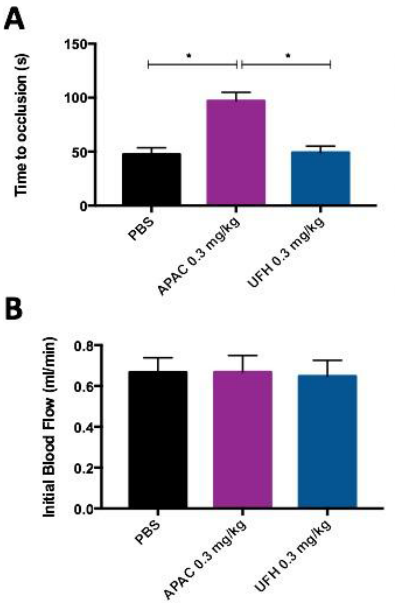

Fig. 2: Systemic IV application of APAC significantly increased time to thrombotic occlusion compared to PBS and UFH (A), whereas initial blood flow measurements did not differ between the groups (B).

PB 083 | Blood Microsampling as a Refined Model of Platelet Thromboembolism *in vivo*

F. Rauzi, E. Smyth, K. Taylor, M. Emerson

Imperial College London, National Heart and Lung Institute, London, United Kingdom

Background: Research in the field of platelet pharmacology requires the use of mortality models of thromboembolism performed in conscious mice which inflict considerable pain and use paralysis/death as endpoints.
Aims: We have developed a refined *in vivo* mouse model of platelet thromboembolism based on blood microsampling which entails the measurement of the fall in circulating platelet counts as platelets accumulate in the pulmonary vasculature following a thromboembolism.
Methods: Three microsamples of blood were collected from the tail vein of anaesthetized Balb/c mice before and after (1 and 10 min) the injection of collagen or thrombin and platelet counts measured. The results obtained were validated by immunohistochemistry where sections of lung were stained for platelet-specific CD41 and by using our established real-time *in vivo* platelet monitoring technique. The effect of anti-thrombotic aspirin on circulating platelet counts was also assessed.
Results: The blood microsampling data showed a significant reduction in platelet counts 1 min after collagen (44.1%) or thrombin (32.1%) which returned to basal values after 10 min. These results correlated with those determined *via* real-time platelet monitoring where the maximum increase in platelet-radioactivity counts (%) in the pulmonary vasculature was found 1 min after collagen and restored after 10 min. Platelet aggregates were observed in the lung tissue of collagen-challenged mice compared to vehicle-control. Treatment with aspirin significantly inhibited the reduction in platelet counts induced by collagen, 23.4%, compared to control groups, 38.8%.
Conclusions: We developed blood microsampling as a novel and simplistic mouse model to study platelet aggregation *in vivo* which refines an animal model to a lower severity level and reduces animal use compared to mortality models. Ultimately, this method has potential value in studying the pharmacological effect of novel therapeutics on platelet function *in vivo*.

PB 084 | Thromboelastography in Mice: Impact of Blood Collection Method

H. Kaur[1], M. Othman[1,2]

[1]*Queen's University, Biomedical and Molecular Sciences, Kingston, Canada,* [2]*St Lawrence College, School of Baccalaureate Nursing, Kingston, Canada*

Background: Blood collection is a critical step in studying coagulation in mice. Cardiac puncture is a standard effective method for collection that provides a good quality and relatively large blood sample but the procedure requires anesthesia and is terminal thus hindering comparative studies of pre/post intervention or follow up studies. Thromboelastography (TEG) is a global sensitive haemostasis test,

which requires 340ul volume and is used in mice studies and animal models.

Aims: To investigate the feasibility of facial vein sampling for TEG analysis in mice and to compare the coagulation results to those obtained via cardiac puncture.

Methods: Citrated whole blood samples (340 uL) were obtained from 10 mice; 12 weeks via cardiac puncture and from 8 other mice via facial vein. Blood was re-calcified with 20ul CaCl2 (0.2 mol/l) and analyzed using TEG 5000, Haemoscope, according to the manufacturer's instructions. Major coagulation parameters were analyzed including R time, alpha angle, K time, MA; clot's maximum strength and CI; the overall clotting activity. Student *t* test was used to compare TEG parameters in the two different groups. P value of < 0.05 was considered a cutoff to define significance.

Results: Facial vein sampling allowed smooth easy blood withdrawal and was well tolerated by mice. There was no significant difference in any of the TEG parameters when cardiac samples were compared to facial ones. The average R time was 7.8±4.6 and 5.4±4.1; p=0.2 in cardiac and facial samples respectively. The average K time was 3.0±1.7 and 3.1±3.2 p=0.4. The average alpha angle was 55.9 ±15.6 and 61.0±18.4 p=0.5. The average MA was 64.3±14.0 and 62.0±12.9 p=0.8. The average CI was 2.4±2.6 and 2.5±1.8 p=0.9.

Conclusions: Our results demonstrate that facial vein sampling does not affect TEG parameters and can be used as an alternative to cardiac puncture in studies where follow up or post intervention is required.

PB 085 | Quantitative Proteomics of Plasma-derived Macrovesicles Identifies Early Systemic Protein Markers of a Hemophilic Bleed in Rats

I.R. León[1], K. Roepstorff[1], B. Vandahl[1], M.R. Larsen[2], M. Kjelgaard-Hansen[1]

[1]*Novo Nordisk A/S, Global Research, Maaloev, Denmark,* [2]*University of Southern Denmark, Biochemistry and Molecular Biology, Odense, Denmark*

Background: Diagnosis of a hemophilic bleed is currently based on unspecific clinical symptoms. Objective systemic biomarkers of bleeding would provide a clinical tool for diagnosis, and supply valuable information in clinical trials aimed at prevention of bleeding. However, it has proven difficult to identify early (< 6h) systemic biomarkers of a hemophilic bleed in plasma. Cellular communication via macrovesicles is a rapid event, and these may carry biomarkers for diseases.

Aims: To identify early systemic signals of a hemophilic bleed by plasma macrovesicle proteomics.

Methods: Blood from hemophilic rats (n=5) was collected prior to and at different time points after an induced knee-bleed (0.5, 2, 4, 6, 24 and 48h). Membrane protein fractions from exosome (EX) and microparticles (MP) from plasma were prepared for each time point. iTRAQ labeling and off-line Hydrophilic Interaction Liquid Chromatography in combination with high accuracy mass spectrometry was used to identify and quantify individual proteins. Subsequent clustering analysis was used to identify temporal patterns of protein regulation in the two distinct vesicle fractions.

Results: In total, 225 and 703 proteins were identified in the EX and MP fraction, respectively. The difference in the number of identifications may in part be due to higher purity of the EX fraction compared to the MP fraction. Twelve protein clusters were identified in the EX fraction, of which three represented proteins with very early response to the bleed (at 0.5 and 2h). The proteins with increased concentration at 0.5h are known to be involved in platelet activation, cytoskeletal activity, coagulation activity on cell surface, and EX release. The proteins increased at 2h are known to be involved in inflammation and acute phase responses.

Conclusions: Our study suggested very early temporal regulations in the plasma macrovesicle composition post hemophilic bleeding, which may potentially guide to early systemic biomarkers of bleeding in hemophilia.

PB 086 | Improved Anticoagulant Effect of Fucosylated Chondroitin Sulfate Orally Administered as Gastro-resistant Tablets

R.J. Fonseca[1], I.D. Sucupira[2], S.-N.M.C.G. Oliveira[2], G.R.C. Santos[2], P.A.S. Mourão[2]

[1]*Universidade Federal do Rio de Janeiro, Instituto de Ciências Biomédicas, Rio de Janeiro, Brazil,* [2]*Universidade Federal do Rio de Janeiro, Instituto de Bioquímica Médica, Rio de Janeiro, Brazil*

Background: Fucosylated chondroitin sulfate is a potent anticoagulant polysaccharide extracted from sea cucumber. Its anticoagulant activity is attributed to the presence of unique branches of sulfated fucose. Although this glycosaminoglycan exerts an antithrombotic effect following oral administration, high doses are necessary to achieve the maximum effect. The diminished activity of FucCS following oral administration is likely due to its degradation in the gastrointestinal tract. However, gastro-resistant tablet formulation may help limit the degradation of FucCS in the gastrointestinal tract.

Aims: We compared the effects of FucCS administered as an aqueous solution and as gastro-protective tablets on coagulation, thrombosis, bleeding and blood pressure. Dabigatran, Rivaroxaban and Apixaban were used in these same assays as positive control drugs.

Methods: Antithrombotic activity in rats was assessed using thromboplastin as the thrombogenic stimulus in the vena cava model. Arterial thrombosis was assessed using Rose Bengal photochemical injury model. Ex vivo anticoagulant action was assessed using thrombin time and anti IIa activity. Bleeding tendency was evaluated using bleeding time model. Statistical analysis was evaluated using ANOVA.

Results: Experiments using animal models of arterial thrombosis demonstrated that FucCS delivered as gastro-protective tablets produced a potent antithrombotic effect, whereas its aqueous solution was ineffective. However, there was no significant difference between the effects of FucCS delivered as gastro-resistant tablets or as aqueous

solution in a venous thrombosis model, likely due to the high dose of thromboplastin used. New oral anticoagulants tested in these experimental models for comparison showed significantly increased bleeding tendencies.

Conclusions: Our study provides a framework for developing effective oral anticoagulants based on sulfated polysaccharides from marine organisms. The present results suggest that FucCS is a promising oral anticoagulant.

PB 087 | Three Point Ligation of Inferior Vena Cava in Rats: Experimental Approach to Study Mechanism of Venous Thrombosis

N. Gupta[1,2], A. Sahu[1], M.Z. Ashraf[1]

[1]*Defence Institute of Physiology and Allied Sciences, Defence Research & Development Organisation, Genomics Division, Delhi, India,* [2]*Jamia Millia Islamia, Dept of Biosciences, New Delhi, India*

Background: Venous thromboembolism (VTE) is an important issue of health care concern. Conditions of reduced blood flow are associated with localized hypoxic milieu, and deep vessel injury remains an uncommon feature during venous thrombus formation. Current understanding about the pathophysiology of venous thrombosis (VT) is often limited by lack of an appropriate model system that could mimic the actual clinical scenario. Although several techniques to restrict blood flow by ligation exist under clinical experimentation, however an effective approach to initiate thrombogenesis in the absence of an overt endothelial damage still remains to be established.

Aims: To introduce certain modifications in the inferior vena cava (IVC) ligation technique and characterize a flow restriction based rat model for venous thrombosis (VT).

Methods: For the proposed model, ligation was introduced at three particular sites i.e. the IVC below the left renal vein, left iliolumbar branch and right iliolumbar branch of male SD rat. This three point ligation technique produced a thrombus which closely resembled the clinical settings.

Results: Compared to the already existing IVC models, the current procedure was relatively simple, reproducible, involved minimal surgical damage and had a high success rate. Taking the advantage that restricted blood flow is associated with a hypoxic milieu; we blocked the transcriptional activity of hypoxia inducible factors-1(HIF-1α) using pharmacological inhibitor- CAY10585, and demonstrated that HIF-1α partly regulates venous thrombus formation. The endothelial injury was identified as a response to hypoxic milieu, accompanied by infiltration of innate immune cells and platelets in case of VT.

Conclusions: The three point ligation based model produces clinically relevant thrombus and can be used to study the mechanism of localized hypoxia induced VT. The proposed model provided evidence for the sequence of events: Reduced blood flow → hypoxia→ endothelial injury→ VT.

PB 088 | Activated factor VII for Hemostasis Enhancement in Factor XI and XIa Inhibitor-treated Primates

M. Wallisch[1,2], A. Buchmüller[3], J. Johnson[2], E.I. Tucker[1,2], M.T. Hinds[2], A. Wilmen[3], V. Laux[3], A. Gruber[1,2]

[1]*Aronora, Inc., Portland, United States,* [2]*Oregon Health & Science University, Department of Biomedical Engineering, Portland, United States,* [3]*Bayer AG, Wuppertal, Germany*

Background: Monoclonal antibodies against FXI or FXIa provide long-lasting antithrombotic anticoagulation without detectable hemostasis impairment in animal models of thrombosis. The development and use of such antibodies may offer safe antithrombotic therapy or prophylaxis, however, reversal might be deemed desirable in cases of clinically relevant bleeding. Since the extrinsic pathway bypasses FXI, treatment with the hemostatic enzyme, FVIIa, may effectively terminate the antihemostatic effect, if any, of FXI inhibition.

Aims: Evaluate the hemostatic and procoagulant effects of recombinant FVIIa (NovoSeven®) in baboons that were anticoagulated with recombinant human FXI(a)-inhibitor antibodies, Bay1213790 and Bay1831865.

Methods: Animals received bolus *i.v.* injections of either Bay1213790 (3-4 mg/kg) or Bay1831865 (0.25 mg/kg), followed by an *i.v.* injection of NovoSeven® (210 or 420 µg/kg) 1-2 hours later. To evaluate anticoagulation activated partial thromboplastin time (aPTT), prothrombin time (PT) were measured in plasma, and non-activated thromboelastometry (ROTEM) was performed in whole blood. Template skin bleeding time (Surgicutt®) and blood loss were measured to assess primary hemostasis impairment.

Results: Both antibodies increased aPTT to >1.7-fold baseline, and whole blood clotting time (CT) during thromboelastometry to >2-fold, but they did not alter the hemostasis markers, PT, bleeding time, and bleeding volume. NovoSeven® shortened both PT and aPTT and normalized the CT. Procoagulant effects lasted for up to 4 hours and were back to pre-reversal anticoagulation levels the next day.

Conclusions: Our data suggest that administration of NovoSeven® reduces the anticoagulant effect of FXI(a) inhibitors, and promotes the hemostatic extrinsic pathway activity. Therefore, it may be useful to support the rapid cessation of bleeding during FXI(a) inhibitor anticoagulation without complete elimination of the antithrombotic effect of FXI(a) inhibition.

PB 089 | The Electrolytic IVC Model of Venous Thrombosis (EIM): A Cost-effective, Highly Reproducible, and Easily Controlled Tool to Investigate Venous Thrombosis under Flow Conditions

O.R. Palmer[1], M.E. Shaydakov[2], J.M. Greve[1], J.A. Diaz[2]

[1]*University of Michigan, Biomedical Engineering, Ann Arbor, United States,* [2]*University of Michigan, Department of Surgery, Vascular Surgery, Ann Arbor, United States*

Background: Animal models are critical to study the biology of venous thrombosis (VT) *in vivo*. The electrolytic model (EIM) was developed to simulate VT in the most likely clinical scenario, i.e. under blood flow conditions.

Aims: EIM has been criticized for the high cost and lack of fibrinolysis characterization. We aimed to decrease cost and further characterize the model.

Methods: VT was induced in C57BL/6 mice aged 10-12 weeks. Electric current was delivered either by the previously described stimulator or a simple precision voltage-to-current converter (VIC) powered by a standard direct current power supply. VIC was validated by measuring thrombus weights (TW) at Day 2 post-VT. Another group of mice was harvested at Day 2, 6, and 11 to investigate the fibrinolytic system. In a separate group of animals the dynamics of thrombus volume was assessed *in vivo* by MRI.

Results: VT was achieved in all mice without complications. The use of a VIC resulted in 90% cost reduction. TWs were similar between VIC and stimulator (19.4±1.8mg vs. 21.5±0.6mg, *p=NS*). Variation in TW reproduced by two investigators (MES, ORP) was less than 10%. Positive immunostaining for plasminogen was observed, with decrement from Day 2 to Day 11, arranged from periphery to the center of the thrombus. PAI-1 was overexpressed (*p< 0.05*), with a down-regulation trend of t-PA (*p=NS*) at Day 2 (Fig. 1). The opposite PAI-1 to t-PA relationship was observed at Day 11 (Fig. 1). Modification of current or time significantly reduced thrombus size (*p< 0.0001*) as assessed by MRI (Fig. 2).

Conclusions: The EIM is highly reproducible and may be performed at minimal cost using a VIC. The fibrinolytic system is suppressed at the acute stage of VT, showing impaired ability to respond to thrombogenesis in the vein wall. The desired thrombus size can be easily manipulated by current and time adjustments. Future studies will target the dynamics of VT composition using MRI, ultrasound and histology.

Figure 1

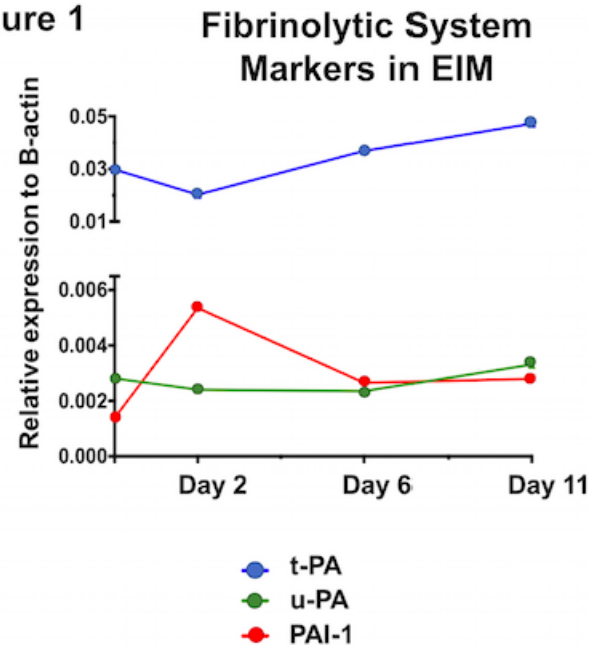

FIGURE 1 Vein Wall qRT-PCR for PAI-1, t-PA and u-PA. The PAI-1 upregulation during acute VT coincides with the downregulation of t-PA.

Figure 2

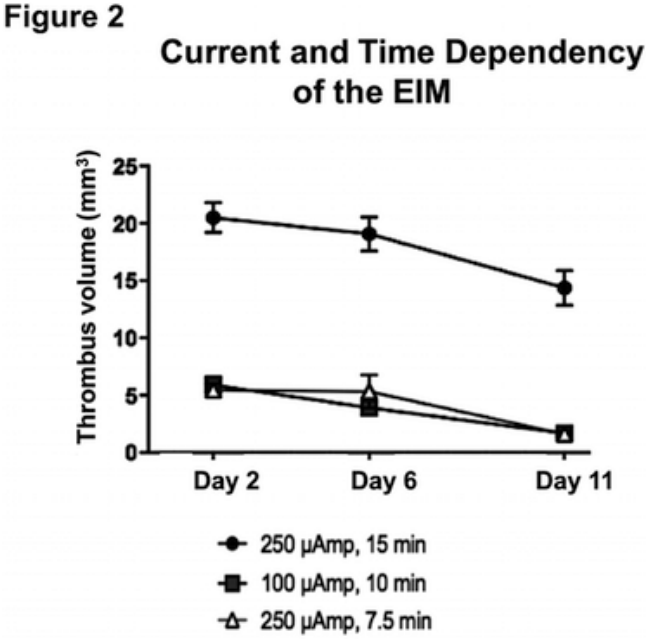

FIGURE 2 Thrombus volume over time was determined by manual tracing of contiguous axial MRI images, showing the current and time dependency of the EIM.

PB 090 | A Functional and Thromboelastometric-based Micromethod for Assessing Crotoxin Anticoagulant Activity and Antiserum Relative Potency against Crotalus Durissus Terrificus Venom

B. Prezoto[1], A. Tanaka-Azevedo[2], J. Kapronezai[3], J. Marcelino[4], J. Mota[1], M. Rocha[2], C. Silva[2], N. Oguiura[3]

[1]Butantan Institute, Pharmacology, Sao Paulo, Brazil, [2]Butantan Institute, Sao Paulo, Brazil, [3]Butantan Institute, Ecology and Evolution, Sao Paulo, Brazil, [4]Butantan Institute, Imunology, Sao Paulo, Brazil

Background: Substitution of rodent lethality assay (RLA) by means of in vitro techniques to assess antivenom potency is relevant to achieve the ‚3Rs' goals on animal experimentation. When one key lethal toxin is identified, then the ability of antivenom to neutralize some of its biological and measurable activities is likely to correlate with lethality neutralization. Crotoxin, toxin responsible for the lethality of crotalic venom, presents anticoagulant activity in vitro.

Aims: Our objective was to adapt sensitive thromboelastometry assay for assessing relative potency of anti-crotalic serum (ACS) in neutralizing anticoagulant effect.

Methods: 280 µL of citrated chicken plasma samples (CPS) were simultaneously incubated (10 min at 37°C) before recalcification with (1) ellagic acid and phospholipid-based activator (EAPA), semilogarithmic doses of (2) purified crotoxin, or (3) ACS.

Results: Clotting time (CT) values of control recalcified CPS are strongly prolonged (1698 ± 189 s, n = 8). EAPA dose sufficient to short CT to 750 s was defined as mean coagulant dose (MCD). Crotoxin

prolonged dose-dependently CT related to MCD of EAPA and 60±13 ng was considered as its mean anticoagulant dose (MAD), displacing CT to 1050 s. In our conditions, 100±18 nanoliters of one specific ACS batch neutralized incoagulability induced by 5MAD of crotoxin (300 ng), reestablishing CT to 1050 s.

Conclusions: Our results show the sensitivity of our method, being the previous potency determined by the in vivo RLA assay in which 1 mL of ACS neutralized 1.8 mg of crotalic venom. Deficiency of factor XII and slow clotting process in chicken plasma turn suitable the elaboration of a dose-response curve, in contrast with short recalcification time of mammalian plasma. Blood samples are collected without significant animal distress and this assay would be useful to substitute rodents in intermediary steps of ACS production. Moreover, it is possible to reduce the amount of toxin and ACS used.

PB 091 | Hemostasis and Fibrinolysis during Learning in Rats

K. Nikolskaya, L. Podorolskaya

Moscow State University, Biolodical Faculty, Moscow, Russian Federation

Background: Investigation of learning processis is enormous problem. In particularity it realizes in different experimental models. Our model permits to study various sides of learning in rats: psycho-emotional state, mental ability and also physiological and biochemical processes, following learning process, including state of hemostasis and fibrinolysis, that are very sensitive to intellectual and emotional loads.

Aims: The aim - to study parameters of hemostasis and fibrinolysis in rats in model of learning to solve complex food-seeking task.

Methods: 120 Wistar rats were learning to solve compound food-seeking task in open labyrinth by special method during 20 seances. Blood probes were takens before experiment and after finishing, and biochemical parameters of hemostasis and fibrinolysis were defined. Control rats (n=50) were in natural conditions of experimental room and were not subjected to intellectual loads.

Results: There were not observed essential changes of hemostasis and fibrinolysis parameters in whole group of experimental animals compared to control. AT111 and APTT level decreased by 8,5%, that demonstrated slight hypercoagulation. But there was simultaneously revealed compensation by fibrinolysis reaction: fibrinolytic activity raised by 13%, t-PA activity increased by 16,5% (p< 0,1). It was evident learning process did not cause sharp biochemical events as it represented natural and necessary action in rat's population. However only 40% of rats had learned to solve the task, 60% had not. Hemostasis and fibrinolysis were different in successful and unsuccessful rats. APTT and AT111 were correspondingly 42±5 c. and 92±10,1% in successful animals and 30,1±4,1c. and 81±7,6% in unsuccessful rats. (p< 0,05). t-PA was 45±4 C.U. in learned and 23±3 C.U. in unlearned rats (p< 0,05)

Conclusions: Unsuccessful learning led to development of moderate hypercoagulable state and possibly prethrombotic situation compared to rats solved the task. It is great favourable factor-talent to learning.

PB 092 | In the Cath Lab - A Novel Rabbit Bleeding Model

I. Meyer, J. Strassburger, A. Trabandt, A. Gaefke

BAYER AG, Wuppertal, Germany

Background: Even though cardiac catheterization is a minimal invasive intervention, a sufficient anti-coagulation and anti-platelet therapy has to be considered; and thrombosis versus bleeding risk needs to be deliberated. Patients undergoing cardiac catheterization typically receive dual anti-platelet therapy (DAPT), a combination of acetylsalicylic acid and $P2Y_{12}$-inhibition, with additional anti-coagulation treatment. This standard of care (SOC) leads to an increased bleeding risk during catheter lab examination, e.g. percutaneous coronary interventions (PCI). Increased bleeding can be monitored at the arterial puncture site and is one of the unwanted adverse events observed in the cath lab.

Aims: Deriving and adopting a novel lapine arterial bleeding model, to mimick the cath lab situation as an experimental setting in rabbits.

Methods: The lapine A. femoralis is prepared and incised via a 27 gauge needle, representing the approximate vessel-needle ratio during PCI. The puncture site is sealed with a pneumatic silicon vessel occluder for 1 or 3 minutes, respectively. The occlusion pressure is adjusted and controlled via a transonic flowprobe, to prevent stasis induction. The outcome is defined as incidence of bleeding and is controlled intrinsically via the ear bleeding time. Complementary to the animal model the procoagulant capacity of catheter material was confirmed in vitro which can be reversed by anticoagulants dose dependently.

Results: 40 percent of Bivalirudin on top of DAPT treated animals, still bleed after 3 minutes of compression. In the group of additional Enoxaparin treatment, 83% of the tested animals bleed even after 3 minutes of puncture-site occlusion. In comparison, control animals with DAPT only treatment do not bleed after 3-minutes-sealing.

Conclusions: Taken together this novel arterial bleeding model successfully simulates bleeding during PCI and demonstrated that additional anticoagulation on top of DAPT extends bleeding at the puncture site, in comparison to DAPT only.

PB 093 | Von Willebrand Factor Effects Vessel Conformation and the Expression of Integrin $\alpha V\beta_3$ and Ang-2 in the Porcine Female Reproductive Tract

H. Allerkamp[1], S. Lehner[1], M. Ekhlasi-Hundrieser[1], C. Detering[1], C. Pfarrer[2], M. von Depka[1]

[1]Werlhof-Institut für Hämostaseologie GmbH, Hannover, Germany, [2]University of Veterinary Medicine Hannover, Institute for Anatomy, Hannover, Germany

Background: Besides its role in coagulation, von Willebrand Factor (VWF) was shown to be involved in angiogenesis, and defects of this pathway might play a role in miscarriage. For this reason, VWF, Integrin $\alpha V\beta_3$ (ITG) and Angiopoietin-2 (Ang-2) were analyzed by immunohistochemistry (IHC) of reproductive tissues in a pig model of Von Willebrand Disease (VWD) type 3 and type 1.

Aims: We aimed to localize VWF and other angiogenic factors in the female reproductive tract of pigs affected by VWD.

Methods: Uterus, oviduct and ovary tissue samples were collected from five mature pigs. Of these, one was affected by VWD type 3, two were heterozygous carriers (HC, type 1) and two were wildtype (WT) individuals. Hematoxylin-eosin staining was implemented for morphological evaluation. Subsequently, IHC was performed to compare the expression of VWF, INT, and Ang-2 among the different genotypes.

Results: IHC showed almost no VWF expression in all examined tissues of the VWD type 3 pig.

For ITG the uterine epithelium and glands of the type 3 pig showed strong granular intracellular staining while the epithelial and glandular cells of the HC pigs were stained diffuse and moderately. The apical cell membrane of epithelium and glands of the WT pigs showed the strongest staining.

For Ang-2, the apical cell membrane of the uterine and oviduct epithelium of the VWD pig showed a clear immunoreaction, which was rarely seen in the HC and WT pigs.

Conclusions: The results of our study confirm effects of VWF on angiogenesis. The staining pattern of ITG can be explained by increased internalization of the protein when VWF is missing in contrast to its stabilization on the cell surface by VWF in WT pigs. The staining pattern of Ang-2 in the VWD pig might be a result of a steady release due to missing of VWF-dependent Weibel-Palade-Bodies, which serve as storage organelles for Ang-2.

PB 094 | Antithrombotic *In-vivo* Effects of Quercetin-tetra-sulphate (QTS) Isolated from *Flaveria bidentis* in an Experimental Thrombosis Model in Mice

H.A. Guglielmone[1], A.M. Agnese[2], S.G. Nuñez-Montoya[2], J.L. Cabrera[2], G.R. Cuadra[3]

[1]Universidad Nacional de Córdoba, Bioquímica Clínica (CIBICI-CONICET), Cordoba, Argentina, [2]Universidad Nacional de Córdoba, Farmacia, Cordoba, Argentina, [3]Universidad Nacional de Córdoba, Farmacología, Cordoba, Argentina

Background: Quercetin 3,7,3´,4´-tetrasulphate (QTS) presents important anticoagulant, antiplatelet and pro-fibrinolytic actions besides inhibitory effects over tissue factor expression in human monocytes.

Aims: In order to evaluate the antithrombotic properties of QTS, this study was designed to determine the *in-vivo* effects of sulfated flavonoids in an experimental thrombosis model in mice.

Methods: QTS was purified from an alcohol/water extract (1: 1) of *Flaveria bidentis* leaves by using a Sephadex G10 column and water as mobile phase. One hour before the thrombotic challenge (tail vein injection of 150 µg of collagen + 1.8 µg of epinephrine), five groups of 10 C57BL6 male mice weighing 28±2 gr received different intraperitoneal (i.p.) doses of QTS (10, 25, 50 or 100 mg/kg, respectively) or i.p. aspirin (20 mg/kg) (antithrombotic agent), as protected controls. Control animals (n = 25) received i.p. vehicle in the same volume as QTS in treated mice. The number of dead or paralyzed mice was evaluated until 15 minutes after injection of the thrombogenic substance and percent protection rate (PR) was calculated by the equation [1-(dead+paralyzed) /total]x100.

Results: PRs were 100, 90, 70 and 20% for 100, 50, 25 and 10 mg/Kg of QTS, respectively. In positive and negative controls, the PRs were 70 and 4%, respectively. Histological studies showed pulmonary thrombi in a dose-dependent manner.

Conclusions: Taken altogether, our results suggest that QTS could be a promising candidate as antithrombotic agent and that this effect could be associated with multiple effects of this compound over the blood coagulation system.

PB 095 | Increase of Fibrinolytic and Anticoagulant Activity by Per Os Administration of Proteinase Complex Longolytin in Rats

T. Sharkova, L. Podorolskaya

Moscow State University, Biolodical Faculty, Moscow, Russian Federation

Background: Longolytin is proteinase complex from imperfect fungi Arthrobotrys longa and has been successfully studied as thrombolytic substance. There are some favorable factors: simplicity of obtaining, little cost and absence of toxicity - that stimulate to search another way of it using, for example as preparation of 'enzymatic therapy'.

Aims: The aim is to use longolytin by per os administration in rats and to reveal influence on hemostasis and fibrinolysis.

Methods: 120 white rats were introduced by 0,1 ml. 3% solution of longolytin in glycerol activity 30-40 C.U. every day during 7 days. There were determined parameters hemostasis and fibrinolysis on 9, 16, 22 days of experiment. Control animals got glycerol (70 rats).

Results: There were observed increase of anticoagulant and fibrinolytic activities in experimental rats: APTT raised on 32%, fibrinolytic activity by euglobulin clot lysis time elevated on 28%, t-PA activity increased in 1,5 times after 9 and 16 days. Fibrinogen level did not exchange. Control animals had not changes in their parameters. These changes prolonged during 16 days and weakened gradually to 20 day of experiment. There were not observed reversed effect in 20 days. Intravenous thrombin infusion realized to animals after experiment finished for determine of its antithrombotic state in blood. 36% of experimental rats died and 66% of control.

Conclusions: Longolytin can create in blood prolonged elevated fibrinolytic and anticoagulant state as necessary defense against thrombosis in different prethrombotic situations.

PB 096 | The Anti-factor XIa Antibody BAY 1213790 is a Novel Anticoagulant that Shows Strong Antithrombotic Efficacy without an Increased Risk of Bleeding in Rabbit Models

A. Buchmueller[1], A. Wilmen[2], J. Strassburger[1], M.V. Schmidt[1], V. Laux[1]

[1]Bayer AG, Drug Discovery, Cardiovascular, Wuppertal, Germany, [2]Bayer AG, Drug Discovery, Protein Engineering & Assays, Cologne, Germany

Background: Coagulation factor XI (FXI) contributes to the development of thrombosis but plays only a minor role in hemostasis and is therefore an attractive target for antithrombotic therapy. Inhibition of FXIa offers the potential to reduce the risk of thrombosis without increasing the risk of bleeding.

Aims: To evaluate the *in vitro* pharmacology of the novel anti-FXIa antibody BAY 1213790 in human plasma and to assess its *in vivo* antithrombotic properties and hemostatic risk profile in rabbits.

Methods: The *in vitro* properties of BAY 1213790 were analyzed using a biochemical FXIa assay, standard clotting assays (activated partial thromboplastin time [aPTT] and prothrombin time [PT]) and a thrombin generation assay (0.1 pM tissue factor) in human plasma. Antithrombotic efficacy of BAY 1213790 was assessed in a rabbit model of arterial thrombosis induced by ferrous chloride. The hemorrhagic effects of BAY 1213790 were evaluated in rabbit models of ear, gum and liver bleeding. BAY 1213790 was administered by intravenous bolus 15 minutes before the injury/surgery.

Results: BAY 1213790 inhibited human FXIa activity with an IC_{50} of 2 nM. At a concentration of 20 nM, BAY 1213790 was associated with a 1.5-fold prolongation of aPTT; there was no significant effect on PT. Thrombin formation was inhibited with an IC_{50} (peak) of 35 nM. In the *in vivo* rabbit models, BAY 1213790 inhibited thrombus formation with an ED_{50} of 0.2 mg/kg without increasing the ear and gum bleeding time. When administered with tissue plasminogen activator (0.1 mg/kg/h), which prolongs ear bleeding time by 1.7-fold, BAY 1213790 (3 mg/kg) did not further increase the bleeding time. In a rabbit liver incision model, BAY 1213790 (10 mg/kg) had no effect on liver bleeding time or volume.

Conclusions: BAY 1213790 is a potent inhibitor of FXIa that shows strong antithrombotic efficacy without increasing the risk of bleeding, therefore offering potential as an anticoagulant with a broad therapeutic window.

PB 097 | Concomitant Administration of Factor IX Replacement Therapy with Immunosuppression Decreases Immunogenicity in Hemophilia B Mice Expressing a Human Major Histocompatibility Complex

Y. Abajas[1], J. Sun[2], G. Hu[2], S. Vanleeuwen[2], P. Monahan[3]

Background: The development of neutralizing alloantibodies directed against factor IX following replacement therapy remains a poorly understood and potentially devastating complication of hemophilia B. Due to the clinical rarity (~2-4%) of factor IX inhibitors and their unique complications including life-threatening allergic reactions and resistance to traditional strategies for immune tolerance, novel approaches for promoting and maintaining tolerance is critical.

Aims: To examine the potential of pharmacologic approaches to promote and maintain an immunologic tolerance when the initial factor IX exposure occurs in the setting of a high risk.

Methods: Factor IX knockout (FIX-/-) mice engineered to express the common human MHC II DR B1*1501 allele instead of mouse MHC II (n=5/group) were administered FIX weekly via the subcutaneous route at a dose of 200 IU/kg for 7 doses. Immunosuppression with anakinra (an IL-1 receptor antagonist) and etanercept (a TNF-alpha inhibitor) were each administered at a dose of 10mg/kg weekly via subcutaneous injection with a control group for comparison. FIX Bethesda inhibitor antibody was assessed at weeks 2, 3, 4 and 8.

Results: 25% of mice that received immunosuppression with either anakinra or etanercept developed low-titer FIX inhibitors by week 6 (2.2 BU/ml and 1.2 BU/ml, respectively). In contrast, 75% of mice in the control group that received weekly SC FIX replacement with no immunosuppression developed FIX inhibitors by week 6 (mean 6.2 BU/ml, range 0.6-20 BU/ml).

Conclusions: Immunosuppression administered concomitantly with FIX replacement therapy during a known high risk event may blunt the immune response and reduce the risk of developing a high titer inhibitor.

PB 098 | Factor VIII Memory Immune Responses, von Willebrand Factor Makes a Difference

J. Chen, J. Schroeder, X. Luo, Q. Shi

Medical College of Wisconsin, Blood Research Institute, Children's Research Institute, Milwaukee, United States

Background: Immune tolerance induction (ITI) with aggressive infusion of FVIII is the current strategy to eradicate FVIII inhibitory antibodies (inhibitors) and restore normal FVIII pharmacokinetics in hemophilia A patients with inhibitors. Whether the use of FVIII products containing VWF will affect the efficacy of ITI is still controversial.

Aims: To explore the impact of VWF on FVIII memory immune responses in hemophilia A mice.

Methods: The T cell proliferation assay and cytokine profile analysis were used to study F8-primed CD4 T cells. The memory B cell-based ELISPOT assay was used to explore F8-specific memory B cells. Adoptive transfer of memory B cell pools into NSGF8KO mice were used as an *in vivo* model to further evaluate the impact of VWF on FVIII memory immune responses.

Results: When $CD4^+$ T cells from primed $F8^{null}$ mice were restimulated with rhF8 plus rhVWF *in vitro*, the percentages of daughter $CD4^+$ T cells were significantly decreased in both the 1 U/ml and 10 U/ml rhF8 treatment groups compared to the groups cultured with rhF8 only (10.4±7.1% and 15.8±8.4% vs 14.0±7.5% and 21.5±10.3%, respectively). The levels of IFNg and IL10 in the rhF8 plus rhVWF groups were significantly lower than in the rhF8 groups. When memory B cell pools from primed $F8^{null}$ mice were cultured with 0.05 U/ml or 1 U/ml rhF8 with or without rhVWF to induce memory B

cell differentiation into antibody secreting cells (ASCs), the number of ASCs in the rhF8 plus VWF groups were significantly less than in the rhF8 groups (3.9±1.7 and 2.2±0.8 vs 44.8±3.1 and 89.5±9.3 ASCs/10^6 cells, respectively). When memory B cell pools were transferred into NSGF8KO mice followed by rhF8 immunization with or without rhVWF, the titers of anti-F8 inhibitors and total IgG in the rhF8 group were significantly higher than in the rhF8 plus rhVWF group (45.9±18.9BU/ml and 5728±2039 vs 23.9±11.6 BU/ml and 2840±1022, respectively).

Conclusions: Our data demonstrate that VWF attenuates FVIII memory immune responses in hemophilia A mice.

PB 099 | New Insights into FV-short Function and Interaction with TFPIα

T. Petrillo, R.M. Camire

The Children's Hospital of Philadelphia, Colket Translational Research Bldg, Pediatrics-Division of Hematology, Philadelphia, United States

Background: Factor V-short is a FV splice variant present at low levels (< 2%) in normal plasma. It lacks residues 756-1458 in the B-domain, which includes the basic region (BR). In full length FV, the BR in concert with acidic region 2 (AR2; 1493-1537) functions as an autoinhibitory unit to keep FV inactive. In FV East Texas bleeding disorder, FV-short is elevated due to enhanced splicing and this paradoxically increases TFPIα. TFPIα through its C-terminal BR forms a high affinity complex with FV-short.

Aims: To examine how TFPIα via its BR regulates FV and FV-short.

Methods: We expressed and purified FV-short and its thrombin resistant variant QQ (709/1545Q) and characterized their interaction with a TFPIα-BR fragment or a full length TFPIα variant-R107A.

Results: In a purified system, we found that FV-short, QQ, and FVa were functionally equivalent when assembled in prothrombinase. FV-short and QQ activity was blocked in the presence of TFPIα-BR while there was no effect on FVa. Fluorescence anisotropy experiments revealed that TFPIα-BR bound with high affinity (Kd< 1 nM) to FV-short with no detectable binding to FVa. In a thrombin generation assay (TGA) using FV-short, both TFPIα-BR and TFPIα-R107A reduced TG. This was not only due to decreased in FV-short procoagulant function but also to delayed cleavage at R1545 as confirmed by the higher sensitivity of the QQ variants to both TFPIα-BR and TFPIα-R107A and by data from western blotting experiments. In contrast to FV-short, there is no detectable binding of TFPIα-BR to plasma-derived FV. However the BR fragment reduced TG in normal plasma. Simultaneous fluorescence and western blotting experiments revealed that TFPIα-BR only binds partially cleaved forms of FV and binding is eliminated once AR2 is removed.

Conclusions: These data show that TFPIα through its BR downregulates TG by engaging forms of FV with an available AR2, such as FV-short and partially proteolyzed FV and AR2 removal by cleavage at 1545 eliminates its ability to impact prothrombinase assembly.

PB 100 | Structural and Functional Characterization of Anticoagulant TIX-5, the Specific Inhibitor of the Activation of FV by FXa

A. Maag[1,2], P. Sharma[1], T. Schuijt[1], W. Kopatz[3], D. Kruijswijk[1], A. Marquart[4], T. van der Poll[1], T. Hackeng[5], G. Nicolaes[5], J. Meijers[3,4], M.H.A. Bos[6], C. van ,t Veer[1]

[1]Academic Medical Center, Center of Experimental and Molecular Medicine, Amsterdam, The Netherlands, [2]Leiden University Medical Center - Department of Thrombosis and Hemostasis, Leiden, The Netherlands, [3]Academic Medical Center, Experimental Vascular Medicine, Amsterdam, The Netherlands, [4]Sanquin Research, Plasma Proteins, Amsterdam, The Netherlands, [5]Maastricht University / Cardivascular Research Institute Maastricht (CARIM), Maastricht, The Netherlands, [6]Leiden University Medical Center – Division of Thrombosis and Hemostasis, Leiden, The Netherlands

Background: The prothrombinase complex consists of factors Xa (FXa) and Va (FVa) on an anionic phospholipid surface and it converts prothrombin into thrombin. Both coagulation factors require activation prior to complex assembly. The specific anticoagulant tick inhibitor of factor Xa towards factor V (TIX-5) inhibits the activation of FV by FXa.

Aims: To unravel the structure-function relationships of TIX-5 that define its mechanism of action.

Methods: The TIX-5 structure was modeled based on homology with the Der F7 allergen, and point mutations were introduced at predicted interaction sites. TIX-5 variants were expressed in *Drosophila* cells, purified by affinity and ion exchange chromatography, and tested for their anticoagulant activity in plasma using the Calibrated Automated Thrombogram (CAT). Interactions of TIX-5 variants with an anionic phospholipid layer were determined by Surface Plasmon Resonance analysis.

Results: The TIX-5 predicted structure was elongated and consisted of 2 beta sheets wrapped around the C-terminal α2 helix. At one end of the structure, two hydrophobic loops were predicted with potential phospholipid binding properties. On the other end, a negatively charged area which potentially interacts with FV and a predicted protein binding site were located. CAT analysis revealed that mutations at both, the negatively charged area and protein binding site, led to decreased anticoagulant activity of TIX-5. Mutations at the predicted phospholipid interaction site led to total loss of anticoagulant activity. Consistently, these mutations also resulted in decreased phospholipid binding.

Conclusions: Our structure-function analysis guided by a homology model of TIX-5 indicates correct prediction of its interaction sites. The results are in line with a protein that inhibits activation of FV by FXa on a phospholipid surface. We have identified the crucial phospholipid- and protein-binding sites on TIX-5 that will aid our understanding of the importance of the FXa-mediated activation of FV in coagulation.

PB 101 | Inhibition of Contact Activation by Histidine Rich Glycoprotein is Mediated by its Histidine-rich Domain

T. Truong[1,2], A. Stafford[2], B. Leslie[2], J. Fredenburgh[2], J. Weitz[2]

[1]McMaster University, Medical Sciences, Hamilton, Canada, [2]Thrombosis & Atherosclerosis Research Institute and McMaster University, Medicine, Hamilton, Canada

Background: We have shown that histidine-rich glycoprotein (HRG) regulates the contact system by binding factor (f) XIIa with high affinity and inhibiting fXII autoactivation and fXI activation. In addition, HRG also binds nucleic acids and polyphosphate and attenuates their capacity to activate the contact system.

Aims: To identify the domain in HRG responsible for binding to fXIIa.

Methods: HRG was isolated from human plasma. The $(HHPHG)_4$ peptide was synthesized based on the His-His-Pro-His-Gly (HHPHG) consensus sequence in the histidine-rich region (HRR) of HRG. FXII autoactivation was performed in the presence of dextran sulphate or silica and activity was monitored by chromogenic assay. Clotting in normal or HRG-deficient human plasma was initiated with silica or activated partial thromboplastin reagent (APTT-SP).
