Background: Patients with congenital FVII deficiency can experience increased bleeding after surgery or trauma and in severe cases may suffer spontaneous and life-threatening bleeds. Replacement of FVII is a mainstay of treatment but is limited by the short half-life of current FVII therapies. A novel, recombinant fusion protein linking coagulation FVIIa with albumin (rVIIa-FP) is being developed for congenital FVII deficiency.

Aims: To compare the pharmacokinetic (PK) profile of rVIIa-FP with rFVIIa and pdFVII.

Methods: A Phase I multicenter, randomized, open-label, parallel-arm, single-dose PK study was conducted in patients with congenital FVII deficiency. Patients received their routine FVII product (30 IU/kg pdFVII or 25 µg/kg rFVIIa ([eptacog alfa]), and were then randomly assigned to receive 100 or 300 µg/kg of rVIIaFP. Serial blood samples were taken for up to 24 h after rFVIIa injection, and for up to 48 h after rVIIaFP or pdFVII injection. FVII was measured by the FVII:C or FVIIa assays. Noncompartmental analysis was performed for derivation of PK parameters.

Results: PK analysis was completed for eight patients; three receiving pdFVII and five received rFVIIa prior to treatment with rVIIa-FP (n=5 at 100 µg/kg and n=3 at 300 µg/kg). The mean half-life of rVIIa-FP at doses of 100 and 300 µg/kg, respectively, was up to 3-fold longer compared to rFVIIa (3.87 and 5.10 vs. 1.69 h; FVIIa assay) and was comparable/longer compared to pdFVII (6.4 and 8.08 vs. 6.28 h; FVII:C assay). At 24 h post infusion, 8/8 rVIIa-FP patients had measurable FVIIa activity vs. 0/5 rFVIIa patients. At 48 h, both doses of rVIIa-FP had higher FVII activity than pdFVII.

Conclusions: rVIIaFP had an improved PK profile compared to rFVIIa in patients with congenital FVII deficiency. Due to rVIIa-FP's longer half-life, a bleeding episode may be treated with a single as opposed to multiple injections, and may facilitate prophylactic management of congenital FVII deficiency.

PB 945 | Bone Properties in Children with Hemophilia A: Influence of Target Joint and FVIII Inhibitor

P. Xafaki[1], A. Balanika[2], H. Pergantou[1], O. Papakonstantinou[3], H. Platokouki[1]

[1]'Aghia Sophia' Children's Hospital, Hemophilia Center - Hemostasis Unit, Athens, Greece, [2]General Hospital of Athens ,Asclepeeio Voulas', Computed Tomography Department, Athens, Greece, [3]University General Hospital of Athens ,Attikon', 2nd Radiology Department, Athens, Greece

Background: Hemophilic children are prone to low bone mass accrual.

Aims: To assess bone material properties in hemophilic children, using peripheral quantitative computed tomography (pQCT) and to correlate findings with clinical data.

TABLE 1 impact of FVIII inhibitor in pQCT bone parameters

	Left tibia	Left tibia	Right tibia	Right tibia
	W/o inhibitors	With inhibitors	W/o inhibitors	With inhibitors
CC	251.4±34.1**	154.2±42.0	245.7±40.9**	162.9±37.4
CA	245.4±31.3**	160.0±40.0	240.8±36.8**	169.6±35.3
SSI	1335.7±241.0**	826.0±16.1	1318.8±207.9**	854.4±117.6
CBD	1027.5±29.8**	962.5±47.4	1020.3±30.4**	969.9±47.0
CTHC	3.39±0.32*	2.36±0.85	3.35±0.45*	2.44±0.78
	Left radius	Left radius	Right radius	Right radius
SSI	114.6±24.2*	81.3±14.1	119.8±23.5*	80.0±15.6

** denotes statistically significant differences at p<0.01 * denotes statistically significant differences at p<0.05

Methods: pQCT scan of both radii (at 4% and 60% site) and both tibiae (at 4% and 65% site) were performed in 31 hemophilic A children (severe 24, mean age 11.2 years). Seven subjects (22.6%) had history of inhibitor, 12 at least one leg target joint (6 right) and 5 in hand (3 left). The following parameters were measured: trabecular, total and cortical bone density and content (TBD, ToBD, CBD, TbC, CC), strength-stress index (SSI), and tibial cortical area (CA), inner and outer bone contour length (PERI, ENDO), cortical, periosteum and endosteum circumference (CTHC, PERIC, ENDOC) and mean cortical thickness (CTH).

Results: All parameters matched for age, height and weight. Right radii TBD values were significantly higher than the left (p< 0.015). In 5 elbow target joints subjects, radius TBD values were significantly lower ipsilaterally, than in non-target hand (186.6±60.4 vs 218.6±39.8, p< 0.05). Left hand target joint subjects had significantly lower left radius TBD values in comparison to subjects without hand target joints (155.4±50.3 vs 215.7±37.9, p< 0.05). There was no similar difference in leg target joints group. Bone quality and geometry parameters were significantly lesser in inhibitor versus non inhibitor group, matched for age and height (Table) with statistically significant side-to-side differences for legs and arms and left side predominance.

Conclusions: Our results suggest a low bone quality and strength in all hemophilic children extremities with FVIII inhibitors, compared to non inhibitor group. Moreover, target joint impact seems to be significant in radius TBD.

PB 946 | Longitudinal Modified Hemophilia Joint Health Scores (mHJHS) in Children, Adolescents, and Adults with Severe Hemophilia A with Long-term rFVIIIFc Prophylaxis

J. Oldenburg[1], R. Kulkarni[2], A. Srivastava[3], J. Mahlangu[4], E. Tsao[5], B. Winding[6], N. Jain[5]

[1]University Clinic Bonn, Institute of Experimental Haematology and Transfusion Medicine, Bonn, Germany, [2]Michigan State University, Department of Pediatrics and Human Development, East Lansing, MI, United States, [3]Christian Medical College, Department of Hematology, Vellore, Tamil Nadu, India, [4]University of the

Witwatersrand and NHLS, Haemophilia Comprehensive Care Centre, Faculty of Health Sciences, Johannesburg, South Africa, [5]Bioverativ, Waltham, MA, United States, [6]Sobi, Stockholm, Sweden

Background: Hemophilic arthropathy is a challenging complication of hemophilia; prophylaxis has been shown to prevent chronic arthropathy.

Aims: To evaluate longitudinal change in joint health with rFVIIIFc prophylaxis during A-LONG (adults/adolescents) and Kids A-LONG and the ongoing extension study, ASPIRE (NCT01454739).

Methods: Joint health was assessed by mHJHS at A-LONG/Kids A-LONG baseline (BL), ASPIRE BL and annually thereafter. A-LONG subjects with mHJHS data at A-LONG BL, ASPIRE BL, and ASPIRE Year 1 [Y1], Year 2 [Y2], and Year 3 [Y3] were included (Kids A-LONG BL, ASPIRE BL, Y1 and Y2 available for kids). Change from A-LONG/Kids A-LONG BL to last visit was analyzed using a paired t-test.

Results: Mean (SEM) mHJHS total score for adults/adolescents with data at all time points (n=28) was 25.0 (2.9) at A-LONG BL. Mean (SEM) change from A-LONG BL was -2.0 (1.2) at ASPIRE BL,-3.8 (1.5) at ASPIRE Y1, -4.5 (1.6) at ASPIRE Y2, and -5.0 (1.5) at ASPIRE Y3 ($P< 0.01$). These improvements were observed regardless of prestudy regimen (**Figure**). Similar results were observed regardless of age or the presence/absence of BL target joints. Subjects were classified according to the median of mHJHS at BL. The half with higher BL mHJHS (>22) had greater mean (SEM) improvements vs A-LONG BL through ASPIRE Y3 (-8.4 [2.6]) than the half with lower initial mHJHS (-1.8 [1.2]). Mean (SEM) improvements at ASPIRE Y3 vs A-LONG BL were observed for both weight-bearing (-1.1 [0.5]) and non-weight-bearing (-3.0 [0.8]) joints. The mHJHS components that showed ≥25% score reduction from A-LONG BL to ASPIRE Y3 were joint instability (-89%), swelling (-46%), joint pain (-31%), and muscle atrophy (-25%). Results from the Kids A-LONG cohort (n=24) also showed mean (SEM) improvement from A-LONG BL to ASPIRE Y2 (-1.2 [0.6]; $P< 0.05$).

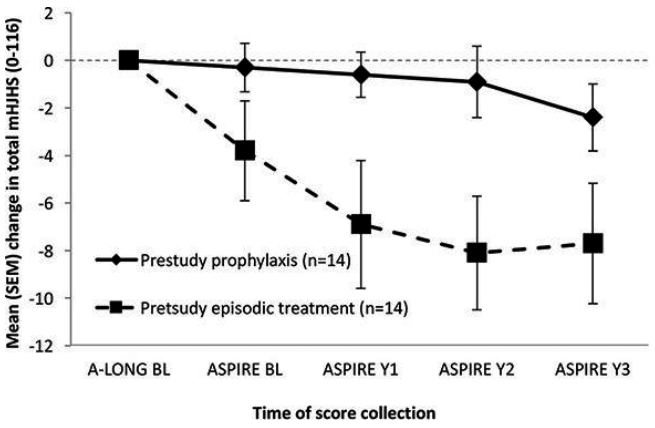

FIGURE 1 Mean (SEM) change from baseline in mHJHS total score and by prestudy regimen from A-LONG BL to ASPIRE Y3 in adults/adolescents

Conclusions: Among subjects receiving long-term rFVIIIFc prophylaxis, continuous annual improvement in mHJHS scores was observed, regardless of prestudy dosing regimen, even among those with reduced joint health at BL.

PB 947 | Obesity and Dosing of Replacement Therapy in Hemophilia; How to Optimize?

H.C.A.M. Hazendonk[1], T. Preijers[2], I. van Moort[1], K. Meijer[3], B.A.P. Laros-van Gorkom[4], F.J.M. van der Meer[5], K. Fijnvandraat[2], F.W.G. Leebeek[6], R.A.A. Mathôt[2], M.H. Cnossen[1], OPTI-CLOT Study Group

[1]Erasmus Medical Center - Sophia Children's Hospital, Rotterdam, The Netherlands, [2]Academic Medical Center Amsterdam, Amsterdam, The Netherlands, [3]University Medical Center Groningen, Groningen, The Netherlands, [4]Radboud University Medical Center, Nijmegen, The Netherlands, [5]Leiden University Medical Center, Leiden, The Netherlands, [6]Erasmus University Medical Center, Rotterdam, The Netherlands

Background: Factor VIII (FVIII) dosing in hemophilia A is based on body weight in kilograms (kg) and a FVIII *in vivo* recovery (IVR) of 2.0 which equals an increase of 2.0IUdL^{-1} per unit of FVIII per kg. Overweight/obese patients have significantly higher IVR values resulting in overestimation of FVIII. The use of other body size descriptors as an alternative to body weight has been discussed.

Aims: To explore the potential of PK-guided dosing based on FVIII population pharmacokinetic (PK) models in overweight/obese hemophilia A patients and to evaluate the use of the body size descriptors ideal-, adjusted- and lean body weight, instead of actual body weight.

Methods: Twenty-two hemophilia A patients (baseline FVIII< 0.05IUmL^{-1}) were classified according to body mass index (BMI), normal: < 25kgm^{-2}(n=5), overweight: 25-30kgm^{-2}(n=12) and obese: >30kgm^{-2}(n=5). All patients received ±50IUkg^{-1} FVIII, with FVIII:C sampling at 4, 24 and 48 hours. Population PK modeling was applied to calculate FVIII plasma concentration over time. Informed consent was obtained after study approval by Medical Ethics Committee.

Results: An earlier reported population PK model for FVIII (Bjorkman et al. 2010) was not able to correctly predict FVIII levels in overweight/obese patients. Therefore, a modified model was constructed, which described individual PK parameters and FVIII levels adequately. Using this model, it was demonstrated that median IVR was significantly higher in overweight (2.65) and obese (3.00) patients in comparison to patients with a normal BMI (2.17) (p< 0.05). IVR-based dosing (using IVR of 2.0) resulted in FVIII trough levels below set target levels for specific bleeding events, most importantly in case of life threatening bleeding.

Conclusions: When PK-guided dosing of factor VIII concentrate is applied it is important to ensure that the population PK model represents all patient groups, including obese/overweight patients. Alternative dosing based on body size descriptors is not equivalent to PK-guided dosing.

PB 948 | Safety of Nonacog Beta Pegol (N9-GP): Results from the paradigm™ Clinical Trials

P. Collins[1], M. Carcao[2], M. Simonsen[3], S. Ehrenforth[4], S. Lentz[5], J.N. Mahlangu[6], M.E. Mancuso[7], J. Oldenburg[8], C. Negrier[9]

[1]School of Medicine, Cardiff University, Division of Infection & Immunity and Systems Immunity Research Institute, Cardiff, United Kingdom, [2]The Hospital for Sick Children, University of Toronto, Division of Haematology/Oncology, Department of Paediatrics and Research Institute, Toronto, Canada, [3]Novo Nordisk A/S, Bagsværd, Denmark, [4]Novo Nordisk, Zürich, Switzerland, [5]University of Iowa Carver College of Medicine, Department of Internal Medicine, Iowa City, United States, [6]NHLS and University of the Witwatersrand, Department of Molecular Medicine and Haematology, Faculty of Health Sciences, Haemophilia Comprehensive Care Centre, Johannesburg, South Africa, [7]Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milan, Italy, [8]University Clinics Bonn, Institute of Experimental Haematology and Transfusion Medicine, Bonn, Germany, [9]Louis Pradel University Hospital, Hemophilia Comprehensive Care Center and Hematology Department, Lyon, France

Background: N9-GP is a recombinant glycoPEGylated factor IX (FIX) with extended half-life, developed for haemophilia B (HB) therapy. Safety and efficacy of N9-GP in previously treated adults, adolescents and children were assessed in the paradigm™ clinical trials.

Aims: To report safety results from the paradigm™ trials:
1 (phase 1 pharmacokinetics);
2 (phase 3 pivotal);
3 (surgery);
4 (phase 3B, extension of paradigm™2 and 3); and the ongoing
5 (paediatric trial, including extension, data cut-off date 1 January 2016).

Methods: Previously treated individuals with HB (FIX ≤2%), without FIX inhibitors, received N9-GP prophylactically (10 or 40 IU/kg, once/week) or on-demand (40 or 80 IU/kg). Safety parameters included reporting of adverse events (AEs), serious AEs and clinical laboratory assessments.

Results: On these trials, 115 males (including 25 children aged 1-12 years) were exposed to N9-GP, with 205 total exposure years; longest trial participation at cut off was 3.75 years. No patients developed FIX inhibitors (≥0.6 Bethesda units) or reported thromboembolic events. 824 AEs occurred. Fourteen serious AEs occurred in 12 patients; all except one were judged unlikely to be related to N9-GP. The event judged as probably related to N9-GP was a severe hypersensitivity/allergic reaction in which the patient was subsequently treated with antihistamine and IV cortisone; the patient fully recovered and was withdrawn from the trial. One fatality was recorded (hepatocellular carcinoma), but judged unlikely to be related to N9-GP. Following evaluation of all AEs, hypersensitivity, pruritus and injection site reactions were considered AEs possibly related to N9-GP, reported in 1, 3 and 4 patients respectively. No systematic changes over time were seen for any haematological, hepatic or renal parameters.

Conclusions: Overall N9-GP was well tolerated and the AE rate was low. One severe hypersensitivity reaction was thought probably related to N9-GP; no other safety concerns were identified.

PB 949 | Perioperative Replacement Therapy in Hemophilia B: Should We "B" More Precise?

H.C.A.M. Hazendonk[1], R. Liesner[2], P. Chowdary[3], M.H.E. Driessens[4], D. Hart[5], D. Keeling[6], B.A.P. Laros-van Gorkom[7], F.J.M. van der Meer[8], K. Meijer[9], R.A.A. Mathôt[10], F.W.G. Leebeek[11], K. Fijnvandraat[10], P.W. Collins[12], M.H. Cnossen[1], OPTI-CLOT Study Group

[1]Erasmus Medical Center - Sophia Children's Hospital, Rotterdam, The Netherlands, [2]Great Ormond Hospital for Children NHS Trust Haemophilia Centre, London, United Kingdom, [3]Katharine Dormandy Haemophilia Centre and Thrombosis Unit, Royal Free Hospital, London, United Kingdom, [4]Netherlands Hemophilia Patient Society, Nijkerk, The Netherlands, [5]The Royal London Hospital Barts Health NHS Trust, London, United Kingdom, [6]Oxford University Hospitals, Churchill Hospital Oxford, Oxford, United Kingdom, [7]Radboud University Medical Center, Nijmegen, The Netherlands, [8]Leiden University Medical Center, Leiden, The Netherlands, [9]University Medical Center Groningen, Groningen, The Netherlands, [10]Academic Medical Center Amsterdam, Amsterdam, The Netherlands, [11]Erasmus University Medical Center, Rotterdam, The Netherlands, [12]Arthur Bloom Haemophilia Centre, Cardiff University, Cardiff, United Kingdom

Background: Hemophilia B is a deficiency of coagulation factor IX (FIX) and characterized by bleeding in muscles and joints. In the perioperative setting, patients are treated with FIX therapy striving for physiological FIX levels to secure hemostasis. Targeting of specified FIX levels is challenging and requires frequent monitoring and adjustment of therapy.

Aims: We conducted an international multicenter study to evaluate perioperative management in hemophilia B, including monitoring of FIX infusions and observed FIX levels, whereby predictors of low and high FIX levels were assessed.

Methods: Hemophilia B patients with FIX< 0.05 $IUmL^{-1}$ undergoing elective, minor or major surgical procedures (2000-2015) were included from ten centers in two countries. Patient, surgical and treatment characteristics were collected. Observed FIX levels were compared to target levels as recommended by guidelines. The study was approved by all Medical Ethics Committee and an opt-out consent procedure was used.

Results: A total of 255 surgical procedures were performed in 118 patients (median age 40 years, median body weight 79 kg). Sixty percent of FIX levels within 24 hours of surgery were below target with a median difference of 0.22 $IUmL^{-1}$ [IQR 0.12-0.36]; while > six days after surgery 59% of FIX levels were above target with a median difference of 0.19 $IUmL^{-1}$ [IQR 0.10-0.39]. Clinically relevant bleeding complications (necessity of a second surgical intervention or red blood cell transfusion) occurred in three procedures (1.2%) and were not associated with low FIX levels. Bolus infusion and minor surgical procedures were predictive of lower FIX levels (OR=5.4 95%CI 3.5-8.3, OR=2.0 95%CI 1.2-3.2).

Conclusions: This study demonstrates that targeting of FIX levels in the perioperative setting is complex and suboptimal, but despite this bleeding is minimal. Alternative dosing strategies taking patient and surgical characteristics, as well as pharmacokinetic principles into account, may help to optimize and individualize treatment.

PB 950 | Identification of Patient and Disease-related Characteristics Influencing the Risk of Bone Fracture in Individuals with Haemophilia

P. Miljic[1], J. Bodrozic[1], D. Miljic[2], D. Lekovic[1], M. Mitrovic[1]

[1]Clinical Center of Serbia, Clinic of Haematology, Belgrade, Serbia, [2]Clinical Center of Serbia, Clinic of Endocrinology, Belgrade, Serbia

Background: Increased prevalence of osteoporosis has been reported in individuals with haemophilia, but real-life data on incidence of fractures in these subjects are lacking.

Aims: To investigate incidence rate of fractures in a cohort of subjects with haemophilia treated in our haemophilia center. We also investigated several patient- and disease- related characteristics in attempt to identify characteristics which may represent risk factors for fracture in individuals with haemophilia.

Methods: In this retrospective cross-sectional study we included 148 male subjects with haemophilia
(57 with severe, 27 moderate and 64 mild haemophilia) mean age 41.2±16 years. All previous fractures were recorded over the last two decades (January 1996 - January 2016). Data was gathered from a total of 2960 patient-years of observation and incidence rate was calculated. The influence of type and severity of haemophilia, age, inhibitor presence, smoking habit, alcohol consumption, use of anti-inflammatory drugs, status of joints, bleeding frequency and body mass index on fracture occurrence have been investigated.

Results: During the observation period for whole cohort of subjects with haemophilia, 36 fractures have been recorded, giving total incidence of 12.2 fractures per 1000 patient-years. In our analysis smoking (p=0.003), frequency of joint bleeds (p=0.037) and number of joints with haemophilic arthropathy (p=0.049) appeared to be associated with increased risk for bone fracture in patients with haemophilia.

Conclusions: Incidence rate of bone fractures in our cohort of subjects with haemophilia is slightly higher than reported for general population (12.2 versus 9.6 per 1000 patients years). Smoking habit, frequency of bleeding and number of affected joints with haemophilic arthropathy were identified as factors which are associated with increased risk of bone fractures in subjects with haemophilia.

PB 951 | Post-partum Bleeding in Women who Are Carriers of and Who Have Bleeding Disorders: A Case-Control Study

S. Wolf[1], S. Montes-Otalvaro[1], B. Shohreh[1], J. Pasi[1,2], H. Daniel[1,2], C. Foley[1], K. Forsyth[1], A. Morris[1], W. Maposa[1], B. Louise[1]

[1]Barts Health NHS Trust, London, United Kingdom, [2]Queen Mary University of London, London, United Kingdom

Background: Women with inherited bleeding disorders or who are carriers (WBD) have been previously reported as having higher rates of primary and secondary post-partum haemorrhage (PPH), even with optimal haemostatic management. In normal pregnancy, risk factors for PPH include age, BMI, parity, anemia, induction of labour (IoL), prolonged labour, mode of delivery, instrumentation and birth weight.

Aims: We hypothesized that higher rates of PPH may be due to higher rates of elective Caesarean section.

Methods: We audited the obstetric care of WBD who delivered at our centre between 2008 and 2016 and compared them to a control group, matched for mode of delivery (vaginal/elective Caesarean/emergency Caesarean). WBD were managed according to national and local guidelines during their pregnancy, puerpeurim and postpartum period. Data was collected from a database.

Results:

TABLE 1 Postpartum mean EBL and PPH in WBD and controls

	WBD (n=65)	Controls (n=130)
Mean EBL (all deliveries)	451ml	420ml
Mean EBL (vaginal deliveries without instrumentation)	316ml	326ml
Mean EBL (Elective Caesareans)	473ml	498ml
Mean EBL (Emergency Caesareans)	754ml	641ml
Primary PPH ((≥500ml for vaginal delivery, (≥1000ml for Caesarean)	11 (17%)	17 (13%)
Secondary PPH	4 (6%)	0 (0%)*

* p< 0.05

There were 65 pregnancies in this study, in 48 WBD. Of these, there were 18 pregnancies in Haemophilia A carriers, 10 in Haemophilia B carriers, 17 in Factor XI deficiency patients, and 20 in von Willebrand disease patients. All women were seen by a multi-disciplinary team and 40 had peri-delivery haemostatic treatment. There were 130 pregnancies in the control arm. There was no significant difference in BMI or parity between groups and no significant difference between groups in first trimester, pre-labour and post-partum haemoglobin. There was an increased rate of IoL in WBD (32% vs. 14%). There was no significant increase in estimated blood loss (EBL) or primary PPH between groups. WBD were more likely to have had a secondary PPH (6% vs. 0 %, P< 0.05).

Conclusions: We have shown that when WBD are matched for mode of delivery to controls, there is no difference in the EBL or rates of primary PPH, despite higher rates of IoL. In our group there is an increase in rates of secondary PPH. Further work is needed to understand how optimal management can reduce this.

PB 952 | Prophylaxis with rIX-FP Reduces Consumption Compared with Previous FIX in Both Adult and Pediatric Patients

M. Escobar[1], E. Santagostino[2], C. Lessinger[3], A. Shapiro[4], J. Oldenburg[5], B. Pan-Petesch[6], W. Seifert[7], the PROLONG-9FP Investigators

[1]University of Texas Health Science Center and the Gulf States Hemophilia and Thrombophilia Center, Houston, TX, United States, [2]Angelo Bianchi Bonomi Hemophilia and Thrombosis Center IRCCS Ca' GrandaFoundation, Maggiore Hospital Policlinico, Milan, Italy, [3]Tulane University Medical Center, New Orleans,

LA, United States, [4]Indiana Hemophilia and Thrombosis Center Indianapolis, Indianapolis, IN, United States, [5]Institute of Experimental Hematology and Transfusion Medicine, University Clinic Bonn, Bonn, Germany, [6]Centre Hospitalier Régional Universitaire de Brest, Hôpital A. Morvan, Brest, France, [7]CSL Behring, Marburg, Germany

Background: rIX-FP, a fusion protein genetically linking recombinant human coagulation Factor IX with recombinant human albumin, was designed with an improved pharmacokinetic profile to extend the dosing interval during prophylaxis therapy (PT).

Aims: To evaluate the impact of an extended dosing interval on FIX consumption in adult and pediatric patients with hemophilia B enrolled into 2 clinical trials.

Methods: Study 1: Previously treated patients (12-65 years) with hemophilia B (FIX ≤2%) received either on-demand treatment with rIX-FP for 6 months before switching to 7-day PT (n=23) or received 7-day PT for 6 months and continued on 7-day PT or switched to 10- or 14-day PT (n=40). Study 2: Pediatric patients (< 12 years; n=27) received 7-day PT with rIX-FP. Consumption of FIX before and during study was compared.

Results: In adults, 7- and 14-day PT with rIX-FP reduced mean monthly FIX consumption compared with previous FIX therapy by approximately 37% and 51%, respectively (7-day: 202.7 IU/kg; 14-day: 157.4 IU/kg; previous FIX: 320.7 IU/kg). Mean dose for patients receiving 7-day PT (n=59) was 47.1 IU/kg versus a mean weekly dose prior to study entry of 69.9 IU/kg. Mean dose for 14-day rIX-FP PT (n=21) was 71.9 IU/kg. In the pediatric population, treatment frequency in those receiving PT prior to study entry was 2x weekly (n=15), 3x weekly (n=2), every 3 days (n=2), every other day (n=1) and weekly (n=4); 7day rIX-FP PT decreased injection frequency for 20/24 patients. Mean weekly dose was considerably lower with rIX-FP PT than with previous FIX for all patients (47.2 vs 107.1 IU/kg), for those aged < 6 years (49.1 vs 138.7 IU/kg) and for those 6 to < 12 years (45.6 vs 80.3 IU/kg).

Conclusions: Compared to previous treatment, prophylaxis with the prolonged dose interval afforded by rIX-FP resulted in a significant decrease in total FIX consumption and a subsequent reduction in the burden of treatment in this group of patients.

PB 953 | Dosing of rVIII-SingleChain Based on Clinical Bleeding Phenotypes Results in Low Bleeding Rates in Pediatric Patients Treated with Prophylaxis Two or Three Times Weekly

M. Simpson[1], K. Fischer[2], J. Oldenburg[3], M.T. Álvarez-Román[4], T. Lambert[5], M. Wang[6], D. Bensen-Kennedy[7], O. Stasyshyn[8]

[1]Rush University Medical Center, Rush Hemophilia & Thrombophilia Center, Chicago, United States, [2]University Medical Center Utrecht, Utrecht, The Netherlands, [3]University Clinic Bonn - Institute of Experimental Haematology & Transfusion Medicine, Bonn, Germany, [4]La Paz University Hospital, Department of Haematology, Madrid, Spain, [5]Bicêtre AP-HP Hôpital and Faculté de Médecine Paris Sud, Paris, France, [6]University of Colorado School of Medicine, Aurora, United States, [7]CSL Behring, King of Prussia, United States, [8]National Academy of Medical Sciences of Ukraine, Institute of Blood Pathology and Transfusion Medicine, Lviv, Ukraine

Background: The safety and efficacy of rVIII-SingleChain was investigated in the AFFINITY program in two pivotal and one extension study. Studies were designed to reflect real-world practice; dose range and regimen were at the investigator's discretion based on bleeding phenotype and FVIII treatment used prior to enrollment. Dose and schedule could be adjusted at any time during the study.

Aims: This analysis evaluated initial and final dose assignment and corresponding bleeding rates in pediatric patients (< 12 years) receiving prophylaxis 2- or 3-times weekly.

Methods: Total and spontaneous annualized bleeding rates (ABR/AsBR) were determined for patients stratified by age group (0 to 6 and 6 to < 12 years) and either initial or final dose assignment. This analysis included pediatric patients assigned to prophylaxis 2- or 3-times weekly (84% of the subjects on prophylaxis therapy) in dosing brackets of 20 to < 30 IU/kg, 30 to < 40 IU/kg and 40 to ≤50 IU/kg.

Results: In the final dose assignment, 24, 19 and 24 patients were assigned a dose of 20 to < 30 IU/kg, 30 to < 40 IU/kg, and 40 to ≤50 IU/kg, respectively. ABR and AsBR were lower in those receiving ≥30 IU/kg than in those receiving < 30 IU/kg. Median ABR for the dosing brackets of 20 to < 30 IU/kg, 30 to < 40 IU/kg and 40 to ≤50 IU/kg was 5.61, 2.75 and 2.34, respectively; median AsBR was 2.10, 0 and 0, respectively. Similar findings were recorded for both 0 to < 6 year and 6 to < 12 year age groups.

Conclusions: Dosing of rVIII-SingleChain based on clinical bleeding phenotype results in low bleeding rates in pediatric patients treated with prophylaxis 2- or 3-times weekly. However, differences in ABR and AsBR suggest children receiving >30 IU/kg are more protected from traumatic bleeding than those receiving < 30 IU/kg. As pediatric patients are a very active population, a starting dose of 30-50 IU/kg 2- or 3-times weekly might be more appropriate.

PB 954 | Factor VIII (FVIII) Inhibitor Testing Using a Validated Chromogenic Bethesda Assay (CBA) in HAVEN 1 (BH29884), a Phase 3 Trial of Emicizumab in Persons with Hemophilia A (PwHA) with Inhibitors

J.I. Adamkewicz[1], C. Schmitt[2], E. Asikanius[2], J. Xu[1], G. Levy[1], B. Kim[1], A. Calatzis[3]

[1]Genentech Inc., South San Francisco, United States, [2]F. Hoffmann-La Roche Ltd, Basel, Switzerland, [3]Roche Diagnostics International Ltd, Rotkreuz, Switzerland

Background: FVIII inhibitors in PwHA are commonly measured using a mixing-clotting method (Bethesda assay), where residual FVIII activity is quantified by 1-stage FVIII activity test. Emicizumab (ACE910), a novel bispecific antibody, is under investigation for prophylactic treatment of PwHA. Emicizumab is not inactivated by heat treatment or FVIII inhibitors, and therefore interferes with standard Bethesda assays, leading to potential false negative results. However, the CBA (Miller, *JTH*, 2012) uses a chromogenic FVIII activity assay containing bovine components that is insensitive to emicizumab, allowing detection and quantification of FVIII inhibitors in PwHA receiving emicizumab.

Aims: Validate CBA for use in presence of emicizumab and measure FVIII inhibitor titer for PwHA with inhibitors enrolled in the HAVEN 1 phase III trial (NCT02622321).

Methods: The CBA was validated using commercially available FVIII inhibitor plasma. Values ≥0.6 chromogenic Bethesda Units (CBU) were considered positive, and titers >45 CBU were right-censored. HAVEN 1 FVIII inhibitor titers were measured in a central lab by CBA using citrated plasma collected at multiple time points. The study was approved by all local site ethics committees; informed consent/assent was obtained.

Results: CBA results from donor plasma (n=6) correlated with the supplier's labeled titer (r^2 = 0.98). No false-positive test results were seen, and addition of emicizumab had no effect. HAVEN 1 data are presented for PwHA who completed ≥7 and ≥24 weeks of emicizumab prophylaxis. Inhibitor titers ranged from 0-45 at each time point. Median titers at baseline, Wk7, and Wk25 were 11.9 (n=102), 8.0 (n=97) and 8.0 (n=50) CBU.

Conclusions: CBA is a robust method for determination of FVIII inhibitor titer, and is accurate even in the presence of emicizumab. Inhibitor titer was measured successfully for PwHA with inhibitors in HAVEN 1 who received weekly emicizumab prophylaxis, and there was a trend toward lower median titers over time.

PB 955 | Recombinant FVIII Product Type and the Risk of Inhibitor Development in Previously Treated Patients with Hemophilia A: Preliminary Results of a Systematic Review and Meta-analysis

A. Cannavò[1,2], S. Hassan[2], S. Gouw[2], F.R. Rosendaal[2], J. van der Bom[2]

[1]*Fondazione IRCCS Ca' Granda - Ospedale Maggiore Policlinico, Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico and Fondazione Luigi Villa, Milan, Italy,* [2]*Leiden University Medical Center, Leiden, The Netherlands*

Background: Inhibitor development in previously treated patients (PTPs) with severe hemophilia A is a rare but severe complication of FVIII treatment. Evidence on product-related immunogenicity is increasing.

Aims: To perform a systematic review of the evidence on the relationship between inhibitor development and recombinant factor FVIII (rFVIII) products in PTPs with severe hemophilia A.

Methods: The following electronic databases were searched; PubMed, Embase, Web of Science, Cochrane database and CINAHL. Longitudinal studies reporting on de novo inhibitor formation in severe (baseline FVIII < 0.01 IU/ml) and moderately severe (baseline FVIII < 0.02 IU/ml) PTPs with hemophilia A (defined as having > 50 exposure days to FVIII at baseline) were included. A random intercept Poisson regression model was used calculate the pooled incidence rate ratio of inhibitor development (RR, 95%CI) according to product type. In addition, a sensitivity analysis was undertaken to assess the robustness of our findings. Eighteen studies had missing or incomplete information, corresponding authors have been asked to provide additional information.

Results: 26 cohorts were included. There were 36 inhibitor events over 17,049 person-years of observation. The incidence rate among PTPs was 2.79 per 1000 person-years (95%CI: 1.54-5.05). Compared with Advate, the pooled RR was 5.54 (95%CI: 0.46-66.60) for Kogenate/Helixate, 1.85 (95%CI: 0.45-7.60) for Kogenate FS/Helixate NexGen, 12.44 (95%CI: 2.69-57.62) for Refacto and 4.04 (95%CI: 0.89-18.41) for Refacto AF. Compared with full-length rFVIII, the pooled RR for B-domain-deleted rFVIII was 4.27 (95%CI: 1.43-12.75).

Conclusions: These preliminary results suggest that some rFVIII products are associated with increased immunogenicity as compared with Advate in severe and moderately severe PTPs with hemophilia A. The final results may change depending on the outcome of our information request to several study authors.

PB 956 | Preliminary Observations from a Prospective, Dose Escalating, Prophylaxis Study in Young Boys with Severe Hemophilia A in China: The China Hemophilia Individualized Prophylaxis Study (CHIPS)

Background: In China, 90% of boys with severe hemophilia A (SHA) manifest significant arthropathy by age six years (Wu R et al Haemophilia, 2014). Short-term pilot studies demonstrated that low-dose prophylaxis (10-15 IU/kg) reduced joint bleeds by 80% but was ineffective in eliminating joint damage
(Wu R et al Haemophilia, 2013). Optimizing prophylaxis in China for boys with SHA is an urgent priority.

Aims: To investigate the efficacy of an individualized, dose escalating prophylaxis protocol in young boys with SHA.

Methods: This is a prospective, ethics approved clinical trial conducted at 2 major Hemophilia Treatment centers in China. Boys with SHA (baseline FVIII < 2%), ages 1-7 years, inhibitor negative, >50 Exposure

TABLE 1 Dose Escalation Criteria

Index Joint Assessment	Parameters	Frequency	Description	Score
Bleeding	Frequency per joint	Any time	≥ 3 bleeds in any single index joint	+ 2
		Consecutive 3 months	≥ 2 bleeds in any single index joint	+ 2
		Consecutive 3 months	1 index joint bleed	+ 1
Joint score by imaging	US based on most severe finding/location	Every 3 months	Changes of Grey-scale US Score = 3	+ 2
			Changes of Grey-scale US Score = 1 and changes of Color Doppler synovial vascularity Score ≥ 1; or changes of Grey-scale US Score = 2	+ 1
Joint Score by physical examination	HJHS score for any index joint	Every 3 months	Change of swelling score on HJHS from 0 to 2 or 1 to 3 (not considered to be related to an acute bleed)	+ 2
			Persistent swelling that is mild (score 1 on HJHS) or moderate (score 2 on HJHS)	+ 1
TOTAL SCORE FOR ESCALATION			Escalate to the next step of prophylaxis	≥ 2

TABLE 2 Baseline Characteristics of the Study Cohort

Characteristic	N	Median	Range	Best - Worst Score
Age	32	5.0	2.3 - 7.9	
CHO-KLAT* Parent Score	15	66.7	46.0 - 78.7	100 - 0
CHO-KLAT* Parent Socio-Economic Context (SEC) module score	15	65.6	33.3 - 84.4	100 - 0
HJHS*	11	6.0	0.0 - 11.0	0 - 124
*Preliminary Results (Ages ≥ 4 years)				

Days and a history of index joint (elbows, knees, ankles) bleeds were eligible. The design included 4 dose escalation steps; Step 1: 10-15 IU/kg x2/week; Step 2: 10-15 IU/Kg, x3/week; Step 3: 15-20 IU/Kg x3/week; and Step 4: 20-25 IU/Kg every other day. A priori escalation criteria (Table 1) was based on the frequency of index joint bleeds, scores from the Hemophilia Joint Health Score (HJHS) and Ultrasound (US) examinations of index joints.

Results: 32 boys were consented and enrolled. Table 2 provides baseline characteristics. Median follow-up was 4 months (range: 2 -5 months). During the first 3 months on study, 10 patients (31%) had their dose escalated: 7 due to bleeding alone and 3 due to a combination of bleeding and/or joint findings on the HJHS and/or US.

Conclusions: This is the first prospective, individualized, dose escalating prophylaxis study for boys with SHA in China with the goal of minimizing bleeding and joint damage. Findings from the HJHS and US examinations to guide dose escalation, in conjunction with index joint bleeds, is a unique feature of this clinical trial. These observations will be useful in the design of cost-effective prophylaxis regimens for boys with SHA in China.

The study is financially supported by Bayer HealthCare Co. Ltd., China.

PB 957 | Pilot Study to Determine the Frequency of Cerebral Microbleeds among Adult Patients with Hemophilia a or B

H. Husseinzadeh[1], T. Chiasakul[2], B. Pukenas[3], R. Wolf[3], M. Kelty[1], P. Gimotty[4], E. Chiang[1], P.F. Fogarty[1], A. Cuker[1]

[1]University of Pennsylvania, Department of Medicine, Division of Hematology/Oncology, Philadelphia, United States, [2]Chulalongkorn University and King Chulalongkorn Memorial Hospital, Thai Red Cross Society, Division of Hematology, Department of Medicine, Faculty of Medicine, Bangkok, Thailand, [3]University of Pennsylvania Perelman School of Medicine, Section of Neuroradiology, Department of Radiology, Philadelphia, United States, [4]University of Pennsylvania, Perelman School of Medicine, Department of Biostatistics and Epidemiology, Center for Clinical Epidemiology and Biostatistics, Philadelphia, United States

Background: Cerebral microbleeds (CMBs) represent small, clinically silent hemorrhagic events. Current data suggest CMBs may portend future stroke, intracranial hemorrhage, and cognitive impairment. The prevalence of CMBs has not been evaluated in patients with hemophilia (PWH).

Aims: To compare the prevalence of CMBs between PWH and normal controls.

Methods: Adults with hemophilia A or B of any severity and controls without a prior diagnosis of a bleeding disorder were recruited. Subjects were excluded if chronically taking an antithrombotic agent other than low-dose aspirin (< 100mg). Clinical and demographic data were collected using a standardized form. All subjects underwent T2*MRI of the brain. Two neuroradiologists blinded to patient group reviewed the scans independently and determined whether CMBs were present. Differences in clinical characteristics were assessed by t-test (continuous variables) and either chi-square or Fisher's exact test (categorical variables). A two-sided p-value of < 0.05 was considered statistically significant. SPSS software (version 22.0) was used.

Results: We recruited 31 PWH and 32 controls. HCV infection was more prevalent among PWH and smoking was more common among controls. Other characteristics were similar between the two groups.

TABLE 1 Demographic and clinical characteristics of study population

	PWH (n=31)	Controls (n=32)	p-value
Age, median (range)	39 (20 - 81)	41 (21 - 69)	0.57
History of Hepatitis C infection, n (%)	19 (61.3)	0 (0)	<0.001
Smoking, n (%)	6 (19.4)	14 (43.8)	0.04
Hemophilia A, n (%)	22 (71)	N/A	N/A
Mild hemophilia, n (%)	7 (23)	N/A	N/A
Moderate hemophilia, n (%)	4 (13)	N/A	N/A
Severe hemophilia, n (%)	20 (65)	N/A	N/A
Use of prophylaxis, n (%)	11 (35)	N/A	N/A
Mean annual units infused	241145	N/A	N/A

Among the two neuroradiologists, Reviewer 1 detected 9 CMBs, 7 (22.6%) in PWH and 2 (6.3%) in controls (p=0.06). Reviewer 2 is completing his interpretations, after which consensus review will be undertaken. Among PWH, those with CMBs were older, used less factor annually, and had higher HCV infection rates compared to those without CMBs. All other characteristics were similar.

TABLE 2 CMB in PWH and associated clinical characteristics (Reviewer 1 only)

	PWH with CMBs (n=7)	PWH without CMBs (n=24)	p-value
Mean age, year (SD)	56 (17)	40 (14)	0.05
Hemophilia A, n (%)	5 (71)	17 (70)	0.97
Mild hemophilia, n (%)	2 (28.6)	5 (20.8)	0.64
Moderate hemophilia, n (%)	1 (14.3)	3 (12.5)	1.00
Severe hemophilia, n (%)	4 (57.1)	16 (66.7)	0.67
Use of prophylaxis, n (%)	2 (28.6)	9 (37.5)	0.66
Mean annual units infused, mean (SD)	83000 (181185)	287271 (415003)	0.04
History of HCV infection, n (%)	7 (100)	12 (50)	0.02
Smoking, n (%)	2 (28.6)	4 (16.7)	0.48

Conclusions: Data from this pilot study suggest that CMBs are common among PWH and may be more prevalent than in normal controls. Increased factor use may be protective. The impact of CMBs on neurocognitive function in PWH and whether prophylactic factor administration reduces the prevalence of CMBs requires further study.

PB 958 | Thrombo-Embolic Events Reported with the Use of Activated Prothrombin Complex Concentrate (APCC) in Congenital Haemophilia: A Cumulative Review on Four Decades

R. Crea[1], A. Novack[2], J. Kennedy[2], S. Raff[3], N. Bajwa[2], A. Gringeri[1]

[1]Shire plc, Global Medical Affairs, Vienna, Austria, [2]Shire plc, Global Medical Affairs, Chicago, United States, [3]Shire plc, Global Drug Safety, Cambridge, United States

Background: The use of bypassing agents has contributed to a better management of bleeding of persons with haemophilia (PWH) and inhibitors. APCC became commercially available 40 years ago in 1975. While bypassing therapy has been proven effective, it introduced a potentially increased risk of treatment-associated thrombo-embolic events (TEEs).

Aims: The small size of clinical trials and post-authorization studies in PWH with inhibitors limits the capability to ascertain risk factors for APCC-associated TEEs. This review provides an overview of all spontaneous and literature TEE cases reported with the use of APCC in congenital haemophilia, documented in the Company's global safety database (GSD).

Methods: The GSD was reviewed for all spontaneous and literature adverse events reports of APCC from 1975 to July 2016, addressing patient demographics, dosing regimens, confounding and risk factors deemed relevant for the development of TEEs in temporal association with APCC treatment.

Results: More than 7 billion units of APCC (beyond 2 million infusions) were distributed during the review period. 85 reports including one or more TEE events were received for PWH, aged 0-76 years (median age of 22).

TABLE 1 Details of reported TEEs in Patients with Congenital Haemophilia

	Number of cases	Median age (range)
All reported TEEs in Patients with Congenital Haemophilia	85	22 years (0-76)
Deep vein thrombosis and/or pulmonary embolism	18	11 years (1-22)
Myocardial infarction/ischemia	17	41 years (8-73)
Cerebrovascular accident	18	55 years (2.5-70)
DIC	18	49 years (0-71)
Other	14	30 years (3-57)

rFVIIa was reported to be received in temporal relationship with APCC in 32/85 (37.7%) of TEEs. From 01 February 2000 to 31 July 2016, 73 TEEs for all indications were received from spontaneous sources (excluding literature), resulting in a reporting rate of approximately 3.5 TEEs/10^5 infusions (3000 U per infusion).

Conclusions: The reporting rate of TEEs associated with APCC is comparable with published data and confirms its long-time overall safety profile. It has been noted that a relevant part of the TEEs occurred in the presence of additional/confounding risk factors such as underlying disease and concomitant medications. The review of all TEEs reported in temporal association with the use of APCC is a valuable resource for the understanding and perhaps the prevention.

PB 959 | Effects of Acute Moderate Physical Activity on Haemostatic Parameters in Severe Haemophilia A Subjects Using a Third Generation B-Domain Deleted Recombinant Factor VIII

C. Merlen, N. Zourikian, C. Thibeault, E. Dubé, A. Bonnefoy, T. Nava, J. St-Louis, G.-E. Rivard

CHU Sainte-Justine, Montreal, Canada

Background: Persons with haemophilia A (HA) are encouraged to perform routine physical activity to improve their quality of life.
Aims: To evaluate the effects of acute moderate exercise on thromboelastography parameters (TEG), von Willebrand factor levels (VWF:Ag) and FVIII pharmacokinetics (PK) in persons with severe HA.
Methods: Eighteen adults (mean age: 27.5 years) were enrolled. At the first study visit, blood samples were drawn prior to FVIII infusion and over the following 24h, while subjects remained sedentary. At the second visit, subjects performed 4 exercise sessions (2x15min stationary cycling and treadmill walking) over a period of 5h (65% of maximum heart rate +/- 10 bpm) and blood samples were taken at same previous time points. TEG, FVIII activity (FVIII:C) and VWF:Ag were compared between the two visits using paired statistical tests (Two-way ANOVA and t-test). The study was approved by the research ethics committee and all subjects provided written informed consent.
Results: FVIII:C and VWF:Ag were significantly higher immediately after the first exercise session compared to rest ($p < 0.05$ and $p < 0.001$, respectively). This difference rapidly disappeared for FVIII whereas it remained significant for VWF:Ag at least 3h after the last exercise session. FVIII half-life (median: 10h [7.33-16.5h] at rest; median: 10.66h [5.66-16.66h] with exercise) and TEG parameters did not differ significantly between rest and exercise. FVIII half-lives measured both at rest and following exercise strongly correlated with baseline VWF:Ag ($r=0.82$; $p < 0.0001$ and $r=0.74$; $p=0.0004$ respectively). The area under the curve (AUC) of VWF:Ag (0,24h) was 14.3% higher following exercise. VWF:Ag AUC (0, 24h) was associated with FVIII clearance ($p=0.036$) and FVIII half-life ($p < 0.0001$) independently of blood group and exercise.
Conclusions: Acute moderate exercise did not significantly alter the PK of a third generation B-domain deleted rFVIII following a standard prophylactic dose.

PB 960 | Clinical Characteristics of Patients with Hemophilia A and B: Preliminary Results of the Hemfil Cohort Study

C.C. Brommonschenkel[1], L.L. Jardim[1], D.G. Chaves[2], M.P. Santana[2], M.H. Cerqueira[3], A. Prezotti[4], C.S. Lorenzato[5], V. Franco[6], S.M. Rezende[1]

[1]Faculty of Medicine - Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, [2]HEMOMINAS, Belo Horizonte, Brazil, [3]HEMORIO, Rio de Janeiro, Brazil, [4]HEMOES, Vitória, Brazil, [5]HEMEPAR, Curitiba, Brazil, [6]HEMOSC, Florianópolis, Brazil

Background: Inhibitor development is the main complication of hemophilia A (HA) and B (HB). Risk factors for inhibitor development are still not completely understood.
Aims: To describe the clinical characteristics of patients included in the HEMFIL study, an ongoing multicenter prospective cohort study on risk factors for inhibitor development.
Methods: Previously untreated patients (PUPs) have been followed up to 75 exposure days (ED) or until inhibitor development. Clinical characteristics were collected using standardized forms. Number of events and respective percentages were calculated for the categorical variables and the median with interquartile range (IQR) for the continuous variables.
Results: Currently, 65 patients were included, 58 (89.2%) with HA and 7 (10.8%) with HB. A total of 53 patients (81.5%) have severe and 9 (13.8%) moderate hemophilia. The median age at inclusion was 10 months [IQR, 6.5-14.0], median weight 9.3 kg [IQR, 8.45-11.0]. Patients were predominantly white (55.4%), blood group O (43.1%) and born by caesarean section (67.7%) with median gestation age of 39.0 weeks [IQR, 38-40]. The median time to breastfeeding was 18 weeks [IQR, 8-25]. Most patients were diagnosed due to bleeding manifestations (75.4%) and 24.6% due to family history (no bleeding). Currently, 52.3%, 44.6%, and 3.1% of patients, respectively, receive prophylactic, on demand and no treatment. Family history of hemophilia was reported in 67.7%, of whom 3.1% also have family history of inhibitor. Allergies were reported by 9 patients (13.8%). A total of 35 patients (53.8%) have completed follow-up, of whom 18 (27.7%) with 75 ED without inhibitor and 17 (26.1%) developed inhibitor.
Conclusions: In this cohort, most of patients are white, have family history of hemophilia, were diagnosed due to bleeding and are on prophylaxis. The inclusion of more patients and a longer follow-up will allow an appropriate analysis between clinical characteristics and inhibitor development.

PB 961 | Target Joint Outcomes with Prophylaxis with rFIXFc in Adults and Adolescents with Hemophilia B: Updated Results from B-YOND

R. Kulkarni[1], K.J. Pasi[2], J. Feng[3], B. Winding[4], A. Ramirez-Santiago[3], N. Jain[3]

[1]Michigan State University, Department of Pediatrics and Human Development, East Lansing, MI, United States, [2]Barts and the London Comprehensive Care Center, London, United Kingdom, [3]Bioverativ, Waltham, MA, United States, [4]Sobi, Stockholm, Sweden

Background: The B-YOND extension trial evaluates long-term safety and efficacy of rFIXFc in adults/adolescents with severe hemophilia B who completed the Phase 3 B-LONG study.
Aims: To present longitudinal data outcomes from subjects with target joints at BLONG entry through the 2nd interim data cut of B-YOND.
Methods: Subjects completing B-LONG enrolled in 1 of 4 treatment groups in B-YOND: weekly prophylaxis (WP; 20-100 IU/kg every 7

TABLE Summary of joint and target joint ABRs[a]

	Pre-study prophylaxis[b]		Pre-study episodic treatment		
	WP (n = 11)	MP (n = 6)	WP (n = 23)	IP (n = 10)	MP (n = 4)
Pre-study joint bleeding rate, median (IQR)	6.0 (2.0, 13.0)	7.5 (4.0, 20.0)	17.0 (9.0, 30.0)	23.0 (18.0, 33.0)	12.0 (10.5, 17.0)
Overall on-study joint ABR, median (IQR)	1.5 (0.0, 3.2)	1.2 (0.6, 4.8)	1.0 (0.5, 3.0)	3.4 (0.9, 5.6)	1.2 (0.3, 6.2)
Overall on-study target joint ABR, median (IQR)	0.4 (0.0, 3.2)	1.1 (0.5, 3.8)	0.5 (0.0, 1.1)	2.1 (0.9, 3.6)	0.0 (0.0, 3.9)

ABR, annualized bleeding rate; WP, weekly prophylaxis; MP, modified prophylaxis; IQR, interquartile range.
[a]Includes data from adult/adolescent subjects with target joint at entry into parent study who entered the efficacy period in B-LONG or B-YOND. n = number of subjects with non-missing data for both prestudy and on-study joint ABR. Subjects are included in each treatment regimen they participated in for the duration of time on that regimen and as such may appear in more than one treatment regimen in BYOND.
[b]One subject on pre-study prophylaxis was in the IP group and entered the efficacy period. This subject had a pre-study joint bleeding rate of 5.0, overall on-study joint ABR of 5.7, and overall on-study target joint ABR of 4.6.

days), individualised prophylaxis (IP; 100 IU/kg every 8-16 days), modified prophylaxis (MP; for subjects not achieving optimal dosing with IP or WP), or episodic treatment. Subjects with ≥1 target joint (major joint with ≥3 bleeding episodes in a 3-month period) at B-LONG entry were evaluated. A target joint resolved if there were ≤2 spontaneous bleeds in the target joint over 12 months. Outcomes were analysed over the cumulative duration of B-LONG through the second B-YOND interim data cut (11 Sep 2015).

Results: Of 117 B-LONG subjects with on-study data, 60 had a total of 166 target joints at baseline. These subjects received a cumulative median (IQR) of 3.4 (1.4-4.2) years of rFIXFc. In subjects with target joints at baseline, on-study overall and target joint annualised bleeding rates (ABRs) with rFIXFc prophylaxis were lower than bleeding rates with prestudy (pre-B-LONG) prophylaxis or episodic treatment (**Table**). 37.5% of WP, 8.3% of IP, and 33.3% of MP subjects had no target joint bleeding episodes during B-LONG/B-YOND, and 100% (37/37) of subjects with evaluable target joints at B-LONG baseline (≥12 months follow-up; no target joint surgery ≤12 months) had target joints resolved. In the WP and IP groups, median (IQR) average weekly prophylactic dose was 45.2 (37.3-55.8) IU/kg and 64.7 (46.7-82.3) IU/kg, respectively; median (IQR) dosing interval in the IP group was 10.3 (8.9-13.2) days.

Conclusions: Long-term rFIXFc prophylaxis resulted in low target joint ABRs and target joint resolution in all adults/adolescents with evaluable target joints at baseline in all dose groups.

PB 962 | Pressure Pain Thresholds Hint at Structural Findings in Knees of Patients with Haemophilia

S. Krüger, M. Hoffmeister, T. Hilberg

University of Wuppertal, Department of Sports Medicine, Wuppertal, Germany

Background: Patients with haemophilia (PwH) suffer from an enhanced pain sensitivity, depending on the joint status. However, the main reason of the altered pain condition is often unknown.

Aims: The objective of this study was to determine, if a comprehensive assessment of altered pain condition is directly linked to changes of underlying anatomical structures in PwH.

Methods: Pressure pain thresholds (PPT) were assessed at 11 different points around the knees of 36 PwH (severe A=29, B=3; moderate A=3, B=1) and 36 healthy controls (C). PPT were used to generate four groups (pain sensitive (PS-) / insensitive (PI-) knees of PwH and C). Structural conditions of underlying anatomic structures were examined by ultrasound sonography (US). Metric data between the groups were analysed by Kruskal-Wallis tests, categorical data by Pearson Chi-Square-tests.

Results: PPT in PwH were statistically significant decreased at all landmarks when compared to C (p≤0.004). US findings assessed across the lateral joint space revealed that especially osteophytes are more pronounced when PPT are decreased (Tab. 1). The synovia tissue, assessed at the suprapatellar region of the knees, was also thickened in PS-PwH when compared to other groups (Tab. 1). In contrast, no differences were found between the groups regarding effusion, whether assessed at the distal edge of m. vastus lateralis (p=0.893), the lateral knee joint space (p=0.417) or the suprapatellar region (p=0.274).

TABLE 1 Selective structural differences between pain sensitive (PS) / pain insensitive (PI) knees of PwH / controls (C). Mean±SD

anatomical structure	PS-PwH	PI-PwH	PS-C	PI-C	p-value
osteophytes femoral (mm)	5.6±5.8	1.3±2.7	0.0±0.0	0.0±0.0	0.000
osteophytes tibial (mm)	2.2±2.9	1.0±2.3	0.0±0.0	0.0±0.0	0.002
synovia tissue (mm)	2.2±2.2	1.1±0.7	0.8±0.6	0.7±0.3	0.001

Conclusions: Significant differences of knee-surrounding structures exist between PwH and C. Particular degenerative changes, in terms of osteophytes and thickness of synovial tissue, are linked with an enhanced pain sensitivity in PwH. However, altered PPT which were not associated with structural findings may be an indicator for a complex modified pain perception of the affected joints. This leads to the conclusion that pain is caused not only by structural, but also by functional alterations in PwH.

PB 963 | Once-weekly Prophylaxis with GlycoPEGylated Recombinant Factor VIII (N8-GP) in Severe Haemophilia A: Safety and Efficacy Results from a Randomised Phase 3 Trial (pathfinder™2)

N. Curry[1], C. Albayrak[2], M. Escobar[3], P.A. Holme[4], S. Kearney[5], R. Klamroth[6], M. Misgav[7], C. Négrier[8], E. Santagostino[9], M. Shima[10], A. Wheeler[11], S.M. Tønder[12], A. Landorph[12], S. Lentz[13]

Background: N8-GP is a glycoPEGylated recombinant FVIII (rFVIII) with an extended half-life developed for use in haemophilia A. N8-GP was well tolerated and efficacious in the main phase of pathfinder™2, a pivotal, ongoing, multinational, open-label phase 3 trial.[1]

Aims: The extension phase of pathfinder™2 investigated the long-term safety and efficacy of N8-GP prophylaxis (PPX) when administered as two separate dosing regimens to a subset of eligible patients.

Methods: For the extension phase, patients aged ≥12 years with ≤2 bleeds during the last 6 months of the main phase in pathfinder™2 on PPX were eligible to be randomised (1:2) to N8-GP PPX either at 50 IU/kg every fourth day (Q4D) or 75 IU/kg weekly (Q7D). Safety and efficacy endpoints were the incidence of FVIII inhibitors (≥0.6 Bethesda units) and the annualised bleeding rate (ABR), respectively.

Results: Fifty-five out of 143 (39%) patients who completed the main phase on PPX received 50 IU/kg Q4D (n=17) or 75 IU/kg Q7D (n=38). During the 24 week treatment period, there were 1539 exposure days in total. No FVIII inhibitors were detected. Median ABR was 0 for both cohorts. Estimated mean ABR was 1.77 and 3.57 for the 50 IU/kg Q4D and 75 IU/kg Q7D cohorts, respectively. In the 75 IU/kg Q7D cohort, 22 patients (58%) did not report any bleeds during the 24 weeks, comparable with the 50 IU/kg Q4D cohort (53%). Nine patients (23.7%) in the 75 IU/kg Q7D cohort reverted to their previous Q4D regimen in accordance with pre-defined criteria in the trial protocol (bleeds [n=8] and investigator's discretion [n=1]).

Conclusions: N8-GP dosed at 50 IU/kg Q4D or 75 IU/kg Q7D was well tolerated in this extension phase of pathfinder™2. More than 50% of patients in both dosing cohorts did not bleed during the treatment period, suggesting that once-weekly dosing is efficacious for a subset of patients with severe haemophilia A.

PB 964 | End-of-trial Results from a Large Multinational Extension Trial (guardian™2) Using Turoctocog Alfa for Prophylaxis and Treatment of Bleeding in Patients with Severe Haemophilia A

S. Lentz[1], D. Janic[2], M.C. Ozelo[3], A. Tiede[4], I. Matytsina[5], L. Korsholm[5], S. Zupančić-Šalek[6], J. Oldenburg[7]

[1]*University of Iowa Carver College of Medicine, Department of Internal Medicine, Iowa, United States,* [2]*University Children's Hospital, Medical Faculty, University of Belgrade, Belgrade, Serbia,* [3]*IHTC ‚Claudio L.P. Correa', INCT do Sangue Hemocentro UNICAMP, University of Campinas, São Paulo, Brazil,* [4]*Hannover Medical School (MHH), Hannover, Germany,* [5]*Novo Nordisk A/S, Søborg, Denmark,* [6]*National Haemophilia Centre, University Hospital Centre Zagreb, Medical School University of Osijek and Medical School University of Zagreb, Department of Thrombosis and Haemostasis Division of Haematology, Department of Internal Medicine, Zagreb, Croatia,* [7]*University Clinic Bonn, The Institute of Experimental Haematology and Transfusion Medicine and the Haemophilia Centre, Bonn, Germany*

Background: Turoctocog alfa (NovoEight®), a recombinant factor VIII (rFVIII) product, has been approved by major regulatory authorities for the prophylaxis and treatment of bleeds in patients with haemophilia A. guardian™2 was a large, multinational, extension trial of turoctocog alfa in paediatric and adult haemophilia A patients from 19 countries who were previously enrolled in the pivotal guardian™1 and guardian™3 trials, or who had completed pharmacokinetic trials.

Aims: To assess the long-term safety and efficacy of turoctocog alfa for the prevention and treatment of bleeds.

Methods: Previously treated patients, aged 1–70 years, with severe haemophilia A (FVIII activity ≤1%) without inhibitors, received prophylactic therapy with turoctocog alfa (20–50 IU/kg once every second day, 20–60 IU/kg three times weekly, or 40–60 IU/kg once every third day or twice weekly), with additional treatment for bleeding episodes. Treatment success was defined as a patient-reported ‚excellent' or ‚good' haemostatic response.

Results: Data are included for more than 6 years from when the first patient was enrolled and a total of 753 patient-years of turoctocog alfa treatment (mean total number of doses: 164 per patient year for patients on prophylaxis; 55 per patient year for patients treated on-demand). No FVIII inhibitors (≥0.6 Bethesda Units) were detected and no safety issues were identified. The overall estimated annualised bleeding rate (ABR) (Poisson estimated mean) for patients on prophylaxis was 2.44 and the median ABR was 1.37 (Poisson estimated mean ABR for spontaneous bleeds was 1.34). The overall success rate for treatment of bleeds during the preventative regimen was 89.8%; 88.2% of all bleeds were successfully treated with 1–2 injections of turoctocog alfa.

Conclusions: The end-of-trial results of guardian™2 show data that support the long-term safety and efficacy of turoctocog alfa in the

prophylaxis and treatment of bleeds in patients with severe haemophilia A.

PB 965 | rVIII-SingleChain in Surgical Prophylaxis: Efficacy and Safety in 35 Surgeries

F. Abdul Karim[1], C. Djambas Khayat[2], J. Mahlangu[3], R. Baker[4], C. Male[5], J. Oldenburg[6], J. Ong[7], S. P'ng[8], M.E. Mancuso[9], C. Leissinger[10], A. Veldman[11], S. Lucas[12], I. Pabinger[5]

[1]*National Blood Centre, Kuala Lumpur, Malaysia,* [2]*Hotel Dieu de France Hospital, Beirut, Lebanon,* [3]*Haemophilia Clinic, Comprehensive Care Centre Charlotte Maxeke Johannesburg Academic Hospital and Faculty of Health Sciences, NHLS and the University of the Witwatersrand, Johannesburg, South Africa,* [4]*Western Australia Centre for Thrombosis and Haemostasis, Murdoch University, Perth, Australia,* [5]*Medical University of Vienna, Vienna, Austria,* [6]*Institute of Experimental Hematology and Transfusion Medicine, University Clinic Bonn, Bonn, Germany,* [7]*Brokenshire Integrated Health Ministries Inc., Davao, Philippines,* [8]*Royal Perth Hospital, Perth, Australia,* [9]*Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milan, Italy,* [10]*Tulane University Hospital and Clinics, New Orleans, United States,* [11]*CSL Behring, Marburg, Germany,* [12]*CSL Behring, King of Prussia, United States*

Background: rVIII-SingleChain, a novel recombinant Factor VIII, was designed as a B-domain truncated construct with a covalent bond between heavy and light chains, resulting in high binding affinity to von Willebrand Factor.

Aims: To investigate the safety and efficacy of rVIII-SingleChain to control hemostasis in pediatric, adolescent and adult patients with severe hemophilia A undergoing surgery.

Methods: Studies in the AFFINITY program were approved by the relevant Ethics committee and national authorities and conducted according to GCP and the Declaration of Helsinki. In the surgical substudies, 28 patients underwent 35 procedures requiring general, spinal or regional anesthesia. Dosing was guided by WFH recommendations. rVIII-SingleChain was used either as a bolus or continuous infusion. Hemostatic efficacy of rVIII-SingleChain during surgery was rated by investigators.

Results: Surgical procedures performed were: abdominal hernia repair, ankle arthroplasty, ankle hardware removal, appendectomy, arthrodesis of the ankle joint, cholecystectomy, circumcision (9), debridement (2), elbow replacement, excision curettage and bone grafting, dental extraction (3), knee arthroscopy, knee replacement (7), knee spacer and immobilization, lengthening of achilles ligament (2), open reduction and internal fixation of ankle and port-a-cath removal. 27 surgeries were performed using bolus infusion while 8 surgeries used continuous infusion of rVIII-SingleChain. In 32 (91%) procedures efficacy was rated as excellent (defined as hemostasis not clinically significant different from normal) and in 3 (9%) surgeries efficacy was rated as good (defined as hemostasis normal or mildly abnormal in terms of quantity and/or quality eg, slight oozing). No related AEs or SAEs were observed during the surgery period.

Conclusions: rVIII-SingleChain provides very effective and safe control of hemostasis during a wide range of surgical procedures when dosed either by bolus or continuous infusion.

PB 966 | Platelet Aggregation and Clinical Phenotype in Pediatric Patients with Severe Hemophilia A (SHA)

M. Rand[1,2], H. Wang[1], E. McMillan-Ward[3], V.S. Blanchette[1,4], S.J. Israels[3,5]

[1]*Hospital for Sick Children, Hematology, Toronto, Canada,* [2]*University of Toronto, Laboratory Medicine and Pathobiology, Toronto, Canada,* [3]*University of Manitoba, Research Institute in Oncology and Hematology, Winnipeg, Canada,* [4]*University of Toronto, Pediatrics, Toronto, Canada,* [5]*University of Manitoba, Pediatrics and Child Health, Winnipeg, Canada*

Background: There is phenotypic heterogeneity in SHA but the underlying biological cause is unknown. We recently examined platelet function in pediatric patients with SHA, reporting there is no intrinsic platelet aggregation defect (Rand et al, Haemophilia 2016,22(Suppl 4):97).

Aims: To investigate the role of platelet aggregation in the bleeding phenotype in SHA.

Methods: In 2 study sites, whole blood platelet aggregation stimulated by ADP, collagen, arachidonate and TRAP was measured in boys with SHA (factor (F)VIII≤1%) using a Multiplate® analyzer. Informed consent was obtained; the study was approved by the Research Ethics Boards. An ‚overall aggregation response' was calculated for each patient as the sum of responses to the 4 agonists. Bleeding severity was determined as age at 1st joint bleed and annual FVIII consumption (U/kg), averaged over 3yrs.

Results: 42 boys with SHA were enrolled from 2 pediatric hemophilia treatment centres, 20 from Site 1 (median age: 11yrs; range: 4-16) and 22 from Site 2 (12yrs; 6-16). The median age at 1st joint bleed was 3.3yrs (0.5-8.1) at Site 1 and 2.4yrs (0.3-8.1) at Site 2. At either site, there were no correlations between platelet aggregation stimulated by individual agonists or the ‚overall aggregation response' and age at 1st joint bleed. The median annual FVIII consumption was 3431 U/kg (1120-5410) at Site 1 and 5203 (1430-9474) at Site 2. Aggregation responses did not correlate with annual FVIII consumption at Site 1. However, at Site 2, there were significant, strong inverse correlations between annual FVIII consumption and both ADP-induced aggregation (r=-0.69; p=0.0004) and the ‚overall aggregation response' (r=-0.55; p=0.008).

Conclusions: These results suggest a role for augmented platelet aggregation, in particular to ADP, as a determinant of a milder clinical phenotype in SHA that warrants further investigation in a larger, multicentre study; the small number of patients examined in the present study may play a role in the differences between the 2 study sites.

PB 967 | Characterisation of the Inhibitor Status of Patients with Haemophilia A in Australia

S. McRae[1], S. Parikh[1], H. Tran[2]

[1]*Australian Haemophilia Centre Directors' Organisation, Melbourne, Australia,* [2]*Alfred Hospital, Melbourne, Australia*

Background: Inhibitor formation is a significant complication of haemophilia treatment and leads to increased bleed frequency and reduced quality of life.

Aims: To evaluate the incidence of inhibitor formation in Australian patients with haemophilia A (HA), and the treatment strategies utilised in patients with inhibitors, using information from a National registry.

Methods: Data was obtained from the Australian Bleeding Disorder Registry (ABDR) on disease severity, age, inhibitor results, and tolerisation therapy. Patients with a positive inhibitor test result were sub-classified based on whether the inhibitor was persistent, had spontaneously resolved, or previous tolerisation had resulted in eradication.

Results: 1514 patients had undergone testing for the presence of an inhibitor, with 242 (16.0%) having repeat positive tests. The incidence was higher in patients with severe HA (174/651, 26.7%) than in non-severe HA (68/855, 7.95%), p< 0.001. Treatment history and recent tests results were available for 135 patients (100 severe HA, 35 non-severe). 47 (32 severe, 15 non-severe) had persistent inhibitors. Patients with severe HA with a current inhibitor were more likely to be on tolerisation therapy (20/32, 62.5%) than those with non-severe disease (0/15). In patients in whom the inhibitor was no longer present, patients with severe HA were more likely to have previously undergone tolerisation therapy than those with non-severe HA (78% versus 45%; p= 0.001) with spontaneous remission more common in the latter group. Of the 62 patients with successful eradication, mean tolerisation time was 582 days
(SD 521).

Conclusions: The incidence of inhibitor formation in Australian patients with HA is similar to previously reported rates, and remains a significant management issue. Tolerisation appeared to be successful in the majority of patients with severe HA in whom it had been attempted. The optimal management of patients with non-severe HA requires further study.

PB 968 | Long-term Quality-of-Life Outcomes with rFIXFc in Adults with Hemophilia B: Results from B-LONG and B-YOND

J. Su[1], J. Feng[1], K.-J. Myren[2], C. Barnowski[1]

[1]*Bioverativ, Waltham, MA, United States,* [2]*Sobi, Stockholm, Sweden*

Background: Long-term quality-of-life (QOL) effects of rFIXFc are being evaluated in the Phase 3 B-LONG clinical trial and the ongoing B-YOND extension study of adults with severe hemophilia B.

Aims: To evaluate longitudinal QOL data in hemophilia B subjects from B-LONG study entry through the second interim data cut of B-YOND at 24-month follow-up.

Methods: Subjects were evaluated using the Haem-A-QOL patient-reported outcome from B-LONG baseline to B-YOND baseline, through the second B-YOND interim data cut (11 Sept 2015) at B-YOND month 24. Last observation carried forward was used to impute missing data. Within group t-tests compared mean change from baseline on Haem-A-QOL total score and sub-domain scores.

Results: Out of 67 B-LONG prophylaxis subjects (age ≥17) with baseline Haem-A-QOL score, 44 had total change scores from baseline to B-YOND month 24 (mean age 31.3, SD 11.9). 24 patients received prophylaxis prior to trial enrollment, 18 on-demand regimen, and 2 with missing data on prestudy regimen. Patients were from North America (27%), Europe (32%), and other continents (41%), and included 68% White, 9% Asian, 9% African-American, and 14% other. Half (52%) had target joints bleeding at baseline and the median prestudy annualized bleeding rate was 10 (IQR 2, 20). QOL improved from B-LONG baseline to B-YOND baseline (median follow-up 12.2 months, IQR 11.8-13.3) with a mean change of 5.7 (p< 0.01). The QOL improvement was maintained over 24 months of follow-up (p< 0.01). An examination of the sub-domain scores over time suggested that the most pronounced improvements were in sports and leisure, followed by physical health, self-view, and feeling sub-domains.

Conclusions: Subjects treated with rFIXFc reported improvements in overall QOL during B-LONG, and these improvements were maintained for 24 months of B-YOND follow-up. The biggest QOL gains reflected engagement in sports and leisure pursuits, physical health, self-view, and feeling Haem-A-QOL sub-domains.

PB 969 | Lower Risk of Factor VIII Inhibitors among Severe Hemophilia A Patients with Indigenous Background from Brazil

A. Tucunduva[1], A.N. Prezotti[2,3], L.H. Siqueira[1], S.A.L. Montalvao[4], C. Lorenzatto[5], D. Fujimoto[6], A. Streva[7], S. Thomas[8], M.C. Della-Piazza[1], C.S. Costa-Lima[1], S.S. Medina[1], M.C. Ozelo[1,3]

[1]*IHTC 'Claudio L.P. Correa', INCT do Sangue Hemocentro UNICAMP, University of Campinas, Campinas, Brazil,* [2]*Hemocentro do Espírito Santo, HEMOES, Vitória, Brazil,* [3]*Faculty of Medical Sciences, University of Campinas, UNICAMP, Department of Internal Medicine, Campinas, Brazil,* [4]*IHTC ,Claudio L.P. Correa', INCT do Sangue Hemocentro UNICAMP, University of Campinas, Campinas, Brazil,* [5]*Hemocentro do Paraná, HEMEPAR, Curitiba, Brazil,* [6]*Hemocentro do Acre, Hemoacre, Rio Branco, Brazil,* [7]*Hemocentro da Bahia, HEMOBA, Salvador, Brazil,* [8]*Hemocentro do Mato Grosso, Cuiabá, Brazil*

Background: Inhibitor of factor (F) VIII involves a complex multifactorial process with several genetic and non-genetic risk factors.

Aims: To assess the influence of genetic factors in the development of FVIII inhibitors in severe HA (sHA) patients from Brazil.

Methods: 422 sHA patients from the five geographic regions in Brazil, with different ethnic background, were enrolled. For ethnicity, we considered the last 3 generations. Inhibitor >0.6BU on at least two occasions by modified-Bethesda assay were considered positive. DNA samples were used for *F8* genotyping and to determine the 12 single nucleotide polymorphisms (SNPs) in immune regulatory genes (*IL10*, *IL5*, *INFG*, *TGFB1*, *TNFA*, *CTLA4* and *HMOX1)* using TaqMan®SNP Genotyping kit.

Results: Presence or history of inhibitor was confirmed in 97/422 (23%), and 82 (19.4%) were high-responding inhibitors (≥5BU). 39/132 (29.5%) of African descents sHA patients had

inhibitor detected, with a two-fold higher risk of inhibitor compared to Caucasians ($p< 0.01$; OR=2.18; 95%CI 1.36-3.50). Interestingly, among the non-black group, patients with indigenous background had significantly lower occurrence of inhibitor 1/38 (2.6%), compared to Caucasians ($p< 0.01$; OR=0.11; 95%CI 0.01-0.89). In addition, *F8* nonsense and frameshift mutations showed higher risk (OR=2.54, 95%CI, 1.17-5.52 and OR=3.08, 95%CI, 1.03-9.22, respectively) compared to *F8* intron 22 inversion (INV22). SNPs in immune regulatory genes indicated increased susceptibility to inhibitor in patients with the -857CT *TNFA* genotype. However, patients with -819TT and -592AA in *IL10* gene and „CG/CG" haplotype in *TNFA* gene have lower risk of inhibitors. However, multivariate analysis showed that none of the significantly genetic risks explained the difference observed in the ethnic groups.

Conclusions: This study contributes to genetic risk factors for inhibitor development. For the first time, we identified an ethnic group with lower risk of inhibitor, despite the same access and type of treatment they received.

PB 970 | Surgery with Turoctocog Alfa: Efficacy and Safety in Bleeding Prevention During Surgery in Patients with Severe Haemophilia a - Results from the Guardian™ Trials

E. Santagostino[1], M. Misgav[2], P. Chowdary[3], F. Abdul Karim[4], S. Lejniece[5], S. Zupančić-Šalek[6], P.S. Miljic[7], B. Brand[8], I. Matytsina[8]

[1]*IRCCS Foundation Cà Granda Hospital, Maggiore Hospital Policlinic, Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Milan, Italy,* [2]*National Hemophilia Center & Thrombosis Unite, Sheba Medical Center, Ramat-Gan, Israel,* [3]*Royal Free Hospital, Katharine Dormandy Haemophilia Centre and Thrombosis Unit, London, United Kingdom,* [4]*National Blood Centre, Kuala Lumpur, Malaysia,* [5]*Rīga East Clinical University Hospital, Chemotherapy and Hematology Clinic, Rīga, Latvia,* [6]*National Haemophilia Centre, University Hospital Centre Zagreb, Medical School University of Osijek and Medical School University of Zagreb, Department of Thrombosis and Haemostasis Division of Haematology, Department of Internal Medicine, Zagreb, Croatia,* [7]*Clinical Center of Serbia, Clinic of Haematology, Belgrade, Serbia,* [8]*Novo Nordisk A/S, Søborg, Denmark*

Background: Novo Nordisk has developed turoctocog alfa (NovoEight®), a recombinant factor VIII (rFVIII) for the prophylaxis and treatment of bleeds in haemophilia A patients. During the pivotal trial in adult/adolescent previously treated patients (PTPs) with severe haemophilia A (guardian™1), patients needing surgery participated in a subtrial to document safety/efficacy of turoctocog alfa in surgical bleeding prevention. Paediatric PTPs in guardian™3 underwent minor surgery as needed. Once the initial trials completed, patients could continue with turoctocog alfa in the guardian™2 extension trial (with surgical subtrial).

Aims: To assess efficacy/safety of turoctocog alfa in the prevention of surgical bleeding during the guardian™ trials.

Methods: Eligible patients required major or minor surgery during the guardian™ trials. Haemostatic efficacy during/after surgery was rated on a 4-point scale (excellent/good/moderate/none) by the Investigator and/or Surgeon.

TABLE Details and outcomes of major surgical procedures in the guardian™ trials using turoctocog alfa for prevention of excessive surgical bleeding

Surgery indication/duration of surgery (h:mm)/Patient age (years)	Duration of surgery (h:mm)	Patient age (years)	Haemostatic response during surgery	Haemostatic response after surgery
• Arthroscopy of left ankle	0:40	24		
• Evacuation of damaged tissue with metallosis; evacuation of broken fragment of the right elbow implant and replacement with new	1:30	47		
• Evacuation of infected joint prosthesis and evacuation of necrotic tissue	2:18	47		
• Revision of right elbow joint endoprosthesis	1:50	47	Excellent	Excellent
• Left knee surgery	1:45	47		
• Closed reduction of fractured nasal bones	1:00	23		
• Appendectomy	0:35	8		
• Implantation endoprosthesis totalis genus 1 sin synoviectomia subtotalis	2:40	25		
• Implantation endoprosthesis totalis genus 1 dex	3:27	25		
• Panproctocolectomy; ileoanal pouch	3:23	21	Excellent	Good
• Left hip arthroprosthesis, reduction finger fracture	3:25	55	Good	Excellent
• Decompressive craniectomy and evacuation of clot	1:30 3:45	27 37		
• Total knee and total hip replacement	1:30	28		
• Right knee arthroprosthesis				
• Revision replacement of the acetabular part and head of the right hip endoprosthesis	1:35 2:05	39 56	Good	Good
• Resection of radial head, preparation of *nervus ulnaris*	2:00 1:50	47 41		
• Laparoscopic cholecystectomy				
• Knee replacement and elbow radial head excision				

Results: In total, 18 major and 66 minor surgeries were included in the analysis results. In all the major and 64 minor surgeries, haemostatic efficacy during/after surgery was rated as either excellent or good in all cases. For the other 2 minor surgeries, 1 had no clinical evaluation and another endoscopy procedure was rated as ‚none'. Details and outcome of individual major surgeries performed are presented in the Table. No FVIII inhibitors (≥0.6 Bethesda Units) were detected. No thromboembolic events were reported and no hypersensitivity/allergic reactions to turoctocog alfa were observed. Results on adverse events, safety laboratory parameters and other safety-related examinations did not indicate clinically significant changes as a result of turoctocog alfa administration.

Conclusions: Prevention of excessive surgical bleeding is an important aspect of haemophilia treatment. The results support that turoctocog alfa has a favourable safety/efficacy profile when used across a wide range of surgical procedures.

PB 971 | Improved Pharmacokinetics of BAY 81-8973 versus Sucrose-formulated Recombinant Factor VIII (rFVIII-FS): Noncompartmental and Population PK Assessment Based on a Single-dose, Randomized, Crossover, Pharmacokinetics Study in Patients with Severe Hemophilia A

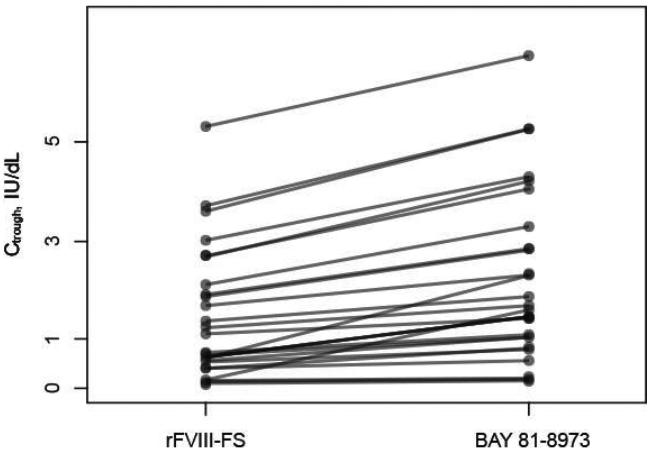
A. Solms[1], D. Garmann[1], A. Shah[2]

[1]*Bayer AG, Berlin, Germany,* [2]*Bayer, Whippany, United States*

Background: BAY 81-8973 is a full-length, unmodified, recombinant human factor VIII (FVIII) with the same primary amino acid sequence as sucrose-formulated recombinant FVIII (rFVIII-FS) produced using newer manufacturing methods.

Aims: To compare the pharmacokinetic (PK) profile of BAY 81-8973 versus rFVIII-FS

Methods: PK samples were collected from 26 male patients aged 12-65 years with severe hemophilia A to compare PK of BAY 81-8973 to rFVIII-FS. Patients were randomized to receive a 50-IU/kg single dose of BAY 81-8973 or rFVIII FS followed by the other treatment after a washout period of ≥3 days. Population PK (popPK) models were developed based on chromogenic assay data for both products and simulations were conducted to estimate trough levels after administration of the products and to project dose and/or time to achieve threshold levels of 1, 3, 5, 10 IU/dL FVIII expected to provide bleeding protection. A similar study previously showed a superior PK profile of BAY 81-8973 versus antihemophilic factor (recombinant) plasma/albumin-free method (Shah et al, *Clin Pharmacokinet*. 2016:Epub).



A solid line indicates that a switch from rFVIII-FS to BAY 81-8973 results in an increase in trough levels for this patient.
C_{trough}=trough level; PK=pharmacokinetic; rFVIII-FS=recombinant factor VIII formulated with sucrose.

FIGURE 1 Estimated PK trough levels at steady state following a dose of 30 IU/kg BAY 81-8973 or rFVIII-FS 3x/week

Results: Mean PK parameters for BAY 81-8973 were higher for area under the curve and half-life and lower for clearance **(Table 1)**, indicating a more favorable PK profile versus rFVIII-FS. Estimations based on popPK models showed higher trough levels for all patients for BAY 81-8973 at steady state following a dose of 30 IU/kg 3x/week **(Figure 1)**. Simulations showed that median time to 1 IU/dL was ~16% (~10 h) longer for BAY 81-8973 versus rFVIII-FS over 25-50 IU/kg doses. The same FVIII threshold level could be achieved with a lower dose of BAY 81-8973.

Conclusions: BAY 81-8973 showed an improved PK profile versus rFVIII-FS based on noncompartmental analysis and popPK. For BAY 81-8973, higher trough levels can be achieved with similar doses and frequencies which can lead to better protection against breakthrough bleeds. Longer time to threshold levels for BAY 81-8973 can allow for less frequent dosing.

PB 972 | Towards the Development of a Core Set of Outcome Measures for Standardized Assessment of Outcomes in Persons with Hemophilia

B. Feldman[1,2], A. Srivastava[3], S. Dover[4], A. Abad[4], V. Blanchette[5,6]

[1]*The Hospital for Sick Children, Division of Rheumatology, Department of Pediatrics, Toronto, Canada,* [2]*University of Toronto, Institute of Health Policy, Management and Evaluation, the Dalla Lana School of Public Health, Toronto, Canada,* [3]*Christian Medical College, Department of Hematology, Vellore, India,* [4]*The Hospital for Sick Children, Research Institute, Child Health Evaluative Sciences, Toronto, Canada,* [5]*The Hospital for Sick Children, Pediatric Thrombosis and Hemostasis Program, Division of Hematology/Oncology, Toronto, Canada,* [6]*University of Toronto, Department of Pediatrics, Toronto, Canada*

Background: There is a lack of systematic use of well-defined outcome measures (OM) in care for persons with hemophilia (PWH). New therapeutics and an emphasis on outcomes in clinical care have resulted in unprecedented activity in OM research. Over the last decade, many tools have been developed, nearly covering all domains of the International Classification of Functioning, Disability and Health (ICF) model. There is an urgent need to define the important OM to be used in the various clinical contexts.

TABLE 1 PK Parameters Calculated Using Noncompartmental Methods*

Parameters	BAY 81-8973 (N=26) Geometric Mean (%CV)	rFVIII-FS (N=26) Geometric Mean (%CV)	Least Squares Mean Ratio (95% CI)	P Value
Cmax, IU/dL	130.1 (23.0)	136.2 (23.8)	0.96 (0.85-1.08)	0.45
AUC, IU·h/dL	1889.2 (36.1)	1583.9 (39.9)	1.19 (1.09-1.30)	0.0003
t1/2, h	13.8 (28.0)	12.0 (28.2)	1.15 (1.06-1.24)	0.0016
MRTiv, h	19.3 (26.8)	16.5 (27.4)	1.17 (1.09-1.25)	<0.0001
CL, dL/h/kg	0.026 (36.1)	0.032 (39.9)	0.84 (0.77-0.91)	0.0003

*Data based on the chromogenic assay.
AUC=area under the curve from time 0 to infinity; CL=clearance; Cmax=maximum concentration; CV=coefficient of variation; MRTiv=mean residence time; PK=pharmacokinetic; rFVIII-FS=recombinant factor VIII formulated with sucrose; t1/2=half-life.

Aims: The aim of this work is to define a core set of OM that should be considered for the assessment of PWH in research and practice, within the ICF framework.

Methods: As a follow-up to a meeting in 2014, we initiated a 5 step process to define a core set, guided by the findings of systematic reviews of tools for joint health scores, activity/participation, and health related quality of life. Step 1 was to develop a list of potential OM by conducting a centre-based survey of a multidisciplinary group of international experts in hemophilia care and PWH (n=55). The survey was for item-generation and classification into the 6 ICF domains. In step 2, individual respondents (n=74) voted on each item. Next, in a 2 day consensus meeting (n=49) the following were discussed: the results from the surveys, systematic reviews, and information from experts in each ICF domain. Two rounds of voting and discussion by participants (steps 3 & 4) occurred for each item from the surveys. In step 5, participants (n=48) were surveyed and voted for their top 5 items from a list of those with >50% agreement identified in steps 3 and 4.

Results: Table 1 shows the response rate for each step in the process.

TABLE 1 Response rate per step in the process

Step in the Process	Response Rate (%)
Step 1: Item Generation, hemophilia treatment centre (HTC) based	55/76 HTCS (72.4)
Step 2: Initial voting, individual based	74/106 individuals (69.8)
Steps 3 & 4: Consensus conference attendees	49/52 individuals (94.2)
Step 5: Final voting, post-meeting, individual based	48/52 individuals (92.3)

Table 2 shows the top 5 OM that emerged from this process.

TABLE 2 Proposed outcome measure core sets

Core set for pediatric patients (% yes to core set)	Core set for adult patients (% yes to core set)
A measure of treatment satisfaction (92.7)	Total bleeding events (88.1)
Hemophilia Joint Health Score (HJHS) (83.3)	EuroQol five dimensions (EQ-5D) (85.4)
A measure of access to treatment (82.5)	A measure of treatment adherence (82.1)
A measure of treatment adherence (72.5)	Hemophilia Joint Health Score (HJHS) (79.1)
Generic performance based physical function (72.1)	Number & location of bleeds per unit time (78.6)

Conclusions: This process generated a core set of OM which should be considered for assessment of outcomes in PWH. This information now requires refinement to define optimal core sets for use in different clinical/research contexts.

PB 973 | Low-dose Factor VIII Infusion in Chinese Adult Haemophilia A Patients: Pharmacokinetics Evidence that Daily Infusion Results in Higher Trough Level than with Every-other-day Infusion with Similar Factor VIII Consumption

B. Hua[1], A. Lee[2], J. Gu[3], K. Li[1], M.-C. Poon[2], Y. Zhao[1]

[1]Peking Union Medical College Hospital, Beijing, China, [2]University of Calgary, Foothills Hospital, Calgary, Canada, [3]Northern Jiangsu People's Hospital, Yangzhou, China

Background: Pharmacokinetics (PK) modeling suggests improvement of trough levels are achieved by using more frequent infusion strategy. However, no clinical study data exists to confirm or quantify improvement in trough level, particularly for low-dose prophylaxis in patients with haemophilia A

Aims: To provide evidence that low dose daily (ED) prophylaxis can increase trough levels without increasing FVIII consumption compared to every-other-day (EOD) infusion

Methods: A cross-over study on 5 daily vs 10 IU Kg^{-1} EOD FVIII infusions, each for 14 days was approved and conducted at the PUMCH. On the ED schedule, trough (immediate prior to infusion), and peak FVIII:C levels (30 mins after infusion) were measured on days 1 to 5; and trough levels alone on days 7,9,11,13; for the EOD schedule, troughs and peaks on days 1, 3, 5, 7; troughs alone on days 2, 4, 6, 9, 11, 13.

Results: Six patients were enrolled. At the 24-hour post-infusion time point, the median trough levels of FVIII:C was higher in the EOD group (6.9, IQR 6.23-9.03 IU dL^{-1}) compared to the ED group (5.6, IQR 4.0-6.6 IU dL^{-1}) given the higher dose (10 vs. 5 IU kg^{-1}) and thus higher peak achieved in the EOD group [29.3 (IQR 23.9-31.5) vs. 17.5 (IQR 14.3-19.13) IU dL^{-1}]. However, by 48 hours, both regimens are at a trough time point and the trough FVIII:C levels in ED group (due to another additional daily infusion) was nearly 2 (range 1.8-2.3) times higher than that in EOD group [5.6 (IQR 4.0- 6.6) vs 2.5 (IQR, 2.01-3.65)]. When steady state trough levels (defined as after 5 consecutive infusions) were achieved in each infusion group (days 6-13 for ED, days 11,13 for EOD), the improvement in trough level remained ~2 times higher in the ED group compared to EOD [5.8 (IQR 4.05-6.8) vs 2.7 (IQR 2.08-4.65)].

Conclusions: Our PK study shows low-dose Factor VIII daily infusion results in higher trough level than with EOD infusion with similar factor VIII consumption in Chinese adult haemophilia A patients.

PB 974 | Association of Factor VIII and Factor IX Mutations, HLA Class II, Tumor Necrosis Factor-Alpha and Interleukin-10 on Inhibitor Development among Thai Hemophilia A and B

A. Chuansumrit[1], W. Sasanakul[1], N. Sirachainan[1], P. Kadegasem[1], P. Wongwerawattanakoon[2], L. Mahaklan[1], O. Nathalang[3]

[1]Faculty of Medicine Ramathibodi Hospital, Mahidol University, Department of Pediatrics, Bangkok, Thailand, [2]Faculty of Medicine Ramathibodi Hospital, Mahidol University, Department of Nursing, Bangkok, Thailand, [3]Faculty of Allied Health Sciences, Thammasat University, Department of Medical Technology, Pathumtani, Thailand

Background: Mutations on factor VIII and factor IX genes as well as polymorphisms of the immune response genes of human leukocyte antigen (HLA)-*DRB1*15*, tumor necrosis factor-alpha (TNF-alpha)-*308A* and interleukin-10 (IL-10)-*1082G* alleles have been suggested to be contributing determinants of inhibitor risk.
Aims: To study the association of factor VIII and factor IX mutations, HLA-*DRB1*15*, TNF-alpha-*308A* and IL-10-*1082G* alleles on the inhibitor development among Thai hemophilia A and B patients.
Methods: A total of 116 hemophilia A patients from 100 families and 42 hemophilia B patients from 36 families were enrolled.
Results: Hemophilia A patients were divided in two groups: 55 patients without inhibitor and 45 patients with inhibitor (25 high titer ≥5 Bethesda unit/mL, 20 low titer). Factor VIII mutations were identified in 97 of 100 families. Twelve were novel. Forty-one of 81 patients (50.6%) with inversion intron 22, large deletion and nonsense mutation developed significantly higher inhibitor than those with missense mutation (2/16=12.5%). No significant difference was found between the frequencies of HLA-*DBR1*15*, TNF-*a*-308A and IL-10-*1082G* among hemophiliacs with and without inhibitor. For hemophilia B patients, factor IX mutations were identified in all subjects. Seven were novel. Unfortunately, one severe hemophilia B patient with nonsense mutation developed inhibitor. He was heterozygote for GA at TNF-alpha and GA for IL-10 genes while another similar hemophilia B patient without inhibitor was homozygote for the wild type of GG for TNF-alpha and AA for IL-10 genes.
Conclusions: For Thai hemophilia A patients with inhibitor, factor VIII mutations showed a significant contribution while the HLA-*DRB1*15* gene had some contribution. However, *-308A* at the TNF-alpha gene and *-1082G* at the IL-10 gene were of lesser impact. On the contrary, TNF-alpha-*308A* and IL-10-*1082G* alleles might be associated with inhibitor development in one Thai severe hemophilia B patient.

PB 975 | Participation of Clinical Psychologist in a Non-hemophilia Treatment Center

A. Nakao[1], J. Yamanouchi[1], T. Hato[1], E. Ishii[2], M. Yasukawa[1]

[1]Ehime University, Department of Hematology, Toon, Japan, [2]Ehime University, Department of Pediatrics, Toon, Japan

Background: An innovative therapeutic management of hemophilia has been implemented at many hospitals in Japan. However, psychosocial support for hemophilia patients and their families is limited because there are few hemophilia treatment centers which can provide multidisciplinary care and support in Japan. Our hospital is a non-hemophilia treatment center and only medical doctors have seen patients with hemophilia. In 2013, one clinical psychologist joined the adult hemophilia care service. Since then the clinical psychologist has contributed to hemophilia health care, and resolved diverse medical and psychosocial issues.
Aims: This study reports on the assessment of these issues.
Methods: We evaluated 13 patients with a median age of 35 (range; 21-69). Ten patients had severe hemophilia and one of them had inhibitors. All patients with severe hemophilia were on regular prophylaxis. A clinical psychologist had interviews with patients and/or families independently of doctor's medical examination, and measured mood and emotion state by POMS2 (Profile of Mood States Second Edition).
Results: The main issues in young patients were self-infusion and transition from pediatric to adult services. In older patients, the major concerns were joint problems including decision of surgical management. Their POMS2 showed that "confusion - bewilderment" became greater scores and „vigor - activity" became lower scores. We thought that these results reflected the relevant mood such as anxiety. In addition, we found that the positive mood state of „vigor - activity" and the negative mode state of „friendliness" in the patients who have serious problems on joints and who have inhibitors.
Conclusions: The clinical psychologist had a large impact on hemophilia health care and the health-related quality of life in hemophilia patients was greatly improved. Addressing the psychological problems in hemophilia is of great value and a clinical psychologist plays an important role even in a non-hemophilia treatment center.

PB 976 | Continuous Infusion of Recombinant Factor IX Fc Fusion Protein during Major Surgery

T. Kanematsu[1], N. Suzuki[2], M. Ogawa[3], M. Kishimoto[1], A. Suzuki[1], H. Kiyoi[3], T. Kojima[4], T. Matsushita[2]

[1]Nagoya University Hospital, Department of Clinical Laboratory, Nagoya, Japan, [2]Nagoya University Hospital, Department of Transfusion Medicine, Nagoya, Japan, [3]Nagoya University Graduate School of Medicine, Department of Hematology and Oncology, Nagoya, Japan, [4]Nagoya University Graduate School of Medicine, Pathophysiological Laboratory Science, Nagoya, Japan

Background: While extended-half-life-recombinant factor IX (EHL-rFIX) is becoming popular among Hemophilia B patients as prophylaxis, hemostatic management of major surgery using such agents is not established.
Aims: To evaluate the efficacy and safety of continuous infusion (CI) of recombinant factor IX Fc fusion protein (rFIXFc), the first EHL-rFIX, in major surgery.
Methods: Tissue-factor-triggered thrombin generation assay was performed by means of calibrated automated thrombogram (Thrombinoscope BV). Other data was gathered from clinical records. Informed consent was obtained from patient, which was approved by the local ethics committee.
Results: Case: The patient is an 81 years old man with mild Hemophilia B. He developed cystic tumor in his pancreas head and required surgery.

Laboratory data: Hct 29.7%, Plt 222×10^9/L, APTT 48.1sec (normal control 30.8sec), Factor IX activity (FIX:C) 14IU/dL. PT, Fibrinogen and other coagulation factors were all within normal limits.

Clinical course: After rFIXFc bolus infusion (95.2IU/kg), CI was started at 3.81IU/hr/kg. Additional 4000IU of rFIXFc was administered to make up for the loss by bleeding (1039mL including ascites) during the surgery. As bleeding was easily controlled after the surgery, we gradually reduced rFIXFc and stopped CI at post-operative day (POD) 15. There were no bleeding or thrombotic complications throughout the course.

Hemostatic analysis: Actual clearance of rFIXFc during the CI was higher than those obtained from Pharmacokinetic (PK) test (table.1). It was similar to those of rFIX (previous data). After the surgery, thrombin generation was better than those of normal control plasma (table.2). This might be due to increased procoagulant factors and decreased anticoagulant factors (data not shown).

Conclusions: We successfully managed major surgery under CI of rFIXFc. The advantage of rFIXFc reducing factors consumption was limited during CI. That seems to be because the clearance during CI strongly depend on the early-phase of distribution.

TABLE 1 Comparison of calculated and actual clearances of rFIXFc and rFIX. *Suzuki N, et al. Haemophilia 2015

	rFIXFc PK (before surgery)	rFIXFc CI (POD7)	rFIX (previous data*)
Clearance(mL/hr/kg)			
Calculated from distribution half-life	2.51		4.0-5.1
Calculated from terminal half-life	0.66		1.7-2.8
Calculated from AUC	2.04		3.3-4.3
Actual clearance during CI		4.10	4.2-5.6

TABLE 2 Course of thrombin generation

			rFIXFc CI	
	Normal control plasma	Baseline	3.81IU/hr/kg (POD7)	1.9IU/hr/kg (POD11)

Peak thrombin (nmol/μL)	85.02	56.22	160.82	132.58
Endogenous Thrombin Potential (nmol min/L)	1118	1383	1378	1295

PB 977 | United States Post-marketing Safety (PMS) Study of rpFVIII in Patients with Acquired Hemophilia A: Preliminary Enrollment Data

R. Crea[1], J.-F. Huang[2], J. Jiang[2], A. Gringeri[1], N. Bajwa[3]

[1]*Shire plc, Global Medical Affairs, Vienna, Austria,* [2]*Shire plc, Biostats & Data Management, Cambridge, United States,* [3]*Shire plc, Global Medical Affairs, Chicago, United States*

Background: Acquired hemophilia A (AHA) is a rare autoimmune disorder characterized by development of neutralizing autoantibodies to circulating factor VIII (FVIII). Obizur is a recombinant, B-domain deleted, porcine-sequence FVIII (rpFVIII) with low cross-reactivity to anti-human-FVIII antibodies for the treatment of AHA.

Aims: Collection of data to assess safety and safety-related factors, utilization and effectiveness of rpFVIII in real-world clinical practice was committed by Shire with the United States (US) Food and Drug Administration.

Methods: This is a multi-center, non-controlled, open-label, non-interventional PMS surveillance study conducted in the US on AHA patients treated with rpFVIII. Prospective and retrospective data will be collected from 40 patients. Statistical analyses will be conducted and include specifically, but not exclusively, descriptive statistics.

Results: A preliminary, unplanned data read-out was carried out on Dec 15, 2016 on 7 subjects (4 males and 3 females, 10 bleeds) with AHA recruited in 5 centers in the US: median age 73 years (range 59-75 years). Demographics details are listed in table 1.

TABLE 1 Demographic details

AGE (years)	Mean	Median	Range
Overall	70.4	73.0	59-75
Males	67.8	68.5	59-75
Females	74.0	74.0	73-75
WEIGHT (kilograms)	Mean	Median	Range
Overall	97.0	85.1	69-159.3
Males	110.4	99.6	83-159.3
Females	79.3	83.7	69-85.1

In 1 subject, an underlying malignancy was reported. Bleed characteristics are described in table 2.

Five of 7 patients were reported to have been treated with other hemostatic drugs before being administered rpFVIII, while 2 subjects were treated with rpFVIII as first option once diagnosed for the specific bleeding event. The median loading dose was 100.2 IU/kg (range 50-203, mean of 122.3 IU/kg).

Conclusions: rpFVIII represents an innovative treatment for AHA subjects and this study, along with the PMS study just started in Europe, will provide real world clinical data on its safety and efficacy profile.

TABLE 2 Bleed characteristics

Patient details (Sex, age, body weight)	Description / severity of initial bleeding event	Location of initial bleeding event	Specific anatomical location of initial bleeding event
Male, 64 yrs, 104.3 kg	Traumatic, severe	Skin	_
Male, 59 yrs, 159.3 kg	Traumatic, severe	Deep (musculoskeletal, retroperitoneal)	Retroperitoneal bleed and hematoma on thigh
Female, 74 yrs, 69 kg	Traumatic, severe	Deep (musculoskeletal, retroperitoneal)	Left pectoralis major and minor muscles
Male, 75 yrs, 94.9 kg	Spontaneous, not severe	Mucosa	Hematuria
Male, 73 yrs, 83 kg	Spontaneous, severe	Deep (musculoskeletal, retroperitoneal)	Neck
Female, 73 yrs, 83.7 kg	Spontaneous, not severe	Other	Right lower extremity from toes to gluteal region, right upper arm
Female, 75 yrs, 85.1 kg	Spontaneous, severe	Deep (musculoskeletal, retroperitoneal)	Left forearm-flexor digitorum profundus muscle and flexor pollicis brevis muscle

Data from real world use of rpFVIII might help with further assessment of dosing regimen and guidance regarding appropriate dosing in order to personalize the treatment for each individual condition.

PB 978 | Initial Safety Results from a Prospective Post-marketing Surveillance Study Using rFVIIIFc in the Real World Setting in Japanese Hemophilia A Patients

M. Taki[1], K. Fukutake[2], M. Kobayashi[3], A. Nagao[4], H. Makioka[5], M. Shiraishi[6]

[1]*St. Marianna University School of Medicine, Department of Pediatrics, Kanagawa, Japan,* [2]*Tokyo Medical University, Department of Laboratory Medicine, Tokyo, Japan,* [3]*Hiroshima University Hospital, Department of Pediatrics, Hiroshima, Japan,* [4]*Ogikubo Hospital, Department of Hematology, Tokyo, Japan,* [5]*Biogen Japan, PMS and Data Management, Tokyo, Japan,* [6]*Bioverativ Japan, Medical, Tokyo, Japan*

Background: Recombinant factor VIII Fc fusion protein (rFVIIIFc), manufactured in a human cell line, was developed to extend the half-life of FVIII. Safety and efficacy of rFVIIIFc in previously treated adults, adolescents, and children with hemophilia A have been demonstrated in the Phase 3 A-LONG and Kids A-LONG studies. rFVIIIFc has been marketed in Japan since March 2015.

Aims: To report initial safety data in subjects in the real world setting from the rFVIIIFc post-marketing surveillance study (PMS) that was initiated as a regulatory requirement in Japan.

Methods: This prospective, multicenter, observational study evaluated safety and efficacy of rFVIIIFc in hemophilia A patients of any age and any disease severity. Data are collected every 6 months using the electronic data-capture system.

Results: Of 123 patients enrolled at 52 sites, 83 signed informed consent for publication and 70 received rFVIIIFc as of 31 Oct 2016. Mean age was 28 years (range: < 1-65). 12 patients were < 6 years; 6 were 6-< 12 years; 11 were 12-< 18 years; and 38 were ≥18 years of age (age not provided for 16 patients). At study entry, 60 patients had >100 exposure days (EDs), 6 patients had 4-99 EDs, and 3 patients had 0-3 EDs. Of the 3 previously-untreated patients, 2 were aged < 1 year and 1 was 2 years. ED data were unavailable for 14 patients. A total of 49 patients had severe (< 1%) hemophilia. Among them, 32 had prophylactic dosing frequency data for prestudy non-rFVIIIFc products and on-study rFVIIIFc. In the patients with severe hemophilia who were dosed ≥3 times per week prestudy, prophylactic dosing frequency was reduced to < 3 times per week (Table 1) with rFVIIIFc. 19 patients have completed 12 months on-study. As of 31 Oct 2016, no inhibitor development, serious allergic reactions, or serious vascular thrombotic events were reported in 70 patients who received rFVIIIFc.

Conclusions: These data support a favorable safety profile for an extended half-life product, rFVIIIFc, in the real world in Japanese hemophilia A patients.

TABLE 1 Dosing Frequency of Eloctate* by Hemophilia Severity**

On study prophylaxis regimen	Severe (<1%) n=32	Moderate (1-5%) n=11	Mild (5-40%) n=6
Every 3 days	8 (25%)	2 (18%)	0
Twice weekly	15 (47%)	4 (36%)	1 (17%)
Every 5 days	2 (6%)	0	0
Weekly	7 (22%)	3 (27%)	5 (83%)
Others	0	2 (18%)	0

*At onset of the study. **Hemophilia severity was not available for 5 patients: 4 were treated twice weekly and 1 was weekly.

PB 979 | Factor Utilization and Costs in Patients with Hemophilia B Using Standard and Extended Half-life Recombinant Factor IX Replacement Products: Real-world Analysis in Japan

T. Karumori[1], S. Hiro[1], A. Chhabra[2], D. Spurden[3], A. Pleil[4], J. Alvir[2], B. Tortella[5]

[1]*Pfizer Japan Inc, Tokyo, Japan,* [2]*Pfizer Inc, New York, United States,* [3]*Pfizer Limited, Surrey, United Kingdom,* [4]*Pfizer Inc, San Diego, United States,* [5]*Pfizer Inc, Collegeville, United States*

Background: Management of hemophilia B requires replacement therapy with factor IX (FIX) coagulation products. Extended half-life

TABLE 1 Analysis of FIX Concentrate IU Utilization Before and After Switching From an SHL to EHL Product (MDV database) - MEDIAN VALUES

	Months Pre-switch				SWITCH	Months Post-switch			
Median Units	10-12 (n=7)	7-9 (n=7)	4-6 (n=8)	1-3 (n=10)		1-3 (n=10)	4-6 (n=6)	7-9 (n=4)	10-12 (n=4)
IU Utilization	40,000	30,000	38,000	31,000		25,500	20,500	27,500	28,500
Factor Costs	¥ 4,122,720	¥ 3,191,610	¥ 4,018,724	¥ 3,296,830		¥ 5,281,332	¥ 4,246,219	¥ 5,690,430	¥ 5,885,545
Total Health care costs*	¥ 4,154,735	¥ 3,240,767	¥ 4,636,173	¥ 3,339,487		¥ 8,801,094	¥ 4,656,339	¥ 5,855,292	¥ 5,946,696

* Total health care costs were calculated for the patients who have FIX treated record. Data presented for the SHL product are specifically for nonacog alfa, and data presented for the EHL product are specifically for eftrenonacog alfa. EHL, extended half-life; SHL, standard half-life.

(EHL) recombinant FIX products are now available along with the existing standard half-life (SHL) FIX replacement products.

Aims: Examine factor utilization and costs for patients in Japan who switched from a SHL to an EHL product in a real world setting.

Methods: Japanese real world data provided by Medical Data Vision Co., Ltd (MDV) was used to compute FIX utilization (number of IUs dispensed) and direct product costs (¥) and total health care costs (¥) among patients with claims data for ≥3 mo before and after switching from an SHL to EHL product (April 2010-October 2016). MDV is the most populated real-world database collected from medical and pharmacy claims data in hospitals, regardless of insurance, for >10 million inpatients and outpatients in Japan.

Patients filled ≥2 FIX prescriptions or 1 FIX prescription with ≥84-day supply. Medians for cost and IUs were used to accommodate for the skewness of data distribution.

Results: Ten patients switched from an SHL (Nonacog alfa) to EHL (eftrenonacog alfa) product and had ≥3 mo of data before and after the switch. Factor replacement costs were uniformly higher after the switch from SHL to EHL in each of the corresponding 3-month time periods examined before versus after the switch. Median quarterly costs were ¥4,122,720, ¥3,191,610, ¥4,018,724, ¥3,296,830 (SHL) and ¥5,281,332, ¥4,246,219, ¥5,690,430, ¥5,885,545 (EHL) while median quarterly metric IUs were 40,000, 30,000, 38,000, 31,000 (SHL) and 25,500, 20,500, 27,500, 28,500 (EHL) in the 12-10 (n=7), 9-7 (n=7), 6-4 (n=8), 3-1 (n=10) and 1-3 (n=10), 4-6 (n=6), 7-9 (n=4), 10-12 (n=4) months pre- and post-switch, respectively (Table 1).

Conclusions: This analysis shows that switching from SHL to EHL product was associated with increased and more variable FIX replacement costs. Further analyses in larger patient populations should be explored.

PB 980 | Long Term Hemostatic Efficacy of Once a Week Administration with a Combination Medicine of Plasma Derived Factor Viia and Factor X for a Hemophilia B Patient with Inhibitor

T. Suzuki[1], Y. Chikasawa[1], T. Hagiwara[1], M. Bingo[1], Y. Yamamoto[1], K. Amano[1,2], K. Fukutake[1,2]

[1]*Tokyo Medical University, Department of Laboratory Medicine, Tokyo, Japan,* [2]*Tokyo Medical University, Department of Molecular Genetics of Coagulation Disorders, Tokyo, Japan*

Background: Case - The patient is a man in his thirties. The closer examinations for repetitive bleedings revealed to diagnose as severe type of hemophilia B at 1-year-old. Since then he had been receiving episodic treatments for his bleedings with several kinds of FIX products, however those treatments were interrupted by allergic/anaphylactic reactions. When he was nineteen, an antibody to FIX initially developed and further reached to 62 BU with a nephrotic syndrome three years later after inhibitor developed. Clinical course: A large amount of rFVIIa has been used for his hemostatic control because of his high frequency of bleeding, therefore once a week administration with Byclot® (Kaketsuken, Japan) as a new bypass agent developed in Japan, which contains plasma derived FVIIa combined with plasma derived FX (pdFVIIa/FX) has been introduced in his routine life.

Aims: Bypass agents are useful and indispensable for hemostatic control for prophylaxis as well as acute bleedings in hemophilic patients with inhibitor. We evaluated the long term hemostatic efficacy in a hemophilia B patient with inhibitor by once a week administration with Byclot®.

Methods: Both the frequency of bleedings and the infusion times were compared at each end of scale between on-demand with rFVIIa and once a week administration with Byclot®.

Results: Mean monthly bleeding episodes and infusion times during their observational periods were 3.8 and 19.3 in on-demand with rFVIIa, and 1.2 and 3.9 in once a week administration with Byclot®, respectively. No thrombotic adverse events were observed in two years with Byclot®.

Conclusions: Both bleeding episodes and infusion times decreased by 68.4% and 79.8% respectively in Byclot®. The ABR also reduced from 45 to 14.5 after introducing once a week administration with Byclot®. Our experiences suggested that once a week administration with Byclot® might be a new option as a regular treatment in hemophilia patients with inhibitor.

PB 981 | Economic Impact of Recombinant FVIII (rFVIII) vs Plasma-derived FVIII with von Willebrand Factor (pdFVIII/VWF) and Low-dose vs High-dose Immune Tolerance Induction in Previously Untreated Hemophilia A Patients (PUPs) in Germany

J. Oldenburg[1], E. Neufeld[2], M.C. Runken[3], K. O'Day[4], K. Meyer[4], J. Spears[3]

[1]University Clinic Bonn AöR, Bonn, Germany, [2]Harvard Medical School, Boston, United States, [3]Grifols SSNA, Research Triangle Park, United States, [4]Xcenda, LLC, Palm Harbor, United States

Background: Inhibitor development to FVIII therapy results in increased complications and economic burden. The SIPPET study found higher inhibitor rates in previously untreated patients (PUPs) treated with conventional rFVIII than with pdFVIII/VWF.

Aims: To quantify the potential economic impact of treating PUPs with pdFVIII/VWF vs rFVIII and eradicating inhibitors with low-dose (LD) vs high-dose (HD) immune tolerance induction (ITI).

Methods: An Excel-based clinical and economic model was run from a German healthcare payer perspective over a 5-year period. One-year-old PUPs initiated prophylactic or on-demand therapy with rFVIII or pdFVIII/VWF. High-titer inhibitor development rates were obtained from the SIPPET study (28.4% for rFVIII and 18.6% for pdFVIII/VWF). PUPs developing inhibitors received LD or HD ITI and bypass agents. Patients successfully tolerized with ITI returned to FVIII treatment, while unsuccessful patients received bypass-agent prophylaxis. Treatment regimens, ITI outcomes, and rates of serious bleeds were based on the literature and expert opinion. All cost inputs were identical between the 2 arms, except for the costs of the 2 antihemophilic agents. Treatment costs were calculated monthly based on patient weight while total costs were over 5 years.

Results: Total 5-year per-patient treatment costs for pdFVIII/VWF were €448,356 for LD and €612,481 for HD ITI while rFVIII resulted in €691,639 for LD and €1,090,694 for HD ITI, saving over €243,000 for LD and €478,000 for high-dose ITI. FVIII costs for patients without high-titer inhibitors were 26% lower for pdFVIII/VWF than for rFVIII. Costs for patients with high-titer inhibitors receiving low-dose ITI were 44% lower for pdFVIII/VWF than rFVIII, and costs for patients with high-titer inhibitors receiving high-dose ITI were 52% lower for pdFVIII/VWF than rFVIII.

Conclusions: Treatment of hemophilia A PUPs with pdFVIII/VWF has the potential to result in significant cost-savings compared to rFVIII, particularly when high-dose ITI is utilized.

PB 982 | Low Dose Long Acting CFC (Eloctate, Biogen) Replacement during Bilateral Total Knee Replacement Surgery (TKA) for Hemophilia A - Feasible and Extremely Cost Effective Approach

S. Apte[1], M. Swamy[2], A. Raiyani[2], A. Joshi[1], K. Subramanian[1], D. Vagasiya[1], H. Balar[1], R. Phatale[1], R. Dange[1]

[1]Sahyadri Speciality Hospital, Dept of Hematology & BMT, Pune, India, [2]Sahyadri Speciality Hospital, Pune, India

Background: Knee arthropathy is crippling situation affecting QOL for PWH. TKA is performed using Total 2000iu/kg of PD or Rec CFC. Literature recommends 1000-1200iu/kg of Total Eloctate for TKA.

Aims: Aim for Feasible, safe & Cost Effective CFC replacement policy for TKA

1) Use lower dose Eloctate during TKA

2) Perform Bilateral TKA in same sitting.

Methods: Data:

1) Total Patients: 6

2) Age: 44 years (28-51years)

3) Pre OP dose: 50iu/kg

4) Pre OP FVIIIc Level: 104 iu/dl (86-126iu/dl)

5) Post OP Eloctate doses: 40-50iu/kg once daily till day 5, then 30iu/kg once daily till Day15.

6) FVIIIc assay:Twice daily for first 3days, Once daily till day7, Alternate day till day 14.

7) Trough FVIIIc level > 60iu/dl for 5 days

8) LMWH Thrombo-prophylaxis & CPM was started from Day 2 post OP.

Results: Total 10 TKA performed on 5 patients where all underwent Bilateral TKA in same sitting.One patient underwent Pseudo tumor excision and TKA in the same sitting,which required extra 50iu/kg dose of Eloctate+ 8PCV+8 FFP + 10 Cryoprecipitate intra OP because of massive bleeding during excision of Pseudo Tumor;following which there was no further bleeding till the day of discharge. No excessive bleeding recorded among rest 5 patients in Peri & Post Op period & did not require any blood products or extra doses of Eloctate till discharge.All patients mobilization was started on day 2. All patients received LMWH prophylaxis with 0.4ml Enoxiparin sc once daily till discharge.No wound or prosthesis infection was noted.

Toatal Eloctate used: Median 550 iu/kg.

Conclusions:

1) Low dose Eloctate replacement is safe and cost effective for TKA in PWH

2) Bilateral TKA in same sitting is feasible and increases cost effectiveness in PWH

3) Thrombo-prophylaxis with LMWH can be done safely in PWH

4) Bleeding events did not increase with low dose Eloctate & LMWH

5) Our protocol offers a cost effective and safe option in resource constraint countries.

PB 983 | Improving Care in Haemophilia: A Qualitative Study

E. van Balen[1], M. Krawczyk[2,3], D. Gue[4], S. Jackson[4,5], S. Gouw[1], J. van der Bom[1], R. Sawatzky[6,7]

[1]Leiden University Medical Center, Leiden, The Netherlands, [2]Providence Health Care Research Institute, Center for Health Evaluation & Outcome Sciences, Vancouver, Canada, [3]Trinity Western University, Langley, Canada, [4]British Columbia Provincial Bleeding Disorders Program, Vancouver, Canada, [5]University of British Columbia, Division of Hematology, Department of Medicine, Vancouver, Canada, [6]Providence Health Care Research Institute, Centre for Health Evaluation & Outcome Sciences, Vancouver, Canada, [7]Trinity Western University, School of Nursing, Langley, Canada

Background: The availability of coagulation factor replacement therapy in industrialized countries has dramatically increased survival of patients with haemophilia. In order to improve patient-centered care

for people with haemophilia, it is important to understand the patients' perspectives of their outcomes and treatments.

Aims: The purpose of this study was to understand the perceived impact of hemophilia and its treatment on patients' quality of life and their health care needs, including information provision and shared decision-making.

Methods: Semi-structured interviews were conducted with 13 patients with different severities of haemophilia A or B at the Adult Haemophilia Program of British Columbia, Canada. Interviews were transcribed verbatim and analysed qualitatively. A second phase of data collection is being planned.

Results: Preliminary results indicate that haemophilia impacts daily activities as well as decisions about education and employment. Care needs do not only pertain to treatment of haemophilia and its associated co-morbidities HIV and hepatitis C, but also to interactions with non-haemophilia care providers. Finally, the clinic's approach to patient engagement through visualization of bleed history and factor use, and information sharing about future treatment options were perceived helpful in addressing additional patient needs.

Conclusions: In addition to addressing clinical needs in haemophilia treatment, there is an opportunity for clinicians to improve patient-centered care, for example by sharing clinical information in a variety of ways, including graphic representations, to facilitate shared decision-making. The results will inform ongoing quality of care and quality of life studies in patients with haemophilia in British Columbia, Canada and in the Dutch Haemophilia in the Netherlands (HiN) study.

PB 984 | Improving the Survival for Life-threatening Hemorrhage with Hemophilia Patient in One Hemophilia Treatment Center for 34 Years

K. Lee[1], J. Kim[2], J. Seo[2], S. Hyun[3], H.-J. Yoon[4]

[1]Kyungpook National University School of Medicine, Daegu, Korea, Republic of, [2]Kyungpook National University Children's Hospital, Daegu, Korea, Republic of, [3]Yonsei University Wonju College of Medicine, Wonju, Korea, Republic of, [4]Kyung Hee University Hospital, Seoul, Korea, Republic of

Background: In life threatening hemorrhage such as brain and abdomen, several important factors are affect for improving the survival. One tenth (223) of hemophilia patients in Korea lived in Daegu city and Kyungpook province and have treated in our regional treatment center.

Aims: We reviewed the result of life threatening hemorrhage and our unique care of hemophilia patients for 34 years.

Methods: Korea Hemophilia Foundation was established in 1991. After that all factor concentrates were free to all hemophilia patients. Home treatment are available for rapid administration of factor concentrate of full required amount. Rapid transportation to emergency room are available for immediate operation. Hot line of mobile phone between patient and doctor for 24 hours are available for emergency care. Monthly group education has done. Prophylactic treatment was started to all who had a life threatening hemorrhage history in our hospital since 1996. But HIRA permitted officially since 2011.

And then recovery rate test was done for the optimal blood level for life threatening hemorrhage patient. Continuous infusion with every 2 to 4 hours reconstitution dilution fluid has been done for preserve in vitro factor activity to all surgery cases.

Results: Thirty five events were intracranial hemorrhage in 17, general surgery in 9 and orthopedic surgery in 9. Age distribution was 0-32 yr (mean; 24.8 yr). Severity was severe (16), moderate (7) and mild (5). Time interval between first symptom and arrival at ER were 15 min to 10 days (mean; 1.7days). We confirmed in vivo factor activity within permissible level in all patients. All recovered from hemorrhage or surgery and are healthy, but one had limping gate and one had mild neurologic sequela for more than 10 years follow-up period.

Conclusions: Education, financial support, home and prophylactic treatment, hot-line, individual pharmacokinetics with effective blood level and fresh concentrate during continuous infusion are important factors to improve the survival of surgery case.

PB 985 | Single Centre Experience of Obstetric Management of Women with Inherited Bleeding Disorders (IBD) in a Multidisciplinary Joint Women's Bleeding Disorders / Obstetric Clinic

B. Madan[1], F. Al-Fararjeh[1], G. Gray[2]

[1]St Thomas' Hospital, The Centre for Haemostasis and Thrombosis, London, United Kingdom, [2]St Thomas' Hospital, Department of Women's Health, London, United Kingdom

Background: The inception of a Multidisciplinary Bleeding Disorders/Obstetric clinic has led to optimal management of pregnant women with IBD as they are known to be at increased risk of bleeding complications in both mother and fetus.

Aims: To report on outcomes of 142 pregnancies in 97 consecutive women with IBD who were seen in the last 5 years in our Centre, which is a tertiary referral centre.

Methods: Retrospective analysis was conducted going through obstetric and hospital records of patients who were seen in the last 5 years with special attention to bleeding complications, clotting factor use, maternal and fetal outcomes. Details of any previous pregnancies were included for women who presented during this period.

Results: Results are presented in the table below. The types of IBD included carriers of haemophilia A and B, VWD, FXI deficiency, platelet function defects and rare bleeding disorders. The last group included fibrinogen disorders, FVII deficiency, FV deficiency, FX deficiency, familial macro-thrombocytopenia and unclassified bleeding disorders. Antepartum haemorrhage (APH) was seen in 5 pregnancies and of these, 3 cases required clotting factor replacement (CFR) - one Haemophilia A carrier woman, one patient with type 2 VWD and one patient with type 3 VWD. Of note, these two patients with VWD had a subsequent pregnancy each and were managed with upfront CFR (three times a week) during these without any bleeding complications.

TABLE 1 Bleeding Complications by Diagnostic Category

Diagnosis	No. of patients	No. of pregnancies	No. of pregnancies requiring Blood Products	No. of pregnancies with Antepartum haemorrhage	No of pregnancies with Postpartum haemorrhage
Haemophilia A	27	36	3	2	2
Haemophilia B	7	11	3	0	1
VWD Type 1	18	26	2	0	3
VWD Type 2	6	10	7	1	0
VWD Type 3	2	6	6	1	3
F XI deficiency	12	18	12	0	2
Platelet function defect	12	13	2	1	1
Rare Bleeding Disorders	13	22	6	0	7

In 6 pregnancies, late amniocentecis was undertaken to inform delivery plans. Significant post-partum haemorrhage was seen in 19 of 142 pregnancies with blood transfusion being required in 5 deliveries.
Conclusions: Overall, the maternal and foetal outcomes were excellent in this high risk patient population. The rate of maternal complications was 3.5% for APH and 19% for PPH. No fetal complications were noted. Obstetric management of women with IBD can be optimised using a multidisciplinary team including haematologists, obstetricians and anaesthetists.

PB 986 | At Home PK to Tailor Prophylaxis

M. Morfini

Italian Association of Haemophilia Centres, Firenze, Italy

Background: PK tailored prophylaxis seems to be the best way of treatment to individualize replacement haemophilia therapy and improve cost/effectiveness. Unfortunately, single dose PK is a quite demanding procedure both for patients, especially children and their parents. Patients and/or parents are generally disappointed for losing four to five consecutive days of school or work.
Aims: To facilitate the compliance of patients to undergo PK, we designed together with Kedrion (Castelvecchio Pascoli, Lucca, Italy) a home PK program NuPreviq service.
Methods: This service has been offered to seven severe haemophilia A patients under treatment with Simoctocog alfa. The number of blood samples has been limited to six: A) at HC: baseline sample, just before infusion and 1st post-infusion hour. B) at patient's home: at 7th-9th, 24th, 48th, 72nd post-infusion hour. All blood samples, performed by a professional nurse, were submitted to high speed centrifugation just after their collection. Four aliquots (0.5 ml each) of platelet poor plasma were frozen immediately in dry ice and then shipped to a central laboratory for FVIII:C assay.
Results: y)FVIII PK was performed by means of One-compartment (1CP) and Two-Compartment (2CP) method (Accovion GmbH, Eschborn, Germany). PK parameters were in the following range: IVR 0.69-2.02 IU/dL/IU/kg; Half-life 14.17-24.51 hrs; Volume of distribution 46.30-131.40 mL/kg. The parameters from the model best fitting the patient's data (1CP in 3 and 2CP in 4 patients) were used to build an array of doses and every 12 hrs intervals according to 1, 3, 4 or 5 IU/dL troughs, as asked by the treater. The range of estimated doses was 18.30-81.70 IU/kg and the interval between bolus was 48-120 hrs.
Conclusions: The accessibility of this home PK service improved the compliance of patients with this procedure providing their treaters with simulated dosing schemes, according to different troughs.

PB 987 | Bayesian Approach to Individualize Prophylaxis of Simoctocog Alfa in Haemophilia

X. Delavenne[1], J. Mercy[1], S. Dantin[2], C. Négrier[1]

[1]*Haematology Division, Louis Pradel University Hospital, Bron, France,* [2]*Octapharma, Boulogne, France*

Background: Prophylaxis with Factor VIII (FVIII) can reduce annual bleeding events in severe haemophilia A patients. However, inter-individual pharmacokinetic (PK) variability of FVIII is large and PK-tailored personalized prophylaxis may help to adjust FVIII activity at the level desired.
Aims: The aims of this study were to develop a Bayesian estimator of simoctocog alfa using a PK population approach and to evaluate its capacity to estimate individual pharmacokinetic parameters using sparse blood samples.
Methods: Data from 3 clinical trials with simoctocog alfa in 86 adults and 61 children/adolescents were compiled. A total of 1114 samples were collected and FVIII was measured centrally. The data analysis workflow consisted of three steps i) to develop a PK population model using non-linear mixed effect models; ii) to develop a Bayesian estimator from the previous estimates; iii) to evaluate the predictive value of Bayesian approach to estimate individual parameters using a limited sampling strategy. FVIII was then measured locally and the values were used centrally to run the predictive model.
Results: Individual PK parameters were estimated with only 2 or 3 blood samples per individual after simoctocog alfa injection, given the prior distribution of the molecule in the population. The results were provided to the haemophilia treaters and their impact on therapeutic adjustment was evaluated.

Conclusions: Pharmacokinetics of FVIII has mostly been empirical so far, with a combination of outcome measures such as clinical bleeding phenotype (ABR) and determination of trough factor VIII activity. The use of individual pharmacokinetics has likely been restricted by the need to collect several samples following FVIII injection. Prophylactic schedule can be adjusted from only a few determinations of drug plasma levels, by means of a population approach and Bayesian analysis. This approach was promoted at the country level in order to help clinicians individualizing treatment.

PB 988 | Sports/Recreational Activity-specific Risks and Drivers of Risk in People with Hemophilia: Results of the Activity-intensity-Risk (AIR) Consensus Meeting of US Physical Therapists

K. Baumann[1], G. Hernandez[2], S. Knight[3], H. Purrington[4], M. Gilgannon[5], M. Karelus[6], J. Newman[7], P. Tobase[8], D. Basoff[9], S. Mathew[9], D. Cooper[9]

[1]*University of Minnesota Health, Health Center for Bleeding and Clotting Disorders, Minneapolis, United States,* [2]*Center for Inherited Blood Disorders, Santa Ana, United States,* [3]*Children's Hospital of Los Angeles, Los Angeles, United States,* [4]*Phoenix Children's Hospital, Phoenix, United States,* [5]*University of Virgina Health Systems, Charlottesville, United States,* [6]*Hemophilia Treatment Center, Las Vegas, United States,* [7]*University of North Carolina, Chapel Hill, United States,* [8]*University of California San Francisco, San Francisco, United States,* [9]*Novo Nordisk Inc, Plainsboro, United States*

Background: Limited evidence supports assessment of activity-associated risks for people with hemophilia (PWH), and general cautions provided in consumer materials generically describe types of risk.

Aims: To assess activity-specific risks in PWH and define inherent and modifiable drivers of increased risk based on consensus of physical therapy (PT) experts.

Methods: Peer-nominated PTs in the US hemophilia treatment center (HTC) network were surveyed on specific risks for injury (6 at-risk joints and bruising, muscle, and head injuries) associated with ~100 sports and other physically intensive activities, including specific positions (eg, baseball pitcher, catcher, field positions). Drivers of risk were identified from free text comments and explored at a consensus meeting. Drivers were categorized as inherent (I), modifiable (M), activity-driven (A), and patient-driven (P).

Results: Of 32 invited PTs, 17 responded to the survey with median (mean) 26.5 (22.4) years as a PT and 15.5 (16.8) years at an HTC; 8 participated in the full-day consensus meeting. Most respondents indicated ≥1 specific risk for each activity, with specific risks identified being largely consistent with free text comments (sample data in **Table** and **Figure**). Key drivers of risk that were identified included progression from recreational participation to year-round competitive play, overtraining, competitive level, tournaments, and improper body mechanics. Inherent risks identified included impact with surface/ball/equipment, players, or falls. Modifiable risks included tricks/stunts and use of safety equipment when not required.

Conclusions: Consensus of experienced US PTs provides insights into activity-specific risks for PWH and drivers of risk that contribute to the range of risk identified by the AIR project. HTC discussions with patients/families concerning participation in activities should include specific consideration of sustainability of participation and patient-driven modifiable risks.

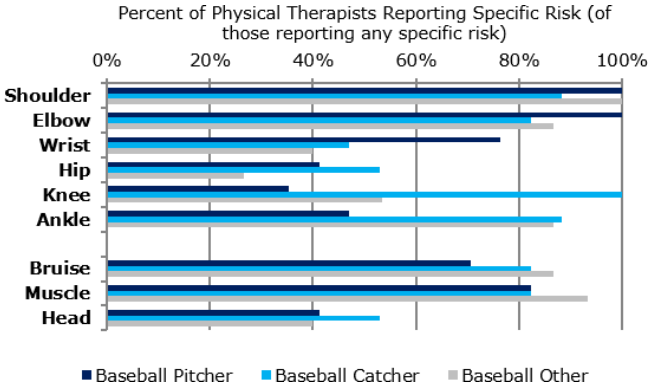

FIGURE 1 Percent of Physical Therapists Reporting Specific Risks for Injury Associated With Baseball (Hardball) Positions (N=17)

TABLE 1 Percent of Physical Therapists Reporting Specific Risks for Injury on Survey and Drivers of Risk Assessed via Consensus Meeting

Activity (number of respondents scoring each activity)	Elbow	Knee	Ankle	Muscle	Head	Overuse/ Over-train	Repetitive Motion	Competitive	Impact - Surface or Ball
Bicycling (n=12)	42%	92%	58%	100%	92%	MP	IP	IA	
Baseball (hardball) - pitcher (n=17)	100%	35%	47%	82%	41%	MP	IA	MP	IA

PB 989 | Preferences of Hemophilic Patients and their Parents on the Characteristics of Replacement Treatment Used in Prophylaxis

M.E. Mancuso[1], E. Santagostino[1], L. Scalone[2,3], P.A. Cortesi[2,3], P. Cozzolino[2,3], G. Cesana[2], L.G. Mantovani[2,3], P.M. Mannucci[1]

[1]*Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Milan, Italy,* [2]*University of Milano-Bicocca, Research Center on Public Health, Milan, Italy,* [3]*CHARTA Foundation, Milan, Italy*

Background: New modified coagulation factors concentrates (e.g. extended half life) are coming into the market, generating expectancies and concerns on which treatment is preferable for patients with hemophilia (PwH).

Aims: Evaluating preferences of PwH and their parents towards the characteristics of prophylactic treatment with different coagulation factor concentrates.

Methods: A discrete choice experiment was conducted. Patients with severe hemophilia without inhibitors aged ≥13 years and parents of those aged ≤17 years were enrolled. Possible options of prophylactic treatment were described with 7 characteristics previously selected for their relevance, including 2-3 possible levels each (Table 1). A fractional factorial combination of every characteristic levels generated 16 scenarios including each a pair of possible treatments. The participants were asked to choose one option for each scenario (Figure 1). The relative importance assigned to each characteristic over the others was estimated with a conditional logistic regression model.

Results: 66 patients (59% haemophilia A) and 32 parents participated. Risk of infections and of inhibitor development were the most important for patients (29% and 17%, respectively) and parents (27% and 33%). The third more important characteristic for patients was frequency of injections (17%), corresponding to the fourth more important for the parents (11%), while the third more important characteristic for parents was time of preparation (8%), followed by additional costs. As regards "Frequency of administration", while parents did not assign a statistically significant preference to any level specified, patients preferred significantly more using a product requiring "1 infusion every 15 days" rather than a higher infusion frequency.

Conclusions: Decisions on treatments must take into account patients clinical needs; the results of this study reveal different preferences between adult PwH and parents of pediatric patients.

TABLE 1 selected characteristics and levels to describe the treatment options

	CHARACTERISTICS	LEVELS
1	Frequency of administration	- 2 infusions per week - 1 infusion per week - 1 infusion every 15 days
2	Risk of infections transmitted by the product	-Increased -Reduced
3	Risk of inhibitors development after treatment	-Increased -Reduced
4	Time necessary to pain relief	- 1 hour - 4 hours
5	Number of injections necessary to solve the symptoms of bleeding	- One - More than one
6	Time of preparation	- 5 minutes - 20 minutes
7	Additional cost	- None (The healtcare taxes remain the same) - The healtcare taxes are doubled (130€ more to be paid monthly on gross income of 1.700€) - The healtcare taxes are tripled (260€ more to be paid monthly on gross income of 1.700€)

PB 990 | Evaluation of Unmet Medical Needs of Hemophilia Patients in Bavaria

H. Lechner[1], A. Schleiermacher[1], K. Berger[2], D. Schopohl[2], W. Schramm[3]

[1]*Bluter Betreuung Bayern e.V. (BBB), Munich, Germany,* [2]*University Hospital of Munich, Department of Hematology/Oncology, Munich, Germany,* [3]*Ludwig-Maximilians-University of Munich, Rudolf-Marx-Foundation for Hemostaseology, Munich, Germany*

Background: Hemophilia care in Germany has achieved a high level. Generally, most hemophilia patients are able to lead a largely normal life. The "Bluter Betreuung Bayern e.V." (BBB), which was originally founded to help HIV-infected hemophilia patients, aims to improve patient support.

Aims: The aim of this study was to evaluate unmet medical needs of hemophilia patients in Bavaria from a patient perspective.

Methods: A questionnaire of 45 items has been designed by BBB representatives. Questions comprised three parts: 1. Demographics 2. General health, substitution therapy, worries in relation to hemophilia, satisfaction with medical care. 3. Wishes related to extra service and information offers, suggestions how to improve hemophilia care. The survey was sent to 290 hemophilia patients and/or their parents in Bavaria in November 2015.

Results: The response rate was 51.4%. For demographics see Table 1.

TABLE 1 Demographics of 146 patients with hemophilia

Age groups [years], number of patients (n)	<15 (66)	15 - 24 (30)	25 - 44 (26)	>44 (24)
Severity of hemophilia n (%)				
Severe	44 (66.7)	20 (66.7)	21 (80.8)	23 (95.8)
Moderate	6 (9.0)	1 (3.3)	1 (3.8)	0 (0)
Mild	13 (19.7)	8 (26.7)	3 (11.5)	0 (0)
Prophylaxis in patients with severe hemophilia n (%)				
"Always"	43 (97.7)	16 (80.0)	14 (66.7)	14 (60.9)
"Often"	0 (0)	3 (15.0)	6 (28.6)	7 (30.4)
"Sometimes"	1 (2.3)	1 (5.0)	1 (4.8)	1 (4.35)
"Seldom" or "Never"	0 (0)	0 (0)	0 (0)	1 (4.35)

Substitution therapy was mostly uncomplicated. More than 80% up to 100% of patients in all age groups reported that the injections were "never" or "seldom" problematic and "never" or "seldom" painful. Satisfaction with medical care was high. "Chronic pain due to hemophilia" increases in patients >24 years old. Patients in the age group 25-44 years worried least regarding future health, safety and availability of factor products, patients aged >44 years most. Overall, 80-100% of patients from all age groups were interested to be informed on the current state of science, 60-72% on topics with regard to social legislation, and 49-74% wished additional information offers from the treating physician.

Conclusions: The survey confirmed the high level of German health care for patients with hemophilia. Most patients wished more information by their treating physicians. Worries of elderly hemophilia patients and chronic pain should be addressed. Offers of the BBB for psychosocial support in addition to the medical care seem to be helpful and needed in all age groups.

This study was sponsored by the Rudolf-Marx-Foundation.

PB 991 | The Occurence of Inhibitors in PUPs Treated with Octocog α in Polish Haemophilia Care Centers

Background: The most challenging complication of haemophilia replacement therapy (HRT) is the occurrence of neutralizing anti-factor VIII alloantibodies (inhibitors - INH) in up to 30% of previously untreated patients (PUPs) with severe haemophilia A (HA), typically during the first 50 days of exposure (EDs) to therapeutic factor VIII (FVIII) infusion. Recently published data showed higher incidence of inhibitors in patients treated with recombinant FVIII than those treated with plasma-derived FVIII (44.5 vs 26.8% respectively).

Aims: Analysis of the INH incidence and efficacy of ITI in PUPs treated with full lengh recombinant FVIII octocog[α in Poland between 2011-2016.

Methods: From 2011 to 2016 in all Polish Haemophilia Care Centers 88 PUPs with severe haemophila A were receiving replacement therapy with octocog α for 2 - 75 months (median 34.6). HRT was initiated[at the age of 0 to 34,5 months (median 10.7). Only 6/88 boys (6.7%) were treated on-demand. Prophylaxis was started at the median age 12.6 months (2.3 - 39,5).

Results: INH was diagnosed in 14/88 (15.9%) cases after 3 - 489 EDs (median 20). Most of them (11/14) were high responders with the peak inhibitor titer (PIT) 5,4 - 716.8 (median 20.1) BU/ml. All of 3 low responders had PIT 2.8 BU/ml. Treatment-related risk factors for inhibitor development were presented in table 1.

Conclusions:

The incidence of inhibitors in PUPs treated with octocog α is lover then reported in patients receiving other forms recombinant factor VIII.

PB 992 | The Impact of a Comprehensive Hemophilia Management Programme in Vulnerable Population

C.A. Montano Mejia[1,2], S. Sarmiento[3]

[1]*Universidad Tecnológica de Pereira, Ciencias Clínicas, Pereira, Colombia,* [2]*Integral Solutions SD S.A.S, Hemophilic Center, Pediatría, Pereira, Colombia,* [3]*Integral Solutions SD S.A.S, Hemophilic Center, Bogota, Colombia*

Background: This project is an observational study which describes the results of a comprehensive management program designed for prophylaxis in hemophilic patients.

TABLE 1 Treatment related risk factors in patients with inhibitors (P - prophylaxis; OD - on demand Me - median

	Peak inhibitor titer BU/ml range / Me	Age at 1st dose of FVIII [months] range / Me	Age at start of prophylaxis [months] range / Me	Number of EDs range / Me	Type of treatment	Surgery	High doses of FVIII due to bleeding
Low responders n = 3	2.8	0 - 11.9 Me = 11.7	11.9 - 22.8 Me = 12.6	6 - 28 Me = 10	P - 3	1	0
High responders n = 11	5,4 - 716.8 Me = 20,1	0 - 32.9 Me = 11.2	0 - 12.2 Me = 11.5	3 - 489 Me = 15	P - 6 OD - 5	4	3 (CNS, GI, massive to scrotum

Aims: Following the gold standard for the treatment of hemophilia, the aim of this study was to assess the impact of a comprehensive prophylactic programme in vulnerable population. The programme guaranteed ambulatory and home care by qualified interdisciplinary professionals. The number of spontaneous bleeding episodes, waiting times for treatment, the number of hospital admissions and the amount of clotting factor used at home to control bleeding, were used to determine the effectiveness of the programme compared to the regular on-demand treatment.

Methods: A sample of 28 patients was included in the program at 11 Integral Solutions Hemophilic centers over a period of 2 years. Retrospective data were obtained through a survey administered at recruitment and participants were followed up while their inclusion in the program. Patients were treated three times a week. The frequency and doses were adjusted according to weight, phenotype and PK.

Results: The mean follow-up time was 1,04 years. On average, each patient received 25,6 UI/Kg per dose (range 16,66 - 35,7 UI/Kg). The average spontaneous bleeding person per year was of 4.71 before their inclusion in the program compared to 0.96 with the program. This represents a reduction of 79.6% in the spontaneous bleeding. While in the program, only a 3% of additional clotting factor was required to control bleeding at home. The average waiting time for treatment within the program was less than 1 hour in 82% of the sample and 1-3 hours in 18%, with no hospital admissions per spontaneous bleeding.

Conclusions: The comprehensive prophylactic program, through the development of individualized protocols to administer the clotting factor at home, increased adherence to treatment and significantly reduced the number of spontaneous bleedings and hospital admissions in patients with hemophilia from vulnerable populations.

PB 993 | The Impact of Long-term Secondary Prophylaxis on Health-related Quality of Life in Adolescents and Adults with Severe Haemophilia A treated with rFVIII-FS

A. Tagliaferi[1], A. Coppola[2], C. Santoro[3], S. Amoresano[4], S. von Mackensen[5]

[1]University Hospital of Parma, Regional Reference Centre for Inherited Bleeding Disorders, Parma, Italy, [2]Federico II University Hospital Naples, Regional Reference Center for Coagulation Disorders, Naples, Italy, [3]Sapienza University of Rome, Department of Cellular Biotechnology and Hematology, Rome, Italy, [4]Bayer, Milan, Italy, [5]University Medical Centre hamburg-Eppendorf, Institute of Medical Psychology, Hamburg, Germany

Background: Benefits of secondary prophylaxis on long-term outcomes in adolescents and adults with severe haemophilia A are scarce. In the context of the Italian POTTER Study (Prophylaxis vs. On-demand Therapy Through Economic Report) the impact of secondary prophylaxis has been evaluated not only on clinical outcomes, but also on the patient perspective.

Aims: To determine the impact of secondary prophylaxis on HRQoL in haemophilia A patients.

Methods: 58 patients from 11 Italian HTC were enrolled and stratified into 2 age subgroups (12-25 and 26-55 years). 53 [27 prophylaxis (P), 26 on demand (OD)] were evaluated with a median follow-up period of 5.4 years. HRQoL was evaluated by generic instruments (SF-36, EQ-5D) and haemophilia-specific instruments (adolescents: Haemo-QoL; adults: Haemo-QoL-A. Data were collected at baseline and at follow-up visits.

Results: According to treatment arms, adolescents had an average age of (P: 16.63 ± 3.76 years, OD: 18.08 ± 5.75 years) and adults of (P: 31.08 ± 3.93 years; OD: 36.87 ± 7.53). Patients on prophylaxis had significantly less joint bleeds compared to on-demand patients (adolescents ABR: 1.97 vs. 16.80; adults: 2.46 vs. 16.71; p< .0043). Differences between on-demand and prophylaxis patients at baseline were significant in the domains ‚physical functioning' (p< .025), ‚role physical' (p< .026), ‚social functioning' (p< .025), ‚role emotional' (p< .032) of the SF-36 and the EQ-VAS (p< .01); moreover in the domains ‚physical functioning' (p< .02), ‚role functioning' (p< .026), ‚worry' (p< .004), ‚consequence of bleeding' (p< .017) and the Total Score (p< .040) of the Haemo-QoL-A, being similar at follow-up visits. Number of bleeds had an impact on patients' HRQoL.

Conclusions: The POTTER study is the first long-term prospective, controlled trial documenting long-term benefits of late secondary prophylaxis in adolescents and adults with severe haemophilia A. Beside clinical benefits patients reported significant improvements also in their HRQoL.

PB 994 | FEIBA Global Outcome Study (FEIBA GO) First Data Read-Out: Real-world Bleeding Frequency in Patients with Inhibitors on Prophylaxis with APCC

C. Escuriola-Ettingshausen[1], J. Windyga[2], P.A. Holme[3], C. Hermanns[4], C. Negrier[5], A.R. Cid[6], S. Rangarajan[7], A. Rocino[8], A. Gringeri[9], R. Crea[9]

[1]HZRM, Haemophilia Centre Rhine-Main, Frankfurt-Möerfelden, Germany, [2]Institute of Hematology and Transfusion Medicine, Department of Disorders of Hemostasis and Internal Medicine, Warsaw, Poland, [3]Oslo University Hospital, Rikshospitalet, Norway Department of Hematology, Oslo, Norway, [4]Saint-Luc University Hopital, Brussels, Belgium, [5]Hopital Louis Pradel, Bron, France, [6]Hospital Universitario y Politécnico La Fe, Unidad Hemostasia y Trombosis, Valencia, Spain, [7]Hampshire Hospitals NHS Foundation Trust, Basingstoke, United Kingdom, [8]San Giovanni Bosco Hospital, Haemophilia & Thrombosis Centre, Naples, Italy, [9]Shire plc, Global Medical Affairs, Vienna, Austria

Background: The FEIBA GO study was designed to capture long-term outcomes on effectiveness, safety and quality of life in subjects treated with APCC in routine clinical practice.

Aims: The primary objective is to describe the hemostatic effectiveness of APCC in different settings (prophylaxis and on demand, including patients on immune-tolerance induction); most relevant secondary objectives are: joint functionality outcomes, safety, health-related quality of life (HR-QoL), daily activity level, acute and chronic pain associated with haemophilia, health resources used.

TABLE 1 Patients analysed in the data read-out

Patients analysed in the data read-out	18	
Median Annualised Bleeding Rate (ABR)	3.7	
Subjects with ABR "0"		16.7%
Subjects with ABR "<2"		22.3%
Subjects with ABR "<3"		39.0%
Median Annualised Joint Bleeding Rate (AJBR)	1.6	
Subjects with AJBR "0"		38.9%
Subjects with AJBR "<2"		55.6%
Subjects with AJBR "<3"		77.8%

Methods: It is a prospective, non-interventional, observational multicenter cohort study in patients with hemophilia A or B and high-responding inhibitors treated with APCC prior the decision to enroll in the study. Target for enrollment is 100 subjects. Treatment regimens are at the discretion of the attending physicians according to routine clinical practice, either in prophylaxis or on demand, including immune-tolerance induction. The observation period per subject will be 4 years.

Results: An initial, unplanned data read-out was carried out on Sept 15, 2016 on 28 subjects with severe haemophilia A and inhibitors (median titer at screening 10 BU, min-max 1-2,410), recruited in 14 haemophilia centres in 8 countries: median age 23 years (range 3-71). 21 of them were on prophylaxis and data were available for 18 and showed in Table 1.

Conclusions: These preliminary findings show that prophylaxis with APCC in inhibitor patients can be effective, as it demonstrably prevents joint bleeding in a proportion of subjects similar to that reported in non-inhibitor patients on replacement prophylaxis. This study will further enhance the knowledge of long-term prophylaxis in the setting of real world data by assessing effectiveness, HR-QoL and safety of APCC in this rare patient population. Data read-out information will be consolidated and expanded on for the other study endpoints in an interim analysis.

PB 996 | Prevalence of Adult-onset Medical Comorbidities and Active Intervention via Web-based Monitoring in Korean Hemophliacs

H.C. Kim[1], S. Jeon[1], H.J. Kim[2]

[1]*Ajou University Medical Center, Hematology-Oncology, Seoul, Korea, Republic of,* [2]*Konyang Univsersity Hospital, Medical Genetics, Daejeon, Korea, Republic of*

Background: With easier access to the coagulation concentrates hemophiliacs the life expectancy of hemophilic patients is approaching to the general population and the prevalence of age-related medical comorbidities is expected to rise. We have followed 136 patients with hemophilia A and B, and monitored closely for their medical comorbidities.

Aims: In this 136 hemophilic cohort we analyzed their age-related comorbidities for overall prevalence, and applied web-based monitoring of their BPs, blood sugars for tighter control.

Methods: Comorbidities monitored were hypertension, obesity, hyperlipidemia, diabetes, and cardiovascular disorder. The medical interventions were web-based monitoring of self-checked BP and blood sugar level of at least once a week, entering data online by the pt and monitored at the clinic by the nurse and physician, and monthly clinic visit for medical intervention.

Results: Of 136 patients, 112 were hemophilia A (82%) and 24 hemophilia B (18%). Their median age was 33 years with range from 3-70 years, 46 (37%) were over age 40. Their average follow-up was 5 years and their average annual factor usage was 5,000units/kg/year/pt. Of the medical comorbidities, hypertension was observed in 15 of 136 (11%) hemophilic pts, obesity in 31 (23%), hyperlipidemia in 22 (16%), diabetes in 12 (9%). Medical comorbidities tended to be higher in older group over 40 years. Web-based monitoring were done in 5 of 15 HBP pts and 3 of 12 DM pts, and compared to non-Web monitor participating pts, the overall control were excellent.

Conclusions: With improved life expectancy in hemophiliacs, the prevalence of medical comorbidities in older age is expected to rise. Therefore, in addition to the management of the hemostatic problems, careful monitoring and therapeutic intervention of their medical conditions are warranted. Active intervention of these age-related comorbidities via web-based monitoring provides excellent care to these pts ridden with life-long struggle with hemophilia-related conditions.

PB 997 | Prevalence of Inhibitors in Tunisian Hemophiliac B

H. Elmahmoudi[1,2], M. Achour[1], H. Ben Neji[1], W. Lahouel[1], F. Ben Lakhal[1], R. Benlakhal[1], K. Zahra[1], W. Hosni[1], B. Meddeb[1], A. Gouider[1]

[1]*UR14ES11, FMT, University of Tunis El Manar, Tunis, Tunisia,* [2]*National Center for Nuclear Sciences and Technologies, Tunis, Tunisia*

Background: Inhibitor development is the major complication encountered in hemophilia. Hemophiliac B patients developed factor IX (FIX) inhibitors with a low prevalence (1.5-3%) compared to hemophiliac A patients.

Aims: Our aim is to establish the prevalence of inhibitors in Tunisian hemophiliac B followed in AOHTC.

Methods: Data were collected from the registry from 2010 to 2016.

Results: Our AOHTC followed 46 patients with hemophilia B. 3 of them developed inhibitors. Diagnosis was performed during routinely screening with Bethesda method. The patients have respectively 8, 9 and 16 old age, with a sever phenotype. The molecular study was done for one patient and the gene defect is due to the nonsense mutation p.Glu72X. Replacement therapy with factor 9 is efficient in 2 patients despite absence of biological response.

Conclusions: Since the prevalence of inhibitors development in Tunisian hemophilia B patients is of 6.5%, it seems to be higher than the reported one in the literature. This may be due to a regular routine diagnosis, a genetic predisposition, the effectiveness of substitution or the extra-plasma distribution of F9. An immunological diagnostic should be studied. Further studies have to be done in order to explain this data.

PB 998 | Pharmacokinetics and Annual Bleeding Rate (ABR) during Prophylaxis with a Full-length Recombinant FVIII: One Center Experience

D. Neme[1], L. Elhelou[1,2], E. Honnorat[3], A. Cocca[3], M. Tezanos Pinto[2,3]

[1]Fundación de la Hemofilia, Hematología, Ciudad Autónoma de Buenos Aires, Argentina, [2]IIHEMA. Academia Nacional de Medicina, Hemofilia, Ciudad Autónoma de Buenos Aires, Argentina, [3]Fundacion de la Hemofilia, Hematología, Ciudad Autónoma de Buenos Aires, Argentina

Background: It is suggested that knowledge of factor half-life, in addition to observation of the bleeding pattern, may help tailor prophylaxis to individual patients. In clinical practice, performing a Pharmacokinetic (PK) study requieres significant commitment of time. The Bayesian estimation method uses a population PK model based on FVIII levels from a large population of patients. Using this strategy, factor half-life may be calculated from two or three time points.

Aims: To analyze PK (with 2 samples used for determination), schedules, ABR and annual joint bleeding rate (AJBR) in patients on prophylaxis with a full-length recombinant FVIII (FLrFVIII) (octocog alfa).

Methods: Files of patients with severe hemophilia A on prophylaxis with a FLrFVIII were evaluated retrospectively, considering the year 2015. Pharmacokinetics and data were analized using a specific tool program (myPKFiT) and Epi Info respectively.

Results: 36 patients were included. Age 3-29 years (mean 12.69). 80% of children (≤12 years) were on primary prophylaxis; 72.2% of the rest of the population (>12 years) were on secondary prophylaxis. Most patients (91.6%) were following a three times a week schedule dosis. In children mean dose was 30.3 IU/kg; in the older group it was 24.3 IU/kg. Mean FVIII half-life was 11.4 hours vs 13.05 respectively (P< 0.0001). Mean FVIII trough levels (48 hours post infusion) was 2.58 %. In children ABR and AJBR were 2.25 and 0.75. In adolescents and adults ABR and AJBR were 1.68 and 0.87. Twenty five patients (69.4%) had cero hemarthrosis. 30% of patients had FVIII trough levels < 1%. In this group, the ABR was 1.63.

Conclusions: Children have lower FVIII half-life and use higher dosis. The ABR and AJBR are low as expected. Although some patients present FVIII trough levels < 1%, the ABR remains very low.

PB 999 | A Unique Case Involving Delivery of Bolus rFVIIa via an Innovative Syringe Pump to a Patient with Haemophilia and Inhibitors Undergoing a Kidney Transplant

J. Stanley, S. Austin

St Thomas' Hospital, Guys and St Thomas NHS Trust, Haemostasis and Thrombosis Centre, London, United Kingdom

Background: Haemophilia patients with inhibitors undergoing surgery under haemostatic cover with recombinant Factor VIIa (rFVIIa) require regular bolus doses, peri-operatively and for a variable number of days afterwards, determined by the type and location of surgery. This places considerable demand on nursing time as it necessitates the timely delivery of doses to ensure optimal haemostasis management. We investigated the use of an infusion pump to deliver timed and accurate rFVIIa bolus doses in a patient undergoing renal transplantation surgery.

Aims: To evaluate the efficacy and safety of using the B-Braun Perfusor® Space syringe pump to deliver frequent regular bolus doses of rFVIIa to a patient with haemophilia and inhibitors undergoing kidney transplant surgery.

Methods: The patient had complex medical issues, including haemophilia with inhibitors, renal disease and HIV positive status. The transplant surgery was electively planned and involved detailed discussions within a multidisciplinary team, to ensure the haematology team were confident of managing haemostasis, and that both the renal transplant team and the patient had full trust in the chosen delivery method for rFVIIa.

Results: The patient was administered rFVIIa via a PICC line. The pump was programmed to deliver an initial rFVIIa bolus dose of 120 mcg/kg, with subsequent doses of 90 mcg/kg every 2 hours for the first 48 hours, then 3-hourly doses for 24 hours, and finally 4-hourly for 64 hours. The pump was then discontinued and the patient was discharged one day later.

Conclusions: The kidney transplant was successful, and the patient made a full recovery. Haemostatically, the procedure went smoothly, with normal blood loss and no complications, bleeding episodes or line infections. This method of rFVIIa administration appears safe and effective, allowing centres to deliver haemostatic cover with great precision in complex surgical cases.

PB 1062 | Abnormal Plasma Clot Formation and Stability Distinguish Bleeding Risk in Patients with Severe or Partial Factor XI Deficiency

G. Pike[1,2], L. Holle[3], J. Burthem[1,2], P. Bolton-Maggs[4,5], F.-C. Lin[6], A. Wolberg[3]

[1]Manchester Royal Infirmary, Central Manchester University Hospitals National Health Service Trust, Haematology, Manchester, United Kingdom, [2]Institute of Cancer Sciences, University of Manchester, Manchester, United Kingdom, [3]University of North Carolina at Chapel Hill, Pathology and Laboratory Medicine, Chapel Hill, United States, [4]Institute of Cardiovascular Sciences, University of Manchester, Manchester, United Kingdom, [5]Serious Hazards of Transfusion Office, Manchester Blood Centre, Plymouth Grove, Manchester, United Kingdom, [6]University of North Carolina at Chapel Hill, Department of Biostatistics and North Carolina Translational and Clinical Sciences Institute, Chapel Hill, United States

Background: Factor XI (FXI) deficiency is a rare, autosomal disorder. Many patients have minimal or no bleeding, whereas others have severe bleeding usually associated with trauma or surgery. Bleeding risk cannot be predicted from plasma FXI antigen or activity levels. A pilot study suggested plasma clotting assays can distinguish bleeding risk in patients with severe FXI deficiency (Zucker et al. 2014 *J Thromb Haem*).

Aims: Validate the ability of plasma clotting, structure, and stability assays and use of contact pathway inhibitor (corn trypsin inhibitor, CTI) for predicting bleeding risk in a larger, independent cohort that includes patients with severe and partial FXI deficiency.

Methods: Research was approved by the medical ethics committee. Blood was collected in the absence or presence of CTI from patients with severe (*N*=14) or partial (*N*=57) FXI deficiency and healthy controls (*N*=49). Patients were divided into non-bleeders (NB, *N*=48) and bleeders (B, *N*=23) based on bleeding after tonsillectomy and/or dental extraction before diagnosis of FXI deficiency. Platelet-poor plasmas were prepared by centrifugation. Clotting was triggered with dilute tissue factor, $CaCl_2$, and phospholipids in the absence/presence of tissue plasminogen activator (tPA). Clot formation and fibrinolysis were assessed by turbidity. Fibrin structure was visualized by confocal microscopy.

Results: FXI:C levels, PT, and APTT did not distinguish between NB and B. In the presence of CTI, B had reduced clot formation rates and lower turbidity change compared to both controls and NB, in both the absence and presence of tPA (P< 0.005). B also had lower fibrin network density than controls or NB. In the absence of CTI, only clot formation rate significantly distinguished B from NB.

Conclusions: Contact pathway inhibition with CTI exposes clotting and clot stability deficits that are highly-associated with bleeding risk in patients with severe and partial FXI deficiency. These assays may have clinical utility for predicting bleeding risk.

PB 1063 | Anti FIXa/FX Bispecific Antibody (Emicizumab) Enhances Plasma Procoagulant Activity In Hemophilia B in the Presence of Very Low Level of Factor IX

K. Ogiwara[1], H. Minami[1], K. Nogami[1], T. Matsumoto[1], T. Kitazawa[2], K. Hattori[2], M. Shima[1]

[1]Nara Medical University, Pediatrics, Kashihara, Japan, [2]Chugai Pharmaceutical Co., Ltd,, Research Division, Kamakura, Japan

Background: Emicizumab is a bispecific antibody that promotes coagulation by bridging FIXa and FX. Minimal plasma level of FIX enough for functional effect of emicizumab remains unknown.

Aims: To elucidate the efficacy of emicizumab under a minimal amount of FIX.

Methods: A dynamic clotting test, thromboelastometry (ROTEM) using blood of severe hemophilia B (HB) patients under prophylactic therapy was performed. Clotting time (CT) and clot formation time (CFT) were evaluated with *ex vivo* addition of emicizumab (50 µg/mL). % fractional shortening of CT+CFT values ($\%FS^{CT+CFT}$) were calculated as [(1 - presence/absence) x 100]. $\%FS^{APTT}$ were also measured in selected patients' plasma.

Results: In 17 HB patients (median FIX:C 1.9 IU/dL, < 0.2~16.5), CT+CFT was shortened in the presence of emicizumab (median $\%FS^{CT+CFT}$ 18%) with large variations (no response~60%). Poor response group ($\%FS^{CT+CFT}$< 10%, n=7) had undetectable FIX activity (FIX:C < 0.2 IU/dL, n=3) or dysfunctional molecule (FIX:Ag/FIX:C ratio >2.0, n=4). $\%FS^{APTT}$ were evaluated in plasmas available from 10 HB patients including 4 poor response patients. In 9 patients (FIX:C 0.9-6.4 IU/dL) median $\%FS^{APTT}$ was 39% (35~45). One patient with FIX:C < 0.2 IU/dL showed no response. To determine the minimal amount of FIX necessary for emicizumab effects, commercial FIX-deficient plasma was spiked with rFIX (0, 0.01, 0.1, 1, 10 IU/dL), resulting in FIX dose-dependent effect of emicizumab ($\%FS^{APTT}$ 7, 11, 19, 26, 30%, respectively). $\%FS^{APTT}$ in FIX-deficient plasma (7%) was reversed to no response after adding anti-FIX antibody, suggesting that very low amount of FIX activity (< 1.0 IU/dL) existed in this FIX-deficient plasma. APTT in the presence of emicizumab with FIX:C of 0.1, 1, 10 IU/dL were equal to FIX:C of 0.6, 11, 114 IU/dL, respectively.

Conclusions: Minimal amounts of plasma FIX (on the order of 0.01 IU/dL) allowed emicizumab to function. Since most of severe HB patients have very low level of FIX, the results imply the possible utility of emicizumab in HB.

PB 1064 | Abrogating Fibrinolysis Does Not Markedly Affect the Bleeding Phenotype or Response to rFVIII Therapy in Mice with Haemophilia A

R. Stagaard[1,2], M.J. Flick[3], B. Bojko[4], K. Goryński[4], P.Z. Goryńska[4], C.D. Ley[1], L.H. Olsen[2], T. Knudsen[5]

[1]Novo Nordisk A/S, Haemophilia Pharmacology, Måløv, Denmark, [2]University of Copenhagen, Department of Veterinary and Animal Sciences, Copenhagen, Denmark, [3]Cincinnati Children's Research Foundation, Division of Experimental Hematology and Cancer Biology, Cincinnati, United States, [4]Nicolaus Copernicus University in Torun, Department of Pharmacodynamics and Molecular Pharmacology, Faculty of Pharmacy, Toruń, Poland, [5]Tom Knudsen, Skævinge, Denmark

Background: Additional knowledge on the role of fibrinolysis and antifibrinolytic intervention in haemophilia is desirable. For example, tranexamic acid (TXA) is indicated for treatment of topical bleeds, especially in the oral cavity, in haemophilia A and B. Its role and potential value as a systemic agent in haemophilia is, however, less well understood.

Aims: To investigate the role of fibrinolysis in haemophilia A, mice lacking both plasminogen (Plg) and FVIII were characterized for bleeding phenotype and response to recombinant coagulation factor VIII (rFVIII) therapy. Moreover, the effect of intravenously administered TXA on bleeding phenotype and response to rFVIII therapy was studied.

Methods: Experiments were conducted in F8-KO and F8-KO/Plg-KO mice using the sensitive tail vein transection (TVT) bleeding model under highly standardized conditions. Test compounds rFVIII (Advate) and TXA (500 mg/kg) were administered intravenously. All animal studies were approved by the Novo Nordisk Ethical Review Council and Cincinnati Children's Hospital Medical Centers Institutional Animal Care and Use Committee.

Results: Total Plg deficiency did not alter the apparent bleeding phenotype of F8-KO/Plg-KO mice when compared to F8-KO mice in the TVT bleeding model. Similarly, intravenously administered TXA did not significantly affect the bleeding phenotype or response to rFVIII therapy in F8-KO mice.

Conclusions: Neither congenital knockout of Plg nor intravenously administered TXA was observed to influence the bleeding phenotype or response to rFVIII in F8-KO mice as assessed by tail vein transection. Thus, the data failed to demonstrate a significant effect of systemic inhibition of the fibrinolytic system in haemophilia A mice.

PB 1065 | Vascular Remodeling in Hemophilic Joint Bleeding is Associated with Vascular Leak: A Possible Mechanism for Re-bleeding

E.J. Cooke[1,2], J.Y. Zhou[1], T.L. Wyseure[2], V. Bhat[1,2], S. Joshi[1], D.L. Durden[1], L.O. Mosnier[2], A. von Drygalski[1,2]

[1]*University of California San Diego, La Jolla, United States*, [2]*The Scripps Research Institute, La Jolla, United States*

Background: Vascular remodeling is associated with hemophilic joint bleeding. Preliminary evidence points to leakiness of the remodeling vessels, which may contribute to frequent re-bleeding in affected joints.

Aims: To study the vascular integrity of remodeling synovial vessels in FVIII-deficient mice after hemarthrosis, and to characterize the associated inflammatory and tissue-reparative pathways.

Methods: Hemarthrosis was induced in FVIII-deficient mice by subpatellar knee puncture. Vascularity was assessed 2 weeks post-bleed by histology, including staining of α-smooth muscle actin (αSMA), and by musculoskeletal ultrasound with Power Doppler to detect microvascular blood flow. Markers of inflammatory and tissue-reparative macrophage M1 and M2 responses, respectively, were analyzed in synovial tissue 1-10 weeks post-bleed by real-time PCR.

Results: Hemarthrosis caused a 2.0-fold increase in vessel number ($p=0.006$) and a 2.9-fold increase in synovial microperfusion ($p<0.0001$). αSMA staining increased 4.0-fold ($p=0.001$) and remained elevated (2.4-fold, $p=0.04$) when corrected for vessel number, indicating thicker, remodeling vessels. A new method was established to measure the permeability of synovial vessels, whereby extravasated Evans Blue dye was quantified in the knee joint by near-infrared fluorescence. Vascular permeability increased 1.4-fold ($p=0.01$) 2 weeks post-bleed compared to uninjured contralateral joints, and returned to near-baseline levels after 4 weeks. Permeability correlated with the extent of microperfusion ($r=0.6579$, $p=0.02$). A transient inflammatory M1 macrophage response in the synovium was superseded by a pronounced elevation of M2 markers 2-4 weeks post-bleed.

Conclusions: The vascular integrity of remodeling synovial vessels associated with hemarthrosis in FVIII-deficient mice is significantly compromised. Vascular changes may be driven in part by a prolonged polarization of macrophages towards the tissue-reparative M2 phenotype, and are likely to promote re-bleeding.

PB 1066 | Development of a Pharmacokinetic-Pharmacodynamic (PK-PD) Model of Fitusiran, an Investigational RNAi Therapeutic Targeting Antithrombin for the Treatment of Hemophilia in Patients with and without Inhibitors

H. Attarwala, V. Goel, K. Madigan, A. Akinc, G.J. Robbie

Alnylam Pharmaceuticals, Cambridge, United States

Background: Fitusiran is a subcutaneously (SC) administered investigational RNAi therapeutic targeting antithrombin (AT) to promote hemostasis in patients with hemophilia.

Aims: To predict liver exposures in hemophilia patients and describe the population PK-PD relationship between fitusiran liver exposure, AT activity and thrombin generation (TG).

Methods: AT and TG data from 41 patients with hemophilia A and B with and without inhibitors from the phase 1 study of fitusiran were used in the development of a population PK-PD model. Observed fitusiran liver concentrations in rats were described by a 2-compartment PK model with 1st order absorption. Rat liver PK parameters were scaled allometrically to predict liver PK in humans. AT activity and TG were modeled using an indirect response model where: 1) fitusiran liver RISC PK (effect compartment) suppressed synthesis of AT thus decreasing AT activity; 2) decrease in AT activity decreased the inhibitory effect on TG, thus increasing TG. The population PK-PD model was subsequently used to simulate expected AT activity and TG response across a wide dose range in patients with hemophilia.

Results: The half-life of fitusiran in human liver was predicted to be ~20 days. Model predicted steady-state median AT lowering at 50mg and 80mg QM dose were 82% and 87%, respectively. Baseline TG (bTG) was identified as a significant covariate for maximum TG: higher baseline TG yielded greater absolute value of maximal TG. Steady-state median TG (at bTG=15nM) was predicted to be 65nM and 71nM, at QM doses of 50 and 80mg, respectively. Difference between peak and trough AT and TG responses was minimal throughout the dosing interval at these regimens. Dose-response relationship for AT and TG showed an asymptote at QM doses >80mg.

Conclusions: The PK-PD model described the time course, extent, and variability in AT and TG responses in patients with hemophilia. This PK-PD model is being used to guide dosing regimens in clinical trials.

PB 1067 | Electrostatic Analysis of Hemophilia B Causative Mutations

M. Meireles[1], E. Bandinelli[2], G. Vieira[2], F. Salzano[2]

[1]*Universidade Federal do Rio Grande do Sul, Genetics, Porto Alegre, Brazil,* [2]*Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil*

Background: Hemophilia B (HB) is a bleeding disorder caused by mutations in the Factor IX (FIX) gene. There are about 1,095 different HB mutations described, with a prevalence of missense mutations. The role of how mutations interfere on FIX function is not clearly

TABLE 1 Mutations included in the study classified according to domain and clusterization by eletrostatic distances

Domain	Cluster[1]	N° of mutated models	Amino acid changes[2] / cluster	Distance[3] from the wild structure	Observations:
GLA	1	4	p.Phe55Cys, p.Phe55Ile, p.Phe55Ser, p.Cys64Tyr	0.0	[1] Clusterization was obtained using the webPIPSA tool, based on a pair-to-pair comparison.
	2	1	p.Cys64Arg	0.3	[2] Sequence changes at the protein level following the Nomenclature for Description of Genetic Variations approved by the Human Genome Variation Society.
	3	2	p.Arg75Gln, p.Arg75Pro	0.6	[3] Distances were calculated with webPIPSA by a pair-to-pair comparison and matrix generation (Da,b=√2-2Sla,b).
EGF1 and EGF2	1	5	p.Cys134Phe, p.Gln143Pro, p.Cys170Phe, p.Cys170Ser, p.Cys170Tyr	0.0

determined; different aspects could be involved, as structural modifications, loss of stability and electrostatic changes.

Aims: To investigate FIX structural and electrostatic effects of previously detected hemophilia B causative missense mutations.

Methods: A total of 54 different HB missense mutations among activated FIX domains were included in the study, 18 of them detected in southern Brazil individuals and the other 36 recovered in the factor ix database. For each mutation, a 3D homology model was generated and the electrostatic potential was calculated. A physicochemical evaluation was conducted through the calculation of the electrostatic distances between models.

Results: The models were compared and clustered according to electrostatic distances, as illustrated in Table 1.

The electrostatic potential distances evaluation revealed that 31 out of 54 mutations were considered as different, compared to the normal model. The electrostatic distances of these 31 mutations compared to normal varied: 0.3 and 0.6 for GLA domain (3/31); 1.5 for the EGF1 and EGF2 domains (14/31); and 0.8 for the serine protease (14/31) domains. Cluster 1 of every domain shows no distance from normal models. Representative models in terms of domains and clusters are presented in Figure 1.

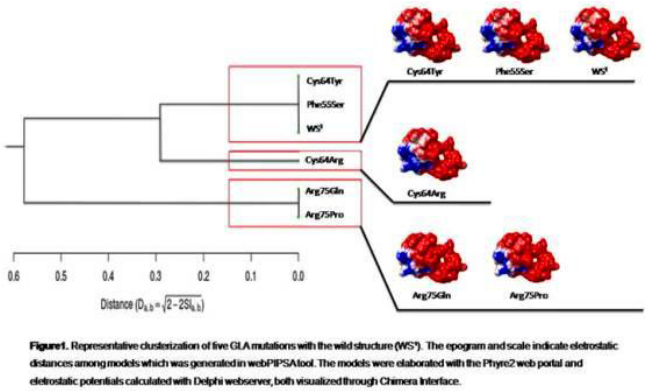

Figure1. Representative clusterization of five GLA mutations with the wild structure (WS¹). The epogram and scale indicate eletrostatic distances among models which was generated in webPIPSAtool. The models were elaborated with the Phyre2 web portal and eletrostatic potentials calculated with Delphi webserver, both visualized through Chimera interface.

FIGURE 1 Representative clusterization of five GLA mutations with the wild structure.

Conclusions: Differences in electrostatic potential apparently influence 31 of the 54 mutations. Five other mutations with normal electrostatic parameters lead to cysteine bridges disruption. The position of the mutations matter, especially considering regions that suffer post-translational modifications or regions involved in stability (disulfide bonds, for example)of the protein; however the mutant

eletrostatic modifications can actively interfere in Factor IX functions, causing HB.

PB 1068 | Identification of Regulatory B Cells in Severe Hemophilia A Patients

D. Matino[1], M. Gargaro[1], A. Turco[1], G. Scalisi[1], S. Linari[2], P. Puccetti[1], A. Iorio[3], G. Castaman[2], F. Fallarino[1]

[1]University of Perugia, Perugia, Italy, [2]Azienda Ospedaliero-Universitaria Careggi, Firenze, Italy, [3]McMaster University, Hamilton, Canada

Background: The occurrence of an immune response blunting the therapeutic efficacy of exogenous factor VIIII (FVIII) is the most relevant adverse event in hemophilia A (HA) treatment. The reason why only a portion of the patients develop neutralizing antibodies - "inhibitors" - to FVIII has, however, been unclear. A regulatory subset of B (Breg) cells has recently been identified that contributes to the maintenance of immunological tolerance in humans and mice. Breg cells can suppress pro-inflammatory cytokine production by dendritic cells and can convert effector $CD4^+$ T cells into $FoxP3^+CD4^+$ regulatory T (Treg) cells. Although Treg cells have been credited with an ability to oppose inhibitor development, no studies have yet investigated any possible contribution of Breg cells to the effect.
Aims: Investigating the ability to induce Breg cells in severe hemophilia A patients with inhibitors.
Methods: In this pilot study, we enrolled 5 severe hemophilia A patients with a history of long-standing, high-titer inhibitors (>5 BU/mL) and 5 age-matched healthy controls. All subjects gave written informed consent in accordance with the Declaration of Helsinki. PBMCs were isolated and cultured for 72 hours in presence or absence of CpG type C oligonucleotide (ODN) to activate Toll-like receptor 9 (TLR9). Cells were harvested and stained with fluorochrome-conjugated antibodies anti-CD19, anti-CD24, anti-CD38, anti-CD138 and analyzed.
Results: Unlike PBMCs from healthy donors, that significantly increased the frequency of $CD24^+CD38^{hi}$ Breg cells at 72 h (untreated: mean = 3.2%, s.d. = 1.1; CpG ODN: mean = 16.5%, s.d. = 3.4; $P< 0.01$), cells from hemophilic patients with inhibitors failed to induce Breg cells when exposed to CpG-C ODN (untreated: mean = 2.8%, s.d. 1.3; CpG ODN: mean = 3.4%, s.d. = 1.4; NS).
Conclusions: Data argue for the differential occurrence of Breg cells in inhibitor positive patients relative to healthy controls after in vitro stimulation with a TLR9 ligand.

PB 1069 | Prophylactic Treatment with Turoctocog Alfa Pegol (N8-GP), a GlycoPEGylated Recombinant Factor VIII, Completely Prevents Development of Arthropathy in a F8 - Knockout Mouse Model of Induced Knee Bleeding

J.B. Hebsgaard, M. Petersen, K. Roepstorff, K.N. Weldingh, M. Ezban, C.D. Ley

Novo Nordisk A/S, Måløv, Denmark

Background: Turoctocog alfa pegol (N8-GP) is a novel glycoPEGylated recombinant B-domain truncated factor VIII (FVIII) product developed for treatment of haemophilia A patients. The extended half-life of N8-GP permits less frequent injections compared with standard FVIII products. N8-GP is currently in clinical development and shown to be safe and effective for prophylaxis and treatment of bleeds in previously treated patients with haemophilia A, where haemophilic arthropathy is the main cause of morbidity.
Aims: To investigate if N8-GP can prevent development of arthropathy following induced knee bleeding in an animal model of haemophilia.
Methods: On days 0 and 7, F8-knockout (F8-KO) mice were anesthetized and received an i.v. injection of 500 IU/kg N8-GP (n=9) or saline (n=10) followed by needle puncture through the infrapatellar ligament to induce a knee bleed. Joint diameter was measured at baseline and on day 8, the day after the second induced knee bleed. On day 14, mice were euthanized and knees were scanned by micro-computed tomography (μCT) followed by histopathological evaluation.
Results: In saline treated mice, induced knee bleeding caused marked swelling measured as increased joint diameter, severe synovitis, and substantial hemosiderin deposition in the joint. Prophylactic treatment with N8-GP prevented hemosiderin deposition and significantly diminished joint swelling ($p< 0.0001$) and development of synovitis ($p< 0.0001$). Bone pathology was assessed by μCT and showed that saline treated F8-KO mice developed significant arthropathy with bone erosions, formation of periosteal bone, and loss of trabecular bone. Prophylactic treatment with N8-GP completely protected against bone pathology.
Conclusions: In a mouse model of haemophilic arthropathy prophylactic treatment with N8-GP diminishes synovitis and completely prevents pathological bone remodelling following induced knee bleeding.

PB 1070 | Two Large *F8* Deletions Possibly Related to the Mechanism of Microhomology-mediated Break-induced Replication (MMBIR) as a Cause of Severe Haemophilia a and Inhibitors

M.M. Abelleyro[1], V.D. Marchione[1], C.P. Radic[1], T. Tetzlaff[2], D. Neme[3], M. Tezanos Pinto[3,4], I.B. Larripa[1], L.C. Rossetti[1], C.D. De Brasi[1,4]

[1]IMEX-CONICET-Academia Nacional de Medicina, Ciudad Autonoma de Buenos Aires, Argentina, [2]Universidad de General Sarmiento, Provincia de Buenos Aires, Argentina, [3]Fundación de la Hemofilia Alfredo Pavlovsky, Ciudad Autonoma de Buenos Aires, Argentina, [4]Instituto de Investigaciones Hematológicas Mariano R. Castex (IIHEMA), ANM. Buenos Aires, Argentina, Ciudad Autonoma de Buenos Aires, Argentina

Background: Large *F8* deletion (LD) genotyping in haemophilia A (HA) (8-15% of severe cases) is important because it associates with the highest risk to develop inhibitors against FVIII replacement therapy.
Aims: Characterisation of the molecular event in two *F8* LDs, detected by consistent absence of exons 7-12 and 5-7 PCR analysis in patients with severe HA (FVIII:C< 1IU/dL) and inhibitor titters of 260 and 13,6BU/mL from family 1 (F#1) and 2 (F#2), respectively.

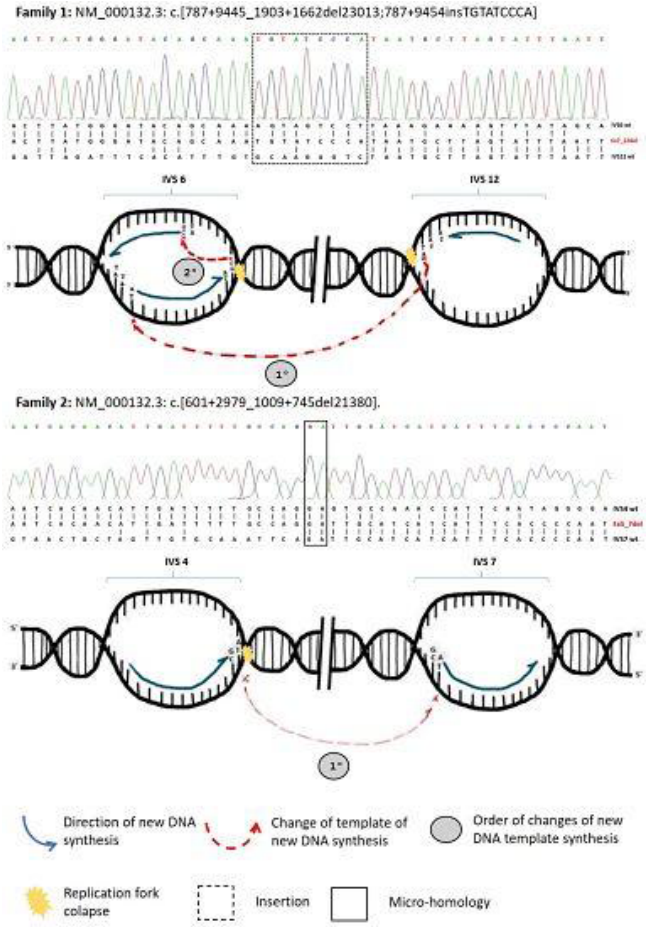

FIGURE 1

Methods: To chase LD breakpoints, PCR tagging schemes were designed by specific bipartition analysis on DNA samples from hemizygous probands. Long range-PCR (lrPCR) amplifications were performed with primers of the nearest 5´- and 3´-positive PCR tags. F#1´s primary lrPCR yielded a specific signal of 7.8kb and F#2´s, of 5.1kb. Restriction analysis of lrPCR products allowed designing new LD-specific amplifications. F#1 (IVS6newup+IVS12newlo) yielded a product of 1.45 kb and F#2 (H617_Delup+H700_Dello), of 1.67kb. Sanger sequencing spanning the breakpoints permitted full characterisation of both events.

Results: F#1 showed a LD of 23kb (ChrX: 154,952,228-154,975,240) NM_000132.3: c.[787+9445_1903+1662del23013;787+9454insTGTATCCCA] and F#2, a LD of 21.4kb (ChrX: 154,968,575-154,989,956) c.[601+2979_1009+745del21380]. F#1 event showed an insertion of 9bp at the recombination site (TGTATCCCA) which is also found at inverted orientation 5bp upstream; and F#2 showed a microhomology of 2bp at the breakpoint junction (Fig. 1). Bioinformatic scanning of sequences surrounding the LD junctions revealed motifs associated with DNA instability (i.e., topoisomerase I consensus cleavage sites, DNA polymerase alpha pause site core sequence, LINE L1 and LTR).

Conclusions: The microhomology between 5´ and 3´ ends, the insertion/synthesis of new material at the breakpoint from vicinal sequence templates and the insertion of nucleotides at the junctions observed in both LD events are consistent with the mechanism of MMBIR (Fig. 1).

PB 1071 | Measurement of Basal Levels of TF, FVII, FVIIa, Free and Total TFPI and FVIIa.AT Complex Levels in Patients with Haemophilia A and B

E. Fosbury

Royal Free London NHS Foundation Trust, Katharine Dormandy Haemophilia and Thrombosis Centre, London, United Kingdom

Background: Phenotypic heterogeneity in haemophilia is a recognised phenomenon. There is also a suggestion that haemophilia B is less severe than A. This is a growing area of interest with the emphasis on individualised care and development of novel therapies targeting regulatory components. The components contributing to the initiation of haemostasis may play a role in moderation of bleeding phenotype.

Aims: This was a study of patients with moderate and severe haemophilia A and B measuring levels of TF, FVII, FVIIa, free and total TFPI, FVIIa.AT complex in the absence of overt bleeding.

Methods: Ethical approval and informed consent were obtained via the KD Coagulation Research Plasma Bank. TF levels were measured with the chromogenic ACTICHROME® TF assay (Sekisui Diagnostics, Invitech, UK); FVII by one-stage PT assay; FVIIa using a STACLOT® FVIIa-rTF clotting assay; Free & total TFPI levels, FVIIa.AT complex by ELISA (ASSERACHROM®, Diagnostica Stago, UK). Local normal ranges were created. Statistical analysis was conducted using non-parametric tests for comparison between diseases.

Results: 51 patients with haemophilia A (6 moderate) and 13 with haemophilia B (2 moderate) were recruited to the study. See Table 1 for

TABLE 1 Results of laboratory assays. Normal range (using 20 volunteers) ± 2SD (mean). Patients 10th, 90th percentile (median). ND=not detected

Assay	All patients	Haemophilia A	Haemophilia B
TF (ND - 2.39 pM; mean 1.04)	0.34 - 0.64 (0.45)	0.34 - 0.64 (0.45)	0.34 - 0.64 (0.45)
FVII (45 - 180 IU/dL)	55 - 119 (84.8)	66 - 120 (87.9)	42.4 - 96.5 (56.4)
FVIIa (10.60 - 62.12 mIU/dL; mean 36.36)	9.2 - 67.3 (34.1)	23.9 - 67.8 (41.5)	3.2 - 18.6 (7.5)
Free TFPI (2.8 - 13.8 ng/ml; mean 8.3)	7.6 - 21.3 (10.2)	7.5 - 18.3 (10.2)	8.1 - 22.2 (9.4)
Total TFPI (31.7 - 88.8 ng/ml; mean 60.2)	48.9 - 82.0 (62.7)	49.3 - 79.5 (63.0)	48.3 - 87.7 (61.3)
FVIIa.AT complex (41.7 - 243.0 pM; mean 142.3)	50.8 - 202.5 (122.7)	97.4 - 220.8 (132.4)	32.3 - 84.0 (47.9)

results. TF levels were equivalent between groups but significantly lower than normal ($p < 0.0005$). All patients with haemophilia B had significantly lower levels of FVII than A ($p = 0.001$). This was also true for FVIIa ($p < 0.0005$). Free & total TFPI levels were equivalent. The levels of FVIIa.AT complex were significantly lower in patients with haemophilia B ($p < 0.0005$).

Conclusions: This was a study investigating the components of the initiation and regulation of haemostasis in haemophilia A and B. All patients had low levels of TF. The results highlight differences between haemophilia A and B with significantly lower levels of FVII, FVIIa and FVIIa.AT complex. TFPI levels are equivalent. Further work is required to understand the underlying mechanisms and potential role in phenotypic heterogeneity.

PB 1072 | *F8*-deficiency in Mice is Associated with Increased von Willebrand Factor (VWF) Content in the Hepatic Endothelium and with Increased VWF Plasma Levels

K. Kiouptsi[1], M. Döhrmann[1], M. Lillich[1], S. Subramaniam[1,2], I. Scharrer[1], S. Jäckel[1,3], U. Walter[1], K. Jurk[1], C. Reinhardt[3]

[1]*University Medical Center of the Johannes Gutenberg University Mainz, Center for Thrombosis and Hemostasis (CTH), Mainz, Germany,* [2]*University of North Carolina, McAllister Heart Institute, Chapel Hill, United States,* [3]*German Center for Cardiovascular Research (DZHK), Partner Site Rhein-Main, Mainz, Germany*

Background: The anti-hemophilic coagulation factor FVIII is synthesized in the liver sinusoidal endothelium and co-stored together with von Willebrand Factor (VWF) in Weibel-Palade bodies of endothelial cells. While VWF is recognized as the carrier molecule of FVIII in plasma, stabilizing FVIII activity by preventing proteolytic degradation, the possible impact of *F8*-deficiency on VWF plasma levels is unresolved.

Aims: To pinpoint if *F8*-deficiency in mice is associated with altered VWF plasma levels.

Methods: The $F8^{-/-}$ mouse model is a useful tool to study hemophilia A, avoiding the confounding variables deriving from the heterogeneity of the disease origin. Therefore, we used a hemophilia A mouse model with disrupted exon 16 of the *F8* gene, which we back-crossed onto a pure C57BL/6J genetic background. In addition to the hemostatic, bleeding, and coagulation characteristics, we analyzed littermates from heterozygous breedings for their hepatic endothelial VWF content, VWF plasma levels, and VWF multimer size.

Results: The expected bleeding phenotype of *F8*-deficiency was noted, that was related to reduced thrombin-induced thrombin generation in platelet-rich plasma. Strikingly, immunohistochemistry analysis of the liver of $F8^{-/-}$ mice revealed increased VWF content in the liver endothelium. Increased hepatic endothelial VWF staining was accompanied by signs of increased hepatic inflammation, as indicated by increased CD45 and TNF-α mRNA levels. VWF plasma levels were significantly elevated in $F8^{-/-}$ mice compared with their co-housed WT littermate controls, but plasmatic ADAMTS13 concentrations and VWF multimer patterns were unchanged.

Conclusions: Collectively, our results demonstrate that *F8*-deficiency in mice is associated with increased VWF content in the hepatic endothelium and with increased VWF plasma levels.

PB 1073 | Feasibility of Prospective Transcriptome Profiling in Previously Untreated Patients with Severe Hemophilia A: NuProtect Gene Expression Satellite Study

P. Batty[1], E. Wozniak[2], E. Savage[2], C.A. Mein[2], D.P. Hart[1]

[1]*Blizard Institute, Barts and The London School of Medicine and Dentistry, Queen Mary University of London, London, United Kingdom,* [2]*The Genome Centre, Barts and the London School of Medicine and Dentistry, Queen Mary University of London, London, United Kingdom*

Background: Inhibitor formation occurs in a third of severe hemophilia A (HA) patients treated with Factor VIII (FVIII) concentrate. This is dependent on genetic and environment factors. There is poor understanding of the immunological mechanisms underlying inhibitor formation and immune tolerance induction (ITI). Evaluation of dynamic changes in gene expression (transcriptome) may identify biomarkers of inhibitor risk and provide novel therapeutic targets.

Aims: To demonstrate feasibility of RNA retrieval from previously untreated patients (PUP) with severe HA to analyze transcriptome changes at first exposure to FVIII and during ITI.

Methods: Blood samples for transcriptome analysis were obtained in an international phase 3 study (NuProtect, ClinicalTrials.gov Identifier: NCT01712438) of a recombinant human cell line FVIII concentrate (hcl-rFVIII, Nuwiq®). Whole blood samples were collected using a bespoke low volume PAXgene (1mL) RNA tube prior to and following first exposure to hcl-rFVIII (up to 20ED or inhibitor) and/or during ITI.

Results: 80 patients from 25 study sites have been recruited to date providing 375 samples (322 extracted). Median age at first FVIII exposure was 13 months (1-146). Median number of samples per patients was 5 (1-18). 16 patients (high titer=9, low titer=7) were known to have an inhibitor within this satellite study, representing a subset of the total recruited to the NuProtect PUP study. The median time to inhibitor formation was 9ED (4-25). Mean RNA yield (SD) was 11.8±8.7μg with all having >1μg (84%, 270/322, >5μg). Mean RNA purity (260/280) was 2.2±0.5. Mean RNA integrity (RIN) was 8.5±1.2 with 92% (296/322) having a RIN≥7 and only 5 samples (5/322, 1.5%) had sub-optimal RIN (≤5) for downstream analysis.

Conclusions: A low volume RNA tube provides an acceptable solution for transcriptome analysis in pediatric studies demonstrating high quality/quantity RNA. This transcriptome library will be one of the largest prospective datasets at first exposure to a protein therapeutic.

PB 1074 | The Bone Disease in Haemophilia: A Possible Role of Coagulation Factors?

M. Sacco[1], S. Lancellotti[1], A. Arcovito[2], G. Battafarano[3], A. Del Fattore[3], R. De Cristofaro[1]

[1]Fondazione Policlinico Universitario A. Gemelli, Catholic University of Rome, Center for Hemorrhagic and Thrombotic Diseases and Haemophilia Center, Roma, Italy, [2]Fondazione Policlinico Universitario A. Gemelli, Catholic University of Rome, Institute of Biochemistry and Clinical Biochemistry, Roma, Italy, [3]Bambino Gesù Children's Hospital, Bone Physiopathology Group, Multifactorial Disease and Complex Phenotype Research Area, Roma, Italy

Background: Until now, the pathogenesis of bone loss associated with severe hemophilia A (HA) remains still unknown; however it could be related to different risk factors, including decreased physical activity, viral infections, bleeding and inflammation. The reduction of Bone mineral density (BMD) seems due to perturbations of the Receptor Activator of Nuclear factor-B RANK Ligand (RANKL) and Osteoprotegerin (OPG) pathways. Moreover, bone cells express protease-activated receptors (PARs) and FVIII deficiency could alter BMD also by decreasing thrombin production.

Aims: This study aimed at investigating the role played by each coagulation factor (FVIII, VWF and thrombin) on osteoclast differentiation and function.

Methods: In vitro assays assessed the effects of the different coagulation factors (VWF/FVIII complex, human rVWF, human full length rFVIII, rFVIII B-deleted and thrombin) on 1) osteoclastogenesis (M-CSF/RANKL-generated osteoclasts) and 2) bone resorption activity (Cathepsin-K and MMP-9 expression).

Results: VWF appears to play a relevant inhibitory effect, showing by itself about 45% reduction of osteoclastogenesis comparable to OPG (the physiologic inhibitor), and even more if is complexed with FVIII (53% inhibition). Thrombin seems to counteract osteoclast differentiation with a variable effect (30-50% inhibition). In contrast, no significant result was obtained by gene expression studies, excluding a role in bone resorption activity.

Conclusions: These findings showed that the biology of osteoclasts is negatively influenced by VWF/FVIII complex. Likewise, thrombin interaction with PARs induces a significant inhibition of osteoclast activity. These results may have important implications in the clinical practice of hemophilia patients to better orient the choice of the FVIII concentrate to prevent bleeding and at the same bone disease in severe HA patients.

PB 1075 | Determinants of Thrombin Generation in Haemophilia A and B

B. Tardy-Poncet[1,2,3], P. Chelle[1,4], A. Montmartin[2], M. Piot[1], M. Cournil[1,4], C. Morin[1,4]

[1]Université de Lyon, Inserm U1059 SAINBIOSE, Saint-Etienne, France, [2]Inserm CIC 1408, FCRIN-INNOVTE, CHU Saint-Etienne, Saint-Etienne, France, [3]European Haemophilia Comprehensive Care Centre, CHU Saint-Eienne, Saint-Etienne, France, [4]Mines Saint-Etienne, CIS-EMSE, Saint-Etienne, France

Background: The thrombin generation assay (TGA) is increasingly used in haemophilia. Thrombin generation (TG) is affected by various coagulation factors and inhibitors, known as determinants. In healthy subjects, fibrinogen and factor XII have been identified as positive determinants of TG, antithrombin and free TFPI being negative determinants (Dielis A, JTH 2008). Would the determinants influencing TG be different in haemophilic patients?

Aims: To identify the determinant factors of TG in haemophilia A and B patients.

Methods: Plasma levels of coagulation factors and inhibitors, as well as TG, were measured in 40 haemophilia A and 32 haemophilia B patients. The effect of the levels of coagulation factors and inhibitors on ETP and peak were analysed using stepwise multi-linear regression models.

Results: In haemophilic A patients, factor VIII was a positive determinant of ETP and peak, whereas TFPI and factor V were negative determinants.

In haemophilic B patients, factor IX was a positive determinant of ETP, whereas antithrombin, protein S, and free TFPI were negative determinants. Factor VII was a positive determinant of peak, whereas free TFPI and factor X were negative determinants.

Overall, TFPI was the major determinant of peak and ETP in haemophilic patients.

Conclusions: Positive and negative determinant factors of TG are not the same in healthy individuals and haemophilic patients. TFPI seems to greatly influence TG in haemophilic patients.

PB 1076 | Unusual Genomic Rearrangement Combined with Inv22 and Wild-type X-chromosome in Severe Hemophilia A Patients

S. Tamura[1], M. Kakihara[1], Y. Hattori[1], E. Hashimoto[1], H. Sakane[1], Y. Takagi[1,2], M. Ogawa[3], T. Kanematsu[4], N. Suzuki[5], A. Takagi[3], T. Matsushita[5], T. Kojima[3]

[1]Nagoya University Graduate School of Medicine, Department of Pathophysiological Laboratory Science, Nagoya, Japan, [2]Research Fellow of Japan Society for the Promotion of Science, Tokyo, Japan, [3]Nagoya University Graduate School of Medicine, Department of Hematology and Oncology, Nagoya, Japan, [4]Nagoya University Hospital, Department of Clinical Laboratory, Nagoya, Japan, [5]Nagoya University Hospital, Department of Transfusion Medicine, Nagoya, Japan

Background: Various genetic defects of coagulation factor VIII gene (*F8*) cause hemophilia A (HA). Intron 22 inversion (Inv22) found in a half of severe HA patients results from a recombination between intra- and extra-genic intron 22 homologous copies.

Aims: In this study, we investigated the brother cases of severe HA with complicated X-chromosomal rearrangement.

Methods: We analyzed gDNA from male probands (7 y/o and 3 y/o, severe HA, FVIII:C < 1%), their mother (39 y/o, FVIII:C = 39.4%), maternal grandfather (67 y/o, FVIII:C = 171.2%), and grandmother (64 y/o, FVIII:C = 147.8%). *F8* Inv22 was analyzed by long-PCR and inverse shifthing-PCR (IS-PCR). Quantitative genome mapping was performed by quantitative-PCR (qPCR). Genomic breakpoint search was performed by inverse-PCR, and direct DNA sequencing. This study

was approved by the ethics Committee of the Nagoya University Graduate School of Medicine.

Results: Long- and IS-PCRs of probands showed a mixed pattern of wild-type (WT) and Inv22 type 2. Mother gDNA also exhibited the same long-PCR pattern of probands. However, maternal grandfather and grandmother displayed a WT genome pattern. Quantitative genome mapping indicated that *F8* from exon 24 to intron 25 were duplicated as compared to WT gDNA. *CLIC2* from exon 1 to intron 3 was also duplicated. From these results, we hypothesized that Inv22 X-chromosome (X-chr) was combined with translocated WT X-chr as a breakpoint between *CLIC2* on Inv22 X-chr and *F8* on WT X-chr. Inverse-PCR and direct DNA sequencing revealed that, in patients, sense-oriented *CLIC2* intron 3 connected to antisense-oriented *F8* intron25 via 3 bases microhomology.

Conclusions: The patients have an unusual rearranged Inv22 X-chr combined with a WT telomeric side of X-chr. We propose a rearrangement mechanism repairing the telomere side of a double-strand broken Inv22 X-chr by microhomology-mediated break-induced replication with WT X-chr.

PB 1077 | Biochemical and Biophysical Characteristics of Commercially Available FVIII Products

R. De Cristofaro[1], M. Sacco[1], S. Lancellotti[1], I. Garagiola[2], C. Valsecchi[2], G. Scaglione[3], M. Basso[1], E. Di Stasio[3], F. Peyvandi[2]

[1]*Catholic University of the Sacred Heart School of Medicine, Institute of Internal Medicine, Department of Hematology-Oncology, Roma, Italy,* [2]*Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Luigi Villa Foundation, Milano, Italy,* [3]*Catholic University of the Sacred heart School of Medicine, Institute of Biochemistry and Clinical Biochemistry, Roma, Italy*

Background: Recombinant and plasma-derived (pd) coagulation factor concentrates available for haemophilia A treatment differ in purity and structure, which might affect their efficacy and immunogenicity. Recently, the SIPPET trial showed that previously-untreated-patients have higher incidence of inhibitor development if treated with recombinant FVIII products. This phenomenon could arise from several features of recombinant products, such as the absence of VWF and albumin, different glycosylation profile or their molecular aggregation.

Aims: This study investigated the purity grade, FX activating ability and aggregation status of three rec-products (Advate [Baxalta], Refacto AF [Pfizer] and Kogenate [Bayer]), compared with four commercially available pd-FVIII concentrates (Haemoctin [Biotest] , Fanhdi [Grifols], EmoclotÒ [Kedrion], and Beriate [CSL Behring]).

Methods: Rec- and pd-factors were studied with FPLC-chromatography, (immuno)-electrophoresis, dynamic light scattering (DLS) and steady-state enzyme kinetics.

Results: DLS data showed that no molecular aggregation was present in the three rec-FVIII products that showed a constant Z-average value (~70 nm) over a range of concentrations similar or even higher than that obtained after their reconstitution (100-250 IU/ml). A similar result was obtained for the pd-concentrates. The presence of VWF content in the pd-FVIII products slightly accelerates the thrombin-induced kinetics of FVIII activation and FVIIIa inactivation.

Conclusions: These results show that, although the molecular dimension, glycosylation profile and presence of different stabilizers are different, the most commonly used recombinant products do not undergo molecular aggregation at pharmaceutical concentrations obtained after their reconstitution. Thus, the hypothesized molecular aggregation of recombinant products cannot be invoked as a plausible cause of their increased propensity to induce formation of FVIII inhibitors.

PB 1078 | Global Assays of Hemostasis among Severe Hemophilia A Boys Detects Variation

F. Pluthero[1], M. Rand[2], V. Blanchette[2], W. Kahr[2]

[1]*Hospital for Sick Children, Cell Biology, Toronto, Canada,* [2]*Hospital for Sick Children, University of Toronto, Haematology/Oncology, Toronto, Canada*

Background: Severe hemophilia A patients vary in FVIII treatment requirements. Optimal treatment limits antigen exposure and expense, and is currently guided by clinical observations (e.g. bleeding frequency). It would also be useful to employ predictive laboratory assessments, but heterogeneity among severe hemophilia A patients is poorly understood.

Aims: To use global hemostatic assays to measure variation in baseline hemostatic function after factor washout in a cohort of hemophilia A boys receiving a range of rFVIII replacement regimens.

Methods: We used thromboelastography (TEG; whole blood) and calibrated automated thrombography (CAT; plasma with and without platelets) with experimental variations including use of the contact activation pathway inhibitor corn trypsin inhibitor and differing concentrations and preparations of tissue factor. Attempts were made to correlate the results of these assays with each other and with clinical parameters to gain insights into their potential utility in the prediction of factor requirements.

Results: We observed that contact pathway inhibition is required for accurate assessment of variation in baseline hemostatic function using TEG and CAT. Both assays detected substantial heterogeneity within our cohort when performed with low tissue factor concentrations, and inter-individual variation was sufficiently large that efforts to find relationships with clinical traits such as factor requirements, were statistically not achievable. Different tissue factor preparations had an influence, with results of TEG and CAT assays performed with Innovin showing a significant correlation. The results of TEG and CAT assays converged towards normal ranges with increasing levels of tissue factor activation, but several severe hemophilia A samples did not reach normal levels of thrombin generation.

Conclusions: Our results indicate that CAT is the most promising assay for further studies of hemostatic function variation in severe hemophilia A patients.

PB 1079 | A Bispecific Antibody Lacks Measurability in Routine Coagulation Assays and Comparability to Factor VIII

R. Hartmann[1], S. Knappe[1], G. Schrenk[1], L.A. Valentino[2], F. Scheiflinger[1], M. Dockal[1]

[1]*Shire plc, Vienna, Austria,* [2]*Shire plc, Chicago, United States*

Background: For optimal management of hemophilia A patients receiving ACE910 non-factor therapy, accurate monitoring is needed. However the best testing methodology is not known.

Aims: To examine the effect of assay type on hemostatic activity monitoring of a sequence identical analogue to ACE910 (SIA) and to assess FVIII activity equivalency.

Methods: SIA was analyzed in 4 commercial chromogenic assay kits; rFVIII served as comparator. Clotting times were measured by APTT using 5 differently composed trigger reagents followed by clot waveform analysis. In TGA, SIA was tested using extrinsic and intrinsic trigger conditions. As needed, concentrations ranged from 2-1200 NM.

Results: Lack of cross-reactivity of SIA to bovine factors rendered only the Biophen FVIII:C test suitable for analysis. As the dose response of SIA and FVIII was not collateral, the chromogenic assay is not a reliable test for FVIII equivalence assessment. APTT was highly sensitive to SIA which resulted in substantial reduction of clotting time at low and potentially non-therapeutic concentrations. Different APTT reagents yielded a FVIII equivalence range of 18-69% (20 nM SIA) and >200% at a presumed clinical concentration of 600 nM. SIA (600nM) only partially restored TG in hemophilia A patient plasmas, resulting in FVIII equivalents of 4-8% (intrinsic) and 16-36% (extrinsic) based on peak thrombin. Assessment of other TG parameters resulted in FVIII equivalency ranging from 0 to >100%.

Conclusions: Analysis of SIA and derivation of FVIII equivalence therefore is challenged by its novel mechanism of action/regulation. FVIII equivalence of SIA cannot be determined using standard FVIII protocols and is highly influenced by assay type, analytical conditions, and parameters used for calculation. Thus, new methods and a product specific standard are required for better prediction of the hemostatic effect of non-factor therapies.

PB 1080 | Efficacy of Anti-TFPI Antibody PF-06741086 Compared to rFactor VIIa in Mouse Hemophilia A Bleeding Models

R. Jasuja, J.E. Murphy, D.D. Pittman

Pfizer Inc., Cambridge, United States

Background: Patients with hemophilia use replacement factor as prophylaxis to prevent bleeds. Some patients develop inhibitory antibodies and become refractory to treatment. Hemophilia patients with inhibitors are currently managed with rFVIIa or aPCC bypass therapy. An alternative approach is to augment the extrinsic tissue factor (TF) pathway by inhibiting Tissue Factor Pathway inhibitor (TFPI). TFPI modulates the initiation of coagulation by directly binding and inhibiting the TF/FVIIa/FXa complex. PF-06741086 is a fully human monoclonal antibody engineered to inhibit TFPI activity.

Aims: Here, we compare the hemostatic effect of PF-06741086 to rFVIIa in mouse bleeding models.

Methods: Hemophilia A (Hem A) mice received a single intravenous dose of PF06741086 (1, 2 or 6 mg/kg), vehicle, or rFVIIa (2, 5, or 10 mg/kg) dosed 30 minutes or 5 minutes before a 3 mm tail clip, respectively. Blood was collected for 10 minutes and quantified against a standard curve of hemoglobin. In a second model, cremaster microcirculation in Hem A mice was observed using intravital microscopy (IVM).

Results: PF-06741086 restored hemostasis at 1 mg/kg (49%), 2 mg/kg (63%), and 6 mg/kg (78%) compared to vehicle treated mice. In rFVIIa treated mice, the highest tested dose of 10 mg/kg reduced bleeding by 55%, with a lower reduction at 5 mg/kg (33%), and no effect at 2 mg/kg. In a laser injury model using IVM, the effect of PF-06741086 (6 mg/kg) was similar to 5 mg/kg of rFVIIa in enhancing platelet clot and fibrin formation. A lower dose of rFVIIa corrected clot formation in the laser injury model compared to a tail clip. Assay sensitivity or vessel size in injury model could explain the difference in efficacy between tail clip and IVM. Data on co-treatment with PF-06741086 and rFVIIa in animal models of hemophilia with will also be presented.

Conclusions: Prophylactic administration of PF-06741086 in hemophilic mice neutralizes TFPI to enhance the extrinsic pathway and bypass deficiencies in the intrinsic pathway of coagulation.

PB 1081 | X Chromosome Inactivation and Plasma Level of Factor VIII and IX in Carriers of Hemophilia A and B

I. Garagiola[1], M. Mortarino[1], M. Biganzoli[1], M.E. Mancuso[1], E. Santagostino[1], F. Peyvandi[2]

[1]*Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico and Fondazione Luigi Villa, Milan, Italy,* [2]*Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico and Fondazione Luigi Villa, Department of Pathophysiology and Transplantation, Università degli Studi di Milano, Milan, Italy*

Background: Hemophilia A and B are X-linked haemorrhagic disorders caused by mutations in *F8* and *F9* genes. Due to recessive inheritance, males are affected, while female carriers, with a wide range of FVIII or FIX levels, are mostly asymptomatic. Bleeding tendency in carriers is extremely variable and rare, associated with low clotting factor levels. This could be ascribed to homozygous *F8* or *F9* mutations or compound heterozygous, numerical or structural X chromosome abnormality, or to skewed X chromosome inactivation (XCI).

XCI is a normal epigenetic phenomenon that occurs early in the embryogenesis when, randomly, one of two X-chromosomes, in females, is transcriptionally silenced.

Aims: To determine whether the low activity of FVIII or FIX (below 20 IU/dL) in hemophilia carriers could be related to XCI.

TABLE 1 Data of carrier females

Case code	Disease	FVIII:C* [50-147 IU/dL]	FIX:C* [70-120 IU/dL]	Family history	XCI skewed	F8/F9 mutation	F8 and F9 variant database
E292	HB	ND	10	No	Yes	c.252+5G>A p.C335W	Yes
E1424			1	No		p.N48Y	No
E1236			13	Yes			Yes

E253		3		Yes			Yes

*one-stage assay; ND: not determined; NA: not available; XP: X paternal chromosome;
§ Antonarakis SE et al, Blood 1995;86:2206-12

Methods: Molecular characterization was performed using PCR, Sanger sequencing, and MLPA analysis. X inactivation status was studied by methylation-sensitive endonuclease digestion, coupled with PCR analysis of a polymorphic repeat of the human androgen receptor (HUMARA) gene.

Results: Eight carriers of hemophilia A and three carriers of hemophilia B exhibited low plasma levels of FVIII:C (range from 3 to 16 IU/dL) and FIX:C (range from 1 to 13 IU/dL). All carriers showed joint bleeding and hematoma after trauma or surgery, and menorrhagia. A specific mutation was found in 10 hemophilia carriers in heterozygous state, as reported in table 1, not justifying alone their low activity levels.

HUMARA results showed unfavourable X chromosome inactivation in all carriers. The ratio of inactive X chromosome to active was dramatically skewed (≥80:20). In two cases of familial hemophilia, only the paternal allele was the active one.

Conclusions: In our group of carriers with FVIII:C and FIX:C level below 20 IU/dL, XCI seems to be an appreciable determinant of clotting factor residual level, even if phenotypic expression is multifaceted sustaining further investigation.

PB 1082 | Turoctocog AlfaPegol (N8-GP) Is Cleared from Subcutaneous Injection Sites without Local Degradation

M. Petersen, L.F. Larsen, H. Pelzer, G. Bolt, A.L. Nielsen, F. Rode, K. Almholt

Novo Nordisk A/S, Global Research, Måløv, Denmark

Background: N8-GP is a glycoPEGylated recombinant factor VIII (FVIII) with high bioavailability after subcutaneous (SC) administration in animal models and may provide a convenient SC therapy for patients with haemophilia A.

Aims: To analyse injection site distribution and absorption/elimination of N8-GP after SC administration in mice.

Methods: F8 gene-knockout mice received a high single (1850 IU/kg) or multiple (3 x 1850 IU/kg, 48 h apart) SC dose(s) of N8-GP or fluorescently labelled N8-GP VivoTag® 680XL. Temporal disappearance from the injection site was quantified with *in vivo* optical imaging. Blood samples were collected for FVIII antigen and activity assays. Micro-distribution of N8-GP at injection sites was studied with immunohistochemistry for FVIII. Any degradation of labelled N8-GP at injection sites was analysed by western blotting for FVIII. The Danish Animal Experiments Council approved all *in vivo* procedures.

Results: SC N8-GP displayed a prolonged presence of FVIII antigen and activity in plasma compared to the expected PK profile of FVIII. *In vivo* imaging suggested a gradual disappearance from injection sites. The fluorescence signal from labelled N8-GP was largely undetectable 48 h post injection and only a faint signal was detected at 72 h. Western blotting and immunohistochemistry demonstrated that a large fraction of the SC N8-GP depot persisted up to 6 h after injection, with a marked reduction at 24 h and minimal N8-GP detected at 72 h. Three injections of N8-GP at the same site did not lead to detectable accumulation. No degraded N8-GP was observed. The immunohistochemical reactivity for N8-GP was mostly interstitial and, to a lesser degree, cell associated. Double immunofluorescence identified a large proportion of these cells as CD11b-positive myeloid cells.

Conclusions: The disappearance pattern of N8-GP from injection sites in mice is supportive of further development of SC N8-GP as a convenient prophylaxis option for patients with haemophilia A.

PB 1083 | Thrombin Generation Profiling in Amish Factor IX Carriers and Controls: Plasma Composition and Bleeding Phenotype

M.C. Bravo[1], S. Gupta[2], C. Nakar[2], M. Heiman[2], A. Shapiro[2], K. Brummel-Ziedins[1]

[1]University of Vermont, Colchester, United States, [2]Indiana Hemophilia & Thombosis Center, Indianapolis, United States

Background: Hemophilia B carriers differ in their factor (F)IX activity levels even in the same pedigree. Although FIX activity serves as a surrogate marker for potential bleeding tendency, understanding

the balance between procoagulant and anticoagulant proteins that regulates thrombin generation may improve assessments of bleeding potential.

Aims: Compare and contrast an Amish cohort of FIX Carriers and Controls with respect to thrombin generation and bleeding scores (BS).

Methods: Samples were collected from 170 Amish subjects, 68 Controls and 102 FIX Carriers, all with c.1025 C>T; p.Thr342Met genetic mutation. Thrombin generation in response to 5 pM tissue factor for each individual was calculated by a mathematical model incorporating levels of procoagulants: FII, V, VII, VIII, IX, X, and the anticoagulants: antithrombin, tissue factor pathway inhibitor and protein C. Thrombin generation parameters included time to clot, maximum rate (MaxR), maximum level (MaxL) and area under the curve. BS was assigned based on the Tosetto scoring system using an in-house developed bleeding questionnaire.

Results: Carriers were significantly younger in age, lower in functional activity of FIX, FVII and in MaxL of thrombin generation as compared to Controls (Table). Anticoagulants were not significantly different between groups. Across the entire cohort, MaxL and MaxR correlated with FIX activity (all r>0.7). FIX activity alone did not correlate with BS (r=0.02). BS was low overall and there was no difference between Carriers and Controls 1.3(0,8) vs. 1.4(0,9). However, when individuals were grouped based on BS (0, 1-2, 3+), there was a trend correlating higher BS with lower MaxL in Carriers, conversely Controls with lower BS trended with lower MaxL.

TABLE 1 Comparison of Carriers and Controls

	Carriers, N = 102	Controls, N = 68	
	Mean ± SD	Mean ± SD	p-value
Age, in years	21 ± 17	35 ± 20	< 0.0001
FIX activity, %	64 ± 27	115 ± 28	< 0.0001
FVII activity, %	108 ± 25	121 ± 33	0.003
Thrombin MaxL, nM	338 ± 116	412 ± 100	< 0.0001

Conclusions: The combination of suppressed procoagulants FIX and FVII in Carriers despite comparable anticoagulants relative to Controls, yielded lower levels of thrombin and trended with higher BS. Further studies are warranted.

PB 1084 | The Global Annual Bleed Rate in Haemophilia: A 2015 Estimate

C. Thompson[1], A. Srivastava[2], M. Skinner[3], J. Stonebraker[4], J. Epstein[1], T. Kauf[5], L. Valentino[5,6]

[1]*Stratevi, Santa Monica, United States,* [2]*Christian Medical College, Department of Hematology, Vellore, India,* [3]*Institute for Policy Advancement Ltd., Washington, United States,* [4]*North Carolina State University, Poole College of Management, Raleigh, United States,* [5]*Shire, Cambridge, United States,* [6]*Rush University, Chicago, United States*

Background: Current global metrics to describe haemophilia burden reflect prevalence and access to care (e.g., IU/capita and proportion of persons with haemophila receiving prophylaxis). Additional metrics reflecting patient outcomes would improve our understanding of the burden of bleeding in haemophilia at the population level.

Aims: The primary objective was to estimate the number of bleeding episodes experienced by the known haemophilia population worldwide and highlight opportunities to collect data to track bleeding outcomes globally.

Methods: A literature-based model was developed to estimate country-specific haemophilia prevalence, broken down by presence of inhibitors, severity, age and prophylaxis use for each country. The primary data source is the World Federation of Haemophilia Annual Global Survey (AGS) (2012-2015). The mean ABRs associated with each severity level, age group, and treatment modality were obtained through a literature search. These were incorporated to estimate the total number of bleeds that occur annually in persons with haemophilia A and B in every country. One-way sensitivity analyses were performed to understand which model input variables contribute the most to the global bleed estimate.

Results: Among the known haemophilia population (n = 189,494), an estimated 2,509,817 bleeds occur yearly. In the projected haemophilia population (n = 658,418), the global ABR may be as high as 12,147,263. Given these results, a bleeding episode is estimated to occur every 3 to 12 seconds.

Conclusions: This project is the first attempt to estimate the total annual number of bleeds for people with haemophilia across the world. The results provide insight into the magnitude of the burden of bleeding to further strengthen our understanding of haemophilia today.

PB 1085 | Mortality of Hemophilia in Brazil: First Report

L. Lemos Jardim[1], J. van der Bom[2,3], C. Caram Deelder[2,3], S. Claudia Gouw[3], M. Leal Cherchiglia[1], S. Meireles Rezende[1]

[1]*Faculty of Medicine, Universidade Federal de Minas Gerais, Belo Horizonte, Brazil,* [2]*Center for Clinical Transfusion Research, Leiden, The Netherlands,* [3]*Leiden University Medical Center, Department of Clinical Epidemiology, Leiden, The Netherlands*

Background: Brazil has the fourth largest population of hemophilia patients in the world, accounting for 11,857 individuals registered in 2015 (World Federation of Hemophilia, 2015). However, mortality rates over the years in this population are unknown.

Aims: To analyse the hemophilia mortality ratio in Brazil from 1997 to 2014, using the Brazilian National Mortality Information System (SIM) as data source.

Methods: Death of patients with hemophilia were identified according to the 10th International Classification of Diseases (ICD-10). Standardized mortality ratios (SMR) were calculated to estimate the rate of overall death of patients with hemophilia relative to that of the Brazilian general male population. Data were adjusted for age

and calendar period. Statistical analyses were performed using Stata (STATA Corp LP, USA).

Results: From January 1997 to December 2014, 821 (94%) patients with hemophilia A (HA) and 53 (6%) patients with hemophilia B (HB) were identified. Mortality of patients with HA was 22% higher when compared with the general male population (SMR 1.22, CI 1.13-1.30). SMR decreased over the years, with exception of the period between 1997-1998, which might have suffered influence of underreported deaths. Hemorrhage was the most frequent cause of death related to hemophilia, described in 268 patients (30.7%). Of these, 142 (53%) presented intracranial haemorrhage. The frequency of HIV related to hemophilia decreased from 1997 (26.5%) to 2014 (12.2%). Otherwise, deaths related with cardiovascular disease increased from 11% to 24% in the same period. A total of 130 (14.9%) deaths were related with hepatitis infection, of whom 110 (84.6%) also presented other liver diseases.

Conclusions: HA patients have a higher risk of death in comparison with general male population. Intracranial hemorrhage is still an important cause of death in Brazilian patients with hemophilia. Death due to cardiovascular disease has increased over the years, following the same tendency observed in the developed world.

PB 1086 | Alternative Payment Models in Hemophilia

B. Jönsson[1], G. Dolan[2]

[1]*Stockholm School of Economics, Stockholm, Sweden,* [2]*Nottingham Comprehensive Care Centre for Haemophilia, Nottingham, United Kingdom*

Background: Intravenous injection with replacement factors VIII and IX is the mainstay of treatment for hemophilia. After decades of similar products, novel therapies with diverse characteristics (eg, long-acting products) have recently been developed. Current payment for replacement factor is based on price-per-unit, but new payment models are needed that acknowledge patient benefit and provider/payer expectations for evidence-based, cost-effective healthcare. For products with similar properties, price-per-unit procurement is reasonable, but entry of diverse therapies into the market drives a need for payment models that support innovation and optimize patient care, accounting for all relevant aspects.

Aims: To develop alternative payment models for hemophilia that foster improvement of patient care and drive innovation.

Methods: An international, multidisciplinary panel of HEOR and hemophilia experts convened to develop concepts for payment models in hemophilia, taking into account strategies to support innovation, while optimizing patient care, and entry of long-acting replacement factor and non-replacement products.

Results: Two payment model concepts were developed: a pay-per-patient model that uses fixed payment based on expected healthcare utilization of an average patient per year, and a pay-per-outcome model where payment is based on achieved outcomes. The pay-per-patient model is expected to lead to physicians and patients selecting treatments that satisfy individual patient needs, while controlling the total cost for the provider/payer. Payment is independent of achieving treatment goals, but influenced by treatment guidelines and local policy. In the pay-per-outcome model, achievement of predefined outcomes is rewarded. This model encourages innovation that improves outcomes better than available products today.

Conclusions: Development of new payment models in hemophilia, such as pay-per-patient and pay-per-outcome models, can improve quality of care, drive innovation, and ensure access to new products.

PB 1087 | Rapid and Cost-effective FVIII Intron Inversion 22 Screening of the Central South African Haemophilia A Population

W. Janse van Rensburg[1], J. Kloppers[1,2]

[1]*University of the Free State, Haematology and Cell Biology, Bloemfontein, South Africa,* [2]*National Health Laboratory Service, University of the Free State, Bloemfontein, South Africa*

Background: An inversion of intron 22 (Inv22) of the FVIII gene is reported in roughly 45% of all severe haemophilia A cases. Until recently, only the Southern Blot assay was available in a single laboratory in Johannesburg, South Africa for Inv22 detection. Therefore, the Inv22 status of a large part of the South African haemophilia A population is mostly unknown.

Aims: The aim of our study was to use our newly developed rapid and cost effective gel-based reverse transcription PCR (RT-PCR) assay to detect the Inv22 mutation in our local haemophilia A population.

Methods: We recruited 59 (n=59) volunteers who attended haematology clinics in Bloemfontein and Kimberley in central South Africa. We recruited 33 (n=33) males with severe haemophilia A, 1 (n=1) male with mild haemophilia A, 20 (n=20) female putative carriers, and 5 healthy controls. Volunteers gave informed consent prior to participation. Venous blood was stabilized on Trizol reagent. RNA was extracted and cDNA synthesis was performed. A conventional PCR was performed according to our newly developed published method and the PCR product was visualized on a 2% agarose gel.

Results: We detected the Inv22 mutation in 10 (n=10) out of the 33 male volunteers with severe haemophilia A, which accounts for roughly 30%. Inv22 was detected in 5 (n=5) of the 20 putative carriers, which is 20%. The Inv22 mutation was detected in neither the male with mild haemophilia A nor any of the controls. All volunteers without the Inv22 mutation (n=44) were positive for the wild-type.

Conclusions: We have successfully implemented the newly developed rapid and cost-effective Inv22 screening assay in our laboratory. The presence of the Inv22 mutation in the central South African severe haemophilia A population is lower than is reported globally (30% vs 45%). However, this may be attributed to the relative low sample numbers. Conversely, we believe that this new relatively uncomplicated method will make more wide-spread Inv22 testing in South Africa a reality.

PB 1088 | Patient Satisfaction of Home Delivery Program in Haemophilia through an Association of Patients

M. Martín-Cerezuela[1], J.E. Megías Vericat[2], E. Monte-Boquet[1], P. Pérez-Huertas[1], M.J. Cuéllar-Monreal[1], M.V. Tarazona-Casany[1], J.L. Poveda-Andrés[1], S. Bonanad-Boix[3]

[1]Hospital Universitari i Politècnic La Fe, Servicio de Farmacia, Valencia, Spain, [2]Hospital Universitari i Politècnic La Fe, Servicio de Farmacia, VALENCIA, Spain, [3]Hospital Universitari i Politècnic La Fe, Unidad de Hemostasia y Trombosis, Valencia, Spain

Background: Most of the clotting factor (CF) dispensations to patients with haemophilia in Valencian Community are centralized in only one hospital, generating frequent visits to hospital, and requiring long travel distances. Since 2011, the Outpatient Pharmaceutical Care Unit (OPCU) established collaboration with the *Hemophilia Patients Association of the Valencian Community* (ASHECOVA) to develop together a home delivery program, allowing patients an easier and convenient access to their treatments.

Aims: To evaluate the satisfaction level of patients included in the home delivery program.

Methods: A questionnaire with 26 questions was used to explore organizational aspects, education and communication between patients and professionals, the use of apps, as well as the satisfaction level of certain aspects that concerned the delivery of medication. The satisfaction was also measured using a previously validated survey (Likert scale), with open answers and 10 possible closed answers
(1 disagree and 10 strongly agree). A specific Google® form was developed for this study.

Results: Thirty-eight of 44 asked patients, answered the survey (men, 38.8 mean age). Benefits mostly reported by 95% of patients were less frequent visits to hospital, reduced time and costs spent in transportation. Ninety-five percent of individuals believed that the program improves treatment adherence and 92% would be interested in using an app for register the CF administration. Frequency and horary of delivery were adequate for 100%. All patients would recommend this system to other patients and overall satisfaction extent was 9.7 (DE: 0.5).

Conclusions: Home delivery program guarantees a proper follow-up of treatments, obtaining full satisfaction evaluation from patients. This program improves patient´s convenience and overall score was very satisfactory. In view of the results, we will implement an app for recording CF administrations.

PB 1089 | Contribution to the Molecular Study of Hemophilia B in an Algerian Population

Y. Ouarhlent[1], A. Zidani[2], M. Yahia[2], N. Lannoy[3], K. Belhadi[2]

[1]Department of Medicine, University of Batna 2, Batna, Algeria, [2]Biotechnology's Laboratory of the Bioactive Molecules and the Cellular Physiopathology, University of Batna2, Batna, Algeria, [3]Department of Biology Clinic - Center for Human Genetics, University Hospital Saint-Luc, Brussels, Belgium

Background: Hemophilia B (HB) is a hereditary X- linked recessive bleeding disorder of coagulation caused by mutation in factor IX (FIX) gene that result in FIX deficiency. Based on the plasma levels of FIX, HB is classified as severe (<1%), moderate (1-5%) and mild (>5-30%) and the severity of the disease is in close correlation with the type and position of the mutation in FIX gene.

Aims: The objective of this study was to identify the mutations that produce different forms of HB disease among Algerian patients, to characterise mutations of the FIX gene and to develop our knowledge about the molecular basis of this disease.

Methods: 9 patients with severe HB, were enrolled in this study. All patients were male. About 5-10 ml of peripheral blood was collected into tubes containing ethylenediaminetetraacetic acid (EDTA), and DNA was extracted by the salting out method. As most of the exons in the HB gene are relatively short, direct sequencing of a complete exon is possible once it has been amplified from genomic DNA with the polymerase chain reaction (PCR) technique , so, all exons of the FIX gene were amplified by PCR. The HB mutation was identified by automated sequence analysis using the Capillary electrophoresis method.

Results: 2 FIX gene mutations were detected, a point mutations (2 missense mutations). The first was c.323G>A (Cys 108 Tyr) located in the epidermal growth factor1 (EGF1) domain ; is coded by exon 4. The second revealed missense mutation 881G>A (p.Arg 294 Gln) within the protease domain, the greater part (codons 280-451) is coded by the largest exon in the FIX gene (exon 8).

Conclusions: This study confirms the correlation between the type of mutation and severity form. we showed in this study, the importance of molecular analysis for the characterization of HB in patients. HB is the result of a genetic error. Identifying this error is very important for patients because it helps to confirm the diagnosis and predict complications of treatment.

PB 1090 | A Hand-held Electronic Patient Diary for Haemophilia Home Care-pilot Study in Poland

P. Laguna[1], H. Bobrowska[2], A. Janik-Moszant[3], A. Klukowska[1], A. Koltan[4], T. Urasinski[5], I. Woznica -Karczmarz[6]

[1]Medical University, Dept of Paediatrics, Haematology and Oncology, Warsaw, Poland, [2]Children Hospital in Poznan, Poland, Dept of Pediatrics and Hematology, Poznan, Poland, [3]Zabrze Medical University, Dept of Paediatrics, Haematology and Oncology, Zabrze, Poland, [4]Collegium Medicum, Nicolaus Copernicus University Torun, Dept of Paediatrics, Haematology and Oncology, Bydgoszcz, Poland, [5]Pomeranian Medical University, Dept of Pediatrics, Hematology and Oncology, Szczecin, Poland, [6]Lublin Medical University, Dept of Pediatrics, Hematology, Oncology and Transplantology, Lublin, Poland

Background: Permanent administration of the missing factor in certain days in order to prevent bleedings is only a prophylactic treatment. To enable the doctors to monitor their patients' treatments, the diaries were introduced, in which those very patients record and write down all the undertaken courses of action. Nevertheless, owing to the fact

that patients see their physicians 1-2 times a year, those courses may turn out to be insufficient.

Aims: The aim of that pilot survey was to assess whether the electronic device can replace a diary and if so, whether will it improve patient care through monitoring both the haemorrhages and the consumption and reserves of the factor VIII. 30 patients from 6 different centres in Poland participated in this survey from 01.12.15 to 31.05.16. The mean age of patients in the study was 2-7 years (range 4.85) All of them were prophylactically given Advate (Baxter) three times a week at a dose of 35-40 IU/kg^{-1}

Methods: -

Results: In six months' time the bleedings were observed in 16 cases, while the other 14 patients didn't undergo any bleeds. Three out of those 16 cases experienced haemarthrosis, two -haemorrhages into soft tissues and the rest eleven - both haemarthrosis and haemorrhages into soft tissues. In ten cases patients that were given the factor VIII on Monday, Wednesday and Friday went through a haemorrhage on Sunday.

A problem with noting blood transfusions down in a diary occurred in three cases. Four patients required increasing the dose due to the reoccurrence of the haemorrhages.

Conclusions: The study shows that the electronic documentation system is feasible for hemophilia patients and provides the physician with the opportunity to monitor patients more closely. However, not all patients seem to be qualified for using that electronic tool, and the tool must run dependably without major errors for ensuring reliability and acceptability.

PB 1091 | Induction of FVIII Tolerance by Gene Transfer of IL2 and Factor VIII Plasmids in Hemophilia A Mice

M.J. Lyle, R.Y. Fu, C.H. Miao

Seattle Children's Research Institute, Seattle, United States

Background: Hemophilia A (HemA) patients lack functional FVIII protein, which results in an inability for the blood to clot when injury occurs. The current treatment for HemA patients is FVIII protein replacement, but this treatment often results in anti-FVIII immune responses, neutralizing the clotting effect.

Aims: Regulatory T cells (Tregs) help balance T effector cells (Teffs) through their suppressive function during an immune response. Tregs possess a high affinity epitope of the IL2 receptor. With a low dose of IL2, the expansion of Treg population exceeds the proliferation of Teffs, leading to a significant increase in activation and number of Tregs and Treg/Teff ratio. The increased suppressive activity can induce tolerance in HemA mice treated with FVIII plasmid gene therapy.

Methods: HemA mice were hydrodynamically injected with either 1 μg, 2 μg or 5 μg IL2 plasmid and 50 μg FVIII plasmid sequentially 2 weeks apart. Both plasmids were driven by a liver-specific promoter (hAAT-HCR). The following assays were performed at various time points: cell staining, APTT, Bethesda, ELISA.

Results: Flow cytometry analysis showed a dramatic increase in Treg population and activation in all three groups, demonstrating that a small amount of IL2 plasmid transferred into liver cells can significantly increase the Tregs. HemA mice injected with 5 μg IL2 plasmid showed a large increase in Teffs and no measurable FVIII levels, possibly due to the inadvertent activation of cytotoxic T lymphocytes. Mice injected with 2 μg IL2 plasmid had less Teff activation than the 5 μg group, and expressed stable levels of FVIII through Week 19 post FVIII plasmid injection. Mice injected with 1 μg IL2 plasmid expressed higher FVIII levels and are monitored for long term tolerance.

Conclusions: Combined gene transfer of FVIII and IL2 plasmids can produce therapeutic FVIII and simultaneously prevent inhibitory antibody formation, thus providing a potentially effective treatment of hemophilia A.

PB 1092 | Therapeutic Expression of Factor VIII Following Ultrasound-mediated Gene Delivery of High-expressing FVIII Variant Plasmids and Immunomodulation in Hemophilia A Mice

M.J. Lyle[1], J. Harrang[1], D. Tran[1], R.Y. Fu[1], C.H. Miao[1,2]

[1]Seattle Children's Research Institute, Center for Immunity and Immunotherapies, Seattle, United States, [2]University of Washington, Pediatrics, Seattle, United States

Background: Ultrasound (US)-mediated gene delivery (UMGD) of a liver-specific (LC)-FVIII plasmid produced averagely ~15% of FVIII expression on day 1 in hemophilia A mice. However, anti-FVIII immune responses ensued following gene transfer significantly decreased FVIII levels.

Aims: In order to achieve persistent FVIII gene expression for therapeutic treatment, several improvements are pursued:

(1) Construct a high-expressing FVIII variant cassette.

(2) Reduce UMGD pressure by increasing pulse durations.

(3) Employ immunomodulation to suppress anti-FVIII immune responses.

Methods: A novel FVIII variant with 10 aa substitutions in A1 domain (F8X10, from Weidong Xiao) is incorporated to generate LC-F8X10. UMGD is carried out using a semi-focused transducer (H158) at acoustic pressure 0.4-2.7 MPa and pulse duration 0.018-0.4 ms. Mice were treated with immunomodulation using either dexamethozone for 5 days to reduce innate and adaptive responses and IL2/IL2mAb complexes for 4 days to induce regulatory T cell expansion or dexamethasone for 10 days and IL2/IL2mAb complexes for 7 days.

Results: LC-F8X10 generates more than 10 fold higher FVIII expression than LC-F8/N6 plasmid. We observe less liver damage following UMGD of LC-F8X10 at 1.0Mpa and 0.4 ms pulse duration evaluated by transaminase levels and histological examination. All groups of mice yield 25- 100% of FVIII on day 1-7. In mice without immunomodulation, FVIII levels drop to undetectable at day 14 and afterwards with

the formation of high-titer antibodies (>50 BU). In mice with shorter immunomodulation, the formation of low titer antibodies (~1 BU) is delayed at day 21 and 28 however the titers increase later. In mice with longer immunomodulation, no inhibitory antibody is observed during experimental duration and the FVIII expression remains at therapeutic levels (10-50%).

Conclusions: UMGD of high-expressing FVIII variant plasmids together with immunomodulation can achieve long-term, safe and effective treatment of hemophilia A.

PB 1094 | Integration Site Analysis in Mice Demonstrates Excellent Biosafety Profile of a Recombinant (R) FVIII Adeno-associated Virus (AAV8) Gene Therapy Product

W. Hoellriegl[1], F.G. Falkner[1], M. Weiller[1], M. Schmidt[2], F. Scheiflinger[1], H. Rotteinsteiner[1]

[1]*Shire plc, Vienna, Austria,* [2]*Genewerk, Heidelberg, Germany*

Background: A safety concern in gene therapy using rAAV is residual integration of the viral genome into the host genome. While rAAV vectors are thought to integrate at non-homologous locations without creating hot spots, Nault et al. (2015) identified chromosomal insertions of wild-type AAV2 that may have activated proto-oncogenes in human hepatocellular carcinoma (HCC). Integration site (IS) analysis of newly developed rAAV vectors is thus warranted to assess AAV gene therapy product biosafety.

Aims: To analyze IS in mice to determine the integration profile, characteristics, and clonal dominance of Shire's rAAV8 investigational product to treat hemophilia A (SHP654).

Methods: FVIII ko mice were treated with SHP654 at doses of 4E+12 and 2E+13 vg/kg. Livers were harvested 1 and 4 months thereafter and processed for DNA isolation. Vector copy number (VCN) was determined by vector specific qPCR. Non-restrictive (nr) and standard linear amplification-mediated (LAM) PCR was used to identify genomic sequences flanking the integrated AAV vector DNA. (nr) LAM-PCR amplicons were sequenced after sample preparation on a MiSeq instrument. Data were processed by (semi-) automated bioinformatic data mining.

Results: Liver transduction levels were ~13.7 and 16.8 for lower vector doses at 1 and 4 months, and ~106.5 and 115.8 for higher doses. Frequency of rearranged fragments correlated with the vector dosage, and ITR breakage occurred homogenously between each vector group. Sequencing of (nr)LAM-PCR products revealed 227 and 187 unique exactly mappable IS in all mice at 1 and 4 months. The frequency of common IS was low at both time points and only few identical IS were detected in repetitive (nr)LAM-PCR amplicons after dosing of SHP654.

Conclusions: IS analysis of SHP654 showed measurable, yet minimal integration (< 0.01%) with no indication of side effects, as neither clonal outgrowth nor preferred integrations in or next to genes previously implicated in HCC formation was observed.

PB 1095 | A Novel Strategy for Liver Cell-based Therapy in a Hemophilia B Model

C.T. Yen[1,2], Y.C. Hsu[1,3], Y.J. Huang[4], I.S. Yu[5], Y.M. Wu[4], S.R. Lin[6,7], S.W. Lin[1,2]

[1]*National Taiwan University, Department of Clinical Laboratory Sciences and Medical Biotechnology, College of Medicine, Taipei, Taiwan, Republic of China,* [2]*National Taiwan University, Center of Genomic Medicine, Taipei, Taiwan, Republic of China,* [3]*Liver Disease Prevention and Treatment Research Foundation, Taipei, Taiwan, Republic of China,* [4]*National Taiwan University Hospital, Department of Surgery, Taipei, Taiwan, Republic of China,* [5]*National Taiwan University, Laboratory Animal Center, College of Medicine, Taipei, Taiwan, Republic of China,* [6]*Chung-Yuan Christian University, Department of Bioscience Technology, College of Science, Taoyuan, Taiwan, Republic of China,* [7]*Chung-Yuan Christian University, Center for Nanotechnology and Center for Biomedical Technology, Taoyuan, Taiwan, Republic of China*

Background: Although hepatocyte transplantation has been demonstrated to be a promising approach for hemophilia B, the poor engrafted efficiency of donor cells in the recipient liver limits its clinical applications. In our previous study, we can control the diameter of the hepatic sinusoids by regulating hepsin levels without adverse effects. We hypothesized that this phenomenon can be applied in hepatocyte transplantation.

Aims: We tested whether the combination of temporally narrowing hepatic sinusoid with a hyperfunctional coagulation factor IX (FIX), FIX-Triple, could enhance the therapeutic efficiency of hepatocyte transplantation in hemophilia B.

Methods: The pretreatment of the anti-hepsin antibody or control IgG was administrated once daily for four days right before transplantation. Hepatocyte transplantation was implemented by the intrasplenic injection of the primary hepatocytes from FIX-WT or FIX-Triple donor mice into the recipient mice.

Results: The anti-hepsin pretreatment increased the transplanted cells in the liver of hemophilia B mice by 2 fold. Due to the enhanced engraftment rate, FIX clotting activity in the hemophilia B mice with the anti-hepsin pretreatment could increase from 0.84 to 1.99% by transplanting FIX-WT donor cells. When replacing FIX-WT with FIX-Triple donor cells, FIX clotting activity could further increase respectively to 4.40% with the control IgG pretreatment and 7.72% with the anti-hepsin pretreatment. Remarkably, the anti-hepsin pretreatment strategy coupled with FIX-Triple donor cells maintained the FIX clotting activity more than 5% after one month of transplantation. This strategy also produced a significant improvement of the bleeding phenotype by tail clipping assay.

Conclusions: Our data suggest that the strategy of controlling the diameter of hepatic sinusoids by the anti-hepsin pretreatment would be useful for improving the cell-based cure in hemophilia B.

PB 1096 | Immunity to AAV8 and Other AAV Serotypes in Healthy Individuals

A. Kruzik, D. Fetahagic, B. Hartlieb, F.M. Horling, F. Scheiflinger, B.M. Reipert, M. de la Rosa

Shire plc, Vienna, Austria

Background: A major challenge for Adeno-associated virus serotype 8 (AAV8) gene therapy is pre-existing anti-AAV8 immunity. Up to 40% patients with pre-existing neutralizing antibodies (Nabs) against AAV8 are currently excluded from clinical trials. The prevalence of anti-AAV8 Nabs and Nabs to other serotypes is not known due to the use of different and not standardized assay protocols and reagents. Development of strategies to circumvent pre-existing anti-AAV8 immunity requires careful assessment of the prevalence of pre-existing immunity to AAV8 and other serotypes with validated assays.

Aims: To determine and characterize the prevalence of anti-AAV8 immunity and co-prevalence of immunity to AAV1, AAV2, and AAV5 in healthy individuals using validated assays.

Methods: Three cohorts of healthy individuals from the US and Europe were selected to assess potential regional differences in pre-existing AAV immunity. The prevalence of anti-AAV8 Nabs was determined using a validated assay. Binding antibodies (Babs) and AAV8 T cell responses were assessed by ELISA and IFNg-ELISPOT, respectively. To assess co-prevalences, Nabs and Babs against AAV1, AAV2, and AAV5 were analyzed.

Results: In contrast to Boutin et al, who report an AAV8 Nab prevalence of about 20%, the prevalence of anti-AAV8 Nabs in this study was 30 - 45%. A high degree of co-prevalence with Nabs against AAV1, AAV2, and AAV5 was detected, which may be due to natural infections or development of cross-reactive antibodies upon infection with one serotype. Anti-AAV8 T cell responses appear to correlate only to some extent with anti-AAV8 Nab prevalence.

Conclusions: The high prevalence of anti-AAV8 Nabs and high co-prevalence of other serotypes independent of geographic region suggest that e.g. patients with pre-existing AAV8 immunity cannot be easily included in gene therapy trials using other AAV serotypes. Thus, strategies to circumvent pre-existing AAV8 immunity are required.

PB 1097 | Development and Application of Methods for the Selective Measurement of the Human Single Amino Exchange Variant Factor IX Padua

A. Weber, A. Engelmaier, D. Voelkel, R. Pachlinger, F. Scheiflinger, H. Rottensteiner

Shire plc, Vienna, Austria

Background: The BAX 335 hemophilia B gene therapy trial relies on the expression of FIX Padua, a naturally occurring single amino acid exchange (R338L) variant with a 10-fold higher activity than that of FIX wild type. Assessment of the gene therapy's success would benefit from methods that enable specific detection of the transgene product.

Aims: To develop FIX Padua-specific methods using a Fab2 mini antibody selectively binding this FIX variant and their application for testing of patient plasma samples of the BAX 335 study.

Methods: A FIX Padua-specific ELISA was established by using the Fab2 mini antibody to capture FIX Padua and a polyclonal anti-FIX antibody to detect bound protein. The performance of this ELISA was checked in terms of accuracy, precision and parallelism. A chromogenic FIX activity assay specific for FIX Padua was developed by similarly capturing FIX Padua with the Fab2 mini antibody.

Results: The ELISA which was designed to selectively capture FIX Padua covered a FIX Padua protein concentration range of 0.9 to 27.1 ng/mL. Spike-recovery carried out with representative patients' samples showed acceptable recoveries and there was no influence of the citrated plasma matrix on the assay performance. There was also a clear correlation between FIX Padua protein concentration and FIX activity, while the presence of functionally inactive FIX had no impact on the assay. The calibration curve of the FIX Padua-specific chromogenic activity assay, carried out after selective capture of FIX Padua with the Fab2 mini antibody, ranged from 0.1 to 3.3 mU FIX Padua/mL, while a normal reference plasma pool introduced in the assay at a FIX concentration of 0.1 U/mL showed no response.

Conclusions: The FIX Padua ELISA can be used in clinical settings to selectively quantify FIX Padua antigen levels. The Fab2 mini antibody offers also the possibility to set up a clinical FIX Padua-specific chromogenic activity assay.

PB 1098 | Biological Significance of Neutralizing Antibodies to AAV8

A. Kruzik, D. Fetahagic, B. Hartlieb, H. Koppensteiner, S. Coulibaly, A. Weber, W. Hoellriegl, F.M. Horling, F. Scheiflinger, B.M. Reipert, M. de la Rosa

Shire plc, Vienna, Austria

Background: Pre-existing neutralizing antibodies (Nabs) against Adeno-associated virus 8 (AAV8) have been shown to efficiently inhibit AAV8 gene therapy, and thus to be a major hurdle in AAV8 gene therapy. Identifying a reliable and efficient anti-AAV8 Nab assay to screen patients who can be treated effectively is therefore crucial.

Aims: The present study was conducted to assess the biological relevance of *in vitro* anti-AAV8 Nab titers to determine those AAV8-Nab titers that can predict which patients are eligible for gene therapy.

Methods: Anti-AAV8 Nab titers in healthy donors were determined by a validated *in vitro* reporter assay using 2x serial dilutions starting at 1:5. Donors with a Nab titer < 1:5 were evaluated as negative. The biological relevance of *in vitro* Nab titers was assessed in comparative *in vivo* studies by injecting NOD/SCID mice with human plasma containing anti-AAV8 Nabs prior to administering AAV8 gene therapy.

Results: The *in vivo* mouse studies showed that an anti-AAV8 Nab titer of 1:5 in the circulation of mice almost completely blocked AAV8-mediated transgene expression in the liver, demonstrating that this titer is of high biological relevance. The 1:5 cut-off appears to be robust since the vast majority of Nab negative healthy donor samples were also negative at dilutions of 1:2.5 and 1:1.25.

Additionally, we could show that low antibody titers (1:5 to 1:40) can be overcome using significantly higher gene therapy doses.

Conclusions: An anti-AAV8 Nab titer of 1:5 is a valid exclusion criterion for clinical studies. Our data suggest that the *in vitro* assay is more

suitable for screening of patients, since the *in vivo* assay cannot detect lower Nab titers (< 1:160) due to dilution of human Nabs in the circulation of mice. Whether low titer anti-AAV8 Nabs can be overcome remains to be confirmed in an immune competent mouse strain.

PB 1099 | Nonclinical Safety Evaluation of a FVIII Gene Therapy Construct in Mice

W. Hoellriegl, M. Weiller, T. Ruthsatz, K. Benamara, H. Gritsch, A. Weber, B. Gangadharan, F.G. Falkner, P.E. Monahan, H. Rottensteiner, F. Scheiflinger, M. Turecek

Shire, Vienna, Austria

Background: Shire is developing a gene therapy to treat hemophilia A using an adeno-associated virus (AAV) vector and a codon optimized human BDD-FVIII transgene.

Aims: The present study was performed to determine the toxicity of our FVIII gene therapy candidate SHP654 (AAV8.BDD-FVIII) following a single intravenous administration at dose levels of $4x10^{12}$, $8x10^{12}$, or $2x10^{13}$ capsid particle/kg to C57BL/6J mice.

Methods: Acute and delayed onset of toxicity and/or reversibility of toxicity during an 18-week observation period, biodistribution to tissues, FVIII activity and development of binding and neutralizing antibodies were assessed. Animals were sacrificed on day 3, in week 3, or week 18 after injection of SHP654 to evaluate toxicity and biodistribution.

Results: Single intravenous administration of SHP654 to C57BL/6J mice was well-tolerated at all dose levels, with no clinical signs, toxicologically relevant effects, or changes in clinical or anatomical pathology observed. In all of the tissue samples harvested, the distribution of SHP654 DNA was dose-related and generally highest at the earliest time point, decreasing significantly by week 18. Consistent with the hepatic tropism of AAV8, SHP654 DNA was predominantly detected in the liver and higher levels were still maintained at this time. In contrast, SHP654 DNA levels in the brain and testes samples were evaluated as negative by week 18. Animals treated with SHP654 showed higher levels of FVIII activity and human FVIII antigen compared to baseline, thus confirming exposure to human FVIII.

Conclusions: On the basis of these toxicological results, the NOAEL in this study was considered to be $2x10^{13}$ cp/kg, which was the highest dose tested.

PB 1100 | Preliminary Results of SPK-9001 Gene Transfer Demonstrate Statistical Improvements on the Health-related Quality-of-Life in Adults with Haemophilia B

S. von Mackensen[1], L.A. George[2], M. Carr[3], A.M. Galvao[2], A.Y. Luk[3], K.A. High[3]

[1]*University Medical Centre hamburg-Eppendorf, Institute of Medical Psychology, Hamburg, Germany,* [2]*The Children's Hospital of Philadelphia, Philadelphia, United States,* [3]*Spark Therapeutics, Philadelphia, United States*

Background: Consistent and sustained FIX activity levels >12% after gene transfer may eliminate spontaneous joint bleeding, reduce factor injections and risks of non-adherence. However, the effectiveness of gene transfer on such patients' health-related quality-of-life (HRQoL) after gene transfer is unknown.

Aims: To determine the impact of gene transfer on HRQoL in haemophilia B adults with ≤2% of FIX activity levels.

Methods: Nine haemophilia B (endogenous FIX level of ≤2 IU/dL) adults (mean age 33.6±13.6 years) received a single $5x10^{11}$ vg/kg infusion of *SPK-9001*, an investigational gene transfer product. HRQoL was assessed pre-vector (baseline) and post-vector (weeks 4, 12, 26 and 52) infusions using the generic EQ-5D and the haemophilia-specific Haem-A-QoL questionnaires. Differences were calculated from baseline (B) to post-vector (PV: recent follow-up assessment). As minimal clinically important differences (MCID) for evaluating subject-level HRQoL improvements responder definitions (RDs) of the Haem-A-QoL domains and EQ-VAS were estimated, based on the one-half standard deviation criterion at baseline.

Results: As of 1/25/2017 data cut-off, nine participants have been followed-up for 12 - 52 weeks after gene transfer. All participants reported in general good HRQoL in the EQ-5D (B: M=80.56±8.8 vs. PV: M=88.22±10.3; no statistical significant improvement). By contrast, significant mean improvements from B to PV were found for the Haem-A-QoL domains ‚Work' ($p< .030$), ‚Treatment' ($p< 0.011$), ‚Future' ($p< 0.004$) and ‚Total Score' ($p< 0.003$). At baseline, 50% thought that ‚never/seldom' "things will be better in the future" compared to 0% at PV. All patients (100%) were defined as HRQoL responders according to the RDs of the Haem-A-QoL ‚Total Score' (3.6-point decrease) and 7 out of 9 patients according to EQ-VAS (4.4-point increase).

Conclusions: Improvements in Haem-A-QoL domains ‚Treatment' and ‚Future' and ‚Total Score' suggest a single infusion of SPK-9001 resulted in meaningful HRQoL improvements.

PB 1101 | Dose Response and Long-term Expression of a FVIII Gene Therapy Construct in Hemophilia A Mice

W. Hoellriegl, M. Weiller, A. Kopić, K. Benamara, H. Gritsch, B. Gangadharan, F.G. Falkner, P.E. Monahan, H. Rottensteiner, F. Scheiflinger, M. Turecek

Shire, Vienna, Austria

Background: Shire is developing a gene therapy to treat hemophilia A, using an adeno-associated virus (AAV) vector and a codon optimized B-domain deleted *F8* transgene.

Aims: The presented studies were performed to investigate the dose response in FVIII activity/efficacy and the long-term expression of FVIII gene therapy candidate AAV8.BDD-FVIII (SHP654) in hemophilic mice.

Methods: Twelve male FVIII knockout mice per group received a single intravenous dose of $1x10^{12}$, $4x10^{12}$, or $1x10^{13}$ vg/kg SHP654 or

10 mL/kg buffer. Human FVIII activity level was determined every 2 weeks for 8 weeks. At the end of the observation period, the animals' bleeding phenotype was assessed using a tail-tip bleeding assay. Long-term expression of SHP654 was assessed in human FVIII transgenic (huFVIIItg) mice. These mice carry a knockout of murine *F8* gene and transgenically express human FVIII mRNA transcripts in multiple tissues from human *F8* cDNA [van Helden et al., 2011], but lack detectable circulating FVIII protein. Thirty huFVIIItg mice received a single intravenous bolus injection of $4x10^{12}$ cp/kg SHP654, and blood samples, taken over 24 weeks, were analyzed for FVIII activity and anti-FVIII antibodies.

Results: Treatment of FVIII knockout mice with $4x10^{12}$ or $1x10^{13}$ vg/kg SHP654 yielded a mean FVIII activity of 0.6 and 2.1 IU/ml on day 56, and significantly reduced blood loss in the tail-tip bleeding assay. After treatment of huFVIIItg mice with $4x10^{12}$ cp/kg SHP654, a mean FVIII plasma activity of 2.9 - 3.8 IU/mL was determined, which persisted over 24 weeks.

Conclusions: SHP654 doses above $1x10^{12}$ vg/kg were shown to be efficacious in FVIII knockout mice, and resulted in persistent FVIII expression in huFVIIItg mice.

PB 1102 | Pre-existing Anti-AAV5 Neutralizing Antibodies Measured Using a Highly Sensitive Assay in Sera of Hemophilia B Patients in a Phase I/II Clinical Trial of AMT-060 Do Not Predict Efficacy of AAV5-mediated Liver-directed Gene Transfer

A. Majowicz, M. Lampen, H. Petry, C. Meyer, V. Ferreira, B. Nijmeijer, M. Tangelder

uniQure biopharma, B.V., Amsterdam, The Netherlands

Background: Gene transfer via adeno-associated viral (AAV) vectors is currently believed to be impaired by the presence of anti-AAV neutralizing antibodies (NAB). Patients (pts) are screened for NAB and excluded from treatment if determined as positive in the assay implemented; however, assays vary in sensitivity. We previously treated 10 pts with severe hemophilia B who tested negative for pre-existing anti-AAV5 NABs as measured by a green fluorescent protein-based assay with an AAV5-hFIX (AMT-060) in a Phase I/II study. Recently a novel, highly sensitive NAB assay based on a luciferase reporter vector became available.

Aims: To re-assess pre-existing anti-AAV5 NAB status in our Phase I/II pts using the luciferase-based assay and determine the relationship of any titers detected to therapeutic outcomes.

Methods: Pre-treatment screening samples from 10 pts with factor IX (FIX) activity < 2% of normal enrolled in a Phase I/II study of AMT-060 were analyzed for anti-AAV5 NAB with the luciferase-based NAB assay. Therapeutic outcomes included FIX activity, AAV5-specific T-cell mediated immunity assessed by human interferon gamma Elispot assay, and liver enzyme levels.

Results: By the luciferase NAB assay, 7/10 pts returned below the limit of detection and 3/10 had positive titers (all in low dose cohort $5x10^{12}$ gc/kg). The pt with the highest NAB titer (1:341) presented the highest FIX activity (6.8%) in the dose cohort. The other 2 pts presented titers of 1:211 and 1:22 and FIX activity of < 2% and 3.0%, respectively. FIX activity spanned the range seen in the entire cohort (< 2-6.8%; n=5). None of the 3 positive pts experienced elevations in liver enzymes post-treatment. No clinically relevant T-cell responses to the capsid were detected.

Conclusions: NAB titers detected by the higher-sensitivity luciferase-based assay in pts with hemophilia B previously screened with the GFP-based assay did not predict efficacy or safety outcomes of AAV5-based gene transfer.

PB 1103 | Manufacturing Scale AAV Vectors: Quantification Strategy for Clinical Trials

M. Bendik[1], R. Necina[1], M. Graninger[1], E. Böhm[1], C. Fiedler[1], B. Kraus[1], D. Mittergradnegger[1], J. Hernandez Bort[1], S. Reuberger[1], W. Herok[1], R. Raim[1], J. Lengler[1], J. Mayrhofer[1], F.G. Falkner[1], W. Hoellriegl[2], C. Konetschny[1], C. Tauer[1], M. Löflund[2]

[1]Shire plc, Orth/Donau, Austria, [2]Shire plc, Vienna, Austria

Background: Classical potency assignment for adeno-associated virus subtype 8 (AAV) clinical trial material aims to quantify the AAV vector by measuring the vector genome DNA. This approach often involves high assay variability, i.e. a coefficient of variability (CV) of ≥ 60%, and thus renders it difficult to control dosing in dose-escalation clinical trials.

Aims: To develop a strategy for potency assignment based on surrogate measurement (AAV8 ELISA) supported by a complementary assay portfolio and consistent large scale manufacturing process.

Methods: The production process for gene therapy vector (AAV8) in a HEK293 cell line was internally developed and scaled up to manufacturing scale for clinical trials. The AAV vector lots produced in pilot (200L) and manufacturing (500L) scale were fully characterized by qPCR, AAV8 ELISA, cryoEM, native agarose gel electrophoresis, and in vivo potency testing of the FVIII gene therapy vector in FVIII ko mice.

Results: Methods qualification and/or validation showed a CV of ≤10% for AAV8 ELISA, ≤43% for qPCR, and ≤1% for cryoEM. The lots produced in pilot and manufacturing scale achieved comparable and constant amounts of full AAV8 vector (73 ±3%) as measured by cryoEM. Since the AAV8 ELISA showed lower variability than qPCR, and the fact that production achieved a constant amount of full AAV8 in all preparations, this assay was used for potency assignment for these lots. The correctness of AAV8 ELISA potency assignment was confirmed in the biological activity assay by dosing AAV8 vector based on the AAV8 ELISA.

Conclusions: AAV8 ELISA appears suitable for potency assignment of clinical trial material to allow greater precision and consistency in dosing during trials, if manufacturing can demonstrate lot-to-lot consistency.

PB 1104 | Gold Nanoparticles: A New Approach for Non-viral Gene Therapy of Hemophilia

M.-K. Holz[1], L. Gamrad[2], K. Roellecke[3], K. Waack[1], A. Heinemann[2], C. Rehbock[2], S. Barcikowski[2], D. Reinhardt[1], H. Hanenberg[1,3]

[1]*University Hospital Essen, Pediatrics III, Essen, Germany,* [2]*University of Duisburg-Essen, Technical Chemistry I, Essen, Germany,* [3]*Heinrich Heine University Duesseldorf, ENT, Duesseldorf, Germany*

Background: Current genetic approaches for hemophilia focuses on viral vectors as transport system to the liver but might lead to malignant transformation. Gold nanoparticles (AuNP) as DNA transport system are completely inert and do not cause immune reactions. The pEPI vector for stable long-term expression contains a scaffold matrix attachment region (SMAR) that facilitates episomal replication without integration. The vector DNA is bound to gold using polyethylenimin (PEI) as linker. This ensures that after cellular uptake, the DNA escapes endosomal degradation.

Aims: To develop AuNPs as carrier system for a non-viral episomally replicating vector in liver cells.

Methods: AuNPs were complexed with PEI and DNA and incubated with different cell lines. Different PEI variants and different relative ratios of the three components were tested. pEPI contains a CMV promotor driving *GFP* as reporter and a G418 resistance gene. A shorter SMAR and the hEF1a promotor were also tested. The transfection efficiency and GFP expression were evaluated by FACS.

Results: 5nm AuNPs were superior to 50nm AuNPs to transport cargo into the cells. The optimal ratio of 5nm AuNP:PEI:DNA was 30µg:9µg:3µg. Coating 5nm AuNP with 25kD linear PEI achieved superior expression compared to branched PEI or JetPEI®. For long-term expression studies using pEPI with short, long and without SMAR, cultures were split 3d after transfection and cells continuously grown for 10 weeks without or with short- or long-term G418 selection. Expression analysis revealed that the short SMAR was always superior to the plasmid with long SMAR. Comparing the CMV with the EF1a promoter in pEPI revealed that EF1a was less subject to silencing. Finally, using AuNP to stably introduce pEPI with a human FVIII cDNA with the short SMAR showed FVIII activity of up to 8% in the cell culture supernatant.

Conclusions: These results show that gold nanoparticles as carriers for DNA are a promising approach for non-viral genetic therapy for hemophilia and other liver disorders.

PB 1105 | Health-related Quality of Life in Pediatric Hemophilia B Patients Treated with rIX-FP

S. von Mackensen[1], W. Seifert[2]

[1]*University Medical Centre Hamburg-Eppendorf, Institute of Medical Psychology, Hamburg, Germany,* [2]*CSL Behring GmbH, Marburg, Germany*

Background: Bleeds, frequent infusions and pain can impact the health-related quality of life (HRQoL) in children with hemophilia, limiting their ability to lead a normal life. In a multi-centre Phase III study (NCT01662531) pediatric patients received weekly prophylaxis with rIX-FP (IDELVION).

Aims: To determine the impact of rIX-FP prophylaxis on HRQoL in pediatric patients.

Methods: 27 children (mean age 5.9±2.93 years) were enrolled. HRQoL was assessed at baseline and at the end of study (EOS) (≥12 months later). Children completed the hemophilia-specific HRQoL questionnaire (HAEMO-QOL) and their caregivers the hemophilia-specific treatment satisfaction (TS) questionnaire (HEMO-SAT$_P$). Scores range from 0-100; decreasing scores indicate improvements in HRQoL and TS. Minimal important difference (MID) between baseline and EOS were calculated based on the Cohen's *d* effect size (ES). ES of *d=0.2* indicate small effects, *d=0.5* medium, and *d=0.8* large effect size.

Results: At baseline 19 children (age group I: 4-7 years (n=12), age group II: 8-12 years (n=7)) completed the respective age group version of the Haemo-QoL, 23 parents filled in the Hemo-Sat$_P$. Children reported good HRQoL (I: M=19.07±16.9; II: M=26.09±6.3); parents showed a high TS in the Hemo-Sat$_P$ (M=14.45±11.2). HRQoL differences between baseline and EOS were not statistically significant in age group I, but a medium ES was found for ‚physical health' (*d*=.601) and ‚treatment' (*d*=.491). Age group II showed a statistically significant improvement from baseline to EOS in the Haemo-QoL total score (p< .037), medium to big ES were found for most of the domains. Parents reported a statistically significant TS improvement in the dimension ‚burden' of the Hemo-Sat$_P$ (p< .034), small ES were found for most of the domains.

Conclusions: Children showed HRQoL improvement between baseline and EOS, this difference reached statistical significance in age group II. Parents reported a significant improvement in TS.

PB 1106 | Hyperfibrinolysis in Children. Prevalence of Hyperfibrinolysis in Mucocutaneous Bleeders of Unknown Cause in a Pediatric Cohort

P. Zuñiga[1], N. Orellana[1], O. Panes[2], D. Mezzano[3]

[1]*Pontificia Universidad Catolica de Chile, Pediatria, Santiago, Chile,* [2]*Pontificia Universidad Catolica de Chile, Laboratorio Hemostasia y Trombosis, Santiago, Chile,* [3]*Pontificia Universidad Catolica de Chile, Hematologia, Santiago, Chile*

Background: The fibrinolytic system includes a broad spectrum of proteolytic enzymes with a critical role in hemostatic-thrombotic balance. It is also involved in pathophysiological conditions associated with acute bleeding. Mucocutaneous bleeding is a major cause of consultation for bleeding at the outpatient clinic. Von Willebrand (vW) disease and platelet function defects are the most frequent congenital coagulation disorders found in this setting. However, a definitive

cause is not found in 60% of bleeders patients, who therefore are categorized as bleeders of unknown cause (BUC).

Aims: Considering the clinical improvement of bleeding in BUC in response to tranexamic acid, an antifibrinolytic agent, and that standard diagnostic procedures do not routinely include evaluation of fibrinolysis, it appears relevant to determine the potential occurrence of hyperfibrinolysis in BUC.

Methods: Methods. Ninety-three BUC patients aged 2-18 years were recruited from January 2011 to December 2013 in an outpatient clinic. A bleeding assessment tool (ISTH-BAT) score and a second hemostatic workup were performed, including platelet count, platelet aggregation and secretion, PT and aPTT, vW disease diagnostic tests and clot lysis time in plasma rich in platelets activated with ristocetin (CLT-PRP-Ris).

Results: Hyperfibrinolysis was found in 36 patients (38%) and of these patients, 23 exhibited an isolated defect (24%). Forty patients were diagnosed as BUC (40%).

Conclusions: There is a high prevalence of hyperfibrinolysis in pediatric BUC patients after secondary hemostasis assessment including CLT-PRP-Ris. However, a cause of bleeding was not found in 40%. Further studies are warranted to confirm our findings.

PB 1107 | Pregnancy in Factor XI-deficient women

R. Santoro, P. Iannaccaro, S. Morgione, M.T. Paparo

Haemostasis and Thrombosis Center, Dpt Haematology, AO Pugliese-Ciaccio, Catanzaro, Italy

Background: Factor XI (FXI) deficiency is a rare bleeding disorder, probably underdiagnosed because patients with severe or partial FXI deficiency do not suffer from spontaneous bleeding but may do so only after hemostatic challenge. In particular, women are exposed to a hemostatic challenge during their menstrual period. The other common challenge for women is childbirth.

Aims: The aims of our study was to evaluate retrospectively the presence of postpartum hemorrhage and possible treatment, in pregnant women with FXI deficiency, of varying severity.

Methods: 22 female patients were available for study. Between these, 12 patients had one or more pregnancies (on the whole 26 pregnancies).The average values were of FXI was 0.30 IU/ml (0.002-0.40 IU/ml). Three patients were homozygous resulting in a severe deficiency of FXI (0.002; 0.002; 0.005; respectively), 19 patients were heterozygous resulting in a mild deficiency of FXI (0.25-0.40 IU/ml).

Results: In our center, just three patients received replacement therapy with fresh-frozen plasma (FFP) at delivery time in six pregnancies (three pregnancies in a bleeder patient with FXI :C 0.005 IU/ml, two pregnancies in another bleeder patient with FXI :C 0.002 IU/ml, and just one pregnancy in another patient with FXI:C 0.002IU/ml) without bleeding symptoms at the delivery. Further pregnancies (20 in nine patients) were carried out without replacement therapy because the patients were no bleeders and with FXI :C levels between 0.25 and 0.40 IU/ml. None of the patients have had bleeding manifestations.

Conclusions: In our patients, no postpartum hemorrhages were depicted, but the three patients with severe deficiency were previously treated with FFP. We believe that pregnancy and labor should be managed in close collaboration with the local hemostasis center. Severely deficient individuals and heterozygotes with a clear history of abnormal bleeding and low FXI level usually require blood product support (FFP or FXI concentrate)for labor, especially if delivery is operative.

PB 1108 | Factor XIII Deficiency and Noonan Syndrome: A Tricky Association

M. Albisetti[1], T. Boesten[1], K. Steindl[2], V. Schröder[3], S. Kroiss Benninger[1]

[1]*University Children's Hospital Zurich, Paediatric Haematology, Zurich, Switzerland,* [2]*Institute of Medical Genetic, University of Zurich, Schlieren, Switzerland,* [3]*University of Bern, Department of Clinical Research, Bern, Switzerland*

Background: Noonan syndrome (NS) is an autosomal dominant disorder associated with different coagulopathies including thrombocytopenia, platelet function disorders and coagulation factor (F) deficiencies. Haemostatic investigations are recommended in all patients newly diagnosed with NS. Only one case of mild FXIII deficiency in a girl with NS was reported so far.

Aims: -

Methods: -

Results: A 6-year-old girl presented with fever and acute abdominal pain. On admission, she underwent diagnostic laparoscopy with resection of a normal appendix and Meckel's diverticulum. Short after surgery, bleeding from the trocar wounds occurred. Her medical history so far was uneventful. There was no personal or family history of bleeding disorders. Laboratory tests revealed a FXIII of 4% with no other haemostatic abnormalities. Daily FXIII replacement of 30 IU/kg during 5 days was required to overcome rapid FXIII consumption with trough levels below 5%, and to resolve bleeding. Further investigations showed normalization of FXIII activity by mixed plasma test, no mutations on FXIII gene and normal FXIII activity in both parents. These results ruled out the presence of an inhibitor and congenital FXIII deficiency, respectively. A more accurate clinical examination of the girl revealed facial features suggestive for NS, which was confirmed by genetic testing. On follow-up, FXIII activity normalized within 2 months and no further bleeding occurred.

Conclusions: We report the first case of a severe FXIII deficiency in a patient with NS. In this patient, NS was diagnosed only after a first bleeding complication occurred. In addition, FXIII deficiency was transient and recovered spontaneously 2 months after the bleeding episode. Our case suggests that a negative bleeding history or normal haemostatic results do not exclude the occurrence of bleeding complications in risk situations in patients with NS. Thus, timely postoperative monitoring of haemostasis is required to prevent bleeding complications in these patients.

PB 1109 | Dysprothrombinemia Caused by the Homozygote Mutation Ala563Val in the *F2* Gene Was Associated with Reduced Thrombin Generation in a Patient with Bleeding Disorder

H. Glosli[1,2], N. Iversen[3], M.S. Le[4], M. Sletten[3], G.K. Halvorsen[2], P.A. Holme[5,6], C.E. Henriksson[4,6]

[1]Oslo University Hospital, Centre for Rare Disorders, Oslo, Norway, [2]Oslo University Hospital, Division of Paediatric and Adolescent Medicine, Oslo, Norway, [3]Oslo University Hospital, Department of Medical Genetics, Oslo, Norway, [4]Oslo University Hospital, Department of Medical Biochemistry, Oslo, Norway, [5]Oslo University Hospital, Department of Haematology, Oslo, Norway, [6]University of Oslo, Institute of Clinical Medicine, Oslo, Norway

Background: Prothrombin (FII) deficiency is a very rare bleeding disorder (1:2 mill), which may be inherited or acquired. Inherited dysprothrombinemia is an autosomal recessive disorder associated with a moderate to severe bleeding tendency.

Aims: We have characterized a patient with frequent bleeding and low FII activity levels, and his close family, for mutations in the *F2* gene and the effect on FII antigen level and thrombin generation (TG).

Methods: Coagulation assays, prothrombin antigen/activity and TG were performed to characterize the mutation. Mutation analysis of the *F2* gene was performed by Sanger sequencing of all the 14 exons and the exon/intron boundaries.

Results: The index patient was a three year old boy suffering from frequent nose bleeds. The boy had an evident prolongation of the prothrombin time and APTT, a strongly reduced FII activity of ~1%, but the FII antigen was normal, thus he had a Type II prothrombin deficiency (dysprothrombinemia). The patient was homozygous for a missense mutation in exon 13 at position c.1688 C>T (Ala563Val), a mutation only previously described in a compound heterozygous patient. The parents and one of the two sisters turned out to be carriers. The parents were first cousins. In the TG assay, lag time and peak were not detected during the first 90 min, suggesting that homozygosity of the mutation leads to an evidently reduced ability to generate thrombin compared to the heterozygous family members. The heterozygous family members had a FII activity of ~50% and the peaks were reduced by 50% in the TG assay. All heterozygotes were asymptomatic and the last sister was unaffected.

Conclusions: Treatment with Octaplex® was started every fortnight, and TG was monitored at through concentration (14 days), at peak concentration and after 1, 2, and 7 days. The TG was markedly reduced already after 7 days and treatment with Octaplex® was changed to once a week. No bleeds have been observed after initiation of prophylactic treatment with Octaplex®.

PB 1110 | Severe Acquired Hemophilia A, B and C Associated with Lupus Anticoagulant in a Child. A Case Report

S. Arghirescu[1], E. Ursu[2], D. Savescu[2], L. Cernat[2], C. Jinca[1], J. Patrascu[3], M. Serban[2]

[1]University of Medicine and Pharmacy ‚Victor Babes', Hemato-Oncology, Timisoara, Romania, [2]Clinical Emergency Children's Hospital ‚Louis Turcanu', Hemato-Oncology, Timisoara, Romania, [3]University of Medicine and Pharmacy "Victor Babes", Timisoara, Romania

Background: Acquired haemophilia (AH) is a very rare disease in childhood, with an incidence of about 0.045/million/year. It is mainly caused by autoantibodies acting as neutralizing inhibitors anti-factor FVIII, very few cases being reported with inhibitors, concomitently targeting multiple other coagulation factors. The association of lupus anticoagulant is exceptional.

Aims: Our *objective* is to present an extremely rare case.

Methods: We performed coagulation tests associated with immunoserological tests for infections and autoimmunity.

Results: We report a 4 years old girl, without past hystory of bleeding disorder, autoimmunity, infection, malignancy or use of medications. She was admitted with a suggestive purpura for Schoenlein Henoch vasculitis, without clinical or exploratory findings for other diseases. The symptoms were mild (only cutaneous manifestations) and the evolution to resolution took about 7 days. But in contrast with the benign clinical expression, the biological exploration revealed major hemostatic alterations, registered in Table 1.

TABLE 1 Hemostatic alterations

	APTT(s)	PT(s)	TT(s)	FVIII(%)	FIX(%)	FXI(%)	FXII(%)
Day 1	113.2	15.9	18.1	0.1	0	0	70
Day 14	97	12.3	16.1	13.5	8.5	7.3	65

The test for inhibitors assessed the results mentioned in Table 2.

TABLE 2 Plasmatic level of inhibitor titre (Bethesda Units - BU)

	Inhibitors anti-FVIII (BU/ml)	Inhibitors anti-FIX (BU/ml)	Inhibitors anti-FXI (BU/ml)
Day 1	3	3.2	-
Day 14	28.85	36.90	5

The child was negative for antinuclear antibody, but she was positive for lupus anticoagulant: anti-cardiolipin and anti-beta 2 glicoprotein remained negative. The child remained clinically asymptomatic, justifying our „ watch and wait" attitude.

Conclusions: In *conclusion*, an AH with multiple coagulation factors inhibitors and biological image of associated hemophilia A, B and C, hypotheticaly connected to a vasculitis and lupus anticoagulant had a spontanous clinical recovery with maintance of low levels of factor VIII, IX and XI. Such favourable asymptomatic evolution could lead to the hypothesis that in children the prevalence of that potentially life-threatening disease could be subject of underdiagnosis.

PB 1111 | A Novel Thrombin-activable Factor X Corrects Acquired Hemophilia A in Rabbit

T. Abache[1], A. Fontayne[1], C. Bourdon[1], A.-S. Dezetter[1], D. Grenier[1], E. Jacque[2], A. Longue[1], V. Pochet-Beghin[1], B. Souilliart[3], G. Chevreux[3], D. Bataille[3], S. Chtourou[2], J.-L. Plantier[1]

[1]LFB Biotechnologies, DITH, Loos, France, [2]LFB Biotechnologies, DIAS, Les Ulis, France, [3]LFB Biotechnologies, DGD, Les Ulis, France

Background: Rendering the factor X sensitive to thrombin was demonstrated *in vitro* to correct FVIII deficient plasma *(Louvain-Quintard et al. J Biol Chem, 2005)*. The advantages of this product are to be a zymogen molecule, possessing a longer half-life than factor VIII and factor IX.

Aims: To generate a novel factor X, more efficiently activated by thrombin and demonstrates its potential *in vivo*.

Methods: A modified factor X was generated by inserting a thrombin cleavage site between the activation peptide and the heavy chain. The molecule was expressed in HEK293-FS cells and purified using an anti-gamma carboxyglutamic domain aptamer.

Results: The molecule was analyzed in mass spectrometry and showed the expected post-translational modifications (11 gla domains, a beta hydroxylation and the activation peptide glycosylations). The presence of the peptide rendered the molecule sensitive to thrombin and allows to maintain the FVIIIa/FIXa complex and the fraction-X of the venom of the Russell's viper activations. In contrast, the activation by the FVIIa/tissue factor complex was diminished. The molecule (15 µg/ml) corrects *in vitro* factor VIII-, factor IX- and factor XI-deficient plasmas with Endogenous Thrombin Potential similar to that when plasmas were spiked with 1U/ml of missing factors. The lag times was increased, however. The pharmacokinetic of the molecule was evaluated in wild-type mice. The half-life was similar than for plasmatic factor X. It was assayed in hemophilia A mice providing a minor correction due to the poor potency of human FXa in mice plasma. A rabbit model of hemophilia A was set up by inhibiting factor VIII with a cocktail of two monoclonal antibodies. The presence of the modified FX *ex vivo* in plasma samples (20 µg/ml) or *in vivo* in treated rabbits (1.7 mg/kg) normalized the blood defect.

Conclusions: A factor X rendered susceptible to thrombin cleavage can correct *in vivo* hemophilia A and can be a novel hemophilia treatment alternative.

PB 1112 | Recombinant Factor VIIa-Albumin Fusion Protein Undergoes Endothelial Cell Protein C Receptor Mediated Internalization and Recycling

I. Glauser[1], J. Chia[1], S. Cattepoel[2], S. Dower[1], A. Verhagen[1]

[1]CSL Limited, Research, Bio21 Institute, Melbourne, Australia, [2]CSL Behring AG, Research, Bern, Switzerland

Background: Recombinant activated coagulation factor VII (rFVIIa) is used to treat bleeding episodes in Hemophilia patients with inhibitory antibodies to FVIII or FIX. Multiple injections are normally required due to the short in vivo half-life of rFVIIa (2-3 hrs). A recombinant FVIIa-albumin fusion protein (rVIIa-FP) has been developed that is well tolerated in healthy volunteers and has a 3- to 4-fold half-life extension relative to rFVIIa. Recycling of rVIIa-FP via interaction of the albumin moiety with the neonatal Fc Receptor, FcRn, has been demonstrated [1] and is a likely mechanism for half-life extension in vivo. Interestingly, FVIIa interacts with endothelial cell protein C receptor (EPCR) and internalised EPCR/FVIIa complex is recycled via the recycling endosome [2]. EPCR is important for the protein C (PC)/activated protein C (APC) mediated anticoagulation pathway and it has been proposed that therapeutic concentrations of FVIIa may augment the coagulation cascade by competitively reducing EPCR binding sites for PC/APC.

Aims: To investigate the impact of albumin fusion on EPCR-mediated internalization and recycling of FVIIa.

Methods: Internalization, intracellular trafficking and recycling of rVIIa-FP was examined by confocal microscopy in 293 cells stably expressing human EPCR.

Results: We demonstrate that rVIIa-FP binds to EPCR in a calcium-dependent manner, is internalized into early endosomes and quickly moves into Rab11a^{+} recycling endosomes. With constant extracellular Calcium, rVIIa-FP remains bound to EPCR and undergoes continuous cycles of internalization and recycling, whereas removal of extracellular Calcium results in the dissociation and release of recycled rVIIa-FP from the cells.

Conclusions: The half-life extended protein rVIIa-FP interacts with EPCR and is recycled in complex with EPCR via the Rab11+ endosome.

PB 1113 | Treatment of Hemophilia A by Injection of FVIII-encoding mRNA

J. Russick[1], S. Delignat[1], K. Kariko[2], S. Lacroix-Desmazes[1]

[1]UMR S 1138 - Centre de Recherche des Cordeliers, Paris, France, [2]VP, BioNTech RNA Pharmaceuticals, Mainz, Germany

Background: Treatment of patients with hemophilia A with exogenous therapeutic FVIII is complicated by important cost, the low half-life of FVIII (10 to 15 hours) and the need for life-long treatment. Injection of erythropoietin-encoding in vitro transcribed mRNA (IVT mRNA) (1) allows the endogenous production of transgenic erythropoietin for few days without innate immune activation.

(1) Kariko, Molecular Therapy, 2012

Aims: Investigate whether the injection of FVIII-encoding IVT mRNA allows the endogenous production of FVIII.

Methods: HEK293 cells were transfected with IVT mRNA encoding B-domain deleted FVIII (FVIII-HSQ), codon optimized FVIII (CoOpSQ) and CoOp FVIII-226/N6 (CoOpN6) formulated in TransIT. TransIT-formulated IVT mRNA was also injected intravenously to

FVIII-deficient mice. FVIII in cell culture supernatant or plasma was detected by ELISA (FVIII:Ag) and chromogenic assay (FVIII:C) over 72 hours.

Results: Cells transfected with CoOpSQ-encoding mRNA produced more FVIII than cells transfected with HSQ or CoOpN6 (0.30±0.02, 0.22±0.01 and 0.16±0.01 nM, respectively) after 48 hours. However, FVIII:C in supernatant was equivalent for the three constructs (0.07±0.01, 0.05±0.01 and 0.07±0.01 nM, respectively). Levels of circulating CoOp SQ in FVIII-deficient mice were 0.71±0.40 nM FVIII:Ag and 0.18±0.15 UI/ml FVIII:C, 48 hours after *in vivo* transfection.

Conclusions: Intravenous injection of FVIII-encoding mRNA permits an endogenous production of transgenic FVIII ≥10% of normal values for up to 72 hours. We will now confirm whether such FVIII levels protect mice in tail clipping assays, and whether the endogenous FVIII production induces a neutralizing immune response upon repeated treatments. At term, our works will allow to compare the efficiency and safety of IVT mRNA with that of alternative therapeutic approaches that are currently under development: gene therapy, bi-specific antibodies and long-lasting FVIII products.

PB 1114 | Clinically-relevant Bioavailability of rIX-FP after Subcutaneous Administration to Rodent and Non-rodent Species

M.W. Nolte[1], S. Herrmann[1], E. Raquet[1], F. Kaspereit[1], W. Krege[1], B. Doerr[1], S. Zollner[2], E. Herzog[1]

[1]*CSL Behring GmbH, Pharmacology/Toxicology, Marburg, Germany,* [2]*CSL Behring AG, CMO Management & Technology, Bern, Switzerland*

Background: rIX-FP, a recombinant fusion protein linking coagulation factor IX with albumin, has recently been approved for intravenous (i.v.) prophylaxis and on-demand treatment of hemophilia B patients. A subcutaneous (s.c.) administration of a factor IX (FIX) product that has a prolonged half-life may allow patients to maintain adequate trough levels without the need for frequent i.v. injections.

Aims: Aim of these studies was to investigate the bioavailability of rIX-FP following s.c. administration to hemophilia B mice, rabbits and pigs.

Methods: Hemophilia B mice received either a single rIX-FP dose of 125IU/kg (i.v. or s.c.) or 250IU/kg s.c. (rIX-FP and rFIX, a marketed recombinant FIX product as study comparator). Thereafter, blood samples were drawn up to four days. In the next study, rabbits obtained a single i.v. dose of 150IU/kg rIX-FP or a s.c. dose of 150 and 500IU/kg rIX-FP, respectively, followed by a 10 day follow up. In the third study, pigs received a single i.v. dose of 250IU/kg or a single s.c. dose of 50, 100 or 241.5IU/kg rIX-FP. Blood samples were drawn up to 17 days. For all studies, determination of human FIX antigen and activity (mice only) plasma concentrations was performed using an ELISA technique and an aPTT-based clotting assay, respectively.

Results: In all species, a dose-dependent increase of rIX-FP plasma levels was observed following s.c. dosing reaching peak plasma levels between 16 and 32 hours post dosing. The respective s.c. bioavailability of rIX-FP was in the range of 22% to 55%. Furthermore, maximum plasma levels reached following rIX-FP dosing were up to seven times higher and AUC (area under the curve) values up to 15 times higher in mice in comparison to rFIX treatment.

Conclusions: Taken together, s.c. administration of rIX-FP to hemophilia B mice, rabbits and pigs was well tolerated and resulted in a clinically-relevant s.c. bioavailability, whilst s.c. pharmacokinetics of rIX-FP were superior to a marketed rFIX.

PB 1115 | Rescue of Multiple Hemophilia B-causing Mutations in F9 Exon 3 by a Unique ExSpeU1

D. Balestra, D. Scalet, F. Bernardi, M. Pinotti

University of Ferrara, Ferrara, Italy

Background: RNA splicing modulation is a promising approach to develop therapies for genetic diseases, with advantages (i.e maintenance of physiological gene regulation; small therapeutic transgene) over gene replacement therapy. Splicing mutations in severe coagulation factor disorders are relatively frequent and we have shown that can be rescued by exon-specific variants of the spliceosomal U1snRNA (ExSpeU1).

Aims: To select a unique ExSpeU1 able to rescue multiple mutations at the 5' splice site (5'ss) of *F9* exon 3, which cause hemophilia B (HB).

Methods: Expression of ExSpeU1s and *F9* minigenes, harboring the c.277G>A, c.277+1G>A/T, c.277+2T>C/G, c.277+4A>G and c.277+5G>A/C mutations, in HEK293 cells and evaluation of *F9* mRNA splicing (RT-PCR).

Results: Minigene expression studies demonstrated that all mutations induce exon 3 skipping, with the +4 and +5 variants also associated to trace level of correct transcripts (~10%). In co-transfection experiments, we screened the rescue activity of a panel of ExSpeU1s, targeting the poorly conserved IVS3 sequences downstream of the 5'ss, to minimize potential off-target effects. We identified an ExSpeU1 targeting the region at +6 intronic position (ExSpeU1sh6) able to remarkably recover correct splicing for the +4 (from ~10% to 19% of transcripts) and particularly the +5 variants (from ~8% to 90%). Intriguingly, this ExSpeU1sh6 appears to be active, albeit in preliminary experiments, also on the +1 and +2 variants (from 0% to ~10%), commonly considered not rescuable.

Conclusions: These data further expand the potential of RNA therapeutics based on ExSpeU1, particularly for disease such as coagulation factor disorders in which even a modest of protein levels can be beneficial to patients. If confirmed, they also provide the first insight into the ability of targeting and rescue the severest as well as most common splicing mutations occurring at the conserved +1 +2 GT dinucleotide.

PB 1116 | Dose-response and Duration of Effect of a Half-life Extended Recombinant Factor VIIa in the Tail Vein Transection Bleeding Model in Haemophilia A Rats

T. Elm, C. Behrens, M. Dainiak, M. Åkesson, J.J. Hansen, M.S. Jensen, I. Hilden, H. Østergaard, M.B. Hermit

Novo Nordisk A/S, Global Research, Måløv, Denmark

Background: Recombinant factor VIIa (rFVIIa) is a safe and reliable option for treatment in haemophilia patients with inhibitors. A rFVIIa variant (NNC947) carrying two mutations (L288Y T239) and a 40-kDa heparosan polymer (HEPtune®, Caisson Biotech) has been shown to be resistant to inhibition by antithrombin, has a 15 fold prolonged half-life in rats and has an *in vitro* activity on par with wild-type rFVIIa.
Aims: Here we test the *in vivo* effect of a rFVIIa variant (NNC947) in a Tail Vein Transection model in haemophilia a (HA) rats.
Methods: Acute effect and dose-response relationship were determined in HA rats by administration of rFVIIa and NNC947 in a blinded fashion 5-min after transection of the left lateral tail vein. Haemostatic effect was assessed from the accumulated blood loss measured in 40 min with vehicle treated wild-type and HA rats as controls. The duration of effect of NNC947 was compared to rFVIIa by administration of 2.7 mg/kg at time points up to 96 hrs before injury.
Results: For both compounds clear dose-response relationships were observed with normalization of blood loss at 2.7 mg/kg. The estimated ED50-values (mean and 95%CI) for NNC947 and rFVIIa were 0.31 [0.11-0.80] and 0.47 [0.20-1.09] mg/kg, respectively, and found not to be significantly different. For both compounds, a time dependent effect on blood loss was observed. In the case of NNC947, normalization of the blood loss was maintained at 6 and 24-hrs time points, whereas animals receiving rFVIIa had already returned to the haemophilic baseline at 6 hrs.
Conclusions: NNC947 is efficacious in stopping an ongoing bleed in HA rats and exhibits a dose-response relationship not significantly different from rFVIIa using the Tail Vein Transection model. A significantly prolonged duration is observed compared to rFVIIa reflecting the prolonged half-life.

PB 1117 | Defining Extended Half-life rFVIII: A Critical Review of the Evidence

J. Mahlangu[1], E. Santagostino[2,3,4], G. Young[5,6], C. Hermans[7], V. Blanchette[8], E. Berntorp[9]

[1]*University of the Witwatersrand, Johannesburg, South Africa,* [2]*A. Bianchi Bonomi Hemophilia and Thrombosis Center, Fondazione IRCCS Ca' Granda - Ospedale Maggiore Policlinico, Milan, Italy,* [3]*IRCCS Ca' Granda Foundation, Milan, Italy,* [4]*Maggiore Hospital Policlinico and University of Milano, Milan, Italy,* [5]*Children's Hospital Los Angeles, Los Angeles, United States,* [6]*University of Southern California Keck School of Medicine, Los Angeles, United States,* [7]*Cliniques Universitaires Saint-Luc, Haemostasis and Thrombosis Unit - Division of Haematology, Brussels, Belgium,* [8]*Hospital for Sick Children, Pediatric Thrombosis and Hemostasis Program, Division of Hematology/Oncology, Toronto, Canada,* [9]*Lund University, Centre for Thrombosis and Haemostasis, Malmö, Sweden*

Background: Key therapeutic advances in hemophilia include new modified recombinant FVIII products designed to extend half-lives (EHL). There is no uniform definition of what constitutes an EHL rFVIII. Such a definition would be useful to understand the properties of standard and EHL rFVIIIs and help enable physicians and payers make informed choices when selecting rFVIIIs.
Aims: To critically assess the published evidence on new and emerging rFVIII products in order to propose a definition to classify EHLs
Methods: We systematically searched PUBMED, EMBASE, and FDA/EMA/Health Canada clinical pharmacology reports for publications, conference presentations, and regulatory submissions on rFVIII products. We included all publications on prospective crossover pharmacokinetic (PK) studies evaluating rFVIIIs with modifications to increase half-lives in adults and adolescents with severe hemophilia A.
Results: Different criteria have been used to define EHL rFVIIIs, including absolute half-life and dosing regimen. In our critical analysis of the published data, a more holistic approach to classify rFVIIIs has evolved to a definition that requires the following:
1. EHL ratio close to the biological limit imposed by von Willebrand factor (1.4) and reduced clearance ratio measured in a PK comparator crossover study
2. Use of technology designed to extend circulating half-life
With additional evidence:
3. Lack of bioequivalence with a standard rFVIII comparator—above the FDA/EMA cutoff of 125% for the 90% confidence intervals for area under the curve ratio
4. Reduced dosing frequency with retention of hemostatic efficacy compared to standard rFVIII for the majority of patients
Conclusions: In this systematic review, a pragmatic definition of EHL rFVIII has emerged. This EHL definition should provide better clarity in clinical discussions surrounding the appropriate use of rFVIII products. At present, only products with fusion molecules or pegylation fulfill the proposed criteria for EHL.

PB 1118 | Nonclinical Immunogenicity and Safety of SHP656 (BAX826), a Next Generation Extended Half-life Recombinant Factor VIII Product

V. Ehrlich, M. Malisauskas, B. Hartlieb, P. Leidenmuehler, F. Horling, B. Dietrich, G. Hoebarth, T. Ruthsatz, S. Dorn, K. Benamara, M. Wolfsegger, A. Weber, H. Gritsch, W. Hoellriegl, M. Turecek

Shire, Vienna, Austria

Background: Hemophilia A is a genetic bleeding disorder caused by missing or defective factor VIII (FVIII). Shire is developing SHP656 (BAX826) as the first EHL rFVIII in which polysialic acid (PSA) is conjugated to Baxalta´s licensed rFVIII product (ADVATE) to extend the circulation FVIII half-life.

Aims: To assess the safety and immunogenicity of SHP656 in different animal species.

Methods: The toxicity and immunogenicity of SHP656 were evaluated in mice, rats, and cynomolgus monkeys. Acute toxicity was assessed in a dose-escalation study in monkeys IV administered 350 and 1800 IU SHP656/kg; repeat-dose toxicity in rats at 80-800 IU/kg, in monkeys at 800 IU/kg for 4 weeks, and in monkeys at 80-600 IU/kg for 31 days (incl. cardiovascular and respiratory safety). Thrombogenicity was evaluated after a single IV administration (900 IU/kg BW) to rabbits (Wessler test). The licensed rFVIII was used as comparator in most of these studies. Comparative immunogenicity was assessed in three mouse models and in two in vitro studies using human primary cells and plasma.

Results: SHP656 was well-tolerated in all species, with no clinical signs directly caused by the test item observed *in vivo* or histopathologically. The NOAEL in the RDT studies was the highest dose tested: 800 IU and 600 IU SHP656/kg BW in rats and monkeys. Toxicokinetics indicated dose-proportional pharmacokinetics. Exposure to FVIII decreased after repeated dosing due to anti-FVIII antibody formation in rats and monkeys. Development of anti-FVIII antibodies is an expected immune response after repeated application of heterologous proteins. In all three mouse models, at all doses, SHP656 showed a reassuring immunogenicity profile.

Conclusions: These results indicate sufficient safety margins to support the maximum clinical dose of SHP656, and a FVIII immunogenicity profile that supports further development.

PB 1119 | Pharmacokinetics and Pharmacodynamics of Subcutaneously Administered Marzeptacog Alfa (Activated) in Hemophilia B Mice

H. Levy, A. Hetherington, N. Usman

Catalyst Biosciences, South San Francisco, United States

Background: The rapid clearance of factor VIIa (FVIIa) requires daily intravenous (IV) administrations to attempt prophylaxis for patients with hemophilia A or B with inhibitors. Subcutaneous (SQ) dosing is a preferred route of administration for convenience and less pain, but has been limited by low bioavailability and potency of the currently marketed FVIIa products. Marzeptacog alfa (activated) (MarzAA), a rFVIIa with enhanced biological properties was developed using a rational protein design approach. Compared to recombinant wild-type FVIIa, MarzAA has 7-fold increased catalytic activity, measured by the rate of Factor Xa generation *in vitro*, in the presence and absence of tissue factor and prolonged duration of effect *in vivo*. A human IV single-dose escalation study up to 30mg/kg showed terminal half-life of 3.5 hrs and dose-dependent pharmacodynamic effects on prothrombin time, aPTT and thrombin generation, along with a good safety profile.

Aims: Determine pharmacokinetics and pharmacodynamics of single and daily dose SQ MarzAA.

Methods: MarzAA was injected into hemophilia B mice IV at 0.5 mg/kg or SQ at 0.5, 0.75 or 1 mg/kg and pharmacokinetics (PK) and aPTT were measured at 1, 2, 4 and 6 hrs. MarzAA was injected daily SQ for 4 days at 0.5 or 1 mg/kg and was sampled at 24, 48, 72 and 74 hrs. aPTT was measured using an assay kit from Sekisui Medical Co and MarzAA antigen using Abcam Factor VII ELISA Kit.

Results: Daily SQ dosing 0.5 mg/kg had trough levels of MarzAA 29.9-76.9 (mean 43.4) ng/mL and increased 2 hours after administration to 267.4-362 (mean 323.9) ng/mL. Daily SQ dosing 1 mg/kg achieved trough levels of MarzAA 50-80.9 (mean 63.7) ng/mL and increased 2 hours after administration to 230.8-729.5 (mean 471.9) ng/mL.

TABLE 1 Antigen levels with Daily Subcutaneous Dosing

Daily dose (mg/kg)	Time (hours)	Mean Antigen level (ng/mL)
0.5	24	38.6
0.5	48	48.8
0.5	72	43.0
0.5	74	323.9
1	24	73.7
1	48	59.4
1	72	58.0
1	74	471.9

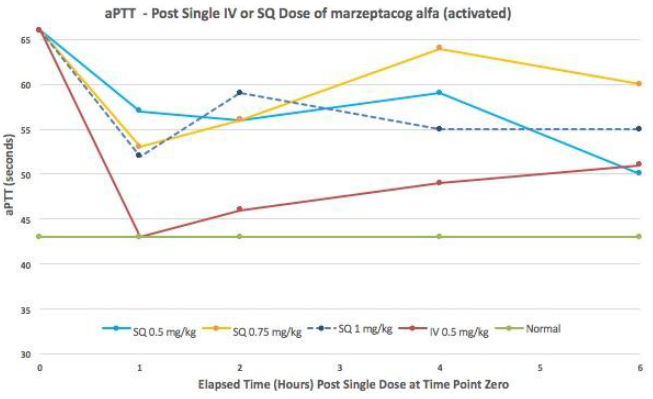

FIGURE 1 aPTT reduction by SQ route compared with IV

Conclusions: The blood levels achieved with daily dosing SQ and increased potency of MarzAA supports the initiation of the Phase 2/3 SQ dosing study in individuals with hemophilia B with inhibitors with a target of achieving normal coagulation pharmacodynamics.

PB 1120 | Underestimation of N-glycoPEGylated Factor IX (N9-GP) Activity in One-stage Clotting Assay Owing to Contact Activator Impairment of N9-GP Activation

E. Persson, C. La Cour Christoffersen

Novo Nordisk A/S, Haemophilia Research, Måløv, Denmark

Background: Factor IX (FIX) activity is routinely quantified by measuring the activated partial thromboplastin time (APTT) in a one-stage (OS) FIX clotting assay. Available APTT reagents provide many combinations of contact activator and phospholipid surface. The recovery of N9-GP, also named nonacog beta pegol, activity against a FIX standard depends on the reagent used. Diverse reagents, containing silica, ellagic acid, or kaolin as the contact activator, may underestimate N9-GP activity.

Aims: To identify the mechanism responsible for the N9-GP activity underestimation obtained with a heterogeneous group of APTT reagents.

Methods: Activated FXI (FXIa) amidolytic activity was measured to assess the influence of APTT reagents/contact activators on the enzymatic activity. The clotting phase of the OS assay was mimicked (contact activation phase omitted, FXIa added to the APTT reagent) by mixing equal volumes of FIX-deficient plasma, N9-GP/FIX sample, APTT reagent/reagent filtrate/contact activator/buffer, and $CaCl_2$ and quantifying the amount of activated FIX (FIXa) formed. Cleavage of N9-GP by FXIa was also monitored by SDS-PAGE.

Results: In the presence of underestimating APTT reagent or isolated contact activator, but not APTT reagent filtrate, clotting phase activation rates of N9-GP and FIX were decreased, N9-GP activation more than FIX activation. Reagent and activator impaired FXIa enzymatic activity. The negative effects are likely owing to FXIa adsorption to the contact activator surface, and activation of FIX then apparently poses a greater steric problem after polyethylene glycol (PEG) conjugation.

Conclusions: Contact activators impair FXIa activity and, of relevance for the OS clotting assay, reduce FXIa-mediated activation of N9-GP to a larger degree than that of FIX. This is likely due to aggravated steric challenges, potentially pertinent to other bulky, long-acting FIX molecules, and leads to underestimation of N9-GP activity.

PB 1121 | Analysis of the Novel Recombinant Factor VIII-SingleChain Protein Predicts A Lower Immunogenic Potential as Compared to Full-length Recombinant FVIII

M. Hofmann[1], A. Verhagen[2], H. Huyhn[2], A. Baz Morelli[2], S. Schmidbauer[3], S. Zollner[4], J. Powell[5], A. Veldman[6], T. Howard[7], E. Maraskovsky[2]

[1]CSL Behring, Research, Marburg, Germany, [2]CSL Limited, Research, Bio21 Institute, Melbourne, Australia, [3]CSL Behring GmbH, Recombinant Product Development, Marburg, Germany, [4]CSL Behring Recombinant Facility AG, Research & Development, Bern, Switzerland, [5]CSL Behring, Medical Affairs, King of Prussia, United States, [6]CSL Behring GmbH, Clinical R&D, Marburg, Germany, [7]Haplomics, Research, Brownsville, United States

Background: Hemophilia A (HA) is a hereditary bleeding disorder. Replacement therapy with plasma-derived (pd) or recombinant (r) FVIII reduces bleeding episodes. However, HA patients require repeated injections resulting in inhibitor development in ~30% of severe HA patients. The rVIII-SingleChain is a novel B-domain-truncated (BDT) molecule purposely designed to express covalently linked FVIII heavy & light chains resulting in increased dosing intervals, stability, homogeneity & clinical efficacy.

Aims: To investigate the immunogenic profile of rVIII-SingleChain compared to other FVIII products.

Methods: rVIII-SingleChain biochemical & immunogenic characteristics were compared with other pd & rFVIII products using biochemical & human-based assays.

Results: rVIII-SingleChain is highly homogeneous & efficiently binds vWF. It is less efficiently internalized by human dendritic cells compared to other rFVIIIs. In contrast, full-length (FL) rFVIII products are more heterogeneous with dissociated FVIII chains & fragments that poorly bind vWF & are potentially available for immune recognition. In the current study, rVIII-SingleChain triggered responses in fewer linker region-specific T cells compared to other BDT or FLrFVIIIs (15% vs 25-35%). The entire rVIII-SingleChain sequence generated fewer HLA-DR/DP/DQ-restricted epitopes compared to pd & FLrFVIII. Adding pdVWF greatly reduced rVIII-SingleChain-derived epitopes (by 67%, 71%, 90% for DR, DP, DQ) but was less effective for FLrFVIII (23%, 22%, 0% for DR, DP, DQ). rVIII-SingleChain had a lower immunogenic profile once bound to pdVWF than either pd or rFVIIIs. These findings are in accordance with clinical data in previously treated patients (PTP) where no rVIII-SingleChain inhibitors developed. An ongoing extension study in previously untreated patients (PUP) is investigating clinical benefit in this population.

Conclusions: These preclinical data warrant testing of rVIII-SingleChain in PUPs to determine clinical benefit.

PB 1122 | Identification of Amino Acid Substitutions in the D´D3 Region of von Willebrand Factor that Increase the Binding Affinity for FVIII

A. Andrews[1], M. Hardy[1], K. Emmrich[1], C. Panousis[1], T. Weimer[2], S. Dower[1], M. Wilson[1]

[1]CSL Limited, Research, Bio21 Institute, Melbourne, Australia, [2]CSL Behring GmbH, Research, Marburg, Germany

Background: Current therapies for severe haemophilia A require intravenous administration of coagulation factor VIII (FVIII) 2-3 times a week for effective prophylactic treatment. FVIII circulates in the bloodstream as a complex with von Willebrand factor (VWF) such that the clearance of FVIII is essentially determined by VWF clearance mechanisms. This association has limited strategies that aim to extend the half-life of the FVIII molecule itself. Alternate strategies to address the VWF component are in turn constrained by FVIII exchange to endogenous VWF generally present in haemophilia A patients. A shift in

this exchange equilibrium through the use of a VWF molecule with enhanced FVIII binding properties may lead to further improvements in the half-life of co-administered FVIII.

Aims: To use both directed and non-directed mutagenesis approaches to identify residues in the D'D3 region of VWF that increase the affinity of VWF for FVIII.

Methods: The N terminal region of mature VWF has been previously identified as a key region for FVIII binding. More than 200 individual and combination mutations at residues S764, L765, S766, P769 and S806 were generated as VWF D'D3 region fragments and expressed in either HEK293 or CHOK1 cells. The resulting proteins were screened by Surface Plasmon Resonance to identify those with improved FVIII binding kinetics. In addition, a VWF D'D3 mammalian display library subjected to random mutagenesis was screened for enhanced FVIII binding variants.

Results: Substitutions at residues S764 and S766 within the VWF D' region and at one position within the D3 region were found to increase FVIII binding affinities, primarily through significant decreases in off-rates.

Conclusions: We have identified amino acid substitutions at a number of VWF residues that increase the affinity for FVIII. These VWF variants may be of value in novel therapeutic strategies to further increase the half-life of FVIII for treatment of haemophilia A.

PB 1123 | Administration of rFVIIa to Concizumab-dosed Monkeys Is Safe and Concizumab Does Not Affect the Potency of rFVIIa in Haemophilic Rabbits

B. Lauritzen, J. Olling, K. Abel, C. Augustsson, K. Balling, I. Hilden

Novo Nordisk A/S, Global Research, Maaloev, Denmark

Background: Concizumab is a high affinity monoclonal antibody directed against the Kunitz2-domain of TFPI. It is currently in clinical development intended for subcutaneous prophylaxis in haemophilia A/B patients with and without inhibitors. A dose-dependent effect of concizumab has previously been demonstrated in haemophilic rabbits (Hilden, Blood 2012 119:5871-8). In inhibitor patients, potential break-through bleedings may be treated with rFVIIa. Both concizumab and rFVIIa are procoagulants; therefore it is considered important to investigate any potential interaction.

Aims: To examine 1) the safety of rFVIIa in concizumab-dosed monkeys and 2) whether concizumab modifies the effect of rFVIIa *in vitro* and *in vivo* in haemophilic rabbits.

Methods: In a safety study, 3 doses of 0.25, 0.5 or 1.0 mg/kg rFVIIa were dosed (iv) to cynomolgus monkeys with 2 hrs intervals in the presence of steady state concentrations of concizumab, obtained by daily sc dosing for 28 days, followed by macro- and microscopic pathological examination.

Concizumab, rFVIIa and their combination was tested in thrombin generation test (TGT) and thrombelastograhy (TEG) using human plasma or whole blood.

Cuticle bleeding was induced in haemophilic rabbits and after 30 min rFVIIa or concizumab+rFVIIa was dosed iv.

Results: No treatment related adverse findings were found in the safety study, i.e. no thrombi or signs of excessive coagulation. Both concizumab and rFVIIa caused increased concentrations of thrombin-anti-thrombin (TAT) and D-dimer, indicating a pharmacological activity of the compounds.

In TGT and TEG, the combined effect of rFVIIa and concizumab was increased as compared to rFVIIa and concizumab alone.

In haemophilic rabbits, rFVIIa dose-dependently reduced blood loss, with no effect on the dose-response curve of rFVIIa by dosing of concizumab immediately before rFVIIa.

Conclusions: Administration of rFVIIa to concizumab-dosed monkeys was safe and the presence of concizumab did not affect the dose-response of rFVIIa in haemophilic rabbits.

PB 1124 | A Monoclonal Antibody with TFPI Neutralizing Activity, Improves the Coagulation Parameters of Hemostatic Assays Performed with Hemophilic Whole Blood

S. Patel-Hett[1], E.J. Martin[2], S. Rakhe[1], P. Sun[1], D.D. Pittman[1], M. Nolte[3], J. Kuhn[3], J.C. Barrett[3], D.F. Brophy[2], J.E. Murphy[1]

[1]Pfizer Inc., Rare Disease, Cambridge, United States, [2]Virginia Commonwealth University, Richmond, United States, [3]Virginia Commonwealth University Medical Center, Richmond, United States

Background: TFPI is an endogenous inhibitor of Factor Xa (FXa) and Factor VIIa (FVIIa), both critical to thrombin generation during coagulation. Restoring FXa and FVIIa activities by inhibiting TFPI may enhance coagulation in hemophilia, where deficiencies in Factor VIII (FVIII) or Factor IX (FIX) impair thrombin generation. Physiologically relevant pools of TFPI that affect coagulation exist free in plasma and released from platelets upon activation.

Aims: We investigated the effect of PF-06741086, a TFPI neutralizing human monoclonal antibody, in comparison to recombinant FVIII or FIX in hemostatic assays run in whole blood from hemophilic patients with and without inhibitors. We also investigated the baseline variability and reproducibility of PF-06741086 in restoring hemostasis by comparing its effect in whole blood collected from the same patients on differing days.

Methods: PF-06741086, recombinant FVIII or FIX, vehicle or isotype control was dosed into whole blood collected from hemophilia A, hemophilia A inhibitor or hemophilia B patients. Whole blood was analyzed in rotational thromboelastography (ROTEM) and thromboelastography (TEG) using tissue factor to activate coagulation.

Results: PF-06741086 induced dose-dependent pro-coagulant responses in ROTEM and TEG assays when added to whole blood from hemophilia patients with and without inhibitors including decreased clotting times and increases in clot firmness parameters. We observed the pro-coagulant effects of PF-06741086 assessed on different days

from the same patient to be consistent and reproducible while noting baseline variability in day to day responses within individual patients.

Conclusions: These studies demonstrate both the in vitro potency and reproducibility of PF-067410867 in improving coagulation parameters in whole blood which contains the two major sources of TFPI affecting coagulation. PF-06741086 is currently under evaluation as a treatment for hemophilia.

PB 1125 | Protein Engineering of Factor X to Restore Coagulation: Building an Alternate Amplification Loop

G.E. Blouse, K.W. Balling, F. Stavenuiter, C. Dan Ley, P.B. Johansen, H. Østergaard, P.S. Gandhi, J.J. Hansen, A.K. Seresht, P. Tiainen, T.N. Krogh

Novo Nordisk A/S, Global Research, Måløv, Denmark

Background: Activated Factor VIII (FVIIIa) and Factor IX (FIXa) form the main complex responsible for generation of sufficient amounts of activated Factor X (FXa) that support normal clot formation. In haemophilia this is impaired by a deficiency of either factor. Current treatments rely on replacement of the missing clotting factors; however, development of neutralizing antibodies has created a need for bypassing therapies. Thrombin-Activatable Factor X (TA-FX) variants are one strategy to re-establish a mechanism for producing adequate FXa and circumvent the lack of a functional FVIIIa/FIXa complex.

Aims: To use rational design and screening of substrate libraries containing thrombin cleavage sites to design novel TA-FX variants that restore coagulation.

Methods: The challenge is to identify a specific and potent thrombin cleavage site. We measured cleavage rates of peptide substrates based on natural thrombin sites as well as a library of potential substrate sequences. Optimal cleavage sequences were introduced into the activation peptide of Factor X in combination with protein engineering strategies expected to enhance cleavage rates as well as minimize the insertion size and number of substitutions. The TA-FX variants were evaluated with respect to in vitro thrombin activation rates, thrombin generation and thromboelastography. In vivo efficacy was evaluated in a tail vein transection model in FVIII-KO mice.

Results: A strong correlation between thrombin activation rates and effect in plasma and whole blood assays was observed. Several variants demonstrated normalized thrombin generation parameters and full restoration of clotting in haemophilic whole blood at concentrations of 50-100 nM. The most potent were further shown to normalize bleeding in a tail vein transection model in haemophilic mice.

Conclusions: These results demonstrate that design of Factor X variants, which can be effectively activated by thrombin, is a feasible concept to restore coagulation.

PB 1126 | Pharmacodynamic Efficacy of a Recombinant Fusion Protein Linking Activated Factor VIIa to Human Albumin (rVIIa-FP) in FVIII and FIX Depleted Plasma with or without Inhibitors

E. Raquet, P. Niebl, B. Doerr, S. Pestel, E. Herzog

CSL Behring GmbH, Pharmacology/Toxicology, Marburg, Germany

Background: Recombinant fusion protein linking coagulation factor VIIa with albumin (rVIIa-FP) is currently in clinical development for treatment of patients with congenital hemophilia A or B with inhibitors. Due to its prolonged plasma and tissue half-life compared to rFVIIa, rVIIa-FP is expected to improve on current available treatment for these patients.

Aims: The aim of this study was to evaluate and compare the efficacy of rVIIa-FP and rFVIIa in factor VIII (FVIII) and factor IX (FIX) depleted plasma with or without inhibitors in vitro.

Methods: rVIIa-FP or rFVIIa were added at concentrations of 0.1 to 500 IU/mL FVIIa activity to human FVIII and FIX depleted plasma with or without neutralizing antibodies. Pharmacodynamic activity in spiked plasma was determined by measuring the activated partial thromboplastin time (aPTT, Pathromtin® SL) on a BCS XP analyzer. Thrombin generation (calibrated automated thrombogram, Thrombinoscope BV, The Netherlands) was quantified after intrinsic activation using a mixture of Phospholipids and Pathromtin® SL.

Results: Data confirmed a clear hemostatic impairment of FVIII and FIX depleted plasma with and without inhibitors as indicated by a prolonged aPTT, delayed onset of thrombin generation (lagtime) and lower peak thrombin levels. Addition of 0.1 to 500 IU/mL rVIIa-FP or rFVIIa in vitro resulted in a concentration dependent correction of coagulation parameters in both, the absence or presence of inhibitory antibodies.

Conclusions: The study demonstrates in vitro comparable, concentration dependent pharmacodynamic efficacy of rVIIa-FP and rFVIIa based on key parameters of hemostatic function, i.e. correction of aPTT and thrombin generation in FVIII and FIX depleted plasma with inhibitors. The potential of rVIIa-FP to improve on the available treatment options of patients with FVIII or FIX inhibitors is currently being evaluated in clinical studies.

PB 1127 | Effect of Phospholipid Vesicle Composition on Activity of FVIIIa-mimetic Bispecific Antibodies

M. Aleman, A. Goodman, E. Kistanova, N. Leksa, R. Peters

Bioverativ, Waltham, United States

Background: As part of the tenase complex, activated factor VIII (FVIIIa) binds to exposed phosphatidylserine (PS) on cell membranes and assembles with activated factor IX and factor X. It has been shown

that FVIIIa binds preferentially to phosphatidylcholine (PC) phospholipid vesicles (PVs) containing both phosphatidylserine (PS) and phosphatidylethanolamine (PE). Recently, a FVIIIa-mimetic bispecific antibody (emicizumab) was developed as a potential treatment for hemophilia A patients with and without inhibitors. We have generated a novel FVIIIa-mimetic bispecific antibody, BS-027125, with improved target specificity over emicizumab. Given that, unlike FVIIIa, FVIIIa-mimetic antibodies do not directly bind phospholipids, it is unclear whether these antibodies will show similar phospholipid preferences.

Aims: To compare the effect of varying PV compositions and concentrations on the activity of an emicizumab biosimilar (Emi-bsim), BS-027125, and recombinant FVIII (rFVIII).

Methods: The procoagulant activity of Emi-bsim, BS-027125 and rFVIII were assessed by a thrombin generation assay triggered with factor XIa. Synthetic PVs tested were composed of either PC/PE/PS (40/40/20%) or PC/PS (80/20%).

Results: As expected, rFVIII activity was ~2.5-fold higher on PE-containing phospholipid vesicles and decreased when either PV was limiting or in excess. Notably, whereas Emi-bsim activity was similar on both PVs, BS-027125 was ~3 fold more active on PE-containing PVs. The PV concentration that supported peak activity was higher for Emi-bsim and BS-027125 than for rFVIII.

Conclusions: The different relative activities of rFVIII and bispecific antibodies on different phospholipid surfaces complicate direct comparisons between these molecules. These results highlight the influence of assay design when benchmarking the activity of bispecific antibody mimetics of FVIIIa. Furthermore, these results suggest Emi-bsim and BS-027125 may function via different mechanisms.

PB 1128 | A New Long-acting Pegylated Recombinant Factor VIII Derived from Single-Chain Factor VIII Engineered to Be Highly Expressed in CHO Cell Line

K.-Y. Kang[1], S.-H. Lee[1], I.-J. Oh[1], M.-S. Oh[2], J.-H. Ryu[1], S.-A. Yang[2], K.-N. Lee[2], J.-S. Kim[2], E.-C. Jo[1]

[1]Mogam Institute for Biomedical Research, Yongin-si, Korea, Republic of, [2]Green Cross Corp., Yongin-si, Korea, Republic of

Background: Prophylactic treatment with coagulation factors requires frequent administration leading to the high cost of therapeutic drugs and patient inconveniences.

Aims: This study aims to develop the affordable long-acting recombinant factor VIII.

Methods: The recombinant single-chain FVIII (scFVIII) constructed by joining the heavy chain to light chain via varying lengths of N-terminus of B-domain were transiently expressed in HEK293 cells to screen the scFVIII with a high expression level and appropriate specific activity. The scFVIII (G4) selected from them was modified with cysteine at the B-domain for pegylation and transferred into CHO-S cells. The Cys-introduced single-chain FVIII (scFVIII (G4_cys)) was then pegylated with maleimide-PEG (40kDa), producing a pegylated scFVIII.

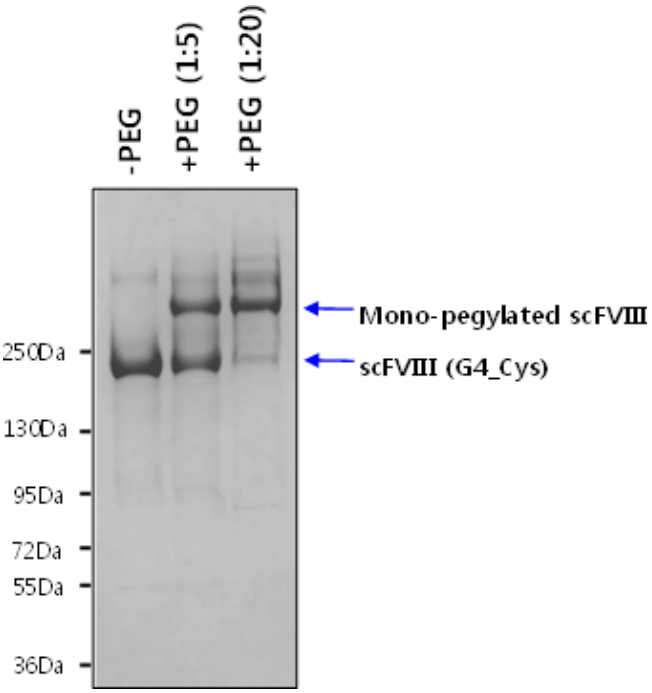

FIGURE 1 Site-specific pegylation of scFVIII (G4_cys) with maleimide-40kDaPEG The molar ratio of scFVIII to PEG at pegylation is 1:5 and 1:20

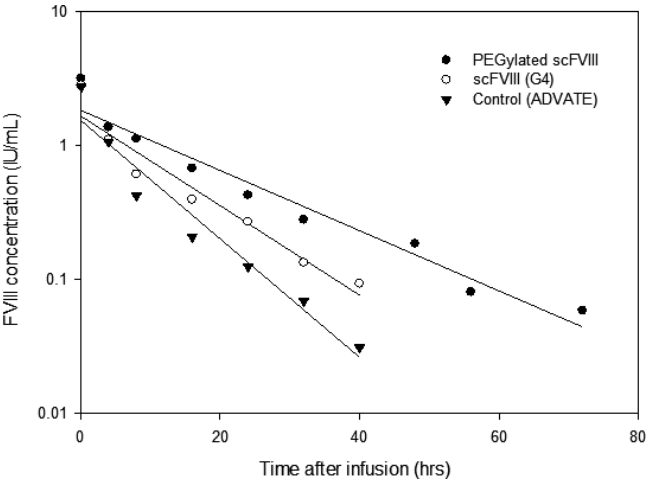

FIGURE 2 Pharmacokinetic study in hemophilia A mice

Pharmacokinetic study (n=3/group, 125 IU/kg) and blood coagulation tests using tail clipping (n=4~13/group, 50, 100, 200 IU/kg) were conducted for the pegylated scFVIII in hemophilia A mice.

Results: The expression level and specific activity of scFVIIIs produced from HEK293 cells varied according to the length of B-domain. The selected clone, scFVIII (G4) has an aPTT/CS ratio close to 1. scFVIII (G4_Cys) was produced in CHO-S cell line at the level of ~90 IU/mL/day in flask culture exchanging whole media daily (pseudo perfusion culture) and site-specifically pegylated to produce the mono-pegylated form.

The pegylated scFVIII has the specific activity (CS, aPTT) comparable to full length recombinant factor VIII and its aPTT/CS ratio was

approximately 1. The half-lives of scFVIII (G4) and its pegylated form were 1.2 and 1.9 fold longer, respectively, than the full-length recombinant FVIII (control).
The acute hemostatic efficacy of the pegylated scFVIII was equivalent to that of control.
Conclusions: The scFVIII (G4_cys) was highly produced from CHO cell line and the site-specifically pegylated scFVIII derived from it reserved the hemostatic efficacy and circulated longer than the control recombinant FVIII in hemophilia A mice.

PB 1129 | Pharmacodynamic Efficacy of a Recombinant Fusion Protein Linking Activated Factor VIIa to Human Albumin (rVIIa-FP) in FVII Depleted Plasma

E. Raquet, P. Niebl, B. Doerr, E. Herzog
CSL Behring GmbH, Pharmacology/Toxicology, Marburg, Germany

Background: Congenital factor VII deficiency is a rare autosomal recessively inherited bleeding disorder. Replacement with FVII concentrates or plasma products is the mainstay of treatment for these patients. The novel recombinant fusion protein comprising activated human coagulation factor VIIa linked to human albumin (rVIIa-FP) is currently in clinical development. Due to its prolonged plasma and tissue half-life versus rFVIIa, rVIIa-FP is expected to improve on current available treatments.
Aims: The aim of this study was to evaluate the pharmacodynamic efficacy of rVIIa-FP and rFVIIa in factor VII depleted plasma mimicking severe FVII deficiency in vitro.
Methods: rVIIa-FP or rFVIIa were added to human FVII depleted plasma at concentrations of 0.1 to 500 IU/mL based on FVIIa activity. Primary parameters for the evaluation of pharmacodynamic activity in vitro were prothrombin time (PT) and thrombin generation. PT was measured using two different reagents (Innovin® and Thromborel® S) on a BCS XP analyzer. Thrombin generation was quantified by calibrated automated thrombogram triggered by the extrinsic pathway using tissue factor (5 pM) and phospholipid containing PPP-Reagent (Thrombinoscope BV, The Netherlands).
Results: Hemostasis of FVII depleted plasmas was impaired as indicated by prolonged PT, delayed onset of thrombin generation (lag-time) and decreased peak thrombin levels. Addition of 0.1 to 500 IU/mL rVIIa-FP or rFVIIa resulted in dose dependent correction of coagulation parameters including PT and correction of thrombin generation.
Conclusions: The study demonstrates comparable correction of key coagulation parameters by rVIIa-FP and rFVIIa in a FVII deficient in vitro system. Current clinical trials are evaluating rVIIa-FP's potential for improving treatment of FVII deficient patients.

PB 1130 | Extended Hemostatic Efficacy of rIX-FP is Confirmed in a Hemophilia B Mouse Model of Arterial Injury

E. Raquet, F. Musch, M. Mischnik, M. Nolte, E. Herzog
CSL Behring GmbH, Pharmacology/Toxicology, Marburg, Germany

Background: rIX-FP, a recombinant fusion protein linking coagulation factor IX with albumin, has recently been approved for intravenous (i.v.) prophylaxis and on-demand treatment of hemophilia B patients.
Aims: This study was conducted to compare the pharmacokinetic (PK) and pharmacodynamic profile of rIX-FP and a marketed recombinant factor IX (rFIX) product in an arterial injury model in hemophilia B mice.
Methods: A clinically-relevant i.v. dose of 50 IU/kg of rIX-FP or rFIX was given to hemophilia B mice. A vehicle-treated group served as negative control. Hemostatic efficacy was assessed in vivo at 3, 24, 48 and 72 hours (h) post administration (p.a.). Arterial injury was induced by placing a ferric chloride-saturated patch of filter paper (10%) on the carotid artery for three minutes. Thereafter, blood flow was monitored over 40 minutes or until thrombotic occlusion using by Doppler sonography. Afterwards, blood samples were drawn and analysed for factor IX (FIX) activity using a one-stage clotting assay.
Results: Absence of occlusive thrombosis was confirmed in all vehicle-treated animals. In FIX-treated groups, hemostatic efficacy was comparable at 3 h p.a. and declined over time. However, treatment with rIX-FP resulted in sustained hemostatic efficacy until 72 h p.a. while rFIX-treated animals had already returned to control levels at this time point ($p = 0.014$). The results were in line with the plasma activity levels of FIX with peak levels determined at 3 h for both treatment groups followed by a time-dependent decrease ($p = 0.0013$). Thereby, FIX plasma activity was in the range of vehicle-treated animals at 24 h after rFIX application. However, an improved PK profile was observed for rIX-FP indicated by a significantly higher FIX exposure over the time ($p = 0.0013$) and activity values above the vehicle control until 72 h p.a..
Conclusions: Prolonged hemostatic efficacy of rIX-FP was demonstrated in hemophilia B mice in comparison to rFIX.

PB 1131 | A Model of the Minimum Half-life Extension Ratio Needed to Reduce the Dosing Frequency of Extended Half-life Recombinant FVIII Products

J. Booth[1], H. Schütz[2], K. Steinitz-Trost[3], H.-Y. Lee[4], A. Bauer[3], M. Wolfsegger[3]
[1]*Shire, Health Economics Outcomes Research and Epidemiolog, Cambridge, United States,* [2]*BEBAC, Vienna, Austria,* [3]*Baxalta Innovations GmbH (Now Part of Shire), Vienna, Austria,* [4]*Baxalta Innovations GmbH (now part of Shire), Zurich, Switzerland*

Background: With new recombinant FVIII (rFVIII) products available, it is crucial to differentiate which should be considered extended half-life (EHL) versus standard products. This supports assessment by physicians, payers, and consequently, appropriate and adequate access for patients. A key defining criterion of an EHL product is having an

EHL ratio. However, a minimal clinically-meaningful half-life (HL) extension ratio has not been defined until now.

Aims: To identify the HL extension ratio required to make a clinically meaningful (one day) reduction in dosing interval while maintaining the same percentage of patients always above a target rFVIII concentration of 1 IU/dL

Methods: The population PK model for standard rFVIII by Björkman *et al*. (2012) was used to estimate the percentage of patients always > 1 IU/dL using a benchmark regimen for rFVIII dosed 3 times weekly (the most commonly prescribed prophylactic dosing frequency in most countries). Then, dosing frequency was reduced to twice weekly and rFVIII HL extended until the percentage of patients always > 1 IU/dL was equal to the benchmark regimen. The result is an estimate of the minimal clinically-important HL extension ratio required to meet the definition of an EHL rFVIII product.

Results: Benchmark doses for rFVIII of 100 IU/kg/week were tested to reflect common rFVIII utilization. This benchmark regimen resulted in 56.6% of patients always > 1 IU/dL. Comparing the benchmark to doses of 80 and 90 IU/kg/week, the fold HL extension required to achieve 56.6% of patients > 1 IU/dL was 1.30 and 1.26, respectively (Table 1).

TABLE 1 The minimum EHL ratio required for a 2x/wk EHL rFVIII to achieve the same proportion of patients always above 1 IU/dL as 3x/wk standard rFVIII

Dose regimen	Proportion of patients always above 1 IU/dL	Half-life extension ratio
Three times per week (benchmark); 30 IU/kg on Day 1 and 3, and 40 IU/kg on Day 5	56.6%	Not applicable
Twice weekly; 40 IU/kg on Days 1 and 3	56.6%	1.3
Twice weekly; 45 IU/kg on Days 1 and 3	56.6%	1.26

Conclusions: Per this model, rFVIII products should show a minimum HL extension ratio of 1.3 for a meaningful reduction in dosing while maintaining the same percentage of patients always above 1 IU/dL FVIII concentration. Future research could investigate the extent to which EHLs that exceed the minimum HL extension ratio criteria may improve rFVIII coverage versus current prophylactic regimens.

PB 1132 | The Safety and Efficacy of IB1001 in Previously Treated Children 12 Years of Age or Younger with Hemophilia

R. Leisner[1], R. Fritz[2], B. MacPherson[2], D. Schaaf[2]

[1]*The North London Paediatric Haemophilia Network, London, United Kingdom,* [2]*Aptevo Therpeutics, Seattle, United States*

Background: IB1001 is a third generation recombinant factor IX approved in the US for the control and prevention of bleeding episodes and for perioperative management of patients ≥12 years of age with hemophilia B. This study evaluated the pharmacokinetics, safety, and efficacy of IB1001 when used in previously treated patients ≤12 years old.

Aims: To evaluate the pharmacokinetics, safety and efficacy of IB1001 in previously treated patients ≤12 years of age with hemophilia B.

Methods: This was a multi-center, non-randomized, open-label study. Patients were assigned either a prophylactic or on demand regimen based on investigator discretion. Bleed control efficacy was evaluated using annualized bleeding rate, subject's rating of efficacy for the degree of bleed control, and the number of infusions required to treat a bleed. Subjects were monitored for adverse events and regularly assessed for the development of inhibitors. The study was approved by an independent ethics committee at each study site. Written informed consent for all patients was provided prior to study entry.

Results: The study included nine patients, all male, with a median age of 9 (range 2-11). All patients were assigned a prophylactic regimen. One patient erroneously received on demand treatment.

The median exposure days for patients on prophylactic treatment was 221 (range 111-404) and the median time between first and last treatment was 46 months. The median total number of bleeds per patient was 1 (range 0-6); two patients experienced no bleeds. The median annualized bleed rate was 0.3 (range 0-1.6). The patient who received treatment on demand experienced 23 bleeds with an annualized bleed rate of 11.

No adverse events related to IB1001 were reported. None of the patients developed factor IX inhibitors during the study.

Conclusions: In this small study, IB1001 appeared safe and effective in preventing and controlling bleeding episodes in previously treated patients ≤12 years of age with hemophilia B.

PB 1771 | Construct and Known Group Validity of Patient-reported Outcome (PRO) Instruments in US Adults and Caregivers of Children with Hemophilia B: Results from the Bridging Hemophilia B Experiences, Results and Opportunities into Solutions (B-HERO-S) Study

T. Buckner[1], R. Sidonio Jr[2], M. Witkop[3], C. Guelcher[4], D. Clark[5], W. Owens[6], N. Frick[7], N. Iyer[8], D. Cooper[8]

[1]*University of Colorado School of Medicine, Aurora, United States,* [2]*Emory University School of Medicine, Atlanta, United States,* [3]*Munson Medical Center, Traverse City, United States,* [4]*Children's National Health System, Washington, United States,* [5]*The Coalition for Hemophilia B, New York, United States,* [6]*Hemophilia Federation of America, Washington, United States,* [7]*National Hemophilia Foundation, New York, United States,* [8]*Novo Nordisk Inc, Plainsboro, United States*

Background: B-HERO-S was a pilot study evaluating the impact of hemophilia on people (men/women) with mild-severe hemophilia B (PWH) and caregivers (CG) of boys/girls with hemophilia B, via standardized and disease-specific PROs.

Aims: To assess construct and known group validity of PROs.

Methods: US PWH completed a 1-hour Web-based survey including EQ-5D-5L (mobility [MO], self-care [SC], usual activities [UA], pain/discomfort [PD], anxiety/depression [AD], calculated Index, VAS), Brief Pain Inventory (BPI; pain interference [PI], pain severity [PS]), Hemophilia Activities List (HAL), and PHQ-9 (depression). CG completed PHQ-9 and GAD-7 (anxiety). Construct validity was assessed using Pearson product-moment correlation (threshold, >0.37). Known group validity was assessed by comparisons to self-reported characteristics based on Kruskal Wallis test (*P* values).

Results: B-HERO-S enrolled 299 PWH and 150 CG of children; most had mild-moderate hemophilia B. In PWH, EQ-5D-5L items/VAS/Index correlated with all BPI items (**Table 1**) and PS/PI domain scores. EQ-5D-5L items (except AD) and VAS correlated with HAL domain scores. EQ-5D UA/PD/AD/Index correlated more highly with PHQ-9 than EQ-5D MO/SC/VAS. BPI PS correlated with most HAL domains and overall scores; BPI worst/least/average/current pain correlated with all HAL domains, composite and overall scores. BPI PI correlated with all HAL scores. PHQ-9 scores correlated with HAL transportation and household tasks. In CG, PHQ-9 and GAD-7 scores were correlated. All known groups had significant differences in EQ-5D items/VAS/Index and BPI PS/PI (**Table 2**). In CG, PHQ-9 had significant differences across all known groups; GAD-7 was significant for all except for age.

Conclusions: The PROs administered in B-HERO-S showed high construct validity with expected directionality. Nearly all PRO domains/scores discriminated between known groups, with greatest significance between items/domains closely matching self-reported characteristics.

PB 1772 | High and Sustained Observed trough FIX Activity Levels with Prophylactic Dosing of IDELVION (rFIX-FP) in Patients with Hemophilia B

G. Castaman[1,2], J.C. Gill[3], J. Roberts[4], J. Jochems[4], Y. Li[4], W. Seifert[4]

[1]Center for Bleeding Disorders, Careggi University Hospital, Florence, Italy, [2]Hemophilia and Thrombosis Center, San Bortolo Hospital, Department of Cell Therapy and Hematology, Vincenza, Italy, [3]Blood Research Institute, BloodCenter of Wisconsin, Medical College of Wisconsin, Children's Research Institute, Milwaukee, United States, [4]CSL Behring, King of Prussia, United States

Background: rIX-FP, a long-acting fusion protein genetically linking recombinant human coagulation Factor IX with recombinant human albumin, is used in the treatment of hemophilia B patients. Maintaining higher FIX activity trough levels enables patients to transition from severe to moderate or mild disease states, thereby reducing bleed frequency. Sustained FIX activity levels are critical to achieving persistent pharmacological effects from FIX replacement therapies.

Aims: To evaluate mean observed trough FIX activity levels in pediatric and adult patients with hemophilia B during prophylaxis with rIX-FP in two clinical trials.

Methods: Adult/adolescent patients (≥12 years) with hemophilia B were assigned to prophylaxis with rIX-FP once every 7- (35-50 IU/kg) or 14-days (75 IU/kg). Pediatric patients (< 12 years) received prophylaxis once every 7 days (35-50 IU/kg). Adult trough FIX activity levels were measured every four weeks before each infusion over a maximum period of ~70 weeks. Pediatric trough FIX activity levels were measured at 4, 12, 24 and 36 weeks. Patients with ≥1 measurement obtained at observed trough were included in the analysis.

Results: A total of 45 and 18 adult patients were included in the analysis of observed trough levels with rIX-FP prophylaxis once every 7 and 14 days (mean doses 47 and 74 IU/kg), respectively. Pediatric patients (N=24) received prophylaxis once every 7 days (mean dose 47 IU/kg). In adult/adolescent patients, once every 7- and 14-day prophylaxis dosing regimens provided mean observed trough FIX levels of ~23% and ~13%, respectively, where >96% of samples were above 5%. Pediatric patients had mean FIX activity levels of ~14%.

Conclusions: This analysis demonstrates that rIX-FP provides consistently high observed trough FIX activity levels with both 7- and 14-day prophylaxis dosing regimens. These findings are consistent with low median annualized bleeding rates observed in both adult and pediatric patient populations.

PB 1773 | Pharmacokinetics of Recombinant Fusion Protein Linking Activated Factor VIIa to Human Albumin (rVIIa-FP) and Eptacog Alfa in Hemophilia Patients with Inhibitors

J. Roberts[1], C. Joch[2], J. Yi[3], S. Puli[1], J. Malanghu[4], E. Santagostino[5]

[1]Clinical Pharmacology & Early Development, CSL Behring, King of Prussia, United States, [2]Clinical Development, CSL Behring, Marburg, Germany, [3]Global Clinical Safety and Pharmacovigilance, CSL Behring, King of Prussia, United States, [4]Haemophilia Clinic, Comprehensive Care Centre Charlotte Maxeke Johannesburg Academic Hospital and Faculty of Health Sciences, NHLS and the University of the Witwatersrand, Johannesburg, South Africa, [5]Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, IRCCS Ca' Granda Foundation, Maggiore Hospital Policlinico, Milan, Italy

Background: Recombinant fusion protein linking activated factor VIIa to human albumin (rVIIa-FP) is a therapeutic option designed to prevent and treat bleeding events in hemophilia patients with inhibitors. It aims to offer reduced infusion frequency and thus address the limitations associated with the short half-life of current rVIIa treatments.

Aims: To compare single-dose pharmacokinetics (PK) of rVIIa-FP to eptacog alfa (rFVIIa) and assess safety of rVIIa-FP in on-demand treatment in hemophilia patients with inhibitors.

Methods: In a Phase II/III multicenter, open-label, dose escalation study of rVIIa-FP for on-demand treatment in hemophilia patients with inhibitors, the first 12 patients underwent single-dose PK evaluation. Patients received a single injection of 90 (n=6) or 270 µg/kg (n=6) rFVIIa (day 1) followed by a single injection of 1500 µg/kg rVIIa-FP (day 3 to 15). FVIIa activity was assessed using StaClot assay. PK parameters evaluated included plasma half-life, area under plasma concentration time curve (AUC) and maximum plasma concentration (C_{max}). The safety of rVIIa-FP during on-demand treatment was also assessed.

Results: Mean baseline-corrected FVIIa activity at 24 h was higher for rVIIa-FP (11.0 IU/ml) compared to rFVIIa (0.06 IU/ml [90 µg/kg] and 0.11 IU/ml [270 µg/kg]). rVIIa-FP had an extended half-life of 8.5 h, more than two-fold higher than rFVIIa (3.0 [90 µg/kg] and 2.6 h [270 µg/kg]). rVIIa-FP produced a larger AUC compared to rFVIIa (863 vs. 112 [90 µg/kg] and 325 [270 µg/kg] IU·h/mL). C_{max} for rVIIa-FP was 76 IU/mL, in between that of the 90 (44.1 IU/mL) and 270 µg/kg (131 IU/mL) rFVIIa groups. No patients developed inhibitors to native FVII and there were no serious adverse events.

Conclusions: rVIIa-FP has an improved PK profile with a longer half-life and prolonged FVIIa activity compared to rFVIIa. In addition, rVIIa-FP showed good tolerability.

PB 1774 | Efficacy and Safety of rFVIIIFc Prophylaxis in Pediatric, Adolescent, and Adult Subjects with Severe Hemophilia A over 3-4 Years: The ASPIRE Study

B. Nolan[1], B.A. Konkle[2], J. Mahlangu[3], K.J. Pasi[4], D. Perry[5], S. Rangarajan[6], G. Young[7], S. Lethagen[8], L.M. Cristiano[9], H. Yuan[9], A. Ramirez-Santiago[9]

[1]Our Lady's Children's Hospital, Dublin, Ireland, [2]Bloodworks Northwest, Seattle, WA, United States, [3]University of the Witwatersrand and NHLS, Haemophilia Comprehensive Care Centre, Faculty of Health Sciences, Johannesburg, South Africa, [4]Barts and the London Comprehensive Care Center, London, United Kingdom, [5]Addenbrookes Hospital, Cambridge, United Kingdom, [6]Hampshire Hospitals, NHS Trust, Basingstoke, United Kingdom, [7]Children's Hospital Los Angeles, University of Southern California Keck School of Medicine, Los Angeles, CA, United States, [8]Sobi, Stockholm, Sweden, [9]Bioverativ, Waltham, MA, United States

Background: The ASPIRE extension study evaluates long-term safety and efficacy of rFVIIIFc in previously treated subjects with severe hemophilia A.

Aims: To present safety and efficacy data from the third interim data cut (Y3) of ASPIRE (11 Jan 2016).

Methods: Eligible subjects completing A-LONG (aged ≥12 y) received 1 of 4 treatments in ASPIRE: individualized prophylaxis (IP), weekly prophylaxis (WP), modified prophylaxis (MP), or episodic treatment (ET); or for those < 12 y who completed Kids A-LONG, IP or MP. Subjects could switch treatment groups at any time. The primary endpoint was occurrence of inhibitor development.

Results: Of 153 adults/adolescents who completed A-LONG, 150 enrolled in ASPIRE, and 78 remained on-study at Y3. Of 67 children who completed Kids A-LONG, 61 enrolled in ASPIRE and 45 remained on-study at Y3. No inhibitors were observed across age groups in ASPIRE. The safety profile of rFVIIIFc was consistent with the parent studies and prior interim analyses. Median (IQR) duration of treatment was 4.1 (3.0-4.2) y (A-LONG subjects) and 2.9 (2.3-3.1) y (Kids A-LONG subjects). Among A-LONG subjects, 19 (12.7%) changed treatment groups at least once. From the end of A-LONG (or Kids A-LONG), 70.3% (90.2%) had no change in dosing interval, while 23.4% (6.6%) extended and 6.3% (3.3%) shortened. Median (IQR) change in weekly consumption at ASPIRE Y3 was 0 (0-0) from end of A-LONG and 0 (0-3.2) from end of Kids A-LONG. Dosing characteristics (Table 1) and ABRs (Table 2) are summarized. Among adults/adolescents, 93.6% (IP), 97.8% (WP), 94.5% (MP), and 99.2% (ET) of bleeding episodes were controlled with 1-2 rFVIIIFc injections. Per subject, median doses to resolve bleeding episodes were 45.6 (IP), 34.1 (WP), 37.1 (MP), and 27.3 (ET) IU/kg. Results were generally similar for pediatric subjects.

Conclusions: The safety and efficacy of rFVIIIFc prophylaxis was confirmed over ~4y in adults/adolescents and ~3y in children. ABRs remained consistently low while maintaining extended prophylactic dosing intervals.

TABLE 1 Summary of dosing characteristics for subjects with an efficacy period treated with rFVIIIFc prophylaxis in ASPIRE (Y3)

	Adults/adolescents		Pediatric subjects (<6 years)[a]	Pediatric subjects (6 to <12 years)[b]	
Median (IQR)	IP (n = 107)	WP (n = 27)	MP (n = 21)	IP (n = 29)	IP (n = 30)
Average weekly dose (IU/kg)	79.2 (73.8, 99.9)	66.0 (62.5, 66.8)	70.8 (62.8, 90.4)	101.1 (88.8, 118.2)	95.3 (82.0, 110.2)
Annualized consumption (IU/kg)[c]	4200.4 (3913.7, 5264.1)	3507.3 (3377.9, 3644.9)	3750.4 (3300.0, 4717.8)	5336.5 (4677.3, 6196.8)	5016.8 (4306.7, 5844.9)
Dosing interval (days)	3.5 (3.5, 5.0)	7.0 (7.0, 7.0)	5.0 (4.0, 6.9)	3.5 (3.5, 3.5)	3.5 (3.5, 3.5)

IP, individualized prophylaxis; IQR, interquartile range; MP, modified prophylaxis; WP, weekly prophylaxis.

[a]Two subjects <6 years of age received MP with the following dosing characteristics: average weekly dose, 82.0 IU/kg and 118.7 IU/kg; annualized consumption, 4,640.6 IU/kg and 6,479.1 IU/kg; dosing interval, 2.3 days and 5.7 days.

[b]One subject 6 to <12 years of age received MP with the following dosing characteristics: average weekly dose, 84.5 IU/kg; annualized consumption, 4,572.3 IU/kg; dosing interval, 3.5 days.

[c]Annualized consumption is the total rFVIIIFc (IU/kg) received during the efficacy period extrapolated to a 1-year interval of time.

TABLE 2 Summary of overall ABR among subjects with an efficacy period in ASPIRE (Y3)

	Adults/adolescents				Pediatric subjects (<6 years)[a]	Pediatric subjects (6 to <12 years)[b]
Median (IQR)	IP (n = 107)	WP (n = 27)	MP (n = 21)	ET (n=13)	IP (n = 29)	IP (n = 30)
Overall on-study ABR[c]	0.8 (0, 2.7)	2.2 (0.4, 5.1)	4.1 (1.2, 10.4)	19.1 (13.9, 30.5)	1.5 (0.5, 2.4)	1.6 (0.8, 3.9)

ET, episodic treatment; IP, individualized prophylaxis; IQR, interquartile range; MP, modified prophylaxis; WP, weekly prophylaxis.

[a]Two subjects <6 years of age received MP and had overall on-study ABRs of 4.1 and 10.7.

[b]One subject 6 to <12 years of age received MP and had an overall on-study ABR of 1.0.

[c]The annualized bleeding rate (ABR) is the total number of bleeding episodes during the efficacy period extrapolated to a 1-year interval of time.

PB 1775 | Comparing the One-stage and Chromogenic Assay: Factor VIII Activity Assay Discrepancy at Baseline Does Not Reflect Assay Discrepancy after DDAVP in Non-severe Hemophilia A

L.M. Schütte[1], I. Van Moort[2], S.C.M. Stoof[1], M.P.M. De Maat[1], F.W.G. Leebeek[1], M.H. Cnossen[2], M.J.H.A. Kruip[1]

[1]*Erasmus University Medical Center, Hematology, Rotterdam, The Netherlands,* [2]*Erasmus University Medical Center - Sophia Children's Hospital, Pediatric Hematology, Rotterdam, The Netherlands*

Background: Measurement of factor VIII activity (FVIII) is used to monitor treatment in hemophilia A (HA) patients. Two assays are generally used, i.e. the one-stage (OSA) and chromogenic assay (CSA). Assay discrepancies were shown in baseline FVIII in non-severe HA and during treatment with FVIII concentrates, but has not been studied in patients receiving DDAVP.

Aims: To investigate discrepancies between the OSA and CSA after DDAVP administration in non-severe HA patients.

Methods: Non-severe HA patients who received a DDAVP test dose (0.3 µg/kg) between 2011 and 2015 were included after informed consent. FVIII was measured with the OSA and CSA before (T0) and after DDAVP administration at 1 (T1) and 4 (T4) hours. Assay discrepancy at T0 was defined as a two-fold difference. Response to DDAVP was defined as complete response (CR) (FVIII ≥0.50 IU/mL), partial response (PR) (FVIII 0.30-0.50 IU/mL) or no response (NR) (FVIII < 0.30 IU/mL). Discrepancy in response at T1 and T4 was defined as a different response category after DDAVP.

Results: Twenty nine non-severe HA patients were included with a median age of 41 years [range 6-67]. At T0, median FVIII with the OSA was 0.20 IU/mL [IQR 0.09-0.27], median FVIII with the CSA was 0.19 IU/mL [IQR 0.09-0.28]. Four patients showed assay discrepancy at T0 (in 3 patients the OSA was higher, in 1 patient the CSA). At T1 17/29 patients (58%) had CR, 9 (31%) PR and 3 (10%) NR based on the OSA. Based on the CSA 22/29 (76%) patients had CR, 4 (14%) PR and 3 (10%) NR. Discrepancy in response was seen in 24% at T1 and 29% at T4. At T1 discrepancy was seen in 2 of the 4 discrepant patients from T0 and in 5 of the 25 non-discrepant patients. The assay resulting in the lowest FVIII:C at T0 also gave the lowest outcome after DDAVP in all these 7 patients.

Conclusions: Assay discrepancy before treatment does not reflect FVIII assay discrepancy after a DDAVP test dose. By using the assay with the lowest FVIII:C before treatment, overestimation of response to DDAVP may be prevented.

Background: Recently a randomized clinical trial (SIPPET) showed that the risk of inhibitor development is nearly doubled in previously

untreated and minimally treated patients with severe hemophilia A treated with recombinant products (rFVIII) compared with plasma-derived (pdFVIII) products containing von Willebrand factor (VWF).

Aims: The aim of this post-hoc analysis of the SIPPET study was to assess the early risk of inhibitor development every 5 exposure days (EDs) and to see whether or not there was a difference between the two groups over the course of time of FVIII exposure.

Methods: 251 children were enrolled in the SIPPET study and randomized to receive a single pd or rFVIII. The outcomes were any FVIII inhibitor levels ≥ 0.4 BU and high-titer inhibitors (peak levels > 5 BU). Survival analysis by Kaplan-Meier and Cox regression were repeated every 5 EDs to assess the association of source of FVIII with inhibitor development over time.

Results: 6 out of 251 patients developed an inhibitor and of those 50 were high-titer; all occurred before 40 EDs. Over the complete observation period, users of rFVIII products had a 87% higher rate of inhibitor development than users of pdFVIII (hazard ratio (HR) 1.87; 95% confidence interval (CI95) 1.17-2.96). However, this risk was particularly high during the first 5 EDs, for both all (HR 3.14, CI95% 1.01-9.74) and high-titer inhibitor development (HR 4.19, CI95% 1.18-14.8). After the first 5 EDs, the difference between two arms was less pronounced, i.e., around two times higher for rFVIII compared to pdFVIII. Table 1 shows the cumulative incidence per time interval for each product class.

TABLE 1 Cumulative incidence per time interval for each product class

	ALL INHIBITOR Cumulative incidence (%)		HIGH-TITER INHIBITOR Cumulative incidence (%)	
Exposure days (EDs)	pdFVII	rFVIII	pdFVII	rFVIII
0-5	3.3	10.3	2.5	10.3
6-10	12.2	10.0	11.7	10.0
11-15	2.7	12.9	0.9	4.4
16-20	3.9	5.1	2.0	2.2
21-25	0	2.3	0	1.5
26-30	2.4	0	0	0
31-35	1.3	2.5	1.5	0
36-40	0	1.4	0	0

Conclusions: The risk of inhibitor development during replacement therapy occurs earlier (0-5 EDs) in patients treated with rFVIII than in those treated with pdFVIII, and remains high until 15 EDs. For pdFVIII, the highest risk came later (6-10 EDs) and this peak lasted shorter. The results of this analysis show the relevance of the early exposure days for inhibitor development.

PB 1777 | Pocket Handheld Ultrasound Has High Accuracy in Identification of Effusions and Major Landmarks in Normal and Hemophilic Joints: Expanding Point of Care for Patients with Hemophilia with Joint Disease

J.Y. Zhou[1], K.C. Rappazzo[1], L. Volland[1], M. Brackman[1], B. Steiner[2], R. Kruse-Jarres[2], D.V. Quon[3], C. Bailey[3], E.Y. Chang[4], A. von Drygalski[1,5]

[1]University of California, San Diego, Division of Hematology/Oncology, Department of Medicine, La Jolla, United States, [2]Washington Center for Bleeding Disorders at BloodWorksNW, Seattle, United States, [3]Orthopaedic Hemophilia Treatment Center, Orthopaedic Institute for Children, Los Angeles, United States, [4]VA San Diego Healthcare System, Radiology Service, San Diego, United States, [5]The Scripps Research Institute, Department of Molecular Medicine, La Jolla, United States

Background: Point-of-care musculoskeletal ultrasound (MSKUS) has proven to be valuable for evaluation of hemarthroses. We previously introduced the concept of handheld devices as a cost-effective alternative to stationary MSKUS, finding high similarity between the two modalities on standard views.

Aims: To determine recognition accuracy and qualitative assessments of landmarks and effusions by different providers with handheld compared to stationary MSKUS devices.

Methods: Ten providers (6 physicians, 3 physical therapists and 1 nurse) trained in MSKUS were provided blinded readings of 144 scrambled joint MSKUS images (72 knee, 40 elbow and 32 ankle views). Parallel images were acquired from healthy volunteers and hemophilia patients at the same session with the handheld GE V2 scan and stationary Logiq S8. Providers were asked to identify landmarks and effusions and qualitatively describe osteochondral integrity, fat pad and other soft tissue characteristics. Adjudicators were a radiologist and a MSKUS experienced hematologist. Study procedures complied with the UCSD Human Research Protection Program.

Results: From 1440 responses analyzed, accurate recognition of major anatomic landmarks was on average 97.6% on handheld compared to 98.6% on stationary images. Correct recognition of effusions was 96.7% on handheld images compared to 99.1% on stationary images (Table 1). Discrepancy between various providers was minimal. There was great variability when interpreting more subtle soft tissue and osteochondral characteristics in the 820 qualitative assessments, most likely due to poorer image quality of the handheld device for these more detailed evaluations.

Conclusions: Notwithstanding limited depiction of soft tissue and osteochondral characteristics, handheld ultrasound devices have high accuracy for recognition of major anatomic landmarks and effusions, highlighting its potential clinical applicability for rapid diagnosis of hemarthroses, especially in resource-restricted settings and patient homes.

TABLE 1 Recognition of various structures on the handheld and stationary ultrasound images

	Bony (% correct)	Cartilage (% correct)	Meniscus (% correct)	Fat pad (% correct)	Effusion (% correct)	Other (soft tissue, bursa, artery) (% correct)
Handheld ultrasound images	97.3	98.2	98.8	97.0	96.7	98.6
Stationary MSKUS images	98.4	100	100	97.0	99.1	98.7

PB 1778 | Influence of Family History on Mode of Delivery in Severe Haemophilia in the UK

E. Chalmers[1], J. Alamelu[2], P. Collins[3], M. Mathias[4], J. Payne[5], M. Richards[6], O. Tunstall[7], M. Williams[8], B. Palmer[9], UKHCDO Paediatric Working Party

[1]Royal Hospital for Children, Haematology, Glasgow, United Kingdom, [2]Evelina London Children's Hospital, London, United Kingdom, [3]School of Medicine, Cardiff University, Cardiff, United Arab Emirates, [4]Great Ormond Hospital for Children NHS Trust Haemophilia Centre, London, United Kingdom, [5]Sheffield Childrens Hospital, Sheffield, United Kingdom, [6]Leeds Children's Hospital, Leeds, United Kingdom, [7]Bristol Royal Hospital for Children, Bristol, United Kingdom, [8]Birmingham Children's Hospital, Birmingham, United Kingdom, [9]National Haemophilia Database, UKHCDO, Manchester, United Kingdom

Background: The risk of intracranial haemorrhage (ICH) is significantly increased in neonates with severe haemophilia and is likely related to trauma at delivery. Whilst instrumental delivery is a well recognised risk factor and should be avoided, debate continues as to whether elective caesarean (CS) delivery is safer than spontaneous vaginal delivery (SVD). Where there is a family history of haemophilia this uncertainty may result in variation in practice.

Aims: To examine the influence of family history (FH) on MOD in severe haemophilia in children born in the UK from 2003-2015 and to assess whether this has changed over time.

Methods: Delivery data from 254 cases of severe haemophilia attending 6 comprehensive care centres was analysed to assess the influence of family history on MOD. Data from deliveries with a negative family history was also compared with data from NHS Maternity Statistics.

Results:

TABLE 1 Mode of Delivery

Mode of Delivery	NHS Maternity Statistics	FHx Negative (N=127)	FHx Positive (N=127)
SVD	343,979 (61%)	83 (65%)	59 (46%)
Instrumental	81,808 (13%)	15 (12%)	1 (1%)
CS - Elective	73,486 (12%)	15 (12%)	49 (39%)
CS - Emergency	92,595 (14%)	11 (9%)	16 (13%)
Unknown	0	3 (2%)	2 (1%)

In those with a negative family history of haemophilia, MOD was in keeping with national NHS Maternity Statistics. In severe haemophilia there was a significant difference in MOD between those with and without a known family history ($p < 0.0005$). In the presence of a positive family history there was a higher proportion of deliveries by elective caesarean section compared to vaginal deliveries. As expected in the positive family history group there were very few instrumental deliveries. Data on deliveries before and after 2010 demonstrate an increase in the proportion of elective caesarean deliveries from 25% prior to 2010, to 58% after 2010.

Conclusions: In the UK a positive family history of severe haemophilia is associated with a higher proportion of elective caesarean deliveries as compared to vaginal deliveries. This has been more marked in deliveries from 2010 onwards and has occurred despite continuing uncertainty on the safest mode of delivery.

PB 1779 | Inhibitor Development in Previously Untreated Patients Treated with Octocog Alfa (ADVATE)

A. Gringeri, K. Steinitz-Trost, H. Chehadeh

Shire plc, Vienna, Austria

Background: Contradicting evidence is available on inhibitor rates in previously untreated patients (PUPs) treated with recombinant or plasma-derived products.

Aims: The aim of this analysis is to review the inhibitor frequency reported in PUPs treated with octocog alfa (ADVATE).

Methods: The relevant clinical studies for ADVATE in PUPs were identified. These included clinical data contained in the marketing authorization file, as well as an internal meta-analysis and relevant investigator-driven studies from published literature. The identified studies were assessed individually for information regarding the frequency of inhibitor development considering the length of follow-up in exposure days (EDs), frequency of inhibitor testing, and known environmental and genetic risk factors for inhibitor development. Also the published data from the SIPPET study were included in this review.

Results: Inhibitor rates in clinical studies are reported in the table.

Conclusions: Inhibitor PUP studies of this FVIII product, even with very thorough monitoring and central lab testing, have never shown an incidence rate greater than 34%, with a pooled estimate incidence in PUPs with severe hemophilia A (FVIII < 1%) of 0.26 (95%CI 0.21-0.30).

TABLE 1

Study	Inhibitor rate in PUPs	Follow-up	Frequency of inhibitor testing	Risk factors
ADVATE PUP study (060103)	16/55 (29.1%)	Median EDs: 76 (min-max 1-414).	Every 5 EDs until the 20th ED and then every 10 EDs or every 3 months	53/55 with FVIII<1%. 17/55 w/ family history of inhibitor. 29/55 with intron 22 inversion. 47/55 were on on-demand.
EPIC study (061002)	6/19 (31.6%)	Early terminated	On EDs (±1 ED) 3, 6, 10, 15, 20, 30, 40, 50	19/19 with FVIII<1%. 12/19 with high risk gene mutation.
ADVATE PASS studies - meta-analysis	5/91 (5.5%) [a]	Median: 384 days	Variable, according to local clinical practice	Not available.
RODIN study	41/157 (28.2%)	75 EDs	In 92% of centers, after every 1 to 5 EDs during the first 20 EDs and every 3 months thereafter	157/157 with FVIII<1%. 22/157 w/ family history of inhibitors. 95/157 w/ high risk gene mutations. 40/157 with peak treatment. 46/157 were on on-demand tx.
FranceCoag study	33/97 (34.0%)	75 EDs	On average, every 6.3 EDs during the first 25 EDs and every 9.9 EDs during the overall follow-up period.	97/97 with FVIII<1%. 9/97 w/ family history of inhibitors. 31/97 had a peak treatment. 41/97 were on on-demand tx.
UKHCDO study	42/172 (24.4%)	75 EDs	Not available (guidelines: every fifth ED until 20 EDs and then less frequently)	172/172 with FVIII<1%. 103/172 with high risk mutations. 26/172 had a peak treatment.
EUHASS registry	13/59 (22.0%)	Not available	Not available	Not available
SIPPET study	13 on Advate. No. of inhibitors not available	Not available	Not available	13/13 with FVIII<1%
PUP inhibitor meta-analysis [b]	104/401 (26%)	Variable	Variable	401/401 with FVIII<1%

PB 1780 | Predictors of Patients with 0 Bleeds during Every-7-days Prophylaxis with BAY 94-9027 in PROTECT VIII

P.A. Holme[1], M. Wang[2], K. Saxena[2], J. Caicedo[2], L.A. Michaels[2], on behalf of the PROTECT VIII Investigators

[1]*Oslo University Hospital and Institute of Clinical Medicine, University of Oslo, Department of Haematology, Oslo, Norway,* [2]*Bayer, Whippany, United States*

Background: PROTECT VIII was a partially randomized, open-label, phase 2/3 trial that investigated the use of BAY 94-9027 for routine prophylaxis and treatment of bleeds in adolescents and adults with severe hemophilia A. Previously treated males aged 12–65 years with severe hemophilia A received BAY 94-9027 for 36 weeks on demand or as prophylaxis at intervals determined after a 10-week run-in period of 25 IU/kg 2x/wk BAY 94-9027 prophylaxis. Patients with ≤1 spontaneous joint or muscle bleed during the run-in were eligible for randomization to 45–60 IU/kg prophylaxis every 5th day or 60 IU/kg every 7th day for 26 weeks (weeks 11-36). As shown in PROTECT VIII, 60 IU/kg BAY 94-9027 every 7th day is feasible and generally well tolerated in select patients (*J Thromb Haemost* 2016:Epub).

Aims: To identify clinical predictors for an annualized bleeding rate (ABR) of 0 during every-7-days prophylaxis with BAY 94-9027 in PROTECT VIII.

Methods: In this post hoc analysis, best responders were defined as patients with an ABR of 0 who did not discontinue or change dosing frequency during weeks 11–36.

Results: In PROTECT VIII, 43 patients were randomized to every-7-days prophylaxis. Of these 43 patients, 11 switched to more frequent dosing after a mean ± SD of 84±38 days (range, 22-131). Sixteen of 32 patients (50%) who remained on every-7-days prophylaxis had 0 bleeds; 15 patients were responders with an ABR of 0. Responders receiving every-7-days prophylaxis who had an ABR of 0 during weeks 11-36 had fewer total and joint bleeds in the 12-month period before study entry and fewer target joints at baseline compared with patients who switched from every-7-days prophylaxis to more frequent dosing **(Table)**. Most or all patients were previously treated with prophylaxis in both groups.

TABLE Baseline Characteristics of Patients Who Received BAY 94-9027 Prophylaxis Every 7 Days

	Responders With ABR of 0 During Every-7-Days Prophylaxis (n=15)*	Patients Who Switched From Every-7-Days to More Frequent Prophylaxis (n=11)	All Patients Receiving Every-7-Days Prophylaxis (n=43)
Age, y, median (Q1; Q3)	31.0 (26.0; 52.0)	38.0 (36.0; 47.0)	37.0 (26.0; 50.0)
Number of bleeds in the last 12 months, median (Q1; Q3)	2.0 (0; 11.0)	3.5 (2.0; 6.0)†	3.0 (1.0; 9.0)
Number of joint bleeds in the last 12 months, median (Q1; Q3)	1.0 (0; 11.0)	2.0 (1.0; 5.0)†	2.0 (0; 8.0)
Presence of target joint, n (%)	10 (66.7)	9 (81.8)	31 (72.1)
Number of target joints per patient, median (Q1; Q3)	1.0 (0.0; 3.0)	2.0 (1.0; 4.0)	2.0 (0.0; 3.0)
Previous prophylaxis treatment, n (%)	13 (86.7)	11 (100)	38 (88.4)

*16 patients who remained on every-7-days prophylaxis had 0 bleeds; 1 patient treated every 7 days discontinued from the study early with 0 bleeds recorded and was not included in the responder group. †Calculated from 10 patients with available data. ABR=annualized bleeding rate.

Conclusions: Number of previous bleeds in the immediate prior 12-month period and number of target joints may be used to identify patients who may benefit and could expect low spontaneous bleeding rates from once-weekly prophylaxis with BAY 94-9027.

PB 1781 | Individualizing Hemophilia Prophylaxis using Thromboelastography (TEG)

R. Carmona, H.S. Lee, E. Marquez, G. Young

Children's Hospital Los Angeles, University of Southern California Keck School of Medicine, Los Angeles, United States

Background: Prophylaxis is the standard of care approach to prevent bleeding/joint disease in severe hemophilia. Individualized dosing, when attempted, is based on factor levels and ignores other components of the coagulation system that vary between individuals. Global hemostasis assays have been studied in hemophilia patients, but these tests have not been used to guide prophylactic dosing regimens.
Aims: To utilize TEG to individualize prophylaxis regimens in patients with severe hemophilia A.
Methods: Subjects on prophylaxis who signed informed consent to participate in an IRB-approved institutionally-funded study were enrolled. All subjects were on standard half-life rFVIII concentrates. After appropriate washout, each subject had kaolin-activated TEG and FVIII PK sampling (pre-dose, peak, and q24 hours) until they reached a predetermined TEG endpoint as follows: when a subject's R time was within 20% of their abnormally prolonged baseline (signifying insufficient clotting activity), they were required to redose. Patients whose prophylaxis regimen was extended beyond their previous regimen were followed for 6 months to monitor for bleeding events.
Results: 18 subjects enrolled (5 withdrew prior to PK testing due to the time commitment), 1 withdrew after declining to extend his dosing interval per his PK results leaving 12. Of these, 10 had their dosing regimen extended (7 to every 72 hours and 3 to every 96 hours) and 7 have completed the study and remained on their extended regimen. Two are still in the follow up period and 1 had a second spontaneous bleed within 28 days before reaching 6 months and was thus considered a failure and resumed his pre-study dosing regimen. See table for data including bleeding in the 9 subjects that did not reach this endpoint.

TABLE 1 Study summary for the subjects who had their dosing frequency extended

Subject ID	Age	Factor	Dose (IU/kg)	Previous prophylaxis regimen	Study dosing regimen	Spontaneous bleeds during the follow up period (6 months)	Completed 6 month follow up	Continued study extended dosing regimen
HTI 3	12	Helixate	35	3 x per week	every 72 hours	2	Yes	Yes
HTI 4	14	Helixate	40	3 x per week	every 96 hours	0	Yes	Yes
HTI 7	17	Advate	35	3 x per week	every 72 hours	0	Yes	Yes
HTI10	5	Advate	50	2 x week	every 72 hours	0	Yes	Yes
HTI 13	12	Advate	40	every other day	every 96 hours	1	Yes	Yes
HTI 14	8	Helixate	45	every other day	every 72 hours	0	Yes	Yes
HTI 15	5	Advate	50	3 x per week	every 72 hours	0	Yes	Yes
HTI 17	9	Advate	30	3 x per week	every 72 hours	0	Ongoing	N/A
HTI 18	23	Advate	35	3 x per week	every 72 hours	1	Ongoing	N/A

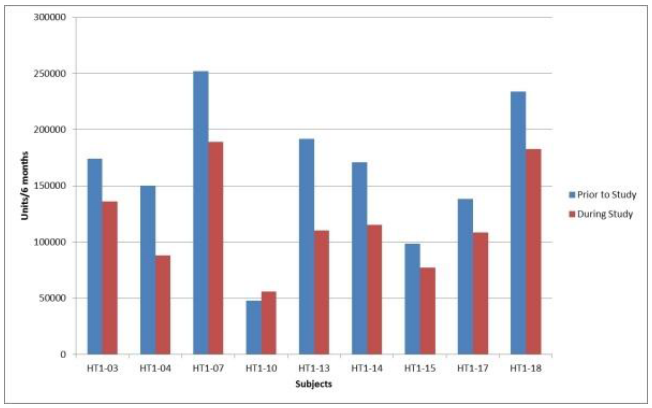

FIGURE 1 Factor consumption pre- and post-regimen adjustment

As a result of the less frequent dosing regimen, overall factor consumption decreased.

Conclusions: These results suggest that TEG is a promising tool which can be used to bring a personalized approached to prophylactic factor therapy in hemophilia.

PB 1782 | Impact of a Product-Specific Reference Standard for the Measurement of a PEGylated rFVIII Activity: The Swiss Multicentre Field Study

O. Bulla[1], A. Poncet[1], L. Alberio[2], L. Asmis[3], A. Gähler[4], L. Graf[5], M. Nagler[6], J.-D. Studt[7], D. Tsakiris[8], P. Fontana[1]

[1]*University Hospitals of Geneva, Geneva, Switzerland,* [2]*University Hospital of Lausanne, Lausanne, Switzerland,* [3]*Center for Perioperative Thrombosis and Haemostasis and Unilabs Coagulation Laboratory, Zürich, Switzerland,* [4]*Lucerne Cantonal Hospital, Lucerne, Switzerland,* [5]*Haemostasis and Haemophilia Centre St Gallen, St Gallen, Switzerland,* [6]*Inselspital University Hospital, Bern, Switzerland,* [7]*University Hospital Zürich, Zürich, Switzerland,* [8]*University Hospital Basel, Basel, Switzerland*

Background: Measuring factor VIII (FVIII) activity can be challenging when it has been modified, such as when FVIII is pegylated to increase its circulating half-life. Use of a product-specific reference standard may help avoid this issue.

Aims: Evaluate the impact of using a product-specific reference standard for measuring the FVIII activity of BAX 855 — a pegylated FVIII — in eight of Switzerland's main laboratories.

Methods: FVIII-deficient plasma, spiked with 5 different concentrations of BAX 855, plus a control FVIII sample, were sent to the participating laboratories. They measured FVIII activity by using either with a one-stage (OSA) or two-stage assay (TSA) against their local or a product-specific reference standard.

Results: When using a local reference standard, there was an overestimation of BAX 855 activity compared to the target concentrations, both with the OSA and TSA. The use of a product-specific reference standard reduced this effect: mean recovery ranged from 127.7% to 213.5% using the OSA with local reference standards, compared to 110% to 183.8% with a product-specific reference standard; and from 146.3% to 182.4% using the TSA with local reference standards compared to 72.7% to 103.7% with a product-specific reference standard.

Conclusions: In this *in vitro* study, the type of reference standard had a major impact on the measurement of BAX 855 activity. Evaluation was more accurate and precise when using a product-specific reference standard.

PB 1783 | Long-term Quality-of-Life Outcomes with rFVIIIFc Prophylaxis in Adult Subjects with Severe Hemophilia A

J. Su[1], E. Tsao[1], J. Feng[1], K.-J. Myren[2], D. Glazebrook[1]

[1]*Bioverativ, Waltham, MA, United States,* [2]*Sobi, Stockholm, Sweden*

Background: Long-term quality-of-life (QOL) effects of rFVIIIFc are being evaluated in the A-LONG clinical trial and ongoing ASPIRE extension study of subjects with severe hemophilia A.

Aims: To present longitudinal QOL data from Hemophilia A subjects at A-LONG study entry through the third ASPIRE interim data cut.

Methods: Subjects were evaluated using the Haem-A-QOL patient-reported outcome. QOL outcomes were analyzed over the duration of the A-LONG study and the third ASPIRE interim data cut (11 Jan 2016) for subjects who had Haem-A-QOL total score change from baseline through ASPIRE month 24. Last observation carried forward imputed missing data. Within-group t-tests compared mean change over time on Haem-A-QOL total score and sub-domain scores.

Results: Out of 105 A-LONG prophylaxis subjects (age≥17) with baseline Haem-A-QOL score, 80 subjects had total change scores from baseline to ASPIRE month 24 (mean age 35, SD 11.4). The sample included 52 patients on prophylaxis prior to trial enrollment and 28 on on-demand regimen. Patients were from North America (34%), Europe (25%), and other continents (41%), and included 69% White, 24% Asian, 4% African-American, and 4% other. Most (66%) had target joint bleeding at baseline and the median pre-study annualized bleeding rate was 13.5 (IQR 4, 30). The sample exhibited improved QOL from A-LONG baseline to ASPIRE baseline (median follow-up 7.2 months, IQR 6.5-8.3), with a mean change of 4.6 ($p< 0.01$). These overall QOL improvements were maintained over 24 months of follow-up ($p< 0.01$). An examination of the sub-domain scores over time suggested that the most pronounced improvements were in Physical Health, Sports and Leisure, and Feeling.

Conclusions: Subjects treated with rFVIIIFc reported significant QOL improvements that were maintained for 24 months of follow-up. The biggest QOL gains reflected Physical Health, Sports and Leisure, and Feeling sub-domains assessed by the Haem-A-QOL.

PB 1784 | Bleeding Events and Safety Outcomes in Persons with Hemophilia A (PwHA) with Inhibitors: The First Large, Prospective, Multicenter, Non-interventional Study (NIS) from a Real World Setting

J. Mahlangu[1], J. Oldenburg[2], M. Callaghan[3], M. Shima[4], E. Santagostino[5], M. Moore[6], M. Recht[7], C. Garcia[8], R. Yang[9], M. Lehle[10], H. Macharia[10], E. Asikanius[10], G. Levy[11], R. Kruse-Jarres[6]

[1]*Haemophilia Comprehensive Care Centre, Faculty of Health Sciences, University of the Witwatersrand and NHLS, Molecular Medicine and Haematology, Johannesburg, South Africa,* [2]*University Bonn, Institute of Experimental Haematology and Transfusion Medicine, Bonn, Germany,* [3]*Children's Hospital of Michigan, Detroit, United States,* [4]*Nara Medical University, Department of Pediatrics, Kashihara, Japan,* [5]*IRCCS Ca' Granda Foundation, Ospedale Maggiore Policlinico, Milan, Italy,* [6]*Bloodworks Northwest, Seattle, United States,* [7]*Oregon Health & Science University, Portland, United States,* [8]*Hospital Mexico, Haematology Department, San Jose, Costa Rica,* [9]*Institute of Hematology and Blood Diseases Hospital, Chinese Academy of Medical Sciences, Tianjin, China,* [10]*F. Hoffmann-La Roche Ltd, Basel, Switzerland,* [11]*Genentech Inc., South San Francisco, United States*

Background: Management of PwHA and anti-FVIII neutralizing antibodies (inhibitors) (PwHAwI) remains an unmet need, with only two bypassing agents (BPAs; aPCC and rFVIIa) available for bleed control/prevention. Emicizumab, a bispecific humanized monoclonal antibody, bridges FIXa and FX to promote coagulation by replacing the function of missing FVIII, and is being developed to treat/prevent bleeds in PwHA with/without inhibitors. This global NIS was designed to assess real-world data (RWD) on bleed rates and treatment (tx) in PwHA, understand disease behavior, and enhance clinical development of emicizumab. The NIS previously showed high annualized bleed rates (ABRs) with episodic and prophylactic BPAs, and a high proportion of bleeds in PwHAwI were not treated (42.7%).

Aims: Present additional prospective RWD on bleed and safety outcomes in PwHAwI, including BPA tx exposure and purpose, from a multicenter NIS prior to rollover to a Phase 3 emicizumab study (NCT02622321). Results by country will be presented for all/treated bleeds and prophylaxis compliance.

Methods: Inclusion criteria: ≥12 y.o. with congenital HA and high-titer FVIII inhibitor history (≥5 Bethesda units/mL); signed informed consent/assent; coagulation product use ≥6 mo.; ≥6 or ≥2 bleeds on episodic or prophylactic tx in last 6 mo., respectively.

Results: 103 PwHAwI on episodic (n=75) or prophylactic (n=28) regimens enrolled from 12 countries; median (range) age, 31 (12-75) years. Coagulation product (episodic and prophylaxis, respectively) was used in 93.3 and 100% of pts; most common, aPCC in 75.7% of all pts-70.7 and 82.1% of pts for bleeds, and 6.7 and 82.1% of pts for usual prophylaxis (**Tables 1-2**).

TABLE 1 Exposure to hemophilia treatments

Regimen	Episodic (n=75)	Prophylaxis (n=28)	All patients (N=103)
aPCC exposed patients (%)	70.7	89.3	75.7
aPCC median number of doses/ median cumulative dose, unit	11 / 34,000	70 / 332,278	20 / 94,029
rFVIIa exposed patients (%)	45.3	39.3	43.7
rFVIIa median number of doses/ median cumulative dose, ug	15 / 112,515	14 / 84,000	14 / 110,030
FVIII exposed patients (%)	4.0	17.9	7.8
FVIII median number of doses/ median cumulative dose, unit	46 / 64,000	67 /137,000	52 / 110,125
DDAVP (intravenous) / Cryoprecipitate/Fresh frozen plasma or whole blood, exposed patients (%)	6.7	0	6.7

Median cumulative dose reported is based on exposure during the NIS

TABLE 2 Purpose of hemophilia treatment

	Episodic (n=75)		Prophylaxis (n=28)		All patients (N=103)	
Hemophilia Medications	% patients who reported use as treatment for bleed*	% patients who reported use as usual prophylaxis*	% patients who reported use as treatment for bleed*	% patients who reported use as usual prophylaxis*	% patients who reported use as treatment for bleed*	% patients who reported use as usual prophylaxis*
aPCC	70.7	6.7	82.1	82.1	73.8	27.2
rFVIIa	45.3	4.0	28.6	25.0	40.8	9.7
FVIII[†]	4.0	0	10.7	17.9	5.8	4.9
DDAVP (intravenous) [‡]	1.3	0[§]	0	0	1.0	0
Cryoprecipitate	1.3	0[§]	0	0	1.0	0
Fresh frozen plasma or whole blood	1.3	0	0	0	1.0	0

*Collected through bleed/medication questionnaire completed by patient/legal guardian via an electronic handheld device. [†] No patients received FVIII long acting treatment. [‡]No patients received DDAVP intranasal treatment. [§]1 patient in the episodic arm received one-time prophylaxis.

Conclusions: Global RWD on coagulation product use show remaining high ABR, proportion of untreated bleeds, factor consumption, and median number of infusions, and therefore a high unmet need for more efficient and easy to use HA tx. Upcoming results will offer new insight on the management of PwHAwI by country.

PB 1785 | Disparities in Age at Diagnosis and Initial Treatment between People with Moderate and Severe Haemophilia A: Evidence from the KAPPA Register

M. Osooli[1], F. Sahin[2], Y. Walli[3], C. Ar[4], P. Holme[5], S. Saulyte-Trakymiene[6], L. Hvitfeldt[7], M. Holmström[8], E. Gouider[9], A. Khelif[10], O. Kassar[11], S. Rauchensteiner[12], K. Steen Carlsson[13], J. Astermark[14], E. Berntorp[14], KAPPA Register Study

[1]Lund University - Centre for Thrombosis and Haemostasis - Skane University Hospital, Malmö, Sweden, [2]Ege University Hospital, Izmir, Turkey, [3]Sultan Qaboos University Hospital, Muscat, Oman, [4]Istanbul University Cerrahpasa, Dept. Hematology Ege Hemophilia Center, Istanbul, Turkey, [5]Oslo University Hospital, Oslo, Norway, [6]Vilnius University Hospital, Vilnus, Lithuania, [7]Aarhus University Hospital, Aarhus, Denmark, [8]Karolinska University Hospital, Stockholm, Sweden, [9]Aziza Othmana Hospital, Tunis, Tunisia, [10]Farhat Hached University Hospital, Sousse, Tunisia, [11]University Hospital Hedi Chaker, Sfax, Tunisia, [12]Bayer Healthcare, Basel, Switzerland, [13]Lund University, Lund, Sweden, [14]Lund University - Centre for Thrombosis and Haemostasis – Skane University Hospital, Malmö, Sweden

Background: Early diagnosis and treatment for haemophilia are critical for maintaining healthy joints and optimal health related quality of life (HRQL). Recent studies have indicated that people with moderate haemophilia also suffer from arthropathy and reduced HRQL. Thus, delay in diagnosis and treatment may alter outcome in moderate haemophilia as well.

Aims: To compare the initial event/cause that led to the diagnosis and ages at first diagnosis and treatment between people with moderate and severe haemophilia A.

Methods: Eligible people with moderate (factor VIII [FVIII]: 1-5 kIU/L) to severe (FVIII: < 1 kIU/L) haemophilia A were included in this study from the KAPPA international register. Participants signed an informed consent prior to enrollment between 2013 and 2016. Chi-square tests, linear regression and Kaplan-Meier estimates were used for data analysis. The Regional Ethical Review Board of Lund University approved the study protocol.

Results: Overall, 94 (17.3%) participants with moderate and 449 (82.7%) with severe haemophilia A were included (Table 1). Median (inter-quartile range: IQR) age was 28 (IQR: 16-43) and 24 (IQR: 11-36) years for people with moderate and severe haemophilia, respectively. Participants with moderate haemophilia got diagnosed and received treatment 2.5 (95% CI: 1.1 - 3.9) and 2.7 (95% CI: 1.1 - 4.3) years later compared to those with severe haemophilia, respectively (Figure 1). The reason for evaluation for haemophilia was more often bleeding events (67.1 vs. 55.0%) and medial/surgical procedures (11.7 vs. 6.2%) in moderate versus severe haemophilia A.

TABLE 1 Characteristics of participants haemophilia severity

	Moderate, n(%)	Severe, n(%)	P
Country of residence			0.053
Nordic*	16 (17.0)	119 (26.5)	
Non-nordic**	78 (83.0)	330 (73.5)	
Reason for diagnosis			0.008
Family investigation	10 (10.6)	91 (20.3)	
Bleeding events	63 (67.1)	247 (55.0)	
Medical/surgical procedures	11 (11.7)	28 (6.2)	
Unknown	10 (10.6)	83 (18.5)	

* Denmark, Norway, Sweden

** Lithuania, Oman, Tunisia, Turkey and United Arab Emirates

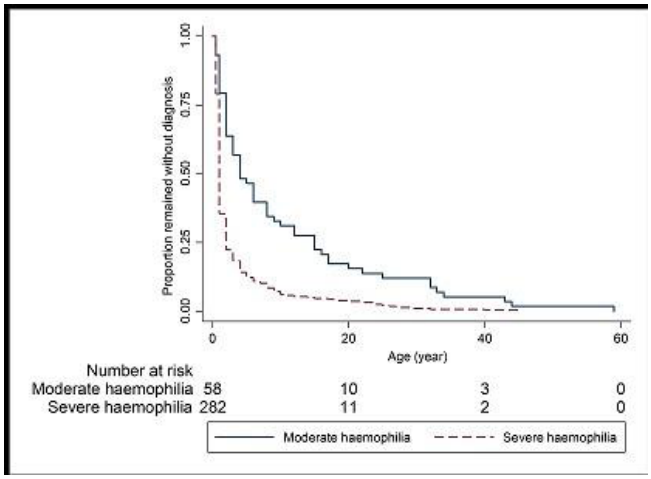

FIGURE 1 Kaplan-Meier estimates of the age at first treatment among people with moderate and those with severe haemophilia A

Conclusions: The majority of participants with moderate haemophilia A received diagnosis and treatment prior to age 5, however later than those with severe haemophilia. Information on early bleeding symptoms likely reflects severity of the bleeding phenotype and can help in planning an optimized long-term treatment strategy for people with moderate haemophilia A to improve their long-term outcomes.

PB 1786 | Low Dose Prophylaxis for Children With Haemophilia - One Year Experience from a Haemophilia Comprehensive Treatment Centre, Kerala, India

N. Sidharthan[1], R. Sudevan[2], V. Narayana Pillai[3], S. Mathew[3], M. Raj[4], D. Viswam[3], C. Joseph[3], A. Sudhakar[4]

[1]Amrita Institute of Medical Sciences, Amrita University, Hematology/Oncology, Kochi, India, [2]Amrita Institute of Medical Sciences, Amrita University, Public Health Research, Kochi, India, [3]Hemophilia Treatment Centre Aluva, Kochi, India, [4]Amrita Institute of Medical Sciences, Amrita University, Kochi, India

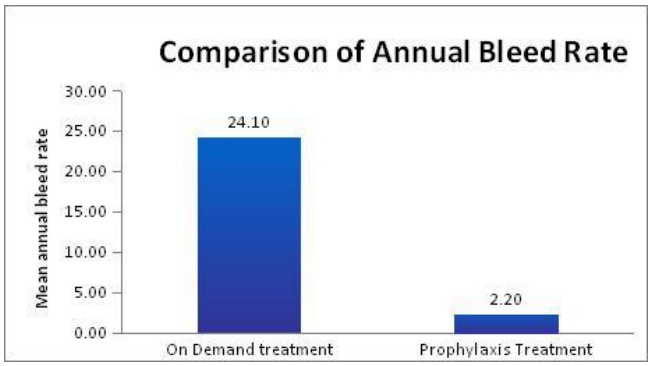

FIGURE 1 Comparison of annual bleed rate

Background: Haemophilia is currently the most effectively and safely treated monogenic inherited disorder in developed nations. Prophylaxis for Haemophilia is a challenge in low and middle income countries due to resource limitations and cost barriers.

Aims: To compare the clinical outcomes of On demand therapy (ODT) and Prophylactic therapy (PT) in children with Haemophilia.

Methods: Ten children with severe Haemophilia A (n=7) and severe Haemophilia B(n=3) under the age group of 5-15years with clotting factor concentrate(CFC) level < 1% were started with low dose plasma derived CFC prophylaxis . All were inhibitor negative with mean exposure of 36.45 days. The dosage was 10-20 IU/kg twice weekly for Haemophilia A and 25-40 IU/Kg once weekly for Haemophilia B. During ODT children received CFC in standard recommended doses. The data collection period was 18 months (6 months retrospectively for ODT and 12 months prospectively for PT).

Results: The mean consumption of CFCs for ODT & PT were 608.49 and 1661.34 IU/kg/year .The cost of CFCs during ODT and PT were USD 1841.16 & 5436.36/person/year respectively. A significant reduction in annual bleed rate was seen from the transition of ODT to PT (24.10 vs 2.20, p < 0.001)(Fig 1) . Similar reductions were observed for number of days of hospital visits/stays (27.40 vs 2.60, p 0.005) (Fig 2) and school absenteeism (52.40 vs 1.40, p 0.008) respectively. The changes in Haemophilia Joint Health Score (HJHS, 4.60 vs 1.45, p 0.08) and Functional Independent score in Haemophilia (FISH, 28.50 vs 31.70, p 0.10) were not significant. Inhibitors were absent for all children throughout the period.

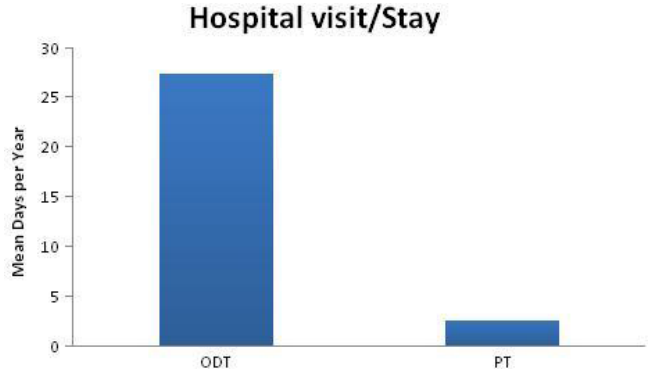

FIGURE 2 Comparison of days of hospital stay/visit

Conclusions: Low dose prophylaxis for severe Haemophilia has clinical benefits and is feasible in resource poor countries. This should be considered as a treatment strategy for severe haemophilia in the developing world.

PB 1787 | Final Results from the PUP-GCP Clinical Trial: A Low Inhibitor Rate in Previously Untreated Patients with Severe Haemophilia A Treated with Octanate

A. Klukowska[1], M. Jansen[2], V. Komrska[3], V. Vdovin[4], L. Belyanskaya[5], S. Lowndes[5], P. Laguna[1]

[1]*Warsaw Medical University, Department of Paediatrics, Haematology and Oncology, Warsaw, Poland,* [2]*Octapharma Produktionsgesellschaft mbH, Vienna, Austria,* [3]*University Hospital Motol, Department of Pediatric Haematology and Oncology, Prague, Czech Republic,* [4]*Morozovskaya Children's Hospital, Moscow, Russian Federation,* [5]*Octapharma AG, Lachen, Switzerland*

Background: Octanate is a human plasma-derived, von Willebrand factor (VWF) -stabilised coagulation factor VIII (FVIII) concentrate which demonstrated haemostatic efficacy in previously treated patients (PTPs) with haemophilia A.

Aims: To assess immunogenicity in previously untreated patients (PUPs), 50 PUPs with severe HA in an open, prospective, multi-national GCP study for an observation time of 100 exposure days, or for maximum 5 years.

Methods: Patients with severe HA without previous exposure to any FVIII or FVIII-containing products were enrolled. Efficacy and tolerability were assessed. Inhibitor assay, according to modified Bethesda method, was frequently tested: at screening, prior to first exposure to Octanate, every 3-4 exposure days (ED 1-20), and afterwards every 10 EDs (ED 21-100), at least every 3 months.

Results: Patients were followed for a mean of 2.8 years (136-2387 days). More than 7,000 EDs were documented. Five (9.8%) of the 51 patients developed inhibitors during the study, 4 of which (7.8%) were high-titre. Of these, 3 (5.9%) were considered to be clinically relevant (those affecting FVIII therapy); other 2 were transient inhibitors that disappeared during regular unchanged Octanate treatment. All clinically relevant inhibitors developed under on-demand treatment and before ED 20. Patients who developed inhibitors had either intron 22 inversions or large deletions. Octanate was well-tolerated and the adverse event profile was consistent with the population studied. The hemostatic efficacy in prophylaxis and treatment of bleeding episodes was generally rated as "excellent".

Conclusions: The data indicate a low overall inhibitor rate for Octanate in PUPs. Five out of 51 patients (9.8%) developed inhibitors, of which 3 (5.9%) were clinically relevant. The data are furthermore consistent with findings in PTPs demonstrating that Octanate is an efficacious and well-tolerated human FVIII for patients with HA.

PB 1788 | Intracranial Hemorrhage in Hemophilia Patients: The Status of Ongoing Retrospective-Prospective Italian Registry (2009-2016)

E. Zanon[1], F. Demartis[2], A. Tagliaferri[3], P. Schinco[4], I. Cantori[5], M. Milan[1], A.C. Molinari[6], C. Biasoli[7], A. Coppola[8], G. Castaman[2], M. Luciani[9], G. Sottilotta[10], E. Santagostino[11]

[1]University Hospital Padua, Hemophilia Center, Padua, Italy, [2]'Careggi' University Hospital, Hemophilia Center, Florence, Italy, [3]Hospital of Parma, Hemophilia Center, Parma, Italy, [4]'Molinette' Hospital, Turin, Italy, [5]Hospital of Macerata, Macerata, Italy, [6]'Gaslini' Hospital, Genova, Italy, [7]Hospital of Cesena, Hemophilia Center, Cesena, Italy, [8]University of Neaples ,Federico II', Hemophilia Center, Neaples, Italy, [9]'Bambin Gesù' Hospital, Rome, Italy, [10]Hospital of Reggio Calabria, Reggio Calabria, Italy, [11]University of Milan, Hemophilia Center, Milan, Italy

Background: .Intracranial hemorrhage (ICH) is the most serious event in patients with hemophilia (PWHs) which leads to disability and in some cases to death. ICH is more frequent in children < 2 years and in adults >50 years. Severe hemophilia and inhibitors proved to be the major risk factor for ICH in PWHs.

Aims: To evaluate incidence, mortality, management and risk factors for ICH.

Methods: From Jan 2009 to Nov 2016 we retrospectively and prospectively (from Nov 2012) collected all ICHs occurred in the PWHs treated in Italian Hemophilia Centers. Clinical features of PWHs, data of ICH management and outcomes were evaluated ctor for ICH in PWHs.

Results: 29 ICH events were found in 4630 PWHs. ABR was 0.89 per 1000 patients. 6 ICHs occurred in children ≤2 yrs (none of the children was on prophylaxis), one in a 4-year-old child during immune-tolerance induction and the remaining 22 in PWHs ≥40 yrs, 50% of whom affected by mild hemophilia. Mean age of adults was 52.7 yrs (± 17.4), 81.8% were treated only on-demand, 42.8% of severe patients were on prophylaxis. 2/22 had inhibitors, 13/22 adults suffered from hypertension, 2 were obese, one had diabetes, 2 hyperlipidemia and one was affected by chronic renal failure. In 51.7% of PWHs, ICH was spontaneous. Surgery was required in 10/29 patients for cerebral hematoma evacuation. 62,1% of patients were treated with FVIII/FIX concentrates or rFVIIa for a mean of 31.7 days (± 5.5), while 37.9% subjects died before starting or during treatment. In all survivors prophylaxis was then continued either lifelong (72.7%) or for 4-6 months (27.3%). 44.4% of survivors became permanently disable.

Conclusions: Up to today the results obtained confirm high incidence of ICH in children ≤2 yrs and in adults ≥40 yrs with hypertension. High incidence was also found in mild hemophilia patients usually considered at very low risk for spontaneous bleeding. 81% of patients were treated on-demand, which indicates the important role of prophylaxis in preventing ICH.

PB 1789 | Evaluation of Outcomes from Long-term Prophylaxis or Episodic Treatment of Patients with Haemophilia A: A Systematic Review

J. O'Hara[1], C. Sima[2], J. Frimpter[3], F. Paliargues[4], P. Chu[4], I. Presch[4]

[1]HCD Economics, Daresbury, United Kingdom, [2]Genentech, a member of the Roche Group, South San Francisco, United States, [3]Health Interactions/NucleusX Market Access, San Francisco, United States, [4]F. Hoffmann-La Roche Ltd, Basel, Switzerland

Background: While short-term efficacy of episodic and prophylactic treatments for haemophilia A (HA) is well documented, there is a need to better understand long-term outcomes of existing treatment strategies in real-world clinical practice.

Aims: To evaluate clinical and humanistic outcomes from long-term prophylaxis or episodic treatment of HA.

Methods: A systematic literature review was conducted using EMBASE, MEDLINE and conference abstracts. Eligible studies were published in English between January 1, 2006 and December 15, 2016. Studies reporting at least 5 years of follow-up for patients with HA receiving prophylaxis and/or episodic treatment were included.

Results: Seventeen studies from 18 publications met the inclusion criteria with 15/17 (88%) including children. Of these, we qualitatively assessed characteristics and outcomes from 9 studies reporting all bleeding events (n=5 studies), joint bleeds (n=6), joint health (n=7), health-related quality of life (HRQoL, n=6) or burden (n=3). Seven studies were limited to severe HA (FVIII < 1%) and 5 to patients without inhibitors. Median follow-up ranged from 5.3-20.3 years. Mean annual bleeding rates ranged from 2.6-11.7 for prophylaxis and from 12.0-33.4 for episodic treatment. Mean annual hemarthrosis episodes ranged from 0.5-3.4 and 13.7-16.6, respectively. Prophylaxis patients had higher HRQoL overall and for several subdomains across studies, missed fewer days from school/work and had greater functional independence. All results were consistent across studies examining subgroups based on prior treatment exposure, age (adults and children), and the effects of switching between prophylaxis and episodic regimens.

Conclusions: Prophylaxis, whose short-term benefits on bleed control are well-documented, conferred better long-term outcomes including fewer bleeding episodes, better joint health and better quality of life. Results from real-world studies suggest higher bleeding rates than clinical studies and remaining unmet needs for long-term management of HA.

PB 1790 | Comparison of the Relationship between Factor IX Activity and Bleeding Risk during Prophylaxis with Nonacog Beta Pegol (N9-GP)

G. Young[1], W.H.O. Clausen[2], C. Négrier[3], B.B. Rønn[2], E. Santagostino[4], J. Oldenburg[5]

[1]University of Southern California Keck School of Medicine, Hemostasis and Thrombosis Center Children's Hospital, Los Angeles, United States, [2]Novo Nordisk A/S, Søborg, Denmark, [3]Hôpital Louis Pradel, Hemophilia Comprehensive Care Center and Hematology Department, Lyon, France, [4]IRCCS Foundation Cà Granda Hospital, Maggiore Hospital Policlinic, Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Milan, Italy, [5]University Clinic Bonn, Institute of Experimental Haematology and Transfusion Medicine, Bonn, Germany

Background: N9-GP (recombinant glycoPEGylated FIX with an extended half-life) has been developed to prevent and treat bleeds in haemophilia B with less frequent dosing and achieve higher FIX activity levels compared to non-modified FIX products. Safety and efficacy of N9-GP for prophylaxis (PPX) and treatment of bleeds were investigated in paradigm™2, the pivotal, multicentre, single-blind, non-controlled, randomised, phase 3 trial.

Aims: To evaluate the impact of FIX activity profile on bleeding risk in patients receiving once-weekly N9-GP PPX, taking N9-GP dose level and time since last dose into consideration.

Methods: Male patients aged 13-70 years with haemophilia B (FIX activity ≤2%) were randomised 1:1 to receive 10 or 40 IU/kg once-weekly N9-GP PPX for 52 weeks. *Post-hoc* analysis compared annualised bleeding rates (ABR) for each arm. FIX activity was assessed at steady-state in a subset of patients (n=59). Bleeding risk by time since last dose was analysed using Cox regression, including regimen and shared frailty to account for within patient correlation.

Results: Estimated ABR for patients in the 40 IU/kg arm was 49% lower versus the 10 IU/kg arm (p=0.033, Table 1). For all bleeds, the instantaneous bleeding risk by time since last dose was 1.93 times higher in the 10 IU/kg arm versus the 40 IU/kg arm (p=0.0123), and 2.72 times higher for spontaneous bleeds (p=0.0143, Table 2). The peak FIX activity at steady-state ranges were 0.72-1.44 IU/ml and 0.23-0.55 IU/ml for 40 and 10 IU/kg, respectively; while the steady state trough ranges were 0.25-0.43 IU/ml and 0.06-0.20 IU/ml. Lower bleeding risk appears to be associated with higher FIX activity, in favour of 40 IU/kg.

Conclusions: Patients achieved greater prophylactic protection with 40 IU/kg N9-GP once-weekly dosing than 10 IU/kg. Achieving close to physiological FIX activity levels for extended time periods could be important in delaying the progression of underlying joint disease for patients with haemophilia B.

Acknowledgements: The authors acknowledge the data analysis contributions of Judi Møss and Silke Ehrenforth (Novo Nordisk employees).

TABLE 1

Table 1. ABR by prophylaxis dose

	Prophylaxis		
	10 IU/kg	40 IU/kg	Both
Number of patients	30	29	59
Number of patients with bleeds, N (%)	25 (83.3)	16 (55.2)	41 (69.5)
Number of bleeds	132	70	202
Bleeds per patient (min; max)	0.0; 17.0	0.0; 17.0	0.0; 17.0
Mean treatment period (years)	0.97	0.96	0.96
Individual ABRs			
N	30	29	59
Median	2.93	1.04	2.04
Interquartile range	0.99; 6.02	0.00; 4.00	0.00; 5.00
Poisson estimate of ABR	4.56	2.51	3.55
95% CI	3.01; 6.90	1.42; 4.43	2.53; 4.98
p-value*	0.402	0.013	0.040
Estimated ABR reduction (adjusted)**			
40 IU/kg versus 10 IU/kg	–	–	0.49
95% CI	–	–	0.05; 0.73
p-value***	–	–	0.033

ABR, annualised bleeding rate; CI, confidence intervals.
ABR estimates based on a Poisson regression model with dose as a factor allowing for over-dispersion and using treatment duration as an offset.
*p-values are from the one-sided test of the null hypothesis that the ABR is at least 4.8 evaluated at the 2.5% level.
**Reduction: 1–ABR relative risk. Adjusted estimates are based on a model with covariate adjustment for prior treatment and historical ABR. The adjusted estimates exclude two patients on 10 IU/kg who are missing their historical ABR. Positive values indicate a decrease in bleeding rate and negative values indicate an increase.
***A two-sided test of the null hypothesis that there is no difference between the two doses evaluated at the 5% level.

TABLE 2

Table 2. Hazard ratio of bleeds by time since last N9-GP dose – for all dosing intervals

	Prophylaxis 10 IU/kg versus 40 IU/kg
All bleeds	
Hazard ratio	1.93
p-value	0.0123
Spontaneous bleeds	
Hazard ratio	2.72
p-value	0.0143
Traumatic bleeds	
Hazard ratio	1.15
p-value	0.4205

The cumulative hazard of bleed versus time since last administered dose was estimated in a Cox-proportional hazard model with treatment included as a fixed effect and patient modelled as a shared frailty. In this shared frailty model, the within-patient correlation is taken into account by assuming patient frailty follows a log-normal distribution.

PB 1791 | Efficacy of rVIII-SingleChain in the Treatment of Adult and Adolescent Patients with Severe Hemophilia A in Europe

R. Klamroth[1], J. Oldenburg[2], P. Chowdary[3], M. von Depka-Prondzinski[4], D. Bensen Kennedy[5], I. Pabinger[6]

[1]Vivantes Clinic Friedrichshain, Berlin, Germany, [2]Institute of Experimental Hematology and Transfusion Medicine, University Clinic Bonn, Bonn, Germany, [3]Katharine Dormandy Haemophilia Centre and Thrombosis Unit, Royal Free Hospital, London, United Kingdom, [4]Werlhof Institut, Hannover, Germany, [5]CSL Behring, King of Prussia, United States, [6]Division of Hematology and Hemostaseology, Medical University of Vienna, Vienna, Austria

Background: rVIII-SingleChain is a novel B-domain truncated recombinant Factor VIII comprising covalently bonded FVIII heavy and light chains, and has high binding affinity for von Willebrand factor. The safety, efficacy and pharmacokinetics of rVIII-SingleChain were evaluated in the AFFINITY program involving patients from around the world.

Aims: To evaluate the efficacy of rVIII-SingleChain in the treatment of hemophilia A patients in Europe.

Methods: Participants ≥12 years with severe hemophilia A (FVIII < 1%) were enrolled in a pivotal trial and received either on-demand or prophylactic infusion of rVIII-SingleChain. Dose and regimen were at the investigator's discretion based on clinical bleeding phenotype and previous FVIII treatment and could be adjusted any time during the study.

Results: Of the 173 patients included in the efficacy population, 85 (49.1%) from 11 European countries were included. 69 patients received prophylaxis and 16 on-demand treatment with

rVIII-SingleChain. Median annualized total and spontaneous bleeding rates (ABR/AsBR) were significantly lower with prophylaxis than with on demand treatment (ABR: 0.00 vs 28.08; p< 0.0001; AsBR: 0.00 vs 22.71; p< 0.0001). These low bleeding rates with prophylaxis in this subset of patients were comparable with those for the overall study population (median ABR: 1.14 and median AsBR: 0.00). Hemostatic efficacy of rVIII-SingleChain was excellent/good in 92.7% of the 563 bleeds treated in Europe compared with 93.8% of 835 bleeds treated in the overall study population.

Conclusions: These data show the efficacy of rVIII-SingleChain in hemophilia A patients in Europe, both as prophylactic therapy and for treatment of bleeding events. Results are consistent with findings from the overall study population and show very low annualized bleeding rates during rVIII-SingleChain prophylaxis.

PB 1792 | Chronic Liver Disease in Elderly People with Hemophilia

C. Qvigstad[1], R.C. Tait[2], S. Rauchensteiner[3], C. Combescure[4], E. Berntorp[5], P. de Moerloose[4], R. Schutgens[6], P.A. Holme[7]

[1]Oslo University Hospital, Department of Haematology, Oslo, Norway, [2]Royal Infirmary, Department of Haematology, Glasgow, United Kingdom, [3]Bayer Healthcare, Berlin, Germany, [4]Geneva University Hospitals and Faculty of Medicine, Geneva, Switzerland, [5]Lund University, Malmo, Sweden, [6]University Medical Center Utrecht, Van Creveldkliniek Department of Hematology, Utrecht, The Netherlands, [7]Oslo University Hospital and Institute of Clinical Medicine, University of Oslo, Department of Haematology, Oslo, Norway

Background: Chronic liver disease (CLD) is frequently seen in the hemophilia population.

The ADVANCE Working Group conducted a cross-sectional, epidemiological study of Hematuria and Hypertension in Hemophilia A and B (the H3 Study) in which patients with hemophilia (PWH) aged

≥ 40 years were included.

Aims: Using data from the H3 Study, the main objective has been to assess statistical associations between CLD and its risk factors, and to suggest implications for treatments.

Methods: Data from 13 European countries were collected at a single time-point (2011-13).

Univariate (UVA) and multivariate (MVA) logistic regression analysis were performed to test for associations with CLD.

Results: 532 PWH were included with either Hemophilia A (n=467) or Hemophilia B (n=65).

127 (24%) were identified with CLD. In the MVA, we have included HCV (OR=21.1, p< 0.001), diabetes (OR=3.0, p=0.02), HAART (OR=1.9, p=0.04) and total cholesterol (OR=0.6, p=0.002) as explanatory variables.

HCV, HAART, total cholesterol, and severe hemophilia were highly statistically significant in UVA.

Age was not significant in either UVA or MVA.

HCV Ab+ was significantly positively associated with CLD. Diabetes was not significant in UVA, but significantly positively associated with CLD after controlling for HCV. HAART was significantly associated with an increased likelihood of liver disease in the MVA. Total cholesterol is strongly negatively associated with CLD.

We found no evidence of interaction effects among the explanatory variables.

No significant associations with age, type of or severity of hemophilia were observed in MVA.

Conclusions: In our data HCV was the most significant factor leading to CLD, consistent with previous research.

We found diabetes significantly associated with liver disease after controlling for HCV.

To prevent CLD, intensified eradication therapy for HCV seems advocated. Furthermore, intensified monitoring and treatment of diabetes could be warranted and represents an interesting candidate for further research.

PB 1793 | Once Weekly Rfix Prophylaxis for Severe-Phenotype Haemophilia B in Normal Clinical Practice: Data from UKHCDO and Finland

M. Scott[1,2], V. Nummi[3], R. Lassila[3], H. Xiang[2], C. Hay[1,2]

[1]Central Manchester University Hospital NHS Foundation Trust - Manchester Royal Infirmary - Manchester Royal Eye Hospital, Manchester, United Kingdom, [2]UK National Haemophilia Database, Manchester, United Kingdom, [3]University of Helsinki and Helsinki University Hospital, Coagulation Disorders Unit, Helsinki, Finland

Background: New understanding of the pharmacokinetics (PK) of factor IX (FIX) in haemophilia B (HB), trials of weekly rFIX prophylaxis (WP) and the advent of enhanced half-life rFIX (EHL-IX) have focussed interest on less frequent prophylaxis with rFIX.

Aims: To collate data from a UK and Finnish cohort with severe HB using WP between 2014/ 2016.

Methods: UK data was derived from Haemtrack diary system. Finnish patients were identified by the Helsinki Haemophilia Centre and data taken from treatment diaries/ medical records. Pearson's coefficient was used to assess relationships between dose, genotype and ABR.

Results: 19 patients aged med. 37 years were selected empirically for WP. Where known, indications were patient choice (50%); poor venous access (15%); inability to self-inject (10%); poor compliance (10%). 11 patients did not comply with prophylaxis or used on-demand treatment prior to the study period (Med. ABR 12.5, Mean 13.0, IQR 5.5 - 20.0). Compliant WP was effective, with a med. ABR of 0.5 (Mean 1.7, IQR 0 - 2.3) using a med. dose of 67 IU/kg/wk; (IQR 40 -74). ABR did not correlate with dose (R= 0.32, p >0.1) or genotype. 8 patients had a trough FIX of < 0.01 - 0.12 IU/ml at 5 to 7-days; 4 trough levels of 0.06 - 0.11 IU/ml at 2 - 4 days. 1 patient had a t1/2 of 12 hrs.

Conclusions: WP with rFIX provided efficacy similar to that reported in clinical trials of WP and EHL-IX., although our cohort used lower doses. It was effective even in patients with a previous high ABR.

Most would have had FIX < 0.01 IU/ml at 7 days, yet still had a low ABR. Bleed protection appeared to extend beyond the point at which circulating F IX could no longer be measured. This supports suggestions that plasma rFIX level and t1/2 are poor surrogates for clinical efficacy. Although not suitable for all, WP may be used effectively in a subgroup of HB patients and could be used more widely. Further comparisons of rFIX WP and EHL-IX are justified.

PB 1794 | Pharmacokinetic Guided Personalized Prophylaxis with Human-cl rhFVIII in Adult Patients with Severe Hemophilia A

C. Kessler[1], M. Shima[2], A.-E. Armstrong[3], J. Bichler[4], S. Knaub[4], G. Pezeshki[5], M. Wang[6], J. Ducore[7]

[1]*Georgetown University Medical Center, Department of Medicine and Pathology - Division of Haematology/Oncology, Washington, DC, United States,* [2]*Nara Medical University, Nara, Japan,* [3]*Helsinki University Central Hospital Comprehensive Cancer Center, Helsinki, Finland,* [4]*Octapharma AG, Clinical Research & Development, Lachen, Switzerland,* [5]*Octapharma USA Inc., Hoboken, United States,* [6]*University of Colorado Denver Hemophilia and Thrombosis Center, Aurora, United States,* [7]*University of California-Davis, Sacramento, United States*

Background: GENA-21 studied pharmacokinetic (PK)-guided personalized prophylaxis with a human cell-line derived recombinant FVIII concentrate (Human-cl rhFVIII) in 66 previously treated adults (PTPs) with severe hemophilia A predominantly treated on-demand before study entry. With Human-cl rhFVIII, the median dosing interval was 3.5 days, 58% of patients received ≤2 infusions per week and 73% of patients did not bleed during the 6 month prophylactic period.

Aims: GENA-21b is assessing the benefit of PK-guided prophylaxis in patients on routine prophylactic treatment prior to study start.

Methods: The ongoing study will enroll 55 adult PTPs with severe hemophilia A from USA, Canada, Europe, and Japan. The study will be approved by local ethics committees and all patients will provide written informed consent. Each patient will receive Human-cl rhFVIII for PK evaluation followed by 1-3 months of routine prophylaxis (30-40 IU/kg every other day or 3 times per week, Phase I). Individual PK data are analyzed from FVIII:C plasma levels to determine the dose and injection interval which should result in a trough FVIII level of ≥1%. Thereafter, prophylaxis will continue for 6 months based on the individually recommended treatment schedule (Phase II).

Results: Snap shot data on approximately 40 patients will be presented at the ISTH meeting. So far, 29 patients have undergone PK with a median half-life of 15.2 hours. The median treatment interval in Phase I regular prophylaxis is 3 times per week, with a median weekly dose of 105.2 IU/kg. For the individualized prophylaxis, 58.6% of patients were recommended to use Human-cl rhFVIII 2 times per week or less with a median weekly dose of 86.6 IU/kg, an 18% dose reduction.

Conclusions: Both in patients treated previously on-demand and in those prophylactically, PK-guided prophylaxis resulted in an extension of the treatment intervals in more than 50% of the patients while reducing the weekly dose as compared to routine prophylaxis.

PB 1795 | Application of Pharmacokinetic-tailored Approach to Prophylaxis in Routine Hemophilia Care

S.E. Croteau, E.J. Neufeld

Boston Children's Hospital, Boston, United States

Background: Best practices for switching from conventional to extended half-life (EHL) factor products have not been defined for hemophilia. Data are lacking to guide individualized approaches for transition to EHL products, incorporating personal half-life assessment, physical activity level, and bleed frequency.

Aims: To examine "real-world" experience transitioning patients to EHL FVIII prophylaxis regimens informed by sparse-sampling estimation of terminal half-life.

Methods: We performed a retrospective chart review of patients considering transition from conventional to EHL products collecting data on prescribed prophylaxis regimen, bleed rate, and activity level. Half-life (t1/2) was estimated by first order decay based on at least 2 post-infusion samples in the terminal portion of the PK curve for both conventional and EHL products.

Results: 22 patients had t1/2 estimation on a conventional FVIII product. Of these, 7 underwent t1/2 estimation following first dose of an EHL product. Post-infusion samples were drawn at mean times of 0.5, 25, and 45 hours. Mean half-life extension was 1.4x baseline (0.99-1.79). Five elected to switch products. Median conventional product dosing was 91.5 IU/kg/week (range: 88-476) which decreased to 62 IU/kg/week (62-179) on EHL product. Median annualized bleed rate (ABR) was 0 prior to product switch and 0 afterward. No patients returned to conventional product. 2 patients did not switch to an EHL product due to minimal change in t1/2; remaining patients expressed satisfaction with conventional product prophylaxis regimen.

Conclusions: Estimation of an individual's factor product half-life supports a tailored prophylaxis regimen. Prescribed prophylaxis regimens based on three relevant parameters (t1/2, bleed history, and activity) rarely match the label recommended regimen. Switching is not for everyone. Comparative effectiveness studies examining health outcomes including quality of life, and economic impact of PK-tailored versus empiric dosing approaches are needed.

PB 1796 | Prevalence of Cerebral Microbleeds and Macrobleeds in Neurologically Asymptomatic Patients of Congenital Hemophilia

P. Malhotra, S. Kumar, S. Mahi, J. Ahluwalia, P. Singh, V. Suri, S. Kumari, N. Varma, S. Varma

PGIMER, Chandigarh, India

Background: Intracranial hemorrhage (ICH) is one of the most serious complication of hemophilia.

Aims: To study whether presence of cerebral microbleeds (CMB) predict future risk of ICH in patients with hemophilia.

Methods: We prospectively studied 53 patients of congenital hemophilia between age group of 12-45 years who had no past history of ICH and who were neurologically asymptomatic. All patients underwent GE-MRI Brain(1.5 Tesla MR unit) to look for the presence of CMB. The brain imaging was done using a T1 spin echo, T2 Fast spin echo & T2 weighted gradient echo sequences in axial plane. In addition, sagittal T1 spin echo & coronal sections were also used. The gradient echo images were analyzed for presence of microbleeds which was defined as small areas (size < 1cm) of rounded area of marked and homogeneous signal loss. Information on severity of hemophilia, presence of inhibitors, sites of bleed and type of therapy (prophylaxis or on demand) was collected from all patients. Informed consent was taken from all patients and the study was approved by institute ethics committee.

Results: There were 47 patients of hemophilia A & 6 were of hemophilia B. Seventeen 17 patients (32%) were having severe hemophilia, 29 (54%) moderate & 7 (14%) had mild hemophilia. Three patients had evidence of ICH (1 CMB + 2 macrobleed) on MRI with a prevalence of 5.7%. Mean factor level among ICH group was lower (0.33%) as compared to non ICH group (3.37%) (p value non significant). Prevalence of inhibitors among study group was 16% and none of the patients with ICH had presence of inhibitors. There was no occurrence of ICH in any patient during 6 months of follow up.

Conclusions: The prevalence of CMB and microbleed in neurologically asymptomatic patients with congenital haemophilia was 5.7%. Their presence did not predict the future risk of ICH in these patients. However, more patients with longer follow up is required to clearly delineate the association between CMB and ICH in patients with congenital haemophilia.

PB 1797 | Long-term Safety and Efficacy of Recombinant Factor VIII Fc (rFVIIIFc) for the Treatment of Severe Haemophilia A: European Subgroup Interim Analysis of the ASPIRE Study

B. Nolan[1], J. Oldenburg[2], G. Castaman[3], I. Woźnica-Karczmarz[4], B. Winding[5], J. Szamosi[5], S. Lethagen[5,6]

[1]Our Lady's Children's Hospital, Dublin, Ireland, [2]Institute of Experimental Haematology and Transfusion Medicine, University Clinic Bonn, Bonn, Germany, [3]Center for Bleeding Disorders and Coagulation, Careggi University Hospital, Florence, Italy, [4]Children's Clinical Hospital name of Prof. Antoni Gebali, Lublin, Poland, [5]Sobi, Stockholm, Sweden, [6]Copenhagen University, Copenhagen, Denmark

Background: The ongoing rFVIIIFc extension study, ASPIRE (#NCT01454739), evaluates the long-term safety and efficacy of rFVIIIFc in adults, adolescents, and children with severe haemophilia A.

Aims: To report interim outcomes for European subjects in ASPIRE.

Methods: Subjects who completed A-LONG or Kids A-LONG could enrol in 1 of 4 treatment groups in ASPIRE: individualised prophylaxis (IP; 25-65 IU/kg every 3-5d, or 20-65 IU/kg on D1 and 40-65 IU/kg on D4 if twice weekly); weekly prophylaxis (WP; 65 IU/kg every 7d); modified prophylaxis (MP; subjects not achieving optimal prophylactic dosing with IP or WP); or episodic treatment (ET). Subjects could change groups at any time. Subjects < 12y could enrol only in IP and MP groups. Primary endpoint: development of inhibitors. Secondary endpoints included annualised bleeding rate (ABR) and rFVIIIFc exposure days (EDs). Data from the 3rd interim data cut (11 January 2016) are reported here.

Results: Of 67 subjects (36 from A-LONG; 31 from Kids A-LONG) enrolled from 12 European countries,

60 remained on ASPIRE as of the 3rd interim data cut. From start of parent study to the interim data cut, subjects had a median of 217 (A-LONG) and 152 (Kids A-LONG) wks of treatment with rFVIIIFc, and a median of 341 (A-LONG) and 312 (Kids A -LONG) cumulative rFVIIIFc EDs. No inhibitors were observed; adverse events were typical of a general haemophilia A population. Median (IQR) ABRs were low with rFVIIIFc prophylaxis (Table 1). Median (IQR) change in weekly prophylactic consumption from end of A-LONG was 0.00 (-7.00, 0.00) and Kids A-LONG 0.00 (0.00, 16.67). In subjects from A-LONG and Kids A-LONG, 92.2% and 92.6% of bleeding episodes, respectively, were controlled with 1-2 injections.

Conclusions: Interim data from European ASPIRE subjects are consistent with the phase 3 parent studies and overall ASPIRE interim analysis. The results confirm the long-term safety of rFVIIIFc and maintenance of low ABR with extended prophylactic dosing intervals in individuals with severe haemophilia A.

TABLE 1 ABRs in European ASPIRE subjects as of the 3rd interim data cut

	A-LONG subjects (N=36)*				Kids A-LONG subjects (n=31)
ABR, Median (IQR)	Individualised prophylaxis, n= 29	Weekly prophylaxis, n =8	Modified prophylaxis, n=2	Episodic treatment, n=2	Individualised prophylaxis n=31
Overall ABR	0.85 (0.00, 2.25)	2.91 (1.35, 5.40)	3.41 (0.00, 6.82)	22.16 (13.86, 30.46)	1.90 (0.50, 3.90)
Spontaneous ABR	0.27 (0.00, 1.87)	2.05 (0.43, 2.52)	3.13 (0.00, 6.25)	11.83 (10.88, 12.77)	0.40 (0.00, 0.90)
Joint ABR	0.57 (0.00, 1.95)	1.65 (0.58, 2.58)	3.13 (0.00, 6.25)	9.65 (6.25, 13.05)	0.76 (0.00, 1.87)

ABR, annualised bleeding rate; IQR, interquartile range. *Subjects may be included in >1 treatment group

PB 1798 | Evaluation of the Impact of Polymorphism/Mutations in Genes Associated to Hemostasis in Clinical Diversity in Patients with Severe Hemophilia

F.M.L. Fonseca[1], N. Temba[1], L.M.M. Oliveira[2], M.V.A. Amorim[2], M.G. Carvalho[1], D.G. Chaves[2]

[1]Faculty of Pharmacy - Federal University of Minas Gerais, Clinical and Toxicological Analyzes, Belo Horizonte, Brazil, [2]Fundação Hemominas, Research, Belo Horizonte, Brazil

Background: Patients with severe hemophilia A and B (< 1% FVIII or FIX) present important clinical variability, mainly in relation to the frequency of bleeding events. The cause of this is still unclear.

Aims: To investigate the possible influence of polymorphisms/mutations in genes of proteins related to blood coagulation on clinical diversity of hemophilia A and B.

Methods: Polymorphisms/mutations on the genes of Factor VII (A353G), promoter region of Protein C (A/G -1641 e A/T -1476), Protein S (A2148G), Factor V Leiden (R506Q) and Prothrombin mutant (G20210A) were investigated in blood samples from 50 patients with severe hemophilia A (HA, n=44) or hemophilia B (HB, n=6) from Fundação HEMOMINAS, Minas Gerais, Brazil. Genomic DNA was extracted and amplified for analysis of polymorphisms and mutations by PCR-RFLP. Annual number of bleeding events was obtained from medical records and compared with the polymorphisms and mutations results by using T test. Brazilian ethics committee approved this study and informed consent was obtained from all patients.

Results: The frequency of polymorphisms/mutations in genes associated with hemostasis is presented in Table 1.

The annual bleedings events mean for 50 patients investigated retrospectively at the period between 2006 and 2016 was 11,5 (SD ± 10,35; CI = 2,86). The number of bleeding events was stratified in values below and above 11,5 and we identified 21 cases above and 29 below this mean value. When both groups were compared as to presence of polymorphisms/mutations, significantly difference was not observed.

Conclusions: The variability in the number of bleeding events in patients with hemophilia A or B, if above or below the mean, could not be related to the genetic profile based on polymorphisms/mutations in proteins related to coagulation process, therefore, other factors must be investigated. Financial support: CAPES, CNPq and FAPEMIG

PB 1799 | The Influence of F8 Mutation and Thrombophilic Genetic Markers on Bleeding Phenotype of Patients Affected with Severe Hemophilia A in the SIPPET Cohort

D., Istanbul, Turkey, [46]Leiden University Medical Center, Department of Clinical Epidemiology, Leiden, The Netherlands

Background: Severe hemophilia A (HA) presents a wide spectrum of bleeding tendency and previous studies suggested that bleeding may be influenced by factor VIII gene (*F8*) mutations and genetic thrombophilic risk factors.

Aims: To evaluate the role of *F8* mutations, prothrombin G20210 mutation (PT) and factor V Leiden (FLV) as determinants of bleeding tendency.

Methods: Bleeding tendency was evaluated considering the occurrence of the first bleeding and the first joint bleeding from birth to the start of prophylaxis or inhibitor development in a cohort of 251 patients with severe HA enrolled in the SIPPET study. Survival analyses were performed to calculate the risk of bleeding according to *F8* mutations and the presence of a mutated prothrombotic allele.

Results: 242/251 (97%) children with severe HA experienced their first bleeding, within the age of 56 months at a median of 7 months (IQR, 2-16); hematoma was the most common type occurring in 80/242 (33%). 115/251 (46%) experienced their first joint bleeding, within 84 months at a median of 21 months (IQR, 10-33). Out of 234 patients with a known *F8* mutation, 197 (84,1%) carried a null-mutation. Table reports the age at bleeding by type of *F8* mutation.

TABLE 1 Age in months at bleeding occurrence, median (interquartile range)

Bleeding event (number)	All patients	Patients with null mutations	Patients with non-null mutations	p-value
First bleeding (242/251)	7 (2-16)	8 (2-16)	6 (2-16)	0.869
First joint bleeding (115/251)	21 (10-33)	21 (10-35)	25 (10-33)	0.667

Patients with a null-mutation did not differ to patients carrying a non-null mutation with a HR of 0.94 (CI95% 0.66-1.33) for the first bleeding and a HR of 0.67 (CI95% 0.41-1.11) for the first joint bleeding. Prevalences of PT and FLV were 2.2% (5/231) and 6.9% (16/231), respectively and no difference has been observed in carriers and non-carriers (for the first bleeding HR 1.35, 0.84-2.16; for the first joint bleeding HR 1.02, 0.47-2.20).

Conclusions: The results of this cohort showed that previously untreated patients bled for the first time mainly within 2 years, and hematoma was the most common site. The age of the first bleeding and of the first joint bleeding did not differ between patients carrying a null or a non-null mutation. *F8* mutations and prothrombotic variants did not explain bleeding severity.

PB 1800 | Extensions of F9 Mutation Spectrum and Genotype-phenotype Heterogeneity in Haemophilia B

M.T.M. Khan[1], A. Naz[2], J. Ahmed[3], T. Sultan Shamsi[4], S. Ahmed[5], N. Ahmed[6], A. Imran[7], N. Farooq[1], M.T.H. Khan[1], A.S. Taj[1]

[1]Institute of Basic Medical Sciences, Khyber Medical University, Haematology, Peshawar, Pakistan, [2]National Institute of Blood Disease & Bone Marrow Transplantation, Thrombosis and Hemostasis Reseach, Karachi, Pakistan, [3]Institute of Basic Medical Sciences, Khyber Medical University, Haematology, Karachi, Pakistan, [4]National Institute of Blood Disease & Bone Marrow Transplantation, Clinical Haematology and Transplant Unit, Karachi, Pakistan, [5]National Institute of Blood Disease & Bone Marrow Transplantation, Genomics Laboratory, Karachi, Pakistan, [6]Children's Hospital & the Institute of Child Health Lahore, Haematology, Lahore, Pakistan, [7]Chughtai Lab Medical Pathology Laboratory, Haematology, Lahore, Pakistan

Background: Hemophilia B (HB), a coagulopathy, is among the first to have been studied genetically. The World Federation of Hemophilia (WFH) Annual Global Survey 2014 reports a total 80 patients with HB. Figures for prevalence of HB in Pakistan reported annually by WFH since 1998 are very inconsistent the reason being lack of a centralized national registry. To date, only one study has been performed on genetic analysis of HB patients from Pakistan, identifying 11 different mutations.

Aims: This study was aimed to detect *F9* genetic alterations in haemophilia B (HB) patients of Pakistani origin. We also aimed at determining the genotype-phenotype relationships in these patients.

Methods: A total of 34 known HB patients from 22 unrelated families were enrolled into the study after obtaining informed written consent. There diagnoses were reconfirmed by determining the F.IX coagulation activity (F.IX:C). Genomic DNA was extracted and PCR amplification of all exons, flanking intronic regions, the promoter region and polyadenylation site was performed. All the mutations were analysed for functional consequences employing in-silico analysis tools. Genotype-phenotype correlation was determined.

Results: A total of 17 different mutations were found in 33 patients. Missense mutations were the most frequent, followed by nonsense mutations. Other mutations included a deletion, a splice site variation and a branch point change. A missense, a short insertion and nonsense novel mutations in exon 2, 6 and 7, respectively, were also identified. F.IX:C phenotypic heterogeneity was found in case of two mutations.

Conclusions: We concluded that the registered F.IX deficient population of Pakistan mainly comprises moderate HB. *F9* mutational spectrum in Pakistani HB patients is heterogeneous. Genotype-phenotypic correlation varies in a significant number of HB patients.

Keywords: Factor IX, Haemophilia B, F9 mutations, Genotype-phenotype heterogeneity

PB 1801 | Evaluate the Situation Diagnosis and Treatment of Hemophilia in Vietnam in 2015

T.M. Nguyen

National Institute of Haematology and Blood Transfusion Vietnam, Hanoi, Viet Nam

Background: In Vietnam, estimated, there are 6,000 patients with hemophilia, 30,000 carriers, in which only 40% is diagnosed and managed.

Aims: Evaluate the situation of diagnosis and treatment for hemophilia patients in Vietnam.

Methods: Cross - sectional survey, analysis without involvement, using questionnaires which was prepared.

Results: Following 506 hospitals received the questionnaires, there're only 149 hospitals responded to the survey (response rate is 39.3%). Survey response rate in central hospitals is 57.1%, in provincial hospitals is 64% and in district hospitals was 33%.

There are 54/ 149 hospitals that have treated and managed hemophilia patients (36.24%); of which there are 8 central hospitals and 32 provincial hospitals.

Most of surveyed hospital have implemented basic coagulation tests (PT, APTT, SLTC, Fib/TT) but in which there is only 62.5% of central hospitals and 18% of provincial hospital have implemented FVIII and FIX assay test. There's only 6 hospitals have implemented inhibitor assay test and there're only 8 hospital did the von Willerbrand diagnosis test.

There is a ratio of 100% of central hospitals surveyed have hematologists. 84% of provincial hospital surveyed have from 1 to 3 hematologists. There is a ratio of 10% of provincial hospitals surveyed have not hematologists and 82.4% district hospitals have not hematologists.

There are 6 hospitals in the survey (the ratio is 4%) had adequate of blood products including fresh frozen plasma, cryoprecipitate, factor concentrates: VIII, IX and VIIa to treat for hemophilia patients.

Conclusions: Most of patients with hemophilia in Vietnam were managed in National Institute of Hematology and Blood Transfusion (NIHBT) and Blood Transfusion of Hematology in Ho Chi Minh city (BTH). The ability to deploy the diagnostic tests of hemophilia in the majority of hospitals is still limited. Blood products (especially factor concentrates) for treatment are only available in some hospitals.

PB 1802 | Low Dose (20 iu/kg/week) Single Infusion Prophylaxis per Week Using Long Acting FVIIIc (ELOCTATE, Biogen) in Severe Hemophilia A: A Cost Effective & Feasible Protocol for Resource Constraint Situation

S. Apte, A. Joshi, K. Subramanian, R. Dange, R. Phatale

Sahyadri Speciality Hospital, Haematology & BMT, Pune, India

Background: Various Intermediate to High dose (50 - 90 iu/kg/week) prophylactic protocols are well established.These are twice or thrice a week infusions. These protocols are out of reach in resource constraint countries.Episodic therapy is NO therapy for PWH.It may be better to use LOW dose prophylaxis than episodic therapy. Multiple infusions been the major issue of compliance.No data is available on once a week infusion of Long acting Eloctate with lower dose prophylaxis regimen.

Aims:

1) Assess efficacy of IV Eloctate 20 iu/kg/week single infusion prophylaxis regimen for Severe Hemophilia A

Outcome assessment at one year:

1) Reduction in Annualised Bleed Rate(ABR)

2) Reduction in days missed

Methods:

Study period: February16 -January17

Data at enrolment:

Number of PWH: 34

Age: 8 (5-11years)

Weight: 24 (19-32kg)

ABR in previous year: 19 (15-32)

Number of target joints: 1 (1-4)

HJHS score: 10/116 (0-22)

FISH score: 30/32 (26-32)

Days Missed: 26 (20-61)

All the patients had more than 50ED on episodic regimen and were Inhibitor Negative at enrolment.All patients were on regular physiotherapy schedule which was continued during study period.IV Eloctate 20iu/kg was infused once a week.Once in three months inhibitor tests were performed.All breakthrough bleeds were documented and treated with extra infusions of Eloctate. Days missed at were documented.Physical assessment was done once in 6months.Eloctate was received through Humanitarian aid Program of WFH.

Results: All patients completed the study showing 100% adherence to infusion schedule.

Outcome assessment for study period:

1) ABR: 3 (3-9)

2) Days missed: 9 (6-20)

3) Total bleeds: 102

4) Extra doses used: 127

5) Average Eloctate used: 1100 iu/kg/year

6) Inhibitor: Nil

There was marked reduction in ABR though no ZERO ABR achieved for any patient.There was no major change in HJHS or FISH score.

Conclusions: Once a week low dose IV Eloctate is feasible & effective prophylaxis regimen for resource constraint countries.

The reduction in ABR may lead to far better HJHS & QOL in long term for PWH.

PB 1803 | Development of the Education Interventions to Enhance Adherence to Prophylactic Treatment in Korean Hemophilia Patients

E.J. Choi[1], H.-J. Yoon[2], S.K. Park[3], S.K. Kim[4], K.Y. Yoo[5], J.Y. Kim[6]

[1]*Daegu Catholic University Hospital, Department of Pediatrics, Daegu, Korea, Republic of,* [2]*Kyung Hee University Hospital, Department of Internal Medicine, Seoul, Korea, Republic of,* [3]*Ulsan University Hospital, Department of Pediatrics, Ulsan, Korea, Republic of,* [4]*Inha University Hospital, Department of Pediatrics, Incheon, Korea, Republic of,* [5]*Korea Hemophilia Foundation, Seoul, Korea, Republic of,* [6]*Kyungpook National University Hospital, Department of Pediatrics, Daegu, Korea, Republic of*

Background: Prophylactic treatment is now considered as a standard management for severe hemophilia patients. Regarding good quality of life and the cost-effectiveness, a patient´s adherence to prophylactic treatment is one of the most important factors to desired outcomes.

Aims: The aims of this study are to know the present adherence of the patients in Korea and to develop the educational interventions to enhance adherence on the basis of the results.

Methods: We used the VERITAS-Pro as a measuring method for adherence to prophylactic treatment with permission to use from the authors of the VERITAS-Pro. We calculated individual scores of adherence and the average scores of six subscales of the patients who participated in this study.

Results: Ninety five eligible patients were recruited for participation from five hemophilia treatment centers. Of the ninety five patients with prophylactic treatment, eighty two patients were hemophilia A and thirteen patients were hemophilia B. The mean age of the were 20.9. (range: 1-63). The mean total score was 40.4 (range: 24-75). Subscale mean scores were 5.99 (Remember), 6.12 (Dosing), 6.22 (Skipping), 7.23 (Communicating), and 8.43 (Time) (Table 1).

TABLE 1 The mean scores of 6 subscales in VERITAS-Pro

Subscales	Scores (mean±standard deviation)
Timing	8.43±3.40
Dosing	6.12±2.33
Planning	6.43±2.48
Remembering	5.99±2.32
Skipping	6.22±2.76
Communicating	7.23±2.92

Conclusions: In this study we evaluated the present level of adherence to the prophylactic treatment in Korean hemophilia patients. We also recognized the need for education programmes focused on the proper time of the regular administration of clotting factor concentrates to the patients with prophylactic treatment. From the base of this result, we made the education card for presentation of importance of morning administration of clotting factor concentrates and guidance of education program of skill for self-infusion (Figure 1). We convinced this whole process can enhance adherence in patients with hemophilia in Korea.

PB 1804 | Immune Tolerance Induction in Patients with Haemophilia using Fc Fusion Recombinant Factor VIII

A. Nagao[1], H. Katayama[1], K. Amano[2,3]

[1]*Ogikubo Hospital, Hematology, Tokyo, Japan,* [2]*Tokyo Medical University Hospital, Department of Laboratory Medicine, Tokyo, Japan,* [3]*Tokyo Medical University Hospital, Molecular Genetics of Coagulation Disorders, Tokyo, Japan*

Background: It has been reported that shorter duration immune tolerance induction (ITI) was achieved in three patients who were treated with rFVIIIFc, a long-acting recombinant factor VIII Fc fusion protein. ITI using rFVIIIFc is therefore expected to be effective for patients receiving haemophilia inhibitor treatment.

Aims: In this study, we describe the time course of the inhibitor titres of two Japanese patients who received initial and rescue ITI with rFVIIIFc.

Methods: This study was conducted at Ogikubo Hospital, Tokyo, Japan. Written informed consent was obtained from the two patient's parents. The two patients were diagnosed with severe haemophilia A (FVIII < 1%) and had anti-FVIII inhibitors.

Results: The clinical characteristics of these patients and the time course of their inhibitor titres are shown in the table and figure. [Case1] A 2-year-old male patient in whom ITI was initiated with rFVIIIFc. Inhibitors were detected with standard half-life rFVIII. After one month, ITI treatment was initiated with rFVIIIFc (110IU/kg, twice a week). This patient underwent an initial course of ITI. [Case 2] A 3-year-old male patient received rescue ITI. Before switching to rFVIIIFc,

the patient had previously received rFVIII for 12 months as ITI treatment; however, the treatment was unsuccessful.

The previous ITI dose was increased to four-fold that of the first regimen; however, the treatment failed. The patient received rescue ITI with rFVIIIFc (180 IU/kg, three times per week).

Conclusions: We reported the cases of two patients who received initial ITI and rescue ITI with rFVIIIFc, in which partially successful outcomes were achieved. rFVIIIFc has been reported to promote Tregs in animal models; accordingly, Tregs may be one of the factors associated with successful treatment. These results suggest that rFVIIIFc may be an effective choice for both initial and rescue ITI.

TABLE 1 The clinical characteristics of the patients undergoing ITI with rFVIIIFc

Case		1	2 ※
Age at inhibitor detection		2 years and 7 months	1 year and 2 months
Exposure days at inhibitor detection		15 days	5 days
Before ITI	First titre level (= peak titre)	6 BU	12 BU
During ITI	Prior ITI	No	Yes
	Age at start of ITI	2 years and 8 months	2 years and 1 month
	Inhibitor titre at initiation	6 BU	5BU
	Peak titre	21 BU	131 BU
	Last known titre	5 BU	32 BU

※The data include prior ITI and rescue ITI with rFVIIIFc

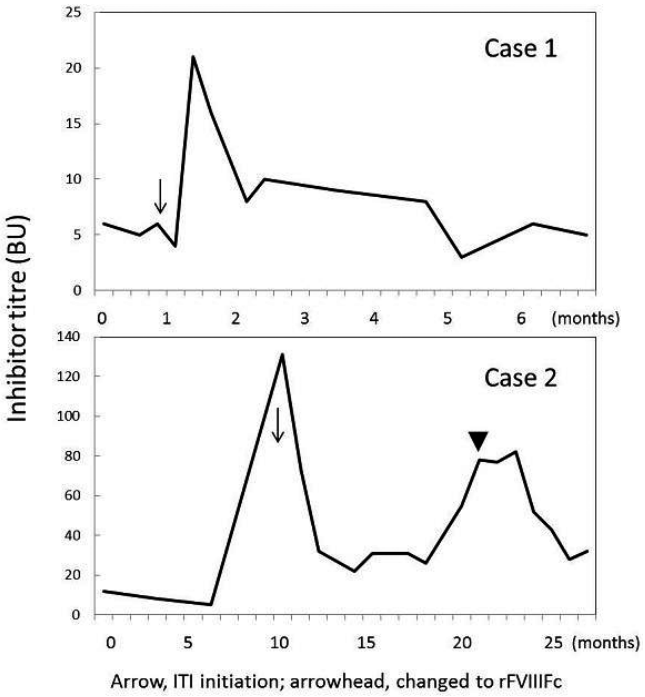

FIGURE 1 The time course of the inhibitor titres

PB 1805 | Spectrum and Origin of Mutations in Sporadic Cases of Haemophilia A in China

Y. Lu

Ruijin Hospital affiliated to Medical College of JiaoTong University, Department of Laboratory Medicine, Shanghai, China

Background: Many newly diagnosed Chinese haemophilia A patients are sporadic cases. In these sporadic HA families, it is important to confirm the origin of the mutation and carrier status.

Aims: In this report, we will introduce the spectrum and origin of mutations in 365 sporadic HA families in China and the methods of carrier and prenatal diagnosis in our center.

Methods: LD-PCR and PCR were adopted for the screening of the intron 22 and 1 inversion respectively. FⅧ sequences were analyzed by direct DNA sequencing. 7 STR sites related to F8 gene were combined together to do linkage analysis to define the origin of mutation in sporadic families. AccuCopy method was used to detect the copy number variations of the F8 gene to confirm deletions or duplications.

Results: In 365 sporadic families, 141 were caused by inversions, 129 were INV22 and 12 were INV1. For the inversions negative families, 127 were due to the point mutations including the splicing mutations, 65 were found small deletions/insertions, 32 were caused by large deletions/duplications. According to the linkage analysis, we confirm the mutation origin of these sporadic families and found that the most of cases got the mutation from the probands' maternal grandfathers (58.59%). For the mutations derived from the maternal grandfathers, the most common was INV22 which presented for 47%. While, for the de novo mutations, the INV22 was only found in 11% families but the point mutation was 54%. Combined with the linkage analysis, we did carrier diagnosis in these families and detected 327 carriers. For prenatal diagnosis, 68 fetuses were normal, 16 were female carriers and 33 were male patients.

Conclusions: According to the results, the mutation types of the sporadic families were characteristic in groups with different origins of the mutations. We can reasonably suggest that intron 22 and 1 inversions screening, F8 gene sequencing and CNVs detection combined with the linkage analysis are available for carrier and prenatal diagnosis in Chinese HA families.

PB 1806 | The Utility of Activated Partial Thromboplastin Time Clot Wave Form Analysis in the Investigation of Hemophilia A Patients Using Destiny Max TM Analyzer

A. Abraham[1], P.O. Sevenet[2], M.-L. Delalande[2], H.F. Margaret[1], T. Geevar[1], S. Singh[1], R. V[1], S. Deivasigamani[3], S.C. Nair[1]

[1]*Christian Medical College & Hospital, Department of Transfusion Medicine & Immunohematology, Vellore, India,* [2]*Diagnostica Stago, Gennevilliers, France,* [3]*Stago India Private Limited, Gurgaon, India*

Background: It is difficult to diagnose the true severity of Hemophilia A (HA) by conventional one-stage aPTT based clotting assay when

FVIII:C level is 1.0 IU/dl or less. The clot formation waveform on a photo-optical detection system, provides information not only on clotting time but also coagulation velocity and acceleration denoted as Min1 and Min2 respectively.

Aims:

- To determine the best possible combination for aPTT clot waveform analysis (CWA) on Destiny Max^{TM} analyzer (Tcoag) with variation in reagents (aPTT S or aPTT HS), calcium chloride concentration (0.020 M or 0.025M), wavelengths (405 or 635 nm) and reagent dilutions by using STA-deficient FVIII plasma spiked with Kogenate at increasing concentrations of FVIII (0.3, 0.6, 1.0 and 2.5 U/dl).
- To assess if CWA could predict the bleeding phenotype independently from FVIII:C assay.

Methods: aPTT assay was performed using TriniClot aPTT S and HS (Tcoag). 29 patients with severe HA, 13 with moderate HA and 103 controls from blood bank donors were included. Severe clinical phenotype was defined as the presence of spontaneous bleeding episodes < 1-year old or joint or muscular bleeding < 3-years of age, ≥2 joints involved or ≥5 factor replacements in a year or the presence of intracranial bleeding.

Results: For the four combinations (S/405, HS/405, S/635, HS/635), the correlation coefficient between FVIII:C and Min1 were respectively 98.6 %, 97.1%, 95.8% and 98.4% (Figure 1). There was a better correlation between Min1 and FVIII:C while using 405 than 635 nm (p< 0.001). There was a significant (p=0.001) correlation of Min1 and Min 2 with the type of hemophilia and bleeding phenotype. Min1 showed a better discrimination of HA type and bleeding phenotype than other CWA parameters (Figure 2).

Conclusions: We conclude that aPTT waveform analysis will be able to define qualitative and quantitative differences in HA patients at FVIII levels < 1% and is useful for the investigation of the clinical phenotype and response to therapy.

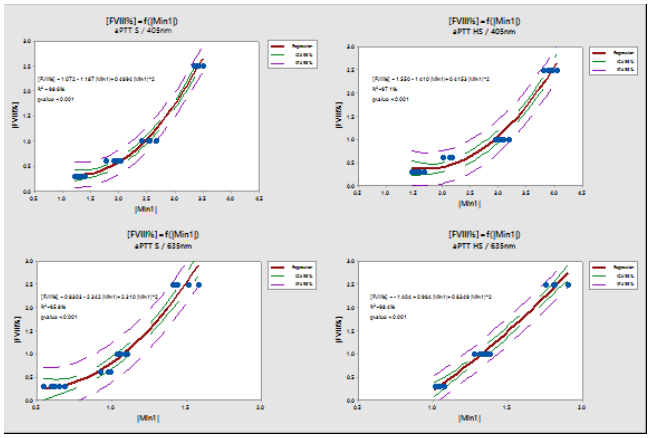

FIGURE 1 Correlation coefficient between FVIII:C and Min 1 based on two reagents (HS and S) and two wavelengths (405 and 635 nm)

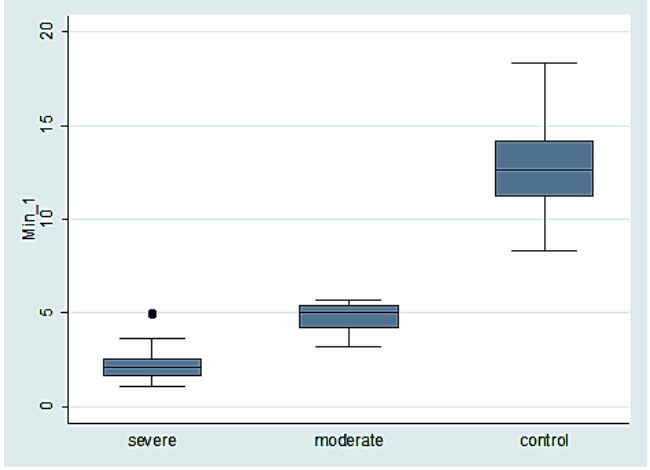

FIGURE 2 Box plot for Min 1 according to HA type (Interquartile range in brackets)

PB 1807 | Pharmacokinetics of Octocog α in Severe Hemophilia A Boys Aged Less than Six Years on Routine Prophylaxis

T. Urasinski[1], T. Ociepa[1], W. Badowska[2], H. Bobrowska[3], Ł. Dakowicz[4], G. Dobaczewski[5], G. Karolczyk[6], A. Klukowska[7], A. Kołtan[8], M. Kostrzewska[9], P. Łaguna[7], W. Młynarski[9], D. Wasiński[10], M. Wlazłowski[11], I. Woźnica-Karczmarz[12], S. Woźniak[1]

[1]Pomeranian Medical University, Dept. of Pediatric Hematology and Oncology, Szczecin, Poland, [2]University of Warmia Mazury, Dept. of Pediatrics, Olsztyn, Poland, [3]Children Hospital, Dept. of Hematology, Poznań, Poland, [4]Medical University of Bialystok, Dept. of Pediatrics, Hematology and Oncology, Białystok, Poland, [5]Medical UniversityWrocław, Dept. of Bone Marrow Transplantation, Oncology and Hematology, Wrocław, Poland, [6]Regional Hospital BurgdorfHospital, Oncology and Hematology Unit, Kielce, Poland, [7]Warsaw Medical University, Dept. of Pediatrics, Hematology and Oncology, Warszawa, Poland, [8]Collegium Medicum N. Copernicus University, Dept. of Pediatrics, Hematology and Oncology, Bydgoszcz, Poland, [9]Medical University of Łódź, Dept. of Pediatrics, Oncology, Hematology and Diabetology, Łódź, Poland, [10]Clinical Hospital, Clinical Pediatrics Dept., Zielona Góra, Poland, [11]Medical University of Gdansk, Dept. of Pediatrics, Hematology and Oncology, Gdańsk, Poland, [12]Lublin Medical University, Dept. of Pediatric Hematology, Oncology and Transplantology, Lublin, Poland

Background: It is believed that personalized prophylaxis guided by: period of life, physical activity, bleeding phenotype and pharmacokinetic parameters (PK) may reduce the number of bleeds in severe hemophilia A (sHA) patients. Young children are physically active in uncontrollable manner and primary prophylaxis aims to prevent bleeds thus PK remain the only tool to „tailor" management. Based on bayesian probability myPKFiT has been developed to assess PK parameters in HA patients treated with octocog α (o-α).

Aims: To assess selected PK parameters (t1/2, time to < 1%) as well o-α activity at different time points in boys aged < 6 yrs. with sHA on prophylaxis with the use of o-α given at the dose 20-40 U/kg three times weekly.

Methods: The study comprised 39 Caucasian boys aged 33-71 (median 59.5) mo. enrolled in Polish nationwide prophylaxis. All patients were given o-α at the dose of 20.9-39.1 (median 31.7) IU/kg 3 x

weekly (usually Mon-Wed-Fri). Blood was sampled twice: 3 and 24 h. from a single dose infusion. o-α activity was assessed in local labs with the use of one-step coagulation assay and analyzed centrally with the use of myPKFiT application.

Results: Results are presented in Tab. 1 and 2.

PK parameters in the group studied were consistent with those presented by manufacturer. It has been shown that 31/39 (79.5%) pts had an o-α threshold >1% 48 h from drug infusion however after the following 12 h it remained >1% in 6/39 (15.4%) only. Moreover o-α thresholds >3% at 24h, 36h and 48 h from infusion were observed in 39/39 (100.0%), 39/39 (100.0%) and 8/39 (20.5%) pts, and >5% in 39/39, 6/39 (15.4%) and 0/39 (0.0%) pts respectively.

TABLE 1 PK parameters of octocog α in the group studied as measured by myPKFiT

	clearance (dL/h/kg)	volume in steady state (dL/kg)	FVIII half-life (h)	time to 1% above baseline (h)
mean	0,044	0,576	9,582	53,45
standard dev.	0,006	0,043	0,722	5,94
min.	0,030	0,500	8,500	43,00
max.	0,055	0,600	11,30	67,00
median	0,037	0,538	9,041	48,22

TABLE 2 Octocog α activity at different time points in the group studied

	0 h (%)	12 h (%)	24 h (%)	36 h. (%)	48 h. (%)
mean	79,55	20,93	8,80	3,79	1,73
standard dev.	16,56	4,76	2,46	1,26	0,61
min.	49,50	12,30	4,80	1,90	1,00
max.	116,10	31,00	14,50	6,80	3,30
median	64,53	16,61	6,80	2,48	1,73

Conclusions: For bleeding prophylaxis in boys younger than 6 years with sHA oc-α shoud be administered at intervals not longer than 48 h. These children would probably benefit if treated with extended half-life products in order to achieve higher FVIII trough level or prolonged intervals between infusion.

PB 1808 | The World Bleeding Disorders Registry: The Pilot Study

G.F. Pierce[1], A. Iorio[2], J. O'Hara[3], S. Diop[4], R. Hollingsworth[5], A. Srivastava[6], D. Lillicrap[7], H.M. van den Berg[8], C. Herr[1], D. Coffin[1]

[1]World Federation of Hemophilia, Montreal, Canada, [2]McMaster University, Hamilton, Canada, [3]HCD Economics, London, United Kingdom, [4]Cheikh Anta Diop University, Dakar, Senegal, [5]Medical Data Solutions and Services (MDSAS), Manchester, United Kingdom, [6]Christian Medical College, Vellore, India, [7]Queen's University, Kingston, Canada, [8]University Medical Center, Utrecht, The Netherlands

Background: Significant gaps in evidence supporting optimal care of bleeding disorders still exist, which are difficult to address with conventional clinical study designs, such as RCTs. The World Bleeding Disorders Registry (WBDR) (ClinicalTrials.gov NCT02776826) is intended to fill these gaps by generating an unprecedented amount of real world data, which will be used for generating evidence to improve the quality of care worldwide.

Aims: The feasibility of conducting a global patient registry was assessed in a pilot study.

Methods: The pilot was an observational, global registry of patients diagnosed with hemophilia A or B, replicating the methodology of the planned WBDR, including the use of a web-based data entry system (McMaster University, Canada). Ethics and patient consents were obtained.

The feasibility of implementing the WBDR was assessed on HTC and patient interest, ability to obtain ethics and successful entry of quality data. Invited HTCs represented the 4 levels of economies based on World Bank´s classification by gross national income (GNI).

Results: Thirty-one of the 40 invited HTCs accepted to participate in the pilot study (78% participation rate). Two HTCs withdrew before applying for ethics, 2 HTCs were declined ethics approval, and 1 was still pending at study closure (Table 1). Twenty-six (90%) HTCs obtained ethics approval. As of database lock on 31 December 2016, 356 patients were enrolled and only 7 patients declined participation (98%). Data quality is currently being assessed. Acceptance of HTCs to participate in the WBDR pilot decreased with increasing GNI (Table 1).

TABLE 1 HTC Disposition: World Bank's Economic Classification by Gross National Income

	Disposition of HTCs by GNI n/N (%)				
HTC Disposition	Total	High-income	Upper middle-income	Lower middle-income	Low Income
Invited	40	14	8	13	5
Accepted	31/40 (78%)	8/14 (57%)	6/8 (75%)	12/13 (92%)	5/5 (100%)
Applied to ethics	29/31 (94%)	6/8 (94%)	6/6 (100%)	12/12 (100%)	5/5 (100%)
Obtained ethics approval	26/29 (90%)	5/6 (94%)	6/6 (100%)	11/12 (92%)	4/5 (80%)

Conclusions: This pilot confirms the interest of HTCs and patients in participating in a global registry, as well as the ethical acceptability and technological feasibility of a worldwide web-based patient registry. The learning from the pilot, including the relationship between GNI and retainment in the pilot, will inform the WBDR, expected to launch mid-2017.

PB 1809 | Data from the Austrian Haemophilia Registry: An Update

J. Rejtö[1], S. Reitter-Pfoertner[1], S. Kepa[1], S. Oberbichler[2], G. Schuster[3], W. Streif[4], C. Male[5], W. Muntean[6], A. Hoerbst[2], P. Neumeister[7], C. Feistritzer[8], I. Pabinger[1]

[1]*Medical University of Vienna, Division of Haematology and Haemostaseology, Department of Medicine I, Vienna, Austria,* [2]*UMIT - University for Health Sciences, Medical Informatics and Technology, Hall in Tirol, Austria,* [3]*Blutspendezentrale, Linz, Austria,* [4]*Medical University of Innsbruck, Department of Pediatrics, Innsbruck, Austria,* [5]*Medical University of Vienna, Department of Pediatrics, Vienna, Austria,* [6]*Medical University of Graz, Department of Pediatrics, Graz, Austria,* [7]*Medical University of Graz, Division of Haematology, Graz, Austria,* [8]*Medical University of Innsbruck, Division of Haematology and Oncology, Innsbruck, Austria*

Background: The Austrian Haemophilia Registry is a web-based patient registry initiated in 2007.

Aims: The primary aim of the Registry is to assess the demographic characteristics of patients with haemophilia (PWH). Secondary aims are to evaluate treatment modalities and potential side effects.

Methods: Data on the various characteristics and treatment modalities of patients from each of the eight Austrian Haemophilia Centers are recorded in a special Registry database.

Results: In total, 796 PWH were included in the Registry at the end of January 2017: 670 patients (84%) with haemophilia A (HA) and 126 (16%) with haemophilia B (HB).

The median age was 35 years (range: 1-94 years). Children (< 18 years of age) represent 19.5% and adults represent 80.5 % of the study population. Of all patients recorded, 39% have severe (factor VIII or IX levels < 1%), 10.5% have moderate (FVIII or FIX 1-5%) and 50.5% have mild (FVIII or FIX 5-50%) forms of haemophilia.

Data is available on the treatment modalities of 97% of patients with severe haemophilia: prophylaxis is applied in 70.5%, while 26.5% receive on demand treatment. The number of severe haemophiliacs on prophylaxis was higher among children/adolescents (91%) than among adults (63%).

Of all patients with severe haemophilia, 37.2% have shown an HCV infection and 12.3% are HIV positive. A co-infection with both, HIV and HCV, has been confirmed in 10.1%.

At present, 3.3% of all HA patients and 6.7% of severe HA patients show an inhibitor - a high-titer inhibitor (> 5.0 Bethesda Units (BU)/ml) was found in 50% of all HA patients with inhibitor and in 47% of severe HA patients with inhibitor. Currently 0.8 % of all our HB patients and 4.2% of severe HB patients have a low-titer inhibitor (< 5.0 BU/ml).

Conclusions: The Austrian Haemophilia Registry covers more than 80% of the assumed number of PWH in Austria. Most patients with severe haemophilia receive prophylaxis. HCV and HIV infection are still a major issue in the Austrian haemophilia population.

PB 1810 | Application of the Pattern and Parameters of the aPTT Clot Reaction Curve in Patients with Hemophilia A and Acquired HA

R.E. Sueldo, R. Porsella, G. Guerrero, P. Do Nascimento, A. Baques, M.D.V. Arias

Unidad Asistencial por mas Salud Dr. Cesar Milstein, Ciudad Autónoma de Buenos Aires, Argentina

Background: The diagnosis of Hemophilia A (HA) and Acquired Hemophilia A (HAadq) is usually performed by measuring the activity of FVIII. ACL TOP coagulometers show the aPTT coagulation reaction curve and calculate the parameters as Max1: maximum value of the first derivative of the curve (velocity), Max2: maximum value of the second derivative (acceleration) and Min2: minimum value of the second derivative (deacceleration). The aPTT second derivative curve (aSDC) is variable may be: single peak (SP), peak with shoulder (PSH), wide peak (WP) or double peak (DP).

Aims: To evaluate the utility of the aSDC and the parameters obtained from the curves in patients with HA and HAadq.

Methods: 63 samples of HA patients (17-80 years, 48 severe HA (SHA), 10 moderate HA (MoHA), 5 mild HA (MiHA). 13 samples from SHA and 17 from HAadq patients presented aFVIII Inhibitor (SHAInh: 12 high titre; 1 low titre, HAadq: 11 high titre; 6 low titre); 41 samples

TABLE 1 aSDC and the parameters obtained from patients with HA and HAadq

	Number of samples		aPTT (sec)	Max1 (dAbs/dt)	Max2 (dAbs/dt2)	Min2	aSDC
CS	41	Median / Range	26,7 / 23,5 - 31,9	287,0 / 210,0 - 383,8	841,6 / 596,5 - 1168,6	-344,7 / (-452,5)-(-233,9)	SP
SHA	48	Median / Range	87,2 / 62,4 - 127,0	48,3 / 15,3 - 148,4	40,5 / 16,8 - 109,1	-4,9 / (-37,6)-(-0,1)	DP
MoHA	10	Median / Range	52,5 / 47,4 - 59,7	119,4 / 75,4 - 167,5	153,4 / 105,7 - 217,6	-59,3 / (-93,7)-(-36,0)	DP
MiHA	5	Median / Range	40,0 / 33,5 - 43,8	207,7 / 139,6 - 290,9	370,3 / 327,2 - 642,3	-162,8 / (-261,2)-(-70,1)	DP, PSH
SHAInh	13	Median / Range	99,0 / 67,4 - 129,1	27,6 / 8,3 - 44,6	27,8 / 12,9 - 58,5	-5,6 / (-9,8) - (0,0)	DP
HAadq	17	Median / Range	81.8 / 41.4 - 127.1	102.8 / 28.0 - 535.2	51.3 / 13.61 - 527.1	-16.2 / (-356.8)-(-0.2)	WP and/or DP

(CS) from patients with no clinical manifestations and normal PT and APTT were used as controls. aPTT (APTT-SP), ACL TOP 300 Instrumentation Laboratory. GraphPad InStat.

Results: Significantly lower values of Max 1, Max 2 and Min 2 are observed in patients with SHA than with MoHA (p:< 0.0001), and also Lower values of Max1, Max 2 and Min2 in patients with MoHA than MiHA (p:0.0027, p:0.0007, p:0.0080 respectively). Additionally, lower values of the three parameters are found in SHAInh than HAadq (p:< 0.0001, p:0.0132, p:0.0087, respectively). SHA Vs SHAInh (p:0.0019, p:0.0510, p: 0.8258 respectively). aSDC were DP in SHA and MoHA, and DP, WP or PSH in MiHA and HAadq , See table 1.

Conclusions: These preliminary study shows that by using the parameters of the aPTT reaction curve it could be possible to differentiate HA severity and also SHAInh from HAadq. In addition, Max1 could be used to differentiate between SHAInh and SHA. However, these findings would require a more data to be confirmed.

PB 1811 | Secondary and Tertiary Prophylaxis in Patients Haemophiliacs, Update from Algiers Experience about One Center

M. Bensadok[1], N. Ferroudj[2], K.W. Chennoukh[2], N. Zidani[2], T. Zidouni[2], M. Ramaoun[2], M. Belhani[2], S. Nekkal[2]

[1]University hospital of Benimessous Algiers, Hematology and Blood Bank, Algiers, Algeria, [2]University Hospital of Benimessous Algiers, Hematology and Blood Bank, Algiers, Algeria

Background: Primary prophylaxis is the gold standard for preserving joint function of care for boys with severe haemophilia A and B, indications in adulthood are less well definided ,is effective in reducing the number of bleeding episodes and prevention of arthropathy. Adoption of this approach has varied from country to country.

Aims: Showing the benefits ,the clinical and psychological impact of secondary prophylaxis.

Methods: We follow up at our center 300 patients with Haemophilia. The population we studied is a cohort of 66 patients 42 adults 24 children . Their ages are between (2-55). Prophylaxis started at an age between (2 and 56) years old, since 7 years.

Results: The patients had higher numbers of joint bleed and of days of work-school lost, regimens starting prophylaxis with infusions one per week introduced ,we observed a remarkable reduction of bleeding frequency from a median of 198 bleeds per year during on demand treatment to a median of 15 bleeds per year during prophylaxis,The prophylaxis reduced the number of absentee days from 2 to 3 times per week to 0 to 1 day per year during the prophylaxis period.

Conclusions: It is unquestionable that prophylaxis at any age reduces the number of joint bleeds and slowed, but did not stop the progression of haemophiliac arthropathy, and in parallel reduces, the patients physical and psychological restrictions, being able to radically transform the lives of severe haemophyliacs.

PB 1812 | Personalized Treatment in Hemophilic Patients in Argentina

A. Baques[1], R.E. Sueldo[2], G. Guerrero[1], P. Do Nascimento[1], K. Santiso[1], M.D.V. Arias[2]

[1]Unidad Asistencial por más Salud Dr. Cesar Milstein, Hemophilia, Ciudad Autonoma de Buenos Aires, Argentina, [2]Unidad Asistencial por más Salud Dr. Cesar Milstein, Hematology Laboratory, Ciudad Autonoma de Buenos Aires, Argentina

Background: Prophylaxis treatment for adults with Severe Haemophilia A must be approached as a group with therapeutic goals of it is own, primarily focusing in improving quality of life and social inclusion of the patient. Although tertiary prophylaxis is controversial regarding cost effectiveness, since most patients have damage in several joints, therefore prophylaxis is focused in this group of patients in delaying progression of joint damage. In Argentina the access for prophylaxis treatment in adults is very limited and traditionally is based on patient weight.

Aims: Evaluate the myPKFiT software, in adults with severe haemophilia A in prophylaxis with Recombinant Coagulation Factor VIII (rFVIII).

Methods: Fifteen patients with severe hemophilia A in prophylaxis treated with rFVIII were studied. They were divided according the dose regimen in: low doses (< 20 IU / kg), standard doses (20 - 40 IU / kg) and high doses (> 40 IU / kg). Mean Age: 38 years old (19-57), Mean weight: 72 Kg (48-93). Mean dose of rFVIII: 2033 IU (2000 - 3000 IU). Dosage of FVIII was done by one-stage coagulometric method in Coagulometer ACL TOP 300 (Instrumentation Laboratories). A myPKFiT program was used to calculate customized pharmacokinetic (PK) curves for patients after the infusion of Octocog alfa rFVIII. The minimum level objective of PK was to maintain the FVIII above 1%, with dosage interval of 72 hours.

Results: When evaluating patients with the software, 9 patients who were in the standard dose category were maintained; the rest changed their dose category. See Table 1 y Table 2.

TABLE 1 Patients without dose change

Patient	Dosis administered IU/Kg	Dosis suggested myPKFiT IU/Kg
1	21.5	28.0
2	25.6	26.9
3	27.8	26.0
4	21.5	23.0
5	25.3	31.7
6	24.4	31.3
7	21.5	24.7
8	23.1	32.5
9	41.7	43.6

TABLE 2 Patients with dose change

Patient	Dosis administered IU/Kg	Dosis suggested myPKFiT IU/Kg
1	36.4	18.8
2	33.3	17.6
3	26.7	14.7
4	29.4	19.4
5	62.5	24.5
6	53.6	32.0

Conclusions: 40% of patients (6/15) changed the dose regimen to lower doses that were suggested by myPKFiT seeing on PK parameters. By these results we implemented in our institution dose regimen based on PK parameters in order to optimize the use of concentrates and getting the profilaxis for a cost effective treatment.

PB 1813 | Global Hemostatic Assay at Different Target Procoagulant Activity of Factor VIII and Factor IX

K. Yoo[1], H.-J. Yoon[2]

[1]*Korea Hemophilia Foundation, Seoul, Korea, Republic of,* [2]*Kyung Hee University Hospital, Hematology-Oncology, Seoul, Korea, Republic of*

Background: Based on reports addressing hemophilia B patients bleed less common and less intensively than hemophilia A, it has been expected that the hemostatic level of factor IX (FIX) activity can be lowered than that of factor VIII (FVIII) activity.

Aims: We compared the hemostatic efficacy of the different hemostatic level of FIX and FVIII activity using global hemostatic assay.

Methods: A total of 17 severe hemophilia patients without inhibitor, aged more than 15 years old were subjected; 12 hemophilia A patients and 7 hemophilia B patients. Factor concentrates were injected to reach the target activity of 60% in hemophilia A and 40% in hemophilia B which is given by Korean health insurance guideline. All patients were in non-bleeding state and kept the wash-out period of 3 days for hemophilia A and 5 days of hemophilia B. Before and on 15 minutes after injections, we conducted one-stage factor assay, thrombin generation assay (TGA), thromboelastography (TEG) and clot-wave form analysis (CWA).

Results: Median ages of hemophilia A and hemophilia B patients were 28 and 33 years old. Baseline FVIII:C and FIX:C were 0.6% and 1.8% and they rose after injection rose to 70.8% and 49.8%. The dosage of FVIII concentrates and recombinant FIX concentrates were 28.4 IU/kg and 50.7 IU/kg. In-vivo recovery (IVR) in hemophilia A and hemophilia B patients recorded 2.43 %/U/kg and 0.91 %/U/kg. Peak thrombin of FVIII and FIX were 451.3 nM and 376.6 nM (P=0.108, normal range, 458 nM±60). TEG index of FVIII and FIX were -1.60 and -3.77 (P=0.004, normal range, -2~+2). MIN2 of CWA of FVIII and FIX were 0.62 and 0.59 (P=1.000).

Conclusions: Global hemostatic assay indicates even though IVR of FVIII and FIX are normal, less amount of FIX is insufficient to normalize hemostatic parameters in comparison with FVIII.

PB 1814 | The Impact of Secondary and Tertiary Prophylaxis in the Reduction of Bleeding Events in Moderate or Severe Hemophilia A or B

B. Alvarez, K.B. Mendonca

Nova Friburgo Regional Blood Center, Nova Friburgo, Brazil

Background: The purpose of this paper is to identify the impact of prophylaxis in the reduction of bleeding events in severe or moderate hemophilia patients A or B assisted at the Nova Friburgo's Regional Blood Center of Nova Friburgo, Rio de Janeiro, from 2009 to 2015.

Aims: To study the incidence of bleeding events before and after the beginning of the secondary and tertiary prophylaxis treatment, comparing their frequency and types.

Methods: This is a Quasi-experimental pre-post test intervention study which inclusion criteria was the severe or moderate hemophilia A or B patients without inhibitor registered at Regional Blood Center of Nova Friburgo.

Data was extracted from the medical chart and/or electronic medical record from Hemovida Coagulopatia Web, from the Brazilian Health Ministry.

The project was approved by the Ethics and Research Committee of Instituto Estadual Arthur de Siqueira Cavalcante - Hemorio before its beginning and with the patient free consent term.

Results: Most patients presented the severe form of hemophilia A;

A reduction of 89,1% in the total number of bleeding complications after the beginning of secondary/ tertiary prophylaxis (from 614 to 67 complications) was noticed, being similar in hemophilia A or B and in the severe or moderate forms;

There was a reduction in the incidence of bleeding events in all situations after intervention, with a significant statistic ($p < 0,05$) for knees, elbows and shoulders;

Observing the quantity of events, the average number of annual complications diminished from 9,1 before intervention to 1,3 after prophylaxis ($p=0,001$); the reduction was statistically significant in all areas ($p < 0,05$), except in muscle bruises.

Conclusions: We can conclude that the secondary/tertiary prophylaxis is efficient in the reduction of bleeding events in severe or moderate hemophilia patients A or B.

PB 1815 | New Methods of Physiotherapy in Patients with Advanced Haemophilic Arthropathy

J. Zawilski[1], A. Dudek[1], K. Zawilska[1,2]

[1]*Diagnostic and Treatment Centre INTERLAB, Poznan, Poland,* [2]*University of Medical Sciencies, Poznan, Poland*

Background: Advanced arthropathy occurs even in young adults with haemophilia, if they have not been properly treated. It has been proved that physical training increases isometric muscular strength and proprioceptive performance in haemophilia patients. Some new methods of physiotherapy, introduced recently, might improve the results of haemophilic arthropathy treatment.

Aims: The aim of this study was to present the new methods of physiotherapy process and their effects on patients with advanced haemophilic arthropathy.

Methods: Five subjects, aged from 32 to 42 years, with severe haemophilia A or B attended physiotherapy in an outpatient ambulatory setting over a 3-month period. The following treatment modalities were performed: walking on AlterG anti-gravity treadmill, deep penetrating electromagnetic stimulation (Salus Talent), manual physical therapy, mobilization and manipulation techniques, active muscle-strengthening exercises, post isometric relaxation (PIR) muscle energy techniques, as well as exercises for improvement of the coordination, postural equilibrium and proprioception exercises using sensorimotor discs. The HJHS (Haemophilia Joint Health Score) has been used to assess the effectiveness of the treatment, VAS scale (Visual Analog Scale) to assess level of pain, TUG test (Timed Up and Go) to assess mobility as well as dynamic and static balance.

Results: Strength of the muscles acting on the joints improved, swelling of joints diminished and the level of pain decreased. An improvement of the dynamic and static balance was found as well. The range of motion did not change. Physiotherapy process did not provoked bleeding episodes in patients with haemophilic arthropathy included to the study.

Conclusions: New methods of physiotherapy including walking on AlterG anti-gravity treadmill, and deep penetrating electromagnetic stimulation (Salus Talent) are an interesting option, which might improve the results of physical training in patients with haemophilic artropathy.

PB 1816 | High Adherence in Adult and Pediatric Patients with Hemophilia B Receiving Prophylaxis with rIX-FP

E. Santagostino[1], G. Kenet[2], J. Oldenburg[3], A. Chan[4], L. Boggio[5], C. Altisent[6], W. Seifert[7], the PROLONG-9FP Investigators

[1]*Angelo Bianchi Bonomi Hemophilia and Thrombosis Center IRCCS Ca' GrandaFoundation, Maggiore Hospital Policlinico, Milan, Italy,* [2]*The Israeli National Hemophilia Center, Sheba Medical Center, Tel Hashomer, Sackler Medical School, Tel Aviv University, Tel Aviv, Israel,* [3]*Institute of Experimental Hematology and Transfusion Medicine, University Clinic Bonn, Bonn, Germany,* [4]*Department of Pediatrics, McMaster University, Hamilton, ON, Canada,* [5]*Rush Hemophilia & Thrombophilia Center, Rush University Medical Center, Chicago, IL, United States,* [6]*Haemophilia Centre, Hospital Universitari Vall d'Hebron, Barcelona, Spain,* [7]*CSL Behring, Marburg, Germany*

Background: rIX-FP is a fusion protein genetically linking recombinant human coagulation Factor IX with recombinant human albumin. In clinical trials, 7-, 10- or 14-day rIX-FP prophylaxis in adults (≥12 years) and 7-day prophylaxis in pediatric patients (< 12 years) achieved median annualized spontaneous bleed rates of 0.00.

Aims: This analysis evaluated adherence to different regimens in two clinical trials of patients with hemophilia B (FIX ≤2%).

Methods: Adults with hemophilia B received either on-demand treatment for 6 months then prophylaxis every 7 days (on-demand arm; n=23) or 7-day prophylaxis for 6 months then, if eligible, prophylaxis once every 10 or 14 days (prophylaxis arm; n=40). Pediatric patients (n=27) received prophylaxis every 7 days. Dose, dosing frequency and rIX-FP consumption was recorded in an e-diary; reported adherence was reconciled with the number of used vials returned at each study visit. Adherence to prophylaxis was determined in terms of schedule (defined as a compliance rate ≥80%; adults and pediatrics) and prescribed dose (adults only).

Results: In the adult study, 94.9% of subjects were adherent to their prophylaxis schedule. Mean prophylaxis compliance rate for the 7-day regimen was similar between on-demand and prophylaxis arms (95.5% and 94.7%, respectively). Mean compliance rates with 10- and 14-day regimens was 90.7% and 97.2%, respectively. Overall, 85.7% of adult patients were dose compliant (within 10% of prescribed dose ≥80% of the time). In the pediatric study, all patients were adherent with the weekly prophylaxis schedule; mean overall compliance rate was 97.9% and was similar between those aged 1-5 years and those aged 6-11 years.

Conclusions: Adherence to prophylaxis schedule is essential for bleed prevention in patients with hemophilia. Data show that 7-, 10- and 14-day rIX-FP prophylaxis regimens result in high rates of compliance and very low bleeding rates in both adult and pediatric patient populations.

PB 1818 | PROTECT VIII: Can Patient Characteristics Predict Eligibility for Less-frequent Prophylaxis Dosing Regimens?

J. Oldenburg[1], L.A. Michaels[2], M. Wang[2], O. Afonja[2], on behalf of PROTECT VIII Investigators

[1]*University Clinic Bonn, Bonn, Germany,* [2]*Bayer, Whippany, United States*

Background: Efficacy of prophylaxis with BAY 94-9027, a prolonged-half-life recombinant factor VIII product, was shown using individually tailored dosing regimens (2x/wk, every 5 or 7 days) in PROTECT VIII, a phase 2/3 study in which previously treated adolescents and adults with severe hemophilia A received BAY 94-9027 for 36 weeks on demand or as prophylaxis (*J Thromb Haemost* 2016:Epub). Prophylaxis intervals were determined after a 10-week run-in period of 25 IU/kg 2x/wk BAY 94-9027 prophylaxis for preselection of patients suitable for less-frequent dosing. Patients with ≤1 spontaneous joint or muscle bleed during the run-in were eligible for randomization to prophylaxis every 5 days (45–60 IU/kg) or every 7 days (60 IU/kg); patients with >1 spontaneous bleed were ineligible for randomization and subsequently received 30–40 IU/kg 2x/wk.

Aims: To identify baseline characteristics of PROTECT VIII patients that are potentially predictive of patients with hemophilia A who may

be considered for every-5th-day or every-7th-day prophylaxis with BAY 94-9027.

Methods: In this post hoc analysis, baseline characteristics were compared for patients who were eligible vs ineligible for randomization to less-frequent dosing regimens in PROTECT VIII.

Results: Based on bleeds in the run-in period, 97/110 patients (88.2%; median age, 34 y) were eligible and 13 patients (median age, 32 y) were ineligible for randomization to less-frequent prophylaxis dosing. Patients eligible vs ineligible for randomization had fewer median total bleeds and joint bleeds in the previous 12 months (5.0 vs 15.0 [total]; 2.0 vs 10.0 [joint]) and fewer median target joints (1.0 vs 2.0; **Table**). A higher proportion of patients eligible vs ineligible for randomization received prophylaxis before the study (81.4% vs 69.2%).

TABLE. 1 Baseline Characteristics of Patients Eligible vs Ineligible for Randomization to Less-Frequent BAY 94-9027 Dosing Regimens

	Eligible for Randomization (n=97)*	Not Eligible for Randomization (n=13)
Age, y, median (Q1; Q3)	34 (26, 46)	32 (24, 37)
Number of total bleeds in previous 12 months, median (Q1; Q3)	5.0 (1.0; 15.0)†	15.0 (9.0; 25.0)
Number of joint bleeds in previous 12 months, median (Q1; Q3)	2.0 (0.0; 11.0)†	10.0 (6.0; 19.0)
Target joint present, n (%)	69 (71.1)	11 (84.6)
Number of target joints per patient, median (Q1; Q3)	1.0 (0.0; 2.0)	2.0 (1.0; 2.0)
Previous prophylaxis treatment, n (%)	79 (81.4)	9 (69.2)

*11 eligible patients were not randomized because randomization arms were full.
†n=95.

Conclusions: Based on PROTECT VIII data, number of previous joint bleeds and target joints are relevant indicators for predicting suitability of patients for less-frequent BAY 94-9027 prophylactic dosing regimens.

PB 1819 | Is Intermediar Intensity Prophylaxis with Factor VIII Sufficient for Improvement of Overall Hemostasis Potential in Hemophilia A Patients?

I. Djunic[1,2], V. Dopsaj[3], I. Elezovic[1,2], P. Miljic[1,2], M. Mitrovic[1,2], A. Novkovic[4], N.M. Hourani Soutari[5,6], J.P. Antovic[5,6]

[1]Clinic for Hematology, Clinical Center of Serbia, Belgrade, Serbia, [2]Medical Faculty of Belgrade University, Belgrade, Serbia, [3]Institute for Medical Biochemistry, Pharmacy Faculty of Belgrade University, Belgrade, Serbia, [4]Clinical Hospital Center Zemun, Belgrade, Serbia, [5]Institute for Molecular Medicine and Surgery, Karolinska Institutet, Department of Clinical Chemistry, Stockholm, Sweden, [6]Karolinska University Hospital, Department of Coagulation Research, Stockholm, Sweden

Background: Prophylaxis with Factor VIII (FVIII) concentrate prevents recurrent bleeding and hemophilic arhtropathy in patients with severe hemophilia A (hA) but it is not widely available due to the high costs.

Aims: To investigate the efficacy of different prophylactic regimens in comparison with on-demand treatment in patients with severe hA using Overall Hemostasis Potential (OHP) as a laboratory tool for estimation of global hemostatic capacity.

Methods: Five patients received FVIII concentrate in standard dose (20 IU/kg three times per week), five received intermediate dose (10-15 IU/kg three times per week), while seven patients received FVIII concentrate only on-demand. Blood samples were collected before the start of prophylaxis and after 3 months, before receiving next dose. OHP and its parameters: Overall Coagulation Potential (OCP) and Overall Fibrinolysis Potential (OFP) were analyzed. Study is improved by medical ethics committee and informed consent was obtained.

Results: OHP was significantly improved after 3 months of treatment with FVIII concentrate (0.99 vs 11.15 and 2.26 vs 9.60 for standard and intermediary dose respectively), while no improvement was observed in on-demand treated patients (2.28 vs 1.94). Similar results were observed for OCP, while no change neither difference between prophylaxis and on-demand treatment was observed for OFP.

Conclusions: Prophylactic treatment with FVIII concentrate improved global hemostasis in hA and this improvement was not directly and only associated with FVIII level. Intermediary dose was as good as standard dose prophylaxis in this context confirming that as it was previously described frequency rather than intensity is the most important for the treatment efficiency. This also indicates that sufficient and safe hemostasis may be achieved with lower cost of the treatment what is very important not only for developing but even countries with large healthcare budgets.

PB 1820 | Can Tertiary Prophylaxis Bring about Zero Bleed in Adult Persons with Hemophilia? A Single Center Observation Study in Japan

T. Fujii[1], T. Fujii[2], N. Yamasaki[1], S. Saito[1]

[1]Hiroshima University Hospital, Division of Blood Transfusion, Hiroshima, Japan, [2]Hiroshima University, Graduate School of Biomedical and Health Science, Hiroshima, Japan

Background: It has been reported that prophylactic infusions of factor concentrates (prophylaxis) were effective to suppress joint bleedings in persons with hemophilia (PWHs). However, it is unclear that prophylaxis contribute to zero bleed or not.

Aims: To clarify the efficacy of tertiary prophylaxis on decreasing annualized joint bleeding ratio (AJBR) in PWHs who received this treatment. And then, we also guess whether the prophylaxis accomplish zero bleed in PWHs' joints or not, by observing the change of their AJBRs.

Methods: Patient diaries from persons undergoing home infusion treatment have been collected from 2002 to 2016. Infusion days,

dose, reasons of infusion and joint bleeding sites in respective patients were identified with reference to their diaries.

Results: The subjects were 35 adult PWHs (A, n=29; B, n=6), who received prophylaxis for more than 2 years continuously and had good adherence to recording their infusion. Because 19 patients (A, n=14; B, n=5) also had the record of on-demand treatment, we could compare their AJBRs before and after introducing prophylaxis. AJBRs before it were statistically more than the first year after starting prophylaxis (11.2 vs 1.5, median, p< 0.001). Comparing AJBR in hemophilia A and in B, AJBR in hemophilia A was dramatically decreased (from 22.8 to 1.25, p< 0.001). On the other hand, in hemophilia B, the change was not so much (from 7 to 3, p< 0.05). Their AJBRs at the second year of prophylaxis were more decreased comparing with them at the first year (1.4 vs 0.5, median, p< 0.01). However, comparing AJBRs at the second year with them at the third year, there was not statistical different. Although 18 of the subjects accomplished zero bleed at the second year prophylaxis, there were 15 PWHs who accomplished it at third year by contrast.

Conclusions: Tertiary prophylaxis is effective to reduce ABR of adult hemophilic patients. However, all of them cannot necessarily achieve zero bleed.

PB 1821 | Personalized Treatment of Pediatric Patients with Severe Haemophilia A. Importance of Pharmacokinetics. Assessment Benefits from Kinetics of Factor VIII (Simoctocog Alpha)

E. Spallino[1], G. D'Antona[1], V. Dicembre[1], F. Gagliano[2], G. Corsello[3]

[1]ARNAS CIVICO Palermo, Clinica pediatrica, Palermo, Italy, [2]ARNAS CIVICO Palermo, Clinica Pediatrica, Palermo, Italy, [3]UNIVERSITà DEGLI STUDI PALERMO, CLINICA PEDIATRICA, PALERMO, Italy

Background: It is now known that both primary and secondary prophylaxis should be adjusted (tailored prophylaxis) for each individual patient since the differences between patients are remarkable for severity, frequency, magnitude and location of bleedings. Simoctocog alpha is the first recombinant B domain deleted FVIII, produced in a human cell line, without chemical modification or protein fusion. Undergoing species-specific post translational modification confers to the product the lack of non-human epitopes as well as a high binding affinity to vWF .

Aims: The focus on our patients was to establish a personalized prophylaxis associated with ABR (Annualized Bleeding Rate) reduction of 96-97%, resulting in an improvement of treated subjects' quality of life.

Methods: Infusion and blood samples were managed at patient's home and sent to a central lab. Individual PK profile has been performed with blood samples collected before Simoctocog alpha infusion and at +0.5, +1, +3, +9, +24, +48, +72 h.

Results: In our center we performed 4 PK in 4 patients with haemophilia A and we decided to modify the prophylaxis according to the individual results. The average bleeding annual rate (ABR) of all patients before the personalized prophylaxis was 41. Preliminary results are confirming what was suggested by the study GENA 21. The kinetic predictions have been made considering a trough of 3% and 5%. On average, in our patients Simoctocog alpha half-life was long (24.51 h) enough that the trough of 1% determined very low values of Cmax and dose. Even with a trough of 3%, the interval of 48 hours with a 10.62 IU / kg dose led to a Cmax of 17%.

Conclusions: Our approach of prophylaxis optimization with Simoctocog alpha allowed us to establish a different dosing schedule for our patients, leading to a reduction of the ABR, reducing the number of weekly infusion, lowering product consumption.

PB 1822 | Splenectomy for Liver Cirrhosis Improved Systemic Condition in HIV/HCV Co-infected Patients with Hemophiliacs

H. Katayama

Ogikubo Hospital, Haematology, Tokyo, Japan

Background: HIV infection no longer became a fatal disease by virtue of an anti-retroviral therapy (ART), however liver cirrhosis (LC) due to HCV is still problematic because it has been the major cause of death in HIV/HCV co-infected patients with hemophiliacs. Once LC develops, liver function never turns back to a former state. Moreover, the risk of developing HCC is remained even if HCV was eradicated. A number of CD4 cells (CD4) in HIV/HCV co-infected patients with LC inclined to decrease due to their splenomegaly.

Aims: A decreased CD4 also might be one of risk factors for developing some opportunistic infections (OIs). We evaluated the efficacy of splenectomy in hemophiliacs with LC retrospectively.

Methods: Splenectomy was performed in five hemophiliacs co-infected HIV/HCV and had less counts of both CD4 and platelets (PLT) with splenomegaly from 1994 to 2015. CD4, PLT, and clinical condition were evaluated before and after splenectomy.

Results: At 6 months after splenectomy median PLT ($\times 10^9$/L) has changed to 205 from 38 and CD4 (/μL) to 529 from 141, respectively. The HIVRNA (VL) has reached to undetectable level in four patients and the rest one who would not have been responding by ART from the HAART era also decreased after splenomegaly. Esophageal varices disappeared in two patients and none showed any complications such as OIs or overwhelming post-splenectomy infections (OPSI). One with meld score13 who had underwent liver transplantation at 42 months after splenectomy still stays in shape.

Conclusions: Splenectomy lead to the elevation of both CD4 and PLT. Hereby their systemic condition was improved than before and further bleeding tendency was also prevented. Finally, whereas hyposplenic states were deeply concerned, these results suggested splenectomy may consider as one of therapeutic options for improving both their immune and hepatic condition in patients with an end stage of liver disease.

PB 1823 | Two Effective Cases of Immune Tolerance Induction Using Turoctocog Alfa Combined with Immunosuppressive Therapy in Non-severe Hemophilia A

C. Yushi[1], K. Amano[1,2], Y. Kamikubo[1], A. Ichiki[1], M. Bingo[1], T. Hagiwara[1], T. Suzuki[1], K. Fukutake[1,2]

[1]Tokyo Medical University, Department of Laboratory Medicine, Tokyo, Japan, [2]Tokyo Medical University, Department of Molecular Genetics of Coagulation Disorders, Tokyo, Japan

Background: Non-severe hemophilia A (NSHA) has a higher risk of developing inhibitors after 100 exposure days (ED); therefore, inhibitor development throughout a patient's lifetime might occur.
Aims: To improve the treatment outcome of NSHA with inhibitors.
Methods: Retrospective patient chart review and literature search.
Results:
Case 1: An 18-year-old man with NSHA. The inhibitor was triggered by therapy with a conventional recombinant factor VIII preparation (rFVIII) for left femoral compartment syndrome when he was 16 years old (100 ED or more), and the titer reached a maximum of 85 Bethesda units (BU). Although the titer decreased and disappeared after 4 doses of 375 mg/m^2 rituximab, it subsequently increased to 14 BU. Immune tolerance induction (ITI) was then initiated with about 80 IU/kg Turoctocog alfa three times a week. The titer was 0 BU at 2 weeks after the initiation of ITI without anamnestic responses. Although the reduction of recovery rate and shortening of half-life was prolonged, remission was obtained 22 weeks after starting ITI.
Case 2: A 42-year-old man with NSHA. The inhibitor was triggered by surgery for cervical myelopathy with rFVIII, and detected as 14 BU just before a single dose of rFVIII against spontaneous muscle bleeding, corresponding to 16 ED. Therefore, hemostasis management was switched to a bypassing agent. Subsequently, the titer increased to 32.8 BU. Thereafter, ITI was initiated with about 80 IU/kg Turoctocog alfa once a day, and the titer was reduced to about 10 BU in 1 week and that state continued. Methylprednisolone 1000 mg once a day for 3 days was added at 5 weeks after the introduction of ITI. The titer decreased to 0.2 BU at 19 weeks after starting ITI, and is currently maintained at this level.
Conclusions: We performed ITI using Turoctocog alfa combined with immunosuppressive therapy only in the two cases reported here. As a result, both patients are improving; therefore, this therapeutic strategy might be an option for the treatment of NSHA with inhibitors.

PB 1824 | Tailored Prophylaxis: A Bridge between QoL and Retrenchment. Our Experience with Simoctocog Alfa

J. Agnelli Giacchello, A. Valpreda, E. Dosio, M. Boccadoro, A. Borchiellini

AOU Città della Salute e della Scienza di Torino, Dipartimento di Oncologia ed Ematologia, CRR Malattie Emorragiche e Trombotiche dell'Adulto, Turin, Italy

Background: Prophylaxis has become the gold standard approach in patients with severe Hemophilia A. The main goals of prophylaxis are converting severe to moderate disease, reducing number of bleeds, preventing or delaying arthropathy and improving Quality of life (QoL). Simoctocog Alfa (Nuwiq) is a new generation recombinant Factor VIII protein; clinical studies with Nuwiq in severe Hemophilia A showed relevant differences between patients with half-life ranging from 6.5 to 32h. These results suggest to tailor patients' treatment with a single dose individual Pk analysis.
Aims: We used Pk to optimize prophylaxis therapy with Nuwiq in an adult patient. He was a 48 years old male, 60 kg, history of high titer inhibitors eradicated, HJHS (Hemophilia Joint Health Score) 60. At the time of accrual, the patient was on prophylaxis with other rFVIII (3.000U x 3/w), maintaining a trough level 0.08 IU/dl with ABR 2 in the previous year.

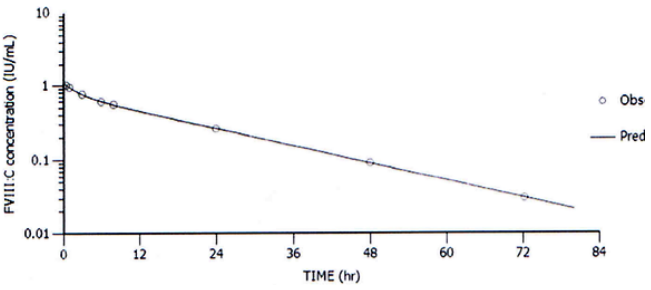

FIGURE 1 Result of individualized analysys of FVIII pharmacokinetics (Pk)

TABLE 1 Simulated Dosing Schemes

Weight (kg)	Nominal Dose (IU/kg)	T1/2 (hr)	C0 (IU/ml)	Target Trough level(IU/ml)	Tau (hr)	Est. dose (IU/Kg)	Est. Cmax (IU/ml)	Est. C0 (IU/ml)
60	50	15.44	1.079	0.08	24	15.2	0.31	0.33
					36	26.1	0.53	0.56
					42	34.1	0.69	0.64
					48	44.7	0.91	0.96
					56	64.0	1.30	1.38
					60	76.6	1.55	1.65
					72	131.2	2.66	2.83

Methods: Infusion and blood samples were performed at Hospital or at patient's home, using NuPreviq service, and sent to central and local lab. Blood samples were collected before Nuwiq 50U/Kg and +0.5, +1, +3, +6, +9, +24, +48 and + 72h after infusion. Demographic data and Pk timing were sent to Accovion with the desired Trough level (0.08 IU/kg). Pk data were analyzed with a 2-compartment model (2CP).

Results: Pk results demonstrated 15.44h half-life, recovery of 2.0 % and levels of 0.09 IU/dl at +48h.

The simulated dosing scheme suggested a 12% reduction dose to reach the tough levels of 0.08 IU/dl at +48h. Therefore, we proposed to our patient a prophylactic regimen of 2.500U x3/w. At 1 year follow-Up ABR was 0 with a good compliance. FVIII needs were reduced from 468.000U/y to 390.000U/y (from 318240€ to 253500€).

Conclusions: Our experience suggests that Pk could be a useful tool to optimize prophylactic therapy. The reduction of total IU of FVIII led to a relevant impact on public health cost containing and on patients' QoL.

PB 1825 | Therapeutic Efficacy of Low-dose Immune Tolerance Inductionin 5 Chinese Severe Hemophilia A Children with Inhibitor in Good Risk

Y. Li, G. Li, Z. Chen, X. Wu, Y. Zhen, L. Tang, R. Wu

Beijing Children's Hospital Capital Medical University, Beijing, China

Background: Immune tolerance induced (ITI) is an effective way to eliminate the hemophilia inhibitor, but by economic constraints, high or medium dose ITI treatment in China is hard to carry out. Low dose ITI is economically feasible.

Aims: This paper aims to review low dose ITI treatment experience at our hemophilia treatment center by collecting information of hemophilia A patients with good risk and their response to ITI treatment, and to evaluate the feasibility of low dose ITI in China.

Methods: Retrospectively collected clinical information of 5 patients at our hemophilia clinic who accepted low dose ITI. Clinical information included the baseline data; Inhibitor found time, degree of peak, ITI bleeding before treatment; ITI treatment start time, application solutions, duration and treatment outcome; bleeding during ITI treatment, and descriptive analysis.

Results: Inhibitor occurred at 57(18-65)months.The peak titer was 13.6BU/ml (3.9-20.2 BU/ml). After the appearance of inhibitor, the average bleeding rate(ABR) was 6.31times/person/month. ITI treatment started at 64 month-old (28-91), and interval between inhibitor appearance to ITI treatment was 20 months (range, 7-26). Low dose ITI was 25 to 50 u/kgQod. For 4 successful cases, inhibitor turned negative at 13 months, 4 months, 8 months and 9 months respectively and remain negative till now.The other case suspended ITI because of inhibitor titer increasing after 3 months. Only 2 cases bleed during ITI treatment, the ABR was 0.21.

Conclusions: Low dose ITI benefits hemophilia A patients with inhibitor and was effective to eliminate inhibitor and control hemorrhage.

PB 1826 | Efficiency of Prophylaxis in an Adult with Hemophilia after Dose Adjustment Using a Bayesian Model FVIII Pharmacokinetics Estimation

M. Canaro, B. Galmes

Hospital Son Espases, Palma, Spain

Background: We describe the case of a 32-year-old patient with severe hemophilia A (HA; FVIII level 0.25%) diagnosed at 12 months of age, serology negative for infectious diseases and no history of inhibitors. His HA clinical history is summarized in Table 1.

TABLE 1 Patient's hemophilia history

Age	Clinical Event	Management and Comments
12 months	Severe hemophilia A diagnosis, serology negative for infectious diseases and no history of inhibitors	Treatment on-demand
10 years	Patient presents target joint (right ankle)	Standard prophylaxis initiated: 20-40 IU/kg 3 × week Right ankle becomes target joint
15 years	Self-administration of factor	Good adherence
16 years	Synoviorthesis of the right ankle	
21 years	Patient suspends prophylaxis	Office work and cycling on occasion
21-29 years	Joint bleeds frequent (15-20 per year) Left ankle becomes new target joint	
29 years	Both ankles present severe functional impairment and pain that hinder walking Advanced arthropathy on MRI	Daily infusions for joint pain, so the patient reinitiates prophylaxis (40 IU/kg 3 × week) and receives physical rehabilitation
29 years	Clinical improvement after 4 months	Infusions are spaced to 2 × week
32 years	Arthropathy pain in the ankles worsens	Prophylaxis adjusted to 28 IU/kg 48 h, and NSAIDs taken on a regular basis. Pain decreased, and mobility was recovered. Pharmacokinetic study performed after 4 months (see methods)

Aims: To describe the experience of prophylaxis adjustment after pharmacokinetic (PK) study performed with web-based software using a published population PK model together with a Bayesian

algorithm, designed for patients receiving octocog alfa, antihemophilic factor (plasma/albumin free method).

Methods: The web-based software myPKFiT® V1.1 (www.mypkfit.com, Baxalta) was used for PK study. The patient had received octocog alfa (Advate, Baxalta) 2000 IU/48 h (28 IU/Kg) for 4 months and 2 samples taken at 4 and 28 h were analyzed (Figure 1-Top). FVIII half-life was 13 h, clearance rate 0.031 dl/h/kg, volume in steady state 0.5 dl/kg, and time to 1% above baseline 68 h. The regimen was adjusted for body weight (77 kg) and a desired trough level of 2% (due to lifestyle and arthropathy; Figure 1-Bottom).

Figure 1. Top: Bayesian pharmacokinetic estimation based on the patient information provided by the web-based software (www.mypkfit.com). The dots represent the two samples taken. Bottom: Simulation of dosage calculation based on desired trough level of factor VIII

Results: The dose in the adjusted regimen was 1343 IU (17.4 IU/kg) every 48 h, thus reducing factor consumption by 38%. The patient has not presented any bleeding event in the past year, and has recovered mobility in both ankles.

Conclusions: myPKFiT® may be useful for designing an adjusted prophylaxis regimen with Advate and, even in a regimen with trough level 2%, factor consumption and costs may be reduced, compared to unadjusted prophylaxis.

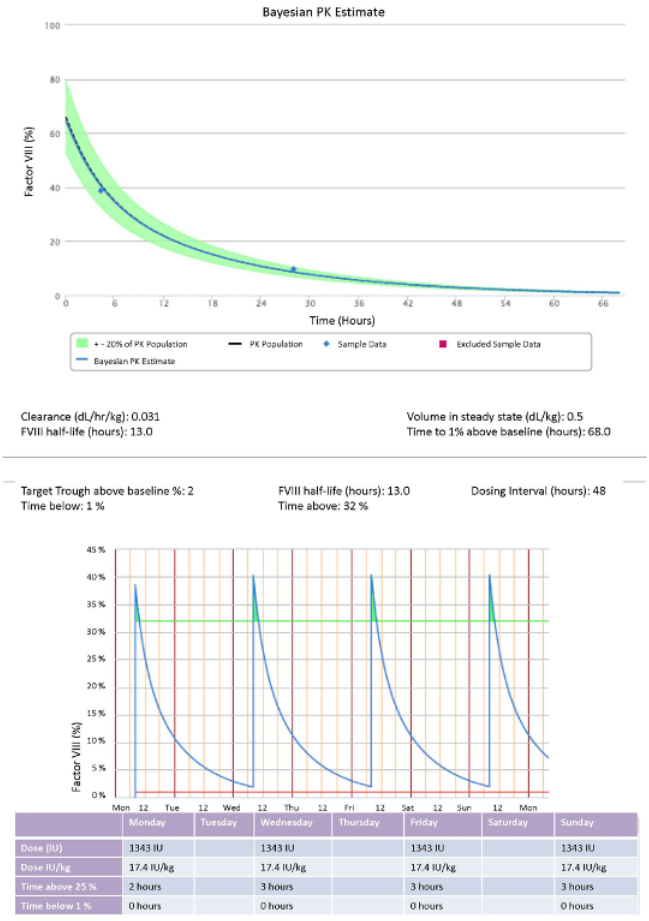

FIGURE 1 Bayesian pharmacokinetic estimation based on the patient information provided by the web-based software (www.mypkfit.com) and simulation

Note: *Labeled use of Advate for prophylaxis in severe HA is 20-40 IU/kg every 2-3 days. myPKFiT® v1.1 requires ≥2 samples taken approx. 3 h apart, 24-32 h after infusion.*

PB 1827 | Evaluating the Frequency of Haemophilia and Bleeding Parameters of Persons with Bleeding Disorder in South East, Nigeria

T. Nwagha[1], S. Okparoka[2]

[1]*University of Nigeria Nsukka/University of Nigeria Teaching Hospital Ituku Ozalla, Haematology, Ituku Ozalla, Nigeria,* [2]*University of Nigeria Nsukka, Physiology, Enugu, Nigeria*

Background: Haemophilia is under reported and under diagnosed in most developing countries like Nigeria Paucity of data, Increased childhood mortality , diease associated morbidity, poor access to factor replacement therapy,comprehensive care and non commitment of government and policy makers towards haemophilia care and management may be contributory.

Aims: To evaluate the frequency of haemophilia among those with bleeding disorders in South East Nigeria.

Methods: A pilot study of fifty consecutive consenting persons with bleeding disorders were convienently recruited from the four tertiary hospitals in South East Nigeria. Blood samples collected in EDTA for platelet count using haematology analyser Mythic 22, platelet poor plasma was used to run Prothrombin time (PT), Activated partial thromboplastin time (APTT), mixing studies and Bioassays for factor VIII and IX assays using the 1-stage APTT based assays . Data was analyzed using the graph pad prism version 6.0.

Results: The study showed 2% of subjects with bleeding disorders had haemophilia. It also showed that 68% of subjects were thrombocytopenic which was the commonest cause of bleeding disorder. The most common bleeding

symptoms was gastrointestinal bleeding (23.4%).Majority of subjects (32.4%) had a bleeding score of four based on MCMDM1VWD bleeding assessment questionnaire

Conclusions: Haemophilia should be considered as a differential diagnosis in patients with bleeding disorders. Thrombocytopenic bleeding are the commonest cause of bleeding disorders and larger multicenter studies are needed to determine prevalence of haemophilia and the likely causes of thrombocytopaenic bleeding in Nigeria.

PB 1828 | Personalized Approach to Treatment due to Pharmacokinetic Study: Description of One Case of Moderate Haemophilia A with Severe Bleeding Phenotype after Switch to Simoctocog Alfa

C. Ambaglio[1], M. Russo[1], F. Zane[1], C. Sacco[1], E. Genini[2], P.S. Preti[1], G. Gamba[1]

[1]*Fondazione IRCCS Policlinico San Matteo, Department of Internal Medicine, Haemophilia Centre, Pavia, Italy,* [2]*Fondazione IRCCS Policlinico San Matteo, Laboratory Analysis Service, Pavia, Italy*

Background: Clinical studies with simoctocog alfa in adults affected by severe haemophilia A revealed half-lives ranging from 6.5 to 32 hours. In order to assess In-Vivo-Recovery and elimination Half-Life, we proposed a pharmacokinetic study to a patient with moderate haemophilia A and severe phenotype -annual bleeding rate (ABR) > 4 despite regural prophylaxis with octocog alfa.

Aims: The study of pharmacokinetic (PK) was proposed in order to reduce spontaneous bleeding that occurred during previous prophylaxis scheme; furthermore we needed to avoid more than two infusions per week, for difficult venous access. We ipothesized a trough level of 0.03 IU/mL.

Methods: The patient has FVIII residual activity of 0.02 IU/mL with severe bleeding phenotype. He is 46 years old, he has active life. He presents severe haemophilic arthropathy of both ankles and elbows. He was treated on demand until 2013 when he started prophylaxis with octocog alfa 40 U/kg two days per week; in 2014 we had to increase dosage to 50 IU/Kg two days per week because of ABR > 4. In April 2016 we switched to simoctocog alfa and we studied PK after infusion of 4000 U simoctocog alfa (52 IU/Kg), exploiting the NuPreviq program.

Results: The In-Vivo-Recovery was 1.86 % per IU/Kg, elimination half-life was 20.10 hrs. Considering an ideal trough level of 0.03 IU/mL and trying to mantain two per week infusions, we adopted the dosage of 40 IU/Kg every 84 hours. The patient has experienced only two spontaneous joint bleeding during the last nine months. The actual dosage of simoctocog is 2000 UI/week lower than the previous scheme, with a favourable reduction of bleeding rate.

Conclusions: Individualized PK analysis permits tailoring the best dosage in order to optimize the control of spontaneous heamorrhages in patients on prophylaxis. In this case we could mantain the frequency of infusions and also decrease the dosage of infused FVIII, obtaining a significative reduction in bleeding manifestations.

PB 1829 | Haemophilia and Acute Coronary Syndrome (ACS)

A.M. Pizzini, D. Galimberti, M.C. Leone, A. Casali, A. Ghirarduzzi

Arcispedale Santa Maria Nuova, Medicina Interna, Reggio Emilia, Italy

Background: Haemophilia A doesn´t protect from cardiovascular (CV) risk: haemophilic population (HP) can present thrombotic problems related to age and risk factors. Acute CV management and secondary prevention in HP presents an increased bleeding risk caused by drugs active on the coagulation pathway need.

Aims: Epidemiologic studies evaluated the prevalence of cardiologic disorders in HP related to age. Below 30 years coronary syndromes have a prevalence of 0,05%, after 60 it rises to 15,2%. In spite of increased CV disease in HP, due to a rise in their life expectancy, there is no standard treatment.

Methods: We describe the case of an acute coronary syndrome (ACS) in a 39 y.o. patient with mild A haemophilia (FVIII 2%, no inhibitor) and with a rare bleeding tendency. He had several CV risk factors: abdominal obesity, hypertension, hypercolesterolemia and smoke. He was treated with FVIII infusion (30 U/Kg), coronarography and bare metal stenting for a proximal IVA stenosis. He was then given unfractionated heparin followed by Enoxaparin at a subtherapeutic dose (6000 U bid , 90 Kg) and duble antiplatelets (DAPT). FVIII infusion was continued for 5 days (2000 U/day) with serum levels 20-60%. DAPT was then continued for a mouth, keeping FVIII prophylaxis at a reduced dose (2000 U every other day with FVIII level of 10%) in the absence of bleeding. When Clopidogrel was stopped we interrupted FVIII too.

Results: At 6 mounths the patient does´t present haemorrhages and he has no inhibitors.

Conclusions: ACS treatment in HP is feasible thanks to a useful collaboration between different specialists. DAPT has a pivotal role in HP, with an acceptable bleeding risk. Further studies are needed to evaluate wich FVIII are best to protect HP both in the revascularization phase and during DAPT period. As a matter of fact HP, erroneously considered to be at low CV risk, should be educated to better control CV risk factors and to reduce this risk of events, expecially in the young.

PB 1830 | The Diagnostic Value of Rotational Thromboelastometry in Patients with Non-severe Hemophilia A

F. Vossough[1], M. Ahmadinejad[2], G. Toogeh[3], M.R. Managhchi[3]

[1]High Institute for Research and Education in Transfusion Medicine-Iranian Blood Transfusion Research Center, Tehran, Iran, Islamic Republic of, [2]Blood Transfusion Research Center, High Institute for Research and Education in Transfusion Medicine, Tehran, Tehran, Iran, Islamic Republic of, [3]Thrombosis Hemostasis Research Center - Vali-Asr Hospital - Emam Khmeini Complex Hospital - Tehran University of Medical Science, Tehran, Iran, Islamic Republic of

Background: Factor VIII activity (FVIII:C) assay in citrated plasma is usually used to diagnose hemophilia A. This test just study the initiation of clot formation, but hemostasis consists of complicated interactions between blood cells and proteins and endothelial. Recently, global assays like Thromboelastometry which study hemostasis in whole blood has become a useful way to evaluate coagulation disorders.

Aims: The aim of this study is to determine the diagnostic value of rotational thromboelestometry in Iranian patients with non-severe hemophilia A and its relation with factor VIII level.

Methods: Rotational Thromboelastometry was performed for 73 patients with mild/moderate hemophilia A by use of INTEM reagent and ROTEG device. FVIII:C was also measured by one-stage clotting and chromogenic assays.

Results: From 73 cases, 45 were classified as mild and 28 as moderate hemophilia A by on-stage FVIII:C assay. The results of ROTEM were not acceptable in 7 patients due to technical errors so they were removed from the study. ROTEM results for 7 patients (6 mild and 1 moderate ones) were normal. In our patients, parameters of the Rotational Thromboelastometry such as coagulation time (CT), clot formation time (CFT), maximum clot firmness (MCF), Alpha angel and

TABLE 1 Results of Rotational Thromboelastometry

	Categorization of the patients according to relation of FVIII:C results by one-stage and chromogenic methods								
ROTEM INTEM Parameters	Non-Discrepant n=26			Discrepant (Lower chromogenic F VIII:C) n=38			Reverse Discrepant (Lower one-stage FVIII:C) n=2		
	Mean	SD	No. of Abnormals	Mean	SD	No. of Abnormals	Mean	SD	No. of Abnormals
CT(S)	258.35	56	19	302.33	64.91	36	234	22.62	1
CFT(s)	81.44	22.2	2	93.41	14.47	10	90	25.45	0
AAngle	73.61	3.95	3	60	72.82	14	72	5.56	1
MCF (mm)	63	5.28	1	72.82	60	5	58	0	0

A5 had a meaningful statistical relation with F VIII:C in the plasma (P value for most of parameters was 0.01). CT (and after that A5) had the most relation with factor VIII level. CT increased in 76% of patients and Alpha angel decreased in 25% of patients.

Conclusions: Increase of CT and decrease of Alpha angel indicate decrease of clot formation rate and clot firmness in hemophilia A patients. CT parameter had a 68 % sensitivity in distinguishing mild hemophilia A patients from moderate ones in our study. Due to the meaningful statistical relation of Rotational Thromboelastometry parameters with F VIII:C level and disease severity it can help physicians as a complementary test to categorize patients as mild or moderate hemophilia A.

PB 1832 | Hemophilia Care in Pakistan

M. Borhany, M. Abid, N. Fatima, T. Shamsi

National Institute of Blood Disease and Bone Marrow Transplantation, Karachi, Pakistan

Background: Hemophilia is a rare congenital disorder characterized by prolonged bleeding, either spontaneously, or after injury. In the developing world,where majority of the hemophiliacs live, awareness of this disease and its management is poorly done.

Aims: Aim was to determine the frequency, clinical picture and treatment information of hemophilia patients in Pakistan.

Methods: A cross sectional, observational study was carried out. Adult and pediatric hemophilia A (HA) and hemophilia B (HB) patients were included. Demographic and management history of patients were recorded and analyzed. Descriptive statistics was applied by using SPSS.

Results: A total of 102 male patients diagnosed as HA(n=69) and HB(n=33) were evaluated. Mean age was 15.34±4.75 years. Age at diagnosis ranged from birth to 5 years. History of consanguinity was present in 91% of cases and significant family history of bleeding in 69% of patients. 46(45%) were severe and moderate types respectively. Hemarthrosis and hematoma were more frequent symptoms in these patients. Surgical history including circumcision was done in 55% patients while 4 patients had major surgeries (hip& femur bones fracture, extensive nasal septum, and head surgery). 29(28%) of patients had transfusion-transmitted infections in which HCV 19(66%) was most prevalent followed by HBV 6(21%) and HIV 4(13%). 14 HA patients (20%) were found to have positive results for inhibitors and none in HB. Treatment included tranexamic acid, fresh frozen plasma, cryoprecipitate, cryosupernatant and factor concentrates on demand.

Conclusions: Hemophilia A and B are common among congenital bleeding disorders. Availability of poor diagnostic facilities and lack of proper management for this group of patients, often leads to wrong diagnosis and inadequate treatment. Rate of transfusion-transmitted diseases, particularly hepatitis C infection, has gained a huge proportion. Comprehensive hemophilia care center with multidisciplinary approach needs to be established in Pakistan.

PB 1833 | Risk Management of Pelvic Pseudotumor in a Patient with Inhibitors and Severe Hemophilia

R. Silva[1], J. Marun[2], D. Perez[2]

[1]Clinica General del Norte, Orthopedics, Barranquilla, Colombia, [2]Clinica General del Norte, Hemophilia, Barranquilla, Colombia

Background: Management of hemophilia patients with inhibitors can be very challenging. On top of that if that patient develops a pelvic pseudotumor in the iliopsoas muscle could be incapacitating in the short-term and can have serious complications in the long term.

Aims: Our aim is to report a successful experience in managing pelvic pseudotumor in patient with inhibitors.

Methods: A 49-year-old patient with severe hemophilia A with inhibitors was admitted in the ER with a clinical picture of about 4 weeks of pain in the lumbar region and left hypochondrium that was exacerbated and associated with deformity in hip flexion and paresthesia of the anterior thigh face. Physical examination revealed a hard mass in the left hypochondrium with hip flexion deformity of 20 degrees. Rx and pelvic MRI revealed a large mass at the level of the left Psoasilliac muscle with defined edges and heterogeneous content with alternating images of hypo and hyper intensity. Psoasilliac Hemophilic Pseudotumor was diagnosed with left femoral-cutaneous nerve lesion. Treatment was started with a bypass agent (FEIBA) since the patient had high response inhibitors. Patient continued with pain and functional limitation of the hip, in addition control images showed that the pseudotumor was getting in contact with the internal cortex of the iliac crest, so it was decided to perform surgical treatment since there was imminent risk of bone erosion due to growth of the pseudotumor.

Results: The patient was taken to surgery service by performing drainage of the pseudotumor, curettage of the walls and filled with a combination of fibrin sealant, demineralized bone matrix and absorbable gel sponge. Successful postoperative status was achieved with the disappearance of pain, improvement of the arches and elimination of the risk of osteolytic erosion of the cortical sheet of the iliac bone.

Conclusions: Our experience shows that pseudotumors in patients with high response inhibitors could correctly be treated with elective surgery and a bypass agent.

PB 1834 | A Study of Home Therapy in Hemophilia Patients

K. Mikyung[1], L. Sunah[2]

[1]*Presbyterian Medical Center, Pediatrics, Jeonju, Korea, Republic of,* [2]*Daegu Fatima Hospital, Internal Medicine, Daegu, Korea, Republic of*

Background: Home therapy has merits, enabling rapid treatment thereby reducing complications,
but difficulty with venous access is a barrier to treatment. There is a paucity of data on this.

Aims: This study investigated the current status of home therapy for patients with hemophilia, and examined problems and potential solutions.

Methods: Patients and their families who were performing home therapy and who attended the camp of the Korea Hemophilia Association in 2014 were asked to complete questionnaires. The questionnaires pertained to complications of infusion and whether (or not) factor infusion was properly performed. Responses were scored on a scale from 1-5, with a high frequency of complications and adequate performance of infusion being allocated relatively higher scores.

Results: The mean score of complications arising from infusion was 1.56±0.46. This was relatively low and was not correlated with the factor infusion training method. The performance of home therapy obtained a relatively high score: 4.46±0.56. The performance score was significantly higher for patients who had practiced infusion with medical personnel, an injection simulator or a video clip.

Conclusions: Although most patients properly performed home therapy, further improvement is needed in training of infusion and keeping records of bleeds. It is essential to establish guidelines on home therapy, develop a standardized patient and family training program, and reinforce the role of hemophilia treatment centers in educating patients and their families.

PB 1835 | Are we Close to International Standards for Hemophilia Care in Tunisia?

H. Elmahmoudi[1,2], M. Achour[1], H. Ben Neji[1], K. Zahra[1], W. Hosni[1], B. Meddeb[1], A. Gouider[1]

[1]*UR14ES11, FMT, University of Tunis El Manar, Tunis, Tunisia,* [2]*National Center for Nuclear Sciences and Technologies, Tunis, Tunisia*

Background: Hemophilia is a genetic bleeding disorder due on defect in the X chromosome, that's why it is more common in males than females and affects roughly 1 in 5,000 males each year. According to the WFH, approximately 70% of PWHA are under diagnosed and untreated, mostly in developing countries.

Aims: We try to evaluate our efforts for hemophilia care in AOHTC in relation to international data.

Methods: For the cross-sectional evaluation we extract data from the AOHTC for the (PWHA) number and from the NIS for the male population number (census 2014). Three indicators are calculated: the percentage difference between the observed and expected hemophilia incidence, the percentage of the total number of PWHA with severe disease calculated and the ratio of adults to children among PWHA standardized to the ratio of adults to children for males in the general population.

Results: Statistical analysis demonstrates the following data:
The percentage difference between the observed and expected hemophilia incidence demonstrates a negative value - 4.37%.
The percentage of the total number of PWHA with severe disease is 48.9%.
The ratio of adults to children among PWHA standardized to the ratio of adults to children for males in the general population is 0.46.

Conclusions: Our results are quite satisfactory demonstrate that a lot of effort was done in the last years in our AOHTC.
The value of percentage difference between the observed and expected hemophilia A incidence (-4.37) it is a negative value but not so important.
The percentage of the total number of PWHA with severe disease in our AOHTC is of 48.6% showing that our health care system reaches an advanced stage of maturity by identifying more mild and moderate than severe PWHA.
The ratio of adults to children among PWHA standardized to the ratio of adults to children for males in the general population is of 0.46, which is near to 1. These results reflect the impact of the support of WFH and the involvement of multidisciplinary teams.

PB 1836 | TAURUS: A Multinational Phase 4 Study Evaluating Real-world Treatment Patterns in Previously Treated Persons with Hemophilia A Receiving BAY 81-8973 for Routine Prophylaxis

K. Meijer[1], U. Scholz[2], B. Siegmund[3], E.A.M. Beckers[4], K. Batt[5], S. Jain[6], S. Rybowski[7], E. Kellermann[8], O. Afonja[7], E. Musi[9]

[1]*University Medical Center Groningen, Department of Hematology, Groningen, The Netherlands,* [2]*Center of Hemostasis, Leizpig, Germany,* [3]*Institute for Thrombophilia and Haemostaseology, Münster, Germany,* [4]*Maastricht University Medical Center, Department of Hematology, Maastricht, The Netherlands,* [5]*Wake Forest School of Medicine, Winston-Salem, United States,* [6]*Hemophilia Center of Western New York and Women and Children's Hospital of Buffalo, Buffalo, United States,* [7]*Bayer US, Whippany, United States,* [8]*Bayer Vital GmbH, Leverkusen, Germany,* [9]*Bayer AG, Basel, Switzerland*

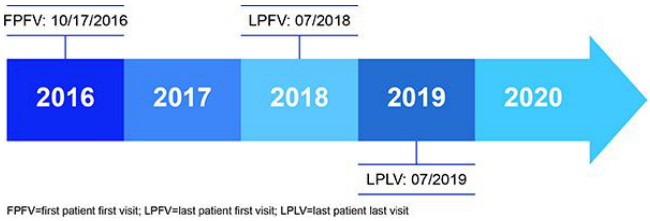

FIGURE 1 TAURUS: Planned Timeline

Background: Routine prophylaxis with BAY 81-8973 using 2x/week and 3x/week dosing was efficacious in the LEOPOLD trials in persons with severe hemophilia A. Observed treatment patterns and outcomes in clinical trials may not adequately represent patient outcomes for treatment outside clinical trials; thus, there is value from a clinical and pharmacoeconomic perspective in supplementing pivotal clinical trial evidence with real-world data.

Aims: To investigate weekly prophylaxis dosing regimens with BAY 81-8973 used in standard clinical practice.

Methods: TAURUS, a multinational, open-label, prospective, noninterventional, single-arm phase 4 study (ClinicalTrials.gov: NCT02830477) includes previously treated males of any age with moderate to severe hemophilia A (≤5% factor VIII [FVIII]:C), ≥50 FVIII exposure days, and no history of inhibitors who are receiving BAY 81-8973 for routine prophylaxis. The primary objective is to investigate the weekly prophylaxis dosing regimens with BAY 81-8973 used in standard clinical practice. Determinants of treatment decisions will be assessed as a secondary objective; other secondary objectives include assessment (in a real-world setting) of the effectiveness of routine prophylaxis with BAY 81-8973, dosing regimens in different age groups and countries, FVIII consumption, changes in treatment satisfaction and adherence, safety, and pharmacokinetics. Data sources include patient medical records, routine clinical visits, patient event and prophylaxis injection diaries, and electronic data capture.

Results: Planned sample size is 350 patients to be enrolled from 9 countries. The study has recently started enrollment; 19 patients from Germany, the Netherlands, and the United States have been enrolled as of January 5, 2017. The anticipated recruitment period is 2 years, with a planned observation period of 1 year **(Figure)**.

Conclusions: TAURUS is designed to obtain real-world data on treatment patterns of routine prophylaxis with BAY 81-8973 to supplement the LEOPOLD clinical trial results.

PB 1931 | Intracranial Haemorrhage Associated with during the Course of Extracorporeal Membrane Oxygenation for Severe Respiratory Failure

D. Jayakody Arachchillage[1,2], M. Passariello[1], T.C. Aw[1], L. Owen[1], W. Banya[1], R. Trimlett[1], A. Kelleher[1], C. C Morgan[1], B. Patel[1,2], J. Pepper[1,2], S. Ledot[1]

[1]*Royal Brompton Hospital, London, United Kingdom,* [2]*Imperial College London, London, United Kingdom*

Background: Intracranial haemorrhage (ICH) is a serious complication in patients supported with veno-venous extracorporeal membrane oxygenation (VV-ECMO), and is associated with a high mortality. It is unknown whether ICH is a consequence of the VV-ECMO or of the underlying respiratory pathology.

Aims: To determine the incidence of ICH at initiation and during the course of ECMO, the associated mortality and predictive markers of ICH in patients with severe respiratory failure

Methods: Data were collected from all 165 patients who received VV-ECMO over a 5 year period from Jan 2011 to Dec 2016 in a single tertiary centre in the UK. Only the patients who had brain CT within 24hrs of initiation of VV-ECMO (total 149) were included for further analysis.

Results: The incidence of ICH was 10% (15/149) within 24hrs of initiation of ECMO compared to 4% (7/149; p=0.02) during the course of ECMO. The baseline characteristics of patients with and without ICH on admission are shown in the Table 1.

TABLE 1 The baseline characteristics of patients with and without ICH on admission for VV-ECMO

Characteristics	With ICH (n=16)	Without ICH (n=132)	p value
Age (years) mean (SD)	48.8 (13.4)	45.3 (14.8)	0.37
Sex Male N (%) Female	11 (68.75) 5 (31.25)	77 (58.78) 54 (41.22)	0.44
Haemoglobin (g/L) median (IQR)	98.0 (88.5, 107.5)	100 (91, 111)	0.43
Platelets (109/L) median (IQR)	115 (85-140)	180 (102-218)	0.03
Prothrombin time (seconds): Median (IQR)	14.6 (11.4, 16.8)	14.0 (12.0, 16.0)	0.67
Activated partial thromboplastin time (seconds): Median (IQR)	41.6 (30.7, 43.0)	33.7 (29.5, 41.0)	0.07
Fibrinogen (g/L) :Median (IQR)	4.3 (2.5-5.1)	4.8 (2.1-5.3)	0.7
CrCL (mL/min) median (CI)	53.5 (20.5-62.4)	111.0 (73-120)	0.0002

Conclusions: Reduced CrCL and low platelet count were strongly associated with ICH within 24hrs of initiation of ECMO.Thrombocytopenia associated with ICH is in keeping with previous studies. Acute kidney injury is a frequent finding in ECMO patients, but its association with ICH within 24 hours of initiation of ECMO has not previously been documented. The higher incidence of ICH within 24hrs of the initiation of VV-ECMO suggests that ICH may be related to the clinical severity of the underlying lung injury rather than the intervention of VV-ECMO. Patients with ICH at the initiation of VV-ECMO had a significantly worse outcome.

PB 1932 | Classic Pathways of Fibrinolytic Activation Are Secondary in Non-traumatic Hyperfibrinolysis

J. Zipperle[1], S. Bahrami[1], H. Redl[1], H. Schöchl[1,2]

[1]Ludwig Boltzmann Institute for Experimental and Clinical Traumatology, AUVA Trauma Research Centre, Vienna, Austria, [2]AUVA Trauma Centre, Department of Anaesthesiology and Intensive Care, Salzburg, Austria

Background: Hyperfibrinolysis (HF) is a severe manifestation of coagulopathy associated with major trauma and out-of-hospital cardiac arrest (OHCA). The activated protein C (APC) has been linked to both conditions. Neutrophil Extracellular Traps (NETs) are suspected to interfere with hemostasis by reciprocally amplifying fibrinolytic activation.

Aims: We aimed to investigate how APC was regulated in hyperfibrinolysis in the absence of a traumatic injury and whether its inhibition was associated with features of NET formation.

Methods: Blood samples of 41 patients who suffered from non-traumatic OHCA were drawn on scene by an emergency physician. HF was diagnosed with a thromboelastometry (ROTEM) maximum lysis (ML) >15%. Plasma levels of APC-PCI, PMN elastase, histonylated (h) DNA fragments (indicator for NETs), sTM (marker of endothelial damage) t-PA, PAI-1, and t-PA-PAI-1-complex were determined and correlated with HF (ML>15%).

Results: Based on ROTEM measurements, 15 patients met the criteria for HF and were compared with 26 patients with a ML< 15 (non-HF). APC-PCI levels were significantly higher (p=0.03) in HF patients. There was a strong correlation (r=0.7, p< 0.001) between neutrophil elastase and hDNA levels (indicative of NETs formation) in all patients. Neutrophil elastase correlated also with sTM levels (r=0.37, p=0.015). T-PA activity (p=0.001) but not antigen levels (p=0.22) were significantly higher in HF patients. None of the other fibrinolytic mediators were elevated in HF compared to non- HF.

Conclusions: Data suggest that a) Inhibition of APC by PCI is associated with non-traumatic HF b) APC correlates with fibrinolytic activation and NETosis, c) NETosis is associated with endothelial cell damage, and d) elevated t-PA activity but not antigen level is associated with HF in OHCA. Apparently, the classic plasmin pathway of fibrinolysis appears secondary in non-traumatic HF.

PB 1933 | Soluble Fibrin Causes an Acquired Platelet GPVI-deficiency in Response to Convulxin, Collagen-related Peptide and Collagen: Implications for Trauma Induced Coagulopathy

S. Diamond, M. Lee, B. Herbig

University of Pennsylvania, Institute for Medicine and Engineering, Philadelphia, United States

Background: Trauma can cause systemic thrombin generation as well as platelet dysfunction. About half of trauma patients display a defect in platelet deposition on collagen in a microfluidic assay.

Aims: We investigated causes of platelet dysfunction during trauma when blood may be exposed to low levels of wound-mediated release of tissue factor.

Methods: Using calcium-dye -loaded platelets, the effect of thrombin exposure and soluble fibrin generation on subsequent platelet GPVI activation was investigated.

Results: Exposure of apixaban-treated platelet-rich plasma (12% PRP) to thrombin (1-10 nM) for 500 seconds, but not ADP or thromboxane mimetic U46619 exposure, dramatically blocked subsequent GPVI activation by convulxin. Thrombin exposure also resulted in GPVI-insensitivity to collagen-related peptide. Consistent with soluble fibrin binding GPVI, the onset of convulxin-insensitivity required 200 to 500 seconds of thrombin exposure, was not mimicked by exposure to PAR-1/4 activating peptides, and was blocked by the fibrin polymerization inhibitor, GPRP. Consistent with the ADP and U46619 results, PAR-1 signaling through G_q was not required since vorapaxar blocked thrombin-induced calcium mobilization but had no effect on the ability of thrombin to cause GPVI-deficiency. Convulxin-insensitivity was unaffected by the ADAM10-inhibitor GM6001, indicating a negligible role for GPVI shedding. Thrombin treatment of washed platelets in purified fibrinogen also produced convulxin-insensitivity that was prevented by GPRP. Exposure of apixaban/PPACK-treated whole blood to thrombin-treated fibrinogen (±GPRP and then PPACK-inhibited) resulted in >50 % decrease in platelet deposition in a collagen microfluidic assay (wall shear rate, 200 s^{-1}) when fibrin was allowed to assemble (no GPRP).

Conclusions: Since only 1% conversion of plasma fibrinogen generates 90 nM soluble fibrin, which greatly exceeds GPVI levels in blood, circulating platelets in trauma patients may display an acquired GPVI-deficiency.

PB 1934 | Acquired Hemophilia A and Concomitant Factor XIII Consumption: A Case Series

J. Abdulrehman[1], B.L. Houston[2], J.M. Teitel[1], M. Sholzberg[1,3]

[1]St. Michael's Hospital, Department of Medicine, Division of Hematology, Toronto, Canada, [2]University of Toronto, Department of Medicine, Toronto, Canada, [3]St. Michael's Hospital, Department of Laboratory Medicine and Pathobiology, Toronto, Canada

Background: Acquired hemophilia A (AHA) is a rare bleeding disorder caused by inhibitors (INH) against factor VIII (FVIII). AHA's effect on hemostasis apart from FVIII depletion is largely unknown. Factor XIII (FXIII) is a coagulation protein that promotes clot stability by crosslinking fibrin strands, and promoting wound healing. Here we report three cases of AHA with ongoing bleeding despite sequential bypassing agent and recombinant porcine-FVIII (rp-FVIII) therapy, found to have secondary FXIII consumption.

Aims: To describe our experience with acquired FXIII deficiency and effective FXIII replacement in three complicated cases of AHA.

Methods: Three cases were retrospectively reviewed at St. Michael's Hospital, Toronto, Canada from 2015 to 2016. Patients with FVIII INH (without congenital hemophilia) and low FXIII antigen were included in the study. FVIII activity was measured using a one-stage-aPTT-based assay, FXIII antigen using a latex immunoassay for subunit a, FVIII INH using the modified Nijmegen Bethesda assay and FXIII inhibition was assessed using a chromogenic assay.

Results: At time of diagnosis of AHA, the FVIII activity was 0.08, < 0.01 and < 0.01 U/ml, and the FVIII INH titer at 4.5, 346, and 42 BU/ml in cases 1, 2 and 3, respectively. FXIII deficiency was identified at median day 3 of hospital admission (case 1-0.08, 2-0.32, 3-0.07 U/ml). FXIII INH testing was negative for case 1 and was not pursued for cases 2, 3. A median of 3 (range 2, 9) doses of plasma-derived-FXIII (pd-FXIII) were given (see Figure 1). All patients achieved hemostasis once pd-FXIII was used in conjunction with conventional AHA therapy. All cases received corticosteroid and rituximab for INH eradication.

Conclusions: Our findings demonstrate that AHA can be complicated by FXIII consumption and that FXIII replacement improves the bleeding phenotype. To our knowledge, this is the first case series describing this association. This preliminary data supports a novel approach to patients with AHA and refractory bleeding.

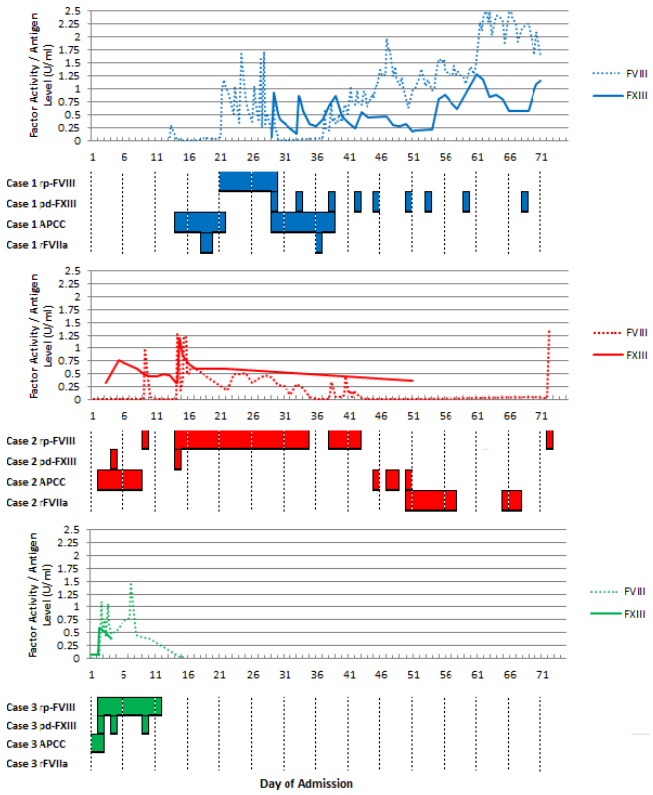

FIGURE 1 Factor Activity, Antigen and Product Support by Time

PB 1935 | Von Willebrand Factor and ADAMTS13 in Bothrops jararaca Envenomation: Involvement of Snake Venom Metalloproteinases and Botrocetin

C. Martos Thomazini[1,2], M. Larami Santoro[1,2]

[1]*Faculty of Medicine, University of São Paulo, São Paulo, Brazil,* [2]*Butantan Institute, São Paulo, Brazil*

Background: Patients bitten by *Bothrops* snakes in South America manifest a bleeding tendency. Systemic clinical manifestations, such as mucous bleeding and thrombotic microangiopathy, share similarities with symptoms of von Willebrand disease and thrombotic thrombocytopenic purpura.

Aims: To study: (a) whether *Bothrops jararaca* venom (BjV) disturbs the steady state of von Willebrand factor (vWF) and ADAMTS13, and to investigate their relationship with BjV-induced thrombocytopenia; (b) the participation of snake venom metalloproteinases (SVMP) and botrocetin, a BjV cofactor for vWF-induced platelet agglutination, in hemostatic disorders.

Methods: Crude BjV was incubated with saline, a metalloproteinase inhibitor (Na_2-EDTA), anti-botrocetin polyclonal antibodies, or glycerol (the vehicle for antibodies). Saline was used as negative controls. Pre-treated-BjV was administered s.c. into Wistar rats and blood samples were collected at 3, 6 and 24h thereafter. Platelet count, vWF antigen quantification (Ag) and vWF collagen-binding (CB) activity, CB/Ag ratio, ADAMTS13 activity, vWF multimer distribution, and factor VIII (FVIII) coagulant activity were analyzed.

Results: BjV-treated rats exhibited intense thrombocytopenia, with the nadir at 6h. There was no statistical significant difference in vWF parameters, although variation was observed. FVIII decreased in rats treated with saline-BjV and botrocetin-inhibited-BjV at 3 and 6h. A drop in ADAMTS13 activity was also observed in saline-BjV treated rats at 3 and 6h. Botrocetin had no important participation in the thrombocytopenia and FVIII consumption evoked by BjV, but SVMP inhibition protected rats from FVIII consumption.

Conclusions: Although proteins that modify vWF function are present in BjV, apparently they showed a minor role in hemostatic disturbances. On the other hand, we show for the first time that BjV causes a drop in ADAMTS13 activity, but its clinical and hemostatic consequences needs further investigation. Financial support by FAPESP and CNPq.

PB 1936 | Efficacy and Safety of Combined Use of aPCC and Antifibrinolytics in Acquired Hemophilia A: Results from the FAIR Registry

E. Zanon[1], S. Pasca[1], G. Gamba[2], G. Giuffrida[3], A. Falanga[4], A.B. Federici[5], I. Cantori[6], S. Siragusa[7], M.G. Mazzucconi[8], G. Piseddu[9], A. Rocino[10], R.C. Santoro[11], C. Lodigiani[12]

[1]*University Hospital of Padua, Hemophilia Center, Padua, Italy,* [2]*University of Pavia, Pavia, Italy,* [3]*University of Catania, Catania, Italy,* [4]*'Papa Giovanni XXIII' Hospital, Immunohematology and Transfusion Medicine, Bergamo, Italy,* [5]*'L.Sacco' University Hospital, Hematology and Transfusion Medicine, Milan, Italy,* [6]*Hospital of*

Macerata, Macerata, Italy, [7]University of Palermo, Hematology and Bone Marrow Transplantation, Palermo, Italy, [8]'Sapienza' University of Rome, Hemophilia Center, Rome, Italy, [9]'Santissima Annunziata' Hospital, Hemophilia and Thrombosis Center, Sassari, Italy, [10]ASL 1 Neaples, Hemophilia and Thrombosis Center, Neaples, Italy, [11]'Pugliese-Ciaccio' Hospital, Hemophilia Center, Catanzaro, Italy, [12]Humanitas Clinical Institute, Rozzano, Italy

Background: Antifibrinolytics combined with aPCC are not routinely administered to patients (pts) with acquired hemophilia A (AHA) due to increased thrombotic risk, but the few reported and published data on this topic seem to show good tolerance, safety and efficacy.
Aims: To evaluate efficacy and safety of combined use of aPCC and antifibrynolytics in the treatment of AHA bleeding and to assess the difference in treatment between a retrospective group and a prospective one.
Methods: 59 pts, 34 retrospective (from Jan 2003 to Dec 2012) and 25 prospective (from Jan 2013 to Dec 2015), with AHA and treated with aPCC were initially enrolled in the FAIR Registry, a study that collected data from 12 Italian Hemophilia Centers. 3 retrospective pts were subsequently excluded cause of a protocol deviation and statistical analyses were carried out in the remaining 56 pts.
Results: 31 retrospective and 25 prospective pts were evaluated. A total of 101 acute bleeds were treated with aPCC, 65.3% of which in the retrospective group. The combined use of aPCC and antifibrinolytics was reported in the treatment of 19/35 bleeding events (54.3%) in the prospective group and of 21/66 bleeds (31.8%) in the retrospective one, showing a statistically significant difference (p=0.034). 20/25 prospective pts (80%) had only one bleed, while 48.4% of retrospective pts had two or more bleeding events (p< 0.05). In all bleeds treated with combined therapy (40/101) the treatment duration was reduced (mean reduction 16.3%) up to a median of 7 days (IQR 1-48). Good tolerance to combined therapy and no thromboembolic events were reported during the study.
Conclusions: The combined use of aPCC and antifibrinolytics in the treatment of AHA proved to be safe and efficacious. In the FAIR Registry prospective pts, many of whom treated with combined therapy, had a statistically significant reduction in bleeds, but further studies are needed to assess whether this association can be routinely used in case of AHA.

PB 1937 | Prediction of Outcome in Acquired Hemophilia A

M. Escobar[1,2], E. Donnachie[1,2]

[1]University of Texas Health Science Center at Houston, Houston, United States, [2]Gulf States Hemophilia and Thrombophilia Center, Houston, United States

Background: Acquired Hemophilia (AH) is a rare bleeding disorder caused by antibodies that neutralize FVIII procoagulant activity (inhibitors). The neutralizing antibodies are detected by the Bethesda assay (BA) however this assay underestimates their level due to type II reaction kinetics and it does not measure non-neutralizing antibodies. Therefore the total antibody response in AH is poorly characterized by this method. As a result inhibitor levels are poor predictors of patient outcome. An alternative to inhibitor levels are anti-FVIII isotypes and IgG subclasses. A recent report showed that the presence at baseline of anti-FVIII IgA antibodies, but not anti-FVIII IgG antibodies, predict recurrence and poor out come in patients with AH.
Aims: Determine the IgA and IgG subclasses of FVIII-specific antibodies in patients with AH at diagnosis and at or about 1 year following diagnosis and relate the findings to their outcome.
Methods: Anti-FVIII IgA and anti-FVIII IgG subclasses (IgG1, IgG2, IgG4) were determined by ELISA and inhibitor levels by BA after IRB approval and informed consent.
Results: In 18 patients with AH the most prevalent anti-FVIII antibody at diagnosis was IgG4 (94%) followed by IgG1 (72%), and IgG2 (67%). IgA was the least prevalent anti-FVIII antibody (38%). We found that there was no association with the presence of anti-FVIII IgA antibodies, nor any of the anti-FVIII IgG subclasses analyzed at diagnosis, with poor or good patient outcome (p=0.3) using Fisher's exact test. 9/18 AH patients had good outcome (complete response to treatment or spontaneous remission). 4/9 patients with good outcome had anti-FVIII IgA antibodies, 1/9 had detectable IgG1 and IgG4 anti-FVIII antibodies at or about 1 year after diagnosis despite the BA being ≤0.6 BU/ml and FVIII activity ≥100%.
Conclusions: Our results did not support a recent report of anti-FVIII IgA antibodies predicting poor outcome for AH patients and found that anti-FVIII IgA and IgG antibodies persist in patients with good outcome.

PB 1938 | Severe Bleeding Diatheses in an Elderly Patient due to Autoantibody against Factor XIII A Subunit; Novel Approach to the Diagnosis and Classification of Anti-FXIII Antibodies

M. Kun[1], N. Szuber[2], É. Katona[1], K. Pénzes[1], A. Bonnefoy[2], B. Bécsi[3], F. Erdődi[3], G.-E. Rivard[2], L. Muszbek[1]

[1]University of Debrecen, Division of Clinical Laboratory Science, Department of Laboratory Medicine, Debrecen, Hungary, [2]CHU Sainte-Justine, Montréal, Canada, [3]University of Debrecen, Department of Medical Chemistry, Debrecen, Hungary

Background: Acquired factor XIII (FXIII) deficiency due to autoantibody is a rare, life threatening bleeding diathesis. Its laboratory diagnosis and classification represents a difficult task.
Aims: Introduction of novel approaches into the diagnosis and characterization of anti-FXIII autoantibody and demonstration their use in the diagnosis of a patient with autoimmune FXIII deficiency.
Methods: FXIII activity, FXIII antigen levels and the titer of anti-FXIII-A antibody were monitored throughout the course of the disease. FXIII activity was measured by ammonia release assay; FXIII-A_2B_2 complex, total and free FXIII-B concentrations were determined by ELISAs. The inhibitory capacity of patient's IgG was expressed as the concentration exerting 50% inhibition of FXIII activation/activity (IC50). The binding constants for the interaction of the autoantibody

with recombinant FXIII-A_2 (rFXIII-A_2) and FXIII-A_2B_2 were determined by surface plasmon resonance (SPR). The truncation of FXIII-A by thrombin was monitored by Western blotting. The inhibition of Ca^{2+} induced FXIII activation and active FXIII (FXIIIa) were assessed by FXIII activity measurement.

Results: The antibody bound to rFXIII-A_2 and FXIII-A_2B_2 with high affinity, the affinity constants (Ka) were $2.66x10^8$ M^{-1} and $1.65x10^8$ M^{-1}, respectively. The autoantibody accelerated the decay of supplemented FXIII concentrate. An IC50 value of 170.1 µg IgG mL^{-1} indicated effective FXIII neutralization. The main neutralizing effect of the autoantibody was the inhibition of FXIIIa. After two months, due to combined therapeutic modalities the autoantibody disappeared and FXIII activity significantly elevated.

Conclusions: The anti-FXIII-A autoantibody exerted a combined effect including inhibition of FXIIIa and acceleration of FXIII decay in the plasma. IC50 and binding constant determinations added important information to the characterization of the autoantibody.

PB 1939 | Usefulness of Anti-factor VIII IgG Antibodies Detection by ELISA in the Management of Patient with Acquired Hemophilia A

L. Mauge[1,2], I. Bozinovic[1], D. Helley[1,2], D.M. Smadja[1], M. Alhenc-Gelas[1], L. Darnige[1]

[1]Georges Pompidou European Hospital, APHP, Hematology, Paris, France, [2]Paris Descartes University - INSERM UMR-S 970, Paris, France

Background: Acquired haemophilia A (AHA) is a rare life-threatening bleeding disorder whose diagnosis must be performed in emergency. Laboratory diagnosis is based on evidence of the association of FVIII deficiency and neutralizing anti-FVIII antibody usually detected by Bethesda assay (BA). A recent publication reports the interesting performance of a recently marketed ELISA for IgG anti-FVIII (Zymutest, Hyphen BioMed)[1].

Aims: To compare the performance of a FVIII ELISA for detection of IgG anti-FVIII antibodies with the BA.

Methods: We retrospectively quantified neutralizing anti-FVIII antibody in 7 patients with AHA followed in our center. ELISA assays were performed on citrate plasma samples frozen at the time of diagnosis during the follow-up (period ranged from 230 to 3300 days). Complete remission was obtained in five patients and partial remission in the other two patients. Three patients relapsed. Twenty-four plasma samples were tested: 7 obtained at the initial diagnosis and 17 during the follow-up of 6 patients. FVIII ELISA is considered positive when OD>0.3.

Results: At the initial diagnosis, the new FVIII ELISA is positive in all 7 patients (BA extreme values: 2-155 UB, ELISA OD: 1.7-2.79, respective positivity limits: 0.6 BU and OD 0.3) with a good correlation to BA. During follow-up, concordant results were observed for 11 samples: positive for 4 (titer BA 1.2-1.5 UB vs DO ELISA 0.4-1.3) and negative for 7. For the remaining 6 samples discrepancies were observed. For 5 of them, the BA titer was 1 BU while the ELISA is negative. Conversely, the BA titer was < 0.6 UB and the OD ELISA was 0.44 for the 6th sample. The discrepancies observed only concerned results at positivity limit.

Conclusions: Although the BA is the reference standard for demonstrating neutralizing antibodies, the detection of FVIII-binding antibodies by ELISA seems a good approach for high titer of neutralizing anti-FVIII antibody but further larger studies are necessary in particular for patients with low titer of anti-FVIII IgG.

PB 1940 | Pulsatility as a Modulator of Circulatory Support-related Acquired VWF Defect

A. Rauch[1,2], F. Vincent[2,3], V. Loobuyck[2,4], M. Moussa[2,5], H. Spillemaeker[2,3], N. Rousse[4], A. Ung[1], D. Corseaux[2], E. Jeanpierre[1], C. Caron[1], A. Dupont[1,2], A. Vincentelli[2,4], E. Van Belle[2,3], S. Susen[1,2]

[1]CHU Lille, Hematology Transfusion, Lille, France, [2]Inserm, U 1011, Lille, France, [3]CHU Lille, Cardiology, Lille, France, [4]CHU Lille, Cardiac Surgery, Lille, France, [5]CHU Lille, Anesthesia, Lille, France

Background: Continuous-flow ventricular assist devices (CF-VAD) are associated with a high incidence of bleeding complications. CF-VAD deliver a high shear blood flow inducing an acquired loss of von Willebrand factor (VWF) high molecular weight multimer (HMW-multimers) that may partially explain the bleeding pattern. CF-VAD also decrease the arterial pulsatility (AP) to a various extent. The residual level of AP has been also reported to directly influence the bleeding risk under CF-VAD. We raised the hypothesis that the intensity of the acquired VWF defect could be modulated by the level of AP under CF-VAD.

Aims: To investigate the effect of AP on the intensity of VWF defect under CF-VAD.

Methods: We investigated both in a mock circulatory loop in vitro and in an experimental swine model the time course of the acquired VWF defect with two clinically implanted Impella CF-VAD. A first swine model was designed to investigate three degrees of AP (low, n=6; intermediate, n=6 or normal, n=6) depending on the combination: maximum flow rate/Impella localization. A second swine cross-over model was used to assess the effect on VWF defect of acute variations of AP under constant high shear conditions. VWF:CB/VWF:Ag ratio and VWF HMW-multimers were used as markers of acquired VWF defect. The assessment of AP *in vivo* was based on the invasive measurement of pulse-pressure (difference between systolic and diastolic arterial pressure).

Results: A similar VWF defect was observed with both pumps in vitro in the absence of vascular bed. In vivo, we observed an inverse relationship between the level of AP and the intensity of the VWF HMW-multimers defect. This relationship was further confirmed in a cross-over swine model demonstrating an endothelial release of VWF modulated by the level of AP (Figure).

Conclusions: We experimentally demonstrated that arterial pulsatility could modulate the HMW-multimers defect observed under CF-VAD.

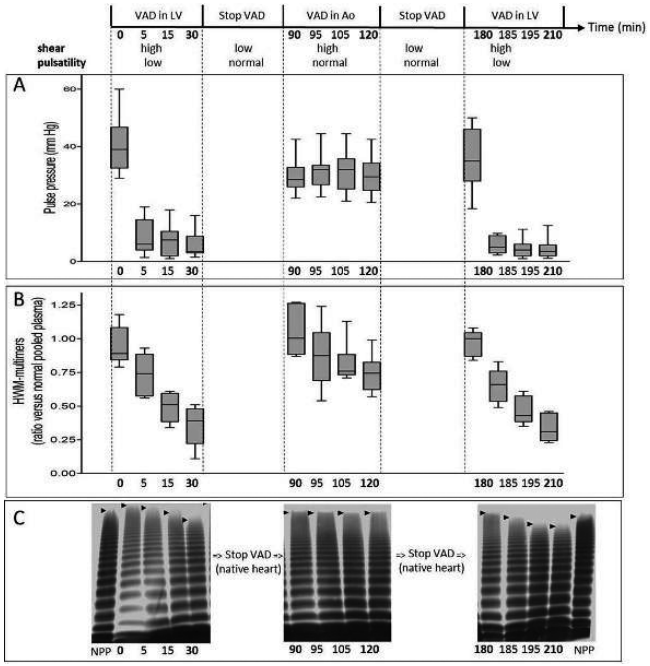

FIGURE 1 Cross-over swine study: Time course of pulse pressure (A) and VWF defect (B: HMW-multimer ratio; C: VWF multimeric profile) under CF-VAD support

PB 1941 | Acquired von Willebrand Syndrome in Infants with Aortopulmonary Shunt

G. Wiegand[1], V. Icheva[1], U. Budde[2], M. Hofbeck[1]

[1]University Children's Hospital, Tuebingen, Germany, [2]MEDILYS Laborgesellschaft mbH, Hamburg, Germany

Background: The acquired von Willebrand syndrome (aVWS) was first described in 1968 by Simone et al in patients with autoimmune diseases. The aVWS is rare in children, most frequently being described in connection with congenital heart defects including aortic stenosis, PDA, VSD and pulmonary hypertension.

Aims: The aVWS often results in increased bleeding tendency such as mucosal-, gastrointestinal- or surgical bleeding. Until now, there are no reports describing aVWS in infants with aortopulmonary shunts.

Methods: Between 07/15-07/16 we evaluated 11 infants < 3 months with univentricular hearts and aortopulmonary shunt (9x BTS, 1x ZAPS, 1x Sano-Shunt) and tested for avWD. The shunt operation was performed between day 5.-180., the blood samples were collected between days 18-260 after surgery. In all these 11 patients we identified avWD with a reduction/loss of the largest VWF multimers.

Results: Despite the limited number of patients, we can presume that nearly 100% of the patients with aortopulmonary shunt present aVWS. Its pathogenesis is explained by the increased activation of the VWF under the influence of the turbulent flow within the shunt. The activated VWF is bound to its specific receptors located on the platelets and on the activated endothelial cells, and undergoes an ADAMTS 13 mediated proteolysis, which leads to the loss of large multimeres. First results show that the VWF swiftly normalizes shortly after suppression of the shunt dependent lung perfusion and switching to a cavopulmonary (Glenn) connection.

Conclusions: So far none of our patients demonstrated an increased bleeding tendency in everyday life. However, we must consider this anomaly as a potential cause of increased blood loss during cardiac catheterizations and operations. Knowledge of the existence of an avWD is therefore necessary for introduction of the replacement therapy with FVIII/VWF products.

PB 1943 | Successful Inhibitor Eradication with Ofatumumab in a Patient with Acquired Hemophilia A

R. Fischer, M. Alrifai, K. Heidinger, B. Kemkes-Matthes

University Hospital Giessen an Marburg, Haemostasis Center, Giessen, Germany

Background: Acquired hemophilia (AH) is a rare autoimmune disorder characterized by the development of neutralizing autoantibodies against clotting factors, mainly factor VIII, leading to various bleeding patterns up to severe and life-threatening bleedings in patients with a negative personal and family history of hemorrhagic disorders. The management of AH focuses on the goals: control and prevention of bleeding (if present or significant), inhibitor eradication, and treatment of the underlying disease (if applicable). Bleeding control can be achieved with recombinant activated factor VII (rFVIIa or NovoSeven® RT), activated prothrombin complex concentrate (aPCC or FEIBA®), or recombinant porcine factor VIII (OBIZUR).

Aims: First-line therapy in inhibitor eradication is prednisolone or cyclophosphamide, second-line is rituximab. Is Ofatumumab an alternative therapy in treatment of acquired hemophilia A?

Methods: Case report: 73-year-old man with Morbus Waldenström and acquired hemophilia (factor VIII < 1%, max. inhibitor titer 36 BU). First-line treatment with prednisolone and cyclophosphamide did not lead to inhibitor reduction and application of mycophenolic acid in exchange for cyclophosphamide was not successful either. Due to an anaphylactic reaction to rituximab in the past which was given for treatment of the M. Waldenström ofatumumab was given alternatively (4 cycles).

Results: This lead to a successful inhibitor eradication.

Conclusions: Ofatumumab and rituximab are specific human monoclonal IgG1 antibodies. Both bind to the CD20 antigen which is expressed on almost all B-cells and eliminates B-cells through several mechanisms, including complement-dependent cytotoxicity. The binding sites of ofatumumab and rituximab to the B-lymphocytes differ. Our case shows that ofatumumab can be applied as an alternative therapy for inhibitor eradication in acquired hemophilia.

PB 1944 | Individualization of Treatment with Recombinant Porcine FVIII (rpFVIII) Depending on Inhibitor Titres in a Patient with Acquired Hemophilia A (AHA)

M. Stemberger[1], M. Spannagl[1], M. Angstwurm[2]

[1]Klinikum der Universität München, Hämostaseologie, Munich, Germany, [2]Klinikum der Universität München, Medizinische Klinik IV, Munich, Germany

Background: Due to the novelty of treatment with rpFVIII experience in regards of optimal dosing and targeted FVIII plasma levels in clinical practice is limited. The pivotal study protocol intended an initial dose of 200 U/kg BW irrespective of the baseline FVIII inhibitor levels. Here we report on the management of a 76 year old patient with AHA who presented with a major gastrointestinal haemorrhage (FVIII level < 1%, human FVIII inhibitor titre 450 BU).

Aims: The aim was to dose rpFVIII respective of the baseline FVIII inhibitor levels and the clinical condition of the patient.

Methods: Treatment with rpFVIII was individualized according to anti-pFVIII inhibitor titres (baseline cross reactivity), FVIII levels and clinical response.

Results: The initial immunosuppressive regimen included both prednisolone and rituximab in standard doses. Despite insufficient bleeding control with rFVIIa the patient experienced a TIA. rFVIIa was discontinued and rpFVIII (50 U/kg BW) was administered without clinical response and FVIII increment

(FVIII inhibitor titre 231 BU, anti-pFVIII inhibitor titre 100 BU). Therefore, treatment with rFVIIa was resumed. Two cycles of immunoadsorption as well as six cycles of plasmapheresis were performed due to persistently high inhibitor titres. Afterwards the patient was retreated with 100 U/kg BW rpFVIII for uncontrollable diffuse bleeding (FVIII-level 8%, FVIII inhibitor titre 7 BU, anti-pFVIII inhibitor titre 19 BU). The 30-min postinfusion FVIII-level increased to 114% with satisfactory hemostasis within 24 hours. Subsequent doses were targeted to reach FVIII levels of approximately >30% and treatment was continued till FVIII levels normalized in week 12 (FVIII level 324%).

Conclusions: Insufficient FVIII increase after initial rpFVIII dosage due to a high baseline cross reactivity of anti human FVIII inhibitors could be altered by immunoadsorption and plasmapheresis. We conclude that readministration of rpFVIII resulted in rapid bleeding cessation at anti-pFVIII inhibitor titres < 20 BU.

PB 1946 | Thrombin Generation in Healthy Controls and Patients with Cirrhosis of the Liver: Comparison between Platelet-rich and Platelet-poor Plasma

T. Siegemund, S. Rabe, R. Siegemund, S. Petros

University Hospital Leipzig, Center of Hemostaseology, Leipzig, Germany

Background: Thrombin generation displays the hemostatic potential of the individual. Platelets play a central role in this physiological process and this may have a compensatory effect in hepatic dysfunction.

Aims: To compare thrombin generation variables from platelet-rich and platelet-poor plasma.

Methods: The study was approved by the institutional ethics board. Healthy controls and patients with cirrhosis of the liver stratified by the Child-Pugh grading were included after an informed consent. Thrombin generation was assessed using the Technothrombin TGA kit and the RC high reagent in platelet-rich plasma (PRP) and in platelet-poor plasma (PPP). Data for lag time, time to thrombin peak and peak thrombin were analyzed and a ratio was calculated by dividing the data from PRP by those from PPP in order to quantify the contribution of platelets.

Results: A total of 68 controls, 34 patients with Child A, 26 with Child B and 12 with Child C liver cirrhosis were included in the analysis. The ratios for lag time and time to thrombin peak were significantly lower in patients than in healthy controls ($p < 0.05$), while the ratio for peak thrombin did not show any significant intergroup difference.

Conclusions: The lower ratios for lag time and time to thrombin peak in patients with cirrhosis of the liver may be a sign of the compensatory effect of platelets on the process of thrombin generation in the face of reduced plasmatic coagulation. These findings underscore the significant role of platelets during thrombin generation in disease processes and measurements in PPP alone may not be sufficient.

PB 1947 | Acquired von Willebrand Syndrome (AVWS): Diagnostic and Treatment, a Single Centre Experience

J. Costa Pinto Prego de Faria, M.D.C. Gómez del Castillo Solano, M. Fernández Docampo, A. Pérez Rodríguez, M.F. López Fernández

Complejo Hospitalario Universitario de A Coruña - Servicio de Hematología y Hemoterapia, La Coruña, Spain

Background: AVWS is a probably under-diagnosed condition, similar to congenital von Willebrand disease (VWD), generally associated with other conditions as: cardiovascular diseases (CVD), monoclonal gammapathy of undetermined significance (MGUS), myeloproliferative syndromes (MS), Immunological diseases, tumors, or other. Treatment of primary condition is the first approach, but acute bleeds therapy and hemorrhage prevention in invasive procedures are needed.

Aims: Incidence of AVWS in patients with different pathologies and bleeding. Analysis of von Willebrand factor (VWF) profile. Analysis of therapy employed and impact on the AVWS.

Methods: Haemostasis study including factor VIII (FVIII:C), VWF antigen (VWF:Ag), VWF ristocetin cofactor (VWF:RCo), VWF collagen binding (VWF:CB) and ratios, and VWF multimeric distribution (SDS-agarose gel) was assessed at initial diagnosis and after different

TABLE 1 Baseline characteristics of all patients and comparison between patients with confirmed diagnostic of AVWS and no AVWS

	All patients	AVWS	No AVWS	p-value	Range of normal values
n (%)	81 (100)	46 (56,8)	35 (43,2)		
Age, years (mean ± SD)	68,7 ± 13,2	67,9 ± 12,9	69,8 ±13,8	0,525	
Male, n (%)	44 (54,3)	26 (56,5)	18 (51,4)		
Bleeding score (mean ± SD)	1,68 ± 2,5	2,37 ± 2,89	0,77 ± 1,55	0,009	
VWF:Ag (UI/dL) (mean ± SD)	177,4 ± 87,4	177,4 ± 93,3	177,4 ± 80,5	0,998	56-158
VWF:RCo (UI/dL) (mean ± SD)	135,4 ± 76,1	117,7 ± 68,4	158,8 ± 80,2	0,016	75-102
VWF:CB (UI/dL) (mean ± SD)	146,6 ± 93,5	120,9 ± 69,8	180,5 ± 109,9	0,004	50-150
VWF:RCo/VWF:Ag (mean ± SD)	0,78 ± 0,24	0,68 ± 0,25	0,9 ± 0,17	0,000	>0,7
Multimeric analysis		46 Abnormal	35 Normal		

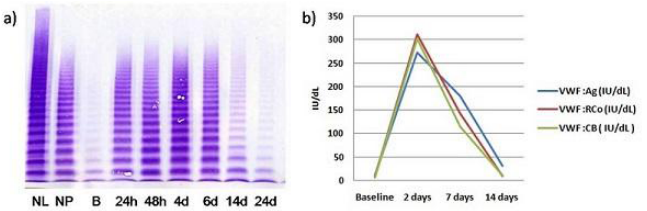
treatments employed (corrective surgery, intravenous immunoglobulins (IgIV), cytorreduction, FVIII rich in VWF concentrates (FVIII/VWF), desmopresin).

Results: We enrolled 81 subjects with suspicion of AVWS: 4 with MGUS, 68 with CVD, 7 with MS, 2 with tumor. AVWS was confirmed in 46 subjects.

3 with MGUS: 1 was diagnosed of myeloma. Severity of hemorrhage was unrelated with the malignancy of the disease. All answered poorly to desmopresin and FVIII/VWF. Answer to IVIg was acceptable in these patients.

Mixed plasma tests did not evidenced antibodies; 37 with CVD: 17 were hospitalized due to haemorragic episodes needing transfusions. 26 were submitted to corrective surgery. After surgery AVWS was resolved; 4 with MS: AVWS resolved after treatment with hidroxicarbamide or anagrelide; 2 with tumor: 1 with prostate cancer resolved AVWS after treatment of cancer. Other with colon cancer presented severe gastrointestinal bleed needing prophylaxis with FVIII/VWF.

Conclusions: Treatment of the underlying disorder resolves the AVWS, but patients face high risk haemostatic challenges, and surgical complications.



a) Multimeric analysis of VWF in SDS-agarose gel (1%) of platelet lysate and plasma of a normal subject (NL and NP), and of subject with AVWS and MGUS at baseline (B) and after IgIV administration at 24 and 48 hours, at 4,6,14 and 24 days (24h, 48h, 4d, 6d, 14d, 24d). b) Representative graphics of the results of VWF:Ag, VWF:RCo and VWF:CB, at baseline and after administration of IgIV.

PB 1948 | Heparin-Like Substance in Patients with Dengue Infection and Prolonged Activated Partial Thromboplastin Time

Y. Chinthammitr[1], N. Tirachaimongkol[1], T. Ruchutrakool[1], B. Suwannawiboon[1], T. Akarawikrai[2], C. Washirasaksiri[1], Y. Nakkinkun[1], T. Binhama[1], S. Sonprasert[1]

[1]Faculty of Medicine Siriraj Hosptial, Mahidol University, Department of Medicine, Bangkok, Thailand, [2]Surin Hospital, Department of Medicine, Surin, Thailand

Background: Dengue infection (DI) can cause severe bleeding, shock and fatal outcome. Thrombocytopenia and coagulopathy contributed to bleeding problem. Previous small study demonstrated a heparin-like substance (HLS) in a few patients with isolated prolonged activated partial thromboplastin time.

Aims: To figure out the cause of prolonged APTT (pAPTT) in patients with dengue infection and its clinical significance.

Methods: Adult inpatients with DI from May 2014 to Oct 2016 were enrolled prospectively. Patients with known coagulopathy or liver disease were excluded. DI was categorized into dengue fever (DF) and dengue hemorrhagic fever (DHF) according to WHO 1997 criteria. All cases were tested for complete blood count, coagulogram, thrombin time (TT), and fibrinogen activity. Plasma samples with pAPTT were further tested for mixing study and assay of intrinsic factors (F.XII, F.XI, F.IX, and F.VIII). Plasma samples with prolonged TT were tested for HLS with protamine titration assay.

Results: A total of 183 patients (78 men) with a median age of 29 years (range 18-77) were diagnosed as DF in 153 (83.6%) and DHF in 30 (16.4%). Clinical bleeding in mild, moderate, and severe forms was found in 0.5%, 35%, and 21% of cases, respectively. Prolonged APTT, prolonged prothrombin time, isolated pAPTT, prolonged TT, and hypofibrinogenemia was found in 50.3%, 6.6%, 45.4%, 21.1% and 21.5%. Mixing study of pAPTT showed correctable in 89%. Median (range) levels of F.XII, F.XI, F.IX, and F.VIII were 56.7% (22.2-217.5), 80.0% (30.0-185.9), 69.7% (29.5-215.6), and 73.5% (31.5-308.1). In multivariate analysis, pAPTT was significantly associated with prolonged TT (P< 0.001). Heparin-like substance was found in all samples with prolonged TT with a median concentration of 1.11 U/mL (range 0.53-3.33). pAPTT was not associated with severe bleeding.

Conclusions: APTT prolongation in dengue infection is associated with the presence of a heparin-like substance in the plasma but not associated with severe bleeding.

PB 1949 | Acquired Hemophilia: Initial Presentation, Management and Outcome. Experience of a Single Hemophilia Centre

F. Vasconcelos, B. Delgado, C. Vaz, M. Carvalho, L. Gonçalves, M. Lopes, C. Koch

Centro Hospitalar São João, Porto, Portugal

Background: The clinical picture of AH is characterized by acute onset of severe bleeding in individuals who had no previously history of bleeding diathesis. Patients generally present with mucocutaneous or soft tissue bleeding including extensive ecchymoses and hematomas. Joint and muscle bleeding, common in patients with congenital hemophilia A, is rare. Treatment aims to stop acute bleeding and eliminate inhibitor.

Aims: Our aim was to perform a retrospective analysis, to assess initial presentation, management and outcome of 9 AH patients treated in our hemophilia centre over the last 15 years.

Methods: Patients diagnosed with AH had a median age of 71 (range:20-85), 6 male and 3 female. At diagnosis, the mean value of FVIII was < 1% (range:< 1%-6.8%), and inhibitor titer 87 BU (range:10-550). Underlying diseases included: postpartum (22.2%), malignancy (22.2%) and 55.6% were considered idiopathic.

Eight patients had bleeding episodes but only 5 patients required hemostatic therapy: bypassing agents (2 FVIIa, 2 aPCC) and the first AH diagnosed patient was treated with high doses of FVIII concentrate (before bypass agent's availability). One patient was diagnosed after a study of a prolonged aPTT on routine coagulation tests and had no bleeding manifestations.

Results: All 9 patients had corticoid therapy (CT) included in initial therapeutic scheme: 3 in monotherapy, 3 with associated immunoglobulin (IG), 2 with associated cyclophosphamide and 1 with CT + IG + cyclophosphamide. A complete remission was achieved in 8 patients (1 died) and 2 patients had relapsed. One patient (with multiple myeloma) only achieved a complete remission when bortezomib was introduced in therapeutic scheme.

Conclusions: Early diagnosis, effective control of bleeding and inhibitor eradication are gold standards to achieve good outcomes. Despite this small cohort of patients, they achieved a high complete remission and low mortality rates. Underlying conditions and relapses were in agreement with published literature.

PB 1950 | Two Patient Cases of Acquired Hemophilia Treated with Recombinant Porcine Sequence FVIII (rpFVIII, OBIZUR®)

E. Armstrong[1], E. Poikonen[2]

[1]Helsinki University Central Hospital, Coagulation Disorders, Dept of Hematology, Helsinki, Finland, [2]Helsinki University Central Hospital, Hematology, Helsinki, Finland

Background: Acquired haemophilia is a rare, often severe bleeding disorder with autoantibody formation against FVIII. The cause is unknown in half of the cases or secondary to underlying autoimmune disorders, malignancy, drugs or post-partum state. Treatment consists of control of bleeding and eradication of the antibody by immunosuppression. Traditionally by-passing agents (aPCC or rFVIIa) are used to control bleeding, but laboratory methods to follow response are lacking. Recombinant porcine sequence FVIII (rpFVIII, OBIZUR®) is a new treatment option allowing precise dosing based on FVIII:C measurements.

Aims: To describe the first two cases in Finland of acquired haemophilia, where bleeding was controlled by rpFVIII replacement therapy using FVIII:C measurements to tailor dosing.

Methods: Two patients were referred to our comprehensive care centre by local hematologists. Recombinant pFVIII was provided by Baxalta for compassionate use as the product was not yet available in our country. FVIII:C was measured by one-stage-clotting assay.

Results: The first patient was a 47-year-old male with a history of skin bruising and painful lower extremity soft tissue hematoma. Prolonged APTT raised suspicion of acquired hemophilia. Bleeding was effectively controlled with three doses (200IU/kg and 2x100IU/kg) of rpFVIII adjusted by FVIII:C levels. The second patient, a 74-year-old male had recurrent thigh and soft tissue bleeds uncontrolled with aPCC. Compared with the first patient, he required higher and more frequent rpFVIII dosing (150IU/kg every 3 hours) for clinical and FVIII:C response.

Conclusions: Our initial experience in controlling bleeding with rpFVIII proved clinically effective and allowed tailored coagulation factor control with individual dosing. On-site around the clock coagulation specialist and laboratory services are required for prompt FVIII:C measurements and interpretation. Anti-porcine antibody testing and evaluation of cost-effectiveness may also be needed to have this treatment option available.

PB 1951 | Acquired von Willebrand Syndrome Associated with Monoclonal Gammopathy: Importance of Hemostasis Screening in the Preoperative Management of Three Case Studies

M. Kurdi, K. Maloum, C. Settegrana, H. Rouatbi, A. Ankri, I. Martin-Toutain

University Hospital Pitié Salpêtrière, Laboratory of Hematology, Paris, France

Background: Acquired von Willebrand Syndrom (AvWS) is a rare heterogeneous bleeding disorder with a percentage varying from 0.04 to 0.13 %. It is occurring in patients with out of family history of bleeding disorders and it is most frequently observed in association with lymphoproliferative, myeloproliferative, immunological and other disorders.

Aims: We describe three cases of AvWS associated with IgG-MGUS in patients scheduled to undergo surgery.

Methods: We found AvWS in three men aged 67, 70 and 79 years known to have IgG-MGUS by a preoperative hemostasis test for a surgery intervention (colposcopy, hip prosthesis and kidney biopsy). None of the cases had a history of bleeding disorders.

Results: The preoperative laboratory findings for these three patients were as follows: prolonged aPTT, normal PT, prolonged platelet plugging time. Plasma levels of FVIII, vWF antigen (vWF:Ag) and activity (vWF:RCo) were low: patient 1 (FVIII=45%, vWF:Ag=45%, vWF:RCo< 10%), patient 2 (FVIII=31%, vWF:Ag=12%, vWF:RCo=15%) and patient 3 (FVIII=18%, vWF:Ag=14%, vWF:RCo=10%). The ratio of vWF propeptide to vWF was elevated in the three cases. None of the three patients had experienced bleeding episodes in the past. The three patients had a kappa IgG-MGUS, with monoclonal pic of 2.2, 1.7 and 2.9 g/L for patient 1, 2 and 3, respectively.

High-dose immunoglobulin infusions were used for the three patients. This treatment normalized their hemostatic tests and they were operated on safely without any bleeding episodes.

Conclusions: In the presence of an associated underlying disease, such as MGUS, investigation of hemostasis is important in the view of the potential gravity of AvWS particularly for patients undergoing surgery. Management includes high doses of immunoglobulin or other treatment strategies to increase the level of associated vWF, in addition to management of the associated pathogenetic disorder.

PB 1952 | Study of Clinical Characteristics, Laboratory Findings and Response to the Treatment of Patient with Acquired Hemophilia in National Institute of Hematology and Blood Transfusion of Vietnam

T.M. Nguyen

National Institute of Haematology and Blood Transfusion Vietnam, Hanoi, Viet Nam

Background: Acquired haemophilia have been well described by many studies in all over the world while in Vietnam there are no studies that work on this subject.

Aims: Study of clinical characteristics, laboratory findings and response to the treatment of patients with acquired haemophilia in the National Institut of Hematology and Blood Transfusion.

Methods:

Subjects: 25 patients with acquired hemophilia diagnosed in the National Institut of Hematology and Blood Transfusion from January 2012 to May 2016.

Methods: Cross-sectional description study with retrospective and prospective.

Results: *Clinical characteristics*: Patients are mostly elderly, found in both men and women. Severe hemorrhage is the prominent symptom, occurs in multiple locations. The three most common bleeding sites are: muscle hemorrhage (68%), purpura (60%), and visceral hemorrhage (20%). *Laboratory findings*: All patients had prolonged APTT, mostly acquired hemophilia A, with a high titre of factor VIII's inhibitor. *About treatment*: Most patients stop bleeding with factor VIII (84%). There are 3 patients who do not respond to the factor VIII but stop bleeding with factor VIIa; Most patients respond to the elimination of the inhibitors by immuno suppression (68%). The average time of remission 13.23 ± 25.5 weeks. Recurrence rate was 17.6%.

Conclusions: Patients are mostly elderly, found in both men and women. Severe hemorrhage is the prominent symptom, occurs in multiple locations. The three most common bleeding sites are: muscle hemorrhage (68%), purpura (60%), and visceral hemorrhage (20%). Most patients have acquired hemophilia A, with a high titre of factor VIII's inhibitor. Most patients stop bleeding with the treatment of high dose of factor VIII concentrate. Most patients respond to the elimination of the inhibitors by immuno suppression . The average time of remission 13.23 ± 25.5 weeks. Recurrence rate was 17.6%.

PB 1953 | Acquired Hemophilia A in China: A Result of a Multicenter, Prosepective Study in China

B. Sun[1], X. Dou[2]

[1]Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin, China, [2]Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin, China

Background: Acquired hemophilia A (AHA) is a rare bleeding disorder caused by autoantibodies to coagulation FVIII. Bleeding episodes at presentation are spontaneous and severe in most cases. Optimal choice of hemostatic therapy is controversial, and there is little available data from prospective study.

Aims: To assess the factor influencing the severity of bleeding and the effectiveness of the different hemostatic therapies among 112 registered patients.

Methods: This is a multicenter, prospective study.We got back the data from participating centers on paper. All analyses were performed using SPSS 17.0 for Windows.

Results: There are 55 males and 57 females in our study, and there is no difference in incidence between sex.Most patients, 96 of 112, had spontaneous bleeding,while 8 patients had Peri- or post-surgery bleeding, 6 other cause and 5 had no data.The most common bleeding cites are cutaneous (75.7%) and muscle (44.3%). The time from bleeding to first hospital visit ranges from 1day to 1500days (mean 20days), and the mean time from first hospital visit to definite diagnosis is 18days.Immune suppression therapeutic regimens include: steroid alone (16%), steroid+Cyclophosphamide (29%), steroid+Rituximab (22%), steroid+Cyclophosphamide+ cyclosporine/Immunoglobulin/Plasmaexchange/Azathiopine(15%), rituximab alone (1%), steroid+ Cyclophosphamide+cyclosporine+Immunoglobulin+Plasma exchange+Azathiopine, (8%), no data (9%).

Conclusions: Some underlying disorders, such as pemphigoid, autoimmune disease, pregnancy, infections and malignancies are related with AHA. Delay of dignosis is related to the severity of bleeding. Bleeding control was significantly higher in patients treated with bypassing agents versus FVIII/DDAVP (95.7% vs 61.2%; P <0.05). Bleeding control was similar between rFVIIa and aPCC (100% vs 94% p<0.05).Immune suppression therapy (steroid or Cyclophosphamide) has a higher remission rate than other choice.

PB 1954 | Clinical Importance of Vascular Wall Antithrombotic Activity Disorder Detection in the Course of Hormonal Replacement Therapy (HRT) and its Pharmacological Correction

S. Ermoshina, N. Khamani, V. Bitsadze

I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

Background: The vascular wall plays an important role in regulation of blood clotting potential.

It´s beyond the question that only pathogenic therapy of prevention, elimination and restriction of every patient condition caused by extensive coagulation can effectively prevent thromboembolic conditions. Complementary treatment intended for vascular wall function improvement greatlu decreases risk of thrombosis episodes. Recently researchers have been placing high emphasis on ω-3 polyunsaturated fatty acids (PUFAs) influence on hemostasis and vitamins influence on homocysteine serum level decrease.

Aims: comparative study of PUFAs and B group vitamins and folic acid complex effect on vascular wall antithrombotic activity in women taking OC and HRT.

Methods: We studied 60 perimenopausal women without bad habits and examined carefully for organ disorders. In the 1st group were included 30 perimenopausal women taking HRT - Femoston 2/10. All women in this group have been given PUFA at 1 g/day and B group vitamins, folic acid at 200 µg/day 1 month before and 2 months in the course of HRT.Other 30 perimenopausal women were included in the second, control group who were given only HRT-Femoston 2\10. In order to estimate vascular wall antithrombotic activity we used application of tonometer cuff on patient arm for short-term (5 min) local ischemia and applying a pressure10 mm Hg.

Results: 3 months PUFAs administration caused decrease of collgen-induced platelet aggregation while ADP-induced aggregation was not affected. After 2 weeks of drug administration t-PA activity reduced from 109,6 ± 7,2% to 71,3 ± 5,0%. In the 1st group there was no homocysteine level increase while in the 2nd group moderate hyperhomocysteinemia was revealed in 5 patients.

Conclusions: Antithrombotic activity of PUFAs is quite sufficient for prevention of procoagulation activity before HRT administration. These results suppose PUFAs to maintain antithrombotic activity of vascular wall.

PB 1955 | Some Haemostatic Parameters and International Normalize Ratio (INR) Values of Patients with Snakebite Envenomation Before, During and After Treatment with Antivenom Snakebite Research, Training and Treatment Centre, General Hospital, Kaltungo, Gombe State, North-Eastern Nigeria

R.A. Anyanwu[1,2], N. Mohammed[3]

[1]Ambrose Alli University, Ekpoma, Medical Laboratory Science, Benin-City, Nigeria, [2]Gombe State Ministry of Health, Gombe, Nigeria, [3]Gombe State Specialist Hospital, Gobe, Nigeria

Background: Snakebite envenomation is a global problem affecting mostly the rural Communities living in the tropics, where basic health facilities are poor.

Aims: To evaluate the effects of envenomation and antivenom on some haemostatic parameters among patients with snakebite envenomation.

Methods: In this observational study, 296 participants comprising of 141 patients with snakebite were treated with Anti-snake-Venom (ASV) and 155 apparently healthy subjects as control. We evaluated platelet, PT, aPTT and INR using Standard Manual Method.

Results: The result showed deranged PT, aPTT, platelet and INR values of the study group on admission, after 6th hour and 24th hour interventions, subjects had their envenomation resolved indicated by 80% PT, 95% aPTT and a normal INR value (0.5-4.0). The mean±SD of PT and aPTT of the controls when compared with the study population were statistically significant (p≤0.05). Age groups that were maximally affected by Snakebite were 18-30 years (55.9%) and the least affected were 0-10 years (3%) and 40 - 70 years (10%). Farming and cattle rearing were the occupations with high snakebite incidence (42% & 30%) respectively. This study also showed that the incidence of snake bite in the study population due to carpet Viper is 83% while that of cobra is 5.7% and unidentified was 11.3% respectively. Rural dwellers were the mostly affected with 82% and 18% of the study population were Urban dwellers.

Conclusions: We concluded that the deranged platelet, PT and aPTT and INR were normalized on intervention with ASV within 24hours. However, we suggested an additional attention of the Federal and State Government in establishing a nearby Health Centres in the rural Communities for easy accessibility by the rural dwellers since they were the most vulnerable to envenomation. Although, further research is required.

PB 1957 | Utility of Measurement of Plasma Thrombin Generation Using Calibrated Automated Thrombography (CAT) in the Management of Acquired Haemophilia

S.Y.M. Tan, W.H. Wong, C.W. Tan, H. Kaur, D. Tan, L.H. Lee, D. Mya, H.J. Ng

Singapore General Hospital, Hematology, Singapore, Singapore

Background: Bleeding risk in acquired haemophilia(AH) is poorly correlated with partial thromboplastin time or inhibitor level. Strategizing pre-emptive by-passing agent use during critical bleeding is highly challenging.

Aims: To determine the role of global coagulation testing using CAT measurement to guide therapy in AH.

Methods: Plasma thrombin generation (TG) data using standard parameters obtained during the course of treatment (non-protocolised) from bleeding AH patients were analysed with clinical features and by-passing agent infusion to determine its value in guiding by-passing agent therapy.

Results: Two AH patients with serious bleeding events were studied. A 44 year-old man (inhibitors >700BU) suffered a spontaneous large subdural haemorrhage which was managed without surgery. Baseline CAT parameters indicated reduced TG. FEIBA 100iu/kg was initially infused 12-hourly. CAT parameters measured using standard methods were beyond measurable ranges suggesting overcorrection of thrombin generation potential. FEIBA was then titrated to 75iu/kg and 50iu/kg 12-hourly over the subsequent 1 week keeping peak/trough CAT parameter within normal ranges. TG potential improved with inhibitor elimination allowing stoppage of FEIBA over the subsequent 2 weeks. He recovered fully with no further bleeding or thrombosis. The second patient, a 70 year-old man (inhibitor 21 BU) had a retroperitoneal bleed and was treated with 50iu/kg FEIBA given 12-hourly. He suffered further bleeding when trough TG measures were below normal. FEIBA was increased to 75 iu/kg 12-hourly and subsequently reduced over 3 weeks with corresponding improvement of CAT parameters and no further bleeding or thrombosis.

Conclusions: Plasma TG measured using CAT and kept within normal range has potential value in guiding by-passing agent dosing and infusion frequency in AH patients with serious bleeding, reducing risk of rebleeds. Optimal target range and frequency of monitoring remain unknown.

PB 1958 | Acquired Haemophilia Patients' Journey from the Exhaustive French Nationwide Database Collecting the Activity in Hospital (Programme of Medicalisation of the Systems of Information - PMSI)

J.-F. Schved[1], A. Aouba[2], A. Borel-Derlon[3], J.-Y. Borg[4], A. Gaude[5], B. Guillet[6], H. Lévesque[7], B. Villette[5]

[1]University Hospital St Eloi, Regional Haemophilia Treatment Center, Montpellier, France, [2]University Hospital of Caen, Department of Internal Medicine, Caen, France, [3]University Hospital of Caen, Haemophilia and von Willebrand Disease Centre, Caen, France, [4]University Hospital of Rouen and INSERM CIC-CRB 0204, Haemophilia Treatment Centre, Rouen, France, [5]Novo Nordisk, La Defense Cedex, France, [6]University Hospital of Rennes and INSERM U 1085, Haemophilia Treatment Centre, Rennes, France, [7]University Hospital of Rouen, Department of Internal Medicine, Inserm U 1096, IRIB, Rouen, France

Background: Epidemiological data on rare bleeding disorders is difficult to collect. Acquired haemophilia (AH) is a rare disease occurring in 1.48/million/year[1].

Aims: To establish if PMSI that could be a supplementary for current registries to define the patients with AH.

Methods: International versions of ICD10* may differ and this used in France by PMSI has no specific code for AH. The whole AH population could not be diagnosed, the authors decided to identify a new population based on elderly patients (≥65yo) treated with by-passing agents (BPA) (rFVIIa/aPCC) for bleedings coding: D66 „Hereditary FVIII deficiency"/D68.4 „Acquired deficiency in clotting factor"/D68.3 „Bleeding disorders due to circulating anticoagulants". The analysis was on 5 years (2010-14).

Results: The population represented 206 patients: 118 for D66; 67 for D68.4 and 21 for D68.3. 67% were treated with rFVIIa. Perhaps some patients belonging to this population didn't have AH but they were certainly few due to the criteria of selection. According to FranceCoag registry[2], since Jan the 1st of 2009, ~76 patients with congenital haemophilia, irrespective of their age, are treated with BPA. Moreover, other elderly patients treated with BPA are very rare.To validate this methodology, the incidence of this population was compared to those of the published registries[3]. The present data were consistent with this of registries over 5 years (~200 patients).

Conclusions: PMSI as an alternative to the registries for characterizing the journey of all AH patients was not possible. However, an elderly (≥65) subpopulation treated with BPA has been identified. A national standardization of the coding for AH should be considered for an optimal epidemiologic and medico-economic use of the PMSI. These results will allow starting the 2nd phase of the project, a detailed analysis of the patients' journey which will help to refine also the population.

PB 1959 | A Report of Clinicians' Attitude Survey of Acquired Hemophilia A for Improving its Prognosis in Japan

Y. Seki[1], O. Nagano[1], H. Nemoto[2], T. Kasami[2], S. Miyakoshi[2]

[1]Uonuma Institute of Community Medicine, Niigata University Medical and Dental Hospital, Department of Hematology, Minamiuonuma, Japan, [2]Niigata University Faculty of Medicine, Department of Hematology, Endocrinology and Metabolism, Niigata, Japan

Background: We previously analyzed a present state and clinical problems of long term outcome of patients with acquired hemophilia A (AHA) in our hospital to know better treatment or management essential for clinical practice. The study revealed mean period to APTT normalization, period to disappearance of inhibitor, all treatment period, and admission period were 42, 61, 96, and 62 days, respectively. High age patients with severe complicated diseases hardly return to society. It is important to treat earlier and comprehensively with making sure long outcome or treatment goal by adequate evaluation of patient or its complicated disease.

Aims: A questionnaire survey for clinicians' attitude of AHA was performed in order to improve its prognosis and to understand situations in 8 hospitals in Niigata Prefecture in Japan.

Methods: It was performed in 2 big base hospitals of wide area, 3 middle core hospitals and 3 small remote place hospitals. One hundred and eithty-five answers were available, contained from 45% of phisicians, 42% of surgeons, and 8% of residents.

Results: Degree of recognition of AHA was about 60%, which was higher in foundation hospitals. Main knowledge source of AHA was daily clinic in foundation hospital and books in core hospitals and remote place hospitals. Seventy to eighty percent of doctors who did not know AHA wanted to know AHA. Ten to twenty percent of doctors encountered AHA, frequently encountered by physicians and orthopedists in that order. Only 5 percent of doctors had a treatment experience of AHA. About 80 percent of doctors wanted to introduce AHA patients to hematologist. About 60 percent of doctors wanted to introduce AHA patients to hemophilia center like hospital which has hematologists.

Conclusions: It is important to know the consultation departments or hospitals in order to improve the medical cooperation system to the department of hematology where treatments are done, which leads to the improvement of prognosis of AHA.

PB 1960 | An Unusually High Incidence of Acquired Haemophilia A in Two Provinces in North-Eastern Italy in the Winters 2014 through 2016

P. Pradella[1], M. Giavitto[1], G. Festini[2], M. Miccio[3], G. Boscutti[4], V. Di Maso[4], M. Vidus Rosin[2], L. Mascaretti[1]

[1]ASUITS, Transfusion Medicine, Trieste, Italy, [2]ASUITS, Haematology Unit, Trieste, Italy, [3]ASUITS, Medicine 3, Trieste, Italy, [4]ASUITS, Nephrology and Dialysis Unit, Trieste, Italy

Background: Acquired Haemophilia A (AHA) is associated with the onset of autoantibodies targeting coagulation FVIII activity in subjects with no personal or family history of bleeding. The reported incidence is 1-4 cases per million population per year with increasing frequency in elderly people. Our Center is a reference coagulation laboratory for the provinces of Trieste and Gorizia with a catchment area of 375.000. In this district the incidence of AHA was negligible before 2014.

Aims: To report a series of consecutive AHA diagnosed in our district from 2014 to 2016 and calculate incidence rates.

Methods: In patients with unexplained elevated aPTT and bleeding symptoms, mixing studies were performed and Lupus anticoagulant was excluded. Presumed AHA cases were immediately notified to clinicians, FVIII level was estimated and the Bethesda assay performed.

Results: From 2014 to 2016, 8 patients (4 males and 4 females, mean age 78.6 years) who were admitted to the Emergency Room for spontaneous bleeding with no history of haemostasis disorders, were diagnosed with AHA. Patients had severe bleeding with inibitor titre in the range 4-210 BU/ml. Their characteristics are summarized in the Table: 7 out of 8 patients were treated in the hospitals of the district with bypassing agents and immunosuppression. Calculated incidence rates of AHA in our area are: 5.33 per million in 2014 and in 2016 and 10.66 per million in 2015.

TABLE 1 Characteristics of patients

ID	Month and Year of diagnosis	Sex	Age	Symptoms	APTT ratio	FVIII level %	Inhibitor titre BU/ml	Underlying disease
1	January 2014	F	76	Subcutaneous bleed	3.19	< 0.5	7.5	Diabetes Mellitus, Hypertension
2	January 2014	F	56	Haematuria, Retroperitoneum bleed	4.11	< 0.5	130	Sjogren´s syndrome Connective tissue disease
3	January 2015	F	75	Haematuria	4.43	1.7	5.7	Breast cancer (in the past)
4	February 2015	M	85	Subcutaneous bleed	2.92	1.6	210	Prostate cancer, chronic renal failure, arterial hypertension, rheumatoid arthritis, dyslipidemia
5	February 2015	M	85	Haematuria	1.86	5.1	4	Chronic renal failure
6	November 2015	M	93	Subcutaneous bleed	3.8	< 0.5	179	none
7	December 2015	M	80	Subcutaneous bleed	3.21	< 0.5	127	Prostate and bladder cancer
8	December 2015	F	79	Subcutaneous bleed	2.19	4.7	5.8	Connective tissue disease, cryoglobulins, parossistic atrial fibrillation

Conclusions: Our data show an unexpected increase in the number of AHA cases in this area starting from 2014, with significantly higher incidence rates compared with data reported in literature. All cases were diagnosed in the coldest months, an unusual finding not reported in previous studies. As no common trait in the clinical history of these patients was found so far, we speculate that infections (possibly of viral origin) might be the reason of the AHA cases recorded in our district. We can also figure out that the real incidence of AHA may be underestimated.

PB 1961 | Acquired Haemophilia: Overcoming Practical Challenges to Deliver Optimal Nursing Care

D. Pollard[1], J. Stanley[2], C. Harrison[3], K. Coutts[4], A. Jones[5], C. Forrester[6], S. Johns[7], E. Warner[8]

[1]Royal Free London NHS Foundation Trust, Haemophilia & Thrombosis Centre, London, United Kingdom, [2]Guy's and St Thomas' Hospital NHS Trust, Haemophilia Centre, London, United Kingdom, [3]Sheffield Teaching Hospitals NHS Foundation Trust, Haemophilia and Thrombosis Centre, Sheffield, United Kingdom, [4]Oxford University Hospitals NHS Foundation Trust, Haemophilia and Thrombosis Centre, Oxford, United Kingdom, [5]Royal Victoria Infirmary, Haemophilia and Thrombosis Centre, Newcastle, United Kingdom, [6]Royal Stoke University Hospital, Haemophilia Centre, Stoke-on-Trent, United Kingdom, [7]Royal Cornwall Hospitals NHS Trust, Haematology, Truro, United Kingdom, [8]Addenbrooke's Hospital, Haemophilia and Thrombosis Centre, Cambridge, United Kingdom

Background: Acquired Haemophilia (AH) is rare. It may present where clinical staff have limited experience. Bleeds may be caused by healthcare professionals delivering basic care, due to a lack of understanding of bleeding risk. Delays liaising with hospitals with experienced Haemophilia teams result in worsening clinical condition, and poor outcomes.

Aims: To identify key themes in nursing people with AH.

Methods: A meeting of Haemophilia Nurse Specialists took place to exchange experiences of nursing AH. A follow up meeting discussed the key themes previously identified.

Results: Raising awareness of treatment and management of AH was identified (preserve life and limb, control bleeding, treat any underlying condition, and clinically evaluate the patient's progress) The delivery of optimal care for AH patients is essential, minimal delay in diagnosis, prompt treatment to stop bleeding, and liaison with (and transfer to) a Centre of excellence. Preventing further bleeding from accidental trauma and invasive procedures is key in nursing management. Considerations for the choice of bypassing agent, include efficacy in controlling bleeds, venous access, volume and frequency of infusions and staff resources available to administer them.

Discussion: The complex nature of AH requires multidisciplinary, expert care. Non-specialist nursing staff should be supported to identify and report early warning signs of bleeding. Practical guidance is needed for nursing care that avoids provoking further bleeding.

Conclusions: The education of non-specialist staff is important. Two main paths are recommended: development of educational materials to disseminate best practice among non-specialists, and publication of the core principles of nursing care of AH in general nursing journals. We welcome input from colleagues, in order to ensure the materials are evidence-based, effective and robust, optimizing outcomes for AH patients in the future.

Sources of support: Medical writing was supported by an educational grant from Novo Nordisk Ltd.

PB 1962 | Pulmonary Thromboembolism due to Lead Poisoning in Opium Addict Patients

B. Shakerian[1], N. Razavi[2]

[1]Shahrekord University of Medical Sciences, Cardiovascular Surgery, Shahrekord, Iran, Islamic Republic of, [2]Azad University of Shahrekord, Genetic, Shahrekord, Iran, Islamic Republic of

Background: Lead poisoning is a major public health problem. Recently, there have been reports of opioid adulteration with lead in Iran. Lead is a toxic metal that affects many organ systems in humans. The following case series is the first of its kind in that pulmonary thromboembolism (PTE) due to lead toxicity has been described.

Aims: Lead is available in the environment widely and affects major organ systems in the body including hematopoietic, respiratory, renal, nervous and cardiovascular systems, mainly through increased oxidative stress, ionic mechanism and apoptosis. Exposure may result from ingestion or inhalation of lead compounds. Diagnosis of lead poisoning depend on a high index of suspicion and a through patient history. Lead is sometimes deliberately added to opium by the smugglers or salesman to increase its weight during trading.

Methods: We report four patients with lead poisoning in Iran, all of whom presented with leg pain and dyspnea. A history of opium ingestion or inhalation was present in each of these patients. None of the patients reported known occupational exposure to toxin and any risk factor for PTE. Clinical finding including the swelling and erythema in lower leg , elevated of jugular venous pressure and decrease O2 saturation. Color doppler sonography In all patients showed deep vein thrombosis. Chest CT were in favour of massive PTE. Lead level were higher than normal.

Results: All patients underwent medical treatment and discharge with good condition.

Conclusions: Opium is still one of the most frequently abuse drugs. Although the amount of lead in opium is usually small, when taken in large amounts opium adulterated with lead can produce toxicity. Lead toxicity should always be consider in cases of PTE with an unknown etiology, especially in a setting were opium abuse is common.

PB 1963 | Hemostatic Alterations in Hematological Disorders Rather than Inherited Coagulopathies

A. Naz[1], F. Ahmed[1], N. Ahmed[1], S. Ansari[2], T. Farzana[2], T. Shamsi[3]

[1]National Institute of Blood Disease & Bone Marrow Transplantation, Thrombosis and Hemostasis, Karachi, Pakistan, [2]National Institute of Blood Disease & Bone Marrow Transplantation, Clinical Hematology, Karachi, Pakistan, [3]National Institute of Blood Disease and Bone Marrow Transplantationn, Clinical Hematology, Karachi, Pakistan

Background: Incidence of haemostatic and thrombotic complications in hematological malignancies are reported in few literature but not much more documented in other hematological disorders like thalassemia, dengue, malignancies and etc. It's a big challenge for hematologist in terms of diagnosis as well as in management of these complications in hematological disorders rather than inherited Coagulopathies.

Aims: To observe and deter mine the frequency of hemostatic abnormalities in all requested investigations from hematology clinic to the department of Thrombosis and Hemostasis in NIBD.

Methods: This cross sectional study was initiated 2 years ago after approval of institutional IRB /ethics committee and written informed consent of patients. Data was documented by clinical research associate in structured questionnaire. Data was analyzed by using simple descriptive tools.

Results: A total of 800 patient's requests were received in the hemostasis department for the haemostatic workup in hematological disorders rather than inherited Coagulopathies. ITP 200(25%) cases with thrombocytopenia. Significant increased levels of PT, APTT, Von Willebrand antigen, fibrinogen, D.Dimer and factor VIII were found in 250(31.2%) pretreated patients of AML, ALL, multiple myeloma and diffuse large B cell lymphoma. Prolonged APTT with positive Lupus anticoagulant in 20 (16.53%) and Cardiolipin Antibody were present in 11(9.09%) 31(3.8%) patients of thalassemia. Marked hematological and hemostatic abnormalities were noted in 319(39.8%) cases of dengue hemorrhagic or dengue like fever.

Conclusions: The present investigations indicate that impaired coagulation parameters in dengue infection and hematological malignancies are more common in our setting. Early detection of haemostatic defects will help to cope up the severity of the disease and reducing morbidity and mortality rates. Early diagnosis and active intervention will help in reducing the bleeding complications and provide better survival with good quality of life.

PB 1964 | Acquired Factor XIII Deficiency in the Inpatient Setting: Retrospective Case Series

F. Chuliber[1], N.P. Schutz[1,2], V. Otero[1], L.H. Barrera[3,4], D. Altuna[5], M.S. López[3], J. Oyhamburu[3,4], S. Viñuales[1,2], D. Penchasky[1,2], J. Arbelbide[1,2], D. Fantl[1,2], M. Martinuzzo[3,4]

[1]Hospital Italiano de Buenos Aires, Hematología, Buenos Aires, Argentina, [2]Instituto Universitario del Hospital Italiano, Medicina, Buenos Aires, Argentina, [3]Grupo Bioquímico. Hospital Italiano de Buenos Aires, Laboratorio Central, Buenos Aires, Argentina, [4]Instituto Universitario del Hospital Italiano, Bioquímica, Buenos Aires, Argentina, [5]Hospital Italiano de Buenos Aires, Servicio de Hematología y Oncología Pediátrica. Transplante de Médula Ósea, Buenos Aires, Argentina

Background: Disproportionate surgery related bleeding has been reported in association with acquired factor XIII (FXIII) deficiency in patients with normal coagulation screening tests.

Aims: To describe the clinical characteristics and outcome of patients with acquired FXIII deficiency and to estimate the frequency of this deficiency in patients with disproportionate bleeding.

Methods: Retrospective case series. All patients studied for FXIII deficiency due to disproportionate or unexplained bleeds between January 2014 and December 2016 were included. An immunotubidimetric FXIIIA subunit test (Instrumentation Laboratory) was performed in real time. FXIIIA < 50% was considered deficiency. Patients less than 2 years old or with suspicion of congenital FXIIIA deficiency were excluded. Descriptive statistics were used. Normal or deficient FXIIIA populations were compared by using Fisher and Mann-Whitney tests (Stata13 software).

Results: 43 patients met inclusion and exclusion criteria, 26 studied because of disproportionate surgery related and 17 because of spontaneous bleeding. Sixteen had FXIIIA less than 50%. Statistically significant differences between groups were found in hematocrit points drop and red blood cell units transfused (table 1).

TABLE 1 Patients ,characteristics Comparison between Groups with or without FXIIIA Deficiency

	FXIIIA deficient	FXIIIA Normal	p
Patients, n	16	27	
Gender, Female/male	14/2	17/10	0.158
Age (years), median,(IQR)	38 (26-55)	46 (18-69)	0.841
Charlson Comorbidity Index, Median (IQR)	2 (1-4)	1 (0-2)	0.11
Surgical bleeding, n (%)	12 (75)	14 (52)	0.199
Spontaneous bleeding, n (%)	4 (25)	13 (48)	0.199
Hematocrit fall, points Median (IQR	5 (3-8,5)	2 (0-4)	0.01
RBC Transfusions, units Median (IQR)	3 (2-4,5)	0 (0-2)	0.001
FXIIIA, % median(IQR)	39 (27,5-43,5)	72 (61-91)	0.0001

Type of bleeding of FXIIIA deficient patients are described in table 2.

TABLE 2 Bleeding manifestations of patients with acquired FXIIIA deficiency

Patients, n		16
Surgical Bleeding, n(%)		12 (75)
	Kidney transplant, n	3
	abdominal surgeries, n	3
	Femoral venipuncture, n	2
	Other surgeries, n	4
Spontaneous Bleeding, n(%)		4 (25)
	Bruises on limbs, n	2
	CNS bleeding, n	2

Plasma derived FXIII concentrate was used in five patients to treat persistent or life-threatening bleeding, stopping it in < 24 hours. Four patients died, none because of bleeding.

Conclusions: In our study, 37% of patients studied because of disproportionate or unexplained bleeds had factor XIIIA deficiency. It is possible that this entity is underdiagnosed in clinical practice. In our experience, most cases were related to postsurgical bleeding, FXIIIA deficient patients bled significantly more, as it was stated by a greater fall in hematocrit and increased transfusion requirement, and in some of them factor XIII replacement therapy helped to stop bleeding.

PB 1965 | Bleeding Manifestations as First Clinical Presentation of Systemic Lupus Erithematosus: A Case of Acquired von Willebrand Syndrome (AVWS)

O. Paoletti, R. Morandini, E. Cancellieri, A. Zimmermann, M. Tala, S. Zambelli, C. Dellanoce, S. Caroli, N. Delpero, E. Spotti, S. Testa

Cremona Hospital, Haemostasis and Thrombosis Center, Department of Laboratory Medicine, Cremona, Italy

Background: AVWS is a rare bleeding disorder often associated with underlying diseases.

Differential laboratory diagnosis between acquired and congenital von Willebrand disease (vWD) could be difficult and a crucial aspect is the personal and family anamnesis.

Aims: We describe a case of this rare disease.

Methods: Clinical and laboratory data were collected on medical record.

Results: *A 39*-year-old woman showed since 2 months recurrent nosebleeds, spontaneous cutaneous hematoma and menorrhagia. In anamnesis she reported 1 pre-term delivery by caesarean section, hypotiroidism treated with tiroxin, Raynaud Syndrome since 1 year, no previous bleedings. Laboratory tests showed microcytic anemia (Hb 9.5 gr/dL), leukopenia and neutropenia, normal platelet count, thyroid profile, liver/renal function and prothrombin time (PT), prolonged activated partial thromboplastin time (PTT ratio=1.73) partially corrected with normal pooled plasma, PFA100 very prolonged. Second level coagulation tests revealed the significant reduction of FVIII activity (FVIII:C=4%) and von Willebrand factor (VWF:Ag=4%, VWF:RCo=2%) and the absence of ristocetin platelet agglutination. Family history was negative for bleeding disorders. Neutralizing FVIII/VWF inhibitor was confirmed by mixing assay. Test for autoimmunity confirmed systemic lupus erithematosus disease. Patient was treated with oral prednisone 1 mg/Kg + hydroxychloroquine 200 mg/die and oral tranexamic acid. We observed the resolution of bleeding manifestations and complete normalization of haemostatic parameters after a month.

Conclusions: AVWS is often unrecognized or misdiagnosed as inherited VWD and its diagnosis is often difficult and delayed. Differently from acquired hemophilia the antibodies in AVWS cannot easily be demonstrated by routine assay and inhibitor activity against FVIII/VWF using coagulative method based on mixing tests is found only in few cases. Our experience demonstrates.the necessity to rapidly identify the bleeding disorder and search for the underlying diseases.

PB 1966 | IPS Derived Vascular Endothelial Cells (vECs) from HA-patients with Nonsense Mutations Are a Potential Cell-model to Study the MHC-driven Risk for Inhibitor Development

H. Singer[1], N. Nüsgen[1], J. Müller[1], J. Oldenburg[1], O. El-Maarri[1,2]

[1]Institute for Experimental Haematology and Transfusion Medicine, University Clinic Bonn, Bonn, Germany, [2]Department of Natural Sciences, Lebanese American University, Byblos, Lebanon

Background: In about 20% of patients with severe Haemophilia A (HA), treatment with replacement FVIII is complicated due to the development of inhibitory antibodies against FVIII. F8 null mutations, like nonsense mutations, have a higher risk for inhibitor formation than other mutation types. Furthermore the location of a specific nonsense mutation influences the risk for inhibitor development. We established patient-specific IPS cells to differentiate into vECs. As endothelial cells have the ability to act as non-hematopoietic antigen-presenting cells (nhAPC), we think these cells are a potential cell-model to study the mutational effect on inhibitor development.

Aims: We differentiated IPS cells from three HA-patients into vECs to localize for intracellular FVIII. Furthermore we wanted to ascertain, if IPS derived vECs have the capability to express MHC-I and MHC-II.

Methods: IPS cells from three HA-patients (R363X, R431X, R1941X) were differentiated into vECs and MACS-separated using CD144 Microbeads. vECs were immunostained with domain-specific antibodies against FVIII and stimulated with IFNγ, to analyze MHC-I and MHC-II expression by FACS.

Results: IPS derived vECs from all three patients present intracellular FVIII and specific endothelial marker like vWF, CD31 and CD144. vECs with a nonsense mutation in the heavy chain show normal intracellular trafficking of FVIII. However, vECs harboring the high-risk inhibitor mutation R1941X, located in the light chain, represent

abnormal intracellular trafficking, when stained with an antibody against the A2 domain of FVIII. After IFNγ stimulation, patient-derived vECs are able to express significant amounts of MHC-I. Low levels of MHC-II were only detectable on IFNγ stimulated HUVEC, but not on IPS derived vECs.

Conclusions: These HA-patient specific vECs enable us to track endogenous mutant FVIII and to study the MHC-I presented FVIII peptide repertoire for each patient in correlation to their risk for inhibitor development.

PB 1967 | Investigation of an F8 Exon 25 Deletion Suggests an Unusual Mutation Mechanism

B. Theophilus[1], A. Guilliatt[2], J. Motwani[1], M. Williams[1]

[1]*Birmingham Children's Hospital NHS Trust, Birmingham, United Kingdom,* [2]*Birmingham Women's and Children's NHS Foundation Trust, Haematology, Birmingham, United Kingdom*

Background: Large deletions or insertions in the FVIII gene (*F8*) underlie severe haemophilia A in approximately 5% of patients. In the few deletion breakpoints characterised to date, a clear transition from 5' to 3' flanking DNA sequence is apparent, proposed to arise from repeat mediated non-allelic homologous recombination (NAHR) or non-homologous end joining (NHEJ).

Aims: We aimed to characterise the breakpoints within *F8* DNA from a boy with severe haemophilia A arising from a deletion of *F8* exon 25.

Methods: A standard primer walking strategy with DNA sequencing was used, followed by an NCBI ‚BLAST' search to aid sequence analysis. PCR was used to determine carrier status in the family.

Results: An approximately 5.5kb deletion was identified including exon 25. The breakpoint sequence included an insertion of approximately 300bp, derived from *F8* intron 22, with a 9bp sequence of unknown origin. The absence of repetitive elements and the presence of inserted sequence at the breakpoint preclude NAHR and NHEJ as mutation mechanisms. Microhomology-mediated break-induced replication (MMBIR) may underlie the observed deletion. The presence of low copy number repeat sequences in intron 22, which form the basis of the *F8* gene inversion causal of about 45% of severe haemophilia A, may predispose the formation of secondary structures such as cruciforms and stimulate MMBIR events. Identification of the breakpoint in the index patient enabled the development of a mutation-specific assay to confirm previous Multiplex ligation-dependent probe amplification (MLPA) based carrier diagnosis in family members.

Conclusions: The present investigation suggests an unusual mutation mechanism as the cause of severe haemophilia A in an index patient. It has enabled confirmation of carrier status in family members, and additionally provides insight into the distinct mechanisms responsible for copy number variation in the human genome.

PB 1968 | Stoichiometry of Immunodominant Factor VIII Immune Complexes

P. Lollar, E.T. Parker, C.B. Doering

Emory University, Pediatrics, Atlanta, United States

Background: Inhibitory antibodies (inhibitors) to factor VIII (fVIII) represent the most significant complication in patients with congenital hemophilia A. FVIII also is the most frequently targeted coagulation factor in autoimmunity. Antibodies recognizing immunodominant epitopes in the fVIII A2 and C2 domains are present in most inhibitor patients. Anti-A2 monoclonal antibody (MAb) 4A4 and anti-C2 MAb 3D12 recognize human inhibitor epitopes. Additionally, 3D12 inhibits the binding of fVIII to von Willebrand factor (VWF). Thus, fVIII complexes formed by 4A4 and 3D12 may be representative of VWF-free immune complexes in human inhibitor plasmas.

Aims: The goal of this study was to determine the stoichiometry of fVIII immune complexes formed by MAbs 4A4 and 3D12.

Methods: Sedimentation velocity of immune complexes formed by varying ratios of 4A4 and 3D12 with a high-expression fVIII construct designated ET3 was conducted at 55,000g and 20 °C by measuring protein absorbance at 280 nm in a Beckman XL-I analytical ultracentrifuge. Sedimentation coefficient ($s_{20,w}$) distributions of fVIII, MAbs and immune complexes were determined using SEDFIT.

Results: The sedimentation coefficients of fVIII in the absence of MAbs and of the MAbs in the absence of fVIII were 7.7 S and 6.4 S, respectively. Singly-ligated, 10.3 S, and doubly ligated MAb, 11.9 S, complexes were identified under conditions of excess MAb and excess fVIII, respectively. A mixture containing equimolar fVIII and 4A4/3D12 MAb binding sites produced a dominant 14.0 S species and an estimated molecular weight of 610 kDa, consistent with a stoichiometry of two fVIII: one 4A4: one 3D12.

Conclusions: These results demonstrate that a biclonal anti-fVIII antibody population can form higher-order immune complexes. These complexes may be a driving factor in the immune response to fVIII by promoting B cell activation and/or antigen presentation. Additionally, these results indicate that analytical ultracentrifugation is a useful tool to characterize fVIII immune complexes.

PB 1969 | Analysis of VWF-FVIII Interaction in Natural pdFVIII/VWF Complex Compared with rFVIII+VWF Complex through a Novel Flow Cytometry Technique

M.I. Bravo, A.M. Ortiz, M. Costa, S. Grancha, J.I. Jorquera

Grifols, Research & Development, Bioscience Industrial Group, Barcelona, Spain

Background: The interaction between VWF and FVIII is crucial for FVIII function and clearance. It has been reported that the binding of VWF of hemophilic patients to the isolated FVIII of certain therapeutic

products may not be complete (Lin Y et al. 2004; Grancha S et al. 2012; Ofosu FA et al, 2012).

Aims: To compare, by a new flow cytometry technique, the natural pdFVIII/VWF complex and preformed rFVIII+VWF complex, regarding the resulting free-FVIII fraction.

Methods: rFVIII and pdVWF were incubated in a ratio 1:1 IU (100 ng FVIII : 10 mg VWF; i.e., conditions equivalent to those of the plasmatic natural pdFVIII/VWF) at 25°C for 15 min. Samples of the obtained rFVIII+VWF and natural pdFVIII/VWF were incubated (25°C; 2 h) with CBA-ESH4 (Cytometric Bead Array with anti-light chain of FVIII), followed by incubation (25°C; 2 h) with Dyn-antiVWF (DynaMag™-2 beads with anti-VWF). The supernatant was incubated (25°C; 2 h) with antiA2-FITC (anti-A2 FVIII marked with Fluorescein). The fluorescent signal of the pellet containing the CBA-ESH4 beads and the antiA2-FITC was measured by FACS Calibur flow cytometer. By using this model, FVIII-bound VWF can be detected through specific fluoresce signal. The assay was performed in duplicate and with 6 concentrations of FVIII (0.1-50 ng) maintaining the 1:1 ratio with VWF.

Results: The fluorescent signal from CBA-ESH4 beads bound to pdFVIII/VWF was 21.7% higher than that from rFVIII+VWF. Measurement of free-FVIII bound to antiA2-FITC indicated that rFVIII+VWF complex contained higher levels of free-FVIII (28.4%) than pdFVIII/VWF (8.7%), regardless the FVIII concentration assayed. Globally the results showed a 19.7% free FVIII in the FVIII+VWF complex, not present in the pdFVIII/VWF.

Conclusions: In agreement with previous reports, formation of the rFVIII+VWF complex resulted in a larger amount of VWF free rFVIII (≈20%) in the rFVIII+VWF complex than in the natural pdFVIII/VWF. The impact of this difference in FVIII products in vivo deserves future research.

PB 1970 | FVIII-vWF Complex Displays Greater Efficiency than Vwf-Free Preparations in Restoring Thrombin Generation in Hemophilic Plasma with Inhibitor under Conditions of Physiological Relevance

C.T. Ammollo[1], F. Semeraro[1], A.M. Mezzasoma[2], N. Semeraro[1], P. Gresele[2], M. Colucci[1]

[1]Aldo Moro University of Bari, Dept. Biomedical Sciences and Human Oncology, Bari, Italy, [2]University of Perugia, Dept. Internal Medicine, Perugia, Italy

Background: Development of factor (F)VIII inhibitor is a serious complication of hemophilia A (HA) treatment.

Aims: To compare the efficacy of three FVIII preparations (FVIIIP) in restoring thrombin generation (TG) in hemophilic plasma with inhibitor, under different experimental conditions.

Methods: FVIIIP were recombinant FVIII (Kogenate), plasma FVIII-vWF complex (Fanhdi) and vWF-free plasma FVIII (Beriate). TG was evaluated by calibrated automated thrombography; thrombin activatable fibrinolysis inhibitor (TAFI) activation by functional assay. Anti-FVIII IgG (FVIII-inh) were purified from a patient with high inhibitor titer. Plasma was obtained from patients with severe HA (FVIII< 1%).

Results: In plasma from a HA patient without inhibitor, the three FVIIIP (1 U/ml) displayed similar efficiency. On the contrary, upon addition of FVIII-inh (2.5 and 5 BU/ml), Fanhdi caused a stronger enhancement of TG and TAFI activation. Similar results were obtained when FVIIIP were incubated in FVIII-inh plasma for 2 h at 37°C or when plasma was supplemented with thrombomodulin (TM, 4 nM). In a model containing endothelial cells (EA-hy926, $625x10^3$/ml) and washed platelets ($250x10^6$/ml), Fanhdi enhanced TG more than Kogenate and Beriate both in the absence (peak increase: 1631, 695 and 1174%, respectively) and in the presence of FVIII-inh (541, 207 and 322%, respectively with 2.5 BU/ml). The effect of Fandhi and Kogenate on TG was also tested in plasma of 12 patients with HA, 6 with inhibitor (1-12 BU/ml) and 6 without. In samples with inhibitor, Fanhdi proved more efficient than Kogenate (both tested at half BU level) in enhancing thrombin generation, median (range) peak increase amounting to 355 (249-1876) and 185 (78-1028)%, respectively (P=0.03). The superiority of Fandhi was also evident in the presence of activated protein C (0.1 μg/mL).

Conclusions: FVIII-vWF complex shows greater hemostatic efficiency in HA plasma with inhibitor as compared to vWF-free preparations, especially under conditions of physiologic relevance.

PB 1971 | 40 kDa PEG of N9-GP is Eliminated from Tissues and Will Reach Steady State after Chronic Dosing

I. Bjoernsdottir[1], O. Sternebring[2], H. Jacobsen[3], J. Sims[4]

[1]Novo Nordisk A/S, Development ADME, Måløv, Denmark, [2]Novo Nordisk A/S, Development PK/PD, Måløv, Denmark, [3]Novo Nordisk A/S, Non-Clinical Project Management, Måløv, Denmark, [4]Integrated Biologix GmbH, Basel, Switzerland

Background: PEG in human tissues has not been measured during clinical development of N9-GP (40 kDa PEGylated rFIX). Data from a rat distribution study with N9-GP was used to estimate terminal elimination half-life ($t_{½}$) and time to steady state (SS) in toxicity studies as well as in clinical trials. To support the robustness of the N9-GP assessment, distribution data from other 40 kDa PEGylated compounds are included.

Aims: To estimate elimination $t_{½}$ and time to SS of PEG in plasma, kidney, liver and choroid plexus in rat and humans using single dose N9-GP distribution data from rat.

Methods: Tissue distribution studies were conducted in rats (n=1/time point) followed for up to 12 weeks post dose after a single i.v. dose of N9-GP[1] and other 40 kDa PEG compounds (same study design and tritium label in PEG). Terminal elimination $t_{½}$ were estimated by linear regression. Applying simple allometric scaling of $t_{½}$, time to SS of PEG was estimated in rat and man for N9-GP.

Results: Consistent decrease of PEG levels in rat tissues was shown for all compounds (Figure 1), with similar tissue elimination $t_{½}$ across

TABLE 1

Table 1 Estimated $t_{½}$ of PEG and time to SS after repeated N9-GP dosing

	Plasma	Kidney	Liver	Choroid plexus
Rat ($t_{½}$ days)	15	16	16	49
Human ($t_{½}$ days)*	59	63	63	192
Rat SS (weeks)**	7	8	8	23
Human SS (month)**	6	7	7	21

* Human $t_{½}$= rat $t_{½}$ x $(BW_{Human}/BW_{rat})^{0.25}$; BW - Body weight; BW_{Human}: 70 kg; BW_{rat} 0.3 kg[2]
** 3.3 x $t_{½}$ (90% steady-state, considered clinically relevant)[2]

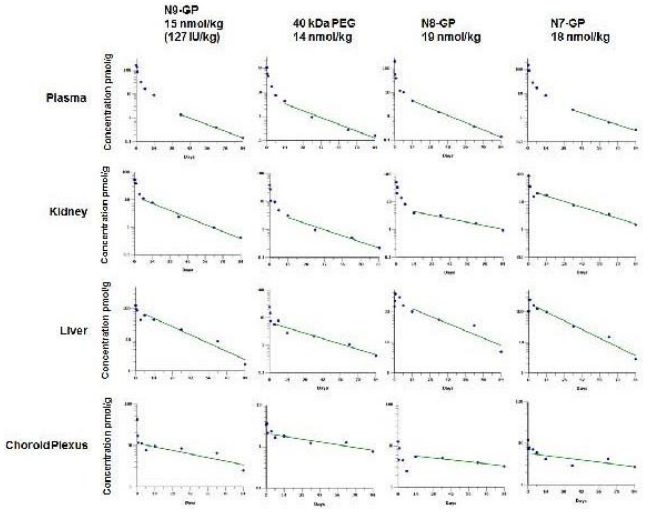

FIGURE 1

compounds. The predicted time to PEG SS in rat is within 7-23 weeks and in humans within 0.5-2 years after repeat N9-GP dosing (Table 1).

Conclusions: Animal distribution studies have shown that 40 kDa PEG is eliminated from tissues over time. For N9-GP, PEG SS is predicted to have been reached in 26-week rat chronic toxicity studies as well as in clinical trials, with no unexpected safety concerns.

Figure 1 Consistent decrease of PEG concentrations in tissues over time.

Blue dots observed data, green lines regression lines used to estimate $t_{½}$.

N8-GP and N7-GP: 40 kDa PEGylated rFVIII and rFVIIa

PB 1972 | Spectrum of F8 Gene Mutations with FVIII Assay Discrepancies in an Irish Patient Cohort with Mild/Moderate Haemophilia A

C. Keenan[1], R. Campbell[1], M. Doyle[1], M. Byrne[1], K. Ryan[1], J. O'Donnell[1,2], B. White[1], N. O'Connell[1]

[1]St. James's Hospital, National Coagulation Centre, Dublin, Ireland, [2]Royal College of Surgeons in Ireland, Dublin, Ireland

Background: FVIII assays can exhibit discrepancies in haemophilia A (HA) patients by FVIII one-stage (FVIII:C) and two-stage (FVIII:Chr) methods. Mutations within the *F8* gene have been associated with discrepancies but many remain undocumented. The coagulation and molecular laboratories at our centre work together to determine the legitimacy of assay discrepancies comparing FVIII assays ratios with known genetic data. However, using the standard ratio cut-off of 0.6 is too stringent, and data within and between families is not always as expected leaving.

Aims: We aim to analyse the FVIII:C, FVIII:Chr, and *F8* genetic data in patients with mild and moderate HA to determine patterns within our patient group.

Methods: Informed consent was obtained and data retrieved from electronic patient records and familial pedigrees. FVIII assays were performed using the HemosIL method and *F8* gene mutations using direct sequencing.

Results: FVIII:C and FVIII:Chr levels were retrieved for 110 patients from 63 families. 22 missense mutations and one splice site mutation (c-219C>T) were detected. The common p.Arg550Cys/His variant was found in 28 patients with mild HA from 9 families (mean ratio of 0.4). p.Met681Ile was found in four unrelated families, and previously not associated with assay discrepancies (mean ratio 0.2). This variant re-assigns the severity from mild to moderate with the lowest FVIII:Chr reduced to 0.01IU/ml. p.Arg1985Gln was found in both discrepant and borderline cases (ratio´s 0.58 vs. 0.72). Inverse discrepancy was detected in two unrelated patients with p.Tyr365His/Cys (ratio´s 0.41 and 0.57) and one with p.Arg1708His (ratio 0.38). Five families had ratio's that were borderline and differing within families (mean ratio 0.70).

Conclusions: The standard ratio cut-off of 0.60 is too stringent to elimiate the presence of a FVIII assay discrepancy. This data suggests that FVIII assay ratio's alone are insufficient and should be analysed alongside genetic data considering familial patterns.

PB 1973 | Identification of High-molecular Weight Species in Commercial Recombinant Factor VIII Products

J.F. Healey, E.T. Parker, P. Lollar

Emory University, Atlanta, United States

Background: The development of inhibitory antibodies to factor VIII (fVIII) is the most significant complication in management of patients with hemophilia A. Recent clinical studies have provided evidence that recombinant fVIII products are more immunogenic than plasma-derived fVIII products. Additionally, some clinical evidence suggests that Kogenate is the most immunogenic recombinant fVIII product. High molecular contaminants, aggregates, or viral-lke particles can increase the immunogenicity of biotherapeutics.

Aims: The goal of this study was to identify and quantitate all macromolecular species present in the recombinant fVIII products Kogenate, Helixate and Advate.

Methods: Vials of Kogenate, Helixate and Advate were reconstituted according to instructions provided by the manufacturers. The solutions were subjected to sedimentation velocity analysis at 105,000 *g* in a Beckman

XL-I analytical ultracentrifuge scanning at 280 nm. Sedimentation coefficient (s-value) distributions were calculated using SEDFIT.

Results: Kogenate and Helixate produced similar results, consistent with their identical manufacturing process. A broad peak at ~ 8 S was present in Kogenate representing 78% of the sedimenting species. Additional species were identified between 12 - 100 S, representing 22% of the product (Fig. 1).

Advate produced a major peak at $s_{20,w}$ 7.8 S representing 77% of the product. Additional species were identified at 5.2 and 11.5 S. There was a broad distribution between 12-20 S representing 7% of the product and negligible material > 20 S (Fig. 2).

Conclusions: Kogenate, Helixate and Advate contain large s-value, high molecular weight species that are significantly larger than the ~8 S species corresponding to full-length, monomeric fVIII. Species up to 100 S were identified Kogenate and Helixate. The amount of high molecular weight material was greater in Kogenate and Helixate than Advate. The high molecular weight material identified in these products may contribute to the immunogenicity of fVIII.

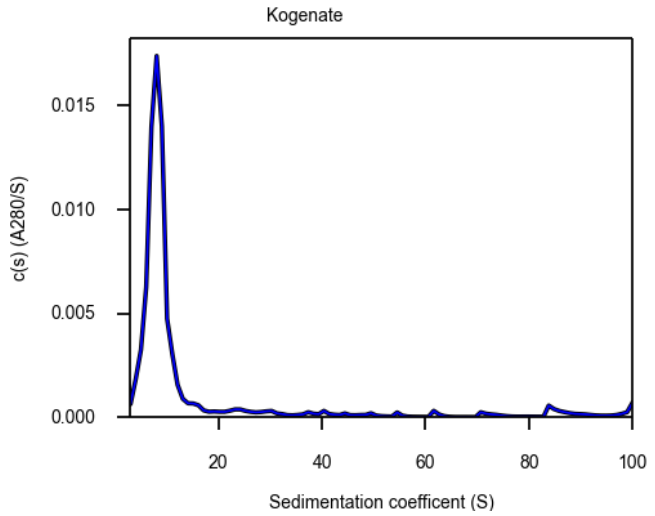

FIGURE 1 Sedimentation coefficient distribution of Kogenate

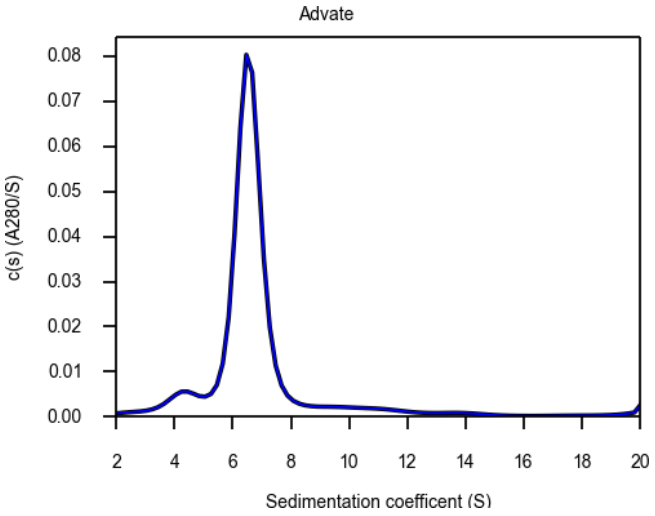

FIGURE 2 Sedimentation coefficient distribution of Advate

PB 1974 | Pharmacokinetics (PK) of N8-GP (Turoctocog Alfa Pegol) Dosed Subcutaneously (SC) to Non-human Primates (NHPs) and Prediction of Human PK Profile

F. Rode, M. Loftager, D.M. Karpf, J.H. Faber, A.V. Groth, J. Haaning

Novo Nordisk A/S, Global Research, Måløv, Denmark

Background: Haemophilia A (HA) treatment requires intravenous (IV) factor VIII (FVIII) administration. N8-GP SC could eliminate the need for IV injections for routine prophylaxis and provide dosing regimens that achieve higher minimum plasma FVIII activities with smaller fluctuations than current IV FVIII therapy.

Aims: To evaluate N8-GP SC absorption in NHPs and develop a human PK prediction model of N8-GP dosed SC to patients with HA.

Methods: Six NHPs received daily doses of N8-GP, 100 IU/kg SC for 3 days, and 5 NHPs received 1 dose of N8-GP IV; 100 IU/kg (n=2) or 250 IU/kg (n=3). Blood samples, drawn over a 96-hour period after first dose, were analysed for FVIII activity with a glycoPEGylated FVIII-specific chromogenic assay. NHP IV and SC plasma FVIII activity-time data were simultaneously modelled using a 2-compartment non-linear mixed-effects PK model for estimation of absorption rate and SC bioavailability.

For human PK predictions following SC administration, a PK model was developed using a 1-compartment model, with population PK parameters of the clearance and volume of distribution from the pathfinder™1 trial in which patients with HA received N8-GP IV (data on file). N8-GP SC absorption PK in patients were assumed similar to NHPs, in line with data with recombinant (r)FVIIa (NovoSeven®), glycoPEGylated rFVIIa (data on file) and rFIX.[1]

Results: The estimated first-order absorption rate constant and SC bioavailability of N8-GP in NHPs were 0.35 h^{-1} and 24%, respectively. The human PK model predicted that daily SC doses of N8-GP 1.9-28 IU/kg would provide FVIII activity trough levels of 1-15%.

Conclusions: This NHP study is the first evaluation of N8-GP PK after SC administration. N8-GP bioavailability in NHPs was higher than that published for rFVIII.[2] The data indicate that human daily SC doses of 1.9-28 IU/kg should achieve FVIII activity trough levels of 1-15%.

PB 1975 | Molecular Characterisation of Variants on Non-coding RNA Genes in the X-inactivation Centre from Three Symptomatic Carriers with Severe Haemophilia A (HA) and Extremely Skewed X-chromosome Inactivation

C.P. Radic[1], M.M. Abelleyro[1], V.D. Marchione[1], L. Primiani[2], M. Candela[3], D. Neme[2], M. Bonduel[4], M. de Tezanos Pinto[2,3], L.C. Rossetti[1], C.D. De Brasi[1,3]

[1]*Instituto de Medicina Experimental (IMEX), CONICET-Academia Nacional de Medicina (ANM), Ciudad Autónoma de Buenos Aires, Argentina,* [2]*Fundación de la Hemofilia Alfredo Pavlovsky, Ciudad Autónoma de Buenos Aires, Argentina,* [3]*Instituto de Investigaciones Hematológicas Mariano R. Castex (IIHEMA), ANM., Ciudad Autónoma de Buenos Aires, Argentina,* [4]*Laboratorio de Hemostasia y Trombosis, Hospital de Pediatría, Prof Dr. Juan P. Garrahan, Ciudad Autónoma de Buenos Aires, Argentina*

Background: Random X-chromosome inactivation (XCI) of one X-chromosome in females achieves dosage equivalency for X-linked genes with males. Non-coding RNA genes were described in the X-chromosome inactivation centre (XIC, Xq13) associated with the inactivation process: *XIST* (X-inactive specific transcript), *JPX* (just proximal to *XIST*) and *FTX* (five prime to *XIST*). We hypothesized that SNPs (single nucleotide polymorphism) may modify XIC gene expression or function impacting its allelic ability to inactivate.

Aims: Study the association between SNP variants on relevant sequences of *XIST*, *JPX* and *FTX* with extremely skewed XCI in three symptomatic carriers with severe HA.

Methods: An extensive genetic variant screening of *XIST*, *JPX* and *FTX* was performed in leukocyte-extracted DNA samples from three symptomatic carriers with severe HA and extremely skewed XCI (97-100%) and 11 controls with random XCI (50-55%) by CSGE (conformation sensitive gel electrophoresis) and Sanger sequencing. Symptomatic carriers were previously *F8* genotyped as heterozygous for severe HA mutations and the phenotypic expression resulted from their association *in cis* with the preferential X-inactive (Radic et al., JTH 2015,13:530-9).

Results: Analysis of the non-coding RNA genes on XIC from the three cases showed no deleterious mutations, but 12 SNP variants out of 161 annotated in public databases: 5/80 SNPs on *XIST*, 4/46 on *FTX* and 3/35 *JPX* in heterozygous status (Table 1). Despite this observation, these variants were also found in controls (Table 1).

Conclusions: This is the first study of *XIST*/*FTX*/*JPX* variants addressing their ability on XCI skewing performed thus far. The finding of SNPs in both groups (i.e., symptomatic carriers and controls) indicated no causal effect on XCI skewing. A suggestive absence of SNP heterocigosity in some DNA segments may indicate the involvement of large deletions that may hinder the ability to inactivate the X *in cis*.

PB 1976 | Clinical Trials and Registries in Rare Diseases: Opponents or Collaborators?

C. Keipert[1], C.J. Jonker[2,3], H.M. van den Berg[3], A. Hilger[1]

[1]*Paul-Ehrlich-Institut, Federal Institute for Vaccines and Biomedicines, Langen, Germany,* [2]*Medicine Evaluation Board, Utrecht, The Netherlands,* [3]*Julius Center for Health Sciences and Primary Care, Utrecht, The Netherlands*

Background: Hemophilia A (HA) is a rare disease with 1 in 5000 male births, which relates to ~250 newborns with severe HA in the EU annually. Due to the concurrent development of FVIII products the number of PUPs mandatory for CTs could be difficult to meet. Well-defined registries might be a potential source to improve knowledge on safety of FVIII products.

Aims: To analyze whether other data sources can complement to clinical knowledge especially on inhibitor development.

Methods: The CT database, established as part of the ABIRISK project and located at the Paul-Ehrlich-Institut, Federal Institute for Vaccines and Biomedicines, with 369 PUPs and minimally treated patients and the first cohort of the PedNet registry with 632 PUPs served as data sources. To analyze comparability of data collection systems, patient characteristics and parameters suspected for potential impact on inhibitor development as well as study design were investigated.

Results: Study design of already conducted CTs in PUPs are too various (e.g. study duration, study population, inhibitor testing) and patient numbers too limited to compare outcomes, whereas patient

cohort and research parameters for all PedNet patients follow the same conditions. The comparison of country, race/ethnicity, genetic mutation, family history of hemophilia and inhibitor development shows that both sources collect valuable data with a quite similar distribution of risk factors and observed inhibitor incidences.

Conclusions: Available PUP-CT data does not allow for comparison of outcomes among different products. The FVIII-Guideline requires key parameters for PUP studies to harmonize research. There are currently 11 HA-PUP studies announced (clinicaltrials.gov), in need of 600 PUPs until 2024. Our results support the assumption that in a rare disease such as HA clinical trials and well conducted registries/cohort studies are potential collaborators, as all available information should be combined to contribute to the knowledge of clinical performance of HA products.

PB 1977 | In Haemophilic Patients, Individual Factor VIII or IX Level for the Correction of Thrombin Generation Is Predictable

B. Tardy-Poncet[1,2,3], P. Chelle[1,4], A. Montmartin[2], M. Piot[1], M. Cournil[1,4], C. Morin[1,4]

[1]Université de Lyon, Inserm U1059 SAINBIOSE, Saint-Etienne, France, [2]Inserm CIC 1408, FCRIN-INNOVTE, CHU Saint-Etienne, Saint-Etienne, France, [3]European Haemophilia Comprehensive Care Centre, CHU Saint-Etienne, Saint-Etienne, France, [4]Mines Saint-Etienne, CIS-EMSE, Saint-Etienne, France

Background: The thrombin generation assay (TGA) assesses the individual clotting potential, which can differ greatly from one haemophilic patient to the other for the same level of factor VIII or IX. Normalization of thrombin generation (TG) is a valuable target for individualizing patient treatment. The factor VIII or IX levels to be reached in order to normalize TG are patient-specific.

Aims: To define in haemophilic patients the individual target levels of factor VIII or IX required to normalize their TG.

Methods: Plasmas from 16 haemophilic patients were spiked with increasing levels of the deficient coagulation factor and TG parameters were measured. The relationships between factor levels and TG parameters were determined by linear regression. The normal values were determined in 40 healthy volunteers.

Results: Despite inter-individual heterogeneity in basal TG and in responses to spiking, a true linear correlation, without any appearance of a plateau, was found between the measured fVIII or fIX levels and endogenous thrombin potential (ETP), peak (P) and velocity (VI) for each individual (median R^2 values: ETP: 0.96; P: 0.99; VI: 0.97). These relationships were characterized by straight lines. This means that two data points might be sufficient to predict individual patient response to antihaemophilic treatment. The slopes of these regression lines correspond to the rates of variation of TG parameters with increasing fVIII or fIX level. The slopes of ETP response to spiking in PPP from HB patients were much steeper than in PPP from HA patients ($p < 0.001$). Similar differences were observed for peak, and for velocity ($p < 0.001$). As a consequence, the target factor level required to normalize TG was significantly lower in PPP from HB patients than in PPP from HA patients ($p < 0.02$) .

Conclusions: Based on the individual response of patient plasmas to spiking, it is possible to define with only two points the target factor VIII or IX levels to be reached in order to normalize TG.

PB 1978 | Factor 8 Assay Discrepancy in a United States Non-severe Hemophilia A Cohort

of North Carolina at Chapel Hill, School of Medicine, Pathology and Laboratory Medicine, Chapel Hill, United States

Background: Significant discrepancy (≥2-fold) between the 1-stage (1SF8) and chromogenic (CF8) assays has been described among patients with non-severe hemophilia A (NSHA).

Aims: To characterize F8 assay discrepancy in NSHA in a multi-ethnic US cohort.

Methods: In this retrospective cohort study, records of patients with NSHA at one hemophilia treatment center (HTC) were queried for 1SF8 and CF8 levels. Demographic data, *F8* genotype, and clinical history were retrieved. Data were analyzed using SPSS version 16.

Results: A total of 114 NSHA patients were identified; 56 (49.1%) had 1SF8 and CF8 performed on the same sample on ≥1 occasions. 47 of these 56 patients (85.7%) manifest discrepant test results; 46 had classical discrepancy while 1 subject had a reverse discrepant profile. Patients with a family history of hemophilia were more likely to demonstrate discrepant test results compared to those without such a history; BMI, ethnicity, HBV or HIV infection, presence of inhibitor, joint disease or therapy type were not significantly associated with discrepant results. Molecular findings demonstrated missense variants predominantly in the A2 domain, with other variants scattered throughout the A1, A3, C1 and C2 domains (Figure 1).

15 subjects had 1SF8 and CF8 assays done on >1 occasion, with 2 patients no longer discrepant and the single reverse discrepancy became a classical discrepancy. 5 subjects underwent a DDAVP trial with a tendency for the 1SF8:CF8 ratio to lessen, especially at 1H post infusion (Table 2).

Conclusions: While findings may be limited by selection bias, there is a high prevalence of F8 discrepancy among patients with NSHA in this US cohort. F8 mutations identified in patients with discrepant results appear similar to those reported previously. Repeat testing may lead to re-classification of patients as discrepant or non-discrepant. DDAVP tends to initially increase CF8 more than 1SF8 leading to a change in the magnitude of the assay discrepancy.

TABLE 2

Table 2. DDAVP Trial in 5 NSHA Patients

PB 1979 | Aberrant Inflammatory Cytokines, Skew T Helper Cells and Decreased Regulatory T Cell Numbers in Hemophilia A Patients with FVIII Inhibitor

D. Zhang, F. Xue, H. Li, R. Yang

Chinese Academy of Medical Sciences & Peking Union Medical College, Institute of Hematology & Hospital of Blood Diseas, Tianjin, China

Background: Current therapy for hemophilia A (HA) is based on intravenous infusion of the FVIII. However, 20-30% of HA patients generate inhibitory antibodies against FVIII. The mechanism of FVIII inhibitor formation is complicated. Aberrant immunologic balance is considered important in the production of FVIII inhibitor.

Aims: The aim of this study was to explore the profile of IFN-γ/TNF-α,T helper (Th) cells and regulatory T cells (Treg) in HA patients.

Methods: Seventy one HA patients and 42 healthy controls (HC) were enrolled in this stuty. Serum IFN-γ as well as TNF-αconcentrations were measured by ELISA. The percentages of CD4+IFN-γ+ Th1, CD4+IL-4+ Th2, and CD4+CD25+Foxp3+ Tregs were analyzed by flow cytometry.

The immunosuppressive functions of CD4+CD25+ Tregs sorted by MACS were studied by mixed lymphocyte reaction.

Results: The serum IFN-γ and levels in HA patients with or without inhibitor (inhibitor+ or inhibitor-) were significantly higher than that of HC ($p< 0.01$), while IFN-γ in inhibitor+ group were significantly higher than that of inhibitor- group ($p< 0.05$). Both the inhibitor+ group and inhibitor- group had significant higher Th1/Th2 ratios than HC ($p< 0.01$). The Tregs in inhibitor+ group were significantly lower than that in the HC ($p< 0.01$) and inhibitor- group ($p< 0.01$), while Tregs in inhibitor- group were significantly higher than that in HC ($p< 0.01$). Sorted Tregs from inhibitor- or inhibitor+ patients with HA showed comparable immunosuppressive activity in vitro compared with HC ($p>0.05$).

Conclusions: The aberrant inflammatory cytokines and skew Th cells and decreased Treg numbers may play roles in FVIII inhibitor production in HA patients.

PB 1980 | Hemophilia A and the Role of Factor VIII in Balancing Pro- and Anticoagulant Processes

V.J.F. Strijbis[1,2], R.M.W. Kremers[1,2], I. van Moort[3], D. Huskens[1,2], S. Bloemen[1,2], H. Kelchtermans[1,2], M. de Maat[3], B. de Laat[1,2]

[1]CARIM, Maastricht University, Synapse Research Institute, Maastricht, The Netherlands, [2]CARIM, Maastricht University, Department of Biochemistry, Maastricht, The Netherlands, [3]Erasmus University Medical Center, Department of Hematology, Rotterdam, The Netherlands

Background: Hemophilia A is a genetic disorder resulting in the partial or complete dysfunction of FVIII. Hemophilia A patients are categorized into mild, moderate, or severe disease, and this severity is associated with the bleeding tendency. However, the optimal method to determine the threshold level of FVIII that is required to prevent severe bleeding is still unknown, and it is also unknown whether this threshold level differs between patients.

Aims: To study the dynamics of thrombin generation and coagulation factor levels in samples of mild, moderate, and severe hemophilia patients.

Methods: Healthy subjects (n=130) and hemophilia A patients (n=39) were enrolled in this study after informed consent was obtained. Thrombin generation (TG) was measured at 1 pM TF and plasma

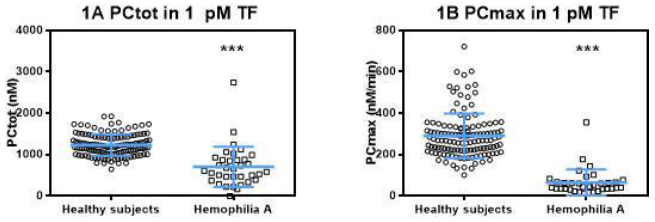

FIGURE 1 1A-B Total prothrombin conversion (PCtot), 1C-D maximum prothrombin conversion (PCmax) in hemophilia A patients (n=39) and healthy subjects (n=130)

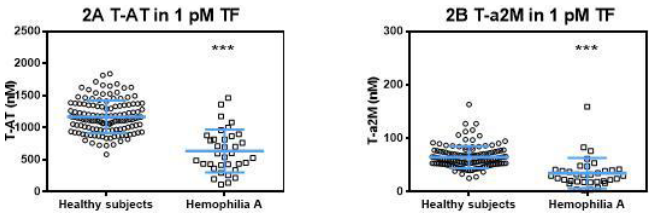

FIGURE 2 2A-B Thrombin-antithrombin (T-AT) complexes, 2C-D thrombin-α¬2M (T-a2M) complexes in hemophilia A patients (n=39) and healthy subjects (n=130)

prothrombin and FVIII levels were determined using one-stage coagulation assays. The dynamics of thrombin generation were studied computationally by quantifying the prothrombin conversion and thrombin inactivation.

Results: TG (ETP) was 55% lower in hemophilia patients at 1 pM TF compared to healthy subjects (p< 0.0001). No differences were observed in FII levels, but total FII conversion (PCtot) and maximum FII peak (PCmax) were significantly lower in hemophiliacs at 1 pM TF: PCtot and PCmax were reduced with 57% (p< 0.0001) and 22% (p< 0.0001), respectively (**figure 1**). The formation of thrombin-inhibitor complexes differed in hemophiliacs at 1 pM TF: thrombin-antithrombin complexes were 55% reduced (P< 0.0001) and thrombin-α_2-macroglobulin level was 54% reduced (p< 0.0001) (**figure 2**).

Conclusions: Even though FII levels are similar in hemophiliacs and healthy subjects, the prothrombin conversion is decreased in hemophilia patients, mainly due to an attenuation of the rate of prothrombin conversion. The reduced prothrombin conversion results in lower T-AT and T-α2M complex levels.

PB 1981 | Towards a Methylation Based Detection of F8 Rearrangements

O. El-Maarri[1,2], A. Sharma[1], A. Jamil[1], N. Nüsgen[1], B. Pezeshkpoor[1], A. Pavlova[1], J. Oldenburg[1]

[1]University of Bonn, Inst. Exper. Haematology and Transfusion Medicine, Bonn, Germany, [2]Lebanese American University, Natural Sciences, Beirut, Lebanon

Background: Inter-chromosome homologous recombination between repetitive inverted identical repeats at Xp28 leads to the two inversion mutation hotspots (the known Intron1 and Intron 22 inversions) that cause severe hemophilia A. Several methods already exist to detect these inversions hotspot; this include Southern blot, RT-PCR, Long range-PCR and Inverse PCR. Each of these methods has it own limitations and advantages. However all are quite laborious and requires between 2 to 4 days time to be performed.

Aims: Heron we worked toward developing a faster method to detect any rearrangement in the F8 gene based on methylation epigenetic changes associated with position effects of DNA rearrangement.

Methods: We screened for methylation changes associated with F8 rearrangements (mainly intron 1 and intron 22 inversions) using enrichment of bisulfite treated DNA followed by massive parallel sequencing of DNA corresponding to the X chromosome. Additionally, we used pyrosequencing to screen for methylation changes at CpG islands and CpG rich region in the F8 gene regions (up to extra genic Intr1h and Intr22h repeats).

Results: The enrichment strategy together with the NGS detected differentially methylated region specific for each type of rearrangement; high discrimination power with both high sensitivity and high specificity were observed. Pyrosequencing data were also largely consisting with the enrichment-NGS data.

Conclusions: Methylation based detection of rearrangement within the F8 gene is a promising rapid and accurate method to detect the two inversion hotspots as well as other rare rearrangements in the F8 gene. An extensive multi-center validation of the method is still pending.

PB 1982 | The Combined Use of Bypassing Agents with Antithrombin Reduction in Plasma of Hemophilia A and B Patients with Inhibitors

T. Livnat[1], A. Sehgal[2], K. Qian[2], H.V. Nguyen[2], B. Sorensen[3], G. Kenet[1]

[1]National Hemophilia Center, Sheba Medical Center, Tel Hashomer, Israel, [2]Alnylam Pharmaceuticals, Cambridge, United States, [3]Codiak BioSciences, Cambridge, United States

Background: An investigational RNAi therapeutic, fitusiran, targeting antithrombin (AT) to improve thrombin generation (TG) and promote hemostasis is in development in patients with hemophilia A (HA) and B (HB) with and without inhibitors. in vitro AT reduction has been shown to correct TG in plasma of patients with inhibitors.

Aims: As treatment with bypassing agents (BPA), rFVIIa and aPCC (FEIBA), is the standard therapy for patients with inhibitors, we aim to assess TG in plasma of patients with HA and HB with inhibitors in the presence of BPA and AT reduction.

Methods: Plasma samples from patients with severe HA and HB with high responding inhibitors were spiked with an anti-AT antibody to reduce AT levels by 80-90%. Plasma was spiked with rFVIIa (1.25 and 2. 5 µg/ml correlated to 45 and 90 µg/kg, respectively) or FEIBA (0.5 and 1U/ml correlated to 37.5 and 75 U/kg, respectively) either alone or in combination with AT reduction. TG was measured by calibrated automated TG assay using 1 pM tissue factor and 4 µM phospholipid.

Results: 11 plasma samples (8 HA; 3 HB) were investigated. Median baseline TG peak height was 16.1 nM (range 0.1-55.9) and 15.5 nM

(range 10.6-32.7) in plasma of patients with HA and HB, respectively, and 220.7 nM (range 136.4-326.6) in 24 healthy male volunteers. AT reduction improved TG peak in plasma of patients with HA and HB to 44.4 nM (range 9.7-83.5). Spiking of 90% AT-reduced plasma with 45 and 90 µg/kg rFVIIa induced an additive increase in TG peak to 76.6 nM (range 18.8-136.8) and 77.4 nM (range 25.0-161.5), respectively. Spiking of 90% AT-reduced plasmas with 37.5 and 75 u/kg FEIBA induced higher TG peak of 83.6 nM (20.7-151.4 nM) and 139.9 nM (range 40.4-228.8), respectively. No significant differences were observed between HA and HB patients.

Conclusions: Peak thrombin levels did not exceed the normal range in this study, suggesting that BPA may potentially be used safely in conjunction with AT reduction.

PB 1983 | Plasma Steady State PEG Concentrations Are Reached in Patients after Once Weekly Prophylactic Treatment with N9-GP

O. Sternebring[1], I. Bjoernsdottir[2], A.J. Benie[3], B.O. Petersen[3], M. Panduro[2], H. Jacobsen[4], J. Sims[5]

[1]Novo Nordisk A/S, Development PK/PD, Måløv, Denmark, [2]Novo Nordisk A/S, Development ADME, Måløv, Denmark, [3]Novo Nordisk A/S, Protein & Peptide Biophysics, Måløv, Denmark, [4]Novo Nordisk A/S, Non-Clinical Project Management, Måløv, Denmark, [5]Integrated Biologix GmbH, Basel, Switzerland

Background: PEG concentration was not initially measured during clinical development of N9-GP (40 kDa PEGylated rFIX). Data from a rat distribution study with N9-GP (tritium radiolabelled in PEG)[1] have shown that PEG is eliminated from plasma and tissues. Using pharmacokinetic modelling and allometric scaling human plasma and tissue concentrations were predicted to reach steady state within 1-2 years. Here new data on human plasma PEG concentrations from ten paediatric patients from the paradigm™ 5 trial are presented.

Aims: To measure PEG concentrations in human plasma after > 2.5 years of once weekly N9-GP prophylactic treatment and to compare these with the predicted steady state levels.

Methods: Nuclear Magnetic Resonance (^{1}H-NMR) was used for quantitative determination of PEG levels (conjugated and/or free) in plasma. Plasma samples from 4-10 patients per time-point collected after ~2.5, ~3.5, and ~4.5 years were analysed. The patients were on once weekly prophylaxis with 40 IU/kg N9-GP (~230 µg/kg PEG).

Results: Human steady state PEG concentrations ranged from 3.3 - 7.3 µg/mL after up to 4.5 years of once weekly prophylactic treatment with 40 IU/kg N9-GP. This was within the range of 2 - 8 µg/mL predicted from the single dose rat distribution study.

Conclusions: The measured clinical PEG plasma concentration confirmed that steady state was reached. The measured PEG concentrations were within the predicted range from the single dose rat distribution study. As plasma PEG concentrations could be predicted from the rat, this indicates that human tissue concentrations may also be predicted from the rat distribution data.

PB 1984 | Thrombin Generation Assay as Additional Tool in Diagnosis of Mild/Moderate Haemophilia A Patients with Discrepancies in FVIII Activity Assays

B. Baran[1], E. Stefanska-Windyga[2], A. Buczma[3], E. Odnoczko[1], J. Windyga[1]

[1]Institute of Hematology and Transfusion Medicine, Department of Hemostasis and Metabolic Disorders, Warsaw, Poland, [2]Institute of Haematology and Transfusion Medicine, Outpatient Clinic for Patients with Coagulation Diseases, Warsaw, Poland, [3]Institute of Hematology and Transfusion Medicine, Department of Disorders of Hemostasis and Internal Medicine, Warsaw, Poland

Background: Approximately 30% of mild/moderate hemophilia A (MHA) patients show discrepancies in factor VIII activity (FVIII:C) measured with one-stage clotting method (Os) *vs* chromogenic method (Chr). Current international guidelines do not recommend one specific type of assay to be used in the diagnosis of MHA.

Aims: To investigate whether thrombin generation assay (TGA) can provide additional information on the hemostatic potential of MHA patients.

Methods: The study group comprised 51 patients (aged 18-79; median 37) from 48 families with confirmed MHA and 21 healthy male controls (aged 21-63; median 35). FVIII:C-Os, FVIII:C-Chr and TGA were performed in all study subjects (MHA patients and controls). Assay discrepancy was defined as ratio of FVIII:C Os/Chr ≥2 or ≤0.5.

Results: Mean value of TGA peak thrombin (TGA-pt) was significantly lower in MHA patients than in healthy controls (43.06±14.79 *vs* 92.20±11.74, respectively). Discrepant FVIII:C results were reported for 25 (49%) patients. In 14/ 25 discrepant patients (54%) haemophilia severity (mild *vs* moderate) differed depending on the assay used. The mean value of TGA-pt (30.65±8.19; median 27.70) for those 14 patients was lower than in the whole MHA group (43.06±14.79; median 43.30).

Conclusions: The study shows a correlation between TGA-pt and factor VIII activity. Measurement with FVIII:C-Os or FVIII:C-Chr assay as well as TGA-pt allows to differentiate between mild hemophilia A patients and healthy individuals. TGA seems to be a useful laboratory tool in MHA diagnosis. Peak thrombin is a particularly useful parameter for confirmation or exclusion of mild hemophilia A, especially if FVIII:C oscillates around 50 IU/dl.

PB 1985 | Burden of Comorbidities in Persons Living with Haemophilia: Insight from the PROBE Phase 2b Study Database

M. Skinner[1], C. Chai-Adisaksopha[2], R. Curtis[3], N. Frick[4], M. Nichol[5], D. Noone[6], B. O'Mahony[6,7], D. Page[8], J. Stonebraker[9], A. Iorio[10]

[1]Institute for Policy Advancement Ltd., Washington, United States, [2]McMaster University, Department of Medicine, Hamilton, Canada, [3]Factor VIII Computing, Berkeley, United States, [4]National Hemophilia Foundation, National Hemophiia Foundation, United States, [5]University of Southern California, School of Policy and Planning Development,, Los Angeles, United States, [6]Irish Hemophilia Society, Dublin, Ireland, [7]Trinity College Dublin, Dublin, Ireland, [8]Canadian Hemophilia Society, Montreal, Canada, [9]North Carolina State University, Poole College of Management, Raleigh, United States, [10]McMaster University, Department of Clinical Epidemiology and Biostatistics, Hamilton, Canada

Background: Optimal care for haemophilia requires an integrated care approach (Pai, Haemophilia, 2016;22:6-16). Generating evidence on the burden of the comorbidities affecting persons living with haemophilia (PWH) will inform modulating the composition of the care team. To this scope we have analysed relevant data collected during the country-level test-retest reliability study of the PROBE questionnaire.
Aims: Investigate the burden of comorbid diseases in PWH as compared to controls.
Methods: PROBE is a 29 items questionnaire investigating patient reported outcome in haemophilia. Face and content validity and test-retest reliability has been previously assessed (Chai-Adisaksopha, HQLO, submitted), and the phase 2b study design and objectives described elsewhere (NCT02439710). With version 2 of the questionnaire we have introduced a standardized list to collect presence or absence of Hepatitis B, Hepatitis C, Stroke, High BP, Angina, Heart Attack, Heart Failure, Asthma, Liver Cancer, Other Cancers, Diabetes, Seizure, Arthritis, Gingivitis, HIV AIDS, Other Disease. Prevalence of each category in survey respondents with and without haemophilia, for severe HA, and for PWH with inhibitors was calculated; ORs were calculated stratifying by age.
Results: We collected 654 surveys in 6 countries. 392 were HA (61.2% severe), 69 HB (59.4% severe). The median age was 33 (IQR 24-56.5) for PWH and 34 (IQR 34-52) for controls. Statistics for the 4 more frequent comorbidities are reported in Table 1 and 2.
Conclusions: Compared to controls (individuals with no bleeding disorder), there is an increased prevalence of arthritis, gingivitis, hypertension and hepatitis C in PWH. Higher gingivitis rates highlight the importance of allied health professionals to supplement the core care team within haemophilia treatment centers. Analysis of PROBE data will allow an assessment of the association of oral health issues with other metrics e.g., upper extremity (elbow) joint heath. This is the first PROBE report of PWH with inhibitors.

PB 1986 | Cost-Effective Algorithm for Molecular Diagnosis of Families with Severe Haemophilia A in Argentina

V.D. Marchione[1], M.M. Abelleyro[1], L. Primiani[2], C.P. Radic[1], D. Neme[2], M. de Tezanos Pinto[2,3], C.D. De Brasi[1,3], L.C. Rossetti[1]

[1]Instituto de Medicina Experimental (IMEX), CONICET-Academia Nacional de Medicina (ANM), Ciudad Autonoma De Buenos Aires (CABA), Argentina, [2]Fundación de la Hemofilia Alfredo Pavlovsky, Ciudad Autónoma de Buenos Aires, Argentina, [3]Instituto de Investigaciones Hematológicas Mariano R. Castex (IIHEMA), ANM., Ciudad Autónoma de Buenos Aires, Argentina

Background: Haemophilia A (HA), the commonest X-linked coagulopathy, is caused by defects in the factor VIII gene (*F8*). Due to *F8* size and complexity and mutational heterogeneity, gene testing in HA still represents a technical challenge. A half of severe HA (sHA) is caused by recurrent inversions disrupting *F8* at IVS22 (Inv22) and IVS1 (Inv1). The rest of sHAs are mostly caused by family-specific large or small del/ins and point mutations.
Aims: Present a cost-effective gene testing algorithm for families with sHA suitable for developing countries.
Methods: Leukocyte-extracted genomic DNA from patients are subjected to sequential *F8* genotyping protocols (Fig 1): Inv22/Inv1

TABLE 1 Burden of comorbidities in haemophilia (Arthritis and Gingivitis)

Comorbidity		Non haemophilia	All haemophilia	All haemophilia A	Severe haemophilia A	Haemophilia A with inhibitors
Arthritis	Prevalence (n/N)	21/157	125/365	109/309	86/224	3/14
	OR (Versus non-hemophilia)	Reference	5.41	6.40	6.81	3.72
	95% CI	--	3.11-9.40	3.57-11.47	3.72-12.46	0.83-16.66
Gingivitis	Prevalence (n/N)	16/161	111/382	92/326	65/236	9/16
	OR (Versus non-hemophilia)	Reference	3.85	3.82	3.38	10.59
	95% CI	--	2.16-6.87	2.10-6.95	1.83-6.28	3.18-35.21

TABLE 2 Burden of comorbidities in haemophilia (Hypertension & Hepatitis C)

Comorbidity		Non haemophilia	All haemophilia	All haemophilia A	Severe haemophilia A	Haemophilia A with inhibitors
Hypertension	Prevalence (n/N)	21/160	87/375	70/319	58/227	1/15
	OR (Versus non-hemophilia)	Reference	3.55	3.69	3.75	0.66
	95% CI	--	2.01-6.28	2.03-6.71	2.04-6.87	0.08-5.58
Hepatitis C	Prevalence (n/N)	0	98/378	79/322	64/231	3/15
	OR (Versus non-hemophilia)	Reference	54.25	50.97	59.40	38.75
	95% CI	--	7.49-392.80	6.94-365.91	8.14-433.37	3.74-401.52

diagnosis by inverse shifting PCR, ver.2016; PCR amplification targeting all relevant *F8* sequences in 38 products to detect large deletions in inversion negative cases (designing specific gap-PCR or qPCR approaches for carrier diagnosis); and conformation sensitive gel electrophoresis (CSGE) screening for small mutations on the *F8* amplimers in multiplex and characterisation of the anomalous CSGE product by Sanger sequencing. Genotype/Phenotype assignment of the observed variant is achieved by applying internationally accepted criteria.

Results: We characterised the causative mutation in 325 families with sHA, whereas 13 families remain uncharacterised (3.8%). We found 153 cases with the Inv22 (47.1%) (82% Inv22 type 1 and 18%, type 2), 4 Inv1 (1.2%), 18 large deletions (5.5%), 58 small ins/del (17.8%), 48 missense (14.8%), 32 nonsense (9.8%), and 12 splicing defects (3.7%).

Conclusions: The presented algorithm allowed characterisation of the sHA causative mutation in 96.2% of families in a relatively rapid and cost-effective way. The remnant 4% may be due to the intrinsic limitation of the CSGE screening (≈95%), the theoretical extent of the *F8* PCR amplification scheme to detect deep intronic splicing defects and other rare mutations, and the failure of gene dosage analyses to detect duplications.

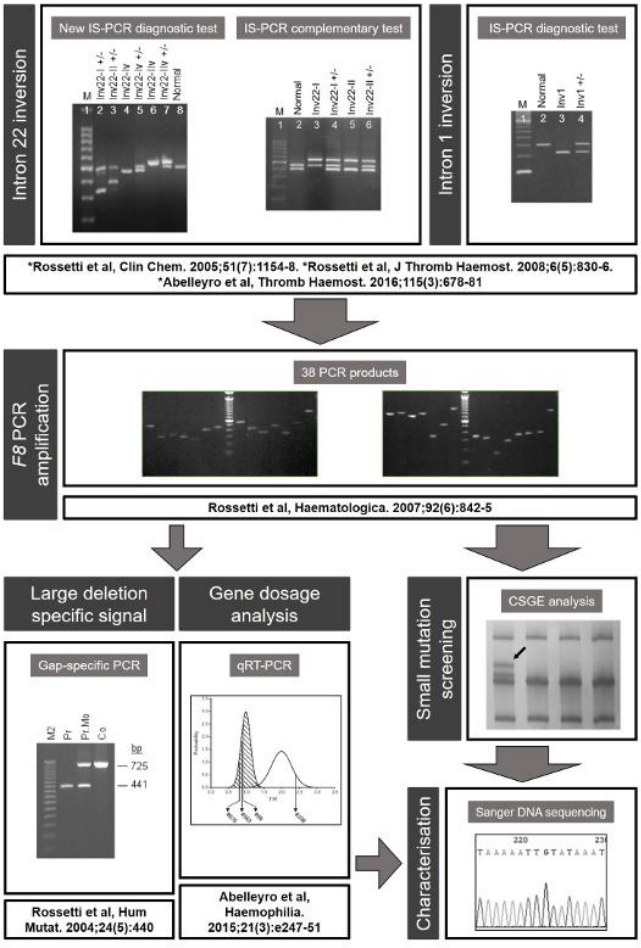

FIGURE 1 Laboratory algorithm for mutational analysis in F8

PB 1987 | Tissue Factor and Phospholipid-activated Thrombin Generation Assays for Detection of Factor VIIa Activity, Dose and Duration of Effect in Mice

S.S. Surov[1], A.R. Rezaie[2], M.V. Ovanesov[1]

[1]*U.S. Food and Drug Administration, Center for Biologics Evaluation and Research, Silver Spring, United States,* [2]*St Louis University School of Medicine, Saint Louis, United States*

Background: Recombinant factor VIIa (rFVIIa) is used for treatment of hemophilia patients with inhibitors. Frequent infusions and high doses are often needed to achieve and sustain hemostasis in patients. Traditional laboratory assays have not been useful in guiding FVIIa therapy but the thrombin generation test (TGT) was proposed for this purpose.

Aims: We used mice to study the relationship between plasma levels of FVIIa activity and its pharmacodynamics as measured by the phospholipids (PL)- and tissue factor (TF)-activated TGT assays *ex vivo*.

Methods: Blood was collected from normal CD1 mice 5 minutes after treatment with 0.125 to 5 mg/kg (a dose escalation study) or 5 min, 30 min, 1 hr, 2 hr, 4 hr, 8 hr, 16 hr and 24 hr after administration of 2.5 mg/kg of FVIIa (a pharmacokinetics [PK] study). FVIIa activity was measured by two commercially available assays, a soluble TF (sTF)-based clotting StaClot (Stago) and an ELISA-based chromogenic assay (AssayPro). TGT was studied using four activation conditions: PL, PL and sTF, and human full length TF (FLTF) with and without PL.

Results: FVIIa activity correlated well with the PL-, PL/FLTF- and PL/sTF-TGT assays (Pearson's r>0.79) and poorly with the FLTF- TGT (r =0.32). The PL/sTF-TGT showed superior sensitivity to FVIIa activity in plasma (~ 1 nM FVIIa), FVIIa dose (0.125 mg/kg), and duration of FVIIa effect (8 hr). The PL- and PL/FLTF-TGT were sensitive to medium doses (1 mg/kg) and effect duration (4 hr). The FLTF-TGT showed poor sensitivity to FVIIa activity (100 nM), dose (1 mg/kg) and effect duration (2 hr).

Conclusions: PL but not FLTF are required for detection of TGT responses to FVIIa in mice. Because sTF reagent dramatically improves TGT assay's sensitivity to FVIIa, an sTF variant of TGT may be more suitable for the optimization of FVIIa dose and dosing intervals.

PB 1988 | Assessment of *F9* Mutation Associated with Inhibitor Development in Japanese Hemophilia B Patients

H. Sakane[1], S. Tamura[1], E. Hashimoto[1], A. Fujioka[1], A. Makiyama[1], N. Kawamura[1], S. Suzuki[1], Y. Takagi[1,2], T. Kanematsu[3], M. Kishimoto[3], M. Ogawa[4], N. Suzuki[3], T. Matsushita[3], H. Yada[5], M. Shima[5], T. Kojima[1], Japan Hemophilia Inhibitor Study

[1]*Nagoya University Graduate School of Medicine, Pathophysiological Laboratory Science, Nagoya, Japan,* [2]*Research Fellow of Japan Society for the Promotion of Science, Tokyo, Japan,* [3]*Nagoya University Hospital, Department of Transfusion Medicine, Nagoya, Japan,* [4]*Nagoya University Graduate School of Medicine, Department of Hematology and Oncology, Nagoya, Japan,* [5]*Nara Medical University Hospital, Department of Pediatrics, Nara, Japan*

Background: Hemophilia B (HB) is an X chromosome-linked hereditary bleeding disorder, which shows a quantitative or qualitative reduction of coagulation factor IX (FIX) due to genetic abnormality of FIX gene (*F9*). In case of HB, FIX replacement therapy is exclusive way to treat hemophiliacs. However, inhibitors against FIX replacement agents can neutralize the therapeutic effect, which is a serious problem in the treatment of HB.

Aims: Japan Hemophilia Inhibitor Study (J-HIS) has launched to investigate the inhibitor developing risk factor in HB. Here, we present a relationship between inhibitor development and *F9* genetic mutation in Japanese HB patients.

Methods: Genomic DNA was extracted from leukocytes peripheral blood. Mutation analysis was performed by direct DNA sequencing using *F9*-specific PCR primer sets. In cases of *F9* large deletions, we identified their breakpoints. The study was approved by the institutional committees for research ethics.

Results: Forty five HB patients including 10 inhibitor positive cases were registered in the J-HIS. We detected causative genetic defects in all HB cases tested, including 37 point mutations (20 missense,
7 nonsense, 8 splice-junction and 2 promoter region mutations) and 8 other genetic abnormalities
(2 insertions, 2 small deletions and 4 gross deletions). All patients carrying inhibitor were severe HB, in which detected *F9* mutations were 5 nonsense mutations, 4 deletions and 1 insertion, leading to frameshift or immature translation.

Conclusions: *F9* mutations of inhibitor positive cases in the J-HIS registered HB patients were all null mutations. This was consistent with the previous report that a severe phenotype of FIX deficiency was the most important factor to expect inhibitor developments. On the other hand, a few *F9* missense mutations have also been found to be responsible for the development of inhibitor. In order to strictly assess the risk factors for developing inhibitor against FIX among Japanese HB patients, further examination is necessary.

PB 1989 | Homogenous Reactivity of Recombinant FVIII against Inhibitors in the Presence of VWF Regardless Origin of Cell Line or Sequence Integrity

M.I. Bravo, A.M. Ortiz, M. Costa, S. Grancha, J.I. Jorquera

Grifols, Bioscience Industrial Group, Research and Development, Barcelona, Spain

Background: In the circulation, FVIII is included in a complex (FVIII/VWF), composed 98% in mass by VWF. In contrast to plasma-derived FVIII antihemophilic products with physiologically-bound VWF (pdFVIII/VWF), purified FVIII products are obtained from plasma (pdFVIII) or are prepared by recombinant DNA technology (rFVIII) using transfected cells from animal or human origin. It is known that VWF from the patient binds to infused VWF-lacking purified FVIII, although it is currently under debate if this bond is comparable to the way FVIII is protected in the natural FVIII/VWF complex.

Aims: To determine reactivity to inhibitors in samples of different commercially available brands of FVIII concentrates, previously allowed to bind VWF.

Methods: Commercial FVIII products, grouped according to VWF content and FVIII origin, were assessed: A to D: pdFVIII/VWF with VWF≥1 (normal plasma: VWF=1); E to G: purified FVIII with VWF=0–0.5 (pdFVIII); H to J: rFVIII produced in Chinese hamster ovary cells; K: rFVIII produced in human embryonic kidney 293F cells. pdVWF and FVIII (2 IU/mL each) were incubated (2 h, 37°C) and then serial dilutions of inhibitor IgG (commercial pool) were added in equal volume. Residual FVIII:C was determined using a chromogenic assay. The inhibitor titer (BU/mL) was determined, tested for FVIII group homogeneity and analyzed by ANOVA.

Results: Titers against products A-D (pdFVIII/VWF) were homogeneous and ranged from 9.1±1.0 BU/mL to 12.3±2.0 BU/mL, comparable to 12.0±0.06 BU/mL of normal plasma (product:plasma ratio: 0.8–1.0). Conversely, titers and product:plasma ratio observed in products E-K containing no or little VWF were significantly above the values of normal plasma (Table 1).

TABLE 1 Ratio product/plasma and inhibitor titer in concentrates of isolated FVIII after incubation with VWF

Purified FVIII origin	Product	BU/mL (range)	Ratio product/plasma(range)	P value vs plasma
Plasmatic	E, F, G	15.2±1.6 to 25.2±3.9	1.3 to 2.1	<0.05 to <0.0001
Recombinant - Animal cells	H, I, J	15.8±2.2 to 21.9±3.9	1.3 to 1.8	<0.01 to <0.0001
Recombinant - Human cells	K	21.2±1.4	1.8	<0.0001

Conclusions: Therapeutic products containing the natural FVIII/VWF complex showed lower reactivity to inhibitors than products of isolated FVIII incubated with isolated VWF, regardless the origin of FVIII: plasmatic or recombinant obtained from cells of animal or human origin.

PB 1990 | Validation of the Factor IX One-stage aPTT Clot Assay Calibrated with Pooled Normal Plasma for the Measurement of N9-GP in Patient Plasma

S. Tiefenbacher[1], M. Robinson[1], M. Høgh Sørensen[2], M. Ezban[2]

[1]*Laboratory Corporation of America, Colorado Coagulation, Englewood, United States,* [2]*Novo Nordisk A/S, Bagsværd, Denmark*

Background: Nonacog beta pegol (N9-GP) is a 40-kDa, glycoPEGylated, recombinant, human coagulation factor IX (FIX) currently in clinical development.

Aims: To validate the FIX one-stage clot assay using HemosIL® SynthAFax activated partial thromboplastin time (aPTT) reagent on a Siemens BCS®XP analyzer for the quantitative measurement of FIX activity in patient plasma containing N9-GP using a pooled normal plasma calibrator.

Methods: The FIX one-stage clot assay was calibrated using pooled normal plasma [CRYOcheck™ Normal Reference Plasma (Precision BioLogic Inc.)] or N9-GP. High (0.1-1.5 IU/mL) and low (0.005-0.1 IU/mL) calibration curves were generated for each assay system. HEPES buffer containing 1% BSA, used as sample diluent on the N9-GP high calibration curve, was replaced with immuno-depleted FIX-deficient plasma to improve accuracy for N9-GP when using pooled normal plasma calibration. Results obtained for 100 N9-GP-treated patient samples when tested in the two assay systems (i.e., N9-GP and pooled normal plasma calibration) were compared.

Results: Acceptable accuracy, precision and linearity were demonstrated for N9-GP, across a quantitation range of 0.010-2.800 IU/mL, when using normal pooled plasma calibration. No significant difference in reported FIX activity was observed when using pooled normal plasma compared to product-specific N9-GP calibration.

Conclusions: The FIX one-stage clot assay with the SynthAFax aPTT reagent can be used for the quantitative measurement of FIX activity in N9-GP-containing patient plasma when calibrated with normal pooled plasma or N9-GP.

PB 1991 | Haemophilia A and B in Costa Rica - An Update of the National Register

L. Salazar-Sanchez[1], A. Pavlova[2], B. Hernandez-Salazar[1], J. Oldenburg[2], P. Chaverri-Saenz[3], M. Sandoval-Leal[3], G. Jimenez-Cruz[3]

[1]University of Costa Rica, Medicine School, San Jose, Costa Rica, [2]University Bonn, Institut of Experimental Hematology Transfusion Medicine, Bonn, Germany, [3]Hospital Mexico CCSS, Hematology Department, San Jose, Costa Rica

Background: Data of national register for haemophilia A(HA) and B(HB) patients in Costa Rica (CR), is of great importance for helping in planning the necessary amounts of treatment concentrates and improvement of treatment protocols and quality of patients' life.

Aims: Here we aim to present an update of epidemiological, genetic and clinical data for HA and HB patients in CR based on our national register.

Methods: The data were collected in 5 years period and recorded in a National register. The register included results for severity of the disease, type of mutation, inhibitor status and carrier status of females.

Results: 208 patients with HA and HB in CR are enrolled in the register. 178 are with HA and 30 with HB. From all HA patients 135 have the severe form, 18 moderate and 25 mild. The number of HA with mild form are underestimated most likely due to the rare bleedings of these patients and insufficient diagnosis. Genetic analyses were performed on 45 severe HA patients. 21(47%) patients were diagnosed with intron 22 inversion, 2 (4%) with missense, 7(15%) with nonsense, 7 (15%) with small del/ins and 7 (15%) with splice-site and 1 (1%) large deletion. The family genetic analyses reveal 37 carriers of HA. Most mutations in HB patients were missense. Only in 1 patient, a large deletion was identified. In 20 patients (44%), all with null-mutations, inhibitors were detected. Most patients are treated on demand, but in the last 2 years, the number of patients on prophylaxes slowly increased.

Conclusions: The mutation profile of HA and HB patients in CR do not differ from the general mutation profile for the disease. The correct diagnostic of carrier status of the females in hemophilia families is of extreme importance for our country, having in mind that some of the patients live in remoted regions of the country with a diminished access to medical care.

PB 1992 | Understanding Hemophilia A and B Factor Replacement Administration Patterns: A Feasibility Study

P. Fogarty[1], D. Spurden[2], J. Alvir[3], B. Tortella[1], M. McDonald[3], A. Chhabra[1], M. Cicchetti[4], L. Lee[5], A. Berk[5], S. Huang[5], A. Plail[6]

[1]Pfizer Inc., Collegeville, United States, [2]Pfizer Limited, Tadworth, United Kingdom, [3]Pfizer Inc., New York, United States, [4]Execupharm Inc., Collegeville, United States, [5]Kantar Health LLC., New York, United States, [6]Pfizer Inc., La Jolla, United States

Background: For both Hemophilia A and Hemophilia B, extended half-life factor replacement therapies (EHLs) require less frequent dosing; however, little is known of real-world administration patterns and cost for EHLs as compared with standard half-life therapies (SHLs). Large US commercial claims databases contain robust longitudinal transaction data, but sparse patient-level clinical data elements. Medical records contain the detailed clinical data, but lack complete medical resource use data and costs over time. Meanwhile, patients are the principal source of information regarding their behaviour, perception of outcomes, motivations and preferences to act, though this may be limited by recall.

Aims: To conduct a feasibility assessment to determine if a dataset of sufficient size and breadth could be constructed to compare the real-world administration patterns and resource utilization of SHLs vs EHLs for hemophilia by combining data from economic claims, medical charts and patient interviews.

Methods: After Central IRB approval, both physicians and patients/caregivers consented to participate in qualitative interviews to assess data availability. Physicians reviewed select patient charts for completeness. Patients were interviewed to review their inputs.

Results: A total of 23 patient/caregiver (15 Hemophilia A and 8 Hemophilia B) and 6 physician interviews were completed. 9 patients (40%) were able to obtain 12 months of claims details; all included pharmacy costs for factor replacement but some lacked specificity on diagnosis, or procedure codes for medical resources. All patients could complete the patient questionnaires. Physicians were able to locate and provide the relevant retrospective patient medical chart data.

Conclusions: This study demonstrates the feasibility of constructing a merged dataset of sufficient size for a robust analysis, which includes information from three distinct sources.

PB 1993 | Prevalence and Possible Risk Factors of Hyperhomocysteinemia in Patients with Severe Hemophilia from North-Western Russia

S. Kapustin, V. Soldatenkov, V. Kargin, V. Shmeleva, L. Aleksanyan, V. Burakov, O. Smirnova, A. Titov, L. Papayan

Russian Research Institute of Haematology and Transfusiology, Saint Petersburg, Russian Federation

Background: Severe hemophilia (SH) is often complicated by joint(s) destruction caused by chronic arthropathy due to recurrent hemorrhagic events and activation of such biological mechanisms as oxidative stress and inflammation. The frequency of increased homocysteine (HCy) plasma level, or hyperhomocysteinemia (HHCy), in patients with SH from North-Western Russia (NWR), it's possible reasons and role in development of arthropathy are not well known.

Aims: To assess the prevalence of HHCy and its possible risk factors in patients with SH from NWR.

Methods: We studied 22 men with severe hemophilia A or B (19 and 3 patients, respectively). Osteoarthritis of large joint(s) was detected in each patient, with the rate of recurrent hemorrhagic events in joint(s) from 6 to 13 per year. Standard ELISA assays to measure HCy plasma level and IgG to hepatitis C virus (HCV) were used. Polymorphism C677T in the methylenetetrahydrofolate reductase gene (MTHFR) was studied by PCR and subsequent restriction analysis. Fisher's exact test was used to assess statistical differences between the groups by calculating odds ratios (OR) with their 95% confidence intervals (CI) and p-value.

Results: Hyperhomocysteinemia (HCy level >13.4 µmol/l) was observed in 8 (36.4%) patients. This rate was more than 4-fold increased when compared to frequency of HHCy (8.8%) in healthy persons from NWR (OR=5.9, 95% CI: 2.2-15.5, p=0.0009). Seropositivity for HCV was detected in 75.0% hemophiliacs with HHCy compared to 57.1% in patients with normal HCy level (OR=2.3, 95% CI: 0.3-15.3, p=0.65). MTHFR 677T allele was present in genotype of 6 (75.0%) patients with HHCy and in 42.9% of other patients (OR=4.0, 95% CI: 0.6-27.3, p=0.2).

Conclusions: We have found high frequency of HHCy in patients with SH. Both genetic (MTHFR polymorphism) and acquired (HCV infection) factors could participate in development of HHCy in this group. Further studies are needed to confirm our data and identify the role of HHCy in development of arthropathy in SH patients.

PB 1994 | A Thrombomodulin Gene Variant Leading to Hyperthrombomodulinaemia and an Inherited Bleeding Disorder

R.C. Tait[1], K. Downes[2], N.J. Mutch[3], E. Leishman[1], A.-L. Latif[1], S.V.V. Deevi[2], C.S. Whyte[3], K. Megy[2], K. Gomez[4], C. Bagot[1], N.I.H.R. Bio Resource[5]

[1]Royal Infirmary, Haematology, Glasgow, United Kingdom, [2]University of Cambridge and NHS Blood and Transplant, Haematology, Cambridge, United Kingdom, [3]University of Aberdeen, Medical Sciences and Nutrition, Institute of Medical Sciences, Aberdeen, United Kingdom, [4]Royal Free London NHS Foundation Trust, The Katharine Dormandy Haemophilia Centre and Thrombosis Unit, London, United Kingdom, [5]Cambridge Biomedical Campus, Cambridge, United Kingdom

Background: Thrombomodulin (TM), expressed on endothelial cells interacts with thrombin driving activation of protein C and thrombin activatable fibrinolysis inhibitor (TAFI). TM variants are associated with thrombophilia, however familial cases with an autosomal dominant bleeding disorder due to a premature stop codon in *THBD* (p.Cys537stop) have been described.

Aims: We investigate a family with a novel *THBD* variant (*THBD: c.1487delC*, p.Pro496Argfs*10) identified in 6 family members with a bleeding phenotype.

Methods: The index case was originally diagnosed with an ‚unspecified bleeding disorder' and abnormal prothrombin consumption index - the molecular aetiology clarified by targeted high throughput sequencing (HTS) with the ThromboGenomics panel v2.8. Plasma TM levels were determined by ELISA and thrombin potential by calibrated automated thrombography. Lysis rates of plasma clots by tissue plasminogen activator were determined by turbidity assays and Hemacore ± carboxypeptidase inhibitor (CPI).

Results: Affected adults have a mild bleeding phenotype (ISTH BAT Scores 4-9) - traumatic haematomas, dental extraction and post-partum bleeds. Coagulation factors and platelet function were normal. Plasma TM levels were grossly elevated (median 556 ng/ml, range 364-698 ng/ml; normal 2.9-7.6 ng/ml) suggesting excess shedding of cellular TM leading to hyperthrombomodulinaemia. Endogenous thrombin potential was marginally reduced. Lysis of plasma clots was delayed compared to control plasma but was dramatically enhanced by inclusion of CPI, indicating that the change in lysis could be attributed to increased TAFIa.

Conclusions: This family represents only the second *THBD* variant to cause a modest bleeding phenotype which likely reflects a partial balancing of reduced thrombin procoagulant activity and increased protein C activation by the attenuated fibrinolytic activity. This finding underscores the utility of targeted HTS in diagnosis of bleeding disorders, permitting family screening and preemptive management strategies.

PB 1995 | Importance of the ADP-dependent Amplification Pathway in Platelet Activation is Influenced by CalDAG-GEFI Expression Level

G. Florence[1], M. Poggi[1], A. Henneuse[1], D. Ghalloussi[1,2], R. Piatt[2], J.-C. Gris[3], S. Claeyssens[4], P.E. Morange[1], P. Nurden[5], A.T. Nurden[5], W. Bergmeier[2], M.-C. Alessi[6], M. Canault[1]

[1]Aix-Marseille Université, Inserm, Inra, NORT, Faculté de Médecine Timone, Marseille, France, [2]University of North Carolina-Chapel Hill, Department of Biochemistry and Biophysics, Chapel Hill, United States, [3]Laboratoire d'Hematologie, Groupe Hospitalo-Universitaire Caremeau, Nîmes, France, [4]CRTH Hôpital Purpan, Toulouse, France, [5]LIRYC, Plateforme Technologique et d'Innovation Biomédicale, Hôpital Xavier Arnozan, Pessac, France, [6]Aix-Marseille Université, Inserm, Inra, NORT, CRPP, Faculté de Médecine Timone, Marseille, France

Background: Homozygous *RASGRP2* variants are associated with severe bleedings. We recently reported two new pedigrees with mutations in *RASGRP2* (p.N67Lfs*24 and p.E260*/C296R) resulting in the complete loss of the encoded protein, CalDAG-GEFI.

Aims: Characterize the platelet function defects in patients carrying homozygous and heterozygous *RASGRP2* variants.

Methods: Flow cytometry, platelet aggregation, adhesion under static and flow conditions and spreading; Rap1 GTPase activation assay: mice with variable CalDAG-GEFI expression.

Results: The mutations blunt CalDAG-GEFI protein expression in transfected GripTite™ 293 MSR cells and patient platelets. Activation of Rap1 and $\alpha_{IIb}\beta_3$ integrin was markedly impaired in patient platelets stimulated with low and intermediate doses of ADP and TRAP-6. In homozygous carriers, maximal aggregation in response to ADP is markedly reduced and slower aggregation velocities are observed upon stimulation with any doses of agonists. Platelets from heterozygous patients or mice expressing low levels of CalDAG-GEFI also showed reduced aggregation to low doses agonists, especially when activated in the presence of a P2Y12 inhibitor. Interestingly, platelets from homozygous and heterozygous patients were unable to form lamellipodia and spread upon stimulation with high dose TRAP-6, while the aggregation response was normal under these conditions.

Conclusions: Partial CalDAG-GEFI deficiency impacts both platelet aggregation and spreading. Our results indicate that the importance of the ADP-dependent amplification pathway is related to CalDAG-GEFI protein expression level.

PB 1996 | Association of Homozygous PAI-1 Deficiency with Cardiac Fibrosis in Humans

S. Gupta[1], S. Khan[2], S. Shah[2], M. Heiman[1], E. Klaychko[2], A.S. Baldridge[2], P. Flevaris[2], D. Lee[2], J. Carr[2], B. Benefield[2], L. Nelson[2], A. Shapiro[1], D. Vaughan[2]

[1]*Indiana Hemophilia & Thombosis Center, Indianapolis, United States,*
[2]*Northwestern University, Chicago, United States*

Background: Complete PAI-1 deficiency is a very rare autosomal recessive bleeding disorder. We have followed for 24 years a family in the old order Amish community with a rare loss-of-function mutation in SERPINE1 encoding PAI-1. Apart from hemostatic changes, murine models of PAI-1 deficiency develop age-dependent cardiac fibrosis.

Aims: To evaluate the cardiovascular status of homozygous PAI-1 deficient patients.

Methods: Study participants included 9 homozygous, 3 heterozygotes and 6 unaffected individuals who underwent cardiac magnetic resonance imaging (MRI). A 32-year-old male with complete PAI-1 deficiency also underwent transthoracic echocardiogram (TEE) at baseline and at follow up.

Results: Six of the 9 homozygotes had cardiac fibrosis ranging from 1-19% (Table[SG1] 1) in contrast to none of the controls or heterozygotes. Only one homozygote (32 year male followed since 12 years of age) had a low ejection fraction (EF). The patient has a moderate bleeding phenotype with trauma-related hematomas, testicular hematoma post hernia repair and post-injury hemarthroses, treated intermittently with oral antifibrinolytics. TEE revealed moderate left ventricular enlargement with global hypokinesis, EF 35%; cardiac MRI revealed significant cardiac fibrosis (19%) in several areas (Figure[SG2] 1). The patient was started on medical therapy-beta- blocker, ACE inhibitor; latter was discontinued after 5 months by patient. Repeat TEE 1 year post-diagnosis revealed stable EF (35%).

TABLE 1 Age, sex and degree of cardiac fibrosis in 9 homozygous PAI-1 deficient patients

Age in yrs at present	Age at diagnosis	Sex	Cardiac fibrosis %
15	2 months	male	13
20	5 months	male	8
22	2 years	female	8
24	10 years	female	1
25	4 years	female	0
31	10 years	female	0
32	12 years	male	19

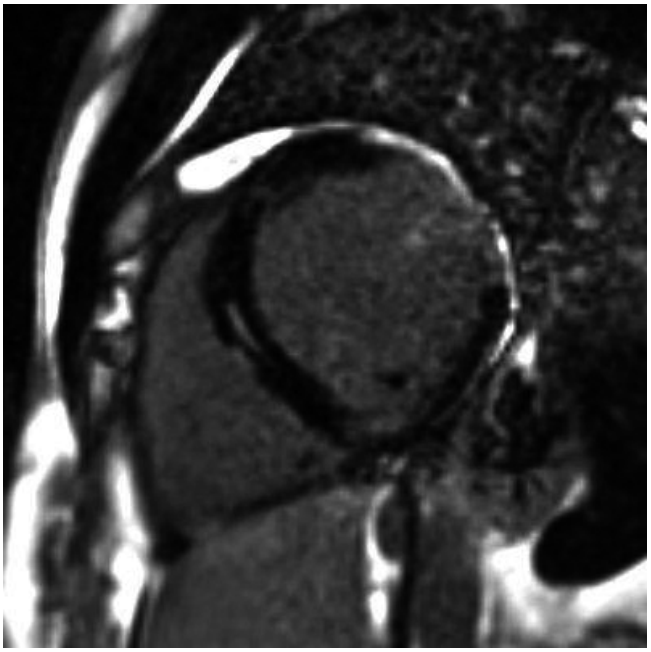

FIGURE 1 Cardiac fibrosis in a homozygous PAI-1 deficient male

Conclusions: Complete PAI-1 deficiency is associated with cardiac fibrosis in humans. We describe a case of fibrotic dilated cardiomyopathy in a patient with complete PAI-1 deficiency, evidence of cardiac abnormalities in the remaining 5 patients evaluated, emphasizing the need for diligent cardiac evaluation in this rare bleeding disorder.

PB 1997 | Molecular, Diagnostic and Clinical Features of 216 Patients from 46 Unrelated Families with FXI Deficiency Caused by Different Recurrent and Sporadic Mutations. Data from A 60000 Inhabitants Spanish Town

M.E. de la Morena-Barrio[1,2], J. Esteban[3], S. Salloum-Asfar[1], J. Padilla[1], A. Miñano[1], I. Campillo[1], J.M. Soria[4], F. Vidal[5,6], J. Corral[1,2], V. Vicente[1,2]

[1]Servicio de Hematología y Oncología Médica, Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, Murcia, Spain, [2]CIBERER, Madrid, Spain, [3]Servicio de Hematología, Hospital Virgen del Castillo de Yecla, Yecla, Spain, [4]Unitat de Genòmica de MalaltiesComplexes, IIB-Sant Pau, Barcelona, Spain, [5]Coagulopaties Congènites, Banc de Sang i Teixits, Barcelona, Spain, [6]Unitat de Diagnòstic i Teràpia Molecular, Valld'Hebron Institut de Recerca, Universitat Autònoma de Barcelona (VHIR-UAB), Barcelona, Spain

Background: FXI is a key procoagulant protease whose deficiency, rare in Caucasians, has minor relevance in bleeding but protects against thrombosis according to animal models.

Aims: To characterize molecular and clinically the cases with FXI deficiency identified in a 60000 inhabitant Spanish town.

Methods: During 20 years, 32,4764 aPTTs from 51,366 patients were analyzed. 1,700 samples with prolonged aPTT (>1.3) were identified. Anticoagulated patients, with a not confirmed prolonged aPTT or with lupus anticoagulant were ruled out. Levels of coagulation factors were quantified by coagulometric assays.

Genetic analysis of *F11* (whole gene sequencing, MLPA and genotyping), biochemical and functional characterization of plasma FXI were performed in 311 members of 46 families and in 150 healthy subjects from the same town.

Results: We identified 46 unrelated cases with FXI deficiency carrying 4 recurrent mutations: p.Cys56Arg, which was present in 2% of the general population, p.Cys416Tyr, c.1693G>A, and p.Pro538Leu. 8 additional mutations (3 new and the first world-wide duplication causing FXI deficiency, Fig1) were also found.

Family studies revealed a total of 216 subjects with FXI deficiency.

aPTT was not prolonged in 31.5% of cases with FXI deficiency.

Bleeding was rare and mild. Interestingly, 9 patients were correctly anticoagulated with acenoucoumarol during 382 months, reporting no bleeding events.

Moreover, 6 cases developed acute myocardial infarction and 8 ischemic cerebrovascular events. Only 2 patients, both with local risk factors, developed venous thrombosis, even though 19 patients also carried prothrombotic SNPs, FV Leiden or prothrombin G20210A.

Conclusions: Our study supports that FXI deficiency, caused by recurrent or odd mutations, (i) might be underestimated in Caucasians; (ii) could protect against venous thrombosis, even if FXI deficiency is moderate; and (iii) causes minor risk of bleeding, also in patients under anticoagulant therapy.

PB 1998 | The International Society on Thrombosis and Haemostasis - Bleeding Assessment Tool (ISTH-BAT) and the Risk of Future Bleeding

M.R. Fasulo[1], E. Biguzzi[1], M. Abbattista[1], F. Stufano[1], M.T. Pagliari[1], I. Mancini[1], M. Gorski[1], A. Cannavò[1], M. Corgiolu[1], F. Peyvandi[1,2], F.R. Rosendaal[3]

[1]Angelo Bianchi Bonomi Hemophilia and Thrombosis Center Fondazione IRCCS Ca' Granda - Ospedale Maggiore Policlinico and Fondazione Luigi Villa, Milano, Italy, [2]Università degli Studi di Milano, Department of Pathophysiology and Transplantation, Milano, Italy, [3]Leiden University Medical Center, Department of Clinical Epidemiology, Leiden, The Netherlands

Background: The International Society on Thrombosis and Haemostasis - Bleeding Assessment Tool (ISTH-BAT) is a validated diagnostic tool that is used in clinical practice in subjects with suspected inherited bleeding disorders.

Aims: To evaluate whether the ISTH-BAT, recorded in patients at first work-up in a tertiary care center, can predict their risk of subsequent bleeding events.

Methods: Observational cohort study that included all consecutive patients referred to Angelo Bianchi Bonomi Hemophilia and Thrombosis Center between 2011 and 2015 because of a suspected bleeding disorder of any sex, age and origin, and able to understand and speak Italian. Only those with ISTH-BAT≥3 were included. The incidence rates (IR) of major (MB) and clinically relevant non major bleeding (CRNMB) events were calculated as the number of events over accrued person-years (py). Main analysis was Cox regression analysis, assessing ISTH-BAT≤ 5 vs >5, and various co-variates, such as sex, age and presence or absence of a final diagnosis.

Results: We recruited 136 patients with a median ISTH-BAT of 4 (range 3-18). Eleven patients (8.1%) had a bleeding event during the follow-up period (one MB, 10 CRNMB). The overall incidence rate of bleeding events was 3.7 per 100 py (95% CI: 1.8-6.6). No difference was observed between patients with a ISTH-BAT ≤5 or >5 (HR 1.2, 95%CI: 0.3-4.6). Similar results were found when ISTH-BAT was considered as a continuous variable (HR 1.1, 95%CI: 0.9-1.4). The incidence rate of subsequent bleeding events was higher in patients with a diagnosis of a hemostatic defect than in those without (IR 7.5 vs 1.9 per 100py, HR 3.0, 95%CI: 0.8-11.8).

Conclusions: The ISTH-BAT does not predict future bleeding events.

PB 1999 | Efficacy and Safety of a New Fibrinogen Concentrate for the Treatment of Bleeding Episodes and Prevention of Excessive Bleeding during Surgery in Children with Congenital Fibrinogen Deficiency

C. Djambas Khayat[1], M. El Khorassani[2], S. Aytac[3], A. Dahmane[4], S. Pujol[4], C. Henriet[4], F. Bridey[4], C. Rothschild[5]

[1]Hôtel Dieu Hospital, Pediatric Haematology, Beirut, Lebanon, [2]Children's Hospital, Mohamed V University, Pediatric Haematology, Rabat, Morocco, [3]Hacettepe University Faculty of Medicine, Ihsan Dogramacı Children's Hospital, Pediatric Haematology, Ankara, Turkey, [4]LFB Biotechnologies, Global Clinical Development, Les Ulis, France, [5]Necker Hospital, Haemophilia Treatment Centre, Paris, France

Background: A triply secured fibrinogen concentrate (LFB FGTW) was demonstrated to be efficient and well tolerated in adults with afibrinogenaemia. Limited data are available regarding treatment in children.

Aims: To investigate the efficacy and safety of replacement therapy in children with fibrinogen deficiency.

Methods: This was an international, open-label study, approved by Ethics Committees. All subject's parents signed an informed consent. Recovery-guided dosing was performed at study entry to obtain optimal plasma fibrinogen concentrations. Target levels were 1.2 g/L for major and 1.0 g/L for minor bleedings/surgeries, as for adults.

Results: Sixteen subjects ranging from 1 to 12 years (8 children ≤6 years) were enrolled. Recovery as measured in 12 subjects ranged from 14.0 to 30.7 g/L per g/kg (geometric mean: 19.1). Eleven children were treated on-demand with a median infusion dose of 0.090 g/kg [range 0.028-0.132] for 17 major and 0.070 g/kg [range 0.039-0.088] for 15 minor bleeding episodes. Physicians' global assessment of response to FGTW treatment (i.e. primary efficacy endpoint) was excellent or good for 97% of episodes. Ten children underwent 11 surgical procedures: 6 circumcisions including 1 orchidopexy were in ≤6 years group (median preoperative dose 0.092 g/kg) and other procedures, all dental extractions were in >6 years group (0.056 g/kg). Haemostasis was rated as excellent in all procedures. Most of the surgical or bleeding events (91%, 39/43) were managed with a single dose of FGTW. In response to the first FGTW administration, the median fibrinogen level was 1.37 g/L for the control of bleeding and 0.97 g/L before surgery. No serious adverse reactions were observed over a large survey period (> 1 year in 12 subjects).

Conclusions: These results provide clinical evidence for the excellent efficacy and safety of FGTW when used in paediatric subjects ≤12 years.

PB 2000 | In Vitro Study of a New Plasma-derived Factor V (FV) Concentrate: Dose-response Evaluation in Plasma from Patients with Congenital FV Deficiency

P. Simioni[1], C. Novembrino[2], C. Bulato[1], M. Boscolo Anzoletti[2], G. Tagariello[3], S. Gavasso[1], C. Berbenni[2], L. Spiezia[1], E. Campello[1], F. Peyvandi[2]

[1]University of Padua, Department of Medicine, Padua, Italy, [2]Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico and Luigi Villa Foundation, Milan, Italy, [3]Transfusion Service, Haematology and Haemophilia Centre, Castelfranco Veneto, Italy

Background: Congenital FV deficiency is a rare autosomal recessive bleeding disorder. Until now fresh frozen plasma has been considered the standard treatment, associated with possible hypervolaemia and other side effects. Recently, a new plasma-derived FV concentrate has been developed and is under evaluation by *in vitro* studies.

Aims: To assess the ability of the drug to restore the hemostatic levels of FV and the normal clotting times and generate safe amounts of thrombin in plasma from patients with congenital FV deficiency.

Methods: PT (prothrombin time), aPTT (activated partial thromboplastin time), FV activity and antigen levels and thrombin generation (TG) (triggered with 5 pM tissue factor) were measured in FV-deficient individuals (n = 10) pre and post *in vitro* spiking of plasma samples with

Control group	1.67 [1.60-1.83]	3.34 [3.20-3.61]	225.80 [211.20-265.00]	748.30 [681.90-912.50]

increasing doses of the drug (0.03-1 IU/mL final concentration). TG was also assessed in a control group (n = 50). Data were evaluated by Wilcoxon test or Kruskal-Wallis test. P value < 0.05 was considered significant.

Results: Tables 1 and 2 report, respectively, coagulation and TG parameters measured with increasing drug concentration. Data are expressed as median and IQR. Normal values of PT, aPTT, lag time and ttpeak have been achieved by 0.25 IU/mL of FV concentrate. FV activity and antigen levels fell within the normal range following the addition of 1 IU/mL of FV concentrate to the plasma samples. A very low dose of FV concentrate (0.03 IU/mL) was enough to normalize peak height and ETP (endogenous thrombin potential).

Conclusions: Most of the parameters analyzed take on normal values using a drug concentration of 0.25 IU/mL. Therefore, the new FV concentrate is able to correct *in vitro* the coagulopathy associated with FV deficiency. Our study demonstrates that the new FV concentrate could potentially offer a major advance for the treatment of patients with FV deficiency.

PB 2001 | Multi-platform Characterization and Application of a Bleeding Assessment Tool in a Cohort of Patients with Factor XIII Deficiency

A. Abraham, H.F. Margaret, T. Geevar, S. Singh, R. V, J. Mammen, S.C. Nair

Christian Medical College & Hospital, Department of Transfusion Medicine & Immunohematology, Vellore, India

Background: Factor XIII (FXIII) is involved in the terminal phase of the clotting cascade resulting in the formation of a stable hemostatic plug. Urea clot solubility test is the standard screening test and confirmation is by quantitative immunoassay for antigen and chromogenic tests for activity.

Aims:

- To characterize patients with inherited FXIII deficiency using all the above diagnostic methods.
- To determine if the ISTH/ SSC Bleeding Assessment Tool (BAT) can be used as a reliable screening tool in these patients.

Methods: The records of 44 patients with FXIII deficiency were reviewed from January 2011 to July 2015. Rotational thromboelastometry (ROTEM) (TEM, Munich, Germany), FXIII antigen assay (LIA, Milan, Italy), urea clot lysis (in-house) and FXIII activity (Berichrom, Dade Behring, Germany) were performed for screening and confirmation. Bleeding scores (ISTH BAT) were obtained from clinical records and were verified by patients.

Results: FXIII deficiency accounted for 1.36% (44/3219) of the total number of patients referred to our laboratory. The frequency of bleeding manifestations is shown (Table 1). The median FXIII antigen level was 0.8 U/dL (IQR: 0 - 2.1 U/dL) and the median FXIII activity level was 6.15% (IQR: 0-8.75%). Since FXIII activity had a lower limit of detection of 10%, it did not correlate with FXIII antigen, BAT and ROTEM. FXIII antigen correlated significantly with lysis on ROTEM (Likelihood ratio: 16.11, Pearson's chi square: 15.04) (Table 2). FXIII antigen with bleeding score (BS significant when ≥ 3 for children, ≥ 4 for males, ≥ 6 for females) also showed a positive correlation. 10/37 patients had maximum lysis of ≤15% even though their bleeding score was ≥ 4 (Sensitivity 72.2%). We found that a cut off of 5% for maximum lysis increased the sensitivity for detecting FXIII deficiency to 94.4%.

Conclusions: FXIII antigen level correlated with BAT and lysis on ROTEM. A cut-off of 5% for maximum lysis (on ROTEM) increased the sensitivity for detecting FXIII deficiency to more than 90%.

TABLE 1 Distribution of bleeding manifestations

SYMPTOMS	NUMBER	PERCENTAGE
Umbilical stump bleed	36/44	82%
Easy bruisability	25/44	57%
Prolonged bleeding following trivial trauma	12/44	27%
Subcutaneous hematomas	6/44	14%
Intracranial bleed	6/44	14%

TABLE 2 Correlation of FXIII antigen with lysis on ROTEM (FXIII antigen divided into 3 groups <= 1,1-5 and >5)

FXIII antigen (U/dl)	Lysis on ROTEM ≤ 15%	Lysis on ROTEM > 15%	Total
≤1	4	12	16
1-5	0	14	14
> 5	3	0	3

PB 2002 | New Bleeding Disorder with Enhanced Fibrinolysis due to Lysinuric Protein Intolerance and Renal Failure

H. Pitkänen[1,2], M. Kärki[3], L. Tanner[4,5], K. Näntö-Salonen[3], H. Niinikoski[6], R. Lassila[7]

[1]*Helsinki University Hospital Research Institute, Helsinki, Finland,* [2]*University of Helsinki, Division of Anaesthesiology, Department of Anaesthesiology, Intensive Care and Pain Medicine, Helsinki, Finland,* [3]*University of Turku, Department of Pediatrics, Turku, Finland,* [4]*University of Turku, Department of Medical Biochemistry and Genetics, Turku, Finland,* [5]*University of Turku, Department of Clinical Genetics, Turku, Finland,* [6]*University of Turku, Department of Pediatrics and Physiology, Turku, Finland,* [7]*University of Helsinki and Helsinki University Hospital, Coagulation Disorders Unit, Department of Haematology, Comprehensive Cancer Center, and HUSLAB and Laboratory Services HUSLAB, Helsinki, Finland*

Background: Lysinuric protein intolerance (LPI), is a rare autosomal recessive transport disorder of the cationic amino acids lysine, arginine, and ornithine affecting intestine, lungs and renal tubules. LPI patients have a poorly characterized bleeding tendency, albeit some reports on low platelet counts and fibrinogen, while also enhanced thrombin and fibrin formation have been reported.

Aims: Our aim was to further depict hemostasis of these patients.

Methods: 15 adult LPI patients (8 female) were enrolled. Bleeding tendency was evaluated with the ISTH/SSC-BAT questionnaire. Routine metabolic and bleeding assays, PFA-100^{TM}, rotational thromboelastometry (ROTEM) and Calibrated Automated Thrombogram (CAT) were performed, data are reported mainly as median and range.

Results: In ISTH/SSC-BAT median bleeding score was 4 (-1-12). 5 patients had mild anemia (123 g/L; 106-147) and 6 presented with mild thrombocytopenia (median 154 E9/L; 95-309). PT and APTT were normal. In 11 patients PFA-100^{TM} adenosine-5-diphophosphate and epinephrine closure times were both prolonged. Functional fibrinogen was 2.5 g/L (1.0-4.3), in 4 patients at < 2.0 g/L. FXIII:C was low, 58 IU/dL (27-141). D-dimer was extremely elevated in all patients, 32 mg/L (13-109). 5 patients carried at least 4 abnormal ROTEM parameters and endogenous thrombin generation (ETP) was lower than in healthy individuals ($p< 0.01$). Interestingly, creatinine correlated negatively with fibrinogen and positively with D-dimer. D-dimer showed strong negative correlation also with base excess and bicarbonate.

Conclusions: LPI is associated with a variable bleeding tendency, characterized by abnormalities in platelet function, thrombin generation and fibrinolysis. Enhanced fibrinolysis associated with metabolic and renal disorder.

PB 2003 | Mutation Profile of Factor X Deficiency

A. Pavlova[1], B. Pezeshkpoor[1], U. Scholz[2], B. Zieger[3], J. Oldenburg[1]

[1]*University Clinic Bonn, Institute of Experimental Haematology and Transfusion Medicine, Bonn, Germany,* [2]*Med. Versorgungszentrum MVZ Labor Leipzig, Leipzig, Germany,* [3]*Division of Pediatric Hematology and Oncology, Department of Pediatrics and Adolescent Medicine, Medical Center - University of Freiburg, Freiburg, Germany*

Background: FX deficiency is one of the rarest coagulation disorders with a great heterogeneity and complexity of the *F10* defects.

Aims: We aimed to evaluate the mutation profile of patients with FX deficiency.

Methods: The coding regions and intron/ exon boundaries of the *F10* gene have been sequenced in all patients. MLPA was used for detection of large deletions/duplications.

Results: The study includes 208 patients with FX deficiency sent for genetic investigation. In 74% (153) of cases disease causative mutation was detected. Most identified mutations were missense (85%), localized to the Gla (exon 2) and the catalytic domains (exons 7 and 8) of FX protein. The mutation Glu142Lys was identified to be with very high recurrence (10%). All other types of defects were distributed as following: nonsense 3%; small del/ins 4%, splice-site 2%; large deletion 6%. In 23 cases the genetic alterations were either compound or homozygous, leading in most cases to severe FX deficiency. In 10 cases combined FVII and FX deficiency was diagnosed, where in 4 cases a large deletion of 13q34 was the cause for the deficiency. The mean FX:C in heterozygous cases was 48%, while in compound or homozygous cases mean FX:C dropped to 4% corresponding to severe type of deficiency. Interestingly, the mutation Glu142Lys, although homozygous, showed moderate reduction in FX:C up to 45%.This genetic alteration, together with other *F10* mutations in compound heterozygous state, sowed FX:C reduction of 20 to 9%, indicating that marked effect of the other genetic defect and a minor effect of Glu142Lys substitution on FX:C.

Conclusions: The molecular genetic profile of FX deficiency is very heterogenic. A good correlation between the clinical phenotype, laboratory findings and genotype would bring more light in the mechanisms of the FX deficiency and would help in better evaluation of the clinical symptoms.

PB 2004 | Retrospective Evaluation of Phenotype and Management of Dysfibrinogenemia and Hypodysfibrinogenemia in a Cohort of Italian Patients

C. Santoro[1], F. Massaro[1], E. Baldacci[1], G. Ferrara[1], F. Malaspina[1], R. Santoro[2], S. Pasca[3], G. Castaman[4], F. Peyvandi[5], M.G. Mazzucconi[1]

[1]*Sapienza University of Rome, Hematology, Department of Cellular Biotechnology and Hematology, Rome, Italy,* [2]*Pugliese-Ciaccio Hospital, Haemostasis and Thrombosis Service, Oncohaematology Department, Catanzaro, Italy,* [3]*University Hospital of Udine, Center for Hemorrhagic and Thrombotic Diseases, Udine, Italy,* [4]*Careggi University Hospital, Center for Bleeding Disorders, Florence, Italy,* [5]*Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Department of Pathophysiology and Transplantation, Università degli Studi di Milano, Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Milan, Italy*

Background: Dysfibrinogenemia (DF) and Hypodysfibrinogenemia (HDF) patients (pts) may experience hemorrhages or thromboses, and the clinical management can be difficult.

Aims: Aim of this study is to obtain information on DF/HDF clinical phenotype and management.

Methods: This is a spontaneous, retrospective, multicenter national study. Data are collected from clinical records.

Results: 41 pts have been enrolled in 3 centers: 35 DF (85%), 6 HDF (15%); 18M, 23F. Median follow up: 7.4 months (1-203). Median age at diagnosis: 36 years (range 3-81). Median fibrinogen activity/antigen level: 53 mg/dL (0-156) and 250 mg/dL (66-380), respectively. 14 pts reported bleeding episodes: epistaxis, hematuria (presence of kidney stones), hematomas, ecchimoses, menometrorrhagia, and gastro-intestinal (presence of esophageal varices), but no specific therapy was required. A portal venous thrombosis occurred in 1 DF patient who underwent splenectomy without replacement therapy; he was treated with warfarin without anti-hemorrhagic prophylaxis. 41 minor/major surgeries were performed in 23 pts. In 10/41 (24%) cases, prophylaxis was administered [Fresh Frozen Plasma in 3, Fibrinogen Concentrate (FC) in 1, Tranexamic Acid in 6]; in 5/41 (12%) cases, Low Molecular Weight Heparin (LMWH) was administered; no hemorrhage occurred. 13 pregnancies occurred in 9 women. In 1 case, LMWH prophylaxis was undertaken during pregnancy, and in 1 other during puerperium. In 2 cases, FC was administered at time of vaginal delivery (VD). 9 VD and 4 cesarean sections were performed without complications.

Conclusions: Pts from this case series experienced few hemorrhagic/thrombotic events. The majority was asymptomatic, and the most severe events were related to associated disorders. Nonetheless this study has the potential to collect data from a numerous population of pts who live in the same country, and therefore to provide useful information to better characterize and manage these rare diseases.

PB 2005 | Use of a Population Pharmacokinetic Model to Determine Pharmacokinetic Parameters of a New Fibrinogen Concentrate in Pediatric Afibrinogenemic Subjects ≤12-year Old

A. Bellon[1], C. Djambas Khayat[2], M. El Khorassani[3], C. Rothschild[4], W. Stevens[5], C. Henriet[1], E. Fuseau[6], F. Bridey[1]

[1]*LFB Biotechnologies, Global Clinical Development, Les Ulis, France,* [2]*Hôtel Dieu Hospital, Pediatric Haematology, Beirut, Lebanon,* [3]*Children's Hospital, Mohamed V University, Pediatric Haematology, Rabat, Morocco,* [4]*Necker Hospital, Haemophilia Treatment Centre, Paris, France,* [5]*LFB Biotechnologies, Strategic Project Management, Les Ulis, France,* [6]*EF Consult, Aix en Provence, France*

Background: Pharmacokinetics (PK) of a triply secured fibrinogen concentrate (LFB FGTW) was first investigated in afibrinogenemic subjects ≥40 kg. Limited data are available in children.

Aims: To develop a population PK (PPK) model with plasma fibrinogen activity (Fg:C) data from afibrinogenemic subjects of all age and weight classes to describe FGTW PK in children ≤12 years and < 40kg and to compare it to other age groups.

Methods: Blood PK samples from 31 afibrinogenemic subjects (1-48 years) were collected over time to determine the Fg:C using a validated Clauss assay. Subjects received a single dose of 0.06 g/kg FGTW in one of 3 clinical trials conducted first in adults, then in adults/adolescents ≥40 kg and finally in children. All or parents thereof signed an informed consent. A PPK model was implemented with NONMEM® using the first order conditional estimation method with interaction.

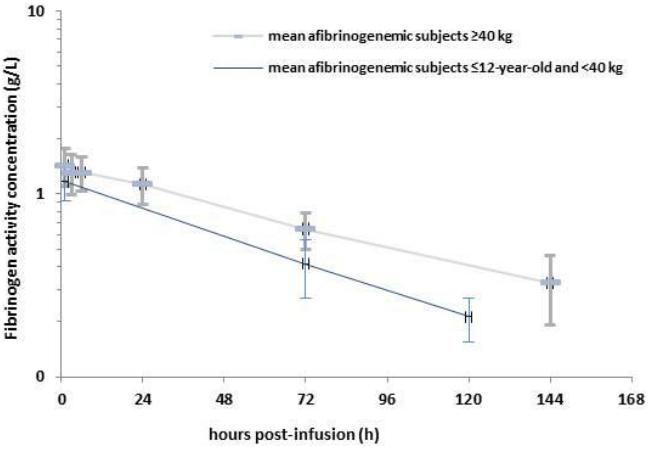

FIGURE 1 Fg:C levels over time in both groups of afibrinogenemic subjects

Results: There was a slightly faster elimination of FGTW in children ≤12 years and < 40 kg (n=12) compared to the other population (n=19) (Fig 1).

A one compartment model with allometric scaling was found to best describe the kinetics of FGTW; additional covariates did not improve the model. Conditional estimates of clearance and distribution volumes adjusted to bodyweight were found to be greater by 64% and 21%, respectively, in children compared to the rest of the population. This led to a shorter elimination half-life estimated at about 2 days in children. Incremental recovery (IR) determined at 1h post-infusion was found to be lower in children with a geometric mean at 19.1 compared to 23.3 (g/L)/(g/kg) in adults and adolescents.

Conclusions: IR and half-life were observed to be lower in the pediatric afibrinogenemic population ≤12 years and < 40 kg. Thus, an approximate 25% higher dose of FGTW would be needed in this pediatric population. An adapted FGTW dosing formula for this age group should be considered to reach the target level of fibrinogen by using 1/IR of 0.053 *vs* the 1/IR of 0.043 applicable to adults/adolescents.

PB 2006 | Safety and Efficacy of Recombinant Factor XIII (rFXIII-A2) in Patients with Congenital FXIII-A Subunit Deficiency Undergoing Minor Surgical Procedures: Results from the Mentor™2 Trial

A. Inbal[1], B. Kerlin[2], D. Nugent[3], J. Oldenburg[4], K. Cepo[5], M.-L. Garly[6], M. Carcao[7]

[1]*Sackler Faculty of Medicine, Sackler Faculty of Medicine, Tel Aviv, Israel,* [2]*Nationwide Children's Hospital, Ohio State University College of Medicine, Columbus, United States,* [3]*Children's Hospital of Orange County, UC Irvine Medical School, Orange, United States,* [4]*Institute for Experimental Haematology and Transfusion Medicine, University Clinic Bonn, Bonn, Germany,* [5]*Novo Nordisk A/S, Medical & Science Biopharm, Søborg, Denmark,* [6]*Nordisk A/S, Søborg, Denmark,* [7]*Hospital for Sick Children, University of Toronto, Division of Haematology/Oncology and Child Health Evaluative Sciences, Research Institute, Toronto, Canada*

Background: Congenital FXIII-A subunit deficiency carries a high risk of intraoperative bleeding in the absence of FXIII replacement. Data on surgical haemostatic coverage using FXIII replacement is scarce. rFXIII-A_2 is the only recombinant product available for use in congenital FXIII deficiency. The safety and efficacy of rFXIII-A_2 when used for prophylaxis and treatment of bleeds was shown to be favourable in the mentor™ trial programme: patients receiving 35 IU/kg rFXIII-A_2 every 4 weeks achieved mean FXIII trough levels between 17 and 19%. Elective surgical procedures were included in mentor™2.

Aims: Report minor surgeries data in patients receiving rFXIII-A_2 prophylaxis during mentor™2.

Methods: mentor™2 was a multinational, open-label, single-arm extension of the pivotal mentor™1 trial. Eligible patients (aged ≥6 years) received 35 IU/kg rFXIII-A_2 every 28±2 days for ≥52 weeks. Elective surgery was permitted during the treatment period; if any procedure required additional FXIII substitution, plasma-derived FXIII was to be given according to local practice.

Results: mentor™2 enrolled 60 patients (median [range] age at enrolment: 26.0 [7.0-77.0] years). Twelve minor procedures (seven dental, five ‚other') were performed in nine patients (median [range] age at time of surgery: 31 [19-59] years; Table). Of these procedures, eight were performed within 7 days of the patient's last scheduled rFXIII-A_2 dose and four were performed 10-21 days after the last dose. No additional FXIII substitution was required for any procedure. Concomitant antifibrinolytics were used in four procedures (tooth extraction [n=3] and colonoscopy [n=1]). No adverse events assessed as possibly/probably related to rFXIII-A_2 treatment were observed.

Conclusions: These data suggests prophylaxis with 35 IU/kg rFXIII-A_2 every 4 weeks provides sufficient haemostatic coverage for the management of minor surgical procedures in patients with congenital FXIII deficiency without additional FXIII treatment.

TABLE 1

Table. Summary of surgical procedures

Type of procedure	No. of procedures	No. of patients	Days since last rFXIII-A_2 dose	No. of procedures requiring antifibrinolytics
Dental				
Tooth extraction + tooth root extraction	1	1	0	0
Tooth (including wisdom tooth) extraction	6	4	0–17	3
Other				
Anterior subcutaneous transposition ulnar nerve carpal tunnel syndrome repair	1	1	1	0
Removal of internal polyp from right ear and partial removal of internal polyp from left ear	1	1	21	0
Suture of left hand after cut	1	1	10	0
Colonoscopy	1	1	1	1
Circumcision revision	1	1	1	0

PB 2007 | Investigation of Medical Indications for PNH Screening Experiment by Flow Cytometry

M. Zhu, W. Shen, L. Dai, J. Yuan, L. Jin

The First Affiliated Hospital of Soochow University, Jiangsu Institute of Hematology, Key Laboratory of Thrombosis and Hemostasis, National Health and Family Planning Commission, Suzhou, China

Background: Paroxysmal Nocturnal Hemoglobinuria (PNH) is an acquired hematopoietic stem cell disorder leading to a partial or absolute deficiency of all glycophosphatidyl-inositol (GPI)-linked proteins. The classical approach to diagnosis of PNH by cytometry involves the loss of at least two GPI-linked antigens on RBCs and neutrophils. But there is not a uniform consensus about the medical indications for PNH clone testing by FCM.

Aims: In order to understand the clinical significance of the PNH screening.

Methods: 4694 individuals were submitted for diagnostic screening of PNH.CD59 was used for RBC analysis based upon physical parameters. We combined FLAER with CD45, CD24, allowing the simultaneous analysis of FLAER and the GPI-linked CD24 on neutrophil and monocyte lineages by CD45 vs side scatter.

Results: PNH clone cells were found in 309/4694 (6.6%) cases. Most commonly individuals were screened because of aplastic anemia (1010/4694,21.5%) and MDS(970/4694,20.7%), followed by hemoglobinuria (896/4694,19.1%), pancytopenia(656/4694,14.0%), hemolytic anemia (448/4694,9.5%), bone marrow failure (233/4694,5.0%), atypical venous thrombosis (76/4694,1.6%), other (405/4694,8.6%). Essentially all patients with classic PNH (108/309,35.0%)report gross hemoglobinuria at some point during the course of their illness. This symptom were absent in patients with PNH-subclincal (190/309,61.5%) because the clone size is often relatively small. PNH clone cell often were found in PNH combined with another specified bone marrow failure disorder, including AA (120/309), MDS(85/309), pancytopenia (4/309).

Conclusions: The FCM screening of GPI-deficient cells shows that the rate of positive results is higher when cases were tested because of hemoglobinuria, anemia,thrombosis and pancytopenia, and much higher in cases previously diagnosed of aplastic anemia or MDS, and therefore screening for PNH in patients with aplastic anemia, or MDS even in the absence of clinical evidence of hemolysis, is recommended at diagnosis and follow-up.

PB 2008 | Clinical and Molecular Data in 15 Italian Subjects with Congenital FXI Deficiency

G. Favuzzi[1], G.L. Tiscia[1], M.R. Lupone[2], F. Cappucci[1], M. Schiavulli[2], V. Mirabelli[3], E. Chinni[1], N. Giuliani[4], R. Caliandro[3], M. Margaglione[5], E. Grandone[1]

[1]IRCCS Casa Sollievo della Sofferenza, Thrombosis and Haemostasis Unit, San Giovanni Rotondo, Italy, [2]Centro Regionale per le Emocoagulopatie, Azienda Ospedale ‚Santobono-Pausillipon', Napoli, Italy, [3]CNR, Istituto di Cristallografia, Bari, Italy, [4]IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy, [5]Univeristy of Foggia, Medical Genetics, Foggia, Italy

Background: Congenital Factor XI (FXI) deficiency is responsible for a bleeding disorder with a high variability in clinical phenotype. To date, many allele variants have been shown to be responsible for the Factor XI deficiency. However, a clear genotype-phenotype relationship is difficult to establish.

Aims: The objective of the study was to describe individuals with Factor XI deficiency, in order to provide novel clinical and molecular insights into such bleeding disorders.

Methods: Fifteen unrelated Italian index cases with congenital FXI deficiency and their relatives were investigated. After the identification of deficiency, we obtained DNA from each subject and performed a direct sequencing with standard procedures.

Results: We identified 5 and 10 individuals with severe and moderate deficiency of Factor XI activity, respectively. Most families (8/15) carried mutations in the Apple 2 domain and 13% of Glu117Stop (type II mutation) was observed. The Glu117Stop (type II) mutation showed a similar allele frequency (13.3%) in respect to other Italian series (18%). 4 novel compound heterozigosity were identified. Bleeding symptoms were present in only 2 severely deficient subjects. They carried the combinations Phe283Leu/Trp501stop and Glu297Lys/Trp501stop, respectively. Bleeding episodes occurred also in the presence of a moderate deficiency in 2 subjects heterozygous for Thr132Met and Gly400Val, respectively. The previously described Phe283Leu mutation (so-called type III) in the presence of a null allele was associated with Factor XI low levels and a bleeding phenotype.

Conclusions: We confirm an unclear prediction of phenotype from mutational data. Further characterization of FXI mutant alleles may allow for a more comprehensive understanding of bio chemical effects and predict for bleeding phenotype better than the unique FXI levels measurement.

PB 2009 | Are Heterozygotes of Factor XIII Deficiency Prone to Bleeding? A New Finding in Area of Rare Bleeding Disorders

M. Naderi[1], A. Dorgalaleh[2], P. Eshghi[3]

[1]Zahedan University of Medical Sciences, Ali Ebn-e Abitaleb Hospital Research Center for Adolescents Health, Zahedan, Iran, Islamic Republic of, [2]Iran University of Medical Sciences, Hematology and Blood Transfusion, Tehran, Iran, Islamic Republic of, [3]Shahid Beheshti University of Medical Sciences, Pediatric Congenital Hematologic Disorders Research Center, Tehran, Iran, Islamic Republic of

Background: Factor XIII (FXIII) deficiency is a rare disorder with high bleeding tendency. Factor activity is 30-70% in individuals with heterozygous FXIII deficiency (FXIIID) and they do not usually experience spontaneous hemorrhage.

Aims: . Since southeast Iran has the largest population with FXIIID, we design this study to assessed bleeding tendency among heterozygote of FXIIID.

Methods: This study was carried out on 53 heterozygote of FXIIID as well as same number of normal population. Initially all individuals were assessed for Trp187Arg FXIII mutation and FXIII activity. Both groups were interviewed by expert staff to record their demographic data and any abnormal clinical presentations in the past. In prospective arm in regular intervals of one-month for a period of three months, bleeding episodes of both groups were recorded.

Results: The mean of FXIII activity of the patient group was 57% and all the patients were heterozygote for Trp187Arg mutation. In control group, the mean of FXIII activity was 105% and all of them were non-mutant. Three (5.7%) individuals experienced umbilical cord bleeding and 16 (32%) women experienced at least on spontaneous abortion while in control group only 1 (2%) of women experienced this episode. Mean bleeding score among cases group for epistaxis, bleeding from minor wounds, bleeding from oral cavity as well as post dental extraction bleeding were higher than control group.

Conclusions: Our findings indicated that heterozygote of FXIIID may complicate by substantial bleeding events, which may threat the life and lead to the requirement of prophylaxis administration.

PB 2010 | FVII Deficiency: Characterization of Three Different Mutations in the FVII Catalytic Domain

M.E. Chollet Dugarte[1,2], E. Andersen[1,2,3], E. Skarpen[4], C.F. Myklebust[1,2], C. Koehler[5], M. Pinotti[6], F. Bernardi[6], B. Thiede[5], P.M. Sandset[1,2,3], G. Skretting[1,2]

[1]Oslo University Hospital, Dept. of Hematology, Oslo, Norway, [2]Research Institute of Internal Medicine, Oslo, Norway, [3]Institute of Clinical Medicine, University of Oslo, Oslo, Norway, [4]Institute for Cancer Research, Oslo University Hospital, Oslo, Norway, [5]University of Oslo, Dept. of Biosciences, Oslo, Norway, [6]University of Ferrara, Dept. of Life Sciences and Biotechnology, Ferrara, Italy

Background: Inherited coagulation factor (F) VII deficiency is the most common among the rare bleeding disorders. Although the mutational pattern of FVII deficiency is well characterized, the intracellular processing mechanisms of mutant FVII molecules have only been investigated for a few mutations.

Aims: To unveil the cellular and molecular mechanisms affecting biosynthesis of FVII in three different mutations in the FVII catalytic domain: the G420V missense change, the deletion p.I289del and the frame-shifted and elongated variant p.A354Vg-p.P464Hfs, all associated with severe bleeding.

Methods: The wild type (wt) and mutant FVII were transiently expressed in CHO-K1 cells. FVII antigen was measured by ELISA and FVII activity by a fluorogenic assay. Synthesis and stability of the FVII mutants were evaluated by pulse-chase stable isotope labelling followed by mass spectrometry based quantitative proteomics (pc-SILAC). Degradation studies were performed using proteasome and lysosome inhibitors. Intracellular localization was assessed by confocal immunofluorescence microscopy.

Results: Secretion of the FVII mutants was severely decreased compared to FVIIwt. No activity of the FVII mutants was detected whereas the activity of FVIIwt was 0.09 IU/ml. The synthesis rate of the FVII mutants was slower and significantly reduced, being between 8 and

20% of the FVIIwt at 6h of the chase. The FVII variants were localized in the endoplasmic reticulum (ER) and none of them were detected in the Golgi apparatus. Degradation by lysosomes or proteasomes was not detectable for the three mutants.

Conclusions: Due to the decreased secretion of the mutants, it is likely to assume that they are not folded correctly in the ER and remain there. Consequently, the mutants are unable to follow the normal transport to the Golgi apparatus.

PB 2011 | Correction of Coagulopathy Related to Severe Factor V Defects with a New Plasma-derived FV Concentrate: An In vitro Study with ROTEM

C. Bulato[1], L. Spiezia[1], C.M. Radu[1], E. Campello[1], S. Gavasso[1], G. Barillari[2], P. Pradella[3], P. Simioni[1]

[1]*University of Padua, Department of Medicine, Padua, Italy,* [2]*Center for Hemorrhagic and Thrombotic Diseases, General University Hospital, Udine, Italy,* [3]*Transfusion Medicine Department, University Hospital, Trieste, Italy*

Background: Fresh frozen plasma is the main therapeutic option in severe FV deficiency because no FV-specific concentrate is still available. However, plasma transfusion can lead to adverse reactions or events. A new plasma-derived FV concentrate has been developed and is under evaluation for clinical use.

Aims: To assess the ability of the new FV concentrate to correct *in vitro* the coagulopathy in severe FV defects.

Methods: ROTEM analysis was performed in 9 patients with severe FV deficiency pre and post *in vitro* spiking of blood samples with increasing doses of the drug (0.01-1 IU/mL) and in 20 healthy volunteers who served as a control group. Two ROTEM assays, INTEM and EXTEM, were used and the following parameters were evaluated: clotting time (CT), clot formation time (CFT), maximum clot firmness (MCF), maximum velocity (MAXV) and area under the curve (AUC). Data were presented as median and IQR and analyzed using Kruskal-Wallis test to compare vs. "control" group. P value < 0.05 was considered significant.

Results: FV-deficient patients had a significantly prolonged CT compared to the normal group (p< 0.0001) both in INTEM and EXTEM. CT values were corrected by the addition of 0.25 IU/mL of FV concentrate both in INTEM and EXTEM. As regards CFT, MCF, MAXV and AUC, no statistically significant differences were detected between patients and controls in none of the assays performed (Table 1 and Table 2).

Conclusions: Our study, conducted on whole blood by ROTEM, reveals that CT is the main parameter impaired in severe FV defects. Replacement with 0.25 IU/mL of the new FV concentrate was able to *in vitro* normalize this parameter. ROTEM could be a useful tool to monitor the replacement therapy by FV concentrate in FV-deficient patients.

TABLE 1 Effect of FV concentrate on ROTEM/INTEM parameters in FV-deficient patients and a control group

	FV (IU/mL)						
INTEM	Baseline	0.01	0.10	0.25	0.50	1.00	Control group

PB 2012 | Molecular Analysis and Clinical Description of an Italian Cohort of Patients with FXI Deficiency

G. Quintavalle, F. Riccardi, G.F. Rivolta, A. Tagliaferri

University Hospital of Parma, Parma Haemophilia Centre, Parma, Italy

Background: Factor XI deficiency is an autosomal recessive bleeding disorder (prevalence 1:1,000,000) caused by mutations in F11 gene (15 exons, 4q35.2). The absence of correlation between genotype, FXI activity and bleedings is described. Symptoms are really heterogeneous and infrequently spontaneous.

Aims: To evaluate relationships between genotype and bleeding manifestations in patients with FXI deficiency.

Methods: Thirty-five patients from Parma Haemophilia Center with FXI:C activity< 0.6 IU/mL were identified by pre-surgical/routine laboratory screening or bleeding history and classified according to clinical phenotype, FXI activity and genotype. The molecular screening of F11 gene was performed with HRM and direct sequencing.

Results: Median age at diagnosis was 25(1-71), median FXI:C 0.37 IU/mL (0.02-0.56). We identified 17 different mutations (missense or truncating), 5 not reported in FXI mutation database.

Four patients were compound heterozygous for pathological mutations: two (FXI 0.002 and 0.019 U/mL) had truncating mutations and were symptomatic (only one with spontaneous mucosal bleedings), the others (FXI:C 0.37 and 0.56 IU/mL) had truncating/missense mutations, without symptoms.

Thirty patients (0.20< FXI:C< 0.6 IU/mL) were heterozygous for pathological mutation, 51% was asymptomatic. Two patients, both with FXI 0.3IU/mL, presented severe bleedings: a female with spontaneous hemarthrosis, post partum and post-surgery bleeding and a boy with intracranial hemorrhage related to cerebral cancer. All the other patients had post-challenge or spontaneous mild bleedings, mainly mucosal.

Conclusions: In our cohort, truncating mutations in compound heterozygosis were associated with severe deficiency of FXI while the association with missense mutations or an heterozygous genotype did not. The bleeding tendency was not related to FXI activity, confirming results of the previous studies and leading to the hypothesis of other predictors of bleeding risk.

PB 2013 | Bernard-soulier Syndrome in Pakistan: Biochemical and Molecular Analysis Leading to Identification of a Novel Mutation

D. Böckelmann[1], M.Y. Jamal[2], E. Lerner[1], A. Naz[2], B. Zieger[1]

[1]*University of Freiburg; Faculty of Medicine, Department of Pediatrics and Adolescent Medicine, Division of Pediatric Hematology and Oncology, Freiburg, Germany,* [2]*Institute of Blood Disease & Bone Marrow Transplantation, Karachi, Pakistan*

Background: Bernard-Soulier syndrome (BSS) is a rare, autosomal recessive bleeding disorder with abnormalities of the platelet GPIb-IX-V complex. Typical are mucocutaneous bleedings, thrombocytopenia, presence of giant platelets and impaired ristocetin- induced agglutination. Three disease-related genes (*GP1BA*, *GP1BB*, *GP9*) harbor mutations of all types. Here, we investigated a Pakistani cohort of 6 juvenile patients out of 5 unrelated families presenting mild to severe bleeding symptoms and 10 family members using biochemical and molecular genetic analyses.

Aims: Aim of the study was to define the phenotype and reveal its underlying pathogenic mutation.

Methods: Blood count, smear and platelet characterization using aggregometry and flow cytometry was done for all 6 patients and partial for family members. Sequencing of coding- and splice site regions of all genes was done for index patients. Variants were analyzed by ALAMUT®. Occurrence in variant databases (dbSNP, EVS, ExAC), ClinVar, the latest BSS international consortium report and *in silico* pathogenic prediction (SIFT, MutTaster, PolyPhen2) were investigated. Genotyping was performed for all family members.

Results: Patients showed macrothrombocytopenia, impaired ristocetin-induced agglutination and severely reduced expression of GPIb/IX. We identified two nonsense mutations in *GP1BA* (NM_000173.6): one of them *novel* (c.21delG,p.Leu8Serfs*22), one reported (rs774388410). In *GP9* (NM_000174.4) we discovered the same missense mutation (c.70T>C,p.Cys24Arg, rs28933378) in 3 index patients from unrelated families. This mutation is already published to be found in BSS patients from India (13 to date) and Pakistan (4 to date).

Conclusions: We report a *novel* nonsense *GP1BA* mutation altering the signal peptide of the alpha chain of GP1b. Our finding of the *GP9* mutation in 3 unrelated families supports the conclusion that this mutation is a founder mutation for South Asians.

PB 2014 | Genotypic Abnormalities in Phenotypic Confirmed Patients with Rare Bleeding Disorders

W. van Heerde[1], A. Simons[2], S. Krouwel[3], S. Schoormans[3], M.R. Nijziel[4]

[1]*Radboudumc, Dept of Laboratory Medicine, Laboratory of Hematology, Hemophilia Care Cente, Nijmegen, The Netherlands,* [2]*Radboudumc, Dept of Human Genetics, Nijmegen, The Netherlands,* [3]*Radboudumc, Dept of Laboratory Medicine, Laboratory of Hematology, Nijmegen, The Netherlands,* [4]*Radboudumc, Dept of Hematology, Hemophilia Care Center, Expertise Center for Hemophilia and Rare Bleeding Disorders, Nijmegen, The Netherlands*

Background: Rare Bleeding Disorders (RBD) are characterized by increased susceptibility to develop hemorrhages because of genetic abnormalities in multiple components of the hemostatic balance. At the moment, at least 135 genes/loci are known as genetic causes for hemostatic disorders.

Aims: To screen for genetic abnormalities to confirm the patients' phenotype.

Methods: Targeted gene analyses were performed on 148 patients with RBD, by classical Sanger sequencing or by ion semiconductor next generation sequencing technology (IonTorrent PGM™). All coding regions including intron-exon boundaries were sequenced. Two

different classes of hemostatic genes were analysed: procoagulant genes (*F2*, *F12*, *F11*, *F7*, *F10*, *F13A1*, *F13B*, *FGA*, *FGB*, *FGG*) and platelet specific genes (*GFI1B*, *GP1BA*, *ITGB3*, *MYH9*, *NBEAL2*). Targeted single gene approach was based on patients' laboratory phenotype in combination with clinical symptoms.

Results: Of the 148 patients tested 38 carried (likely) pathogenic mutations and 8 carried variants of unknown pathogenicity (VUS) in procoagulant genes. For the more heterogeneous platelet abnormalities only 3 out of 38 patients had (likely) pathogenic mutations, 1 patient with a VUS.

Conclusions: The patients' phenotype was an important parameter for targeted single gene approach to detect genotypic abnormalities in RBD patients. The overall yield to detect pathogenic mutations was 27% in procoagulant abnormalies. The targeted single gene approach was resolved in only 11% in cases with primary hemostasis abnormalities. To increase the yield we recently implemented whole exome sequencing (WES) as a diagnostic test. WES allows analysis of a large panel of genes in one single test. The hemostatic gene panel we designed contains currently 135 genes proven to be involved in hemostatic disease including genes involved in primary hemostasis (platelet and vessel wall) and secondary hemostasis (coagulation and fibrinolysis). If the diagnostic panel reveals a negative result exome wide analysis will be performed.

PB 2015 | Evaluation of the Use of Bleeding Assessment Tools in FXI Deficiency

G. Gidley[1,2,3], A. Cumming[4], J. Thachil[2], C. Hay[2], M. Sutherland[4], S. Keeney[2], B. Sempasa[4], P. Bolton-Maggs[5,6], J. Burthem[1,2]

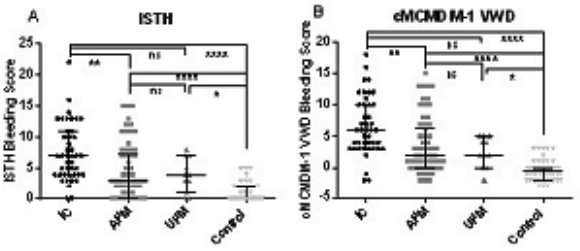
[1]University of Manchester, Institute of Cancer Sciences, Manchester, United Kingdom, [2]Central Manchester University Hospital NHS Foundation Trust - Manchester Royal Infirmary, Haematology, Manchester, United Kingdom, [3]St James's University Hospital, Haematology, Leeds, United Kingdom, [4]Central Manchester University Hospital NHS Foundation Trust - Manchester Royal Infirmary, Molecular Diagnostics Centre, Manchester, United Kingdom, [5]NHS Blood and Transplant, SHOT Office, Manchester, United Kingdom, [6]University of Manchester, Institute of Cardiovascular Sciences, Manchester, United Kingdom

Background: The bleeding history is paramount to assessment of FXI deficiency; however variability exists as to what constitutes a significant bleeding history.

Aims: To assess utility of ISTH and condensed MCMDM-1 VWD bleeding assessment tools as descriptive, diagnostic and predictive measures in FXI deficiency and determine the impact of diagnostic setting on bleeding scores (BS).

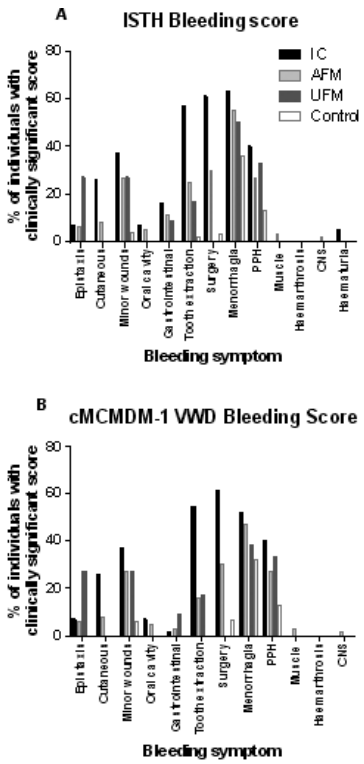
Methods: BS were determined in 116 adults from 69 FXI-deficient families and 50 healthy individuals. Plasma FXI:C levels and thrombin generation assays (TGA) were performed along with F11 mutation analysis. Ethical committee approval and participant consent were obtained.

Results: Statistically higher BS were demonstrated in index cases (IC) (n = 43) compared to affected family members (AFM) (n =62) (diagnosed through family screening); patterns of bleeding were similar but a higher percentage of IC reported symptoms. Unexpectedly, no difference in BS was seen between AFM and unaffected family members (UFM) (n =11) and UFM reported more bleeding symptoms and had statistically higher BS than normal individuals (n=50) (Fig.1 and Fig. 2).No correlation was seen between FXI:C levels and either BS (P>0.5), or between heterozygous mutation type and BS. Both BS correlated with ETP in IC (P< 0.003) but only with ETP in AFM who had undergone procedures in areas of high fibrinolytic activity (P< 0.0093). Neither BS had diagnostic utility in family screening (ROC AUC< 0.5212, P>0.82) and mucocutaneous scores derived from each BS held no predictive value for past bleeding (ROC AUC< 0.647, P>0.14).



Lines and bars represent median and interquartile range. * P < 0.05, ** P< 0.01, *** P < 0.001, **** P < 0.0001, ns, not significant. Tested with ANOVA Kruskal Wallis test with Dunn's multiple comparisons test.

FIGURE 1 Comparison of ISTH (A) and cMCMDM-1 VWD (B) bleeding scores in 4 different study groups



A clinically significant score was defined as = 1 for menorrhagia, post partum haemorrhage (PPH) ,muscle bleeds and haemarthrosis, =3 for central nervous system (CNS) symptoms and =2 for all other symptoms. Frequencies for tooth extraction, surgery, childbirth/PPH only include data from individuals who underwent these procedures. Frequencies for menorrhagia only included data from females.

FIGURE 2 Frequency of clinically significant bleeding symptoms in 4 study groups

Conclusions: Importantly we show that diagnostic setting influences BS in FXI deficiency and that UFM report more bleeding than expected. BS can be used as descriptive but not diagnostic tools. Correlation of ETP with BS raises the possibility that BS may determine bleeding phenotype in IC and a select group of AFM who have been previously challenged by procedures high risk for bleeding in FXI deficiency. Prospective studies are required to confirm this.

PB 2016 | Clinical Presentation and Management of Glanzmann's Thrombasthenia: A Case Study

I. Sasmaz, B. Antmen, B. Karagun, G. Leblebisatan, Y. Kilinc

Cukurova Universitesi, Pediatric Hematology, Adana, Turkey

Background: Glanzmann′s thrombasthenia is a very rare, characterized by a life-long mucocutaneous bleeding tendency, absent or severely reduced platelet aggregation . Mucocuteanous bleeding, gingival hemorrhages, menorrhagia, gastrointestinal bleeding, hematuria can be seen in patients with Glanzmann′s thrombasthenia.

Aims: In this study, we aim to report the patients with Glanzman's thromboastenias bleeding sites and treatment modalities of 25 patients.

Methods: From 1995 to 2016, we retrospectively reviewed medical records of 25 patients with Glanzmann′s thrombasthenia and discussed with the literature.

Results: Twenty five patients with Glanzmann′s thrombasthenia, age range from 1 to 17 years were included in this study. The ages of onset were between 3 days and 7 years of age. Mucocutaneous bleeding was the most common clinical presentation (%92). Intracranial haemorrhage (ICH) was seen in one patient after trauma. Menorrhagia was seen in 3 girls who were in the age of menstruation. Three patients referred to our centre with gastrointestinal bleeding and one patient with hyphema. Three patients are diagnosed after circumcision. Twenty five of 4 patients have surgical operations including circumcision and teeth extraction. Thrombocyte suspensions, local therapies, antifibrinolytic agents and recombinant FVIIa were used for bleeding control before and during surgery patients performed surgeries. Oral contraceptives were given to the patients with menorrhagia.All bleeding episodes of these patients were successfully treated and there is no other complication or death.

Conclusions: Glanzmann′s thrombasthenia is a rare hematologic disorder. The clinical presentation with mucocutaneous bleeding can range from mild to severe to life threatening. Affected patients may manifest with severe haemorrhagic symptomps early in life. In this case series with Glanzman thromboastenias we report bleeding characterizations and management of different site of haemorrhage in 25 patients.

PB 2017 | Prevalence of Menorrhagia in Women Diagnosed with Congenital Bleeding Disorders

M. Borhany, N. Fatima, M. Abid, T. Shamsi

National Institute of Blood Disease and Bone Marrow Transplantation, Karachi, Pakistan

Background: Menorrhagia is defined as abnormally heavy or prolonged bleeding during menstrual cycle andblood loss exceeding 80 ml per cycle. It is the most common symptom in women of reproductive age with congenital bleeding disorders. However, there is paucity of data on the incidence, diagnosis and treatment of bleeding in women with these disorders in developing countries.

Aims: Here we report the frequency, clinical picture and types of congenital bleeding disorders among women with menorrhagia.

Methods: An observational study was carried out amongst females diagnosed with congenital bleeding disorders. Frequencies of bleeding disorders with respect to menorrhagia were calculated and chi square test was applied to observe the association of prevalence of menorrhagia amongst all bleeding disorders.

Results: A total of 116 females with congenital bleeding disorders, including factor deficiencies (FI, FV, FVII, FXI, FXIII), platelet function disorders (Glanzmann's Thrombasthenia (GT), Bernard Soulier Syndrome (BSS), and Storage pool disorder (SPD) and Von Willebrand disease (VWD)were studied. The mean age was 12.69±10.13 years. Of the entire cohort, 65(56%) females were found to be in the reproductive age and out of them 41(63%) had menorrhagia with mean age of 22.2±7.4 years. Menorrhagia was more commonly observed in BSS, FI, FV, FXIII and SPD patients followed by VWD, FVII and GT.Pictorial blood assessment chart (PBAC) >100 were observed in all subjects. We intended to observe the association of frequency of menorrhagia amongst all bleeding disorders and it was found that menorrhagia was evenly prevalent in all bleeding disorders.

Conclusions: These results demonstrate that menorrhagia is prevalent among all congenital bleeding disorders. Therefore, women,especially in the reproductive age with menorrhagia, should be further evaluated for hemostatic disorders.

PB 2018 | Thrombotic Complications in a Patient with Congenital Afibrinogenemia

S. Vakalopoulou[1], A. Papagianni[2], M. Stagou[2], P. Kotsi[3], G. Vasileia[1]

[1]Haemophilia Center of Northern Greece, Hippokration Hospital, Thessaloniki, Greece, [2]Hippokration Hospital, Nephrology Department, Thessaloniki, Greece, [3]2nd Blood Transfusion Center, Haemophilia Center, Laikon General Hospital, Athens, Greece

Background: Congenital afibrinogenemia (CA) is a rare inherited bleeding disorder characterized by complete absence of plasma fibrinogen. Patients with CA present with bleedings but paradoxically thrombotic events have also been reported.

Aims: Present a case of a patient with CA and hepatitis C (HC) showing both bleeding and thrombotic events whose management remains difficult and challenging.

Methods: Female, 31 years old, diagnosed with CA, because of postnatal cephalhematoma. She was compound heterozygote for mutations in fibrinogen A gene.

Results: The patient presented recurrent mucosal hemorrhages, menorrhagia, hemoperitoneum and hemarthrosis and treated with plasma or fibrinogen concentrates (FC). She was on prophylaxis with FC since 2011. In 1996 she was diagnosed with HC virus infection and ten years later she successfully treated with antiviral drugs. At that time she developed hypertension, ischemic lesions of the toes and progressive renal failure and she received corticosteroids and rituximab for vasculitis associated with HC. A year later her renal function and hypertension deteriorated. Computed tomography angiography revealed stenosis of both renal and other intra abdominal arteries. The patient underwent an angioplasty of the right renal artery. During the following years she had two episodes of thrombosis (superior mesenteric artery and left internal jugular and subclavian vein). Her renal function gradually deteriorated and in 2015 she started on regular hemodialysis but she presented thrombosis on the left femoral vein, probably related to the dialysis catheter. Thrombotic events were treated with low molecular weight heparin. In 2016 she underwent renal transplantation from a living related donor (mother).

Conclusions: Although the combination of anticoagulation and replacement therapy is an effective treatment for the thrombotic events occurred to the patients with CA, the maintenance of the fragile balance between thrombosis and bleeding is quite difficult.

PB 2020 | Identification of Novel and Recurrent Mutations in F13B Gene Causing Mild FXIII Deficiency

V. Ivaskevicius, A. Biswas, S. Singh, A. Pavlova, J. Oldenburg

University Clinic Bonn - Institute of Experimental Haematology & Transfusion Medicine, Bonn, Germany

Background: Severe FXIII deficiency is a rare, autosomal recessive bleeding disorder affecting approximately one in 1-3 million people. On the other hand the heterozygous FXIII deficiency is expected to be more common occurrence affecting approximately one out of 1000 inhabitants.

Aims: Characterization of *F13B* gene mutations in mild FXIII deficiency.

Methods: We report the results of the screening of *F13B* gene mutations in a mild FXIII deficiency patient cohort (FXIII activity < 65% of normal) of German-Caucasian descent. Genomic DNA of these patients has been analyzed by direct sequencing of the *F13A1* and *F13B* genes between 2009 and 2015 using previously described protocols. All detected missense mutations were analyzed on mutation prediction servers and also by modeling them using protein modeling tools. The missense mutations were also cloned into expression vectors transfected heterologously into *HEK293t* cell lines and their expression products analyzed.

Results: Eight novel and one recurrent heterozygous *F13B* gene mutations were identified. The majority of patients (10/13) carried missense mutations, while the remaining three patients showed distinct genetic defects revealing one small deletion (c.1958delT), one small insertion (c.365insA) and one splice site (IVS5-1G>A) mutation in intron 5. Among six different missense mutations, five were novel (p.Phe42Val, p.Tyr163His, p.Cys213Trp, p.Val266Pro, p.Ala416Glu) all affecting highly conserved regions of the FXIII-B Subunit. One previously described missense mutation (pCys336Phe) was found in 5 out of 13 analyzed patients. *In vitro* and *in silico* analysis shed light on the causality of the missense mutations.

Conclusions: Eight novel potentially causative mutations underlying mild FXIII deficiency have been identified within *F13B* gene. The p.Cys336Phe mutation seems to be a common mutation causing mild FXIII deficiency in the German-Caucasian population.

PB 2021 | Bleeding Score as a Diagnostic Tool in Patients of Autosomal Recessive Inherited Bleeding Disorders

A. Naz[1], N. Ahmed[2], S. Tariq[2], S. Amanat[3], F. Raziq[4], T.S. Shamsi[1]

[1]National Institute of Blood Disease and Bone Marrow Transplantation, Karachi, Pakistan, [2]Children Hospital Lahore, Haematology, Lahore, Pakistan, [3]Atomic Energy Commission Islamabad, Islamabad, Pakistan, [4]Hayatabad Medical Complex Peshawar, Peshawar, Pakistan

Background: To establish the quantitative method for the assessment of bleeding manifestation is a big challenge for the clinicians.Bleeding pattern vary significantly between disorders and patients, even with the same disorder.The incidence of autosomal recessive bleeding disorders (ARBD) is rare as compared to other bleeding disorders. These are prevalent in those geographical locations where consanguinity is common and occur frequently in homozygosity.

Aims: To establish the utility of bleeding scores(BS) as a diagnostic tool for the patients
with ARBD in different regions of Pakistan.

Methods: Patient's data of this cross-sectional study was collected from different hematology centers in Pakistan using Tosetto *et al* bleeding score.Diagnosed patients with ARBD were recruited after obtaining written consent and approval from ethical committee during last four years. Data was recorded in a structured questionnaire.

Results: Out of 211 patients with ARBD; 95 (33.8%) had VWD type 3 with a BS of 13.5,GT in 27 (9.6%) with a BS of 11,BSS in 7 patients (2.5%) with BS of 11, deficiencies of fibrinogen in 34 patients (12%) and BS of 12.5, FXIII in 13 (4.6%) and BS of 11.5, FVII in 12 (4.3%) and BS of 12, FV 9 (3.2%) BS of 11,8(2.8%) vitamin K-dependent clotting factor and BS of 12, FX in 2 (0.7%) BS of 12, FII in 2 (0.7%) with a score of 10, FXI deficiency and combined FV &VIII in 1 (0.4%) each and a BS of 10 and 11.5 were found respectively.

Table 1.1: Frequency and Severity of Bleeding.

ARBDs	Gum bleeding %	Hem arthr osis %	Hemat oma %	Epistaxis %	Menorrh agia ~ %	Umbilical cord bleed%	Bleeding after trauma%	Bruise s %	ICH %	Bleeding Grades*	Bleeding score¶
VWD type 3 disorder.	53.2	7.6	16.15	32.3	11.4	10.45	-	12.3	-	II	13.5
Fibrinogen	6.25	18.75	50	25	-	-	68.7	43.75	-	II	12.5
Factor XIII	84.6		46.15	69.2	46.1	84.6	38.4	69.2	7.69	II	11.5
Factor VII	75	66.7	58.3	91.6	46.1		91.6	75	16.6	III	12
Factor V	77.8	22.2	66.7	55.6	55.6	-	44.4	55.6	11.1	II	11
Vitamin K dependent clotting factors	87.5	-	62.5	25	37.5	62.5	87.5	62.5	-	II	12
Glanzmann Thrombasthenia	85.7	-	14.2	71.4	28.5	57.1	100	71.4	-	II	11
Factor II	100	50	100	50	50	-	-	50	-	II	10
Factor X	50	100	100	-	100	100	-		-	II	12
Combined Factor V and VIII	100	100	100	-	-	-	-	100	-	II	11.5
Factor XI	100	-	100	100	-	-	100	100	-	II	10
Bernard Soulier syndrome	100	-	100	100	-	-	100	100	-	II	11

*Calculated on the basis of WHO bleeding grades. ¶based on Tosetto et al bleeding score calculation scale. ICH: intracranial hemorrhage.
~ Reported in adult female patients.

FIGURE 1 Frequency and Severity of Bleeding

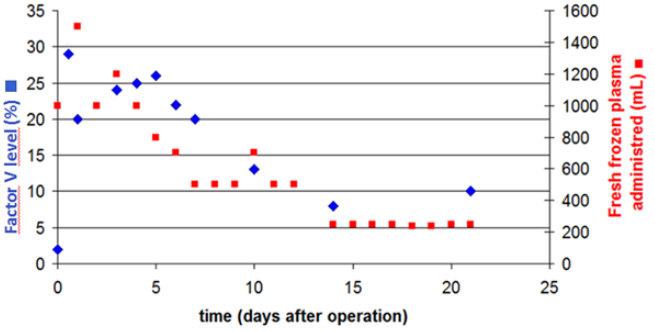


FIGURE 1 Factor V level and substitution with fresh frozen plasma in the peri- and postoperative period

Conclusions: At the end of this study it was found that bleeding score with an average of 11.5 is positively associated with an ARBD. This prediction is useful in diagnosing a patient with these disorders and help to make correct treatment decisions.

Keywords: Autosomal recessive, coagulation factors, BAT, bleeding scores.

PB 2023 | Acute Coronary Syndrome in a Patient with Factor V Deficiency: A Case Report

S. Anzej Doma, D. Andoljsek, I. Preloznik Zupan

University Medical Centre Ljubljana, Hematology Department, Ljubljana, Slovenia

Background: Occasional thrombotic phenomena are seen even in rare congenital bleeding disorders. Due to rarity of factor (F) V deficiency there are no guidelines in the available literature on how to manage such patients.

Aims: A patient with FV deficiency and acute coronary artery thrombosis is presented.

Methods: Standard coagulation tests were used, FV activity was determined by one-stage PT based assay.

Results: Case presentation: A 75-year old caucasian man with a congenital FV deficiency (FV level 2%), diabetes mellitus type 2, arterial hypertension and hyperlipidemia presented with unstable angina pectoris. His aPTT was 69,3 s, PT/INR was 0,35/2,09, antibodies against FV were negative. Prior to coronarography he received 1200 mL of fresh frozen plasma (FFP) (15 mL/kg), that raised his FV to 28%; he received standard antiaggregation therapy (acetylsalicylic acid, clopidogrel) and 5000 IU of standard heparin. Three-vessel coronary disease, including occlusion of LAD, and a 90% stenosis of right internal carotid artery was diagnosed. The patient was prepared for CABG and TEA ACI dex. We calculated the half- life of FV to be 19 hours. Prior to the operation he received 12 mL FFP/kg, raising FV level to 29%. FV level was kept above 20% the first 7 days after the surgery by administering FFP daily, along with acetylsalicylic acid 100 mg/d and a prophylactic dose of enoxaparin. Postoperative complications were serous pleural effusions and paroxisms of atrial fibrillation. From the second week after the operation till complete healing of the wounds FV level was maintained above 10%. No bleeding was noticed. Patient was released from the hospital 25 days after the surgery taking 100 mg acetylsalicylic acid per day.

Conclusions: Level of FV above 20% was sufficient to maintain proper haemostasis during invasive coronary diagnostics and a major cardiac surgery in a FV- deficient patient, receiving also standard antiaggregation therapy and a prophylactic dose of low-molecular weight heparin.

PB 2024 | Congenital Hypoprothrombinemia Presenting in the Neonatal Period: Report of 2 Cases in South of Iran

M. Bordbar[1], M. Karimi[1], A. Bazrafshan[2], M. Aali[2], K. Kamali[3]

[1]*Shiraz University of Medical Sciences, Hematology Research Center, Shiraz, Iran, Islamic Republic of,* [2]*Shiraz University of Medical Sciences, Shiraz Hemophilia Comprehensive Center, Dastgheib Hospital, Shiraz, Iran, Islamic Republic of,* [3]*Shiraz University of Medical Sciences, Shiraz, Iran, Islamic Republic of*

Background: Prothrombin deficiency is the rarest inherited bleeding disorder. It usually presents with mucocutaneous bleeding, hemarthrosis and post surgery or post trauma hemorrhage. Rarely, the disease may manifest in the neonatal period with bleeding tendency.

Aims: We are going to introduce 2 babies with prothrombin deficiency who were diagnosed in the neonatal period with umbilical, gastrointestinal and intracranial hemorrhage.

Methods: The babies (a girl and a boy) were admitted simultaneously to a nursery ward in Shiraz, south of Iran. The girl was a preterm baby who was admitted due to GI bleeding and IVH grade II detected by transcranial ultrasonography. The boy was a term neonate who was admitted for umbilical stump bleeding and cephalhematoma following a difficult NVD (figure 1). Both families were living in a village near Shiraz and the parents were first cousin.

Results: The coagulation profile revealed a prolong PT and aPTT in both cases which were corrected with mixing study. Vitamin K administration didn´t correct their tests. Screening for common pathway factors showed prothrombin deficiency in both cases while other factors were normal (3.5 and 14 U/dL respectively). Their parents were heterozygote for prothrombin deficiency with factor II levels ranging from 61 to 76 U/dL. Fresh frozen plasma was infused twice weekly and they were discharged from hospital in good general health.

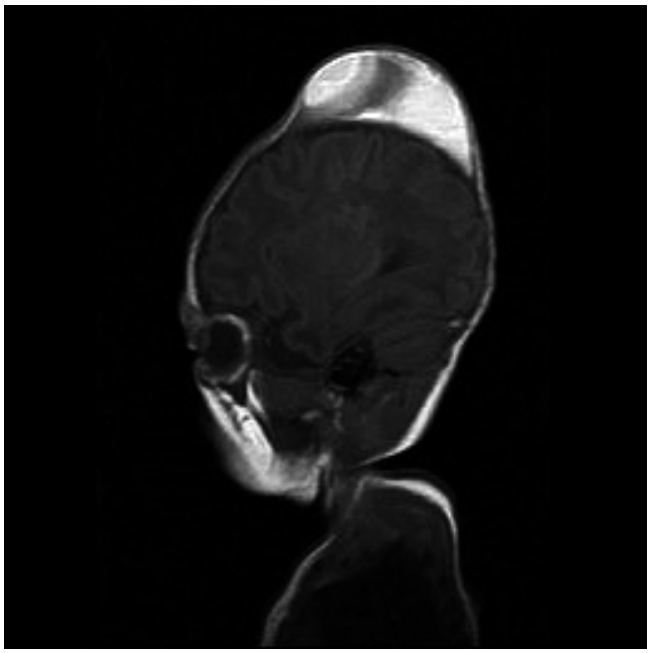

FIGURE 1 A large postero-lateral aspect cephalhematoma in the case with prothrombin deficiency

Conclusions: Prothrombin deficiency can present in the neonatal period with cephalhematoma as well as bleeding from CNS, GI and umbilical stump. As consanguineous marriage is common in some part of Iran, it is recommended to perform a mass screening program in this regions provided that an index case is detected.

PB 2025 | Rare Bleeding Disorders in the Netherlands (RBiN)

J.L. Saes[1], S. Schols[1], Y. Smit[1], M. Peters[2], K. Meijer[3], F.J.M. van der Meer[4], M. Cnossen[5], R. Schutgens[6], L. Nieuwenhuizen[7], W. van Heerde[8,9], M. Nijziel[1]

[1]Radboud University Medical Center, Haematology, Nijmegen, The Netherlands, [2]Academical Medical Center Amsterdam, Amsterdam, The Netherlands, [3]University Medical Center Groningen, Groningen, The Netherlands, [4]Leiden University Medical Center, Leiden, The Netherlands, [5]Erasmus Medical Center, Rotterdam, The Netherlands, [6]University Medical Center Utrecht, Utrecht, The Netherlands, [7]Maxima Medical Center Eindhoven, Eindhoven, The Netherlands, [8]Radboud University Medical Center, Laboratory for Haematology, Nijmegen, The Netherlands, [9]Radboud University Medical Center, Department of Laboraroy Medicine, Nijmegen, The Netherlands

Background: Rare Bleeding Disorders (deficiencies of fibrinogen, factor II, V, V&VIII, VII, X, XI, XIII, α2-antiplasmin or plasminogen activator inhibitor 1) have a diverse clinical presentation, varying bleeding scores, bleeding episodes, health-related quality of life and laboratory parameters.Therefore, correlations between genotype and phenotype are difficult to establish.

Aims: To describe epidemiology, bleeding tendency, laboratory parameters, quality of life and molecular genetic spectrum of all known patients in the Netherlands with rare bleeding disorders (RBD). In addition, the study aims to further explore the relationship between clinical and laboratory phenotype and genotype.

Methods: Cross-sectional multicentre observational study in all patients registered in Dutch Haemophilia Treatment Centers (HTC) with known RBD, aged 1-99 years. After informed consent patients are asked to fill out questionnaires on bleeding, socio-demographic characteristics, clinical characteristics (bleeding tendency, treatment, development of antibodies), medical history (hospital admissions, medication used), needle phobia, sports and physical activity, quality of life and functional limitations. ISTH-BAT and other bleeding assessment tools will be performed and validated for RBD. Blood and saliva samples will be collected for laboratory testing, including the Nijmegen Haemostasis Assay (NHA). Whole exome sequencing (WES) will be performed to unravel the patients genotype. Currently our WES strategy includes 128 bleeding related OMIM-proved genes, which will be further expanded when indicated.

Results: Inclusion of patients for the Rare Bleeding disorders in the Netherlands (RBiN) study will start in 2017. So far, 269 patients have been identified in all HTC in the Netherlands.

Conclusions: The RBiN study will provide new insight in the relationship between the clinical and laboratory phenotype and the genotype in rare bleeding disorders.

PB 2026 | Identification of Two Novel F5 Compound Heterozygous Mutations in Two Norwegian Patients with Severe Factor V Deficiency N

N. Iversen[1], H. Glosli[2], M. Sletten[1], M. Skogstad Le[3], M. Hellum[3,4], M. Tinholt[1,5], P.A. Holme[4,6], C. Henriksson[3,4]

[1]Oslo University Hospital, Department of Medical Genetics, Oslo, Norway, [2]Oslo University Hospital, Department of Paediatric and Adolescent Medicine, Oslo, Norway, [3]Oslo University Hospital, Department of Medical Biochemistry, Oslo, Norway, [4]University of Oslo, Institute of Clinical Medicine, Oslo, Norway, [5]Oslo University Hospital, Department of Haematology, Olso, Norway, [6]Oslo University Hospital, Department of Haematology, Oslo, Norway

Background: "Mary" was the first factor V (FV) deficiency patient discovered by Owren (1943). FV deficiency is a rare autosomal recessive bleeding disorder (1:1 mill). The bleeding symptoms range from mild to severe.

Aims: In two unrelated Norwegian FV deficient patients, and their parents, we characterized the F5 gene mutations and the effect on FV antigen (ag)/activity and thrombin generation (TG).

Methods: FV ag (ELISA)/activity and TG (CAT) were measured. Mutation analysis of the F5 gene was performed by Sanger sequencing of the exons and the exon/intron boundaries.

Results: Proband 1 (girl, 13 yrs) had severe bleeding tendency with mucosal bleedings since early childhood, easily bruising and heavy menstrual bleedings. FV ag/activity were < 1%. Lag time/peak (TG parameters) were not detected during 90 min. Two heterozygous missense mutations in the F5 gene were found; c.6293 C>T (Pro2098Leu) in exon 23, which is identical to Mary's mutation, and c.5990 C>G (Tyr1997Cys) in exon 21. The second mutation in proband 1 is novel, and an inhibitor against FV has evolved after treatment with

Octaplasma. NovoSeven is successfully used to limit her bleeds. Proband 2 (girl, 16 yrs) had moderate bleeding tendency with easily bruising and heavy menstrual bleedings. FV ag/activity were < 1% and lag time/peak evidently reduced. She also carried two compound heterozygous missense mutations in F5: c.6293 C>T (Pro2098Leu) in exon 23 (Mary's mutation) and c.5408 A>G (His1803Arg) in exon 16. For both probands, the healthy parents had FV ag of 60-98% and FV activity of 42-59%.

Conclusions: We identified that both FV deficiency patients had inherited compound heterozygous F5 mutations, with Mary's mutation in common. Both probands had Type I FV deficiency and evidently reduced TG. The different bleeding phenotypes in these two probands, and perhaps also the inhibitor evolvement, is likely to be explained by the c.5990 C>G (Tyr1997Cys) mutation, which was exclusive for proband 1.

PB 2027 | Retrospective Evaluation of Phenotype and Management of A-hypo-Fibrinogenemia in a Cohort of Italian Patients

C. Santoro[1], F. Massaro[1], E. Baldacci[1], G. Ferrara[1], A. Ferretti[1], R. Santoro[2], S. Pasca[3], G. Castaman[4], F. Peyvandi[5], M.G. Mazzucconi[1]

[1]Sapienza University of Rome, Hematology, Department of Cellular Biotechnology and Hematology, Rome, Italy, [2]Pugliese-Ciaccio Hospital, Haemostasis and Thrombosis Service, Oncohaematology Department, Catanzaro, Italy, [3]University Hospital of Udine, Center for Hemorrhagic and Thrombotic Diseases, Udine, Italy, [4]Careggi University Hospital, Center for Bleeding Disorders, Florence, Italy, [5]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Department of Pathophysiology and Transplantation, Università degli Studi di Milano, Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Milan, Italy

Background: A-Hypo-Fibrinogenemia (AF, HF) patients (pts) may experience hemorrhages or thromboses, and the clinical management can be difficult.

Aims: To obtain information on AF/HF clinical phenotype and management.

Methods: This is a spontaneous, retrospective, multicenter national study. Data are collected from clinical records.

Results: 2 AF and 12 HF pts have been enrolled (6M, 8F). Median follow up: 39 months (1-553). Median fibrinogen activity/antigen level: 78 mg/dL (0-150)/73 mg/dL (0-140). 5 pts had epistaxis, hematomas, ecchimoses, menometrorrhagia, intra-abdominal bleeding, gum bleeding, hemarthrosis. Fresh frozen plasma (FFP), Fibrinogen Concentrate (FC), cryoprecipitate, whole blood, tranexamic acid were administered in the majority of these events.

One ischemic stroke, 1 lower limb arterial and 1 cerebral sinus thrombosis, 1concomitant aortic and inferior vena cava thrombosis occurred: 3 events during FC therapy, 1 during puerperium. Heparin, LMWH, anti-platelet agents, fibrinolytic agents, warfarin were then administered.

One gastrectomy, 1 lower limb amputation, 5 gynecological, 1 otorhinolaryngological and 1 plastic surgery were performed in 2 AF and 3 HF pts: in AF pts, FC or FFP prophylaxis was administered while in HF pts was not. Bleeding was observed after 2 surgeries performed without prophylaxis.

8 pregnancies occurred in 3 HF women: 2 vaginal deliveries (VD) and 2 cesarean sections (CS) were performed; 4 spontaneous abortions occurred. In 3 cases, FC prophylaxis and in 4 LMWH was administered during pregnancy. One venous thrombosis, 2 hemorrhages, 1 DIC, complicated 4 pregnancies. FC was administered at delivery and LMWH during puerperium, for the 2CS. No complications at delivery occurred.

Conclusions: AF/severe HF (≤50mg/dL) pts may experience significant hemorrhagic/thrombotic events, which are difficult to manage. The need exists to collect more data, to provide useful information to better characterize and manage these rare diseases.

PB 2028 | Factor X Deficiency Followed by a Tertiary Pediatric Hematology Center

G. Aydogan, Z. Salcioglu, F. Akici, N. Ozdemir, H. Sen, C. Bayram, A. Aycicek, E. Uysalol, G. Ersoy, I. Al, T. Tahtakesen, E. Arslantas

S.B. Kanuni Sultan Suleyman Education and Research Hospital, Pediatric Hematology, Istanbul, Turkey

Background: Congenital factor X (FX) deficiency is a rare bleeding disorder inherited as an autosomal recessive trait with an incidence of 1 : 500 000-1 000 000. It is more common in populations with high rate of consanguineous marriages. A total or partial deficiency of FX causes an impairment of clot formation, leading to a haemorrhagic disease, which manifests with bleeding symptoms of different severity,also unprovoked.

Aims: We analysed the clinical manifestations, laboratory phenotype in 19 patients from Turkey affected with severe FX deficiency.

Methods: The clinical findings, laboratory data, management and outcome in a group of Turkish children diagnosed with FX deficiency in Hematology Clinic of Kanuni Sultan Suleyman Education and Research Hospital were evaulated.

Results: The most frequent bleeding episodes in patients were epistaxis and easy bruising. As a life threatening event intracranial bleeding was reported in 4 of our 19 cases. All of **3** adolescent girls have severe menorrhagia with accompanying iron deficiency anemia. Four patients have intramuscular bleeding, 3 patients have often gingival bleeding, two patients hemarthrosis and two patients bleeding due to operation. Four patients with mild deficiency didn't have any bleeding.One patient with severe intracranial bleeding and recurrent hemarthrosis is under PCC prophilaxis. The adolescent girls with menorrhagia are using oral contraceptives and often PCC during menstruation.

Conclusions: In frequent intracranial attacks prophylaxis is still discussed. There is limited number of reports about PCC prophylaxis. We think that, prophylactic treatment used for hemophilia patients should be considered as an initial therapeutic option for patients with rare factor deficiencies and a severe clinical course, and for those with a factor deficiency that can lead to severe bleeding.

PB 2029 | Correlation of Hemorrhagic Complications with Novel Mutations in FGA And FGG: In Punjabi Congenital Afibrinogenemia Patients

T. Khan[1], A. Naz[1], A. Imran[2], T. Shamsi[1]

[1]National Institute of Blood Disease and Bone Marrow Transplantation, Coagulation and Hemostasis, Karachi, Pakistan, [2]Chughtai's Lab, Coagulation and Hemostasis, Lahore, Pakistan

Background: Congenital afibrinogenemia (OMIM # 202400) inherited as an autosomal recessive trait,manifests with little or absent levels of fibrinogen in plasma. Phenotypic expression of factor I deficiency is still not unanimously established in research literature globally due to vast variability in symptoms which may ranges from minimal bleeding to catastrophic hemorrhage.

Aims: To assess and establish the association between phenotype expression and identified genotype as a reference for future cases.

Methods: This descriptive and cross sectional study was complied with the Declaration of Helsinki, conducted in Karachi and Lahore. Patients with fibrinogen deficiency (Tested by fibrinogen functional assay from Laboratoire Stago, Asnieres, France) were screened for mutations in fibrinogen gene by direct sequencing. Bleeding score also calculated by using Tosetto'sbleeding assessment tool (Tosetto et al).

Results: Total 18 patients were evaluated with mean age group10±2 yrs. All patients were with markedly prolonged PT/APTT and fibrinogen levels (< 0.1g/l). The complication other than common bleeding symptoms in FGA was an intracranial bleed with a history of bone cyst while patient with mutation in FGG showed hemorrhagic appendix and repeated episodes of minor intracranial bleeds.

Conclusions: A high bleeding score is correlated well in both cases. The clinical manifestations of congenital afibrinogenemia in our local population are more or less same as reported in global literature. Few exceptions do exists as we are now observing the slight frequent occurrence of rare complications in our set of patients.

PB 2030 | Treatment of a Rare Case of Congenital A/Hypo Dysfibrinogenemia with Fibrinogen Concentrates: Comparison between Fibrinogen Levels and ROTEM® Parameters

H.A. Guglielmone[1,2], F. Gonzalez[3], B. Rossi[4], S. Marun[5]

[1]Universidad Nacional de Córdoba, Bioquímica Clínica (CIBICI-CONICET), Cordoba, Argentina, [2]Sanatorio Allende, Laboratorio de Hematologia, Cordoba, Argentina, [3]Hospital Italiano, Laboratorio de Hemostasia, Cordoba, Argentina, [4]Hospital Italiano, Servicio de Hematologia, Cordoba, Argentina, [5]Felsan Argentina, Cordoba, Argentina

Background: Congenital hypodysfibrinogenemia is a rare autosomal recessive disorder characterized by extremely low levels of plasma clottable fibrinogen (Fg:Act) and disproportionate immunoreactive Fg (Fg:Ag) concentrations. Fg replacement therapy is effective for treating bleeding episodes in congenital Fg disorders and Fg concentrate has become a standard-of-care in several centers and is recommended for severe bleeding in surgical and trauma patients.

Aims: We report a case of a/hypodysfibrinogenemia in a woman treated with 2 gr of Fg concentrate (Haemocomplettan P®, CSL Behring) before a bone marrow biopsy and the effectiveness of treatment was monitored by Fg:Act, Fg:Ag and ROTEM®

Methods: 60-year-old female with a life-long mild disorder characterized by heavy menorrhagia and prolonged bleeding after tooth extractions. Her mother and a cousin presented similar symptoms. At age of 56, she had a large hematoma in the upper third of the left leg after a sprained knee. In 2010, she was diagnosed with non-Hodgkin lymphoma and underwent chemotherapy, being declared free of disease in late 2014. Laboratory studies showed prolonged prothrombin time, aPTT, thrombin and reptilase time but normal coagulation factors and degradation fibrinogen/fibrin products. Fg:Act and Fg:Ag levels were 15 and 40 mg/dL, respectively (reference range: 200-400 mg/dL).

Results: Minimal bleeding was reported with negligible estimated blood loss. No further treatment was administered and no bleeding complications were reported despite the low levels of Fg (< 100 mg/dL). No changes were observed 60 min after administration of Fg concentrates by ROTEM®. EXTEM, FIBTEM or INTEM parameters were compared to basal values.

Conclusions: In this patient with a/hypodysfibrinogenemia, Fg concentrate was not effective. The results provided by ROTEM showed a correlation with the levels of Fg: Act and Fg: Ag.

PB 2031 | A New Autosomal Dominant Inherited FVIII Defect: Evidence of a Novel Genetic Determinant of Circulating FVIII Levels

V. Daidone, E. Galletta, A. Casonato

University of Padova, Department of Medicine, Padova, Italy

Background: Inherited coagulation factor VIII (FVIII) deficiency is associated with hemophilia A due to mutations in the X-linked FVIII gene; von Willebrand disease (VWD) types 1 and 3, with little or no von Willebrand factor (VWF), the major transporter of circulating FVIII; type 2N VWD with a defective capacity of VWF to bind FVIII; LMAN1 or MCDF alterations causing a combined FV-FVIII defect. We describe a family with a FVIII deficiency caused by none of the above.

Aims: To genetically characterize the disorder and identify new genetic determinants of circulating FVIII levels.

Methods: We investigated the patients' hemostatic and genetic profile using DNA and RNA analyses, and we performed a genome-wide association study (GWAS).

Results: Fourteen family members were studied, and 8 of them (both males and females, from three generations) carried the FVIII defect. The proband, a 51-year-old man with a lifelong mild bleeding history (bleeding score=8), had low FVIII levels and a low FVIII/VWF:Ag ratio, inherited as an autosomal dominant trait (Table 1). All other hemostatic parameters explored were normal. No FVIII or VWF gene mutations were found. FVIII survival and clearance (after DDAVP

TABLE 1 Main hemostatic findings in the proband and some of his relatives

Patients	PT %	PTT sec	FVIII U/dL	VWF:Ag U/dL	FVIII:C ratio	VWF:CB U/dL	VWF:CB ratio	VWF:FVIIIB U/dL	VWF:FVIIIB ratio
Proband	96.7	43.9	27.4	61.3	0.45	57.5	0.93	60.5	1.09
Brother	90.0	42.3	82.0	186.7	0.44	167.1	0.89	210.9	1.13
Sister	63.1	46.1	41.0	92.3	0.45	78.7	0.86	84.4	0.92
Father	94.0	37.3	76.0	77.4	0.99	59.9	0.75	72.6	0.88
Mother	104.0	38.2	85.0	142.3	0.61	161.8	1.16	121.4	0.97
Normal range	80-100	24-36	60-160	60-160	≥0.75	65-150	≥0.75	65-150	≥0.75

infusion) were normal, and no anti-FVIII antibodies emerged. Whole-family GWAS revealed four genomic regions segregating with the defect (chr5:77,218,488-79,351,544; chr7:78,193,129-79,791,947; chr15:40,377,092-45,123,614; and chrX:142,475,363-155,270,560) spanning 21.3Mb (< 1% of the whole genome). The proteins currently known to be involved in FVIII synthesis, release, survival and catabolism all mapped outside these regions, ruling out their involvement as potential disease-causing genes.

Conclusions: Our results suggest a new mechanism and/or gene(s) involved in determining FVIII levels, that seems to have a role in the biosynthetic/secretory phases of FVIII production, mapping within a restricted genomic portion with clearly defined boundaries.

PB 2032 | Rare Bleeding Disorders: Snapshot from a Tertiary Care Hospital of Pakistan

A. Rashid[1], A.M. Memon[2]

[1]*Aga Khan University Hospital, Pathology & Laboratory Medicine, Karachi, Pakistan,* [2]*Aga Khan University Hospital, Karachi, Pakistan*

Background: The rare bleeding disorders (RBD) include inherited deficiencies of coagulation factors other than factor VIII and IX. RBD are transmitted in an autosomal recessive fashion and represent 3-5% of all inherited disorders. Patients with RBD can present with mild to severe life-threatening bleeding. RBD often remain undiagnosed and may result in fatal outcome.

Aims: To determine the frequency of RBD in Pakistani population presented to a tertiary care hospital.

Methods: A retrospective three years analysis was done from January 2014 till December 2016 at Aga Khan University Hospital, Pakistan. Ethical exemption was sought from institutional ethical review committee. Data was extracted by using ISD 9 coding for clotting factor deficiency including factors I, II, V, VII, X, XI, XII, XIII and combined deficiencies of factor V & VIII. Frequencies were generated for quantitative variables.

Results: Out of 335 patients with clotting factor deficiency, 44 (13%) were diagnosed with RBD. The mean age at presentation was 21 years (1 month-75 years). Male to female ratio was 1:1. Of 44 patients, 16 (37%) were found to be factor VII deficient followed by factor XIII,13 (33%); factor V and Fibrinogen, 5 (11%) each; factor X, 3 (7%); factor XI, 1(2%) and combined deficiency of factor V and VIII, 1 (2%). The most common presenting symptom was gum bleeding (34%), epistaxis (23%), hematuria (18%), intracranial bleeding (9%), joint bleeding (4%), bruising (7%) while 5% were asymptomatic and diagnosed on pre-operative workup of prolonged coagulation profile.

Conclusions: Thirteen percent patients were diagnosed with RBD, factor VII deficiency (37 %) being the most common. The data on rare bleeding disorders would serve to constitute RBD database registry on national level that will help in genetic counseling, early diagnosis, validation of bleeding scores and evaluation of bleeding risk assessment; especially prior to surgical interventions and formation of consensual therapeutic measures.

PB 2033 | Severe Congenital Factor VII Deficiency in Northern Region of Turkey

D. Albayrak[1], C. Albayrak[2]

[1]*Samsun Medicalpark Hospital, Pediatric Hematology, Samsun, Turkey,* [2]*Ondokuz Mayis University, Pediatric Hematology, Samsun, Turkey*

Background: Congenital factor VII deficiency is a rare genetic coagulation disorder with a prevalence of 1/500.000 population. However, it is possible more common in populations in which consanguineous marriage ratio is high. Thus, frequency will be different in each country. Patients with factor VII deficiency may have severe bleeding symptoms or be asymptomatic.

Aims: In this study, we present clinical presentation and demographic features of our patients of factor VII deficiency retrospectively.

Methods: We retrospectively reviewed medical records of 12 patients with FVII deficiency in Ondokuz Mayis University, Department of Pediatric Hematology between 2005 to 2014 and discussed with the literature.

Results: Twelve patients (7 male and 5 female) with FVII deficiency were included in the study. Ages at diagnose were ranged from six month to sixteen years. Median factor VII level was 5.6% and ranged from 2% to 17.4%. Mucocutaneous bleeding was the most common clinical presentation. Four cases undergo surgical operations, four circumcision and one thyroid biopsy. Activated factor VII were used for bleeding control. Activated factor VII dose was 30 mcg/kg/dose in 4 hour interval and total 6 doses in circumcision operations; and 30 mcg/kg/dose in 4 hour interval total 3 doses in thyroid biopsy. Bleeding control was good in operations.

Conclusions: Our cases in this study had relatively less bleeding episodes and no patient has a severe bleeding episode. We didn't see any

thromboembolic complications during and after therapy. No bleeding was seen after surgery. FVII deficiency is relatively frequent in Turkey. Most of them is mild and asymptomatic cases. Presented cases is severe cases but they have no severe bleeding history and a prophylaxis requirement.

PB 2034 | Evaluation of Rare Factor Deficiencies in Presurgical Plasma Samples

Z. Kaya, Ç. Özütok

Gazi University Medical Faculty, Pediatric Hematology, Ankara, Turkey

Background: Rare factor deficiencies account for 3% to 5% of all inherited coagulation factor deficiencies. Most asymptomatic cases of rare factor deficiency are diagnosed based on PT and APTT.

Aims: We retrospectively investigated the results of rare factor levels in patients who had prolonged PT and/or APTT on preoperative screening.

Methods: Data were collected from 719 patients who, over a 1-year-period, had been referred to our hemostasis laboratory to determine the cause of prolonged PT and APTT in presurgical plasma samples. The samples were analyzed in an ACL TOP 700 coagulation analyzer. All patients had normal lupus anticoagulant tests. Factor deficiency samples were classified based on factor activity levels below 50% of the lower limit of our laboratory's range.

Results: Fifty-six patients (median age, 8 years; range, 1-21 years; 54% males) were identified as having rare factor levels. Among these cases, the respective frequencies of FVII deficiency, FXI deficiency, FXII deficiency, and FV deficiency were 76%, 14%, 6% and 4%. The level of FVII below 40% was observed in 23/56 (41%) patients. PT was 4s longer than the upper limit of our laboratory's normal range in 16 cases of FVII level below 30%, PT was prolonged by 2-4 s in 24 cases of FVII level 30% to 50%, and PT was prolonged by less than 2 s in three cases of FVII level below 15%. APTT was 4 s longer than the upper limit of our laboratory's normal range in all cases of FXI and FXII deficiency with factor level below 50%. Both PT and APTT were prolonged more than 4 s in two cases of FV level below 1%.

Conclusions: The frequency of rare factor deficiencies in our study is similar to previous reports. Measurement of rare clotting factor levels may not be necessary in samples with mildly (< 4 s) prolonged APTT, particularly in cases of presurgical screening.

PB 2035 | Spotting of Two Novel Mutations in FGG Gene: In Unrelated Patients of Congenital Afibrinogenemia in Pakistan

T. Khan[1], A. Naz[1], A. Biswas[2], A. Goodeve[3], N. Ahmed[4], S. Ahmed[1], T. Shamsi[1], J. Oldenburg[2]

[1]National Institute of Blood Disease and Bone Marrow Transplantation, Coagulation and Hemostasis, Karachi, Pakistan, [2]Institute of Experimental Hematology and Transfusion Medicine, Bonn, Germany, [3]Sheffield Diagnostic Genetics Service, Sheffield, United Kingdom, [4]Children's Hospital, Pediatrics, Lahore, Pakistan

Background: Congenital afibrinogenemia (OMIM # 202400) transmitted as autosomal recessive trait is considered as a rare inherited bleeding disorder with little or absent levels of fibrinogen in circulating blood. The swiftly increasing numbers of new cases of this disorder in Pakistan in strong association with consanguinity is now placing a big question mark on its rarity.

Aims: To screen FGG gene for possibly existing mutations after sequencing FGA and FGB genes.

Methods: This descriptive and cross sectional study was conducted in Karachi and Lahore, fully complied with the Declaration of Helsinki. Patients with fibrinogen deficiency (Tested by fibrinogen functional assay from Laboratoire Stago, Asnieres, France) were screened for mutations in fibrinogen gamma (FGG) genes by direct sequencing after sequencing of FGA and FGB.

Results: Out of 18patients, three were found to have novel mutations in FGG. These mutations are so far the first to be detected and reported in FGG in Pakistan. Out of three, two mutations are Nonsense and were identified in two siblings and one is a frameshift mutation.

Conclusions: Congenital afibrinogenemia is a rapid growing problem in countries such as Pakistan where consanguinity is frequently practiced. This study illustrates the fact that the incidence of mutations occurring in FGG is also growing fast in our populationand these are no longer rare mutations.

PB 2036 | Factor VII Deficiency: One Novel Mutation and Genotype-phenotype Correlation in Patients from Southern Italy

G. Tiscia[1], G. Favuzzi[2], E. Chinni[2], D. Colaizzo[2], L. Fischetti[2], M. Intrieri[3], M. Margaglione[4], E. Grandone[2,5]

[1]Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy, [2]IRCCS Casa Sollievo della Sofferenza, Thrombosis and Hemostasis, San Giovanni Rotondo, Italy, [3]University of Molise, Medicine and Health Sciences, Campobasso, Italy, [4]University of Foggia, Medical Genetics, Foggia, Italy, [5]CSS, San Giovanni Rotondo, Italy

Background: Inherited FVII deficiency is an autosomal recessive trait and constitutes the most frequently diagnosed rare coagulation disorder. Genotype and phenotype are poorly correlated.

Aims: To add insights into molecular and clinical aspects of FVII deficiency. Here, we present molecular and clinical findings of 7 apparently unrelated patients with FVII deficiency.

Methods: From 2013 to 2016, 7 (4 male, 3 female) subjects were referred to our Centre because of a prolonged PT identified during routine or pre-surgery examinations or to undergo investigations for a bleeding episode. Informed consent was provided by patients. Mutation characterization has been performed by using a series of *in silico* applications: PROMO, SIFT, and Polyphen-2. Structural changes in FVII protein were analysed by using the SPDB viewer tool.

Results: We identified 3 compound heterozygous/homozygous and 4 heterozygous individuals with FVII deficiency. Overall, molecular investigations revealed 8 mutations. To the best of our knowledge, 1 mutation identified is novel: the c.1199G>C (p.Cys400Ser) mutation

within the exon 9. Also, we identified the c.-54G>A polymorphism (rs367732974) in *F7* 5'-upstream region, that has been never reported in FVII deficiency, although in EXAC database, this polymorphism shows an allele frequency < 1%. *In silico* predictions identified differences in binding sites for transcription factors for the c.-54G>A variant. In a silico approach, by means of the SPDB viewer tool, we visualized the possible damaging effect of p.Cys400Ser on FVII active conformation, leading to a breaking of a disulphide bridge. Also, we identified the c.-30A>C, c.430+1G>A, p.Val214Gly, p.Ala304Val, p.Gly391Ser, p.Cys400Ser, c.805+1G>A mutations. We recorded a CNS bleeding. Bleeding tendency was heterogeneous and no genotype/phenotype relationship have been observed.

Conclusions: Our findings further suggest that independently of the mutation affecting FVII levels, environmental factors heavily influence the clinical phenotype.

PB 2037 | Successful Delivery in an Afibrinogenemia Patient after Three Abortions: A Case Report and Review of Literature

M. Karimi[1], M. Bordbar[1], M. Aali[2], A. Bazrafshan[1], H. Tavoosi[2], J. Gerdabi[3]

[1]*Hematology Research Center, Shiraz University of Medical Sciences, Shiraz, Iran, Islamic Republic of,* [2]*Shiraz Hemophilia Comprehensive Center, Dastgheib Hospital, Shiraz, Iran, Islamic Republic of,* [3]*Shiraz Comprehensive Coagulation Laboratory, Dastgheib Hospital, Shiraz, Iran, Islamic Republic of*

Background: Afibrinogenemia is accompanied with miscarriage and prophylaxis is recommended as soon as pregnancy is confirmed.

Aims: We present an afibrinogenemia patient with a novel mutation having successful delivery after three abortions.

Methods: A 23 -year- old female who was diagnosed as an afibrinogenemia at the age of 5 years old. The genetic analysis showed a homozygote new nonsense mutation [g.4347G>T; Gly358Stop]). The patient was on prophylaxis on the third pregnancy starting at gestational age of 7 weeks but was unsuccessful.

Fibrinogen concentrate (Haemocomplettan P, CSL Behring) was given with dose of 60 mg kg^{-1} thorough her 4th pregnancy. The total dose or frequency (one to three times per week) was increased as pregnancy advanced based upon her weight and fibrinogen activity levels. Tranexamic acid intravenously (15 mg kg^{-1}) was started one hour prior to delivery followed by 1 mg/kg/hour continuous infusion for 48 hours. It was switched to oral throughout post-delivery day 7.

Results: NTProphylaxis was commenced at gestational age of 4 weeks for her 4th pregnancy. Our case had the keep target level of between 50-100 mg dl^{-1} during first and second and 100 mg dl^{-1} during third trimesters and at term (table 1). The patient had no bleeding event during pregnancy leading to successful normal vaginal delivery at gestational age of 40 weeks.

Conclusions: Maintaining fibrinogen trough level of 50-100 mg dl^{-1} during pregnancy with the aim of keeping level of 100 mg dl^{-1} as pregnancy ended seems to be safe. This case report underscores prophylaxis should be started early in pregnancy. Moreover, normal vaginal delivery is superior to cesarean section because of lesser risk of thrombosis if clinically implemented. Antifibrinolytic drugs might be an alternative option to hold fibrinogen concentrate and reduce the risk of thrombosis if not contraindicated. This strategy was successful in our case without any thrombosis or significant bleeding events.

PB 2038 | Are Screening Coagulation Tests Useful to Predict the Clinical Phenotype in Patients with A/Hypo/Dysfibrinogenemia? A Single Institution Experience

H.A. Guglielmone[1,2], S. Minoldo[3], M.A. Alvarez Bollea[2], G.D. Jarchum[2]

[1]*Universidad Nacional de Córdoba, Bioquímica Clínica (CIBICI-CONICET), Cordoba, Argentina,* [2]*Sanatorio Allende, Laboratorio de Hematologia, Cordoba, Argentina,* [3]*Sanatorio Allende, Laboratorio de Hematologia-Sanatorio Allende, Cordoba, Argentina*

Background: A/hypo/dysfibrinogenemia (a/hypo/dys) is a rare congenital disorder characterized by mutations in any of the three fibrinogen (Fg) genes (FGA, FGB, FGG) that encode the three polypeptide chains (Aα,Bβ,γ) of the fibrinogen molecule. Most carriers of this disorder are asymptomatic (A), while a few patients may present either thrombotic (T) or bleeding (B) disorders.

Aims: We intended to establish whether the use of standard coagulation assays allows predicting the clinical phenotype in 17 patients with a/hypo/dys and thus, improving the use of the therapeutic resource.

Methods: Patients were recruited at Sanatorio Allende, Córdoba, Argentina and 4, 2 and 11 of them respectively presented different mutations in *FGA*, *FGB* and *FGG* genes; the clinical phenotypes were: 9 A, 3 T and 5 B. Prothrombin time (PT); aPTT, thrombin and reptilase time (TT and RT) as well as functional and antigen Fg (Fg:f and Fg:Ag) were performed using standard procedures.

Results: TP and aPTT showed normal or slightly prolonged times while TT and RT were significantly prolonged with a mean of 65 sec (range: 17-200 sec, normal range: 11-14 sec) and 45 sec (range: 15-75 sec, normal range: 12-15 sec), respectively. Fg:f and Fg:Ag showed an average of 92 mg/dl (range: 9-170 mg/dl, normal range: 200-400 mg/dL) and 168 mg/dl (range: 31-301 mg/dl, normal range: 200-400 mg/dl), respectively.

Conclusions: Unfortunately, screening clotting assays do not allow to predict the clinical phenotype in a/hypoDysFg patients and are also unhelpful for improving early prophylaxis to protect them from thrombotic and/or hemorrhagic events.

PB 2039 | Congenital Afibrinogenemia Case Presenting with Surrenal Bleeding and Cervical Hematoma

H. Kızılocak[1], N. Özdemir[1,2], Z. Şalcıoğlu[3], B. Koç[3], E.P. Uysalol[3], C. Bayram[3], G. Dikme[1], T. Celkan[1]

[1]*Istanbul University, Cerrahpasa Medical Faculty, Pediatric Hematology-Oncology, Istanbul, Turkey,* [2]*Kanuni Sultan Süleyman Training and Research Hospital, Pediatric Hematology-Oncology, Istanbul, Turkey,* [3]*Kanuni Sultan Süleyman Training and Research Hospital, Istanbul, Turkey*

Background: Congenital afibrinogenemia is a rare autosomal recessive disorder. Clinical manifestations vary in severity.

Aims: Here we present a congenital afibrinogenemia case who presented with surrenal bleeding and cervical hematoma.

Methods: -

Results: A 50 day baby presented with a cervical mass. He was born full -term from second degree consanguineous parents. His history revealed severe umblical cord bleeding. Plasma fibrinogen level was undetectable. Cervical USG revealed a hematoma which caused torticollis. Abdominal USG showed a surrenal mass consistent with hematoma. Prophylactic treatment with plasma derived fibrinogen concentrate was started. Surrenal hematoma regressed and disappeared on follow-up. Cervical hematoma regressed however persisted under treatment. Physiotherapy was started under factor replacement.

Conclusions: Afibrinogenemia is usually associated with mild to moderate bleeding and patients may present with umblical cord, gum and nose bleeding. There is still no consensus on standart treatment approach. Some patients may have a more severe phenotype and experience intracranial bleeding or atypical presentation. Secondary prophylactic replacement therapy is recommended in selected cases however optimal fibrinogen level to prevent spontaneous bleeding is yet to be investigated.

PB 2040 | Severe Congenital Factor X Deficiency in the Northern Region of Turkey: Successful Prophylaxis with Activated Prothrombin Complex Concentrates

C. Albayrak[1], D. Albayrak[2]

[1]*Ondokuz Mayis University, Pediatric Hematology, Samsun, Turkey,* [2]*Samsun Medicalpark Hospital, Pediatric Hematology, Samsun, Turkey*

Background: Congenital factor X (FX) deficiency is a rare autosomal recessive bleeding disorder that is estimated to occur in a frequency of 1:1 000 000. Bleeding symptoms in patients with FX deficiency range from a mild bruising tendency and intracranial haemorrhage.

Aims: In this study, we evaluated children with severe congenital FX deficiency in our Pediatric Hematology Department which is a tersier reference center in the northern region of Turkey.

Methods: Between last ten-year period, three patients have been diagnosed as severe congenital FX deficiency in our center. All of them had been admitted to hospital spontaneous life-threatening intracranial haemorrhage (I) in a few days old. INR and APTT were both markedly prolonged. All coagulation factors analysis demonstrated normal results, except for FX activity (FX:C)< 1%. The family histories revealed a consanguineous marriage in the parents. The children were treated and operated with fresh frozen plasma (FFP) and activated prothrombin complex concentrates (aPCC). But a few days later, spontaneous life-threatening ICH were recurred and treated and operated.

Results: In Turkey, because purified FX concentrate and prothrombin complex concentrate is not yet available, FFP are the main therapeutics used. For patients who suffer intra-cranial haemorrhage, FFP infusion results in severe squeal. FFP is no available in living site of patient, compliance will be poor and long-term use of FFP has other risk. For this reason, we seek an alternative treatment for prophylaxis. aPCC contain some amount of factor X. It is a commercial product and ready to use in Turkey as bypass agent. Our patient can be used this concentrate We obtain an approval for each patient from national health authority to use off-label aPCC prophylaxis two times a week, 50IU/kg/dose.

Conclusions: Our patients were used aPCC prophylaxis for 10, 4 and 2 years respectively. They did not experience any new bleeding under prophylaxis. We think that aPCC may be used in prophylaxis of FX deficiency.

PB 2041 | Pseudoxanthoma Elasticum-like Disease with Deficiency of Vitamin K-dependent Clotting Factors, Hypofibrinogenemia and Cutis Laxa Features: A Case Report

K. Taouli Allal[1], M. Hanini[1], O. Boudghene Stambouli[2], S. Bouali[3], I. Gaouar[3]

[1]*Tlemcen University, Hematology Laboratory, Tlemcen, Algeria,* [2]*Tlemcen University, Dermatology, Tlemcen, Algeria,* [3]*H. University Tlemcen, Laboratory Hematology, Tlemcen, Algeria*

Background: Pseudoxanthoma elasticum (PXE)-like syndrome is characterized by the association of PXE and cutis laxa (CL) features with a deficiency of vitamin K-dependent clotting factors. It was first described in 1971 and was identified as a distinct genetic entity in 2007 with analysis of the GGCX (-glutamyl carboxylase) gene, which is involved in congenital defciency in vitamin K-dependent clotting factors. Here we report a new case of this extremely rare syndrome.

Aims: A 30-year-old female patient was seen for the emergence for recurrent cardiac tamponade after pericardial and pleural puncture and pericardial drainage; clinical survey found signs of slight panhypopituitarism. The interrogation of patient revealed gastrointestinal bleeding in 2015.

Physical examination revealed yellowish papules and plaques and retinal angioid streaks. A skin biopsy revealed polymorphous and fragmented elastic fibers in the reticular dermis. These were mineralized, as was demonstrated by Von Kossa staining.

Methods: Laboratory tests showed insufficient thyroid-stimulating, low cortisol, a hypogonadism and low coagulation factors.

VitaminK-dependent clotting factor deficiency led us to a diagnosis of PXE-like syndrome. A molecular study of the GGCX gene showed compound heterozygosity.

Results: The GGCX gene is usually responsible for PXE-like syndrome. GGCX encodes a -

glutamyl carboxylase necessary for activation of gla-proteins. Gla-proteins are involved both in coagulation factors in the liver and in the prevention of ectopic mineralization of soft tissues. Uncarboxylated forms of gla-proteins in fibroblast would thus enable mineralization and fragmentation of elastic fibers.

Conclusions: Digestive manifestations are unusual; however, pseudoxanthomaelasticum should be considered in all cases of gastrointestinal bleeding for no apparent reason. Early diagnosis allows prevention and measures to control the risk factors and limit the progression of complications.

PB 2042 | Rare Inherited Coagulation Disorder (RICD) in Females - Data from a Developing Country

S. Hussain[1], S. Baloch[2], A. Gaffar[3], A. Najmuddin[3], S. Aqeel[3], F. Musheer[4], S. Nawaz[5]

[1]Fatimid Foundation, Haematology Department, Karachi, Pakistan, [2]Fatimid Foundation, Quality Assurance, Karachi, Pakistan, [3]Fatimid Foundation, Haemophilia Department, Karachi, Pakistan, [4]Fatimid Foundation, Haemophilia Department, Lahore, Pakistan, [5]Fatimid Foundation, Haemophilia Department, Multan, Pakistan

Background: Clinical spectrum of RICD is less clearly defined in females. Pakistan has poor health resources and a high rate of consanguinity. This makes the likelihood of RICD relatively higher in our population. Due to the societal pressure to marry and reproduce at an early age, the risk of bleeding during childbirth is also increased.

Aims: To assess the clinical spectrum of RICD in females registered at a not-for-profit organization.

Methods: In this case series from 1st October till 31st December 2016, we analyzed retrospective data collected from medical record files. Tests performed included prothrombin time (PT), activated partial thromboplastin time, mixing studies, thrombin time, factor assay, clot solubility test in 5 M urea and fibrinogen level. Socio-demographic data, bleeding phenotype and treatment details were also recorded.

Results: Twenty three females with RICD were identified. Of these, 5 (22%) were below 12 years of age and 18 (78%) were in the reproductive age group (12 to 49 years). History of consanguineous marriage was present in 10 (44%). Median age of onset of the first episode of bleeding was at 2 years (range; 2 months to 12 years). Factor V deficiency (n=5, 22%) was the most frequent followed by factor X deficiency (n=4, 17%), hypofibrinogenemia (n=4, 17%), afibrinogenemia (n=4, 17%), factor VII (n=2, 9%) and factor XIII deficiency (n=2, 9%). Based on the results of mixing studies, factor X and factor V deficiency were suspected in n=2 (9%) females. Mucocutaneous bleeding (n=19, 83%) was the most common presentation. Menorrhagia (n=3, 13%), umbilical stump (n=7, 30%) and musculoskeletal (n=10, 44%) bleeding were also present. Miscarriage (n=1) and postpartum haemorrhage (n=1) occurred in females with afibrinogenemia and factor V respectively. All females were treated with fresh frozen plasma and cryoprecipitate.

Conclusions: The most common RICD in females was factor V deficiency. Clinical spectrum was different from that of western population. Treatment was mainly with blood components.

PB 2043 | Congenital Factor V Deficiency

E. Yakovleva, N. Konyashina, L. Gorgidze, O. Polevodova, E. Likhacheva, M. Kumskova, N. Zozulya

National Research Center for Hematology, Moscow, Russian Federation

Background: Congenital FV deficiency is rare bleeding disorder with an estimated incidence of 1 in 1000000. There is a variable spectrum of bleeding manifestations ranging from epistaxis to life-threatening hemorrhages. Severity is defined as mild (> 5% of factor activity), moderate (1%-5%) and severe (< 1%).

Aims: To assess the clinical-laboratory features of FV deficiency in 2 patients.

Methods: A 25- year-old woman (patient A) and a 30-year- old man (patient B) were examined. Patient A suffers from menorrhagia. Bleeding episodes of patient B consist trauma-related bleeds, hemartroses, muscular hematomas, gastrointestinal bleeding. Both have a negative family history for bleeding disorder.

Were performed standard coagulation assay, as well as global hemostatic tests: activated partial thromboplastine time (APTT), prothrombin ratio (PR), international normalized ratio (INR), thrombin time (TT), concentration of fibrinogen, factors of prothrombin complex, thromboelastography (TEG) and rotational thromboelastometry (ROTEM).

Results:

Data of patient A: APTT 35s (29-36); PR 53,4%(70-120), INR 1,44(0,85-1,35); FV 34% (70-120). Parameters of TEG (R, K, α MA, LY 30) and ROTEM (EXTEM, INTEM: CT, CFT, α, A10, A20, MCF, ML) are normal.

Data of patient B: APTT 155s; PR 12%; INR 5,18; FV 0,4%. Parameters of TEG are changed: α 7,9° (22-58); R 75 min (9-27); MA 34mm (44-64).

Results of ROTEM are changed too. EXTEM: CT 697s (38-79); CFT 425s (34-159); α 33° (63-83), A10 28mm (43-65); A20 47mm (50-71). INTEM: CT 1490s (10-240); CFT 299s (30-110); α 43° (70-83), A10 33mm (44-66); A20 43mm (50-71).

Conclusions: Patient A has mild FV deficiency according to factor FV activity level and mild bleeding phenotype of the disease. Patient B has severe FV deficiency according to factor FV activity level and severe bleeding phenotype of the disease. In both cases, the FV activity level has correlation with the severity of bleedings. The activity FV reduction by half does not cause changes in the TEG and ROTEM.

PB 2044 | Von Willebrand Factor Deficiency Reduces Experimental Liver Fibrosis in Mice

J. Luyendyk[1,2,3], N. Joshi[2,3], A. Kopec[1,3], J. Ray[1], H. Cline-Fedewa[1], D. Groeneveld[4], T. Lisman[4]

[1]*Michigan State University, Pathobiology and Diagnostic Investigation, East Lansing, MI, United States,* [2]*Michigan State University, Pharmacology and Toxicology, East Lansing, MI, United States,* [3]*Michigan State University, Institution for Integrative Toxicology, East Lansing, MI, United States,* [4]*University of Groningen, Department of Surgery, Groningen, The Netherlands*

Background: Liver diseases are associated with complex changes in the hemostatic system and elevated levels of the platelet-adhesive protein Von Willebrand factor (VWF) are reported in patients with acute and chronic liver damage. Although elevated levels of VWF are associated with fibrosis in the general population, the role of VWF in acute and chronic liver injury has not been examined in depth in experimental settings.

Aims: We tested the hypothesis that VWF deficiency inhibits experimental liver injury and fibrosis.

Methods: Wild-type and VWF-deficient mice were challenged with a hepatotoxic dose of carbon tetrachloride (1 ml/kg; CCl_4) either once to induce acute liver injury, or twice weekly for six weeks to induce liver fibrosis.

Results: VWF deficiency did not significantly affect acute CCl_4-induced hepatocellular necrosis in mice. Chronic CCl_4 challenge, twice weekly for 6 weeks, significantly increased hepatic stellate cell activation and collagen deposition in livers of wild-type (WT) mice. Interestingly, hepatic induction of several profibrogenic and stellate cell activation genes was attenuated in VWF-deficient mice. Moreover, birefringent sirius red staining (indicating type I and III collagens) and type I collagen immunofluorescence indicated a reduction in hepatic collagen deposition in CCl_4-exposed VWF-deficient mice compared to CCl_4-exposed WT mice.

Conclusions: The results indicate that VWF deficiency attenuates chronic CCl_4-induced liver fibrosis without affecting acute hepatocellular necrosis induced by this classic hepatotoxicant. Moreover, the results constitute experimental evidence to suggest that elevated plasma VWF levels in patients with cirrhosis are mechanistically linked to the progression of liver fibrosis.

PB 2045 | Genotypical Classification of Patients with von Willebrand Disease

W. van Heerde[1], A. Simons[2], S. Krouwel[3], S. Schoormans[3], B. Laros[4], P. Brons[5], M.R. Nijziel[6]

[1]*Radboudumc, Dept of Laboratory Medicine, Laboratory of Hematology, Hemophilia Care Center, Nijmegen, The Netherlands,* [2]*Radboudumc, Dept of Human Genetics, Nijmegen, The Netherlands,* [3]*Radboudumc, Dept of Laboratory Medicine, Laboratory of Hematology, Nijmegen, The Netherlands,* [4]*Radboudumc, Dept of Hematology, Hemophilia Care Center, Nijmegen, The Netherlands,* [5]*Radboudumc, Dept of Pediatrics, Hemophilia Care Center, Nijmegen, The Netherlands,* [6]*Radboudumc, Dept of Hematology, Hemophilia Care Center, Expertise Center for Hemophilia and Rare Bleeding Disorders, Nijmegen, The Netherlands*

Background: Von Willebrand disease (vWD) is a bleeding disorder caused by inherited defects in the concentration, structure or function of Von Willebrand Factor (vWF). vWD can be divided in three subclasses, but classification remains difficult.

Aims: We improved vWD classification by performing *VWF* direct sequencing for diagnostic purposes.

Methods: Targeted gene analysis was performed on 504 patients suspected to have vWD, either by classical Sanger sequencing or by ion semiconductor next generation sequencing technology. All coding regions including intron-exon boundaries were sequenced. Large deletions/duplications in the *VWF* gene were detected by MLPA. Recently whole exome sequencing (WES) was implemented to search for *VWF* and other genetic abnormalities.

Results: 504 patients were analysed. 311 patients had a *VWF* genetic abnormality. Mutations found were 11 nonsense, 299 missense and 9 splice-site mutations, 25 small deletions, 7 duplications and 15 large deletions detected by MLPA. 193 patients had no mutations in the *VWF* gene. Of all mutations detected 315 were reported previously and 51 were novel. The novel mutations found were 3 nonsense, 29 missense and 4 splice-site mutations, 3 duplications and 12 small deletions. 78 patients were carrying the D1472H polymorphism affecting the von Willebrand Factor Ristocetin cofactor activity. The first WES results showed combinations of *VWF* abnormalities with other autosomal recessive abnormalities in genes involved in other primary hemostasis disorders like Hermansky Pudlak Syndrome.

Conclusions: Our systematic targeted genotypic approach resulted in 62% of the cases in vWD confirmation and in 91% of the confirmed cases a vWD classification. Since the overall yield to detect (likely) pathogenic mutations was only approximately 60% with the conventional targeted gene analysis approach and bleeding scores do not always match, we recently implemented WES. That approach resulted in additional genetic abnormalities affecting primary hemostasis including vWD.

PB 2046 | Common VWF Sequence Variants Associated with Higher VWF and FVIII Are Less Frequent in Subjects Diagnosed with Type 1 VWD

V. Flood[1,2], J. Johnsen[3], P. Christopherson[2], S. Haberichter[1,2], R. Udani[2], D. Bellissimo[4], K. Friedman[2], R. Montgomery[1,2]

[1]*Medical College of Wisconsin, Pediatric Hematology, Milwaukee, United States,* [2]*Blood Research Institute, BloodCenter of Wisconsin, Milwaukee, United States,* [3]*BloodWorks Northwest, Seattle, United States,* [4]*University of Pittsburgh, Pittsburgh, United States*

Background: Genetic variation in the *VWF* gene is associated with von Willebrand Factor (VWF) and factor VIII (FVIII) levels in healthy individuals.

Aims: We hypothesized that *VWF* DNA variants associated with higher VWF or FVIII could impact the diagnosis of type 1 von Willebrand disease (VWD).

Methods: We examined VWF antigen (VWF:Ag), VWF ristocetin cofactor activity (VWF:RCo), VWF propeptide (VWFpp), and FVIII levels along with *VWF* gene sequencing in subjects enrolled in the Zimmerman Program for the Molecular and Clinical Biology of VWD.

Results: We found *VWF* c.2880G>A associated with higher VWF (means 149, 107) and FVIII levels in healthy controls ($p < 0.001$), as previously reported. *VWF* c.2880G>A was significantly more common in controls (36% European American, 61% African American) than in subjects diagnosed with type 1 VWD and VWF:Ag < 30 (20%, $p < 0.005$). Two other *VWF* variants in linkage disequilibrium, c.2365A>G and c.2385T>C, were associated with higher VWF and FVIII ($p < 0.001$). *VWF* c.2365A>G was also more common in healthy controls (49% European American, 88% African American) than type 1 VWD subjects (35%, $p < 0.001$). VWF:Ag, VWF:RCo, and FVIII were not statistically different in type 1 VWD subjects who had these *VWF* variants compared to type 1 VWD patients without them. There was no difference in ABO blood group, VWFpp levels (excluding subjects with known VWF clearance defects), or bleeding score using the ISTH bleeding assessment tool. When other pathogenic *VWF* sequence variants were excluded, similar results were obtained. *VWF* variant frequencies were similar to healthy controls for subjects with a historical diagnosis of type 1 VWD but current VWF:Ag >50 or with a diagnosis of type 2 VWD.

Conclusions: These data suggest that certain *VWF* sequence variants associated with elevated FVIII and VWF levels may be protective against a diagnosis of type 1 VWD. These findings were independent of other sequence variants in *VWF*, supporting the independent effect of c.2880G>A and c.2365A>G/c.2385T>C on VWF levels.

PB 2047 | Interactomics of the Weibel-palade Body Exocytotic Machinery

M. Schillemans, M. Wahedi, D. van Breevoort, M. van den Biggelaar, J. Voorberg, R. Bierings

Sanquin Research, Plasma Proteins, Amsterdam, The Netherlands

Background: Endothelial cells store Von Willebrand factor (VWF) in elongated secretory organelles, so called Weibel-Palade bodies (WPBs). Upon vascular damage or stress WPBs undergo exocytosis, which is orchestrated by a complex network of proteins consisting of Rabs, Rab-effectors and the SNARE complex. Genome wide association studies (GWAS) for genetic determinants of VWF levels have identified a number of new regulators that are part of the SNARE complex (STXBP5 and syntaxin-2) arguing that exocytosis of WPBs is a significant determinant of VWF levels. We have previously identified STXBP1, syntaxin-2 and syntaxin-3 as downstream targets of the Rab27A-Slp4-a complex which promotes WPB exocytosis. Despite the overlap between mechanistic and GWAS studies, we currently do not know the exact composition of the WPB exocytotic machinery and how all these individual components together orchestrate WPB release.

Aims: We used an unbiased iterative interactomics approach to identify new components of the WPB exocytotic machinery to further elucidate the mechanisms that control VWF secretion.

Methods: Lentivirally expressed mEGFP-tagged fusion proteins were pulled down from endothelial cells using GFP nanobody conjugated magnetic beads. Specific interactors were identified using mass spectrometry.

Results: We determined the endothelial interactome of syntaxin-3 and identified a number of SNARE proteins (NSF, SNAP23, STXBP2 and STXBP5) as well as regulators of microvilli formation. Using pull-downs we show that the C-terminal VAMP-like domain (VLD) of STXBP5 is indispensable for the interaction with syntaxin-2, -3 and -4. Subsequent proteomic profiling of the STXBP5 VLD interactome identified a large number of additional SNARE proteins. STXBP5 N436S, a variant containing a nonsynonymous SNP that is linked to decreased VWF levels, still interacts with syntaxin-2, -3 and -4.

Conclusions: Our data provide mechanistic detail on how SNAREs proteins regulate release of VWF from endothelial cells.

PB 2048 | Structural Thermodynamics of a Clinically Elusive High-affinity von Willebrand Factor Binding to Platelet GPIbα

A. Tischer[1], V. Machha[1], J. Frontroth[2], M. Brehm[3], T. Obser[3], R. Scheppenheim[3], L. Mayne[4], S.W. Englander[4], M. Auton[1]

[1]Mayo Clinic, Division of Hematology, Rochester, United States, [2]Servicio de Hematologia y Oncologia, Hospital de Pediatr'ia, ,Prof. Dr. Juan P. Garrahan', Laboratorio de Hemostasia y Trombosis, Buenos Aires, Argentina, [3]University Medical Centre Hamburg-Eppendorf, Department of Paediatric Haematology and Oncology, Hamburg, Germany, [4]University of Pennsylvania, Johnson Research Foundation, Department of Biochemistry and Biophysics, Perelman School of Medicine, Philadelphia, United States

Background: Mutation of the cysteines forming the disulfide loop of the platelet GPIbα adhesive A1 domain of von Willebrand factor causes quantitative VWF deficiencies in the blood and von Willebrand disease. Two patients with C1272W and C1458Y mutations presented with DDAVP-induced severe thrombocytopenia that quickly relapsed to normal platelet counts and deficient plasma VWF.

Aims: The focus of this study is to determine how loss of the VWF A1 domain disulfide bond induces gain-of-function and identify the structural determinants for high-affinity by comparing the structural and functional properties of normal disulfide intact A1 with a reduced and carboxyamidated A1 that blocks the formation of the disulfide.

Methods: Using surface plasmon resonance, analytical rheology, and hydrogen-deuterium exchange mass spectrometry (HXMS), we decipher thermodynamic mechanisms of A1-GPIbα mediated platelet adhesion and resolve dynamic secondary structure elements that regulate the binding pathway.

Results: Constrained by the disulfide, dynamic selection between weak and tight binding conformations of A1 by GPIbα takes precedence and drives normal platelet adhesion to VWF. Unrestrained, loss of the disulfide partially disorders A1 and preferentially diverts

binding through an induced fit pathway with high-affinity contacts between locally disordered structures in both A1 and GPIbα. HXMS identifies an asymmetry of structurally dynamic and ordered regions common to both variants indicating that A1 lacking the disulfide retains native-like structural properties in the partially disordered state. Firm platelet adhesion to VWF is complemented by the dynamic flexibility of GPIbα and its ability to efficiently sample disordered conformations of A1 for high affinity contacts.

Conclusions: With these methods in place, structure-resolved mechanistic phenotyping of VWD becomes a real possibility that when combined with genotyping enables the prediction of how VWD patients manifest the symptoms of disease.

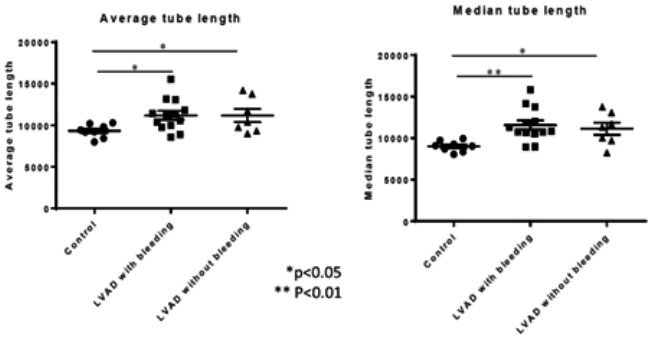

FIGURE 1 Plasma angiogenesis assay results in LVAD and control plasma

PB 2049 | Pro-angiogenic Signal in Plasma of Left Ventricular Assist Device Patients

A. Sharma[1], Y. Wang[1], D. Mukhopadhyay[1], R. Safford[2], J. Blackshear[2]

[1]*Mayo Clinic, Biochemistry and Molecular Biology, Jacksonville, United States,* [2]*Mayo Clinic, Cardiovascular Diseases, Jacksonville, United States*

Background: All continuous flow left ventricular assist device (LVAD) patients have loss of high molecular weight multimers (HMWM) of von Willebrand factor (VWF),.20-40% develop gastrointestinal bleeding (GIB), and arteriovenous malformation (AVM) is the most common finding. AVMs are a known complication of congenital von Willebrand disease(CVWD), and CVWD plasma is pro-angiogenic in vitro.

Aims: We tested the hypothesis that LVAD plasma would emit an exaggerated pro-angiogenic signal.

Methods: We compared results of plasma angiogenesis assays (PAA), an in vitro assay that stimulates endothelial cells to proliferate and form new blood vessels in matrigel, and angiogenic cytokine/protein levels in 20 LVAD patients, compared to those of 8 controls.

Results: PAA experiments revealed increases in average tube length and median tube length in the LVAD plasma compared to controls, with a trend toward more tube formation in LVAD patients with a history of GIB (figure).

Loss of VWF HMWM was found in all LVAD patients, but in none of the controls, and LVAD patients also had far higher total VWF antigen levels compared to controls (188±72 U versus 89±20 U, p< 0.001). Compared to control plasma LVAD plasma showed significantly increased pro-angiogenic cytokines, endothelin 1, angiopoietin 2, and macrophage inhibitory protein 1a. VEGF2 levels did not show significant differences in the LVAD plasma when compared to the controls. Surprisingly, there were also significant elevations of anti-angiogenic proteins; tissue inhibitors of metalloproteinases 1 and 2, and endostatin (p< .01). These cytokine signals in LVAD plasma also tended to be the strongest in the LVAD patients with GIB.

Conclusions: As in CVWD, LVAD plasma increases in vitro angiogenesis. In LVAD patients, several pro-angiogenic cytokines are amplified, but not VEGF2, as are compensating anti-angiogenic factors, such as endostatin, suggesting a feedback loop in this pathologic condition.

PB 2050 | Characterisation of Q1541R, a Novel von Willebrand Factor Variant Causing Type 2A von Willebrand Disease - ADAMTS13 Cleavage of Type 2A Variants under Shear Stress

T. McKinnon[1], V. Jenkins[2], F. Zhang[3], M. Laffan[1], J. O'Donnell[4]

[1]*Imperial College London - Hammersmith Hospital Campus, London, United Kingdom,* [2]*Cardiff University, Cardiff, United Kingdom,* [3]*Lehigh University, Bethlehem, United States,* [4]*St James's Hospital, Dublin, Ireland*

Background: Type 2A Von Willebrand Disease (VWD) is characterised by loss of high molecule weight multimers caused by either defects in dimer or multimer formation, or enhanced susceptibility to ADAMTS13 proteolysis. Here we describe a novel VWF variant, Q1541R located in the A2 domain of VWF that results in a moderate to severe bleeding phenotype.

Aims: To characterise the effect of the Q1541R mutation on VWF function and assess cleavage under shear stress.

Methods: Expression of wild type (wt)VWF or VWF-Q1541R in HEK293 cells was assessed by VWF ELISA & pseudo Webiel-Palade body formation examined by confocal microscopy. Multimer formation, collagen binding, GPIb binding & static ADAMTS13 cleavage assays were performed using standard methods. Unfolding of the A2 domain was determined using optical tweezers. A shear based assay system was used to investigate the effect of the mutation on VWF function under shear stress.

Results: VWF-Q1541R was expressed at a marginally lower level than wtVWF, but formed normal storage vesicles in HEK293 cells & exhibited a full range of multimers with normal collagen & platelet binding function. Under static conditions VWF-Q1541R was more susceptible to ADAMTS13 proteolysis & required less force to unfold the A2 domain. Furthermore when HEK293T cells were co-transfected with ADAMTS13, the type 2A variants were proteolysised significantly faster. Under shear stress VWF-Q1541R mediated comparable VWF mediated platelet capture to collagen. Intriguingly,

when VWF-Q1541R was perfused over collagen with ADAMTS13, although a reduction in platelet capture was observed the reduction was similar to that seen with wild type VWF. Similar observations were also made with two common type 2A variants G1629E and E1638K.

Conclusions: The novel Q1541R variant results in VWD due to enhanced ADAMTS13 proteolysis. Interestingly, the increased ability of ADAMTS13 to proteolyse type 2A variants is lost when VWF is exposed to a collagen surface under shear stress.

PB 2052 | FVIIIa Mimicking Bispecific Antibody (Emicizumab) Improved Thrombus Formation of Type 2N von Willebrand Disease (VWD) under Both High and Low Shear Conditions

H. Yaoi[1], Y. Shida[1], T. Kitazawa[2], K. Hattori[2], M. Shima[1], K. Nogami[1]

[1]*Nara Medical University, Pediatrics, Kashihara, Japan,* [2]*Chugai Pharmaceutical Co., Research Division, Kamakura, Japan*

Background: Type 2N VWD is characterized by low FVIII:C attributed to the defect in the ability of VWF to bind FVIII and the phenotype is similar to mild and moderate hemophilia A. emicizumab is a humanized bispecific antibody that promotes coagulation by bridging FIXa and FX, replacing the function of missing FVIIIa. Threfore, we hypothesized that emicizumab may benefical for the management of type 2N VWD.

Aims: We performed the *ex vivo* flow chamber experiments to analyze the effect of emicizumab in type 2N VWD.

Methods: Whole blood obtained from patients with type2N VWD (n=5) was perfused into the collagen-coated flow chamber with or without FVIII/VWF, FVIII, VWF and emicizumab under high($2500s^{-1}$) and low ($50s^{-1}$) shear conditions. Formed thrombus was fixed and immunostaining was performed to visualize platelets, VWF and FVIII. Thrombi were observed with confocal laser scanning microscopy. The obtained images were analyzed by Image Pro Premier 3D, and surface coverage (SC) and average thrombus height (HT) were calculated.

Results: Type 2N VWD demonstarated defective thrombus formation under both shear (high: SC 13%, TH 0.91μm, low: SC 3.8%, TH 0.47μm). Addition of FVIII/VWF (final concentration; *f.c.* 1U/mL) most improved thrombus formation. Addition of VWF (*f.c.* 1U/mL), or FVIII (*f.c.* 1U/mL) demonstrated partial improvement (high; SC 31, 28, 28%, TH 3.2, 2.4, 2.4 μm, low; SC 7.0, 3.7, 8.5%, TH 0.63, 0.42, 0.62 μm, respectively in order). Addition of emicizumab (100 μg/mL) improved thrombus formation under both high and low shear conditions (high; SC 27%, TH 2.8μm, Low; SC 8.4%, TH 0.42μm).

Conclusions: The reason why emicizumab improved thrombus formation especially under high shear can be explained by its rapid function since emicizumab is readily active and does not require the activation process. Therefore, emicizumab could be an alternative therapy for type 2N VWD.

PB 2053 | Perioperative Management of von Willebrand Patients with Desmopressin; Towards a Predictive Population PK Model

J.M. Heijdra[1], M.J.H.A. Kruip[2], F.W.G. Leebeek[2], M.H. Cnossen[1], 'OPTI-CLOT' Study Group

[1]*Erasmus University Medical Center - Sophia Children's Hospital, Pediatric Hematology, Rotterdam, The Netherlands,* [2]*Erasmus University Medical Center, Hematology, Rotterdam, The Netherlands*

Background: Von Willebrand disease (VWD) is the most common inherited bleeding disorder. In low to moderate risk procedures, patients in whom desmopressin (DDAVP) has been proven effective in a test, can be treated with DDAVP, aiming for FVIII/VWF target levels as defined in Dutch National Guidelines.

Aims: To evaluate perioperative management with DDAVP in VWD patients in relation to FVIII/VWF target levels, in order to improve prediction of effect by construction of a population pharmacokinetic (PK) model.

Methods: In this retrospective observational cohort study, VWD patients (historical VWF levels ≤0.30 $IUmL^{-1}$ or FVIII ≤0.40 $IUmL^{-1}$) treated in the Hemophilia Treatment Center of Erasmus University Medical Center- Sophia Children's Hospital undergoing a procedure between 2000-2016 were included. DDAVP dosing and achieved perioperative FVIII/VWF levels were compared to target levels.

Results: A total of 159 procedures in 79 patients were analyzed (Table 1). FVIII/VWF levels were available for 20 surgical procedures in 16 patients. During the first 36 hours, 86.4% of FVIII levels (Figure 1) and 63.3% of VWF:RCo levels were above target level (0.80 $IUmL^{-1}$). In 7 dental procedures, all FVIII/VWF levels were above target level (0.50 $IUmL^{-1}$) in this period. Bleeding complications occurred in only 3.8% and were unrelated to FVIII/VWF levels. Very high FVIII plasma levels (≥ 2.0 $IUmL^{-1}$) were reached in 59.1% of patients. DDAVP was administered 2-3 times in 9 procedures.

TABLE 1 Patient characteristics

	Total cohort	Patients with measured perioperative FVIII/VWF levels
Patient characteristics	N (%) or median [IQR]	N (%) or median [IQR]
Number of patients	79	22
Type 1 VWD	75 (95)	21 (95)
Total procedures	159	27
Dental procedures	71 (45)	7 (26)
Surgical procedures	88 (55)	20 (74)
Baseline VWF:Ag	0.32 [0.27-0.43]	0.31 [0.26-0.43]
Baseline VWF:RCo	0.25 [0.20-0.29]	0.25 [0.20-0.29]
Baseline FVIII	0.47 [0.35-0.57]	0.50 [0.44-0.58]

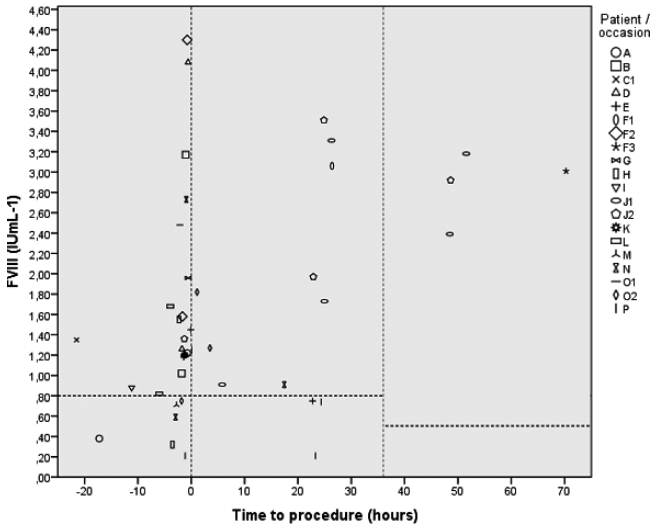

FIGURE 1 FVIII levels (IUmL-1) during the perioperative period in surgical procedures

Conclusions: DDAVP treatment is effective in this group, as patients achieve adequate FVIII/VWF plasma levels. Perioperative bleeding complications are rare, although some patients do not reach target levels. However, a large proportion of patients achieve very high FVIII plasma levels, with a potential risk of thromboembolic complications. In conclusion, better prediction of DDAVP response, both after first and consecutive dosing, may be realized by construction of population PK models, thus personalizing treatment in VWD patients.

PB 2054 | In-Frame Heterozygous Large Deletion in von Willebrand Factor (VWF) Gene in a Patient with Severe Bleeding Manifestations Might Accelerate VWF Clearance

H. Yadegari[1], N.M. Marquardt[1], V. Ivaskevicius[1], O. Rawley[2], L. Swystun[2], D. Lillicrap[2], J. Oldenburg[1]

[1]*University Clinic Bonn, Institute of Experimental Hematology and Transfusion Medicine, Bonn, Germany,* [2]*Queen's University, Dept. Pathology and Molecular Medicine, Kingston, Canada*

Background: We identified an in-frame heterozygous large deletion spanning exons 4 to 34 of von VWF gene in an index patient (IP) with type 3 von Willebrand disease (VWD). Curiously, the IP suffers frequently from bleeding episodes in spite of prophylaxis treatment.

Aims: This study aimed to determine the pathological mechanisms by which this single gene defect interferes with the VWF life cycle.

Methods: Blood outgrowth endothelial cells (BOECs) were isolated from blood of IP and healthy individuals. The wild-type or deleted VWF cDNA was transiently expressed in HEK293T cells. Assessment of antigen levels and multimer profile of the VWF in supernatant of the BOECs and HEK293T cells were performed. Subcellular location of the VWF in BOECs was evaluated by confocal microscopy scanning. VWF transcript analysis was done by using RNA extracted from the BOECs.

Results: RNA analysis assured biosynthesis of normal VWF transcription allele as well as an aberrant deleted transcript. Surprisingly, the mean of secreted VWF levels from the patient-derived BOECs was only slightly reduced compared with those of the healthy donors (63% vs. 72% respectively). Multimer analysis of the secreted VWF displayed loss of large and intermediate multimers along with shift in mobility of small multimers. Likewise, studies in HEK293T cells showed nearly normal secretion but a major defect in multimer structure. Confocal immunofluorescent analysis revealed a relatively strong VWF staining in IP-derived BOECs. However, the Weibel-Palade-bodies in IP-BOECs seemed smaller compared to those within normal BOECs.

Conclusions: Our results suggested that the deleted VWF protein (p.Asp75_Cys1948del) *is incorporated into VWF multimers and has a dominant-negative impact on multimer synthesis.* We speculate that the secreted chimeric VWF is cleared from plasma more rapidly than normal VWF.

PB 2055 | Acquired von Willebrand Disease in Patients with Extracorporal Membrane Oxygenation: The VWF:GPIbM/VWF:Ag Ratio is a Sensitive Diagnostic Tool

S. Flommersfeld[1], K. Dielmann[2], T. Vassiliou[2], U.J. Sachs[3]

[1]*Universitiy Hospital Marburg, Transfusion Medicine, Marburg, Germany,* [2]*Universitiy Hospital Marburg, Department of Anaesthesiology and Intensive Care, Marburg, Germany,* [3]*Justus-Liebig-University Giessen, Institute for Clinical Immunology and Transfusion Medicine, Giessen, Germany*

Background: Extracorporeal membrane oxygenation (ECMO) is associated with bleeding that is not fully explained by the use of anticoagulant/antiplatelet drugs. The loss of high molecular weight multimers (HMWM) of von Willebrand factor (VWF) has been described in patients with extracorporal assist devices, leading to acquired von Willebrand disease (AVWD). Both frequency of AVWD in patients on ECMO and appropriate support strategies are still unsettled.

Aims: We examined the presence of AVWD in adult patients on ECMO with unexpected bleeding (n=13).

Methods: The diagnosis of AVWD was based on the ratio of activity (VWF:GPIbM) to VWF antigen and multimer analysis. Bleeding episodes and use of blood products were monitored.

Results: Mean patient age was 60 (range, 40-86). Only 3 patients were on veno-venous ECMO for respiratory failure, while 10 were on veno-arterial ECMO after cardiac surgery. ECMO was started within 2.5 days after surgery (range, 0-14). Bleeding symptoms commenced around day 10 (range, 1-47). VWF:Ag and VWF:GPIbM were elevated in most patients (358%; range, 194-600; and 205%, range 80-348). The VWF:GPIbM/VWF:Ag ratio was decreased in all patients (mean 0.59; range, 0.23-0.82). In the multimer analysis, loss of HMWMs was seen in all 13 patients. All patients had platelets >50 G/l, normal prothrombin time, and most had a prolonged aPTT (mean 49 sec; range

35-71) under Argatroban. Out of 13 patients, 11 underwent massive transfusion protocols including VWF concentrate (mean 14 TIE; range, 5-58 TIE). Bleeding was successfully controlled in all patients. However, 12 patients died in the due course.

Conclusions: AVWD is frequently present in bleeding patients with ECMO support. At a cut-off of 0.8, VWF:GPIbM/VWF:Ag ratio is a sensitive diagnostic tool for AVWD. No additional markers could be identified for patients with severe bleeding. Clinical trials assessing early diagnosis and intervention strategies for patients with AVWD on ECMO are urgently required.

PB 2056 | Different Modes of Association between Protein Disulfide Isomerase PDIA1 and VWF in von Willebrand Disease

M.A. Brehm, S. Vollmers, G. König, T. Obser, R. Schneppenheim

University Medical Center Hamburg-Eppendorf, Pediatric Hematology and Oncology, Hamburg, Germany

Background: Thiol oxidoreductases are critically involved in the production of von Willebrand factor (VWF) multimers. In the endoplasmic reticulum (ER), intra-monomeric disulfide bonds are formed which mediate protein folding. Formation of disulfides between the C-termini of two VWF monomers is catalyzed by protein disulfide isomerase isoform A1 (PDIA1) to produce VWF dimers, and multimerization is realized in the Golgi apparatus by formation of N-terminal inter-dimer disulfide bonds catalyzed by the VWF propeptide.

Mutations in the VWF gene can lead to von Willebrand disease (VWD); the most common congenital bleeding disorder. A variety of these VWF mutants exhibit defects in multimer biosynthesis, storage and secretion and are intracellularly retained.

Aims: The aim of this study is to determine whether PDIA1 is involved in cellular retention of VWD mutants.

Methods: We started the study with eleven VWD type 3 mutants, which were investigated by immunofluorescence after transient expression in HEK293 cells. Parallel staining of endogenous PDIA1 was employed to visualize VWF-PDIA1-association and measurement of fluorescence intensities revealed influence of the VWF mutant expression on PDIA1 levels.

Results: Our preliminary data indicate three different modes of mutant-VWF-PDIA1-association: 1) Most propeptide mutants exhibited normal PDI co-localization compared to wildtype VWF, 2) Expression of mutants p.Gly39Arg, p.Leu129Arg and p.Tyr271His was associated with a slight increase in PDIA1 expression level, 3) The cysteine mutants p.Cys2431Tyr and p.Cys2533Arg induced an alteration in PDIA1 localization that was associated with formation of big, ER-localized clusters containing VWF and PDIA1.

Conclusions: PDIA1 might be involved in different mechanisms underlying VWD. We are currently conducting studies to elucidate the connection between PDIA1 and VWF misfolding and degradation pathways in VWD type 3.

PB 2057 | Mutational Screening of a Type III VWD Cohort from Cohort Reveals 19 Novel Mutations in the VWF Gene

S. Ahmed[1], A. Biswas[2], A. Naz[1], H. Yadegari[2], N. Ahmed[3], N. Saqlain[4], A. Imran[5], F. Raziq[6], T.S. Shamsi[1], J. Oldenburg[2]

[1]National Institute of Blood Disease & Bone Marrow Transplantation, Karachi, Pakistan, [2]Institute of Experimental Haematology and Transfusion Medicine, University Clinic in Bonn, Bonn, Germany, [3]Children Hospital Lahore, Haematology, Lahore, Pakistan, [4]Children Hospital Lahore, Haematology, Karachi, Pakistan, [5]Chughtai Lab Lahore, Haematology, Lahore, Pakistan, [6]Hayatabad Medical Complex Peshawar, Peshawar, Pakistan

Background: von Willebrand disease type III (Type III VWD) is a rare congenital autosomal bleeding disorder. It is characterized by quantitative defect in von Willebrand factor (VWF) secondary to a mutation in *VWF* gene. The incidence rate of this disorder in Pakistan is quite high owing to the cultural practice of consanguinity.

Aims: To screen *VWF* gene for mutations in a type III VWD Pakistani cohort and to study their genotype-phenotype correlation.

Methods: A total of 48 patients with type III VWD were enrolled in this study and informed consent was taken. Blood and plasma samples were collected from the patients using routine procedures. DNA was extracted from peripheral blood leucocytes. Mutational analysis was performed by direct gene sequencing on automated ABI-3130 Genetic Analyzer. Phenotypic investigations comprising FVIII activity (FVIII:C), VWF antigen (VWF:Ag) and VWF ristocetin cofactor activity, were carried out at National Institute of Blood Diseases and Bone Marrow Transplantation (NIBD). Impact of missense mutations were assessed by missense prediction tools (Polyphen-2, SNPGo, Provean, SIFT and Mupro). The 13 novel missense mutations were analyzed by molecular modeling tools to predict their putative impact on the structure of the protein.

Results: We identified a total of 31 mutations in the 46 index patients. These included 17 missense (13 were novel), 7 nonsense, 2 small deletions (both novel), 2 insertions (one was novel) and 3 splice site mutations (all 3 novel). All mutations were predicted to be causative using the *in silico* and protein modeling tools.

Conclusions: We found a very heterogenous spectrum of mutations in the Pakistani type III VWD cohort. A majority of them (62%; 19/31) were novel. Using *in silico* tools we were able to prove the causality of the 13 novel missense mutations.

PB 2058 | Effect of Elongational Flow on von Willebrand Factor Cleavage by ADAMTS13

M. Bortot[1,2], D. Bark[3], K. Neeves[4], K. Leiderman[5], A. Fogelson[6], S. Aguila Martinez[7], C. Ng[2], J. Di Paola[2]

[1]University of Colorado, Bioengineering, Aurora, United States, [2]University of Colorado, Pediatrics, Aurora, United States, [3]Colorado State University, Mechanical Engineering, Fort Collins, United States, [4]Colorado School of Mines, Chemical & Biological Engineering, Golden, United States, [5]Colorado School of Mines, Applied Mathematics & Statistics, Golden, United States, [6]University of Utah, Mathematics, Salt Lake City, United States, [7]Royal College of Surgeons in Ireland, Irish Centre for Vascular Biology, Dublin, Ireland

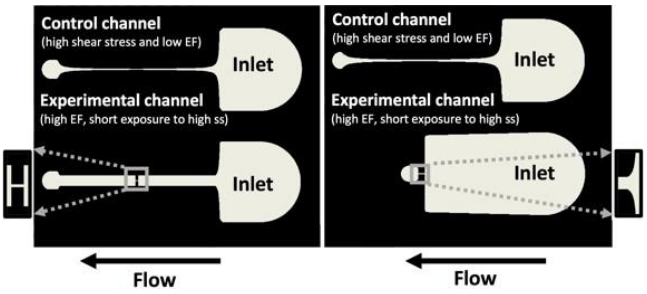

FIGURE 1 a) Abrupt 90° angle with varying EF magnitude b) Hyperbolic function region with constant EF magnitude

Background: Acquired von Willebrand Syndrome (aVWS) is characterized by loss of high molecular weight multimers (HMWM) of von Willebrand factor (VWF). Loss of HMWM of VWF in aVWS is commonly attributed to the presence of high shear stress (SS) that causes VWF to unravel, exposing cleavage sites to ADAMTS13. However, sufficient SS to cause VWF conformational changes is only present close to the vessel wall. Conversely, abrupt constrictions such as those in severely stenosed vessels or vascular assist devices (VADs) cause elongational flows (EF) across the majority of the vessel/channels. Our hypothesis is that EF will have a greater effect on VWF cleavage than SS alone.

Aims:

i) Evaluate the effect of EF magnitude on VWF cleavage and

ii) Identify the contribution of EF relative to SS for VWF cleavage

Methods: Flow simulation software was used to design microfluidic devices with either high SS and low EF (control channel) or high EF with minimal exposure to high SS (experimental channel) to evaluate relative contributions to cleavage. Recombinant ADAMTS13 was added to 1.5 µl of citrated human plasma diluted in buffer. The samples were placed in channel inlets and allowed to flow forward-back through the channel for various times (1, 3, 5 and 14 hours). Reaction products were analyzed by western blotting and multimer analysis. This assay was repeated at varying SS and EF conditions.

Results: Two sets of flow chambers were designed and optimized (Figure 1). Under high EF conditions cleavage was confirmed by western blot with the characteristic 176 kDa and 140 kDa fragments as well as loss of HMWM.

Conclusions: Judiciously designed flow chambers allowed to evaluate the effect of EF on VWF cleavage. Multimer analysis showed higher loss of HMWM in the EF channel when compared to SS alone. Results from these studies could provide guidance for the design of blood-contacting VADs to prevent aVWS.

PB 2059 | Wound Healing is Not Delayed in Mice with Reduced von Willebrand Factor in Spite of the Presence of a Severe Bleeding Tendency

M. Hoffman[1], K. Gorman[1], G. Pitoc[2], B. Sullenger[2], D. Monroe[3]

[1]Duke University School of Medicine, Pathology, Durham, United States, [2]Duke University School of Medicine, Surgery, Durham, United States, [3]University of North Carolina at Chapel Hill, Medicine/Hematology, Chapel Hill, United States

Background: von Willebrand Factor (vWF) recruits platelets to sites of injury by binding between exposed collagen and platelet GPIbα, particularly at sites of high shear. vWF is necessary for hemostasis, but can also play a key role in arterial thrombosis and vascular disease. Our group is currently testing an RNA aptamer that blocks vWF binding to GPIbα as an antithrombotic. We have previously shown that cutaneous wound healing is impaired in hemophilia B mice.

Aims: The Aim of the current study was to test the hypothesis that reduced vWF activity similarly impairs healing.

Methods: We studied C57BL mice injected with vehicle or vWF aptamer, as well as vWF knockout (KO) mice. The maximal effect of aptamer was 2-5 hemostasis events in 30 min in a saphenous vein (re)bleeding assay, compared to 20-25 in controls. vWF KO mice did not stop bleeding in 30 minutes. Healing was assessed in mice given a dose of aptamer that impaired hemostasis for >10 days. A skin punch biopsy model was used, as in our previous studies. Wound size was measured daily. The wound area was harvested for histology. Inflammation without tissue injury was induced by applying cantharidin, followed after 24 hr by sacrifice and tissue harvesting.

Results: There was no difference in time to healing between control and aptamer-treated mice, with all wounds healed at 10 days. There was also no statistically significant difference in wound size at any time. Wounds on vWF KO mice were also healed by 10 days. Cantharidin induced a similar level of leukocyte influx in treated, vWF KO and control mice. Aptamer-treated and vWF KO mice showed a small amount of inflammation-induced hemorrhage, though much less than that seen in thrombocytopenic mice.

Conclusions: Surprisingly, vWF does not play a major role in cutaneous wound closure. Lack of vWF led to only a modest degree of inflammation-induced hemorrhage, despite the presence of a severe hemostatic defect in a large vessel bleeding model.

PB 2060 | Variability in von Willebrand Factor Parameters in Blood Outgrowth Endothelial Cells from Healthy Controls

A. de Jong, E.M. Weijers, R.J. Dirven, M.J. Streur, J. Eikenboom

Leiden University Medical Center, Einthoven Laboratory for Vascular and Regenerative Medicine, Department of Thrombosis and Hemostasis, Leiden, The Netherlands

Background: Blood outgrowth endothelial cells (BOECs) are mature endothelial cells derived from peripheral blood. BOECs are a powerful tool to study pathophysiological mechanisms of vascular diseases. We use BOECs to study von Willebrand factor (VWF), an endothelial protein of which defects relate to von Willebrand disease (VWD). However, to understand the pathophysiology of VWD, a detailed overview of VWF parameters in BOECs from healthy controls is necessary.

Aims: Determine the normal range of VWF parameters in BOECs from healthy controls.

Methods: Cultures of separate colonies (n=16) of BOECs derived from six donors were established. Experiments were performed on BOECs confluent for four days and at passage four. Additionally, two clones were followed during increasing passage numbers. Surface marker expression was determined by FACS to confirm endothelial lineage and to define the normal range of several markers. Storage of VWF in Weibel-Palade bodies (WPBs) was visualized by immunofluorescent staining. VWF:Ag secretion in 24 hours was measured in medium by ELISA and plotted against cell density determined by ImageJ (ITCN plugin).

Results: All BOECs were CD14/CD45 negative and CD31/CD146 positive and stored VWF in WPBs, confirming endothelial lineage. High variability was observed in the percentage of CD34, CD133 and VEGFR2 positive cells, cell density and VWF:Ag levels. VWF:Ag levels significantly correlated with cell density (R^2 = 0.90, P< 0.0001). Also, per increase of passage number the cell density decreased, which correlated with VWF:Ag levels as well (R^2 = 0.92, P< 0.0001).

Conclusions: High variability in cell surface markers, secreted VWF:Ag levels and cell density was observed in BOECs from healthy controls. Interestingly, VWF:Ag levels measured in confluent cells, significantly correlated with cell density, suggesting that smaller cells secrete more VWF. These results highlight the importance of understanding VWF parameters in BOECs from healthy controls.

PB 2061 | A Cell-based Assay to Quantify αIIbβ3 Integrin Binding of von Willebrand Factor Mutants

G. König, T. Obser, R. Schneppenheim, M. Brehm

University Medical Center Hamburg-Eppendorf (UKE), Pediatric Hematology and Oncology, Hamburg, Germany

Background: Integrin $\alpha_{IIb}\beta_3$ is a major constituent of the platelet membrane that plays an essential role in platelet adhesion and aggregation. It specifically recognizing the arginine-glycine-aspartic acid (RGD) sequence present in several adhesive proteins. Upon platelet activation the complex undergoes a conformational change that permits binding to fibronectin, vitronectin, thrombospondin, fibrinogen, and von Willebrand factor (VWF).

VWF is a large multi-domain plasma glycoprotein essential to primary hemostasis. VWF can directly interact with platelets, as it exhibits binding sites for GPIbα, which is part of the platelet membrane receptor GPIb-IX-V (binding site located in the VWF A1 domain), and for $\alpha_{IIb}\beta_3$ (via the RGD sequence in domain C4).

Aims: We strive to investigate the influence of von Willebrand disease-associated mutations in the C-domains of VWF on interaction with platelets via $\alpha_{IIb}\beta_3$.

Methods: We developed a cell-based binding assay by stably co-transfecting HEK293 cells with the two integrins α_{IIb} and β_3. To mimic activation of the complex a constitutively active mutant was generated by introducing a single missense mutation in β_3. Binding was determined by addition of the $\alpha_{IIb}\beta_3$-presenting cells to immuno-adsorbed VWF. The complex was detected by anti-$\alpha_{IIb}\beta_3$ and an HRP-coupled secondary antibody. After addition of the HRP substrate 3,3',5,5'-tetramethylbenzidine), optical absorbance at 450 nm was measured using an ELISA reader for quantification of $\alpha_{IIb}\beta_3$ binding.

Results: We validated our assays by using mutant p.Asp2509Gly, in which the RGD sequence was inactivated, as a negative control. As expected no binding was observed. We further investigated binding of the C-domain mutants p.Cys2257Arg, p.Arg2464Cys, and p.Cys2671Tyr. All of them exhibited decreased binding with the strongest effect by exchange of Cys2257.

Conclusions: We successfully established and validated a cell-based assay that allows quantification of binding of RGD-motif containing proteins to membrane incorporated $\alpha_{IIb}\beta_3$.

PB 2062 | Heterozygous Splicing Mutations Associated with Severe Type 1 von Willebrand Disease

G. Castaman[1], A. Coppola[2], A. Volta[3], A. Kura[3], S. Linari[1], L. Pieri[1], F. Demartis[1], B. Giusti[3]

[1]Center for Bleeding Disorders and Coagulation, Careggi University Hospital, Florence, Italy, [2]Regional Reference Center for Coagulation Disorders, Federico II University Hospital, Naples, Italy, [3]Atherothrombotic Disease Unit, Careggi University Hospital, Florence, Italy

Background: A large proportion of type 1 von Willebrand disease (VWD) cases are associated with missense mutations scattered over the entire von Willebrand factor gene (VWF). A few mutations are caused by stop codon or splice site mutations. In these patients usually VWF levels of 30 - 50 U/dL are observed and bleeding history is mild.

Aims: To report four novel heterozygous splice site mutations associated with a full penetrance and expressivity pattern.

Methods: Whole VWF gene and intron-exon boundaries were sequenced by Sanger methodology. FVIII coagulant activity, von Willebrand factor antigen and ristocetin cofactor activity were assessed by routine methods. Bleeding history was assessed by the ISTH-BAT.

Results: Four different families were evaluated including 6 patients. FVIII ranged from 30 to 48 U/dL, VWF antigen and activity were always below 20 U/dL. Bleeding history was significant in all (BS > 6). A novel c.3538+1 G>T in intron 26, two novel changes at the same splice site in intron 33
(c.5657+1 G>T and c.5657- 1 G>C) and a novel deletion between intron 28 and exon 29 (c.5054-18_5063delTCCTGGTTGTCTTTGCAG ACTGCAGCCA) were detected. No other mutations or possible functional polymorphisms were identified. The reduction of FVIII and VWF levels were homogeneous within the families.

Conclusions: Rare splice site mutations in *VWF* can be associated with clear penetrance and expressivity suggesting possible skipping

of exons resulting in dominant-negative effect on the normal VWF allele. mRNA studies are undergoing to elucidate the pathophysiology of these splicing abnormalities.

PB 2063 | Single Centre Audit of Laboratory Testing in Sub-classification of Type 2 von Willebrand Disease

R. Kohli[1,2], P. Batty[1], S. Platton[1], K.J. Pasi[1], L. Bowles[1]

[1]The Royal London Hospital, London, United Kingdom, [2]Pathologists Lancet Kenya, Nairobi, Kenya

Background: Laboratory tests in the diagnosis of von Willebrand Disease (VWD) consists of assessment of von Willebrand Factor (VWF) function. Patients with type 2 VWD display heterogeneity in phenotype and treatment response, with treatment options including plasma derived VWF concentrates or desmopressin (DDAVP). Trial of efficacy of DDAVP in those without contraindication as recommended by the British Committee for Standards in Haematology (BCSH) is important as lower response rates have been reported in those with type 2 (2A, 2M and 2N) VWD.

Aims: To audit compliance with laboratory testing in the sub-classification of patients with type 2 VWD.

Methods: Retrospective single centre (The Royal London Hospital Haemophilia Comprehensive Care Centre) review of laboratory testing and DDAVP trial against recent BCSH guidelines of patients registered with type 2 VWD.

Results: Of the 334 patients currently registered with VWD, 79 were classified as type 2. The median age was 37 years (1-96 years) with a slight female preponderance (M:F 1:1.3). Although, 76% (n=60) of type 2 VWD patients were registered as being sub-classified (2A, 2B, 2M or 2N), multimer testing had been performed in 21 patients (35%). A FVIII binding assay to confirm a diagnosis of type 2N was performed in 2 patients (33%, 2/6). No patient registered with type 2B VWD or with loss of high molecular weight multimers had testing of Ristocetin-Induced Platelet Aggregation. One patient had genotype testing and none a trial of DDAVP. Changes in guidelines for VWF activity:antigen (< 0.6) resulted in reclassification of 5 patients from type 2 to type 1 VWD.

Conclusions: Despite national guidance there was low uptake of secondary testing for type 2 VWD subclass confirmation. No patient received testing of DDAVP response which may relate to loss to follow up or contraindication. Increased awareness of this treatment option may reduce VWF concentrate exposure. Re-classification due to changes in recent guidelines was seen in a small number of patients.

PB 2064 | Von Willebrand Factor Testing through the Ages: A Review of Recent Results from the ‚Royal College of Pathologists of Australasia Quality Assurance Program'

R. Bonar[1], E. Favaloro[2]

[1]RCPAQAP, Haematology, St Leonards, Australia, [2]ICPMR, Westmead Hospital, Westmead, Australia

Background: von Willebrand disease (VWD) is the most common inherited bleeding disorder but due to its heterogeneity its diagnosis can be difficult. Six types of VWD are characterised on the basis of quantitative or qualitative defects in von Willebrand factor (VWF). A panel of tests are therefore required. Such tests include both antigenic (VWF:Ag) and functional (e.g., ristocetin co-factor (VWF:RCo); collagen binding (VWF:CB)) assays.

Aims: To evaluate performance of laboratories enrolled in the RCPAQAP Special Haemostasis program for identification of VWD. To identify and characterise errors associated with incorrect results and/or interpretation to analytical or post-analytical event.

TABLE 1 Sources of error in VWD identification

Sample ID	Sample type	Total Errors	Total Errors Errors comprised	Analytical errors: N (% of errors)	Limited test panel: N (% of errors	Misinterpretation: N (% of errors)
VW13-03a	Normal	3	Type 1 (1) Type 2A/2B (2)	0	2 (67)	1 (33)
VW13-03b	VWF deficient (~10U/dL)	6	Type 1 (3) Type 3 (3)	0	4 (67)	2 (33)
VW13-08a	Mild/Mod type 1	10	Type 2A/2B (6) Type 2M (4)	5 (50)	5 (50)	0
VW13-08b	high molecular weight VWF deficient 'type 2'	4	Type 1 (4)	0	3 (75)	1(25)
VW14-08a	Type 2M VWD	19	Normal (17) Equivocal (2)	5 (26)	10 (53)	4 (21)
VW15-08a	Type 2M VWD (duplicate of VW14-08a)	16	Normal (15) Equivocal (1)	5 (31)	10 (63)	1 (6)
VW15-08b	high molecular weight VWF deficient 'type 2'	10	Type 1 (4) Type 3 (2) Other (4)	1 (10)	3 (30)	6 (60)
VW16-03b	high molecular weight VWF deficient 'type 2'	10	Type 1 (8) Type 3 (2)	6 (60)	3 (30)	1 (10)
VW16-08a	Acquired (type 2) VWD	9	Normal (1) Type 1 (8)	1 (11)	3 (33)	5 (56)

Methods: Data was collected from over 60 participants and analysed using robust statistics (median, mean and CV) and interpretations reviewed for incorrect interpretation of correct results, limited test panels and poor performance of testing.

Results: A review of recent challenges is summarised in table 1 and identified: (a) a VWF deficient sample (VW13-08a) resulted in nearly 20% incorrect interpretations of type 2 VWD; half of which were attributed to use of a limited test panel. (b) A type 2M VWD patient sample sent twice in separate years (VW14-08a; VW15-08a) yielded ~25% of participants failing to identify the qualitative defect and discordant functional/antigenic ratio, with limited test panels being the main cause of error. (c) Several high molecular weight (HMW) VWF deficient samples (VW15-08b; VW16-03b) yielded nearly 20% incorrect identifications of type 1 or type 3 VWD.

Conclusions: From this data, supported by other published data, laboratories are recommended to perform a VWF:Ag assay plus preferably several functional assays representing different activities (ie, glycoprotein Ib and collagen binding) in order to avoid errors in VWD identification. Limited test panels excluding this combination were a cause of significant error and impede laboratories from correctly diagnosing VWD.

PB 2065 | Comparing Platelet-dependent von Willebrand Factor Activity Assays in 661 Patients with von Willebrand Disease - from the WiN Study

J. Boender[1], J. Eikenboom[2,3], J. van der Bom[4,5], K. Meijer[6], J. de Meris[7], K. Fijnvandraat[8], M.H. Cnossen[9], B. Laros-van Gorkom[10], E. Mauser-Bunschoten[11], M.P.M. de Maat[1], F.W.G. Leebeek[1], WiN Study Group

[1]*Erasmus University Medical Center, Hematology, Rotterdam, The Netherlands,* [2]*Leiden University Medical Center, Thrombosis and Hemostasis, Leiden, The Netherlands,* [3]*Leiden University Medical Center, Einthoven Laboratory for Experimental Vascular Medicine, Leiden, The Netherlands,* [4]*Leiden University Medical Center, Clinical Epidemiology, Leiden, The Netherlands,* [5]*Sanquin Research, Jon J van Rood Center for Clinical Transfusion Medicine, Leiden, The Netherlands,* [6]*University Medical Center Groningen, Hematology, Groningen, The Netherlands,* [7]*Netherlands Hemophilia Society, Nijkerk, The Netherlands,* [8]*Emma Children's Hospital, Academic Medical Center, Pediatric Hematology, Amsterdam, The Netherlands,* [9]*Erasmus University Medical Center - Sophia Children's Hospital, Pediatric Hematology, Rotterdam, The Netherlands,* [10]*Radboud University Medical Center, Hematology, Nijmegen, The Netherlands,* [11]*University Medical Center Utrecht, van Creveldkliniek/department of Hematology, Utrecht, The Netherlands*

Background: Measuring von Willebrand factor (VWF) activity is crucial for the diagnosis and classification of von Willebrand disease (VWD). Historically, ristocetin co-factor activity is used, but new commercial assays are now also available. Large side-by-side comparisons between these assays in VWD patients are urgently needed.

Aims: To compare three widely used VWF activity assays in a large cohort of VWD patients.

Methods: We included 661 VWD patients (historically lowest VWF ≤30 U/dL) from the nationwide "Willebrand in the Netherlands" (WiN) Study. We compared VWF activity assays based on: 1) binding of VWF to a monoclonal antibody directed against the GP1b binding domain of VWF (VWF:Ab, HemosIL® von Willebrand Factor Activity, Instrumentation Laboratory), 2) induction of platelet agglutination by ristocetin (VWF:RCo, BC von Willebrand Reagent, Siemens) and 3) binding of VWF to a recombinant gain-of-function mutant platelet glycoprotein 1b fragment (VWF:GP1bM, INNOVANCE VWF Ac, Siemens).

Results: All assays were highly correlated (r >0.95). Bland-Altman plots showed a small bias between assays (fig 1).

An absolute difference >10 IU/dL between assays was found in 16% to 24% of cases. In 248/643 patients (38.6%), VWF:RCo was below the detection limit of 12 IU/dL; 111 of these had VWF:Ag < 20 IU/dL and therefore an incalculable VWF:RCo/VWF:Ag ratio. Clinical agreement, defined as matching VWD type (using VWF activity/antigen ratio 0.6), was 89% for VWF:RCo and VWF:GP1bM, 92% for VWF:RCo and VWF:Ab, and 83% for VWF:GP1bM and VWF:Ab. In 8/21 patients classified as type 3 VWD based on VWF:Ag < 5 IU/dL and propeptide < 4 U/dL, VWF:GP1bM results were between 5 and

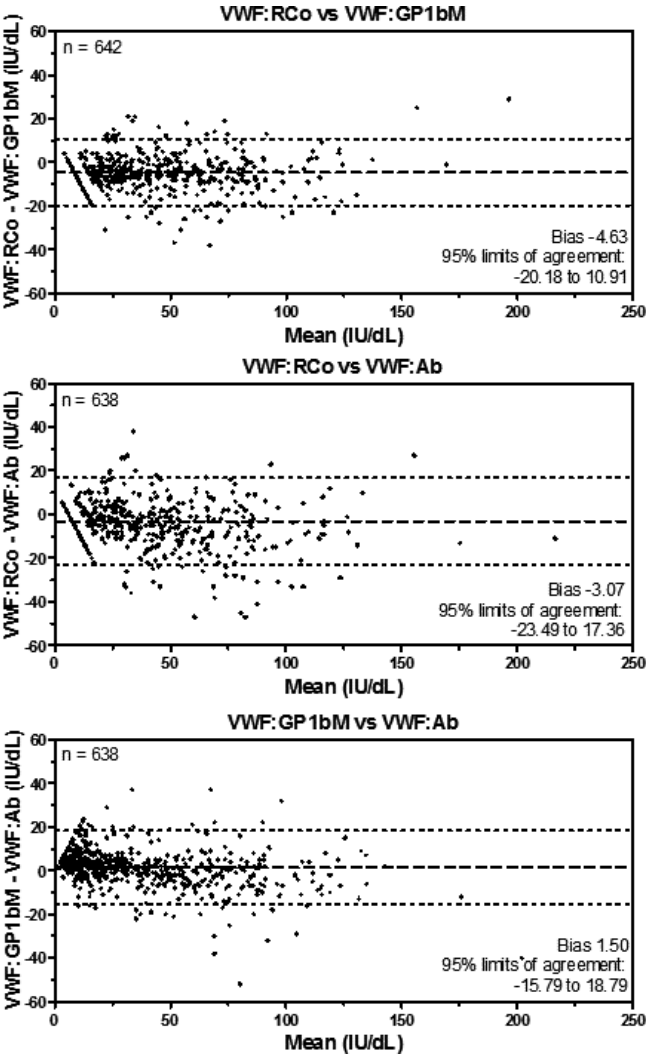

FIGURE 1 Bland-Altman plots of VWF:RCO, VWF:GP1bM and VWF:Ab

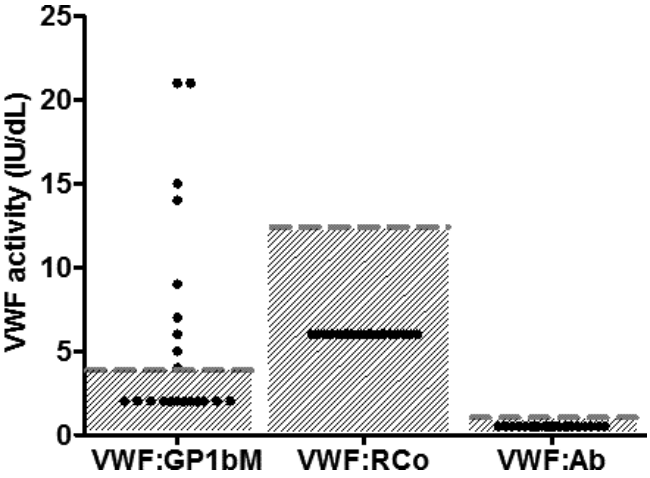

FIGURE 2 Assay results in type 3 VWD patients (VWF:Ag <5 IU/dL and VWFpp <4 U/dL) (----- limit of detection for each assay)

21 IU/dL whereas for both VWF:RCo and VWF:Ab all results were below the detection limit (fig 2).

Conclusions: In 17% of VWD patients VWF:RCo could not differentiate type 1 and 2 VWD. Almost 40% of type 3 VWD cases were missed by VWF:GP1bM. The choice between platelet-dependent VWF activity assays has a significant impact on the classification of VWD.

PB 2066 | Occurrence of Subclinical and Late Arthropathy in Patients with von Willebrand Disease

G. Castaman[1], S. Linari[1], F. Demartis[1], L. Pieri[1], C. Martinoli[2]

[1]*Center for Bleeding Disorders and Coagulation, Careggi University Hospital, Florence, Italy,* [2]*DISSAL, University of Genoa, Genoa, Italy*

Background: Joint bleeds (JB) are reported in a minority of patients with von Willebrand disease (VWD) but may lead to structural joint damage. Prevalence, severity and impact of JB in VWD are largely unknown. A recent study in the Netherlands (WIN study) showed that about 25 % of VWD patients with VWF level < 30 U/dL self-reported JB. Type 3 VWD may develop chronic arthropathy by clinical-radiologic evidence. Interestingly however a large proportion of patients with type 3 VWD do not show clinically evident joint bleeding. The role of ultrasound joint evaluation has not been systematically evaluated in VWD and the role of previous unrecognized minimal joint bleeding has not been investigated.

Aims: To evaluate clinical and ultrasound manifestations of joint bleeding in an Italian population of patients with type 3 VWD compared with a reference sample of type 1 and 2 VWD patients.

Methods: Ultrasound evaluation of knee, elbow and ankle was performed by the same investigator and scored according to the HEAD-US score (Thromb Haemost 2013; 109:1170). Fifteen patients with type 3 VWD (6 M and 9 F, age 20 - 61) and 26 patients with type 1 and type 2 VWD (11 M and 15 F) were evaluated.

Results: FVIII was < 5 U/dL in all type 3 VWD patients and ranged from 7 to 32 U/dL (median 13 U/dL) in type 1 and 2 VWD. All had VWF levels < 10 U/dL. Six patients (40 %) with type 3 VWD had US evidence of arthropathy (score ranged from 5 to 21) and all had radiological evidence of joint disease. All had the first joint bleeding < 15 years of age. No clinical and US evidence of joint disease was detected in all the other patients with type 1 and 2 VWD.

Conclusions: Joint disease is frequent in type 3 VWD but not invariably linked to the FVIII level. Joint disease associated with subclinical joint bleeding appears unlikely in patients with type 1 and 2 VWD. These results again emphasize the role of low FVIII in inducing clinical and instrumental evidence of joint disease in type 3 VWD.

PB 2067 | The Effect of Thioredoxin-1 on von Willebrand Factor Function

V. Ruiz De Miguel, M. Laffan, T. McKinnon

Imperial College London - Hammersmith Hospital Campus, London, United Kingdom

Background: Von Willebrand Factor contains a significant number of cysteine residues with some of these in the free-thiol form. However it is not understood how & where these become unpaired. Thioredoxin-1 (TRX) is a ubiquitously expressed enzyme that catalyses the formation & reduction of disulphide bonds. We hypothesised that TRX may be responsible for the formation of free-thiols in VWF.

Aims: To determine the effect of TRX on the free-thiol content of VWF.

Methods: VWF was purified from Haemate P by gel filtration. Plasma was obtained from healthy donors. Recombinant TRX was activated with thioredoxin reductase before use. Static collagen binding, multimers gel analysis & GPIb binding assays & free-thiol analysis were performed using standard methods. Assessment of VWF function under shear stress was performed in a flow chamber assay.

Results: TRX induced the formation of new free-thiols in a concentration and time dependent manner & TRX addition to plasma resulted in an increase in VWF free thiols. Functional assays demonstrated a loss of collagen binding and GPIb binding function. Multimer analysis showed a loss of multimers with higher concentrations of TRX, however despite collagen binding being affected at low concentrations of TRX, the multimeric pattern was not affected sufficiently to cause this. Mass spectroscopy analysis of TRX treated VWF highlighted the formation of new thiols in the D4 & C-domains of VWF and significantly highlighted C1142 (responsible for multimers formation) & C1872 (forms part of the A3 disulphide loop) as being unpaired. Consistently, TRX treated VWF perfused over collagen demonstrated reduced platelet capture & the addition of TRX to whole blood before perfusion significantly reduced thrombus formation.

Conclusions: TRX can specifically attack the disulphide bonds responsible for multimer formation & maintaining the structural integrity of the A3 collagen binding domain & thus may therefore be a novel regulator of VWF function at sites of injury.

PB 2068 | The Prevalence of Bleeding Disorders in Women with Histologically Proven Endometriosis

S. Heynemann[1], R. Dauer[2], C. Barnes[3], S. Grover[4,5]

[1]Royal Melbourne Hospital, Melbourne, Australia, [2]Eastern Health, Haematology, Melbourne, Australia, [3]Royal Children's Hospital, Haematology, Melbourne, Australia, [4]Royal Childrens Hospital, Department of Gynaecology, Melbourne, Australia, [5]University of Melbourne, Melbourne, Australia

Background: Mild bleeding disorders affect 1% of the population. An increased prevalence of heavy menses in women with endometriosis has been known, but the rate of bleeding disorders in women with histologically proven endometriosis has never been studied.

Aims: To establish the rate of bleeding disorders (von Willibrands disease and platelet dysfunction) in women with histologically proven endometriosis.

Methods: Women with proven endometriosis were recruited from outpatient clinics. All women underwent screening using a modified international bleeding score.(The modification to the score included family history and mittleschmerz pain, both factors shown to be predictive of bleeding disorders).This modification increased the likelihood of women being tested; nontested women were presumed to be normal. Subjects with a history of excessive bleeding tendency (considered evident if bleeding score was >4 if nulliparous/>5 if parous or if ≥3 symptoms present) underwent tests for detection of a bleeding disorder. Evaluation included platelet function and relevant clotting factors utilising: Prothrombin Time, activated Partial Thromboplastin Time, von Willebrand Factor (Antigen, Ristocetin Cofactor, Collagen Binding Activity), Factor VIII, Platelet Function Analyser-100® - Collagen/Epinephrine, Collagen/Adenosinediphosphate.

Results: Of 56 women (with histopathological confirmation of endometriosis) aged 18-48 years (mean 32.8 years, standard deviation 7.3 years), 7.4% had results outside expected range on initial vWF screening and 11.5% had prolonged closure times for PFA-100® (excluding prolonged results due to known NSAID use < 14 days prior to testing).

Conclusions: This is the first study to demonstrate an elevated rate (17.7%)of abnormal bleeding tests on testing for both VWD and platelet dysfunction in women with endometriosis and suggests a potential new avenue of intervention for endometriosis management.

PB 2069 | Report of the ISO15189 Accreditaion of the Hydragel 5 von Willebrand Multimers Assay. A within-day Method

A. Lemaitre[1], G. Nouadje[2], G. Beaulieu[2], H. Bautista[2], S. Eeckhoudt[1]

[1]Cliniques Universitaires Saint Luc, Laboratoire d'Hémostase, Bruxelles, Belgium, [2]Sebia, Lisses, France

Background: The electrophoresis of the vWF multimers allows to assess the distribution of vWF multimers in the plasma and is required to type von Willebrand disease (VWD). Until now, multimers assay was performed using home-made, time consuming and non-standardized methods. In 2016, Sebia has launched a new kit (Hydragel 5 von Willebrand Multimers) on the Hydrasis 2 Scan system. The purpose of this work is to evaluate its performances.

Aims: The electrophoresis of the vWF multimers allows the characterization of the distribution of vWF multimers in the plasma and is required to type von Willebrand disease (VWD). Until now, multimers assay was performed using home-made, time consuming and non-standardized methods. In 2016, Sebia has launched a new kit (Hydragel 5 von Willebrand Multimers) on the Hydrasis 2 Scan system. The purpose of this work is to evaluate its performances.

Methods: VWD-typed plasma samples were used for testing the specificity of the Hydragel test. Intra-day and inter-day (3 consecutive days) reproducibility have been tested using normal and pathological controls and patients. 3 different ECAT samples belonging to independent surveys where employed for exploring the accuracy of the test. Absence of inter-sample carry-over was assessed with a VWD type 3 sample. Multimers test was carried following manufacturer's instructions.

Results: Hydragel test displayed an excellent reproducibility; electrophoretic patterns were conserved in their distribution as well as in their intensity. An arbitrary fractioning of patterns allowed calculating the relative concentration (%) of each multimers subset. Type 2A and type 2B yielded complete and/or partial loss of HMW and IMW. We did not observe any inter-sample carry-over.

Conclusions: Based on the obtained results, we achieved to get the ISO15189 accreditation (June 2016) of the Hydragel 5 von Willebrand multimers and its now introduced in our lab's routine. The excellent reproducibility of the test may help to reach a good homogeneity in results reporting.

PB 2070 | Comparison of Three Different Factor VIII Assays in 154 Patients with Type 3 von Willebrand Disease: Results from the 3WINTERS-IPS Cohort

J. Goudemand[1], C. Caron[1], E. Jeanpierre[1], Z. Badiee[2], M.-R. Baghaipour[3], L. Baronciani[4], J. Batlle[5], E. Berntorp[6], I. Bodo[7], U. Budde[8], G. Castaman[9], J. Eikenboom[10], P. Sacco University Hospital & School of Medicine, Milan, Italy

Background: Patients with type 3 VWD have undetectable VWF levels. Usually the FVIII:C level is less than 5 IU/dL although higher levels (10-15 IU/dL) have been reported.

Aims: The aim of the study was to measure FVIII in a well-defined cohort of patients with type 3 VWD by using 3 different assays: one-stage clotting (FVIII:C), chromogenic (FVIII:am), antigen (FVIII:Ag) to establish their baseline FVIII concentration.

Methods: Patients diagnosed as type 3 VWD were recruited in the course of the 3WINTERS-IPS study. The phenotypic profile was checked in central laboratories. For this study only the patients with VWF:Ag < 1 IU/dL were selected. FVIII was determined by 3 assays 1) FVIII:C with FVIII deficient plasma (Siemens) and APTT reagent Triniclot (Stago) 2) FVIII:am (Hyphen BioMed) 3) FVIII:Ag by ELISA Asserachrom (Stago).

Results: In the 154 selected patients, FVIII measurements showed variation which was dependent on the type of assay (p< 0.001): FVIII:Ag > FVIII:C > FVIII:am (see Table).

TABLE

	FVIII:am (IU/dL)	FVIII:C (IU/dL)	FVIII:Ag (IU/dL)
Mean ± SD	1.23 ± 0.72	2.30 ± 0.73	3.97 ± 1.16
Median	1.3	2.2	3.8
IQR	< 1 - 1.7	1.8 - 2.8	3.2 - 4.7
Range	< 1 - 3.0	1 - 4.4	< 1 - 7.5

All patients had measurable FVIII:C (≥1 IU/dL). About 20% patients had no detectable FVIII:am, but only 1 had undetectable FVIII:Ag. Nineteen % of the patients had > 5 IU/dL FVIII:Ag, whereas none of them had FVIII:C or FVIII:am > 5 IU/dL. There was a good correlation between FVIII:C and FVIII:am (r:0.825; p< 0.001) and between FVIII:C and FVIII:Ag (r:0.318; p< 0.001) but FVIII:am and FVIII:Ag did not correlate.

Conclusions: In this study reporting the measurement of FVIII by using 3 different assays in a large cohort of patients with type 3 VWD, we observed strongly decreased FVIII:Ag concentration due to the increased clearance of FVIII in the absence of VWF. In addition, functional activities of FVIII are lower than FVIII:Ag due to the role of VWF in FVIII activation/inactivation. The presence of VWF in the FVIII deficient plasma reagent used for FVIII:C or the longest incubation time in the chromogenic assay could explain their differences. The 3 assays are not equivalent in type 3 VWD.

PB 2071 | Treatment of Gastrointestinal Bleeding Episodes with Recombinant von Willebrand Factor (rVWF) in Patients with Severe von Willebrand Disease (VWD): Sub-analysis from Pivotal Phase III On-demand Study

F. Leebeek[1], M. Chapman[2], B. Ploder[3], A. Sytkowski[2], A. Novack[4], B. Ewenstein[2]

[1]Erasmus University Medical Center, Hematology, Rotterdam, The Netherlands, [2]Shire, Inc., Cambridge, United States, [3]Shire, Inc., Vienna, Austria, [4]Shire, Inc., Chicago, United States

Background: Gastrointestinal (GI) bleeds occur in up to 20% of patients with VWD, most closely associated with the absence of ultra-large VWF multimers (ULM), generally observed in Type 2A and 3 VWD. Higher doses and longer duration of VWF replacement therapy is usually needed to resolve GI bleeds compared to bleeds at other sites and may even be unsuccessful. rVWF is a VWF concentrate in which ULM, the most hemostatically effective VWF multimers, are preserved, due to lack of exposure to ADAMTS13 during manufacturing.

Aims: A prospective, phase 3, randomized, clinical trial (NCT01410227) has been conducted to assess the efficacy and safety of rVWF-rFVIII and rVWF in the treatment of bleeds in subjects with severe VWD. The present sub-analysis was conducted on patients who experienced GI bleeds and were treated with rVWF.

Methods: The initial dose of rVWF was co-administered with rFVIII at a ratio of 1.3:1 and rVWF was administered alone after a hemostatic FVIII:C level was achieved. Efficacy was rated on a nominal 4-point scale (none=4 to excellent=1).

Results: 4 subjects (all with Type 3 VWD) experienced 6 GI bleeds (2 mild, moderate and severe). The median age of patients who experienced GI bleeds was 32.5 years (26-42). 100% of GI bleeds treated with rVWF had a hemostatic rating of excellent (83%) or good (17%) (Table 1). A total of 67% (4/6) required only 1 infusion of rVWF to successfully treat the GI bleed, with a mean of 1.3 infusions. The median

TABLE 1 GI Bleed Sub-Analysis: Bleed Characteristics and Efficacy

Patient #	# of Bleeds Treated on Study	Severity of GI Bleed	# of Days Treated with rVWF †	Clinical Efficacy Rating	# of rVWF Infusions to Resolution	Time to Resolution (hours)*
1	4	Major/Severe	0	Excellent	1	Unknown
2	6	Moderate	3	Excellent	1	1.75
2	6	Moderate	7	Excellent	1	2.67
3	2	Minor	3	Excellent	1	18.58
3	2	Minor	0	Good	2	Unknown
4	1	Major/Severe	3	Excellent	2	14

†Days from bleeding onset to first infusion, *Time from 1st infusion of rVWF to resolution of bleeding episodes

time to resolution was 8.3 h (1.75-18.6 h) in 4 of the 6 bleeds where it was known. The median total dose of rVWF per bleed was 60 IU/kg (53.6-121.0 IU/kg), and median dose per infusion of rVWF was 58.7 IU/kg (53.5-60.5 IU/kg). 2 possibly related non-serious AEs occurred in 2 patients (tachycardia & infusion site paraesthesia).

Conclusions: In this small case series of 4 subjects, rVWF was safe and effective at achieving hemostatic efficacy in the on-demand treatment of 6 GI bleeds in patients with severe VWD.

PB 2072 | Type of Renal Replacement Therapy, Access and von Willebrand Factor (VWF) Function

J. Blackshear[1], D. Chen[2], R. Safford[3], N. Aslam[4]

[1]*Mayo Clinic, Jacksonville, United States*, [2]*Mayo Clinic, Hematopathology, Rochester, United States*, [3]*Mayo Clinic, Cardiovascular Diseases, Jacksonville, United States*, [4]*Mayo Clinic, Internal Medicine, and Nephrology, Jacksonville, United States*

Background: Acquired von Willebrand syndrome occurs in native cardiovascular disorders with intravascular turbulence, with blood pumps and prosthetic valves. Anemia and gastrointestinal bleeding from angiodysplasia also occur in dialysis patients, but the prevalence of VWF abnormalities based on dialysis modality and access is unknown.

Aims: Patients undergoing dialysis, or scheduled for surgical arteriovenous fistula (AVF) creation were targeted for enrollment as follows: hemodialysis (HD) with tunneled catheter (CATH), 10, HD with AVF, 10, peritoneal dialysis (PD), 5, and pre- and post-AVF creation, 10.

Methods: Blood tests measured included VWF activity and antigen, platelet function analyzer-100 collagen adenosine diphosphate closure time (PFA-CADP), and VWF multimers. Results after2/3 enrollment are presented.

Results: VWF high molecular weight multimer loss in the range of severe aortic stenosis (AS) was seen in 5 /13 patients with an AVF, but none of the CATH or PD patients, p=0.13, figure. The VWF multimer ratio trended lower in HD patients, median (IQR) 0.13 (0.12-0.16), versus 0.16 (0.14-0.19), p=0.09. Additional trends included abnormal PFA-CADP in 56% of HD versus 17% of PD patients, p=0.16, and trends toward higher activity and antigen in PD versus HD. PFA-CADP was elevated in 64% of AVF patients versus 20% of non-AVF patients, p=0.047. VWF multimers were abnormal in 21% of AVF compared to 10% of non-AVF patients (NS). A history of gastrointestinal bleeding was present in 4 patients, 18%, 2 with abnormal multimers. The normalized multimer ratio in the bleeding patients was (median IQR) 0.72 (0.64-0.80) compared to 0.86 (0.77-0.92) in the non-bleeding patients, p=0.15.

Conclusions: Laboratory findings of acquired von Willebrand syndrome may be present in 1/4-1/3 of HD patients with AVF but not in HD with CATH or in PD. Thus, AVF may be a source of acquired von Willebrand syndrome in some HD patients.

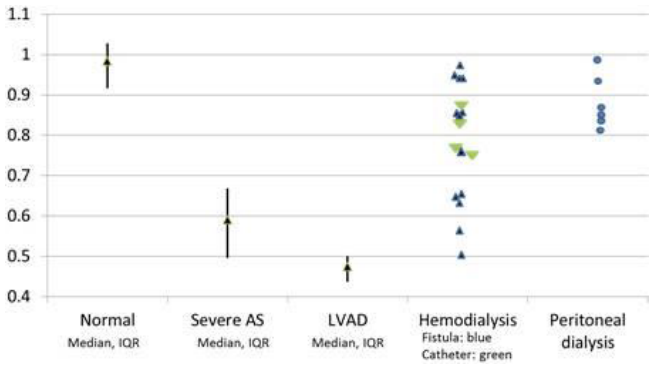

FIGURE 1 Normalized multimer ratio >15/2-15. AS=aortic stenosis, LVAD=left ventricular assist device

PB 2073 | Retrospective Single Centre Study of On-demand and Treatment Prophylaxis in 24 Patients with Type 3 von Willebrand Disease

M. Hendelmeier[1], V. Hornick[1], D. Wirtz[2], N. Marquardt[1], H.-H. Brackmann[1], G. Goldmann[1], J. Oldenburg[1]

[1]*University Hospital Bonn, Transfusion Medicine and Haemostaseology, Bonn, Germany*, [2]*University Hospital Bonn, Orthopedics, Bonn, Germany*

Background: Prophylaxis with coagulation factor concentrate is the standard of care for patients with haemophilia, but few studies have assessed prophylaxis in patients with severe forms of von Willebrand disease (VWD). The present study determines patterns of prophylaxis use and clinical outcomes in patients with type 3 VWD.

Aims: Rates of bleeding, joint damage and factor concentrate consumption were compared in patients who received prophylaxis and those who received on-demand therapy.

Methods: Data of 24 patients with type 3 VWD were retrospectively reviewed. Bleeding frequency, joint damage, and factor concentrate consumption were assessed.

Results: The median age was 34 years (range: 10-66), the median age at time of presentation was 10.5 years (range: 0-46), and the total observation period was 496.5 years (mean 20.69 years per patient). Fifteen patients received prophylaxis for a period of time and nine received only on-demand therapy. Patients who received continuous prophylaxis had fewer bleeding events per observation year (2.7) than those who received episodic on-demand therapy (5.0) or permanent on-demand therapy (4.6). Thirteen patients (54.2%) had arthropathy in at least one joint; eight of these patients had received prophylaxis. Joint status was substantially better in patients who had received primary prophylaxis than in those who had received secondary prophylaxis (total Petterson score 1.4 vs. 24.5). Factor concentrate consumption was greater in patients who received secondary prophylaxis (3146 U/kg BW/year) than in those who received primary prophylaxis (1761 U/kg BW/year).

Conclusions: Long-term prophylaxis is beneficial in most patients with type 3 VWD. Early initiation of prophylaxis may provide optimal protection against bleeding events and joint damage.

FIGURE 1 VWF Act/Ag ratio (normal >/=0.80), left and Normalized mutlimer ratio (normal=1.0), right

Results: Four women and 15 men were tested after HM II implantation 1.6±1.1 years after implant, and 9 women and 22 men 0.3±0.3 years after HW implantation (p< 0.001 for difference in time of testing). We found no difference in levels of either VWF:Act or VWF:Ag levels. However, VWF:Act / VWF:Ag trended higher in the HW patient, 0.76±0.14 versus HM II, 0.69±0.07, p=0.05 (figure, left panel). VWF multimer ratios showed similar trends with, HW versus HM II, multimer ratio >15/2-15, 0.9±0.03 versus 0.8±0.02, p=0.16, multimer ratio >10/2-10, 0.27±0.07 versus 0.25±0.05, p=0.15, normalized multimer ratio >15/2-15, 0.51±0.09 versus 0.44±0.05, p=0.06 figure, (right panel), and normalized multimer ratio >10/2-10, 0.61±0.13 versus 0.57±0.05, p=0.24).

Conclusions: In this relatively small study limited by differences in time of acquisition of samples, we see evidence of favorable trends in severity of AVWS by two independent tests of von WIllebrand factor function in the lower rotational speed LVAD.

PB 2074 | Trends in Severity of Acquired von Willebrand Syndrome with Lower Rotational Speed Left Ventricular Assist Device

J. Blackshear[1], S. Schettle[2], D. Joyce[2], D. Chen[3]

[1]Mayo Clinic, Cardiovascular Diseases, Jacksonville, United States, [2]Mayo Clinic, Thoracic and Cardiovascular Surgery, Rochester, United States, [3]Mayo Clinic, Hematopathology, Rochester, United States

Background: Bleeding related to acquired von Willebrand syndrome (AVWS) is a major source of morbidity and mortality in patients with left ventricular assist device (LVAD) support. New pump designs with reduced rotational speed and axial versus centrifugal flow may reduce blood shear stress and consequently lessen the severity of AVWS.

Aims: We sought to compare quantitative measures of AVWS in patients implanted with Heartmate II ™ (HM II) with usual rotational speeds of 9400-9600 RPM to patients implanted with Heartware ™ (HW) with usual rotational speeds of 2600 RPM.

Methods: After implantation, von Willebrand factor antigen (VWF:Ag), and activity (VWF:Act) and VWF multimers by gel electrophoresis were done on all patients. As measures of AVWS severity, we calculated VWF:Act / VWF:Ag, VWF multimer ratio >15/2-15 monomers, VWF multimer ratio >10/2-10 monomers and the two multimer ratios normalized to the plasma control sample from the electrophoresis run.

PB 2075 | Prevalence of von Willebrand Disease among Saudi Students: from Saudi Screening Program for Bleeding Disorders (SSBD)

T. Owaidah[1], E. Abu- Douleh[1], A. Abdul Albanyan[1], H. Al Zahrani[1], M. Saleh[1], A. Almomen[2], K. Alsaleh[2], A. Alsulaiman[3]

[1]KFSHRC, Riyadh, Saudi Arabia, [2]KSU, Riyadh, Saudi Arabia, [3]kfshrc, riyadh, Saudi Arabia

Background: The Saudi Screening Program for Bleeding Disorders (SSBD) is a national screening program for bleeding disorders among students.

Aims: The aim of this analysis of the SSBD study was to estimate the prevalence of Von Willebrand disease (VWD) among students (male / female) in Saudi Arabia.

Methods: Over 2 years trained interviewers surveyed 2,000 students (male /female) at a university in Riyadh, Saudi Arabia using a detailed questioner based on MCMDM1 - VWD. Any students answered one or more of the 11 questions had been subjected to sample collection and detailed coagulation factor measurements. Initial evaluation consists of (CBC, PT, PTT, ABO and PFA-100) and followed by testing for all coagulation factors including testing for VWF:Ag, VW: RCof and FVIII) assay according to standard techniques.

Results: Out of 2000 surveyed students (age were from 17 to 22 years), 730 had answered yes for more than one bleeding questions,

but only 326 students had agreed for blood sampling. After initial hemostasis laboratory testing, 117 were suspected to have VWD. A confirmatory VWD assays were carried out and identified 9 students with low level of vWF /FVII. The estimated prevalence of VWD among Saudi Adolescents in general population was 2.7%.

Conclusions: This is initial results of the first epidemiological survey of bleeding disorders in Arab ethnicity. Our results suggest that the prevalence of VWD might be higher than reported in other populations. We are continuing to survey more areas in the country and increase the sample size of this survey.

PB 2076 | Molecular Caracterization of Type 2 von Willebrand Disease

S. Freitas[1], D.C. Gonçalves[2], C. Velloso-Rodrigues[3], A.N.L. Prezotti[4], M.S. Renni[5], S.M. Rezende[1]

[1]*Federal University of Minas Gerais, Belo Horizonte, Brazil,* [2]*Fundação Hemominas, Belo Horizonte, Brazil,* [3]*Federal University of Juiz de Fora, Juiz de Fora, Brazil,* [4]*Centro de Hematologia e Hemoterapia do Espírito Santo, Vitória, Brazil,* [5]*Centro de Hematologia e Hemoterapia Arthur Siqueira Cavalcanti, Rio de Janeiro, Brazil*

Background: von Willebrand disease (VWD) is the common inherited bleeding disorder. Type 2 VWD is characterized by qualitative deficiency of VW factor (VWF) and is classified in subtypes 2A, 2B, 2M and 2N.

Aims: The purpose of this study is to characterize the molecular basis of type 2 VWD in a cohort of Brazilian patients.

Methods: Eligible patients presented bleeding symptoms and ≥ 2 tests revealing vWF:Rco/vWF:Ag ratio below 0,7. Five pairs of primers were designed to amplify exons 17, 18, 19, 20 and 28 of the VWF gene. The amplified fragments were sequenced in equipment Genetic Analyzer 3130 (Applied Biosystems). The sequences obtained were compared to wild-type allele (CCDS8539.1 from NCBI) using the BioEdit and Sequence Alignment program (version7.2.5). ISTH database of VWD mutations was checked when a base change was found.

Results: Samples from 32 patients, belonging to 28 families with type 2 VWD were included, median age of 37 years (interquartile range, 22,5 - 48,5), 65% female. So far, exon 28 was sequenced 29 patients (90,6%), of whom exon 18 and 20 were sequenced in 5 (15,6%) and 7 (21,8 %), respectively. A total of 8 mutations were identified in association with type 2 VWD and all are registered in the ISTH database (Table 1).

The bleeding score (BS, ISTH 2011) was applied in 27 patients (84,3%), of whom only 3 patients (9,3%) presented value BS > 3 (2 male) and > 5 (1 female). Another 10 base changes were found, all of which are reported in ISTH or NCBI databases (Table 2).

Conclusions: So far, we identified 7 different mutations, associated with type 2 VWD and 10 polymorphisms, all changes reported in published databases. We confirm that the molecular characterization of type 2VWD sequencing is useful in the definition of the diagnosis of the disease. This is an ongoing study and additional molecular defects will be reported upon completion of the work.

PB 2077 | Validation of a Rapid Diagnostic Approach with Automatic Tests in a Cohort of Chinese Patients with von Willebrand Disease: Results from the Chinese-Italian CReWilAct Study

Z. Yu[1], J. Yin[1], W. Zhang[1], Z. Wang[1], Z. Ma[1], X. Bai[1], C. Ruan[1], C. Bianchi[2], D. Intini[2], A. Lattuada[3], E. Sacchi[3], A.B. Federici[2]

[1]Jiangsu Institute of Hematology, Key Laboratory of Thrombosis & Hemostasis of Ministry of Health, The First Affiliated Hospital of Soochow University, Suzhou, China, [2]Hematology & Transfusion Medicine, L. Sacco University Hospital, Department of Oncology and Hematology, Milan, Italy, [3]Hematology and Transfusion Medicine, L. Sacco University Hospital & School of Medicine, Department of Oncology and Hematology, Milan, Italy

Background: von Willebrand disease (VWD) is the most common inherited bleeding disorder caused by quantitative and/or qualitative defects of von Willebrand factor (VWF). VWD correct diagnosis remains still problematic in many developed and developing countries.

Aims: A cross sectional study [Chinese Registry of von Willebrand disease with Instrumentation Laboratory approach using Automatic Tests (CReWILAcT)] was designed by the Centers of Suzhou and Milan to evaluate the appropriate approach to VWD diagnosis.

Methods: Chinese and Italian healthy subjects were used as controls versus Chinese VWD. The 3 main VWF activities (VWF:Ag, VWF:RCo, VWF:CB) were measured in citrated plasma by the automatic ACL-ACUSTAR (Instrumentation Laboratory, Bedford, USA) systems using commercially available reagent kits. The data of these 3 tests were expressed versus International Standard in IU/dL with their sensitivity and variability assessed. 3 steps were planned:

a) in lyophilized samples from 2 normal individuals and 6 cases with known VWD types available at NIBSC of London, UK;

b) in 70 Chinese and 65 Italian healthy subjects with O and non-O blood groups;

c) in 108 VWD followed in China.

Results: Sensitivity/Variability (CV) of VWF:Ag, VWF:RCo, VWF:CB were < 1 (5%), < 1 (7%) and < 1 (6%), respectively.

In step a, in 2 blind exercises, both labs could confirm diagnosis of normal controls or VWD2A, VWD2B and VWD2M.

In step b, VWF levels (Mean±SD) of O blood groups were lower than non-O in both Ch (34/36) and It (32/33) cases: VWF:Ag [Ch=89±51/102±38); It=70±26/102±38); VWF:RCo [Ch=97±36/114±33); It=74±29/101±31); VWF:CB [Ch=87±27/102±25); It=77±25/114±33).

In step c, in Ch VWD, the total mean±SD (range) of activities were: VWF:Ag [16±14(< 1-67)]; VWF:RCo [13±12(< 1-46); VWF:CB [13±13 (< 1-47)]. Using VWF:RCo/Ag VWF:CB/Ag ratios VWD3(24), VWD1/2N(43), VWD2A(21), VWD2B(8), VWD2M(13) could be confirmed.

Conclusions: These results support the use of such an automatic approach for VWD diagnosis in routine labs world-wide.

PB 2078 | The Self-association of Ristocetin

P. Lollar, W. Deng

Emory University, Atlanta, United States

Background: Ristocetin promotes platelet aggregation and agglutination in the presence von Willebrand factor. This phenomenon is the basis for the VWF ristocetin cofactor assay that is widely used to diagnose von Willebrand disease. NMR studies have revealed that ristocetin self-associates. Platelet function studies indicate that the self-association of ristocetin is required for promotion of VWF ristocetin cofactor activity.

Aims: The goal of this study was to characterize the self-association of ristocetin.

Methods: Ristocetin (Bio-Data) was characterized by HPLC and ESI mass spectrometry. The self-association of ristocetin was studied by sedimentation velocity analysis at 260,000 *g* and 20 °C in a Beckman XL-I analytical ultracentrifuge (AUC) using interference optics. Sedimentation coefficient (c(s)) distributions and weight-average sedimentation coefficient (s_w) isotherms were calculated using SEDFIT and SEDPHAT.

Results: Ristocetin was >95% pure by HPLC with a molecular mass of 2068 Da, consistent with its known structure. c(s) distributions produced s_w values increasing from 0.70 S to 1.00 S at concentrations of ristocetin ranging from 0.6 to 6.8 mM. The s_w isotherm fit a monomer-dimer self-association model yielding estimates of 1.3 mM (2.7 mg/mL) for the dimerization constant and $s_{20,w}$ values of 0.68 S and 1.18 S for monomeric and dimeric ristocetin. c(s) distributions displayed a single peak, consistent with a rapid monomer-dimer equilibrium.

Conclusions: SV AUC is a powerful method to study weakly self-associating systems and allowed characterization of the self-association of ristocetin, which has been difficult to characterize because its high self-association constant. The concentration of ristocetin used in clinical assays varies from 0.5-1.5 mg/mL. Our results indicate that this range is below the ristocetin dimerization constant. This predicts that the assay is sensitive to small variations in the concentration of ristocetin and may contribute to the problematic variability of the assay.

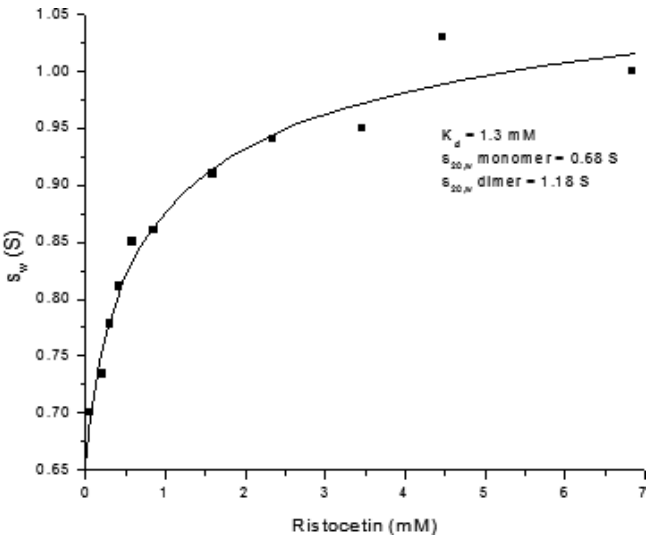

FIGURE 1 Weight-average sedimentation coefficient isotherm for ristocetin

PB 2079 | VWD2M Genotype Carrying Double Heterozygous Mutations with More Severe Phenotype than Classic VWD2M

A.I. Woods[1], J. Paiva[2], A.C. Kempfer[1], A. Blanco[2], A. Sanchez Luceros[1], M.A. Lazzari[1]

[1]IMEX-CONICET-Academia Nacional de Medicina, Laboratory of Hemostasis and Thrombosis, Ciudad Autónoma de Buenos Aires, Argentina, [2]Instituto de Investigaciones Hematologicas- Academia Nacional de Medicina, Hemostasia y Trombosis, Ciudad Autónoma de Buenos Aires, Argentina

Background: We have characterized a group of VWD2M patients (2MC) by VWF:RCo/VWF:Ag (RCo/Ag)< 0,6, normal multimers, DDAVP test and mutations (Mt) in the A1 domain of VWF.

Aims: To describe the phenotype resulting from muco-cutaneous bleeding symptoms, in the presence of double heterozygous Mt: a novel missense Mt, and its association with a deletion in a 2M patient (P). To compare the phenotype of P with that of 2MC.

Methods: Tests considered for comparison between P and 2MC: FVIII:C (one-stage method), VWF:Ag (Ag) (ELISA), VWF:RCo (RCo) (aggregometry). DDAVP response, tested before and after 90min of intravenous infusion.

Exon 28 of *VWF* gene was analyzed in P and 100 healthy controls (HC).

Results: P: boy (8-yr) (blood O group); ISTH bleeding score (BS)=6; epistaxis requiring tamponades; bleeding after tooth eruption and extraction; easy bruising; gum bleeding; normal multimers and VWF:CB (collagen type 1).

2MC (n=31): BS=4.6±3.2. Laboratory tests in table 1.

P showed lower FVIII:C, VWF:Ag and the DDAVP response than those in 2MC. Two Mt were found in *VWF* gene: 1) c.4276C>T (p.R1426C) in A1 domain, and 2) c.4944delT (p.P1648fs*45) in A2 domain.

p.R1426C was absent in HC, predicted as damaging by in silico analysis (PolyPhen-2, Mutation Tester, SIFT), and submitted by us to the ISTH-SSC-VWF database.

Conclusions: We report here a novel Mt: p.R1426C, and its association with a deletion, in a severe VWD2M phenotype. The lower FVIII:C, and VWF:Ag would probably be by the combination of the blood O group and the presence of p.P1648fs*45 which was reported as type 1 (ISTH-SSC-VWF database). In these situations, we should be aware of the selection of appropriate treatment.

PB 2080 | The Occurrence of Prothrombotic Mutations in a Patient with von Willebrand Disease and Symptomatic Bleeding Disorder

A. Sikorska[1], J.M. Teliga-Czajkowska[2], B. Ceglarek[3], K. Bykowska[3], B. Baran[3], J. Windyga[4]

[1]Institute of Hematology and Transfusion Medicine, Department of Hemostatic Disorders and Internal Medicine, Warsaw, Poland, [2]Medical University of Warsaw, Department of Obstetrics and Gynecology Didactics, Warsaw, Poland, [3]Institute of Hematology and Transfusion Medicine, Department of Hemostasis and Metabolic Disorders, Warsaw, Poland, [4]Institute of Hematology and Transfusion Medicine, Department of Hemostatic Disorders and Internal Medicine, Department of Hemostasis and Metabolic Disorders, Warsaw, Poland

Background: VWD is genetically inherited and is clinically heterogeneous. Moreover, the coexistence of other hemostatic defects may enhance or weaken the predisposition for bleeding.

Aims: Assessment of the impact of prothrombotic mutations on the clinical picture of bleeding disorder in a patient with VWD.

Methods: Activity of FVIII (FVIII:C) and von Willebrand factor (VWF), ristocetin cofactor activity (VWF:RCo) as well as of VWF factor antigen (VWF: Ag) were determined using Siemens reagents (BCS Siemens). The method of Křížek et al. (2000) was used for analysis of von Willebrand factor multimers. The G20210A mutation in the prothrombin gene, the G1691A mutation in the V (factor V Leiden), and C677T methylenotetrahydrofolate reductase gene (MTHFR) mutation were determined using RFLP / PCR (EURx, Poland).

Results: A 22 year old woman was referred with symptoms of bleeding disorder. Bleeding episodes appeared in childhood and consisted in nose and mouth bleeds, extensive bleeding following extraction of milk teeth, and heavy menstrual bleeding. Medical history revealed occurrence of VTE and arterial thrombosis in the families of both mother and father as well aa bleeding episodes in the mother's family (CNS bleeding). The patient was diagnosed with von Willebrand disease type 1: FVIII:C - 108% ; VWF:RCo - 29%; VWF:Ag - 44% and VWF:RCo / VWF:Ag ratio 0.66; the VWF multimer structure was normal. Further tests revealed the presence of heterozygous factor V Leiden mutation, heterozygous G20210A mutation of prothrombin gene and homozygous C677T MTHFR mutation coexistent with hyperhomocysteinemia. Family studies showed heterozygotic factor V Leiden mutation and heterozygous C677T MTHFR gene mutation with hyperhomocysteinemia in the mother and G20210A prothrombin

TABLE 1 Phenotypic profile of P and 2MC

	FVIII:C (IU/dL)	Ag (IU/dL)	RCo (IU/dL)	RCo/Ag	CB (IU/dL)	CB/Ag
P pre DDAVP	24	18	<10	0.5	14	0.78
P post DDAVP	45	34	<10	0.26	not done	not done
P post/pre ratio	1.87	1.88	1			
2MC pre DDAVP	52.6±16.5	36±20	8.9±3.8	0.35±0.19	35.4±27.3	0.9±0.23
2MC post DDAVP	126.8±42.6	100.2±59.4	37.2±28.8	0.33±0.15	not done	not done
2MCpost/pre ratio	2.41±0.9	3.15±0.8	3.8±2.2			
Normal range	50-150	50-150	50-150	>0.6	60-130	>0.6

gene mutation (heterozygous) and MTHFR C677T mutation (homozygous) coexistent with hyperhomocysteinemia in the father and his brother.

Conclusions: The prothrombotic mutations does not show significant impact on hemostatic function in the patient with type 1 VWD.

PB 2081 | Von Willebrand Factor (VWF) Propeptide (VWFpp) and VWFpp to VWF Antigen (VWF:Ag) Ratio in Assessment of Inherited (VWD) and Acquired (AVWS) von Willebrand Disease

K. Bykowska[1], E. Czajkowska[2], A. Misiak[3], A.J. Sikorska[4], D. Zakrzewski[5], B. Baran[1], B. Ceglarek[6], J. Windyga[1,7]

[1]Institute of Hematology and Transfusion Medicine, Department of Hemostasis and Metabolic Disorders, Warsaw, Poland, [2]Institute of Hematology and Transfusion Medicine, Department of Hematology, Warsaw, Poland, [3]Institute of Hematology and Transfusion Medicine, Department of General, Oncological and Metabology Surgery1, Warsaw, Poland, [4]Institute of Hematology and Transfusion Medicine, Department of Disorders of Haemostasis and Internal Medicine, Warsaw, Poland, [5]Institute of Cardiology, Warsaw, Poland, [6]Institute of Hematology and Transfusion Medicine, Department of Disorders of Hemostasis and Internal Medicine3, Warsaw, Poland, [7]Institute of Hematology and Transfusion Medicine, Department of Disorders of Hemostasis and Internal Medicine, Warsaw, Poland

Background: VWFpp is essential for proper biosynthesis of VWF. After cleavage from mature VWF, noncovalent complex of VWF and VWFpp is packed into Weibel-Palade bodies of endothelial cells and α granules of platelets. After release to plasma the complex dissociate and its elements circulate independly.

Aims: It has been assumed that the VWFpp/ to VWF:Ag ratio (VWFpp/VWF:Ag) is an important biomarker of VWF clearance.

Methods: 50 healthy persons; 108 with VWD and 21 patients with AVWS: 11 with essential thrombocythemia, 3 with antibodies to VWF, 7 with aortic valve stenosis. We determined Factor VIII (VIII:C), VWF ristocetin cofactor activity (VWF:RCo) and VWF antigen (VWF:Ag) by Siemens; VWFpp by Sanquin, collagen binding activity (VWF:CB) by Technoclone and VWF multimetr structure by Krizek et al., 2000.

Results: The following results were obtained: 1)control group: VWFpp/VWF:Ag 0,49 - 1,8. 2) patients: a) with VWF:Ag< 5% and VWF:RCo< 5% - 6/7 had VWFpp < 1 (type 3 VWD) and 1/7 - VWFpp/VWF:Ag - 16,0; b) with VWF:RCo< 10% and VWF:Ag>5% - 8/9 had VWFpp/VWF:Ag >2; c) with VWF:RCo 10-20% - in 8/29 -VWFpp/VWF:Ag was >2; d) with VWF:RCo 20-30% - VWFpp/VWF:Ag - in 1/11 was >2; e) with VWF:RCo 30-40% - VWFpp/VWF:Ag ratio was >2 in 2/28; f) with VWF:RCo 40-50% - in 24/24- VWFpp/VWF:Ag ratio was within normal range.

AVWS patients with essential thrombocythemia and aortic stenosis had normal VWFpp/VWF:Ag ratio. Patients with antibodies in a course of monoclonal gammapathy had pathological ratio of VWFpp/VWF:Ag 3,57; 6,54; 4,57 respectively.

Conclusions: Increased VWFpp/VWF:Ag ratio was determined more frequently in VWD patients with VWF:RCo < 20% with type VWD 2. In AVWS patients, VWFpp/VWF:Ag ratio was within normal range; except for patients with antibodies against VWF.

PB 2082 | Extensive Bilateral Mandibular Pseudotumor in a Boy with Type 3 von Willebrand Disease (VWD) Treated with Plasma Derived VW/Factor VIII Concentrate (FC): Diagnosis, Treatment and Outcome

J.P. Frontroth[1], G. Sciuccati[1], M. Hepner[1], L. Galluzzo[2], C. Pepe[1], S.E. Annetta[1], G. Pieroni[1], M. Bonduel[1]

[1]Hospital de Pediatría ‚Prof. Dr. Juan P Garrahan', Servicio de Hematología y Oncologia, Buenos Aires, Argentina, [2]Hospital de Pediatría ‚Prof. Dr. Juan P Garrahan', Servicio de Patología, Buenos Aires, Argentina

Background: Pseudotumor is a rare complication of hemophilia whereas it was exceptionally described in VWD.The pathogenesis and therapy of pseudotumor remain elusive.

Aims: To describe the diagnosis, therapy and outcome of a boy with type 3 VWD with bilateral mandibular pseudotumor treated with FC(*Humate-P*®).

Methods: Case report.

Results: A Peruvian 6-year-old boy was referred to our center. He had severe epistaxis, gingivorragia, bruising and anemia since the first year of age. He had no hemarthrosis. Laboratory results support the diagnosis of type 3 VWD: VWF:Ag: < 1 IU dl^{-1}, VWF:RCo: undetectable, FVIII:C: 4 IU dl^{-1}.His mother is dead and his father has VWF:Ag: 45 IU dl^{-1}, VWF:RCo: 31 IU dl^{-1}, FVIII:C: 88 IU dl^{-1}. Exon 28 (PCR/Sanger):no variant was detected, multiplex ligation-dependent probe amplification: no large deletion was found, next generation sequencing results are pending. At 13-year-old he developed progressive painless slow-growing tumefactions in the angles of both mandibles. CT scan detected bilateral osteolytic lesions. A surgery biopsy showed osseous trabeculae, blood clotting material and a cystic wall with intense hyalinization and collagenization. Moderate inflammatory infiltrates and marked osteoblast bone remodeling was also found. FC was given followed by prophylaxis with 50 IU VWF ristocetin cofactor/kg two times a week during 50 months.

Conclusions: We present a boy with extensive mandibular pseudotumor treated with FC followed by long-term prophylaxis who achieved a complete and sustained bone resolution. The role of VWF in osteoclast differentiation could be involved in this response.

PB 2083 | Laboratory Identification of von Willebrand Disease: A Contemporary Approach

E.J. Favaloro[1,2], S. Mohammed[1], S. Oliver[1], K.K.E. Lau[1], L. Pasalic[1,2]

[1]ICPMR, Westmead Hospital, Westmead, Australia, [2]Sydney Centres for Thrombosis and Haemostasis, Westmead, Australia

Background: von Willebrand disease (VWD) is reportedly the most common inherited bleeding disorder, with high rates of acquired events also documented. VWD arises from quantitative and/or qualitative deficiency/defects in von Willebrand factor (VWF), a plasma

TABLE 1 Summary of representative sample VWD results (refer Figure 1)

Lane ID	Method Group	VWD type	VWF:Ag	VWF:CB	VWF:RCo	CB/Ag	RCo/Ag	Lab Interp
2	ELISA/plt agg	2M	100	87	23	0.87	0.23	2M

protein with multiple activities. VWD shows significant heterogeneity with six recognised types, representing quantitative deficiency of VWF (partial, Type 1; complete, Type 3) or diverse qualitative defects (Types 2A, 2B, 2N, 2M). However, recognition of VWD by labs, including correct assignment of type, suffers from high error rates, potentially due to analytical issues (eg, poor or inconsistent methodologies; limited test panels) or post analytical issues (eg, misinterpretation of test results).

Aims: To evaluate contemporary laboratory methods used for identification of VWD as an aid to diagnosis, and identify patterns that may most effectively facilitate diagnosis.

4	VWD-2M	**47**	66	**17**	1.40	**0.36**
5	VWD-2A	**45**	**19**	**10**	**0.42**	**0.22**

FIGURE 1 Sample multimer gels (refer to Table 1)

Methods: Retrospective and prospective evaluation of test results from a large panel of samples comprising VWD, non-VWD, and therapy (eg, VWF concentrate, DDAVP) associated samples with a battery of contemporary methods.

Results: Sample results are shown in Table 1 and Figure 1. Different assays yield differential utility according to VWD type. For example, AcuStar **c***hemiluminescence* methods were best at identification of low level VWF, and thus best facilitated early identification of Type 3 VWD, and best discrimination of Type 1 vs 2A/2B/2M VWD. However, ELISA methods were better at discriminating Types 2A vs 2M VWD. VWF glycoprotein Ib binding results approximated ristocetin cofactor results.

Conclusions: Laboratories should select the best methods and test panels able to identify VWD. A composite and sequential approach provides the best opportunity for effective diagnosis of VWD.

PB 2084 | Importance of Classification and Genetic Tests in the Diagnosis of von Willebrand Disease Type 2B and 2N

A. Kerényi[1], J. Kállai[2], R. Gindele[2], I. Szegedi[3], J. Hársfalvi[4], A. Szederjesi[5], Z. Szabó[2], C. Kiss[3], I. Bodó[5], Z. Bereczky[2], L. Muszbek[2], J. Kappelmayer[1]

[1]*University of Debrecen, Faculty of Medicine, Department of Laboratory Medicine, Debrecen, Hungary,* [2]*University of Debrecen, Faculty of Medicine, Division of Clinical Laboratory Science, Department of Laboratory Medicine, Debrecen, Hungary,* [3]*University of Debrecen, Faculty of Medicine, Department of Pediatrics, Debrecen, Hungary,* [4]*Semmelweis University, Department of Biophysics and Radiation Biology, Budapest, Hungary,* [5]*St. István and St. László Hospital, Department of Hematology and Stem Cell Transplantation, Budapest, Hungary*

Background: Von Willebrand disease (VWD) is the most frequent inherited bleeding disorder caused by a dysfunction of primary hemostasis. Type 2 VWD includes a wide range of qualitative abnormalities of von Willebrand factor (VWF) resulting in different subtypes. Type 2B VWF variants have increased affinity for platelet GPIb. Type 2N is characterized by markedly decreased VWF affinity for coagulation factor VIII (FVIII).

Aims: We present three cases with these VWD subtypes to demonstrate the importance of thorough laboratory investigation for the exact diagnosis.

Methods: Coagulation screening tests, immunological and functional assays of VWF, FVIII activity and classification VWD tests (including ristocetin-induced platelet aggregation; RIPA, VWF:FVIII binding assay) and DNA sequencing were performed.

Results: Patient1 is a 13 year old girl who had prolonged menstrual bleeding. Among hemostasis tests the only abnormality was enhanced low-dose RIPA, which suggests type 2B VWD. With molecular genetic test a heterozygous p.P1266L mutation was found in exon 28 of the VWF gene. Patient2 and patient3 are 9 and 10 year old girls without bleeding symptoms, in their cases hemostasis screening tests were carried out before tonsillectomy and prolonged APTT was detected due to low FVIII activity (22% and 19%, respectively). VWF levels and VWF activities were in the reference range. Their extremely low VWF:FVIII binding ELISA assay results verified type 2N VWD. DNA sequence analysis showed that patient2 carries homozygous p.R854Q mutation in exon 20, while this mutation was identified in the heterozygous state in patient3 who also displayed the p.Y795C mutation in heterozygous form in exon 18 of the VWF gene.

Conclusions: These cases show that despite normal immunological and functional assay results the patient may suffer from rare VWD subtypes, therefore classification VWD tests followed by molecular genetic investigation have to be performed.

MANAGEMENT OF THROMBOEMBOLISM

PB 256 | Relevance of Polypharmacy for the Clinical Outcome of Patients Receiving Oral Anticoagulation Therapy - Results from the thrombEVAL Study

L. Eggebrecht[1,2], M. Nagler[1,2,3], S. Göbel[2,4,5], H. Lamparter[2,3], K. Keller[2,3,4], C. Bickel[6], M. Lauterbach[7], C. Espinola-Klein[8,9], R. Hardt[2,10], T. Münzel[3,4,5], P.S. Wild[1,3,5], J.H. Prochaska[3,4,5]

[1]Preventive Cardiology and Preventive Medicine, Center for Cardiology, University Medical Center of the Johannes Gutenberg University, Mainz, Germany, [2]Center for Translational Vascular Biology (CTVB), University Medical Center Mainz, Johannes Gutenberg-University, Mainz, Germany, [3]Center for Thrombosis and Hemostasis, University Medical Center of the Johannes Gutenberg-University, Mainz, Germany, [4]Center for Cardiology - Cardiology I, University Medical Center of the Johannes Gutenberg-University, Mainz, Germany, [5]DZHK (German Center for Cardiovascular Research), Partner Site Rhine Main, Mainz, Germany, [6]Federal Armed Forces Central Hospital Koblenz, Department of Medicine I, Koblenz, Germany, [7]Barmherzige Brüder Hospital Trier, Department of Medicine 3, Trier, Germany, [8]Center for Cardiology - Cardiology I, University Medical Center of the Johannes Gutenberg-University Mainz, Mainz, Germany, [9]Center for Translational Vascular Biology (CTVB), University Medical Center Mainz, Johannes Gutenberg-University Mainz, Mainz, Germany, [10]Center for General Medicine and Geriatric Medicine, University Medical Center Mainz, Johannes Gutenberg University, Mainz, Germany

Background: Polypharmacy (PP) is associated with negative clinical outcome in various settings and commonly observed in patients receiving oral anticoagulation (OAC) therapy.

Aims: To investigate the effect of PP on OAC-specific outcome (i.e. thrombotic and bleeding events) and non-specific outcome (i.e. hospitalization, all-cause mortality) among patients receiving vitamin K-antagonists (VKA).

Methods: Information on 2,011 individuals from the prospective, multi-center thrombEVAL study were available for analysis. Data were obtained from clinical visits, computer-assisted personal interviews, self-reported data and laboratory measurements. Information on study endpoints were validated by medical records and subsequently adjudicated. PP was defined as the intake of ≥5 drugs (including VKA).

Results: In total, the prevalence of PP was 84.1% (n=1,691) in the study sample, with 44.7% (n=899) of subjects receiving 5-8 drugs (moderate PP) and 39.4% (n=792) ≥9 drugs (marked PP). Time in therapeutic range was lower in individuals with moderate and marked PP (70.8%, IQR 53.5%/85.2% and 65.1%, IQR 45.9%/81.9%, respectively) in comparison to subjects without PP (74.2%, IQR 50.0%/90.5%). During the 2-year follow-up, the incidence of bleeding, hospitalization and all-cause mortality was higher in PP individuals and increased significantly with severity of PP (Table). In Cox regression analysis with adjustment for age, sex, cardiovascular risk factors and comorbidities, clinically-relevant bleeding (HR 1.71; 95%CI 1.05-2.78; P=0.032) and all-cause mortality (HR 2.25; 95%CI 1.41-3.59; P< 0.001) were independently associated with marked PP, whereas moderate PP ($HR_{bleeding}$ 1.44;95%CI 0.90-2.32 and $HR_{mortality}$ 1.37;95%CI 0.85-2.19, respectively) did not pass the threshold of statistical significance for both endpoints.

Conclusions: The presence of PP affects quality of OAC therapy and the incidence of clinical outcome of anticoagulated patients, which

TABLE 1 Incidence of anticoagulation-specific and non-specific outcome according to polypharmacy status

	Incidence of adverse events			
	No polypharmacy	Moderate polypharmacy	Marked polypharmacy	
	[no./100 patient-years] (95%CI)	[no./100 patient-years] (95%CI)	[no./100 patient-years] (95%CI)	P for trend
Thromboembolic events	5.3 (3.4/8.0)	3.5 (2.6/4.8)	4.5 (3.3/6.0)	0.67
Clinically-relevant bleeding	5.3 (3.4/8.0)	10.0 (8.3/12.0)	14.4 (12.1/16.9)	<0.0001
Major bleeding	3.7 (2.1/6.0)	7.0 (5.6/8.7)	9.5 (7.7/11.6)	0.003
Hospitalization	54.5 (47.7/61.9)	71.0 (66.3/76.0)	97.2 (91.2/103.5)	<0.0001
All-cause mortality	5.1 (3.2/7.7)	8.2 (6.6/10.0)	15.1 (12.8/17.7)	<0.0001

might be clinically-relevant for risk stratification and management of OAC therapy.

PB 257 | Thromboembolic and Bleeding Risk of Patients with Left-sided Mechanical Heart Prosthesis: The FCSA-START-Valvole Study

D. Poli[1], R. De Caterina[2], V. Pengo[3], E. Antonucci[4], L. Migliaccio[4], E. Grifoni[1], N. Maggini[1], M. Moia[5], S. Testa[6], G. Palareti[4], FCSA-START group

[1]Azienda Ospedaliera Universitaria Careggi, Firenze, Italy, [2]Università degli Studi di Chieti, Chieti, Italy, [3]University of Padua, Department of Cardiac, Thoracic and Vascular Sciences, Padova, Italy, [4]Fondazione Arianna Anticoagulazione, Bologna, Italy, [5]Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy, [6]Ospedale di Cremona, Cremona, Italy

Background: Patients (pts) who have received a mechanical prosthetic heart valve implantation need to be treated with a vitamin K antagonist (VKA).

Aims: Aim of the study was to evaluate adverse events during treatment.

Methods: In the frame of the START Register (Italian Survey on Anticoagulated Patients Register), we conducted an observational retrospective multicenter study among 33 centers affiliated to the Italian Federation of Anticoagulation Clinics (FCSA). FCSA centers follow pts for the management of anticoagulant treatment, perform INR test and prescribe written daily VKA dosage. Patients were followed-up with the aid of specific dedicated softwares; quality of anticoagulation, bleeding and thrombotic events occurring during the follow-up were recorded. Centers were asked to provide information on each patient in whom a left-sided mechanical prosthetic heart valve was implanted after 1998, with follow-up data.

Results: We enrolled 3027 pts; in this sub-study we analyze 2357 pts (77.9%) with mechanical prosthesis, 1928 (81.8%) on warfarin and 429 (18.2%) on acenocoumarol, followed for a median of 9.7 yrs. More time was spent below the intended therapeutic range in mitral than aortic prosthetic valve (**Table 1**).

TABLE 1 Characteristics of patients

Males, N (%)	1301 (55.2)
Median age at implantation, yrs (IQR)	59.0 (49.7-65.7)
Total follow-up (x 100 pt-years)	24080
Aortic, N(%)	1382 (59.7)
Mitral	666 (28.8)
Mitro-Aortic	33 (1.20)
Median time spent below TR (%) (IQR)	24 (12-36)
Median Time spent within TR (%) (IQR)	60 (47-74)
Mitral: median time spent below TR (2·5-3·5 INR) (%) (IQR)	26 (15-38)
Aortic: median time spent below TR (2·0-3·0 INR) (%) (IQR)	14 (5-25)

TABLE 2 Bleeding and thrombotic events in relation to site of implantation

Site of implantation	Major Bleeding, N (rate % pt-yrs)	Thrombosis,N (rate % pt-yrs)
Aortic	144 (1.01)	72 (0.5)
Mitral	62 (0.89)	74 (1.07)
Mitro-aortic	33 (1.20)	17 (0.62)

Relative risk for thromboembolism of mitral vs aortic prosthetic valve was 2.39 (95%CI 1.70-3.36; p< 0.0001). No difference for bleeding risk was found in relation to valve position.

Conclusions: In this cohort of patients with a mechanical heart prosthesis the rate of adverse events was low. No differences were recorded for bleeding in relation to the site of implantation. The rate of thrombotic events was higher in pts with mitral valves, probably due to their known higher thrombogenicity, but also to a higher rate of inappropriately low INR in anticoagulation management of these patients.

PB 258 | Warfarin Binds to a Hydrophobic Pocket within the Oxidized Open State Human VKORC1 Conformation

K.J. Czogalla[1], A. Biswas[1], K. Höning[2], V. Hornung[2,3], K. Liphardt[1], M. Watzka[1], J. Oldenburg[1]

[1]Institute of Experimental Hematology and Transfusion Medicine, University Clinic Bonn, Bonn, Germany, [2]Institute of Molecular Medicine, University Hospital Bonn, Bonn, Germany, [3]Gene Center and Department of Biochemistry, Ludwig-Maximilians-Universität München, Munich, Germany

Background: Vitamin K 2,3-epoxide reductase complex subunit 1 (VKORC1) catalyzes the reduction of vitamin K quinone (K) and vitamin K 2,3-epoxide (K>O). This process is essential for further modification of vitamin K dependent coagulation factors leading to their biological activity. VKORC1 is also a drug target of 4-hydroxycoumarins, as warfarin is used in therapy and prevention of thrombosis. Over-anticoagulation results in serious bleedings but can be reversed by administration of K.

Aims: To identify the preferred oxidized/reduced state of human VKORC1 (*hVKORC1*) to which warfarin binds.

Methods: Models of *hVKORC1* in different oxidized/reduced states were generated based on the X-ray crystallographic structure of a prokaryotic VKOR enzyme and with energy minimization techniques. Warfarin was docked on all these models. All these models were also submitted to the Encom and ANMpathway server for conformational sampling. Warfarin dose responses of mutated VKORC1 residues of cysteines in the loop or the active centre were measured in CRISPR/cas9 engineered VKOR deficient *HEK293T* cells.

Results: Best docking poses for warfarin were generated for an open loop conformation of the oxidized form of hVKORC1 (Cys43-Cys51 and Cys132-Cys135 disulphide bonds). Conformational sampling of hVKORC1 models suggests a conformational switch between the

open loop fully oxidized and closed loop partially oxidized state during reduction of K vitamers. This is blocked by warfarin binding to the open oxidized state. Shifted warfarin dose responses were measured when loop cysteines were mutated to alanine or serine.

Conclusions: Our results challenge the current concept of non-competitive warfarin inhibition since we demonstrate that K vitamers and warfarin share binding sites with F55 as central residue binding either the substrate or inhibitor. We suggest a competitive slow tight binding inhibition where warfarin binds VKORC1 in the oxidized form and is outcompeted by vitamin K when loop cysteines get reduced by oxidoreductase partners.

PB 259 | The Contribution of Genetic Variants that Are Associated with Venous Thrombosis or with Vitamin K Antagonist Dosage, alone or Combined, to the Risk of Major Bleeding in Patients Treated with Vitamin K Antagonists

N. van Rein[1], W.M. Lijfering[2], M.H.A. Bos[3], J.J. Swen[1], F.J.M. van der Meer[3], P.H. Reitsma[3]

[1]Leiden University Medical Center, Department of Clinical Pharmacy and Toxicology, Leiden, The Netherlands, [2]Leiden University Medical Center, Department of Clinical Epidemiolgy, Leiden, The Netherlands, [3]Leiden University Medical Center, Department of Thrombosis and Haemostasis, Leiden, The Netherlands

Background: Genetic variants in several genes are associated with venous thrombosis and the required dosage of vitamin K antagonists (VKA). However, data on the association between these variants and major bleeding in VKA-treated patients is limited.

Aims: To estimate the risk of major bleeding in VKA-treated patients in relation to 3 genetic variants that are associated with venous thrombosis or with VKA dosage.

Methods: The BLEEDS cohort comprises 16,570 patients who started VKA therapy between 2012 and 2014. Patients were followed until a major bleed, the end of VKA therapy, death, or December 31st 2014, whichever came first. From the cohort, we assembled a case-cohort study including all 326 cases with a major bleeding and a random sample of 978 patients at baseline (subcohort). Risk estimates of major bleeding based on all 3 genetic variants were estimated separately and in a risk score comparing the presence of 1 and 2-3 genetic variants versus those who had 0 genetic variants. Hazard ratios (HRs) and 95% confidence intervals (CIs) were estimated by means of weighted Cox regression.

Results: DNA was available from 246 cases and 834 subcohort patients. The mean age was 71 years and 54% were male. Allele frequencies were 93% for rs6025 in Factor V, 39% for rs505922 in ABO and 16% for rs9934438 in VKORC1. Individual genetic variants were associated with an increased risk of major bleeding, with hazard ratios (HRs) of 1.27 (95%CI 0.66 to 2.44) for rs6025, 1.05 (95%CI 0.78 to 1.41) for rs505922 and 1.39 (95%CI 0.95 to 2.03) for rs9934438. When considering genetic variants concomitantly with 0 variants as a reference, 1 variant was associated with a HR of 1.73 (95%CI 0.59 to 5.10) and 2 or 3 variants with a HR of 2.18 (95%CI 0.74 to 6.38).

Conclusions: Multiple genetic variants associated with venous thrombosis or VKA dosage increase the risk of major bleeding in VKA-treated patients.

PB 260 | Assessment of the Efficacy of a Novel Tailored Vitamin K Dosing Regimen in Lowering INR in Over-anticoagulated Patients

E. Kampouraki[1], P.J. Avery[2], H. Wynne[3], T. Biss[4], J. Hanley[4], K. Talks[4], F. Kamali[1]

[1]Newcastle University, Institute of Cellular Medicine, Newcastle upon Tyne, United Kingdom, [2]Newcastle University, School of Mathematics & Statistics, Newcastle upon Tyne, United Kingdom, [3]Freeman Hospital, Older People's Medicine, Newcastle upon Tyne, United Kingdom, [4]Royal Victoria Infirmary, Department of Haematology, Newcastle upon Tyne, United Kingdom

Background: Current guidelines advocate the use of fixed-doses of oral vitamin K for the reversal of excessive anticoagulation in warfarinized patients (either asymptomatic or with minor bleeds). Over-anticoagulated patients present with a wide range of International Normalized Ratio (INR) values and response to fixed doses of vitamin K varies. Consequently, a significant proportion of patients remain outside their target INR 24 hours after vitamin K administration making them prone to either haemorrhage or thromboembolism.

Aims: To compare the performance of a novel tailored vitamin K dosing regimen to that of a fixed-dose regimen with the primary measure being the proportion of over-anticoagulated patients returning to their target INR 24h later.

Methods: The study was approved by the National Research Ethics Service-Committee North East, Newcastle & North Tyneside. After obtaining informed consent, 181 patients with an index INR >6.0 (asymptomatic or with minor bleeding) were randomly allocated to receive orally either a tailored dose (calculated according to index INR and body surface area), or a fixed-dose (1 or 2mg) of vitamin K. The patients' INR was checked 24h after vitamin K dosing.

Results: Compared to the fixed-dose regimen, the tailored dose resulted in a significantly greater proportion of patients returning to within target INR range (68.9% v 52.8%; p=0.026), whilst a significantly smaller proportion remained above target INR range (12.2% v 34.0%; p< 0.001). There was no significant difference between the two dosing regimens in the proportion of patients (18.9% v 13.2%) with over-corrected INR at 24 h.

Conclusions: Individualisation of vitamin K dosing is simple to implement in the clinic and is significantly more accurate than fixed-dose regimen in lowering INR in excessively anticoagulated patients.

PB 261 | Clinical Usefulness of the SAMe-TT2R2 Score: A Systematic Review and Meta-analysis

J.H.A. van Miert[1], S. Bos[2], N.J.G.M. Veeger[3], K. Meijer[1]

[1]University Medical Center Groningen, Haematology, Groningen, The Netherlands, [2]University Medical Center Groningen, Internal Medicine, Groningen, The Netherlands, [3]University Medical Center Groningen, Clinical Epidemiology, Groningen, The Netherlands

Background: It has proven hard to predict the time in the therapeutic range for vitamin K antagonist therapy. The SAMe-TT2R2 risk score was developed to predict therapy outliers before start of treatment. It is now also used as a proposed decision rule to provide extra care, or to indicate DOAC therapy for those at high risk of poor VKA control. However, the studies supporting this use assessed diverse cutoffs for outcome and their predictive value has not been well evaluated.

Aims: To evaluate the predictive value and clinical usefulness of the SAMe-TT2R2 score.

Methods: We performed a systematic review in Embase and PubMed for original research papers or abstracts assessing the SAMe-TT2R2´s performance to predict low TTR. A meta-analysis was done with cutoffs for score (≥ 2 and ≥ 3) and TTR (< 70%), such that a high score predicts low TTR. Different cutoffs were harmonised by multiple simulations with patient characteristics from the individual studies.

Results: 18 studies were identified and used in the meta-analysis (4 and 2 times directly, 9 and 10 times harmonised for scores ≥ 2 and ≥ 3, respectively). A score ≥ 2 yielded a sensitivity of 42% (95% CI 29-54%) and specificity of 66% (54-78%) to predict TTR < 70%. A score ≥ 3 had a sensitivity and specificity of 34% (12-55%) and 70% (48-92%), respectively. The positive likelihood ratios were 1.26 (1.16-1.36) for a score ≥ 2, and 1.28 (1.12-1.43) for a score ≥ 3; the negative ones were 0.88 (0.83-0.93) and 0.97 (0.90-1.03), respectively. This shows that the post-test probabilities hardly differ from the prior probability (prevalence) (see also Figure 1).

Conclusions: The SAMe-TT2R2 score does predict low TTR, but the effect is small. Its effect on individual patients is too limited to be clinically useful. Therefore, the evidence does not support the use of the aforementioned decision rules.

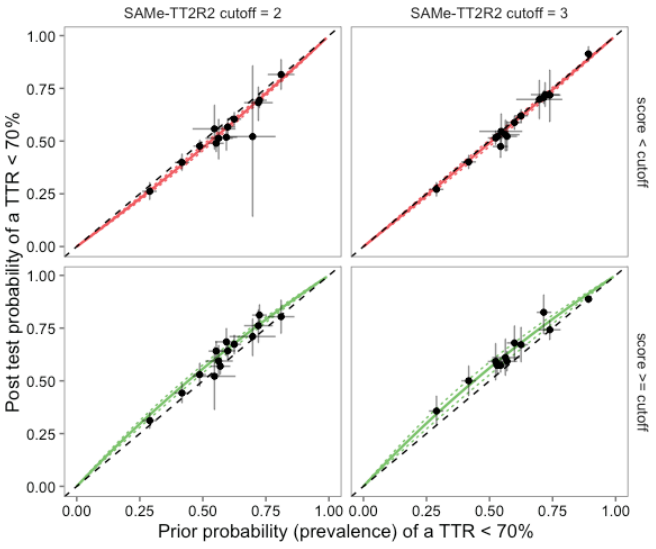

FIGURE 1 Benefit of the SAMe-TT2R2 score for different prevalences. Based on likelihood ratios from meta-analysis and results of individual studies

PB 262 | Safety of Long Term Warfarin Therapy in Real Clinical Practice: Predictors of Major and Non-Major Clinically Relevant Bleedings

E. Kropacheva, O. Zemlyanskaya, A. Dobrovolsky, E. Panchenko

Russian Cardiology Research and Production Center, Laboratory of Atherothrombosis, Moscow, Russian Federation

Background: In spite of available of novel anticoagulant, warfarin (W) is still remained most prescribed medicine in different clinical cases. The main complication of W is bleeding (Bl).

Aims: To estimate the frequency of major Bl and non-major clinically relevant Bl (definition as in GARFIELD Registry) and separately gastrointestinal bleedings (GIB) in patients, received warfarin as mono therapy and in combination with one or two antiplatelets.

Methods: Our prospective study involved 315 pts (181 males), aged 63,1±10,1 years with AF or VTE, prescribed W :among those as monotherapy (n=227), double antithrombotic (n=58) and triple antithrombotic therapy (n=30). Follow up periodwas 6,9 ±4,75 years.

Results: The overall incidence of all Bl (major, non-major clinically relevant and minor) was 8,66/ 100pts-year among all pts with W. The incidence rate of major Bl in W -monotherapy, double and triple antithrombotic therapy was 2,44; 3,63;8,0/per 100 person-years respectively. The incidence rate of non-major clinically relevant Bl in W -monotherapy, double and triple antithrombotic therapy was 1,96; 4,84; 16,0per 100 person-yearsrespectively. By multifactor discriminate analysis four parameters were specified as predictors of combination major Bl and non-major clinically relevant Bl: omeprazole intake (F=14,1, p=0,0002), labile INR(F=9,25, p=0,0025), history of recurrent minor bleedings (F=6,42, p=0,011) and amiodarone therapy (F=4,46, p=0,035). Relative risk of GIB was significant higher in triple antithrombotic therapy (RR 3.02, CI 1.2-9.1,p=0.029), but not on double therapy (RR 1.42, CI 0.52-4.8,p=NS).

Conclusions: In our study four parameters: omeprazole intake, labile INR, history of recurrent minor bleedings and amiodarone therapy,-were specified as predictors of combination major Bl and non-major clinically relevant Bl on long term W therapy. Triple antithrombotic therapy is relevant risk factor gastrointestinal bleedings.

PB 263 | Decreased Bone Mineral Density in Fontan Patients Receiving Long-term Warfarin

C. Attard[1,2], P. Monagle[1,2], V. Ignjatovic[1,2], P. Simm[1,2], C. Munns[3,4], A. Timmi[5], K. Du Plessis[1], J. Chapman[1], Y. d'Udekem[1,2]

[1]*Murdoch Childrens Research Institute, Haematology, Parkville, Australia,* [2]*University of Melbourne/The Royal Children's Hospital Melbourne, Paediatrics, Parkville, Australia,* [3]*The Children's Hospital at Westmead, Sydney, Australia,* [4]*University of Sydney, Paediatrics and Child Health, Sydney Medical School, Sydney, Australia,* [5]*University of Melbourne, Biomechanics, Melbourne, Australia*

TABLE 1 Comparison of BMD of patients receiving aspirin versus warfarin (**P Value ≤0.001)

Warfarin Vs Aspirin						Age-adjusted Z-Scores			
	N	M:F	Age (years)	Height (cm)	Weight (kg)	Whole Body	Right Hip	Left Hip	AP Spine
Warfarin	42	23:19	**24 ± 8	165 ± 11	63 + 15	**-1.47 ± 1	**-1.08 ± 1.16	-1.1 ± 1.17	**-1.26 ± 1.16
Aspirin	24	14:10	18 ± 6	160 ± 34	64 ± 14	-0.48 ± 1.19	-0.3 ± 0.92	-0.55 ± 1.22	-0.47 ± 1.09

Background: Patients who undergo Fontan procedure are at increased risk of thrombosis. To mitigate this risk, they frequently receive life-long thromboprophylaxis, usually with warfarin or aspirin. Warfarin, a vitamin K antagonist, may be associated with decreased Bone Mineral Density (BMD). Aspirin, via prostaglandin modulation, may also have a negative impact. However there is no previous comparative data. Reduced BMD is of particular concern when medication is commenced prior to peak bone mass acquisition, such as in the Fontan population.
Aims: To determine if long-term warfarin use is associated with lower BMD compared to aspirin use in Fontan patients.
Methods: This cross-sectional study utilized the Australian & New-Zealand Fontan registry to recruit participants, who were required to have been on their current thromboprophylaxis medication for at least 5 years. BMD was assessed using DXA (Hologic Discovery W, University of Melbourne; Lunar Prodigy 2000, Children's Hospital at Westmead). BMD and subsequent age-adjusted z-scores were calculated for whole body, hips and anteroposterior (AP) spine. Z-scores of participants on warfarin were compared to those on aspirin using an unpaired student's t-test.
Results: Table 1 shows that participants receiving warfarin had reduced BMD compared to age-matched reference population, and significantly lower BMD than their aspirin counterparts at 3 of the measured sites.
Conclusions: This study demonstrates that long-term warfarin use is associated with decreased BMD compared to that of patients on aspirin following the Fontan procedure. Early detection of patients at risk of osteoporosis is important as early intervention may improve outcomes. Therefore, patients on long-term warfarin should be considered for regular BMD screening. These findings are an important consideration in the risk benefit analysis of whether warfarin or aspirin is the better method of anticoagulation for young people with Fontan circulation.

PB 264 | Predicting Recurrent Venous Thromboembolism in Patients with Deep-vein Thrombosis: Development and Internal Validation of an Simply Applicable Prediction Model (Continu-8)

M. Nagler[1], S.M. van Kuijk[2], H. ten Cate[3], M.H. Prins[2], A.J. ten Cate-Hoek[3]

[1]Inselspital, Bern University Hospital, and University of Bern, Department of Haematology and Central Haematology Laboratory, Inselspital, and Department of Clinical Research, Bern, Switzerland, [2]Maastricht University Medical Centre, Department of Clinical Epidemiology and Medical Technology Assessment, Maastricht, The Netherlands, [3]Maastricht University Medical Center, Thrombosis Expertise Center and Laboratory of Clinical Thrombosis and Haemostasis, and Cardiovascular Research Institute, Maastricht, The Netherlands

Background: Existing prediction models for recurrent thromboembolism (VTE) are complicated to apply in clinical practice, mainly because of the need to stop anticoagulant treatment for D-dimer measurements.
Aims: To develop and internally validate a simply applicable prediction model for recurrent VTE that can be used without stopping anticoagulant treatment.
Methods: Cohort data of 497 patients treated between 2003 and 2013 in a clinical care pathway at Maastricht University Medical Center were used. Variables in the model (D-dimer, unprovoked DVT, male gender, factor VIII levels) were derived from literature and multivariate logistic regression analysis. For reasons of practicality d-dimer was removed from the model. This set of predictor variables was added to a cox proportional hazards regression model. Resulting regression coefficients were converted to integers to provide a scoring rule. The scoring rule was internally validated using bootstrapping techniques.
Results: Patients were followed for a median of 3.12 years (IQR 0.78, 3.90). The overall recurrence rate was 3.7/100 patient-years (95% CI 2.9, 4.8); 64/ 479 (13%) patients developed recurrent VTE. The

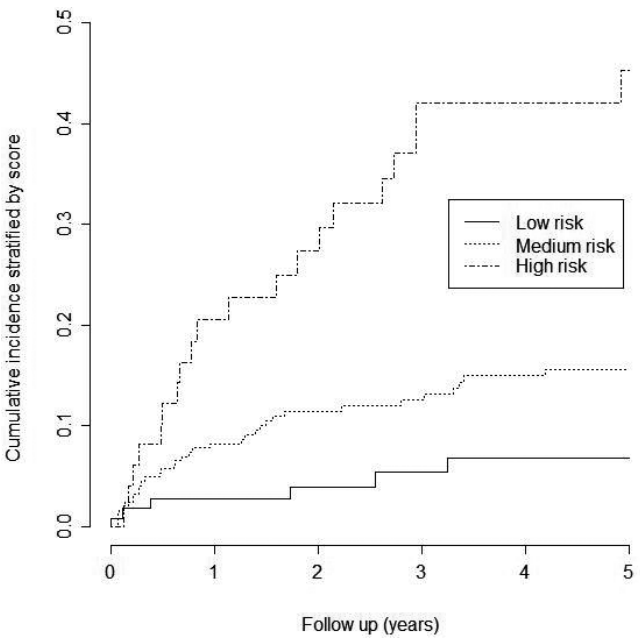

FIGURE 1

scoring rule consisted of unprovoked DVT (yes: 2 points), male sex (yes: 2 points), and factor VIII > 211 % (yes: 1 point). After converting to integers, the score ranged from 0 to 5 and was categorized into three groups (i.e. low risk [score 0], medium risk [scores 1, 2, or 3] and high risk [scores 4 and 5]). Cummulative incidences are illustrated in; the concordance statistic was 0.68.

Conclusions: Internal validation of a proposed prediction model for recurrent VTE ("continu-8 score") that can be potentially used in all patients (provoked and unprovoked) during anticoagulant treatment, demonstrated a moderate distriminative ability in patients with DVT. If externally confirmed in other settings, the continu-8 score provides a easy applicable assessment tool for all patients with DVT in clinical practice.

PB 266 | Anticoagulation Control in Premenopausal Women with Mechanical Heart Valves Using Vitamin K Antagonists: Room for Improvement

C.S.B. Veen[1], J.S. Biedermann[1,2], F.W.G. Leebeek[1], M.J.H.A. Kruip[1,2]

[1]*Erasmus University Medical Center, Hematology, Rotterdam, The Netherlands,* [2]*STAR - Medical Diagnostic Center, Rotterdam, The Netherlands*

Background: High quality of anticoagulation control is essential for safe and effective treatment with vitamin K antagonists (VKA) in patients with mechanical heart valves (MHV), as these patients are at high risk of bleeding and thrombotic complications. Variability of coagulation factors during the menstrual cycle may cause differences in quality of anticoagulation control between premenopausal women and other patient groups.

Aims: To investigate anticoagulation control in women with MHV on VKA.

Methods: We included a cohort of patients treated with VKA for a MHV, who were monitored by a Dutch Anticoagulation Clinic and started VKA therapy between 2005 and 2015. Quality of anticoagulation control in premenopausal women with MHV, defined as percentage of time in therapeutic range

(TTR, Rosendaal method) and as cross-sectional proportion (CSP), was compared with that of postmenopausal women and age-matched men. A waiver for informed consent was obtained by the local ethics committee.

Results: In total 1348 patients were eligible for inclusion, of whom 41% were female. Of these, 118 patients were ≤40 years at inclusion, 47% were female. In women ≤40 years, more INR-measurements were performed during follow-up than in age-matched men (55,7% vs. 44,3% of total measurements;

p< 0.001). Median TTR was significantly lower in women compared to men (70.1% vs. 73,3%; p=0.022). Furthermore, premenopausal women had a significantly lower TTR compared to postmenopausal women (64,4% vs. 70,6%; p=0.015). Overall, CSP was similar in males and females (p=0.66). However, premenopausal women had a lower CSP (60,7%) compared to postmenopausal women (67,5%; p=0.31) and age-matched men (67,2%; p=0.46).

Conclusions: This study shows that menopausal status is associated with anticoagulation control. Anticoagulation control is worse in premenopausal women compared to postmenopausal women and age-matched men. As these patients are at significant risk of complications, optimization of VKA therapy in young women is of great importance.

PB 267 | Involvement of Antithrombotic Therapy in Intracranial Bleeding: A Tertiary Hospital Experience

V. Pons, P. Raheja, K.J. Flores, P. Olivera, T. Canals, E. Johansson, V. Cortina, M. Constans, F. Bosch, A. Santamaria

Vall d'Hebron University Hospital, Haemostasis Unit. Haematology Department, Barcelona, Spain

Background: Intracranial bleeding (IB) is a major cause of death and is the most feared complication of antithrombotic therapy (AT). Little data is available on the clinical course and prognosis of these patients.

Aims: To describe the clinical profile, etiology and management in patients diagnosed with IB in a tertiary hospital.

Methods: A retrospective analysis was performed in a consecutive series of patients older than 18 years with the diagnosis of IB from the 1st of January to the 30th of June 2015. The demographic characteristics, clinical presentation, etiology, treatment strategies, and outcome were studied.

Results: A total of 213 patients [median age 72 yo (29-96), 57% male] were included in the analysis; The most frequent localization of the IB was intraparenchymal (35.6%), followed by subdural (30.9%) and subarachnoid (24.4%). Initial clinical presentation was heterogeneous, headache being the most common finding in the subarachnoid cohort, loss of consciousness in the subdural cases, and focal neurological signs in the intraparenchymal subgroup. Additionally, less than half (46%) received antithrombotic treatment, of which 38% were with acetylsalicylic acid 100 mg (ASA), 34% with a vitamin K antagonist (two-thirds of which were within therapeutic range) and 5% with DOACs. We would like to highlight that only 28% of these patients received antithrombotic reversal agents. With regards to the etiology, 35% were due to head trauma, 10% to aneurysm or vascular malformation, 29% to unknown causes and 7% due to AT without previous trauma. Mortality in patients on AT was 25% and 20% in non AT cases.

Conclusions: In just 6 months, our cohort reflected a high number of IB, mostly due to head trauma injuries. Half of them were on AT, out of which, the majority received ASA and VKA. Although reversal agents are one of the mainstays of the treatment, only 30% received them Thus elucidating the possible impact of AT decision and management in this patient set.

PB 268 | One-year Medical Costs and Predictors of Costs of Pulmonary Embolism: A Prospective Study

J.-P. Galanaud[1], A. Ternisien-Payerols[2], V. Georgescu[2], D. Pontal[2], P. Aubas[2], I. Quéré[2], G. Mercier[2]

[1]Montpellier University Hospital, Internal Medicine, Montpellier, France, [2]Montpellier University Hospital, Montpellier, France

Background: Pulmonary embolism (PE) is a frequent and severe disease and an important driver of costs. Available medico-economic studies are retrospective. Most of them were conducted in North America and only focused on initial in-hospital costs. Clinical and social predictors of costs have not yet been assessed.

Aims: To prospectively assess long-term medical costs and social and clinical predictors of these costs of acute PE in France.

Methods: Prospective, monocentre, observational medico-economic study. From May 2012 to May 2013, all patients hospitalized for an objectively confirmed PE were included and followed up one year. Hospital-acquired PE patients were excluded. In-hospital costs were estimated from the French hospital discharge database and we prospectively collected after patients were discharged all relevant PE-related costs. We assessed the influence of demographics, of social and clinical characteristics of patients at baseline, of initial severity of PE and of rehospitalisation on these costs.

Results: 204 patients were included. Their mean age was 67 years. Proportion of patients with low-, intermediate- and high-risk PE was respectively of 48% (n=97) 47% (n=95) and 6% (n=12). Mean total cost was 10,886€ (US$ 11,452) (Table 1) and was mainly driven by total (81%) and initial (62%) hospitalization costs. Initial severity of PE (p=0.01), index PE occurring while on therapeutic anticoagulation (p=0.04) and likely low compliance to treatment (assessed at baseline) (p=0.01) independently predicted one-year PE costs. A lower weight, an initial anaemia and regular visit to primary care physician or nurse prior to index PE event also increased one-year costs but results failed to reach statistical significance (0.05< p< 0.10).

TABLE 1 Description of one-year Pulmonary Embolism-related costs of patients hospitalized for a symptomatic Pulmonary Embolism

	Mean costs 2016 € (SD)	Mean Costs 2016 US$ (SD)
In-hospital Costs		
Initial hospitalisation	6,758 (6,455)	7,109 (6,791)
Post-acute care & readmission (bleeding, recurrence, cancer screening)	2,031 (5,654)	2,136 (5,948)
Total in-hospital costs	8,819 (8573)	9,277 (9,019)
Total ambulatory costs	2,070 (1,970)	2,177 (2,072)
1-year Total costs	10,886 (8,905)	11,452 (9,368)

Conclusions: One-year direct medical costs of PE are high and hospitalizations represent most of this cost. Initial severity of PE, occurrence of PE while on anticoagulants and likely low compliance to treatment significantly increased these costs.

PB 269 | The Impact of Antiphospholipid Syndrome and Related Comorbidities in the Quality of Oral Anticoagulation

G.G. Yamaguti-Hayakawa[1], M.P. Colella[1], E.V. de Paula[1], J.M. Annichino-Bizzacchi[1], F.A. Orsi[1,2]

[1]University of Campinas, Hematology and Hemotherapy Center, Campinas, Brazil, [2]University of Campinas, Department of Clinical Pathology, School of Medical Sciences, Campinas, Brazil

Background: Oral anticoagulation with vitamin K antagonists (AVK) is the mainstay in the management of Antiphospholipid Syndrome (APS). An adequate monitoring of anticoagulation is important to reduce morbi-mortality in APS patients, since they may still present with recurrent thromboembolic events despite proper treatment.

Aims: This study aimed to compare the characteristics and quality of oral anticoagulation between patients with different indications of VKA use.

Methods: The quality of anticoagulation was evaluated by Time in Therapeutical Range (TTR). Clinical data was obtained from patients' electronic medical records. The differences among groups were determined by one-way ANOVA and the association between variants was obtained by linear regression. The hazard ratio for recurrence of thrombosis and bleeding was assessed by Cox Regression.

Results: We evaluated 517 patients assisted from January, 2014 until January, 2016 - the patients´ and treatment´s data are described in Tables 1 and 2. Among APS patients, we found a lower mean value of TTR, when compared to the atrial fibrillation/prosthetic valve (AF/PV) cohort (61±19% *vs* 67±16%, p= 0.028), even though the APS group received higher doses of AVK (64.9±35.2mg *vs* 41±17.5mg, p= 0.001).

TABLE 1 Clinical characteristics of patients under anticoagulation

	AF/PV	APS	DVT
Number of patients	144 (27.5%)	141 (27.3%)	232 (44.7%)
Age (y)	60±10.6	43.1±12.1	53±12.2
Gender (M:F)	1:1.3	1:2.3	1:1.2
Atrial fibrillation:metallic prosthetic valve	1:1.8	-	-
Venous thrombosis:arterial thrombosis	-	1:0.4	1:0.1
Comorbidities*	4 (2.8%)	54 (38.3%)	84 (36.2%)

The continuous variables above are expressed by mean ± standard deviation and the categorical variables are expressed by number and percentage.

*Main comorbidities were systemic auto-immunity, cancer, chronic kidney and liver disease and benign hematologic pathologies.

TABLE 2 Anticoagulation therapy data

	AF/PV	APS	DVT
TTR	67±16	61±19	63±19
TTR ≥ 65%	83 (57.6%)	65 (46.1%)	116 (50%)
Recurrence of thrombosis	0	7 (5%)	3 (1.3%)
Bleeding events	31 (21.5%)	15 (10.6%)	48 (20.7%)
Maximum AVK weekly dose (mg)	41±17.5	64.9±35.2	54.3±26.1
Mean time between visits (days)	58±15.5	53±21.9	61±25.5

The continuous variables above are expressed by mean ± standard deviation and the categorical variables are expressed by number and percentage.

No differences were observed in mean TTR values between the APS and venous thromboembolism (VTE) cohorts. There was a higher frequency of comorbidities in the APS and VTE groups in comparison to the AF/PV group (38.3% and 36.2% *vs* 2.8%; $p < 0.0005$). The presence of comorbidities was associated with lower TTR values and accounted for 6.3% of its variability along with age and gender ($F(4, 512) = 8.62$, $p < 0.0005$). Despite the higher AVK doses and lower TTR values, the APS cohort presented with a lower number of bleeding events (HR 0.33; $p=0.003$) with similar incidences of recurrent thrombosis.

Conclusions: APS patients still represent a clinical challenge nowadays and the quality of AVK therapy in this group may differ from other AVK users.

PB 270 | Predicting Recurrent Venous Thromboembolism in Patients with Deep-vein Thrombosis: External Validation of a Prediction Model

M. Nagler[1], S.M. van Kuijk[2], H. ten Cate[3], M.H. Prins[2], A.J. ten Cate-Hoek[3]

[1]Inselspital, Bern University Hospital, and University of Bern, Bern, Switzerland, [2]Maastricht University Medical Centre, Department of Clinical Epidemiology and Medical Technology Assessment, Maastricht, The Netherlands, [3]Maastricht University Medical Center, Thrombosis Expertise Center and Laboratory of Clinical Thrombosis and Haemostasis, and Cardiovascular Research Institute, Maastricht, The Netherlands

Background: Predicting the risk of recurrent venous thromboembolism (VTE) remains challenging, and existing prediction models are still incompletely evaluated.

Aims: To externally validate an existing prediction model for recurrent VTE in a contemporary cohort of patients with proximal deep vein thrombosis (DVT).

Methods: The DASH score (D-dimer, Age, Sex, Hormonal therapy), a prediction model developed in patients with unprovoked VTE only, was applied to data of patients with provoked as well as unprovoked proximal DVT. All patients treated between 2003 and 2013 in a clinical care pathway at Maastricht University Medical Center were prospectively followed for up to 11 years from cessation of anticoagulation treatment. Analyses were stratified for provoked and unprovoked DVT, and c-statistics were calculated as a measure of predictive performance. Differences between risk groups (i.e. low risk, intermediate risk and high risk) were assessed by Kaplan-Meier plots and log-rank test.

Results: Sixty-four of 479 patients, followed for a median of 3.12 years (IQR 0.78, 3.90), developed recurrent VTE (13%); the overall recurrence rate was 3.7 per 100 patient-years (95% CI 2.9, 4.8). The c-statistic of the DASH score was 0.68 (95% CI 0.61, 0.74). After stratification the c-statistic was 0.73 (95% CI: 0.61, 0.86) for patients with provoked, and 0.63 (95% CI: 0.54, 0.71) for patients with unprovoked DVT.

Conclusions: External validation confirmed the predictive value of the DASH score in patients with unprovoked as well as provoked proximal DVT. However, the discriminative capability is only moderate and the implementation in clinical practice is hampered by the need to stop anticoagulation treatment prior to D-dimer testing.

PB 271 | Clinical Characteristics Associated with Diagnostic Delay of Pulmonary Embolism in Primary Care: A Retrospective Observational Study

J. Hendriksen[1], M. Koster- van Ree[1], M. Morgenstern[1], R. Oudega[1], R. Schutgens[2], K. Moons[1], G.-J. Geersing[1]

[1]University Medical Center Utrecht, Julius Center for Health Sciences and Primary Care, Utrecht, The Netherlands, [2]University Medical Center Utrecht, Van Creveldkliniek, Department of Internal Medicine, Utrecht, The Netherlands

Background: Pulmonary embolism (PE) is listed among the diagnoses most frequently missed, or delayed, in clinical practice. Current evidence on diagnostic delay comes largely from studies performed in emergency departments (EDs), whereas evidence from primary care is scarce.

Aims: To evaluate the extent of delay in the diagnosis of PE in primary care, and to identify determinants that are associated with such diagnostic delay.

Methods: We performed a retrospective observational study in six primary care practices across The Netherlands. Patients with an objectively confirmed diagnosis of pulmonary embolism (ICPC-code K93) up to June 2015 were extracted from the electronic medical records. For all these PE events we reviewed all consultations with their general practitioner (GP) and scored any signs and symptoms that could be attributed to PE in the 3 months prior to the event. Also, we documented actual comorbidity and the diagnosis considered initially. Delay was defined as a time gap of >7 days between the first potentially PE-related contact with the GP and the final PE diagnosis. Multivariable logistic regression analysis was performed to identify independent determinants for delay.

Results: In total 180 incident PE cases were identified, of whom 128 patients had one or more potential PE-related contact with their GP within the three months prior to the diagnosis. Based on our definition, in 33 of these patients (26%) diagnostic delay was observed. Older age (age >75 years) (OR 5.1 (95%CI 1.8-14.1)) and the absence of chest complaints (OR 5.4 (95%CI 1.9-15.2)) were independent determinants for diagnostic delay. A respiratory tract infection prior to the PE diagnosis was reported in 13% of cases without delay, and in 33% of patients with delay (p=0.008).

Conclusions: Diagnostic delay of more than seven days in the diagnosis of pulmonary embolism is common in primary care, especially in elderly and if chest complains, like pain on inspiration, are absent.

PB 272 | Variability in Calculation of Time in Therapeutic Range for Quality Control Measurement of Warfarin

S. Siddiqui[1], C. De Remer[2], J. Waller[3], R. Abraham[2], J. Gujral[1]

[1]Medical College of Georgia at Augusta University, Internal Medicine, Augusta, United States, [2]University of Georgia College of Pharmacy, Augusta, United States, [3]Augusta University, Biostatistics, Augusta, United States

Background: Time in therapeutic range (TTR), a widely recognized quality control metric of warfarin anticoagulation, measures the time a patient's international normalized ratio (INR) is within the desired range. The TTR value can vary depending on the method used (cross-sectional, Rosendaal, or traditional) and can thus be a skewed indicator of anticoagulation control. However, the different quantification approaches have been inadequately evaluated in literature for the clinical setting.

Aims: The aim of this study is to investigate variance and bias between the different TTR methods.

Methods: We conducted a 21-week retrospective study of patients on warfarin in an anticoagulation clinic. The clinic's TTRs were calculated using each method and then repeated with added tolerances per CHEST guidelines; the results are listed in Table 1. The wide range in values obtained is indicative of the dependence of TTR on the quantification method used and should be taken into careful consideration prior to analyzing provider performance. The following tests were conducted to quantify differences between the traditional and Rosendaal methods: paired t-test, correlation between size of the TTR and bias, and Bland-Altman plots.

Results: The traditional method resulted in significantly higher TTR values than the Rosendaal method, with high variability between the methods in both positive and negative directions. There was also a lack of independence between the size of the TTR and bias with the addition of tolerance (Table 2 and Figure 1). Thus the different methods are not measuring the TTR similarly and the addition of tolerance can further alter results predicting control of anticoagulation achieved.

Conclusions: The method used to calculate TTR can distort the provider´s perception of anticoagulation achieved. The impact of this perception could falsely imply control that is absent from practice. More evaluation is needed to determine the impact on clinical care.

TABLE 1 Results for TTR Methods with Added Tolerances

Method	TTR Result (n=612)
Rosendaal	55.1
Traditional	56.5
Traditional +/-0.2	71.4
Traditional +/-0.5	85.7
Cross-sectional	66.0
Cross-sectional +/-0.2	81.8
Cross-sectional +/-0.5	91.5

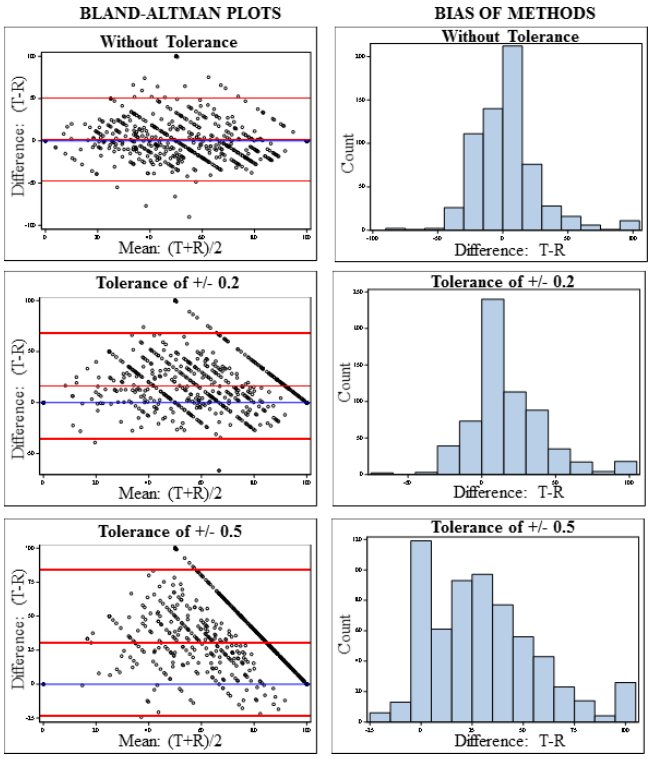

FIGURE 1 Bland-Altman Plots (Difference vs Mean) with Corresponding Bias Distribution Graphs of Traditional and Rosendaal Methods

PB 273 | D-dimer Levels Predict Clinical Outcomes in Patients with Mechanical Heart Valve Replacement during Oral Anticoagulation Therapy

L. Zhang[1], L. Yanli[2], J. Yang[1], Z. Zhang[1]

[1]Wuhan Asia Heart Hospital, Wuhan University, Department of Clinical Laboratory and Pathology, Wuhan, China, [2]Wuhan Asia Heart Hospital, Wuhan University, Heart Center, Wuhan, China

Background: Thrombosis and bleeding are main outcomes of patients after mechanical heart valve replacement (MHVR), however, there are still no useful marker to predict these outcomes.

Aims: To investigate whether D-dimer can predict outcomes in patients with MHVR during oral anticoagulation therapy.

Methods: Patients suffered MHVR in Wuhan Asia Heart Hospital between 2013 January and 2014 June were screened. Patients were

assigned to abnormal D-dimer group and normal D-dimer group according to d-dimer levels measured three months after the oral anticoagulation beginning. All patients were followed up for 24 months or until the observation of end points, which included thrombotic events, bleeding events and all-cause deaths. The anticoagulation therapy was monitored once per 1-2 months by the international normalized ratio (INR), and the target was INR 1.8-3.0.

Results: A total of 640 patients were included in analysis, 88 of whom had abnormal d-dimer levels and 552 of whom have normal d-dimer levels. During a follow-up period of 24 months, a total of 47(7.3%) events were observed. The incidence of total events among patients in abnormal d-dimer group, was significantly higher than that of normal d-dimer group (15 vs 32,17.0% vs 5.8%, p< 0.01, HR:5.6); There were 23(3.6%) thrombotic events totally, the incidence of thrombotic events among patients in abnormal d-dimer group was significantly higher than that of normal d-dimer group (10 vs 13, 11.4% vs 2.3%, p< 0.01, HR:15.7). There were 18 (2.8%) all-cause deaths totally, the all-cause mortality among patients in abnormal d-dimer group was significantly higher than that of normal d-dimer group (7 vs 11, 8.0% vs 2.0%, p< 0.01, HR:10.4). Total 19 bleeding events were observed, there was no significant difference in the incidence of bleeding events between two groups (2 vs 17, 2.1% vs 3.3%, p=0.77, HR:0.8).

Conclusions: D-dimer could be a useful marker to predict thrombotic events and all-cause deaths in patients with MHVR.

PB 274 | Prevention of Recurrent Gastrointestinal Bleeding in Anticoagulated Patients with Vitamin K Antagonists: Randomized Study Comparing Warfarin with Bemiparin

J. Mateo Arranz[1], M. Carrasco Exposito[1], A. Ardevol Ribalta[2], E. Alvarado Tapias[2], N. Vilalta Seto[1], J.A. Millon Caño[1], C. Villanueva Sanchez[2], J. Fontcuberta Boj[1]

[1]Sant Pau Hospital, Unit Hemostasia and Thrombosis, Barcelona, Spain, [2]Sant Pau Hospital, Digestive Pathology, Barcelona, Spain

Background: Acute digestive haemorrhage (DH) in anticoagulanted patients is highly prevalence of unknown etiology and considerable rate of haemorrhagic recurrence. Low molecular weight heparins offer a better pharmacokinetic profile and more stable anticoagulation levels, so they may be safer than coumarins

Aims: Evaluate if bemiparin at adjusted anticoagulant doses, decreases DH recurrences compared to warfarin

Methods: A prospective, open, controlled, and randomized study was carried out between 2012-2016. We were included patients with anticoagulant treatment and severe DH of unknown etiology or with the presence of multiple lesions. Patients were randomized in 2 groups: warfarin (INR range suitable for its indication) vs bemiparin (0.4-1.0 Uanti-Xa / ml peak)

Results: We included 46 patients (24 Bemiparin vs 22 warfarin). Mitral valve prothesis (5 p), multiple prothesis (4), atrial fibrillation (AF) embolic (6), AF + valvulopathies (18), venous thromboembolism(4), isolated AF with CHADS2> 3 (5). The diseases were homogeneously distributed between both groups.

The mean follow-up was 1,123 days (range 434-1,689). DH were of diverticular origin in 19 (41.3%), angiodysplasia 4 (8.7%) and unknown 23 (50%). The groups were comparable in age, sex, and other baseline characteristics. There was no difference in the severity of the DH. INR at time of index event DH was supratherapeutic in similar percentage in both groups. The recurrences were 6 (27%) warfarin vs 0% bemiparin (p = 0.004). No embolic events were seen. Complications related to their basal cardiovascular disease were 14% warfarin vs 17% bemiparin. Survival was similar (11% vs. 15% at 12 months, respectively, HR = 2.5, 95% CI = 0.5-12.7, p = 0.27).

Conclusions: The use of bemiparin (dose-adjusted anti-Xa levels) decreases long-term DH recurrence compared to warfarin. No thromboembolic complications were observed despiteof the high thromboembolic risk.

PB 275 | Has the Introduction of the DOACs Moved Patients with Labile INRs from Warfarin Therapy?

T. O Halloran[1], D. O Keeffe[2], J. Conway[2], O. Power[2], C. Holt[2], M. Watts[2]

[1]University of Limerick, Limerick, Ireland, [2]University Hospital Limerick, Limerick, Ireland

Background: Warfarin therapy is first line for long term anticoagulation but patients with labile INRs, measured by TTR, should be considered for DOAC (NICE UK, MMP Ireland). If patients with low TTRs are switching to DOAC therapy, the mean TTR of the patients remaining on warfarin therapy should improve.

Aims: This study investigates if the mean TTR of the warfarin clinic at University Hospital Limerick has been affected by the introduction of the DOACs to the market in 2011.

Methods: A retrospective study of all INR tests performed by the clinic from June 2008 to July 2016 was conducted. The data was divided into years. TTR Rosendaal method was calculated for all patients with > 2 months anticoagulation and ≥3 INR tests. The patients were divided into two groups short term (≤4 months) and long term (>4 months) anticoagulation. A one-way ANOVA of the yearly TTR was performed. The patients achieving TTR of >=70% were identified.

Results: There is an overall reduction in patients on warfarin therapy since 2013.

The numbers of patients on short term warfarin therapy has reduced (101-52) since 2013, although the percentage achieving target TTR has decreased (59-33%).

The numbers of patients on long term warfarin therapy has reduced since 2013 (895-864). The mean TTR of the long term group has increased (74.9% to 76.3%), a one way ANOVA showed a statistical difference p=0.04).

The mean of the combined group increased from 74.5-75.3% since 2013 (ANOVA p=0.001).

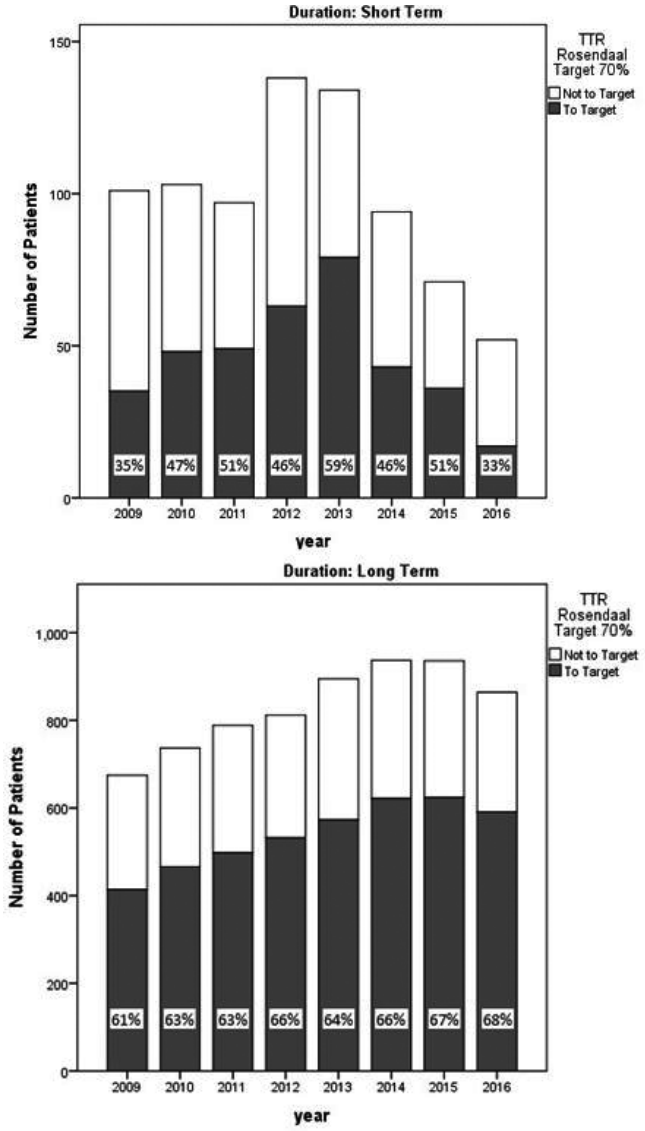

FIGURE 1 Long and Short term anticoagulation patients and percentage of patients achieving TTR target of 70%

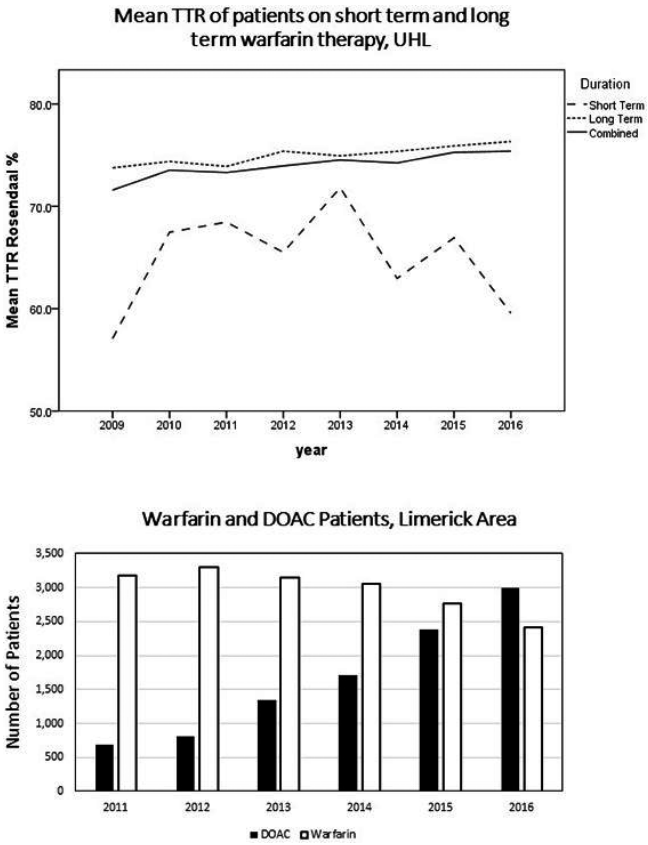

FIGURE 2 DOAC and warfarin use shown with mean TTR of the long and short term anticoagulation groups

Conclusions: The reduction of patients on warfarin therapy, is likely due to the introduction of the DOACs. The cohort on short term therapy is relatively more affected.

There is a small increase in mean TTR for those on long term therapy which may reflect some patients, with labile INRs, actively switching to DOAC therapy.

The combined TTR of the clinic has increased due to improved TTR in the long term group and a reduction in numbers in the short term group. There is clearly potential for improvement; 32% of patients in the long term group have TTRs below target.

PB 276 | Risk of Recurrence after Stopping Anticoagulation in Patients with a First Episode of Unprovoked Venous Thromboembolism: A Systematic Review and Meta-Analysis

F. Khan[1,2], A. Rahman[1], M. Carrier[1,2,3], C. Kearon[4], J. Weitz[4], S. Schulman[4], F. Couturaud[5], P. Prandoni[6], S. Eichinger[7], C. Becattini[8], G. Agnelli[8], H. Buller[9], T. Rodger et al. (2016)	Prospective observational study	663	51.4	53.2 (range 18-95)	194 isolated PE; 346 isolated DVT; 123 DVT+PE	Known cancer; Known Thrombophilia; Prolonged immobilization; Recent trauma; Recent surgery	Antiphospholipid antibodies; Protein C/ Protein S/Antithrombin deficiency; Combined/"Double Hit"

TABLE 2 Risk of Recurrence After Stopping Anticoagulant Therapy (AT)

Study	Number of recurrent VTE events	Number of Patient-Years of Follow-up	Risk (%) per patient-year (95% Confidence Interval)	
In the first year after stopping AT				
Agnelli et al. 2001	11	89.431	12.30 (5.03 - 19.57)	
Rodger et al. 2016	62	600.110	10.33 (7.76 - 12.90)	
Pooled	73	689.541	10.55 (8.13 - 12.97)	
In the first 2 years after stopping AT				In the second year after stopping AT
Kearon et al. 1999	17	62.044	27.40 (14.38 - 40.42)	Currently Not Available
Couturaud et al. 2015	25	268.817	9.30 (5.65 - 12.95)	Currently Not Available
Rodger et al. 2016	96	1115.520	8.61 (6.88 - 10.33)	6.60 (4.38 - 8.82)
Pooled	138	1446.381	10.92 (6.11 - 15.73)	Currently Not Available

AT indefinitely, is primarily governed by the long-term risk of recurrence when treatment is discontinued. This risk however, is not well established, hindering decision making.

Aims: We sought to more precisely quantify the absolute, long-term risk of recurrent VTE over standardized time intervals of 1, 2, 5, 10, and 20 years after stopping AT in patients with a first unprovoked VTE.

Methods: We performed a systematic review and a meta-analysis of randomized controlled trials and prospective cohort studies involving unprovoked VTE patients who had completed at least 3 months of initial AT; and who were followed-up for the standardized time intervals of 1, 2, 5, 10 and 20 years (± 3 months) after stopping AT. The primary outcome of the rate of recurrent VTE was calculated for each study from the total number of recurrent events and the corresponding number of patient years of follow-up. We used a random-effects model to pool study results and reported a weighted estimate of the absolute risk per patient-year.

Results: We included 22 eligible studies in our analyses, and contacted the primary investigators of each study for additional data. Based on currently available data from 4 studies (1,053 patients; **(Table 1)**, the pooled absolute risk of recurrence during the first year was 10.55% per patient-year (95% CI, 8.13-12.97), and 10.92% per patient-year (95% CI, 6.11-15.73) during the first 2 years after stopping AT **(Table 2)**.

Conclusions: In unprovoked VTE patients, the risk of recurrence when AT is discontinued appears to be high. Final/updated numbers and conclusions will be provided once final data clarifications are supplied from all investigators. A clear-cut estimate of this risk will help guide the optimal duration of AT for such patients.

PB 277 | Outcome of Vitamin K Antagonist Associated Bleeding in Patients Treated with Prothrombin Complex Concentrate: The ROVAP Study

M.P.A. Brekelmans[1], R.A. Abdoellakhan[2], L.J.J. Scheres[1,3], J.S. Biedermann[4], B.A. Hutten[5], K. Meijer[2], H. ten Cate[6], M.V. Huisman[7], M.J.H.A. Kruip[4], S. Middeldorp[1], M. Coppens[1]

[1]Academic Medical Center, Vascular Medicine, Amsterdam, The Netherlands, [2]University Medical Center Groningen, Department of Haematology, Groningen, The Netherlands, [3]Leiden University Medical Center, Department of Clinical Epidemiology, Leiden, The Netherlands, [4]Erasmus University Medical Center, Department of Haematology, Rotterdam, The Netherlands, [5]Academic Medical Center, Department of Clinical Epidemiology, Amsterdam, The Netherlands, [6]Cardiovascular Research Institute Maastricht, Maastricht University, Department of Internal Medicine, Maastricht, The Netherlands, [7]Leiden University Medical Center, Department of Thrombosis and Hemostasis, Leiden, The Netherlands

Background: Vitamin K antagonists (VKA) are widely used for the treatment and prevention of thromboembolism. In patients with severe VKA-associated bleeding, haemostasis can be restored swiftly by prothrombin complex concentrate (PCC).

Aims: To evaluate clinical outcome of patients treated with PCC for VKA-associated bleeding.

Methods: We performed a retrospective cohort study of consecutive patients who received PCC for VKA-associated bleeding in five Dutch hospitals. Data was collected by chart review on medical history, VKA-related bleeding event, procedures and interventions to treat the bleed, international normalized ratio (INR), haemostatic efficacy, thromboembolic (TE) complications, and mortality. Haemostatic efficacy was classified as excellent, good, or poor for different bleeding localizations based on haemoglobin decrease over 24h (gastrointestinal [GI] bleeding), hematoma expansion (intracranial haemorrhage [ICH]), or cessation of visible blood loss (Sarode, *Circulation* 2013).

Results: One hundred patients were included. The mean age (±SD) was 74±12 years, 54% were male and 79% received VKA for atrial fibrillation. Most patients presented with ICH (41%) or GI bleeding (36%). Almost 80% of the patients received 10 mg vitamin K in addition to PCC. Median baseline INR was 3.9 (IQR 2.9-5.8). One hour after start of infusion, the INR was available for 50 patients and of these, 35 (70%) had an INR ≤1.4. Effective haemostasis was not assessable in 34 patients with ICH, since repeat CT was not performed routinely. Effective haemostasis was achieved in 47 of 66 (71%) patients (35 excellent, 12 good efficacy). TE complications were reported in 5 patients and 22 deaths (60% bleeding-related) were observed within 30 days after PCC administration.

Conclusions: PCC was shown to achieve effective haemostasis in 71% of patients with VKA-associated bleeding. TE complication rates were low, but mortality rates rather high, probably due to the large number of patients presenting with ICH.

PB 278 | Association of 5'-untranslated Region / Exonic VKORC1 Mutations with Vitamin K Antagonist Resistance: Results of the GFHT Cohort Study

E. Lesteven[1,2], J. Fréchaud[3], C. Moreau[4], M. Babayan[3], A. Veyradier[1,2], P. Gaussem[3], J.-L. Golmard[5], M.-A. Loriot[4,6], V. Siguret[1,3], on behalf of the GFHT

[1]Hôpital Lariboisière, AP-HP, Laboratoire d'Hématologie Biologique, Paris, France, [2]Université Paris Diderot, Sorbonne Paris Cité, Paris, France, [3]UMR_S 1140-Inserm Université Pari Descartes, Sorbonne Paris Cité, Paris, France, [4]Hôpital Européen Georges Pompidou, AP-HP, Service de Biochimie - UF de Pharmacogénétique, Paris, France, [5]Université Pierre et Marie Curie, Département de Biostatistiques, Paris, France, [6]UMR_S 1147-Inserm, Université Paris-Descartes Sorbonne Paris Cité, Paris, France

Background: Rare patients (pts) require unusual very high doses of vitamin K antagonist (VKA) and may not achieve therapeutic INR despite proper dose escalation. Relationships between vitamin K oxydoreductase gene *(VKORC1)* variations and their impact on VKA resistance are poorly known in clinical practice.

Aims: To address this issue, we conducted a multicenter cohort study to identify new *VKORC1* causes of VKA resistance and to evaluate their impact on resistance.

Methods: Patients were eligible if they received a VKA daily dose ≥ 2-fold mean maintenance dose (D) given in normal responders with combined *g.-1639GGVKORC1/CYP2C9*1/*1* genotype. A standardized questionnaire was prospectively fulfilled. *VKORC1* exons and 5´-untranslated region (UTR) on 2 kb were sequenced. Patients were also genotyped for *CYP2C9 (2*/*3)* and *CYP4F2* (p.Val433Met) SNPs. A resistance index (IRes) was defined as (effective dose/D)x100. Potential influence of patient characteristics on IRes was analysed wirh univariate and multivariate statistical models.

Results: Of the 278 analyzed pts, 94 (33.8%) carried ≥ 1 *VKORC1* mutations. At least one exonic mutation was identified in 76 pts (27.8%), corresponding to 18 distinct mutations (8 new ones); 57 pts (20.9%) presented ≥ 1 mutations corresponding to 13 5'-UTR variations (4 new ones). To be non-Caucasian was the only non-genetic variable associated with a higher IRes (p=0.0123). Carriers of an exonic mutation had a higher IRes ($p< 10^{-4}$). Interestingly, carrying both exonic and 5'-UTR mutations (excluding *-1639AVKORC1*) was associated with a lower IRes than carrying an isolated exonic mutation (p=0.005). Finally, mutations located in warfarin binding domains or in the reticulum lumen according to Czogalla *et al.* (2016) were associated with higher IRes, $p=10^{-4}$ and $p< 10^{-4}$, respectively.

Conclusions: Our study provides new data on the impact of *VKORC1* mutation location on VKA resistance. *VKORC1* status knowledge may help physicians in VKA escalation strategies or to propose alternative oral anticoagulant.

PB 279 | Repeated Serial D-Dimer (DD) Measurement after Anticoagulation Therapy (AT) withdrawal to Identify Patients (PTS) at Risk for Venous Thromboembolism (VTE) Recurrence

B. Cosmi[1], C. Legnani[1], M. Cini[1], G. Guazzaloca[1], G. Rodorigo[1], G. Palareti[2]

[1]*University Hospital S.Orsola-Malpighi, Angiology and Blood Coagulation, Bologna, Italy,* [2]*University of Bologna, Cardiovascular Diseases, Bologna, Italy*

Background: The DULCIS study (Palareti et al, Blood 2014) has shown that serial DD measurements (during and after AT withdrawal) is suitable in clinical practice for identification of pts in whom AT can be safely discontinued.

Aims: Since a number of pts who resumed AT subsequently to a first positive serial DD assessment repeated this procedure after a second period of AT, aim of this study was to evaluate the results of the second serial DD measurement procedure.

Methods: 107 outpts [71 males; age: 66 years (20-84)] with a first VTE [prox. deep vein thrombosis (DVT): n=52, DVT + pulmonary embolism (PE): n= 35, and isolated PE: n=20] were investigated. They had resumed AT after a positive result in a first serial DD measurement; after a median period of 7 months they repeated the serial DD procedure as previously performed (before stopping AT and after 15, 30, 60 and 90 days). The same age/sex specific DD cut-offs adopted in the first serial measurement (those proposed by the DULCIS study) were used. All pts were followed for a median period of 25 months and VTE events (proximal DVT, with or without PE, or isolated PE) recorded.

Results: At the second serial DD evaluation, DD was persistently negative in 18 (16.8%) pts who stopped AT, whereas DD resulted positive in 89/107 (83.2%) pts who were advised to resume AT; however, only 70 resumed AT while 19 refused. Primary outcomes occurred in: 1/18 pts [5.6% (95%CI: 0.1-27.3); 1.6% pt/y (95%CI: 0.01-8.5)] with persistently negative DD who stopped AT and in 7/19 pts [36.8% (95%CI: 16.3-61.6); 17.1% pt/y (95%CI: 7.1-32.0)] who had positive DD results but refused to resume AT. In the 70 pts with positive DD who resumed AT no VTE events occurred.

Conclusions: These data indicate that a second serial DD measurement after a first positive procedure is mainly confirmatory of positive results in the large majority of pts (83.2%), and cannot be recommended as routine.

PB 280 | Safety and Efficacy of Warfarin in Patients with Thrombocytopenia

Y.F. Lai[1], C.W. Tan[2], D.Y.T. Goh[3], S.Y. How[3], K.Y. Lee[3], V.W.P. Tham[3], M.C. Kong[3], H.J. Ng[2]

[1]*Sengkang Health, Singapore, Singapore,* [2]*Singapore General Hospital, Haematology, Singapore, Singapore,* [3]*Singapore General Hospital, Singapore, Singapore*

Background: Patients with moderate thrombocytopenia and comorbidities requiring anticoagulation are currently sub-optimally treated because of bleeding concerns. Guidance on anticoagulating such patients is currently lacking because of limited data on safety and efficacy of anticoagulation in such patients.

Aims: To evaluate the safety and efficacy of warfarin in patients with moderate thrombocytopenia.

Methods: This retrospective study compared the incidence of bleeding and thrombosis in a cohort of warfarinized patients with sustained platelet counts below 100 x 109/L against a cohort with normal platelet counts (>140 x 109/L). Primary outcomes of safety and efficacy were determined by incidence rate ratios (IRR) of bleeding and thrombotic events. International Normalized Ratio (INR) and platelet counts during adverse events in thrombocytopenic arm were secondary outcomes.

Results: 137 thrombocytopenic patients (104,985 patient-exposure days) were compared against 939 normal patients (715,193 patient-exposure days). IRR of minor, major bleeding and thrombosis amongst thrombocytopenic patients were 3.03 (95% CI: 1.57- 5.60), 1.48 (95% CI: 0.44-3.98), and 0.807 (95% CI: 0.09 - 3.43) respectively. Median INR and platelet count readings during minor and major bleeds were 3.60 (IQR: 2.70 - 4.12) and 3.12 (IQR: 2.82 - 4.22), and 99 ×109/L (IQR: 77.0 - 147.0 ×109/L) and 115 x109/L (IQR: 107.5 - 169.5 ×109/L) respectively.

Conclusions: Warfarinized thrombocytopenic patients are at higher risk of minor bleeding complications with a higher tendency for major bleeding but derive similar benefits against thrombotic events compared to normal patients. Bleeding events are associated with higher INRs. A narrow INR target with an upper limit below 2.5 together with closer anticoagulation monitoring may improve safety of patients.

PB 281 | AF Patients on VKAs: Heart Failure is Associated with Worst Quality of Anticoagulation and Higher Bleeding Risk. Results from the START Register

D. Poli[1], E. Antonucci[2], L. Migliaccio[2], S. Testa[3], V. Pengo[4], F. Marongiu[5], A. Tripodi[6], G. Palareti[2], START-Register participants

[1]*Azienda Ospedaliera Universitaria Careggi, Firenze, Italy,* [2]*Fondazione Arianna Anticoagulazione, Bologna, Italy,* [3]*Hospital of Cremona, Cremona, Italy,* [4]*University of Padua, Department of Cardiac, Thoracic and Vascular Sciences, Padova, Italy,* [5]*Università degli Studi di Cagliari, Cagliari, Italy,* [6]*Fondazione IRCCS Ca' Granda - Ospedale Maggiore Policlinico, Milano, Italy*

Background: In patients with atrial fibrillation (AF) heart failure (HF) is a risk factor for stroke and its frequency is higher when AF is associated with coronary artery disease (CAD). HF is associated with volume overload, pulmonary congestion, peripheral edema and systemic venous congestion involving the liver. Warfarin metabolism can be reduced with prolonged half-life leading to overanticoagulation.

Aims: Aim of this study was to evaluate if HF is associated to a worst quality of anticoagulation expressed as time in therapeutic range(TTR) and to higher bleeding risk in a cohort of AF patients enrolled in the prospective multicenter START Register.

TABLE 1 Characteristics of patients

	Heart Failure	No Heart Failure	p
Patients	506	3010	
Males (%)	298 (58.9)	1623 (53.9)	0.04
Median Age, yrs(range)	78 (41-91)	76 (28-98)	0.000
Follow-up (x 100pt yrs)	764	5143	
Antiplatelet drugs	103 (20.4)	462 (15.3)	0.006
Median (IQR) Time above therapeutic range (%)	11 (4-19)	9 (4-16)	0.02
Median (IQR)Time in therapeutic range (%)	64 (52-75)	67 (55-77)	0.001
Median (IQR)Time below therapeutic range (%)	21 (12-33)	20 (12-30)	ns
Major Bleeds (rate x100pt-yrs)	20(2.6)	66(1.3)	0.01

Methods: Patients' demographic and clinical data were collected as electronic file in anonymous form in the web site of START-Register (ClinTrials Gov Identifier: NCT02219984). Here we present data on 3516 patient-streated with Vitami K antagonist (VKA) for AF. Quality of anticoagulation was evaluated, major bleeds occurred during follow-up was recorded.

Results: We evaluated 3516 AF patients on vitamin K antagonists, 506 of whom (14.7%) with a history of HF. Clinical characteristics of patients are reported in table 1. Among HF patients CAD is more frequent and the quality of anticoagulation is significantly worst with respect to patients without HF. In particular time in therapeutic range (TR) is significantly lower and time above TR longer. During follow-up 86 major bleeding were recorded , 20 occurred in patients with HF. Patients with HF have higher bleeding risk in comparison to patients without HF: RR 2.0(95% CI 1.17-3.40); p=0.01.

Conclusions: AF patients with HF patients show a less good quality of anticoagulation, versus those without HF, with longer time spent above the TR and carry a higher risk for bleeding.

PB 282 | Thrombotic Complication Rates Following Anticoagulation Reversal: A Retrospective Evaluation of Prothrombin Complex Concentrates

J. Shaw[1], R. Buyting[2], M. Latrous[3], M. Tokessy[4], N. Cober[4], E. Saidenberg[5], G. Le Gal[5], M. Carrier[5], L. Castellucci[1]

[1]*The Ottawa Hospital, Department of Medicine, Ottawa, Canada,* [2]*Ottawa Hospital Research Institute, Ottawa, Canada,* [3]*University of Ottawa, Ottawa, Canada,* [4]*The Ottawa Hospital, Ottawa, Canada,* [5]*The Ottawa Hospital, Division of Hematology, Ottawa, Canada*

Background: Effective reversal of anticoagulants for life-threatening bleeding events and emergent procedures can be challenging. In Canada, patients on vitamin K antagonists (VKAs) receive prothrombin complex concentrates (PCCs), with or without vitamin K. PCCs have also been used for direct oral anticoagulant (DOAC) associated bleeding, before specific antidotes were available.

Aims: To describe the clinical outcomes of PCC reversal in patients with VKA and DOAC-associated life-threatening bleeding or needing emergent surgery.

Methods: A retrospective chart review of consecutive patients receiving either activated PCC for reversal of DOAC anticoagulation or PCC for reversal of VKAs between January-June 2014 at The Ottawa Hospital was performed. Thrombotic complications and associated mortality were evaluated up to 30 days post-PCC.

Results: A total of 11 patients received activated PCC for reversal of DOAC anticoagulation

(Table 1, Table 2). There were 5 patients on dabigatran, 3 patients on rivaroxaban and 3 patients on apixaban. Activated PCC dosing ranged from 1812 IU to 6000 IU. A single patient experienced a transient ischemic attack (TIA) within hours of aPCC administration (30-day thromboembolic complication rate = 9.1%). 30-day overall mortality was 36.4% (4 deaths). There were 3 fatal bleeding events, and no fatal thromboembolic events.

A total of 194 patients received PCC for reversal of warfarin anticoagulation (Table 1, Table 2). PCC doses ranged from 1000 IU to 2500 IU. The 30-day thromboembolic complication rate was 5.2% (4 deep veins thromboses, 2 myocardial infarctions, 2 TIAs, 2 strokes). The 30-day overall mortality rate was 16.0%

(31 deaths), with 8 deaths attributable to fatal bleeding and 2 deaths attributable to thrombotic events.

TABLE 1 Patient Demographics

Characteristic	*aPCC-DOAC Cohort (n=11)*	*PCC-Warfarin Cohort (n = 194)*
Age (Mean, Years)	83.9	76.3
Male (%)	72.7	54.1
CHADS2 (Mean)	3.1	2.5

TABLE 2 Indications for Anticoagulation and Reversal

	aPCC-DOAC Cohort (n=11)	PCC-Warfarin Cohort (n = 194)
Anticoagulation Indication		
Atrial Fibrillation	9	123
VTE	2	34
Atrial Fibrillation + VTE	0	17
Mechanical Valve	0	16
Other	0	20
Reversal Indication		
Major Bleeding	8	87
Pre-Operative Reversal	3	107

Conclusions: Administration of aPCC for DOAC reversal appears to be associated with a relatively similar thromboembolic complication rate as compared to PCC administration for warfarin reversal. Larger prospective studies are required to confirm these findings.

PB 284 | Assessment of the Quality of Oral Anticoagulation Control at Two Hospital-based Clinics in Brazil

R.G.L. Silva, C.M. Bertollo, I.G. Ferreira, L.C. Brant, M.A.P. Martins

Universidade Federal de Minas Gerais, Belo Horizonte, Brazil

Background: Warfarin remains widely used by patients with cardiovascular diseases. When using warfarin, the quality of oral anticoagulation control is a critical determinant to minimize the risk of bleeding and thromboembolic events. Anticoagulation control is usually assessed by the time in therapeutic range (TTR) which is recommended to be above 60%.

Aims: To assess the quality of oral anticoagulation control at two pharmacist-managed anticoagulation clinics (AC) using two different measurement methods.

Methods: This study included adults with indication of continuous warfarin use. Patients were recruited at two AC of public hospitals in Brazil (2014-2015). Anticoagulation control was assessed by time in therapeutic range (TTR) and by the proportion of International Normalized Ratio (INR) values in range. These methods were compared by the Spearman correlation coefficient ($p < 0.05$). The study has been approved by the Research Ethics Committee, and all patients signed an informed consent.

Results: A total of 554 patients were studied, 57.4% female. The median age was 63.7 (Quartile 1 (Q1) 54.3; Quartile 3 (Q3) 73.6) years. The most frequent indication for warfarin therapy were AF/flutter (n=427; 77.1%) (Table 1). TTR variation was 12.7-99.5% and 344 (61.6%) patients had TTR ≥60%. The proportion of INR values in range was 53.5% (Q1 43.5%; Q3 62.5%) with a variation of 14.0-92.3%. The proportion of INR values in range was 53.5% (Table 2). There was a high correlation (0.88; $p < 0.001$) between these methods.

TABLE 1 Sociodemographic data of studied patients at two hospital-based anticoagulation clinics

Sociodemographic data	AC 1 (n=242)	AC 2 (n= 312)	Total (n=554)
Age, median (Q 1; Q3)	68.4 (58.7; 76.0)	61.0 (51.25; 70.1)	63.7 (54.3; 73.6)
Female, n (%)	131 (54.1)	187 (59.9)	318 (57.4)
Race, n (%)			
Non-White	172 (71.1)	204 (65.4)	376 (67.9)
White	70 (28.9)	108 (34.6)	178 (32.1)
Montly income - US dollars, median (Q 1; Q3)	221.4 (221.4; 284.0)	184.5 (110.7; 221.4)	221.4 (137.0; 221.4)

Currency conversion, $1.00 US dollar=R$ 3.27 Brazilian Reais (12/26/2016).

Abbreviations: AC, anticoagulation clinic; Q1, Quartile 1; Q3, Quartile 3.

TABLE 2 Clinical data of studied patients of two hospital-based anticoagulation clinics

Clinical data	AC 1 (n=242)	AC 2 (n= 312)	Total (n=554)
Indications for oral anticoagulation, n (%)			
Atrial fibrillation/flutter	196 (81.0)	231 (74.0)	427 (77.1)
Mechanical heart valves	20 (8.3)	117 (37.5)	137 (24.7)
DVT/pulmonary embolism	3 (1.2)	9 (2.9)	12 (2.2)
Stroke/transiente ischemic attack	90 (37.2)	18 (5.8)	108 (19.5)
TTR, median (Q 1; Q3)	66.8 (57.0; 76.7)	61.5 (52.2; 72.0)**	64.3 (54.0; 74.0)
Fraction of INR in therapeutic range, median (Q 1; Q3)*	53.9 (44.4; 63.22)	53.0 (43.2; 62.0)**	53.5 (43.5; 62.5)

Abbreviations: AC, anticoagulation clinic; DVT, deep venous thrombosis; TTR, time in therapeutic range; Q1, Quartile 1; Q3, Quartile 3.

*TTR and fraction of INR in therapeutic range calculated for 546 patients.**No access to INR for eight patients at AC 2.

Conclusions: The studied pharmacist-managed AC have achieved an adequate oral anticoagulation control in Brazilian patients with low socioeconomic status. This study enables us to contextualize the performance of two hospital-based public AC in the context of internationally used parameters to predict warfarin-related events. Pharmacists may be important as part of multidisciplinary teams, to improve patient education and the quality of warfarin use in low- and middle-income countries.

PB 285 | Factors Associated with Postoperative Hemorrhage in Patients Undergoing Dental Surgery

A.L. Rocha, A.F. Souza, M.A.P. Martins, M.G. Fraga, D.V. Travassos, A.C.B. Oliveira, D.D. Ribeiro, T.A. Silva

Universidade Federal de Minas Gerais, Belo Horizonte, Brazil

Background: Anticoagulant and antiplatelet therapies are widely used to prevent and treat thromboembolism. Dental surgery in patients under antithrombotic therapy is of concern. Anticoagulant therapy may increase the risk of peri/post-operative bleeding.

Aims: To investigate factors associated with postoperative bleeding in patients under therapy with anticoagulant or antiplatelet drugs undergoing dental surgery.

Methods: This cohort employed a retrospective chart review of patients on antithrombotic therapy and undergoing dental surgery (2010-2015) at a hospital-based dentistry service. We surveyed sociodemographic and clinical data, including peri/postoperative bleedings. INR values were used to calculate the time in therapeutic range (TTR). We investigated the factors associated with postoperative bleeding using odds ratios (OR) calculations with 95% confidence intervals (CI). The study was approved by the

Research Ethics Committee, and patients signed an informed consent.

Results: The mean age was 57 (±14.2) years, 57% male. A total of 179 patients underwent 293 dental surgeries. Eight cases of perioperative and 12 of postoperative bleeding were recorded. The complications were generally managed with local measures and did not require hospitalization. The mean TTR was 64% for patients without bleeding complications and 67% for those with postoperative bleeding. We found association of postoperative hemorrhage with increased perioperative bleeding (OR 8.88; 95% CI 1.51-52.20), therapeutic-INR 2.5-3.5 (OR 3.76; 95% CI 1.03-13.73) and the combination of anticoagulant and antiplatelet therapies (OR 1.85; 95% CI 1.43-2.50).

Conclusions: Dental surgery in patients under antithrombotic therapy might be carried out without altering the regimen because of low risk of peri and postoperative bleeding. However, patients with increased perioperative bleeding or taking the combination of anticoagulant and antiplatelet therapies should be closely follow up because of increased risk of postoperative complications.

PB 287 | Thrombin Generation Test: A Reliable Tool to Evaluate the Pharmacodynamics of Vitamin K Antagonist Rodenticides in Rats

G. Jourdi[1], S. Lefebvre[2], B. Le Bonniec[1], E. Curis[3,4], P. Gaussem[1,5], V. Lattard[2], V. Siguret[1,6]

[1]Inserm UMR_S 1140, Université Paris Descartes, Sorbonne Paris Cité, Paris, France, [2]Veterinary School of Lyon, USC 1233 INRA-Vetagro Sup, Lyon, France, [3]Laboratoire de Biomathématiques, Université Paris Descartes, Sorbonne Paris Cité, Paris, France, [4]DBIM, Hôpital Saint Louis, APHP, Paris, France, [5]Service d'Hématologie Biologique, Hôpital Européen Georges Pompidou, APHP, Paris, France, [6]Service d'Hématologie Biologique, Hôpital Lariboisière, APHP, Paris, France

Background: Vitamin K antagonist (VKA) rodenticide pharmacodynamics (PD) has been extensively studied in rodents with traditional laboratory tests based on clotting time which are insensitive to physiological inhibitors and intrinsic amplification of the clotting cascade.

Aims: We wondered if thrombin generation test (TGT) could add value to PD study of VKA in rats.

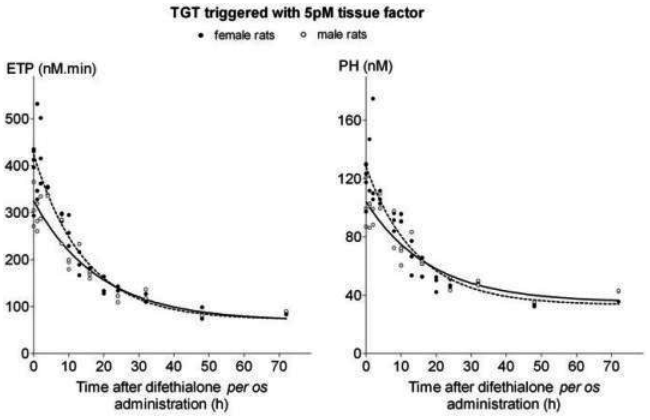

FIGURE 1 Kinetics of thrombin generation parameters (ETP, PH) after difethialone intoxication

Methods: Difethialone (10 mg/kg) was administered *per os* to 78 OFA-Sprague Dawley rats, and its PD was studied over a 72h-period using TGT (Calibrated Automated Thrombogram) on platelet poor plasma along with prothrombin time (PT) and vitamin K dependent factor activities (FII, FVII, FIX and FX), before (T0) and 1, 2, 4, 8, 10, 13, 16, 20, 24, 32, 48 and 72 hours after intoxication.

Results: Triggered with either 5 or 20 pM tissue factor, thrombin generation was fully inhibited at T24. To obtain reliable TGT parameters, samples were complemented with pooled normal rat plasma (3/1, v/v). Complementation allowed obtaining peak height (PH) and endogenous thrombin potential (ETP) all along the study-period. PH and ETP as a function of the intoxication time fitted well exponential decay models (Figure). TGT results confirmed the known significantly more pronounced procoagulant basal level in females compared to males for ETP and PH ($p< 0.0001$ and $p=0.0015$, respectively). ETP and PH decrease were observed very early after VKA intoxication, with comparable half-lives: 10.5h (CI95% [8.2; 13.6]) for ETP and 10.4h (CI95% [7.8; 14.1]) for PH. In contrast, PT prolongation was observed 2 hours post-intoxication in males and even 8 hours in females. Finally, we observed that FVII and FX decreased firstly, followed by TGT parameters (ETP, PH), while FII and FIX decreased later on.

Conclusions: We demonstrated that TGT run on samples from intoxicated rats previously complemented with pooled normal plasma is a reliable tool to evaluate VKA rodenticide PD, allowing exploration of both hyper- and hypo-coagulability states in rodents.

PB 288 | The Efficacy of 3-mg versus 5-mg Warfarin Initiating Dose and Corresponding Dosing Schedule in Thai Patients Diagnosed with Venous Thromboembolism

B. Suwanawiboon, W. Rotchanapanya, K. Mahaprom, N. Sermsathanasawadi, Y. Lalerd, W. Thongnoppakhun, C. Limwongse

Faculty of Medicine Siriraj Hosptial, Mahidol University, Bangkok, Thailand

Background: Currently, the initiation of warfarin with a dose between 5 and 10 mg was recommended for the treatment of venous thromboembolism (VTE). However, variation in warfarin requirement has been reported with a lower maintenance dose required by the Asians. Presently, the optimal initiating dose in patients of different ethnic groups is unknown.

Aims: To evaluate the efficacy of a lower warfarin initiating dose and a corresponding dosing schedule in Thai patients with VTE.

Methods: Patients diagnosed with VTE were randomized to receive warfarin 3 mg/d or 5 mg/d for the first 2 days (day 1-2). Subsequent dose was adjusted according to the INR and the corresponding dosing schedule. The INRs were measured at baseline, on day 3, 5 and 8. Blood for *CYP2C9* and *VKORC1* SNPs were collected. The primary outcome was the number of patients who achieved the target INR (2.0-3.0) within 8 days. The study was approved by the ethic committee.

Results: A total of 56 patients were enrolled, 28 patients in each group. The mean age was 46.9±16.3 years. Thirty-six patients (64.3%)

had deep vein thrombosis. There were no significant differences of baseline characteristics between the groups. Seventeen patients (60.7%) in the 3-mg group and 22 patients (78.6%) in the 5-mg group achieved the target INR within 8 days (p=.146). However, there were significantly more patients in the 5-mg group who achieved the target INR earlier on day 5 comparing with those in the 3-mg group (53.6% vs 25%, p=.029). None of the patients had INR>5.0.The prevalence of *CYP2C9* *1/*1 and *VKORC1*-1639G>A was 92.9% and 53.6%, respectively. In addition, *VKORC1*-1639G>A was associated with the likelihood to achieve the target INR within 5 days (OR 3.81, 95%CI 1.19-12.16, p=.021).

Conclusions: The efficacy of 3-mg warfarin starting dose with subsequent dose adjustment was similar to that of 5-mg on day 8 after warfarin initiation. However, 5-mg initiating dose resulted in more patients who achieved therapeutic INR earlier on day 5.

PB 289 | Barriers to Implementing an Extended INR Testing Interval Policy for Stable Warfarin Patients: A Mixed Methods Study in Five Anticoagulation Clinics

G. Barnes[1], S. Misirliyan[1], S. Kaatz[2], E. Jackson[1], B. Haymart[1], E. Kline-Rogers[1], J. Kozlowski[3], G. Krol[2], J. Froehlich[1], A. Sales[1]

[1]University of Michigan, Ann Arbor, United States, [2]Henry Ford Hospital, Detroit, United States, [3]Huron Valley Sinai Hospital, Commerce Township, United States

Background: Patients on chronic warfarin therapy require regular INR monitoring. Recent studies have challenged the need for monthly INRs in the most stable patients, suggesting the safety of extended INR testing intervals (up to 12 wk).

Aims: To explore barriers to implementing an extended INR testing interval for stable warfarin-treatment patients managed in nurse/pharmacist-run anticoagulation clinics.

Methods: Using a mixed-methods approach, we conducted semi-structured interviews with eight anticoagulation nurse or pharmacist staff members at five participating anticoagulation clinic sites to assess barriers to implementing a new extended INR testing interval policy. Interview guides were based on the Tailored Implementation for Chronic Disease framework. Informed by these interviews, we surveyed all anticoagulation clinical staff (n=62) about their self-reported utilization of extended INR testing intervals and specific barriers to implementing this practice.

Results: From the interviews, four themes emerged:

(1) staff overestimating their actual use of extended INR testing intervals,

(2) barriers to electronically reviewing existing INR values and the need to provide additional education for eligible patients,

(3) broad support for an electronic medical record flag to identify potentially eligible patients, and

(4) the importance of personalized nurse/pharmacist feedback.

In the survey (65% response rate), staff report offering extended INR testing intervals to 56% (46%-66%) of eligible patients. Most survey responders (24; 60%) agreed that an eligibility flag in the electronic medical record would be very helpful. Twenty-four (60%) of respondents agreed that periodic, personalized feedback on use of extended INR testing would also be helpful.

Conclusions: Leveraging information system notifications, reducing additional work load burden for participating patients and providers, and providing personalized feedback are strategies that may improve adoption and utilization new policies in anticoagulation clinics.

PB 290 | Vitamin K Antagonists Compared to Low-molecular-weight Heparins for Treatment of Cancer-associated Venous Thromboembolism: An Observational Study in Routine Clinical Practice

P. den Exter, J. Hooijer, T. van der Hulle, J.P. van Oosten, O.M. Dekkers, F.A. Klok, M.V. Huisman

LUMC, Leiden, The Netherlands

Background: Since several trials have demonstrated that low-molecular-weight-heparin (LMWH) is superior to vitamin-K-antagonist (VKA) in preventing recurrent VTE in patients with cancer-associated VTE, guidelines now recommend LMWH mono-therapy in this setting.

Aims: We evaluated whether this shift resulted in improved outcomes in routine clinical practice.

Methods: We performed a cohort study of consecutive patients with cancer-associated VTE during 2001 and 2010. We compared the risks for recurrent VTE, major bleeding and mortality between patients diagnosed before and after 2008 during 6-month routine follow-up.

Results: A total of 381 patients were included, of which 234 (61.4%) were diagnosed before 2008. Before 2008, 23% of the patients were treated with LMWH, thereafter this percentage was higher: 67%. The 6-month cumulative incidence for recurrent VTE was 10.6% in patients diagnosed before 2008 versus 9.3% for patients diagnosed after 2008 (risk difference (RD) -1.1%, 95%CI -6.3, 5.3). The respective risks for major bleeding were 8.0% versus 6.3% (RD -1.6%, 95%CI -3.8-5.8), and 40% versus 42% (RD 1.8%, 95%CI -8.8, 12) for overall mortality (Table 1). The mean time in therapeutic range of patients treated with VKA was 61%.

TABLE 1 Patient outcomes

Outcome	Diagnosed before 2008 (n=234)	Diagnosed since 2008 (n=147)	Difference (95% CI)
Recurrent VTE	8.6%	7.5%	-1.1% (-6.3-5.3)
Major bleeding	6.4%	4.8%	-1.6% (-3.8-5.8)
Mortality	40%	41%	+1.8% (-8.8-12)

Conclusions: Despite a clear shift towards LMWH as agent of choice for cancer-associated VTE, we did not observe a clear improvement in terms of recurrent VTE and bleeding complications.

PB 291 | External Quality Assessment of the POCT Prothrombin Time Determination - the 6-Year Experience with the Evaluation of the Postanalytical Phase

P. Kessler[1], M. Budina[2]

[1]Nemocnice Pelhrimov, Department of Hematology and Transfusion Medicine, Pelhrimov, Czech Republic, [2]SEKK Company, Pardubice, Czech Republic

Background: The accuracy of the International Normalized Ratio (INR) determination is important for the anticoagulation care, just as proper interpretation of the INR is. The evaluation of the postanalytical phase as a subject of external quality assessment (EQA) has been added to the EQA of Point of Care Testing (POCT) prothrombin time determination in Czech Republic.
Aims: To analyze the results of the postanalytical phase evaluation as a part of 22 EQA cycles.
Methods: Each participant received two brief case histories with 3 questions (Q1: Is the INR below, within, or above the therapeutic range? Q2: Should the dose of warfarin be reduced, unchanged, or increased? Q3: What interval to the next INR measurement do you recommend?) The answers were classified as correct (leading to optimal treatment) acceptable (leading to suboptimal, but not harmful treatment) and incorrect (leading to potentially harmful modification of warfarin treatment). Correct and acceptable results were considered as successful. The Mann-Whitney test was used for the statistical analysis.
Results: 7378 triplets of answers were evaluated. The answers of (mean±SD) 85.5±13.4%, 85.2±14.6% and 79.9±15.7% of participants to Q1, Q2 and Q3, respectively, were successful and the answers of 85.5±13.4%, 80.4±17.8% and 66.9±18.8% of participants to Q1, Q2 and Q3, respectively, were correct. The answers to Q1 were more frequently successful ($p=0.03767$) and correct ($p < 0.00001$), than answers to Q3 and the answers to Q2 were also more frequently successful ($p=0.04253$) and correct ($p= 0.00037$), than answers to Q3.
Conclusions: The results of this study are in concordance with the real word clinical experience; the inappropriately long interval to next INR determination in an unstable patient is the most frequent mistake in the anticoagulation care, leading often to bleeding complications.

PB 292 | The Incidence of Thromboembolic and hEMorrhagic (ITEM) Complications in Patients on Anticoagulant Therapy. A Dynamic Parallel-group Cohort Study

S. Testa[1], G. Palareti[2], O. Paoletti[1], G. Castaman[3], F. Catalano[1], F. Cora'[4], M. Di Paolo[5], P. Esteban[1], S. Mannino[6], R. Morandini[1], A. Maroni[7], I. Nichele[5], M. Tala[1], A. Tosetto[5]

[1]Hemostasis and Thrombosis Center, AO Istituti Ospitalieri di Cremona, Cremona, Italy, [2]Malattie Cardiovascolari, Università di Bologna, Bologna, Italy, [3]Hemophilia and Thrombosis Center, Azienda Ospedaliera Universitaria Careggi, Florence, Italy, [4]San Bortolo Hospital, ULSS 8 Berica, Emergency Department, Vicenza, Italy, [5]San Bortolo Hospital, ULSS 8 Berica, Hematology Department, Vicenza, Italy, [6]AO Istituti Ospitalieri di Cremona, Direction, Cremona, Italy, [7]San Bortolo Hospital, ULSS 8 Berica, Direzione Servizi Socio Sanitari, Vicenza, Italy

Background: Different healthcare models have been proposed to manage patients undergoing anticoagulant therapy but there are no studies comparing strategies and the effectiveness of Hemostasis and Thrombosis Centers (H&TC) work organization.
Aims: To evaluate:
1) Any difference in use of anticoagulant drugs (prevalence and type) in the two healthcare models and
2) the incidence of major bleeding and thromboembolic complications in patients on VKA and DOAC in two areas using different management strategies.
Methods: The ITEM study is a dynamic cohort study of patients receiving oral anticoagulant therapy performed in two districts, Cremona and Vicenza, North Italy. While these two areas share comparable health resources, the Cremona Anticoagulant Clinic (AC) offers a highly organized telemedicine system connecting with the peripheral health care units (general practitioners, nursing homes, home patients) managing nearly 90% of anticoagulated patients. The Vicenza AC operates only about 5% of all anticoagulated residents. All patients presenting at the local Emergency Department with a major complication(either thrombotic or hemorrhagic) of anticoagulant treatment are prospectively enrolled. The study is seized to demonstrate, after a 24-months follow-up, a 35% reduction of major bleeding and thrombotic events in the Cremona cohort.
Results: Follow-up started on February 1st, 2016 in Cremona and in March 1st, 2016 in Vicenza. At an 8-months interim analysis, use of anticoagulant was greater in Cremona than in Vicenza (2.1 vs. 1.4%, $p< 0.001$). The rate of thromboembolic events in patients on VKA was 1.5% in Vicenza and 0.9% in Cremona (corresponding to a 60% reduction of events by the telemedicine model). The incidence of bleeding complications was 0.2% in Cremona vs. 0.1% in Vicenza.
Conclusions: These preliminary results suggest that the availability of a telemedicine model may promote the use of anticoagulant drugs, with a possible relevant reduction of thromboembolic manifestations.

PB 293 | Specific Inhibition of Endogenous VKOR Enzymes by Oral Anticoagulants Reveals Lower VKORC1L1 Susceptibility due to Different Binding Site

K. Liphardt[1], K.J. Czogalla[1], K. Höning[2], V. Hornung[2], M. Watzka[1], J. Oldenburg[1]

[1]University Clinic Bonn, Institute of Exp. Haematology and Transfusion Med., Bonn, Germany, [2]University Clinic Bonn, Institute of Molecular Medicine, Bonn, Germany

Background: Coumarins like warfarin are widely used as oral anticoagulants (OACs) that are prescribed to treat and prevent thromboembolism. In addition, coumarins are used as rodenticides since the 1950s. OACs inhibit vitamin K epoxide reductase (VKOR) activity, thereby reducing the availability of vitamin K (K) hydroquinone, thus leading to reduced γ-carboxylation of vitamin K dependent proteins. Vitamin K 2,3-epoxide reductase complex subunit 1 (VKORC1) and its paralog VKORC1-like1 (VKORC1L1) are enzymes which catalyze the reduction of K 2,3-epoxide to K hydroquinone.

Aims: Half-maximum inhibitory concentrations (IC_{50} values) of different 4-hydroxycoumarins and 1,3-indandiones were determined. Furthermore, warfarin binding on both VKOR enzymes were investigated by means of *in silicoand in vitro* analysis.

Methods: *VKORC1* and *VKORC1L1* gene expression was knocked out in HEK 293T cells using the CRISPR/Cas9 gene editing technique. *VKORC1* and *VKORC1L1* knockout HEK cells were transfected with human *F9* cDNA and incubated with vitamin K and various OACs. The resulting FIX activity served as a marker for VKR activity. In a second approach, *in silico* binding studies were performed to identify warfarin binding site in VKORC1L1. *In vitro* experiments were performed in double knockout cells for expression of *F9* and VKOR variants.

Results: OACs inhibited VKORC1 more efficiently compared to VKORC1L1. Enzyme specificity was even more pronounced when using the 1,3-indandiones. In contrast, rodenticides showed no marked difference in IC_{50} values of VKORC1 and VKORC1L1. To elucidate different inhibition pattern, *in silico* and *in vitro* studies were performed. Loop swapping indicated that this region is responsible in OAC binding. *In silico* analysis further restricted warfarin binding to three arginines in VKORC1L1.

Conclusions: VKORC1 and VKORC1L1 are enzymes both susceptible to various OACs. The warfarin binding sites for VKORC1 and VKORC1L1 are located in the loop but are different with respect to position and interacting residues.

PB 294 | A comparison of management strategies for patients with warfarin-induced bleeding

P. Dobesh[1], B. Trevarrow[1], C. Duncan[1], P. Malinowski[1], K. Guiliano[1], K. Gundabolu[2]

[1]*University of Nebraska Medical Center College of Pharmacy, Pharmacy Practice, Omaha, United States*, [2]*University of Nebraska Medical Center College of Medicine, Internal Medicine, Omaha, United States*

Background: While 4 factor prothrombin complex concentrate (4PCC) is recommended for management of warfarin-induced bleeding, many clinicians still use fresh frozen plasma (FFP) and vitamin K. Concerns with the use of 4PCC include inexperience, cost, and risk of thrombosis, while concerns with avoiding 4PCC include extended time needed for efficacy.

Aims: Compare the safety and efficacy of the management of warfarin-induced bleeding with 4PCC vs a strategy without 4PCC.

Methods: This retrospective study included patients at our hospital with a major bleeding event on warfarin from 11/12 to 10/16. Patients receiving other anticoagulants were excluded. Patient data and outcomes were collected from patient charts. All descriptive data are shown as mean ± standard deviation.

Results: We identified 88 patients with warfarin-induced major bleeding treated with 4PCC (n=27) and without 4PCC (n=61). Patient demographics were not significantly different (Table).

TABLE 1 Patient Demographics

	4 Factor PCC (n=27)	No 4 Factor PCC (n=61)	p-value
Age (years)	74 ± 12	71 ± 13	0.31
Male (%)	63%	62%	0.95
Weight (kg)	86.3 ± 27.6	88.1 ± 23.7	0.75
HAS-BLED Score	2.4 ± 1.0	2.4 ± 1.2	1.0
Atrial fibrillation	56%	48%	0.49
Venous thromboembolism	30%	15%	0.14
Left ventricular thrombosis	3.7%	16%	0.16
Valvular disease	7.4%	21%	0.13
Stroke	3.7%	0.0%	0.31

Patients with 4PCC vs without 4PCC had similar baseline INR values (4.1±2.6 vs 3.6±1.9). Patients receiving 4PCC were more likely to have cranial bleeds (74% vs 41%; p=0.01), less likely to have gastric bleeds (7.4% vs 57%; p< 0.01), and less likely to receive PRBCs (22% vs 51%; p=0.01) and FFP (19% vs 82%; p< 0.01). Vitamin K was similar in use (81% vs 77%) and dose (8.5±4.0 vs 8.3±3.7mg). While overall reversal success was similar between the groups (70% vs. 62%), 4PCC provided significantly faster INR normalization (2.1±2.0 vs 30.0±26.7hrs; p< 0.01) and time to bleeding cessation (20±27 vs 37±32hrs; p=0.02). Use of surgery to control bleeding was less common with 4PCC (19% vs 33%). Length of hospital stay and mortality (18% vs 13%) were not different. No thrombotic events were reported within 30 days.

Conclusions: Reversal of warfarin-induced bleeding with 4PCC provided faster resolution and reduced the use of other blood products. While patient outcomes were not different, this may be due to our small sample size.

PB 295 | Provision of External Quality Assurance for Post Analytical Assessment of Point of Care Haemostasis Tests

D.P. Kitchen[1], S. Munroe-Peart[1], L. Brown[1], S. Kitchen[2], I. Jennings[1], T. Woods[1], I. Walker[1]

[1]*UK NEQAS for Blood Coagulation, Sheffield, United Kingdom*, [2]*Sheffield Teaching Hospitals NHS Foundation Trust, Coagulation, Sheffield, United Kingdom*

Background: UK National External Quality Assessment Scheme for Blood Coagulation (NEQAS BC) has been providing External Quality Assurance (EQA) for Point of care POC tests for 20 years.

Aims: In this report, the aim was to increase awareness of the importance of post analytical assessment within our POC programmes.

Methods: For POC D-dimer testing users receive a sample with a brief clinical history including age and Wells score and using their result are asked to state whether or not the patient requires further investigation. Surveys are scored if there is 80% or more agreement. Over 3 years 11 samples have been distributed for users of Triage and Cobas

TABLE 1 Results of the anticoagulant dosing exercises 1-3

			Recommnedations from CDSS users		Recommendations from Non CDSS users	
Exercise	Past INRs	Previous Daily dose	New daily dose median (range)	Recall for testing median (range)	New daily dose median (range)	Recall for testing median (range)
1	INR increasing above target over 7 week period	7mg	6.4mg (2-8mg)	7 days (7-28)	6.4mg (2-7mg)	7 days (2-28)
2	INR decreasing below target over 12 week period	7mg	7.7mg (1-9.1mg)	7 days (2-42)	7.7mg (1-10mg)	7 days (1-42)
3	INR increasing to top of target over 10 week period	5mg	5mg (3-5mg)	21 days (3-70)	4.8mg (2.5-5mg)	14 days (1-70)

h232 devices. For Triage users 9 surveys have been scored. In only 5/9 there was 100% agreement on interpretation. For h232 users, 9/11 samples were able to be scored but in only 1/9 was there 100% agreement on interpretation.

Results: In an assessment of INR dosing using virtual patient results in which users are encouraged to input the data into their local computer dosing support system (CDSS), 3 exercises have been completed. In 2/3 exercises the CDSS recommended follow-on warfarin dose was within 1mg of the median recommended dose in ≥90% but in 1 exercise only 76% were in agreement. A small number of results were potentially dangerous.

Conclusions: There is growing acceptance that EQA should include assessment not only of the analytical phase but should include pre- and post-analytic phases. The data presented strongly supports the need for external assessment of operator ability to interpret the results which they generate.

PB 296 | Warfarin Toxicities: Risk Factors and Management - Data from a Developing Country

S.A. Ali[1], A. Rashid[2], B. Moiz[2]

[1]*Patel Hospital, Karachi, Pakistan,* [2]*Aga Khan University Hospital, Karachi, Pakistan*

Background: Vitamin K Antagonists (VKA) has been the cornerstone in management and prevention of thromboembolic diseases. With the advent of target specific anticoagulants having encouraging results for safety and efficacy clinical trials, there is a paradigm shift in the use of VKA as standard. However in developing countries, where there is cost restraint VKA is still widely used. Bleeding is the most serious complication associated with oral anticoagulant. We studied the spectrum of bleeding complications in patients presented with warfarin toxicity in our institute.

Aims: To evaluate bleeding complications, risk factors and management strategies in patients with warfarin toxicity.

Methods: This was a retrospective study. All patients on warfarin who presented with bleeding complications from January - December 2015 were included in the study. Age, gender, indications, risk factors for bleeding, severity and management were reviewed from patient's record. Data was recorded on a predesigned proforma.

Results: The cohort included 51 patients (mean age 59 +/- 10 years, 64% male). Majority of patients were taking oral anticoagulant for therapeutic purpose most common being Atrial fibrillation (n=32, 63%). 76% (n=39) patients had one or more of co-morbidities. Common risk factors included old age (n=31, 60%) and hypertension (n=22, 43%). Major bleeding as per ISTH criteria was observed in 13 individuals (25.4%). Most common site of bleeding was gastrointestinal (n=17, 33%) followed by mucosal bleeding (n=13, 25%). Intracranial bleeding leading of death was observed in one case. The drug was discontinued in all cases with transfusion of fresh frozen plasma and use of Intravenous vitamin K supplementation in 33% (n=17) and 94% (n=48) cases respectively.

Conclusions: The rate of major bleeding and fatal complication with oral anticoagulants in our population where VKA are still preferred over novel anticoagulants is low. With regular monitoring, patient education and prompt management, bleeding complications can be reduced.

PB 297 | Use of a 4-factor Prothrombin Complex Concentrate for Warfarin Reversal prior to Urgent Surgery

B. Trevarrow[1], P. Dobesh[1], M. Wolfe[1], K. Gundabolu[2]

[1]*University of Nebraska Medical Center College of Pharmacy, Pharmacy Practice, Omaha, United States,* [2]*University of Nebraska Medical Center College of Medicine, Internal Medicine, Omaha, United States*

Background: While 4 factor prothrombin complex concentrate (4PCC) is recommended for the management of warfarin-induced major bleeding, its role in reversal of warfarin prior to urgent surgery is not well defined. If safe, the rapid onset of action would make 4PCC an attractive option for these patients.

Aims: Assess the efficacy and safety of 4PCC in warfarin reversal prior to urgent surgery in real world practice.

Methods: This retrospective study included all patients who received 4PCC at our hospital for reversal of warfarin for urgent surgery from 11/14 to 11/16. Success was defined as achieving an INR ≤1.5 prior to surgery. Patients receiving other anticoagulants were excluded from the analysis. Patient demographics, medication use, laboratory values, and outcomes were collected from patient charts. All descriptive data are presented as mean ± standard deviation.

Results: We identified 27 patients who received 4PCC for warfarin reversal prior to urgent surgery. Patients were 68% male, age 63.4±12.9 years, weight 96.4±26.1kg, and BMI 32.8±8.7. Indications for warfarin and most common indications for surgery are in Table 1.

TABLE 1 Indications for warfarin and surgery

Indications for Warfarin, n (%)	
Atrial fibrillation	12 (44)
Valve disease	7 (26)
Left ventricular assist device	6 (22)
Venous thromboembolism	2 (7)
Indications for Surgery, n (%)	
Heart transplant	7 (26)
Craniotomy	4 (15)
Bowel resection	3 (11)
Other (1 or 2 of each)	13 (48)

The weekly warfarin dose was 33.0±16.8mg, baseline INR of 3.1±1.7 and HASBLED Score of 1.6±0.7. Aspirin was also used in 13 patients. The 4PCC dose was 2581±886 U at 28.1±10.5 U/kg. Vitamin K was used in 15 patients and FFP in 8 patients. INR normalized to ≤1.5 in 21 patients (78%) within 1.4±1.2 hours. Time from 4PCC to surgery was 5.6±8.3hrs. INR prior to surgery was 1.3±0.3. Surgery lasted 4.8±3.4hrs with and estimated blood loss of 546±779mL. There were 7 thrombotic events within the following 30 days. Seven patients died during hospitalization, 1 due to thrombosis. 50% of surviving patients were discharged on anticoagulation.

Conclusions: While 4PCC was not 100% successful, it did provide a rapid strategy for warfarin reversal prior to urgent surgery. The thrombotic risk of 4PCC in this setting will require analysis in larger studies.

PB 298 | Can Results Be Improved on Vitamin K Antagonists (AVKs) Therapy ?

A.B. Vilaseca[1], G. Vidmar[1], R. Barbera[2], H. Beccari[1]

[1]*Clinica San Camilo, Hematologia y Hemostasia, Ciudad Autónoma de Buenos Aires, Argentina,* [2]*Clinica San Camilo, Clinica Medica, Ciudad Autónoma de Buenos Aires, Argentina*

Background: Prolongation of life leds to a sustained increase in the number of patients undergoing anticoagulant therapy. Perhaps it is time to focus on the education of the medical community, and raise awareness that these drugs must be handled by experts doctors. As well as insulin or chemotherapy all are in the category of high risk drugs.

Aims: In order to evaluate if the Time in Therapeutic Range (TTR) could be improved by the experience of the Hematologist and not only with the use of Technology Point of Care (POC) two populations of patients were compared.

These two populations received attention in the same Anticoagulation Clinic and were controlled with POC. One population attended by the young medical staff with „Non-strict physician instructions" (NSI) and the other with „strict instruction"(SI) by older staff.

Methods: Strict instruction included an education program using a web page. The use of one pillbox,and quick report of changes in other drugs prescribed. Retrospective analysis of 242 patients INR tested with POC technology (Coagucchek XSPro-Roche Diagnostics) were analyzed,130 patients in attention with SI, and 112 with NSI.

Time in Therapeutic Range (**Rosendaal Method for % INR in range)** and, Percentage of Test in Range (TINR%) were calculated. Comparative analysis of independent samples with a T Test, Confidence Interval (CI 95%) and median was performed in both groups.

Software SPSS 18.0 version was used in Statistic Analysis.

Results: NSI population shows TTR 57.,2% and TINR 52,2% versus SI population TTR 66,6% and TINR 63,2%.

Conclusions: The outcome of anticoagulant therapy with antivitamin K antagonist depends not only on the technology used in the control tests but also on the experience of the treating physician,and patient motivation.We are convinced of the need to raise awareness in society and in the medical community that the success of Anticoagulant Therapy (AVKs or DOACS) depends, not only on the drug chosen but also, on patient and his / her environment education and motivation.

PB 299 | Genetically Determined Hypersensitivity to Vitamin K Antagonists Caused by a c.109G>A (p.Ala37Thr) Mutation in the Factor IX Propeptide: The First Case Identified in Poland

E. Odnoczko, J. Falkowska, B. Baran, A. Buczma, E. Stefanska-Windyga, J. Windyga

Institute of Haematology and Transfusion Medicine, Warsaw, Poland

Background: Hypersensitivity of coagulation factor IX to vitamin K antagonists (VKA) is a rare congenital bleeding disorder that manifests only during VKA therapy. The bleeding tendency is related to severe reduction of FIX clotting activity, the level of which is much lower than that of other vitamin K-dependent coagulation factors. Two genetic alterations at locus 37 (previous -10) in exon 2 of the *F9* are associated with hypersensitivity to VKA: c.109G>A (p.Ala37Thr) and c.110C>T (p.Ala37Val).

Aims: Up to now bleeding diathesis associated with c.109G>A (p.Ala37Thr) mutation in *F9* have been reported in very few cases only.

Methods: A 74-year-old male patient was admitted to our Centre with recently presented bleeding disorder. Few months earlier he received acenocoumarol due to mechanical heart valve implantation. Plasma coagulation studies comprised screening tests and assessment of coagulation factors activity with one-stage assay using BCSXP Coagulation Analyser and Siemens reagents. Mutation analysis of *F9* was performed by direct Sanger sequencing of all coding regions and exon/intron splicing sites on the ABI Genetic Analyzer.

Results: Laboratory tests revealed anemia (hemoglobin 6.9g/dl) and prolongation of PT with INR 1.95. APTT was significantly prolonged (61.2s n.25-33s), fibrinogen and thrombin time - within reference range. FIX:C was less than 2IU/dl (n.50-150IU/dl) while levels of other

vitamin K-dependent factors II, VII and X were 51.5IU/dl, 26.5IU/dl and 26IU/dl, respectively. Factor V,VIII, XI and XII activity was normal. *F9* genetic analysis revealed c.109G>A variant. VKA was discontinued and normalization of coagulation test results and bleeding was reported.

Conclusions: To our best knowledge, this is the first case of genetically determined FIX hypersensitivity to VKA identified in Poland. Although the genetic mechanism of congenital hypersensitivity to VKA was discovered about 20 years ago, such cases are still worth presenting to increase the awareness of physicians and laboratory diagnosticians.

PB 300 | Vkorc1 and cyp2c9 Gene Polymorphisms in the Healthy Russian and Buryat Respondents in Trans-Baikal Region

O. Bolshakova, B. Pushkarev, A. Emelyanov, Y. Vitkovsky

Chita State Medical Academy, Physiology, Chita, Russian Federation

Background: Prevalence of CYP2C9 and VKORC1 gene polymorphisms widely study in Russian population. These are necessary for effective therapy of chronic atrial fibrillation with warfarin.

Aims: The aim was to study the prevalence of CYP2C9 and VKORC1 gene polymorphisms in Russian and Buryat respondents in Trans-Baikal region.

Methods: The study included 72 healthy respondents aged 40 to 60 years (31 Russian and 41 Buryat subjects). Genetic polymorphism was detected by PCR.

Results: It was found the frequencies of genotypes Arg/Arg and Arg /Cys of CYP2C9*2 gene among the Russian respondents were 74% and 26% respectively. In Buryats the polymorphic variants of this gene were follow: 95% - Arg/Arg genotype and 5% - Arg/Cys genotype. No statistically significant difference in the frequencies of genotypes among the Russian and Buryat were found. Genotype Cys /Cys was not detected in any of the studied groups. The frequencies of genotypes G/G, G/A, A/A of VCORK1 gene (polymorphic marker G3730A) in Russian were 7%, 74% and 19% respectively, that is statistically significantly different from the prevalence of these genotypes in Buryats (76%, 24%, and 0% respectively).

Conclusions: It was found the frequency of allele Cys of gene CYP2C9*2 is 12% in Russian population in Trans-Baikal region, which corresponds to European sings. But the same allele occurs at 2.4 times more rarely in Buryat respondents in Transbaikalia. Distributions of VCORK1genotypes in Trans-Baikal region differ from those in Moscow region: the genotype GG follows at almost 5 times more rarely among the Russian population in Trans-Baikal region than in Moscow region, while the incidence of genotype G/A, and A/A of gene VCORK1 is approximately the same. The frequency of homozygotes for the G allele of the gene VCORK1 (G3730A) was significantly higher among the representatives of Buryats and it was 1/12 of the studied, than among the Russian, while heterozygotes of this gene at 3 times more common in the Russian compared with Buryats.

PB 301 | The Use of Prothrombinex Alone to Reverse Warfarin in Orthopaedic Patients Requiring Emergency Surgery

R. Stokes[1], H. Seymour[2], P. Kruger[1], S. P'ng[1]

[1]Fiona Stanley Hospital, Haematology Department, Perth, Australia, [2]Fional Stanley Hospital, Perth, Australia

Background: Warfarin, a vitamin K antagonist, requires reversal prior to surgery for patients with acute orthopaedic injuries. Prothrombinex (PTX) is a lypholyzed concentrate of mostly coagulation factors II, IX, and X that is used to reverse warfarin. However, its therapeutic use without the addition of vitamin K (VK) is not well established, and theoretically has the potential to increase the risk of haemorrhage and cost in these patients.

Aims: Establish the efficacy and safety of PTX alone in warfarinized orthopedic patients.

Methods: A retrospective audit was conducted on all orthopaedic admissions to a Tertiary Hospital who received PTX with or without VK to reverse warfarin prior to emergency surgery between 3rd February 2015 and 3rd February 2016. Outcomes included time to surgery, length of hospital admission, haemorrhagic and thrombotic complications, and mortality. Results were compared to a control group of patients who received only VK for warfarin reversal.

Results: Of 48 patients, 4 were excluded because they were on a NOAC rather than warfarin, leaving 44 for analysis. Of these, 17 patients (38.6%) received VK prior to surgery in addition to PTX. The mean time to theatre was 23.8 hours (1.3 - 57) for those who received VK and PTX, compared to 23.4 hours (5.4 - 51.8) for the PTX group. With the mean time to haemostatic support following initial INR being 15.8 hours (2.3 - 52.5) and 18.2 hrs (4.2 - 38.3) respectively. The average length of hospital stay was 8.4 days (2 - 27) and 8.8 days (3 - 43) respectively. Analysis of the control group is pending. The 30d mortality rate was 6 (13.6%), 3 in each group. The total number of thrombotic complications documented was 3 (11.1%) in the PTX only group, and 5 (29.4%) in the VK and PTX group.

Conclusions: This audit supports the use of prothrombinex alone in the emergency setting to reverse warfarin's anticoagulant effect. There was no increased rate of haemorrhagic complications or mortality associated with the use of prothrombinex alone.

PB 303 | Utility of a new Point of Care system, Coag S, for Vitamin K Antagonist Therapy in a Rural Family Practice

F. Kiss[1], J. Antal[2]

[1]Family Medical Practice, Biharugra, Hungary, [2]Diagon Ltd., Haemostasis R&D, Budapest, Hungary

Background: Vitamin K Antagonists (VKAs) are still the most widely applied anticoagulants in the prophylaxis of thrombotic diseases. In contrast with Direct Oral Anticoagulants VKA anticoagulation provides a real - although relatively narrow - Therapeutic Range (TR) and the intensity

of anticoagulation could be characterized by a simple, internationally approved figure, the INR. VKA anticoagulation requires regular laboratory determination of the INR offering a tool to determine the efficiency of the treatment, the Time in Therapeutic Range (TTR). TTR is the proportion of time a patient spent within a predetermined Therapeutic Range. In rural environments where the access to a laboratory could be restricted, Point of Care (POC) INR measurements from capillary blood offer a suitable alternative, especially in the case of elderly patients where appropriate collection of venous blood sample can also be difficult.

Aims:

(i) Calculation of patient TTRs referring to one year period of stable VKA treatment.
(ii) Evaluation of the utility of the Coag S POC system.
(iii) Identification of practice specific factors influencing the efficiency of the treatment.

Methods: The study covers a retrospective review of records of 1 year follow up (2016). TTRs were calculated with the Rosendaal method. The practice covers 1679 persons and POC VKA management were chosen by 49 patients. Patients who underwent short term or interrupted VKA treatment were excluded thus 25 patients were eligible with TR from 2 to 3 INR.

Results: Patient description and TTRs are summarized in Table 1.

TABLE 1 Patient description and TTRs

Patient Charateristics		Patient Number	TTR [%]	Average Number of Tests	Average Time Between Tests [day]
Gender	Male	12	68.69	13	28
	Female	13	74.53	10	34
Age	50-59	4	79.39	12	34
	60-69	7	78.74	11	33
	70-79	6	67.83	11	32
	80-89	8	64.68	13	27
Total		25	71.73	11	31

Conclusions: Coag S is a suitable POC tool to monitor VKA treatment providing i.) appropriate TTRs and ii.) convenient VKA management. iii.) Advanced age associated with lower TTR but in contrast with the literature patients till 70 years of age can maintain TTR above 75% and women show higher adherence than men requiring significantly less frequent monitoring.

PB 304 | Duration of Anticoagulation in First Venous Thromboembolism (VTE) in the Newcastle upon Tyne Hospitals NHS Foundation Trust (NUTH): A Quality Improvement Project

L. Tafesh, K. Talks

The Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom

Background: Anticoagulation duration after first VTE is based on multiple factors, including thrombosis site, bleeding/recurrence risk and patient choice. In NUTH, practice is to anticoagulate for a minimum of three months in provoked or distal VTE and six months in unprovoked proximal VTE. A risk/benefit analysis informs whether to discontinue or extended treatment. D-dimer monitoring and DASH scores inform recurrence risks following discontinuation.

Aims: To determine the proportion of patients with first VTE who have their anticoagulation duration assessed at the appropriate interval (three months in provoked or distal and six months in unprovoked proximal), who have a risk/benefit analysis documented, and who have D-dimer monitoring and a DASH score calculated in those who have discontinued anticoagulation.

Methods: The sample was extracted from a database of patients with a first VTE between 01/02/16 and 31/05/16 who were followed up in NUTH. Clinic letters were reviewed to determine when anticoagulant duration was assessed, whether a risk/benefit analysis was documented, and in those who had anticoagulation discontinued, whether D-dimers were monitored and a DASH score calculated.

Results: 40 of 69 patients who were followed up were assessed at the correct interval. 57 of 69 had a risk/benefit analysis documented. Of the 34 patients who had their anticoagulation discontinued, 27 had D-dimer monitoring and 2 had a DASH score calculated. Table 1 shows results breakdown by VTE subtype.

TABLE 1 Results by VTE subtype

	Distal DVT	Provoked proximal DVT	Unprovoked proximal DVT	Provoked PE	Unprovoked PE
3 month review	0/3	6/9	n/a	15/17	n/a
6 month review	n/a	n/a	10/19	n/a	9/21
Risk/benefit analysis	1/3	8/9	17/19	15/17	16/21
D-dimer monitoring	1/3	4/5	9/11	8/10	5/5
DASH score	0/3	0/5	1/11	0/10	1/5

PB 305 | Out of Range INR Values Increase Healthcare Interaction Time in Four Large Anticoagulation Clinics

G. Barnes[1], X. Gu[1], E. Kline-Rogers[1], C. Graves[1], E. Puroll[1], K. Townsend[2], E. McMahon[2], T. Craig[2], J. Froehlich[1]

[1]University of Michigan, Ann Arbor, United States, [2]Pfizer, Inc, US Medical Affairs, New York, United States

Background: The impact on anticoagulation staff work time and healthcare utilization of a single out of range (OOR) INR value not associated with a bleeding or thromboembolic complication among chronic warfarin-treated patients is not well described.

TABLE 1 Work Time by Phase of Interaction and Activity

	Pre-Interaction		Interaction		Post-Interaction	
	OOR INR	Control INR	OR INR	Control INR	OOR INR	Control INR
Total (57 OOR, 92 control)	1.2 (0.8-1.8) minutes	1.0 (0.7-1.4) minutes	2.3 (1.4-4.5) minutes	1.2 (0.7-2.3) minutes	1.5 (0.8-3.2) minutes	0.7 (0.2-2.0) minutes
Phone Call (34 OOR, 58 control)	0.9 (0.6-1.5) minutes	1.0 (0.7-1.4) minutes	4.0 (2.3-5.5) minutes	1.8 (0.9-3.3) minutes	1.9 (0.9-4.8) minutes	0.9 (0.3-2.5) minutes
Voicemail (19 OOR, 18 control)	1.4 (1.1-2.0) minutes	1.2 (0.5-1.6) minutes	1.1 (0.5-1.7) minutes	1.2 (0.9-1.2) minutes	1.1 (0.5-1.8) minutes	0.7 (0.2-1.4) minutes
E-mail (1 OOR, 5 control)	1.5 minutes	0.7 (0.5-1.1) minutes	0.1 minutes	0.1 (0.1-0.1) minutes	0.4 minutes	0.2 (0.1-0.2) minutes
Letter (0 OOR, 3 control)	n/a	0.6 (0.4-1.0) minutes	n/a	0.2 (0.2-0.3) minutes	n/a	0.1 (0.1-0.6) minutes
Other (3 OOR, 8 control)	3.0 (1.8-3.1) minutes	1.8 (1.1-3.2) minutes	n/a	n/a	n/a	n/a

Aims: To compare the anticoagulation staff time required to manage and document an OOR vs. in-range INR value.

Methods: At four large phone-based anticoagulation clinics in Michigan, warfarin-treated patients with atrial fibrillation (AF) or venous thromboembolism (VTE) were identified. Direct observation occurred during 8.5 full work days by trained observers. Work time was divided based on the phase of work (pre/during/post-interaction) and type of activity. Measurements are described as median and interquartile ranges (IQR) and compared using Wilcoxon rank-sum tests.

Results: Fifty-nine OOR INR values and 92 control INR values were observed during the study period. Most patients were known to the provider (79.7% and 88.0%, respectively) with similar length of warfarin treatment (mean±SD 3.2±3.4 years and 3.5±4.2 years, respectively) for OOR INR and control INR patients, respectively. Total median time involved for each OOR INR value was 5.1 minutes (IQR 3.7-9.5) vs. 2.9 minutes (IQR 1.8-5.8) for control INR values (p< 0.001).

Time spent on pre-interaction preparation was similar for OOR INR patients (1.2 min [0.8-1.8]) and control INR patients (1.0 min [0.7-1.4]; p=0.20). Time spent interacting with patients (2.3 min [1.4-4.5] vs. 1.2 min [0.7-2.3], p< 0.001) and post-interaction documentation (1.5 min [10.8-3.2] vs. 0.7 min [0.2-2.0], p=0.002) were longer for OOR INR patients versus control INR patients.

Conclusions: Warfarin-treated patients who experience OOR INR values without any bleeding or thromboembolic complication require more anticoagulation clinic staff time than control INR patients. A more complete understanding of patient management time requirements may improve anticoagulation clinic models.

PB 306 | Evaluation of Time in Therapeutic Range in Anticoagulated Patients with Venous Thromboembolism. A Single-center, Retrospective, Observational Study

Z. Tazi Mezalek[1,2], M. Bourkia[1], W. Ammouri[1,2], W. Mounfaloti[1], F.Z. Iraqi[1], M. Maamar[1], H. Harmouche[1], R. Razine[2,3], M. Adnaoui[1,2]

[1]Ibn Sina Hospital, Internal Medecine / Hematology, Rabat, Morocco, [2]Mohammed V University, Faculty of Medicine, Rabat, Morocco, [3]Laboratoire Recherche et Biostatistique et Recherche Clinique et Epidemiologie, Rabat, Morocco

Background: Patients with venous thromboembolism (VTE) frequently require vitamin K antagonists (VKAs) to prevent recurrent events, but their use increases hemorrhage risk.

Aims: We performed a study to assess the quality of international normalized ratio (INR) control, using time in therapeutical range (TTR) and to identify predictors of poor control and to examine the relationship between INR control and adverse outcomes in VTE patients.

Methods: We performed an observational, retrospective study, including all patients hospitalized for VTE who attended the internal medicine department of a Moroccan hospital (2010-2013), whose target INR was 2.0-3.0. The primary outcome under investigation was the TTR calculated according to F.R. Rosendaal's algorithm.

Results: 171 VKA-treated patients were evaluated; 53.2% men. The average age of our patients at diagnosis was 49.8 ± 16.6 years [17-92].The most common location of VTE was the lower limbs with 91.8 % cases; proximal in 83.6%. Five etiological groups have been ddistinguished : thrombophilia (5.8%), Behcet disease (9.4%), neoplasia (14.6%), with transient risk factor (34.5%) and idiopathic (35.7%). Patients were followed for a mean period of 178 days. The mean TTR was 41.2% (SD 32.9%) and 74.3% the patients had a mean TTR < 65%. The rates of major bleeds and thromboembolic events were 0.5% and 2.2%, respectively. In the statistical analysis, having a cancer and a non idiopathic VTE were negatively associated with a lower TTR (p < 0.05). ¨The rates of major bleeds and thromboembolic events were 0.5% and 2.2%, respectively. In the statistical analysis, having a cancer and a non idiopathic VTE were negatively associated with a lower TTR (p < 0.05).

Conclusions: Anticoagulation control needs to be improved in our unit. These results are informative and may help to identify patients who will require closer monitoring or innovative strategies to optimize the outcomes of oral anticoagulant therapy.

PB 453 | Safety and Efficacy of Edoxaban Compared with Warfarin for the Treatment of Acute Symptomatic Deep-vein Thrombosis in the Outpatient Setting

A. Medina[1], G. Raskob[2], W. Ageno[3], A.T. Cohen[4], M.P.A. Brekelmans[5], C.Z. Chen[6], M.A. Grosso[7], M.F. Mercuri[7], A. Segers[8], P. Verhamme[9], T. Vanassche[9], P.S. Wells[10], M. Lin[7], S.M. Winters[6], J.I. Weitz[11], H.R. Büller[5]

[1]University of Oklahoma Health Sciences Center, College of Medicine, Oklahoma City, United States, [2]University of Oklahoma Health Sciences Center, College of Public Health, Oklahoma City, United States, [3]University of Insubria, Department of Clinical and Experimental Medicine, Varese, Italy, [4]Guy's and St Thomas' Hospitals, King's College, Department of Haematological Medicine, London, United Kingdom, [5]Academic Medical Center, Department of Vascular Medicine, Amsterdam, The Netherlands, [6]Daiichi Sankyo, Inc, Global Medical Affairs, Parsippany, United States, [7]Daiichi Sankyo Pharma Development, Clinical Development, Edison, United States, [8]Itreas BV, Amsterdam, The Netherlands, [9]University of Leuven, Vascular Medicine and Haemostasis, Leuven, Belgium, [10]University of Ottawa, Ottawa Hospital Research Institute, Department of Medicine, Ottowa, Canada, [11]Thrombosis & Atherosclerosis Research Institute and McMaster University, Hamilton, Canada

Background: Direct-oral-anticoagulants streamline outpatient treatment of venous thromboembolism (VTE). However, the registration trials have not reported outcomes separately for patients managed either as outpatients or in the hospital.

Aims: We performed a subgroup analysis of the Hokusai-VTE study comparing the efficacy and safety of edoxaban with warfarin in outpatients.

Methods: Hokusai-VTE was a randomized double-blind trial in 8292 patients comparing edoxaban with warfarin for the treatment of acute VTE. All patients received initial therapy with enoxaparin or unfractionated heparin for at least 5 days. Treatment as an outpatient was at the discretion of the treating physician. Data on hospital admission was recorded for the last 5223 consecutively enrolled patients. Edoxaban or warfarin was given for at least 3 months and up to 12 months. The incidences of recurrent VTE and clinically relevant bleeding (major or non-major) were documented. The study was approved by institutional review boards and informed consent was obtained.

Results: Of the 5223 patients, 1414 (27%) were managed entirely as outpatients (724 in the edoxaban and 690 in the warfarin groups). The initial presentation was symptomatic deep-vein thrombosis (DVT) in 1183 of these patients (84%) and pulmonary embolism in 231 patients (16%). Of the DVT patients, recurrent VTE occurred in 18 (3.0%) given edoxaban and in 21 (3.6%) given warfarin (risk difference [edoxaban-warfarin] -0.61, 95% CI -2.65 to 1.42). Clinically relevant bleeding occurred in 46 patients given edoxaban (7.7%) and in 48 patients (8.3%) given warfarin (risk difference -0.59, 95% CI -3.68 to 2.49). Major bleeding occurred in 8 patients given edoxaban (1.3%) and in 8 patients (1.4%) given warfarin (risk difference -0.04, 95% CI -1.36 to 1.27).

Conclusions: Most patients chosen for outpatient management had symptomatic DVT at presentation. For outpatient treatment of DVT, a regimen of heparin followed by edoxaban had similar efficacy and safety to a regimen of heparin and warfarin.

PB 454 | Reliability and Validity of a Point of Care Test from Urine Samples of Patients on Therapy with Apixaban, Rivaroxaban and Dabigatran

J. Harenberg[1,2], U. Warttinger[3], S. Hetjens[4], R. Schreiner[5], C. Giese[3], H.-J. Roth[5], R. Krämer[3], C. Weiss[4]

[1]Medical Faculty Mannheim, Mannheim, Germany, [2]DOASENSE GmbH, Heidelberg, Germany, [3]University of Heidelberg, Inorganic Chemical Institute, Heidelberg, Germany, [4]Medical Faculty Mannheim, Biometry and Statistics, Mannheim, Germany, [5]Medical Service Center Dr. Limbach and Colleagues, Heidelberg, Germany

Background: The determination of the absence or presence of direct oral anticoagulants (DOACs) may be required in emergency situation of patients. They are excreted between 30% and 80% into urine. A point of care test (POCT) was developed to determine the absence or presence in urine samples of patients.

Aims: We aimed to analyze the reliability and validity of the POCT from urine samples patients on treatment with apixaban (A), rivaroxaban (R) and dabigatran (D).

Methods: Urine samples were obtained from patients (n=29 per group) treated with A (5mg bid), R (20mg od), D (110mg or 150mg bid) and patients without anticoagulant therapy (controls, C). Teststrips with pads containing the reagents (dry chemistry) for determination of A, R, and D were incubated with patient`s urine for 10 min. Then colours on the pads were white (A, R) and rose (D) in the presence (positive) and yellow (A, R) or ochre (D) in the absence (negative) of DOAC. The colours were objectified using the CMYK colour scale. Two observers identified independently the colours the pads visually by naked eye in comparison to the colour of the CMYK scale. Teststrips were photographed in a lightbox. Colours were analysed by ImageJ software program (grey scale). The concentration of DOACs was measured by liquid chromatography tandem mass-spectrometry (LC-MS/MS).

Results: The reliability (kappa index) and validity of the POCT were 100% (95% confidence intervals 74 to 100%) for A, R, and D. Ranges of results of ImageJ did not overlap for negative or positive results of colours on pads for A, R, and D using POCT. Validity was calculated using concentrations of DOACs (LC-MS/MS), which were below 10 ng/ml in control samples, 202 to 6.667ng/ml (A), 169 to 9.579 ng/ml (R) and 1.057 to 15.996ng/ml (D).

Conclusions: The present POCT from urine samples of patients offers a rapid, reliable and valid detection of DOACs in medical emergency situations. Additional pharmacological investigations and a study in a real-world setting are performed.

PB 456 | XALIA-LEA, a Non-interventional Study Comparing Rivaroxaban with Standard Anticoagulation for Initial and Long-term Therapy in Deep Vein Thrombosis

A.G.G. Turpie[1], L.G. Mantovani[2], S. Haas[3], R. Kreutz[4], D. Monje[5], J. Scheinder[6], M. van Eickels[6], M. Gebel[7], M. Tamm[7], W. Ageno[8]

[1]Hamilton Health Sciences, Medicine, Hamilton, Canada, [2]University of Milan Bicocca, CESP-Center for Public Health Research, Monza, Italy, [3]Formerly Technical University Munich, Munich, Germany, [4]Charité Universitätsmedizin, Institute of Clinical Pharmacology and Toxicology, Berlin, Germany, [5]Bayer Vital GmbH, Leverkusen, Germany, [6]Bayer AG, Berlin, Germany, [7]Bayer AG, Wuppertal, Germany, [8]University of Insubria, Department of Clinical and Experimental Medicine, Varese, Italy

Background: XALIA-LEA is a complementary study to XALIA. Regional enrolment differed; the later start date enabled the inclusion of patients with isolated pulmonary embolism (PE) in XALIA-LEA after approval.

Aims: To provide rivaroxaban safety and effectiveness information from routine practice in an unselected venous thromboembolism (VTE) population from Latin America, Eastern Europe, Middle East, Africa and Asia.

Methods: Patients aged ≥18 years, with objectively confirmed acute deep vein thrombosis and/or PE, with intended anticoagulant treatment for ≥3 months were eligible. Patients received rivaroxaban or standard anticoagulation (heparin/fondaparinux alone or overlapping with/followed by a vitamin K antagonist [VKA]). Therapy type, dose and duration were at the physician's discretion. VTE and major bleeding Cox regressions were adjusted for cancer and stratified by index VTE type. The all-cause mortality Cox regression was stratified by cancer and index VTE type.

Results: XALIA-LEA enrolled 1987 patients between Jun 2014 and Oct 2015; 8 patients did not receive anticoagulant therapy and 7 received other non-VKA oral anticoagulants, and were excluded from the primary analysis. Early switchers (n=285) given >2-14 days heparin/fondaparinux or 1-14 days VKA before starting rivaroxaban were included in a separate sensitivity analysis. The primary analysis comprised 1285 rivaroxaban- and 402 standard anticoagulation-treated patients (Table 1). Annualized rates of: major bleeding 2.7% (n=19) and 8.2% (n=15) (HR=0.35; 95% CI 0.18-0.69); recurrent VTE 2.6% (n=18) and 8.3% (n=15) (HR=0.33; 95% CI 0.17-0.67); and all-cause mortality 4.2% (n=29) and 15.8% (n=29) (HR=0.27; 95% CI 0.16-0.45), respectively.

Conclusions: XALIA-LEA provides information on VTE treatment in regions not studied in XALIA. Baseline characteristics between groups were more similar than in XALIA (including age and cancer rates). Safety and effectiveness outcomes with rivaroxaban were consistent with XALIA.

TABLE 1 Baseline demographic and clinical characteristics

Characteristic N (%) unless otherwise stated	Rivaroxaban (N=1285)	Standard anticoagulation (N=402)
Age (years), mean (SD)	59.6 (17.1)	58.0 (18.0)
Male sex	623 (48.5)	180 (44.8)
Asia Pacific	720 (56.0)	167 (41.5)
Eastern Europe, Middle East and Africa	473 (36.8)	196 (48.8)
Latin America	92 (7.2)	39 (9.7)
First available Creatinine Clearance <50 ml/min	126 (9.8)	61 (15.2)
DVT only (remaining patients had PE with or without DVT)	882 (68.6)	238 (59.2)
Cancer at baseline	216 (16.8)	69 (17.2)
Previous VTE	150 (11.7)	55 (13.7)

PB 457 | Rivaroxaban for Initial Therapy in Patients with Pulmonary Embolism. A Real-life Study

P. Di Micco[1], J. Trujillo-Santos[2], A. Merah[3], A. Fidalgo[4], J.R. Vela[5], I. Mahe[6], A. Bura-Riviere[7], J. Bascunana[8], B. Valero[9], M. Monreal[10], RIETE Investigators

[1]Ospedale Buonconsiglio Fatebenefratelli, Internal Medicine and Emergency, Naples, Italy, [2]Hospital General Universitario Santa Lucía, Murcia, Spain, [3]CHU Saint-Etienne, Hôpital Nord, Medecine Therapeutique, Saint-Etienne, France, [4]Hospital Universitario de Salamanca, Internal Medicine, Salamanca, Spain, [5]Hospital Universitario Miguel Servet, Internal Medicine, Zaragoza, Spain, [6]Hopital Louis Mourier, Internal Medicine, Paris, France, [7]Hôpital de Rangueil, Vascular medicine, Toulouse, France, [8]Hospital Infanta Leonor, Internal Medicine, Madrid, Spain, [9]Hospital General Universitario de Alicante, Internal Medicine, Alicante, Spain, [10]Hospital Universitario Germans Trias i Pujol de Badalona, Internal Medicine, Barcelona, Spain

Background: The efficacy and safety of initial therapy with rivaroxaban in patients with acute pulmonary embolism (PE) has not been consistently studied yet in real-life studies.

Aims: To compare the outcomes during rivaroxaban therapy in PE patients, according to starting rivaroxaban in less than 48 hours, from day 3 to day 7, or beyond the eight day after PE diagnosis.

Methods: We used the RIETE (Registro Informatizado Enfermedad Trombo Embólica) database to compare the rate of VTE recurrences,major bleeding and death during therapy with rivaroxaban.

Results: From January 2013 to September 2016, 1518 PE patients received rivaroxaban initially: 591 (39%) starting within the first 48 hours, 402 (26%) from day 3 to day 7 and 525 (35%) beyond the 8th day. Patients starting rivaroxaban within the first 48 hours were younger and were less likely to have renal insufficiency than those starting later. Otherwise, there were few differences in other clinical characteristics or risk factors for PE among subgroups. During rivaroxaban therapy (mean, 192 days), the rate of major bleeding was: 2.20 (95%CI: 0.80-4.78), 2.31 (95%CI: 0.74-5.39) and 0.65 (0.07-2.35) major bleeds per 100 patient-years, respectively. One patient that started beyond the 8th day had a recurrent PE and no patient died of PE or bleeding.

Conclusions: The use of rivaroxaban in patients starting < 48 hours after PE carried similar rates of PE recurrences or major bleeding than in those starting the drug later.

TABLE 1 Outcomes according to rivaroxaban starting

	Rivaroxaban starting < 48 hours		Rivaroxaban starting 3-7 days		Rivaroxaban starting ≥ 8 days	
	N	Events per 100 patient-years	N	Events per 100 patient-years	N	Events per 100 patient-years
Patients, N		591		402		525
Duration of therapy (days)		167±120		194±153		211±209
DVT recurrences	1	0.37 (0.005-2.04)	2	0.92 (0.10-3.34)	0	-
PE recurrences	0	-	0	-	1	0.33 (0.004-1.81)
Major bleeding	6	2.20 (0.80-4.78)	5	2.31 (0.74-5.39)	2	0.65 (0.07-2.35)
Overall death	4	1.46 (0.39-3.75)	2	0.92 (0.10-3.34)	7	2.28 (0.91-4.69)
Fatal PE	0	-	0	-	0	-
Fatal bleeding	0	-	0	-	0	-

PB 458 | Impact of Age, Comorbidity and Polypharmacy on the Efficacy and Safety of Edoxaban for the Treatment of Venous Thromboembolism: An Analysis of the Randomized, Double-blind Hokusai-VTE Study

T. Vanassche[1], P. Verhamme[1], P.S. Wells[2], A. Segers[3], W. Ageno[4], M.P.A. Brekelmans[5], C.Z. Chen[6], A.T. Cohen[7], M.A. Grosso[8], A.P. Medina[9], M.F. Mercuri[8], S.M. Winters[6], G. Zhang[10], J.I. Weitz[11], G. Raskob[12], H.R. Büller[5]

[1]*University Hospitals Leuven, Dept. of Cardiovascular Sciences, Leuven, Belgium,* [2]*University of Ottawa, Ottawa Hospital Research Institute, Department of Medicine, Ottawa, Canada,* [3]*Itreas BV, Amsterdam, The Netherlands,* [4]*University of Insubria, Department of Clinical and Experimental Medicine, Varese, Italy,* [5]*Academic Medical Center, Department of Vascular Medicine, Amsterdam, The Netherlands,* [6]*Daiichi Sankyo Inc., Global Medical Affairs, Parsippany, United States,* [7]*Guy's and St Thomas' Hospitals, King's College, Department of Haematological Medicine, London, United Kingdom,* [8]*Daiichi Sankyo Pharma Development, Clinical Development, Edison, United States,* [9]*University of Oklahoma Health Science Center, College of Medicine, Oklahoma City, United States,* [10]*Daiichi Sankyo Pharma Development, Biostatistics, Edison, United States,* [11]*Thrombosis & Atherosclerosis Research Institute and McMaster University, Hamilton, Canada,* [12]*University of Oklahoma Health Science Center, College of Public Health, Oklahoma City, United States*

Background: Many patients with venous thromboembolism (VTE) have multiple comorbidities and take many concomitant medications, which represents a higher risk for both recurrent VTE and bleeding, particularly in the elderly. The lack of comparative data of direct oral anticoagulants (DOACs) versus warfarin in these complex patients may result in physician preference to utilize monitored warfarin therapy.

Aims: To determine the effects of advanced age, comorbidities, and polypharmacy on the efficacy and safety of edoxaban and warfarin.

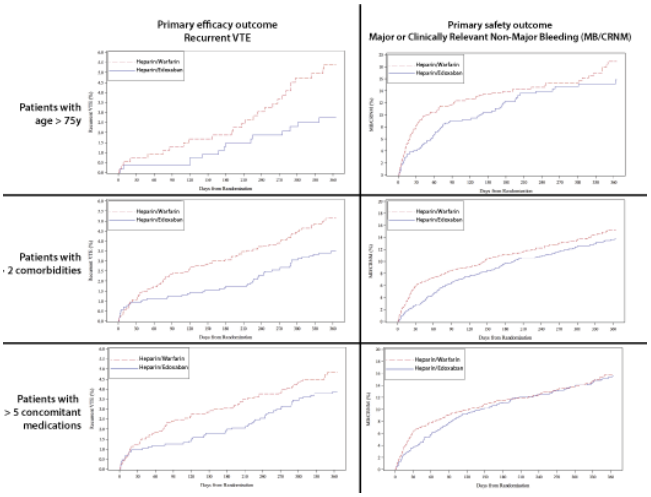

FIGURE 1 Primary efficacy and safety outcome in subgroups of frail patients

TABLE 1 Outcomes by categories of frailty

	Recurrent VTE			Major or clinically relevant non-major bleeding		
	edoxaban, n/N, rate (%)	warfarin, n/N, rate (%)	HR (95% CI)	edoxaban, n/N, rate (%)	warfarin, n/N, rate (%)	HR (95% CI)
<80 years	123/3866 (3.2%)	131/3857 (3.4%)	0.94 (0.73-1.20)	311/3866 (8.0%)	377/3857 (9.8%)	0.81 (0.70-0.94)
≥80 years	7/252 (2.8%)	15/265 (5.7%)	0.51 (0.21-1.24)	38/252 (15.1%)	46/265 (17.4%)	0.87 (0.56-1.33)
no comorbidities	11/571 (1.9%)	9/590 (1.5%)	1,23 (0.51-2.97)	44/571 (7.7%)	38/590 (6.4%)	1,23 (0.80-1.89)
1-2 comorbidities	64/1853 (3.5%)	52/1778 (2.9%)	1,19 (0.82-1.71)	119/1853 (6.4%)	167/1778 (9.4%)	0,67 (0.53-0.85)
>2 comorbidities	55/1694 (3.3%)	85/1754 (4.9%)	0,66 (0.47-0.93)	186/1694 (11.0%)	218/1754 (12.4%)	0,86 (0.71-1.05)
≤2 concomitant medications	43/1256 (3.4%)	32/1168 (2.7%)	1,25 (0.79-1.97)	73/1256 (5.8%)	82/1168 (7.0%)	0,82 (0.60-1.13)
3-5 concomitant medications	32/1328 (2.4%)	41/1357 (3.0%)	0,79 (0.50-1.26)	87/1328 (6.6%)	138/1357 (10.2%)	0,62 (0.47-0.81)
>5 concomitant medications	55/1534 (3.6%)	73/1597 (4.6%)	0,78 (0.56-1.11)	189/1534 (12.3%)	203/1597 (12.7%)	0,96 (0.79-1.18)

Methods: Using data from the Hokusai-VTE study, we report rates of recurrent VTE and of clinically relevant bleeding by age category (< 65, 65-75, and >75; < 80 vs ≥80 years), by comorbidities (0, 1-2, >2) and by concomitant medications (< 3, 3-5, >5). We present hazard ratios (HR) and corresponding 95% confidence intervals (CI) for edoxaban versus warfarin. Kaplan-Meier methodology was used to construct time-to-event curves. Pre- and post-dose levels of edoxaban were measured at the month 3 visit by mass spectrometry. For warfarin-treated patients, the time in therapeutic range was calculated. The study was approved by institutional review boards; informed consent was obtained.

Results: Recurrent VTE increased with advanced age, with multiple comorbidities, and with polypharmacy in warfarin-treated patients. Edoxaban was more effective in patients age ≥75 years and in patients with multiple comorbidities (*Table 1*, *Figure 1*). In the 517 patients above 80 years, recurrent VTE rates were 2.8% for edoxaban and 5.7% for warfarin (HR 0.51, CI 0.21-1.24). Bleeding increased with age, comorbidity, and polypharmacy regardless of treatment, but the relative safety of edoxaban versus well-managed warfarin was maintained. Age, comorbidity and polypharmacy did not impact on edoxaban pre- and post-dose levels.

Conclusions: Our data should reassure physicians that edoxaban is convenient, more effective and at least as safe as warfarin in these high-risk patients.

PB 459 | Prothrombin Complex Concentrate for Reversal of XA Inhibitors - Real Life Data

G. Spectre[1,2], A. Steimatzky[1], A. Shacham[1,2], V. Yahalom[3], S. Nakav[4], Y. Belnick[5]

[1]Rabin Medical Center, Hematology, Petah Tikva, Israel, [2]Tel Aviv University, Sackler Faculty of Medicine, Tel Aviv, Israel, [3]Rabin Medical Center, Transfusion & Apheresis Service, Petah Tikva, Israel, [4]Rabin Medical Center, Hematology Laboratory, Petah Tikva, Israel, [5]Rabin Medical Center, Internal Medicine D Hasharon Hospital, Petah Tikva, Israel

Background: The recommendation for reversal of Xa inhibitors with Prothrombin Complex Concentrate (PCC) is based on limited experience in healthy volunteers and real life data is lacking.

Aims: Outcome of patients who received PCC for reversal of XA inhibitors.

Methods: A retrospective study of patients who received 4 factors PCC between 4.2015 -1.2017 at a tertiary academic hospital. Decision for reversal was made by a coagulation expert.

Results: Forty/70 patients (mean age 78±10 years, 72% male, 90% with atrial fibrillation) received PCC at a mean dose of 30+11 u/kg for reversal of apixaban (n=25), rivaroxaban (n=13) or enoxaparin (n=2). Indication was major bleeding in 28(70%), mostly intracranial hemorrhage (ICH) (19/28, 68%). Seventeen patients (42%) including 5 with bleeding, required reversal for an urgent surgery/procedure; 7 abdominal, 3 neurosurgical, 2 orthopedic and 1 thorax surgery, 3 cholecystomy tube insertion and 1 vaginal procedure. Surgeons reported good hemostasis for all patients, blood products were given in 3/17 surgeries (2 orthopedic and 1 gynecology). Six of 17(35%) patients died 1-46 days after PCC, none due to bleeding. Among 19 patients with ICH, 6 were discharged home, 10 to rehabilitation/nursing homes, among them 4 unconscious or necessitated mechanical ventilation, 3 died 2-29 days after PCC (17.6%). During this period 17 patients treated with PCC for warfarin ICH, 5 discharged home(NS) and 9 (53%) died within 30 days (p=0.07). Drug levels obtained before and after PCC in 5 patients and were reduced in approximately 34-50% except for one patient with high levels and no reduction. 30 days thrombotic complications occurred in one patient (2.5%).

Conclusions: Good hemostasis in surgery obtained after PCC in patients under XA inhibitors despite incomplete reversal of drug levels. Thirty-day mortality from ICH tended to be lower in patients under XA inhibitors who received PCC as compared to warfarin treatment. Our findings support the use of PCC in these patients.

PB 460 | Clinical Characteristics and Treatment of Patients with Cancer-associated Venous Thromboembolism: Results from the GARFIELD-VTE Registry

J.I. Weitz[1], A.G.G. Turpie[2], S. Haas[3], W. Ageno[4], P. Angchaisuksiri[5], H. Bounameaux[6], S.Z. Goldhaber[7], S. Goto[8], G. Kayani[9], J. Dalsgaard Nielsen[10], S. Schellong[11], L.G. Mantovani[12], P. Prandoni[13], A.K. Kakkar[9,14]

[1]McMaster University and Thrombosis and Atherosclerosis Research Institute, Hamilton, Canada, [2]McMaster University, Hamilton, Canada, [3]Technical University of Munich, Formerly Department of Medicine, Munich, Germany, [4]University of Insubria, Department of Clinical and Experimental Medicine, Varese, Italy, [5]Ramathibodi Hospital, Mahidol University, Department of Medicine, Bangkok, Thailand, [6]University Hospitals of Geneva, Faculty of Medicine, Geneva, Switzerland, [7]Harvard Medical School, Boston, United States, [8]Tokai University School of Medicine, Kanazawa, Japan, [9]Thrombosis Research Institute, London, United Kingdom, [10]Copenhagen University Hospital, Copenhagen, Denmark, [11]Krankenhaus Dresden Friedrichstadt, Dresden, Germany, [12]University of Milano-Bicocca, Milan, Italy, [13]University of Padua, Padua, Italy, [14]University College London, London, United Kingdom

Background: Patients with active cancer are susceptible to venous thromboembolism (VTE). Although guidelines recommend low-molecular-weight heparin (LMWH) for cancer-associated thrombosis (CAT), direct oral anticoagulants (DOACs) and other agents also are prescribed.

Aims: To compare the clinical characteristics of VTE patients with and without active cancer and to determine the initial anticoagulant treatment patterns for CAT using data from the GARFIELD-VTE prospective global registry.

Methods: Baseline data in 701 patients with active cancer were compared with those in 7307 patients without active cancer who received initial anticoagulant treatment between 2014 and 2016.

Results: Patients with active cancer tended to be older than those without active cancer (median [IQR]: 65.7 yrs [56.2-73.6] and 59.4 yrs [45.1 -71.5], respectively), and more were of Asian ethnicity (31.7% and 14.6%, respectively). Common sites of underlying cancers in men, women and overall are shown in the Table below. The proportion of patients with deep-vein thrombosis (DVT) was similar in patients with and without cancer (59.3% and 61.3%, respectively) as was the proportion with pulmonary embolism ± DVT (40.7% and 38.7%); a slightly

higher proportion of cancer patients had upper limb DVT (12.2% and 8.1%, respectively). Patients with active cancer were more likely to receive LMWH monotherapy or another parenteral anticoagulant as initial therapy than those without cancer (64.0% and 13.1%, respectively), and were less likely to receive a DOAC with or without a heparin lead-in (22.8% and 53.2%, respectively).

Conclusions: These data show differences in the clinical characteristics and treatment patterns of VTE in patients with and without active cancer. In keeping with guidelines, the majority of cancer patients are treated with LMWH monotherapy. However, DOACs are prescribed in almost 25% of patients.

TABLE 1 The most common sites of cancer in VTE patients

Men (n=219)		Women (n=232)		Overall (n=451)	
Lung	21.9%	Gynecological	22.0%	Lung	17.3%
Colorectal	15.5%	Breast	18.1%	Colorectal	12.4%
Prostate	11.4%	Lung	12.9%	Gynecological	11.3%
Urological	9.1%	Colorectal	9.5%	Breast	9.3%
Lymphoma	8.2%	Lymphoma	7.8%	Lymphoma	8.0%

PB 461 | Rivaroxaban for Scheduled Work-up of Patients with Suspected Deep Venous Thrombosis: A Prospective Interventional Outcome Study - The Ri-Schedule study

S. Frønes[1], M. Qarboush[1], C. Tøvik Jørgensen[1], N. Raouf[2], J. Gleditich[2], A. Dahm[3], P.M. Sandset[4], W. Ghanima[1,4]

[1]Østfold Hospital, Medicine, Grålum, Norway, [2]Østfold Hospital, Grålum, Norway, [3]Akershus University Hospital, Lørenskog, Norway, [4]Oslo University/Institute of Clinical Medicine, Oslo, Norway

Background: Scheduled work-up of deep vein thrombosis (DVT) can reduce the need for emergency diagnostic imaging and avert prolonged waiting of patients in the emergency room (ER). Current guidelines suggest using low molecular weight heparin (LMWH) if the diagnostic work-up is expected to be delayed. The Ri-Schedule study aims to investigate the safety of rivaroxaban in the pre-diagnosis phase of DVT and the feasibility of scheduled work-up according to a predefined criteria.

Aims: Our aim is to report the study design and preliminary results on the feasibility of scheduled work-up after including 50% of the estimated sample size.

Methods: Ri-Schedule is a prospective outcome study (NCT02486445). The primary endpoint is safety of rivaroxaban (15 mg every 12 hours, max 2 tablets) defined as the composite endpoint of serious bleeding and/or death related to bleeding encountered within 48 hours after the last tablet was ingested if DVT was excluded or until the initiation of anticoagulant if a DVT was diagnosed. The feasibility is defined as the proportion of patients who can be managed according to the criteria shown in the table. Patients are recruited from the ER of Østfold Hospital, Norway. Work-up of suspected DVT includes Wells score, D-dimer and compression ultrasonography. The study was approved by the Regional Ethics Committee and consent is acquired from all patients.

Results: Out of 1195 screened patients, 836 have been recruited in 22 months. Of these 328 (39%) fulfilled the predefined criteria and received rivaroxaban to allow for scheduled work-up; 333 (40%) did not meet criteria 1-10 (table) while 175 (21%) had already received LMWH and were therefore not given rivaroxaban. DVT was diagnosed in 136 (16%) patients. No death has been encountered so far in the study due to scheduled work up.

Conclusions: Scheduled work-up was allowed in 40% of the patients according to the study criteria. This figure is likely to be higher if the final study results support the implementation of these criteria in the future.

TABLE 1 Selection criteria for scheduled work-up of DVT

1	Diagnostic work-up is expected to exceed 2 hours
2	Absence of active cancer
3	No suspicion of PE
4	No suspicion of active or recent bleeding
5	No signs of threatened circulation or intractable pain in the lower limb
6	Physician considers it safe to discharge the patient
7	Absence of comorbidity that require hospital admission and GFR >45 ml/min
8	Absence of contraindication to rivaroxaban
9	Absence of logistic factors that may hinder scheduled work-up
10	Patient do not oppose discharge before diagnosis is completed

PB 462 | Real-world Adherence with Direct Oral Anticoagulants in Adults with Atrial Fibrillation

B.S. Manzoor, S.M. Walton, T.A. Lee, L.K. Sharp, W.L. Galanter, E.A. Nutescu

University of Illinois at Chicago, Chicago, United States

Background: Adherence to anticoagulation (AC) therapy is critical as it directly impacts clinical outcomes and healthcare utilization.

Aims: To evaluate patterns of medication adherence and persistence in a real-world setting in atrial fibrillation (AF) patients treated with direct oral anticoagulants (DOACs).

Methods: AF patients newly initiating a DOAC with a minimum of 6 months of continuous health plan enrollment pre and post-index date (date of first DOAC) were identified from the Truven Health MarketScan® Commercial and Medicare Supplemental databases (2009-2013). DOAC adherence (proportion of days covered (PDC)), persistence and predictors of adherence were assessed at 6 and 12 month post-index.

Results: Of 57,048 AF patients included, 51.8% (N=29,523) were AC naïve and 48.2% (N=27,525) were non-AC naïve (age: 67.0±12.7 vs. 71.1±11.3 years, p< 0.001; male: 18,282 (61.9%) vs. 16,787 (61.0%), p=0.0216, respectively). A majority of patients received dabigatran as their index DOAC (N=42,129; 73.8%). The mean PDC in AC naïve and non-AC naïve patients at 6 and 12 months was 72.2% vs. 83.2% (p< 0.001) and 63.7% vs. 79.8% (p< 0.001), respectively. Persistence with

DOAC therapy in AC naïve and non-AC naïve patients at 6 and 12 months ranged from 59.2% and 76.0% (p< .0001) to 31.7% and 50.8% (p< .0001), respectively. Predictors of higher DOAC adherence were older age and higher number of concomitant medications; and of lower adherence were higher number of comorbidities and AC naïve user status.

Conclusions: While medication adherence and persistence declined over time, both were lower (at 6 and 12 months post-index) in AC naïve compared to non-AC naïve patients. Our findings can help target future strategies or interventions on patient education and AC management in those naïve to DOAC therapy. Future investigation should examine potential reasons for differences in DOAC adherence and persistence between non-AC vs. AC naïve patients, and its implication on patient outcomes.

PB 463 | Oxygen Saturation to Improve Risk Stratification in Hemodynamically Stable Patients with Acute Pulmonary Embolism

C. Becattini[1], M.C. Vedovati[1], P. Pruszczyk[2], S. Vanni[3], M. Cotugno[4], V. Stefanone[3], M.G. De Natale[1], M. Kozlowska[2], F. Mannucci[3], L. Guirado Torrecillas[4], G. Agnelli[1]

[1]University of Perugia, Internal and Cardiovascular Medicine-Stroke Unit, Perugia, Italy, [2]Warsaw Medical University, Department of Internal Medicine and Cardiology, Warsaw, Poland, [3]Azienda Ospedaliero-Universitaria Careggi, Florence, Italy, [4]Hospital Clinico Universitario Virgen de la Arrixaca, Murcia, Spain

Background: In patients with acute pulmonary embolism (PE), risk stratification for short-term death is crucial to drive clinical management. The European Society of Cardiology (ESC) proposed a risk stratification model based on clinical risk scores (PESI or sPESI), right ventricle dysfunction (RVD) and elevated serum troponin (2014 ESC model).

Aims: To assess whether the accuracy of the 2014 ESC model to predict in-hospital death in hemodynamically stable patients with acute PE can be improved by the inclusion of patient oxygen saturation.

Methods: Consecutive hemodynamically stable patients with symptomatic, confirmed PE included in prospective cohorts were merged in a collaborative database and included in the study if information on sPESI score, oxygen saturation in air at admission, RVD (at echocardiography or CT angiography) and serum troponin were available. Patients' risk was classified as low (sPESI zero), intermediate-low (sPESI>0, RVD or increased troponin) and intermediate-high (RVD and elevated troponin). The primary study outcome was in-hospital death occurring within 30 days.

Results: Of 863 patients, 237 (27.5%) were categorized as low-risk, 468 (54.2%) as intermediate-low risk and 158 (18.3%) as intermediate-high risk according to the 2014 ESC model. Death occurred in 69 patients (8.0%), and in particular in 1.7% of low, 10.3% of intermediate-low (HR 5.88, 95% CI 2.11-16.34) and 10.8% of intermediate-high risk (HR 6.37, 95% CI 2.12-19.06) patients. Oxygen saturation in air lower than 85% at admission was an independent predictor of death (HR 3.36, 95% CI 2.00-5.63) across the 2014 ESC risk categories. c-statistics showed an improvement of the discriminatory power by including oxygen saturation in air lower than 85% to the 2014 ESC model (0.73; 95% CI 0.67 - 0.79 vs. 0.69, 95% CI 0.63 - 0.75).

Conclusions: A model adding a simple and routine test as oxygen saturation to the 2014 ESC model has an incremental prognostic value for risk stratification in hemodynamically stable patients with acute PE.

PB 464 | Direct Anticoagulants and Vitamin K-antagonists Exert Differential Effects on Markers of Subclinical Cardiovascular Disease: Results from the MyoVasc Study

L. Eggebrecht[1,2], A. Schulz[2,3], S.-O. Tröbs[2,4,5], M. Dib[2,4], S. Schwuchow[2,4], S. Göbel[2,4,5], S. Dieselmeier[2,4,5], N. Arnold[2,4], T. Gori[2,4,5], K.J. Lackner[2,5,6], H. ten Cate[7,8], T. Münzel[4,5,8], P.S. Wild[3,5,8], J.H. Prochaska[4,5,8]

[1]Preventive Cardiology and Preventive Medicine, Center for Cardiology, University Medical Center of the Johannes Gutenberg-University, Mainz, Germany, [2]Center for Translational Vascular Biology (CTVB), University Medical Center Mainz, Johannes Gutenberg-University Mainz, Mainz, Germany, [3]Preventive Cardiology and Preventive Medicine, Center for Cardiology, University Medical Center of the Johannes Gutenberg-University Mainz, Mainz, Germany, [4]Center for Cardiology - Cardiology I, University Medical Center of the Johannes Gutenberg-University Mainz, Mainz, Germany, [5]DZHK (German Center for Cardiovascular Research), Partner Site Rhine Main, Mainz, Germany, [6]Institute of Clinical Chemistry and Laboratory Medicine, University Medical Center of the Johannes Gutenberg-University Mainz, Mainz, Germany, [7]Thrombosis Expertise Center Maastricht, Cardiovascular Research Institute Maastricht and Maastricht University Medical Center, Maastricht, The Netherlands, [8]Center for Thrombosis and Hemostasis, University Medical Center of the Johannes Gutenberg-University Mainz, Mainz, Germany

Background: Experimental data indicate differential effects of novel oral anticoagulants (NOAC) and vitamin K-antagonists (VKA) on the development and progression of (subclinical) cardiovascular disease (CVD).

Aims: To compare the effects of NOACs compared to VKAs on intermediate CVD phenotypes.

Methods: In the prospective, single-center cohort study MyoVasc, 2,000 individuals aged 35 to 84 years with documented cardiac dysfunction were enrolled between 2013 and 2016. In a highly standardized clinical visit, parameters of cardiovascular structure and function were assessed and concentrations of humoral biomarkers were measured.

Results: Overall, the sample comprised 229 NOAC users and 404 VKA users. Multivariable analysis adjusted for age, sex, traditional cardiovascular risk factors and comorbidities revealed an independent relationship between NOAC vs. VKA intake and better diastolic function (E/E´: β -0.23 [-0.36/-0.10]; p< 0.001), less left ventricular mass (β -5.4 g/m2.7 [-11/-0.25]; p=0.041), lower log-NT-pro-BNP (β -0.38 pg/ml [-0.67/-0.096]; p=0.0094) and higher levels of ApoA-1 (β +0.12 g/L [0.042/0.20]; p=0.0029). In propensity score weighted analyses, the most pronounced differences between NOAC and VKA intake were observed for E/E´ (Δ-2.36), stiffness index (Δ-0.5 m/s), ApoA-1 (Δ+0.06 g/l), ejection fraction (Δ-1.7%), left ventricular mass (Δ-1.98 g/m2.7), NT-pro-BNP (Δ-139 pg/ml) and CRP (Δ-0.4 mg/l;

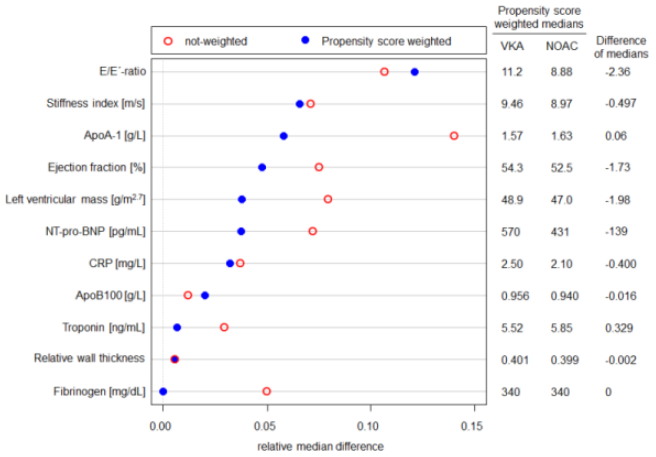

FIGURE 1 Differences in surrogate markers of cardiovascular disease and inflammatory biomarkers in VKA users and NOAC users

Figure). Sensitivity analyses in the homogeneous subsample of individuals with atrial fibrillation (CHA_2DS_2-VASc score ≥1, exposure to anticoagulation therapy ≥3 months) and in a subsample excluding individuals with symptomatic heart failure confirmed the consistency of the results.

Conclusions: The present analysis demonstrates differential relations between biomarkers of cardiovascular structure and function and lipid metabolism in individuals with VKA and NOAC therapy. The potentially beneficial effect of NOACs needs to be further elucidated and may be relevant for the management of anticoagulation therapy.

PB 465 | Lifelong Apixaban Treatment Is Cost-effective for Idiopathic Venous Thromboembolism

L. de Jong[1], M. Huisman[2], M. Postma[1,3]

[1]University of Groningen, Unit of PharmacoEpidemiology and PharmacoEconomics (PE2), Groningen, The Netherlands, [2]Leiden University Medical Centre, Thrombosis and Haemostasis, Leiden, The Netherlands, [3]University Medical Center Groningen (UMCG), Institute for Science in Healthy Aging & healthcaRE (SHARE), Groningen, The Netherlands

Background: Dutch guidelines advise lifelong anticoagulant treatment with direct oral anticoagulants (DOACs) or vitamin K antagonists (VKAs) for Dutch patients with idiopathic venous thromboembolism (VTE) who do not have high bleeding risk.

Aims: The aim of this study was to analyze the economic effects of lifelong treatment of apixaban in the Netherlands, based on updated and adapted previous modelling exercises for use of apixaban in acute VTE-patients.

Methods: We performed a cost-effectiveness analysis (CEA) simulating a population of 1,000 VTE patients. Two different treatment strategies were tested: lifelong apixaban treatment vs. no treatment after the first 6 months (base case analysis). In scenario analysis, the initial treatment period of 6 months with LMWH/VKA was also included. The primary outcome of the model is the incremental

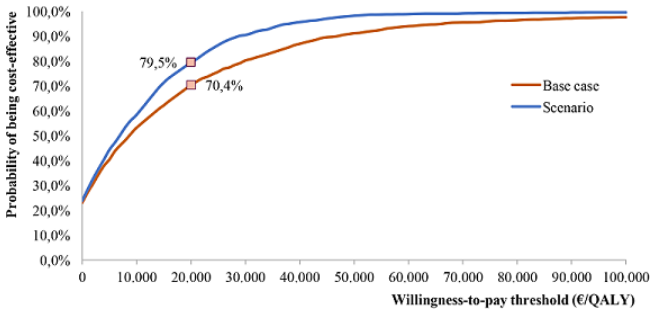

FIGURE 1 Cost-effectiveness acceptability curve: base-case and scenario analysis

cost-effectiveness ratio (ICER) in costs (€) per quality adjusted life-year (QALY), with one QALY defined as one year in perfect health. To account for any influence of the uncertainties in the model a probabilistic sensitivity analysis (PSA) was conducted, in which the ICER was recalculated 2,000 times while varying all input parameters over their range. These results were summarized in a cost-effectiveness acceptability curve (CEAC). The treatment was considered cost-effective with an ICER less than €20,000/QALY, which is the most commonly used willingness-to-pay (WTP) threshold for preventive drugs in the Netherlands and other European countries.

Results:

The model showed a significant reduction in recurrent-VTE and no increase in major bleeding events for lifelong treatment. Deterministic results showed ICERs of €9,830/QALY and €8,231/QALY in the base case and scenario analysis, respectively. The probability of being cost-effective at a WTP threshold of €20,000/QALY of 70.4% and 79.5% respectively resulted, see CEAC in figure 1.

Conclusions: Lifelong treatment with apixaban is effective and cost-effective in Dutch VTE patients with idiopathic VTE.

PB 466 | Factors Associated with the Anticoagulant Regimen and Duration of Hospitalization in Patients with Acute Pulmonary Embolism: FOCUS, a Prospective Multicenter Cohort Study

Background: The ongoing multicenter ´Follow-up after acute pulmonary embolism´ (FOCUS) observational study has set out to prospectively follow, over a 2-year period at predetermined intervals with standardized follow-up (FUP) protocols, the clinical and hemodynamic course of 1,000 unselected patients with confirmed acute symptomatic pulmonary embolism (PE).

Aims: To examine the association between the patients´ baseline characteristics and 1) the type of anticoagulant drug prescribed as well as 2) the length of hospitalization.

Methods: Baseline data of the patients enrolled as of December 2016 were analyzed. Multivariable stepwise logistic models were fit with clinically relevant covariates to study their association with 1) prescription of vitamin K antagonists (VKA) or ‚single oral drug therapy' with a non-vitamin K-dependent oral anticoagulant (NOAC), and 2) length of hospitalization < 48 hours. FOCUS was approved by ethics committee and patient informed consent obtained.

Results: Data of 575 patients who completed FUP visit on discharge were analyzed. Of these, 78 (13.6%) were discharged on VKA, 305 (53.0%) on rivaroxaban, 101 (17.6%) on apixaban, and 91 (15.8%) on parenteral agents (*Table 1*).

The absence of right ventricular dysfunction markers (adjusted Odds Ratio [aOR] 2.1 [95% Confidence Interval 1.2-3.7]), a negative history of renal dysfunction (aOR 4.8 [2.3-10.0]), and simplified Pulmonary Embolism Severity Index indicating low clinical risk (aOR 3.8 [2.0-7.1]) were associated with NOAC prescription. Patients on NOAC were more often discharged within 48 hours from admission (*Table 2*).

Conclusions: Overall, the majority of acute PE patients enrolled in FOCUS were discharged on rivaroxaban or apixaban. Although principally approved for all stable PE patients, NOAC were mainly prescribed in patients with low clinical risk and no right ventricular dysfunction. NOAC use was associated with shorter length of hospitalization compared to VKA.

TABLE 2 Factors associated with a hospitalization of 48 hours or shorter in patients receiving either NOAC or vitamin K antagonists

	Crude Odds Ratio (95% Confidence Interval)	Adjusted Odds Ratio (95% Confidence Interval)
NOAC use	5.3 (1.6-17.2)	4.0 (1.1-13.2)
Age >=75 years	0.4 (0.2-0.8)	-
Male sex	0.9 (0.5-1.4)	-
Active cancer	0.3 (0.1-2.0)	-
Right ventricular dysfunction detected at echocardiography or computer tomography scan, or positive cardiac biomarkers	0.04 (0.01-0.3)	0.04 (0.01-0.3)
Personal history of renal dysfunction	0.6 (0.2-1.8)	-
Diabetes mellitus	0.2 (0.05-0.9)	0.2 (0.1-1.0)
Chronic heart failure	0.2 (0.02-1.3)	-
Body mass index >40 or weight >120 kg	0.5 (0.2-1.4)	-

TABLE 1 Baseline characteristics of the patients included in FOCUS

	Vitamin K antagonist (n=78)	Rivaroxaban (n=395)	Apixaban (n=101)	Parenteral agent (n=91)
Age (years), mean (Standard Deviation)	64.9 (16.0)	58.5 (14.7)	66.3 (14.7)	64.5 (13.6)
Male sex, n (%)	47 (60.3)	160 (52.2)	48 (47.5)	51 (56.0)
Body mass index >40 or Body weight >120 kg, n (%)	10 (12.8)	27 (8.9)	10 (9.9)	6 (6.6)
Active cancer, n (%)	7 (9.0)	13 (4.3)	2 (2.0)	32 (35.2)
Estimated glomerular filtration rate <30 mL/min, n (%)	10 (12.8)	6 (2.0)	3 (3.0)	1 (1.1)
sPESI = 0, n (%)	13 (16.7)	165 (54.1)	37 (36.6)	30 (33.0)

PB 467 | Real-life Use of Non-vitamin K Antagonist Oral Anticoagulants in Patients with Cancer Associated Venous Thromboembolism: Data from a Prospective Cohort

A. Mancuso[1], M.C. Vedovati[1], L. Pierpaoli[2], U. Paliani[3], S. Conti[4], E. Filippucci[5], A. Ascani[6], S. Radicchia[1], G. Galeotti[3], G. Agnelli[1], C. Becattini[1]

[1]University of Perugia, Perugia, Italy, [2]Ravenna Hospital, Ravenna, Italy, [3]Hospital of Città di Castello, Città di Castello, Italy, [4]S. Matteo degli Infermi Hospital, Spoleto, Italy, [5]S. Giovanni Battista Hospital, Foligno, Italy, [6]S.Maria Hospital, Terni, Italy

Background: Cancer associated venous thromboembolism (CAT) has an increased risk of recurrence. The use of novel oral anticoagulants (NOACs) is controversial in patients with CAT.

Aims: The aim of this study is to assess mortality, recurrent VTE and bleeding complications in patients with and without CAT receiving NOACs.

Methods: Consecutive patients with acute objectively confirmed venous thromboembolism (VTE) receiving NOACs within 1 month from the diagnosis are included in an ongoing prospective cohort study started in September 2013.

Results: 678 patients were included (mean age 66 years) of whom 132 with CAT (19.7%). 54 patients with CAT (41%) were on CHT or RT and 29 (22%) had a metastatic disease. Site of cancer were genitourinary, breast, gastrointestinal, lung and haematological in 25, 24, 22, 17 and 6 %, respectively. ECOG score at NOAC prescription was 0, 1, 2, 3 and 4 in 35, 23, 6, 18 and 18% of CAT patients, respectively. Index PE occurred in 38.6% and 40.7% of patients with CAT and without (p=0.65). 186 out of 273 patients with PE (68.1%) also presented a DVT. DVT only was observed in 61.4% and 59.4% of patients with CAT and without (p=0.68).

435 patients had at least 3 months of follow-up (mean 10.1 months). 250 continued treatment (57.4%), 139 suspended (32%) and 46 died (10.6%): 36 were cancer related deaths (78.3%). Non cancer related death occurred in 2 patients with CAT and in 8 patients without (2.4% vs 2.3%, p=0.92). No fatal VTE recurrences occurred. One patient with cerebral metastases died from intracranial bleeding. Overall VTE recurrences and clinically relevant bleedings occurred in 9 vs 19 patients with and without CAT, respectively (10.9% vs 5.4%, p=0.03).

Conclusions: In our real-life study, one-fifth of patients with VTE prescribed with NOACs have cancer. A trend toward higher rates of both recurrence and bleeding was observed in CAT compared to non-CAT patients, with similar rates of non cancer related mortality.

PB 468 | The YEARS Algorithm for Suspected Pulmonary Embolism Leads to Much Shorter Diagnostic Turnaround Time than Conventional Algorithms

C.E.A. Dronkers[1], L.M. van der Pol[1,2], T. van der Hulle[1], C. Tromeur[1], C. Heringhaus[3], A.T.A. Mairuhu[2], M.V. Huisman[1], F.A. Klok[1]

[1]Leiden University Medical Center, Department of Thrombosis and Hemostasis, Leiden, The Netherlands, [2]HagaHospital, Department of Internal Medicine, The Hague, The Netherlands, [3]Leiden University Medical Center, Department of Emergency Medicine, Leiden, The Netherlands

Background: Recently, the safety of the YEARS algorithm (fig 1), designed to simplify the diagnostic work-up of PE, was demonstrated (YEARS study, 2016 ESC abstract 5727). We hypothesize that by design, YEARS is associated with a shorter diagnostic turnaround time at the emergency ward due to simultaneous assessment of pre-test probability and D-dimer level.

Aims: To investigate whether implementation of the YEARS diagnostic algorithm is associated with a shorter diagnostic turnaround time compared to the conventional algorithm.

Methods: We selected consecutive outpatients with suspected PE included in the YEARS study (n=308) and ADJUST-PE study (Righini M et al, JAMA 2014; n=233) Different time points of the diagnostic process were extracted from the electronic patients chart system (Table 1). Patients who were initially evaluated for a different acute condition, i.e. myocardial infarction, were excluded from this analysis.

TABLE 1

		Conventional algorithm		Years algorithm		
Turnaround time between:	Patient cohort	Number of patients	Mean time minutes (SD)	Number of patients	Mean time minutes (SD)	Mean absolute difference (95%CI),p value
Start of diagnostic algorithm and order for CT scan	All patients referred for CT scan	162	133(69)	219	82(44)	51 (40-60), p<0,001
Start of diagnostic algorithm and initial dose of anticoagulant	All patients with proven PE	57	261(105)	119	215(87)	46 (17-76), p=0,002
Start of diagnostic algorithm and discharge from emergency ward	All patients managed without CT	68	189(106)	89	135(69)	54 (27-82), p<0,001
Start of diagnostic algorithm and discharge from emergency ward	All patients	233	271(114)	308	215(109)	56 (36-77), p<0,001

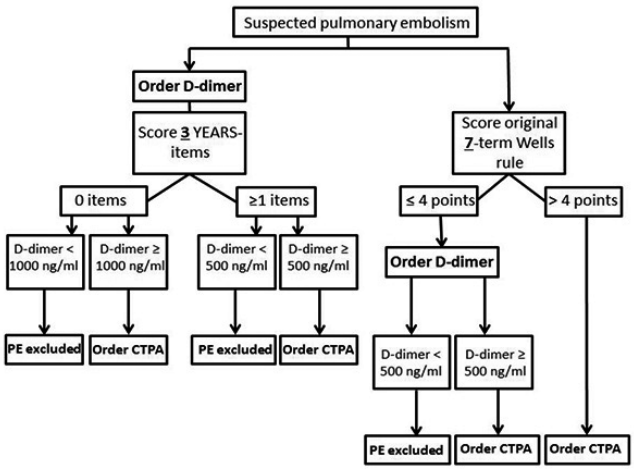

FIGURE 1 The YEARS algorithm versus conventional algorithm

Results: All predefined diagnostic turnaround times were significantly shorter after implementation of YEARS. Specifically, the time between start of the diagnostic algorithm and order for CT-scan decreased from 133 to 82 minutes (min) and patients were discharged earlier from the emergency ward: 189 versus 135 min for patients managed without CT and 271 versus 215 min for the complete study population. Importantly, patients diagnosed with PE by CTPA received the first dose of anticoagulants 46 min (95%CI 17-76) faster than those managed according the conventional algorithm.

Conclusions: YEARS was shown to be associated with a significantly shorter diagnostic turnaround time compared to the conventional diagnostic algorithm, leading to faster treatment initiation in case of confirmed PE and more efficient use of the emergency ward resources.

PB 469 | The Assessment of Apixaban Reversal in a Porcine Trauma Mmodel by Thrombelastography (TEG)

M. Honickel, N. Akman, O. Grottke

RWTH Aachen University Hospital, Department of Anesthesiology, Aachen, Germany

Background: Approved point of care tests for direct oral anticoagulants (DOAC) are currently unavailable. For the thrombelastography (TEG) device, a DOAC cartridge with a specific FXa-inhibitor-channel has been developed (AFXA).

Aims: To assess the efficacy of TEG as point of care device to measure the concentration of the FXa-inhibitor apixaban in a preclinical model, following andexanet reversal.

Methods: Given ethical approval, 15 pigs received oral apixaban (3 d, qd). Standardized trauma consisted of blunt liver injury and bilateral femur fractures. 15 min after trauma, animals randomly received 1) Ringer's solution (control, n=5), 2) andexanet bolus (1000 mg, n=5), or 3) andexanet bolus+infusion (1000 mg + 600 mg/h for 2 h, n=5).

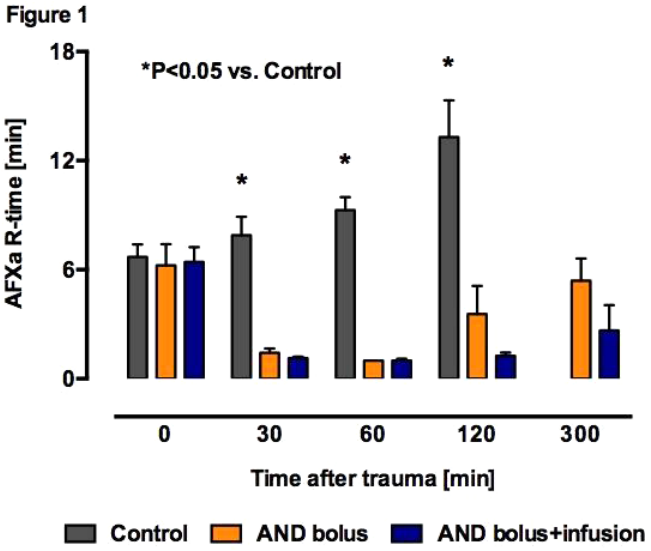

FIGURE 1 TEG6s AFXa R-time [min

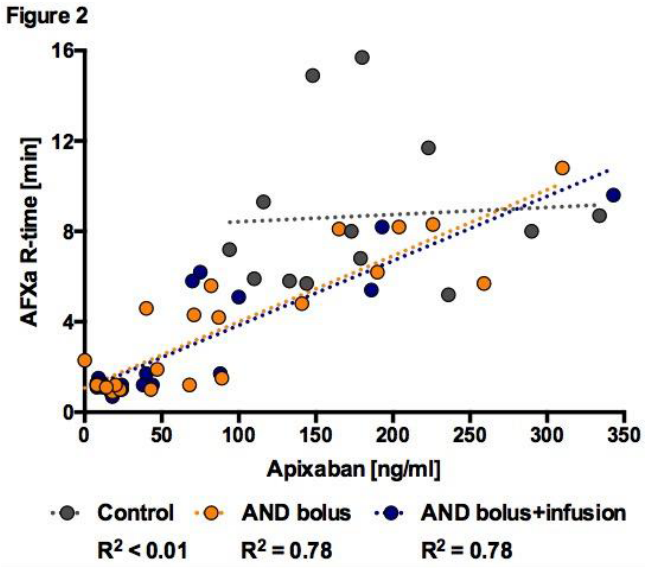

FIGURE 2 Correlation between AFXa R-time and Apixaban concentration

Animals were observed for 300 min or until death. Apixaban levels (anti-FXa assay), TEG and blood loss (BL) were recorded. ANOVA (mean±SEM) and Pearson's r were used.

Results: Apixaban levels prior to trauma infliction were comparable (183±26 ng/mL, n=15). Andexanet bolus or bolus+infusion resulted in about 70% reduction in total BL as compared to control animals (control: 3913±235 mL). Due to clearance of andexanet (1), apixaban levels returned faster after bolus compared to bolus+infusion (Fig.1). The increase of apixaban concentrations was detected by TEG (120 and 300 min post trauma). The difference in concentrations of apixaban strongly correlated with the AFXA R-time, both before trauma and after andexanet dosing (bolus and bolus+infusion: R^2=0.78; Fig.2). However, in control animals, no correlation between AFXA R-time

and apixaban levels after trauma was measured due to continuous blood loss (R^2< 0.01).

Conclusions: The present data show that new generation of TEG cartridges might be effective as point of care test to assess the concentration of apixaban. However, consumptive coagulopathy with massive blood loss may affect this correlation.

PB 471 | Plasma Fibrin Clot Properties in the G20210A Prothrombin Mutation Carriers Following Venous Thromboembolism: The Effect of Rivaroxaban

J. Siudut[1,2], A. Janion-Sadowska[3], J. Natorska[1,2], M. Zabczyk[1], A. Stanisz[1], A. Undas[1,2]

[1]Jagiellonian University Medical College, Cracow, Poland, [2]John Paul II Hospital, Cracow, Poland, [3]Świętokrzyskie Cardiology Centre, Kielce, Poland

Background: G20210A prothrombin mutation is associated with two- to three-fold increase in the VTE risk, but its prothrombotic mechanism is still unclear.

Aims: We investigated whether the G20210A prothrombin mutation modifies plasma fibrin clot properties in patients after venous thromboembolism (VTE) and how rivaroxaban treatment affects these alterations.

Methods: We studied 34 prothrombin mutation heterozygous carriers and sex- and age-matched 34 non-carriers, all at least 3 months since the first VTE episode, before and during treatment with rivaroxaban. Clot permeability (K_s) and clot lysis time (CLT) with or without elimination of thrombin activatable fibrinolysis inhibitor (TAFI) were assessed at baseline, 2-6 hours after and 20-25 hours after intake of rivaroxaban (20 mg/d).

Results: At baseline, the prothrombin mutation group formed denser clots (K_s -12%) and had impaired fibrinolysis (CLT +14%, and CLT-TAFI +13%) compared with the no mutation group (all p< 0.05) and were similar to those observed in 15 healthy unrelated prothrombin mutation carriers. The G20210A prothrombin mutation was the independent predictor for K_s and CLT before rivaroxaban intake. At 2-6 hours after rivaroxaban intake, clot properties improved both in G20210A carriers and non-carriers (K_s +38% and +37%; CLT -25% and -25%; CLT-TAFI -20% and -24%, respectively, all p< 0.001), but those parameters were worse in the prothrombin mutation group (K_s -12.8%, CLT +17%, CLT-TAFI +13%, all p< 0.001). Rivaroxaban concentration correlated with fibrin clot properties. After 20-25 hours since rivaroxaban intake most clot properties returned to baseline.

Conclusions: The G20210A prothrombin mutation affects alterations to clot density and lysability. Rivaroxaban treatment, though improves fibrin clot properties, cannot abolish more prothrombotic fibrin clot phenotype observed in prothrombin mutation carriers following VTE.

PB 472 | A Cross-Sectional, Multinational, Multidisciplinary Survey of Physicians Surrounding the Management of Bleeding Complications in the Setting of Direct Oral Anticoagulant Use

J. Shaw[1], L. Castellucci[1], D. Siegal[2], I. Stiell[3], S. Syed[4], J. Lampron[5], P. Dorian[6], H. Dhaliwal[7], G. Stotts[8], P. Wells[9], M. Carrier[9]

[1]The Ottawa Hospital, Department of Medicine, Ottawa, Canada, [2]McMaster University, Division of Hematology, Hamilton, Canada, [3]The Ottawa Hospital, Department of Emergency Medicine, Ottawa, Canada, [4]McMaster University, Department of Anesthesiology, Hamilton, Canada, [5]The Ottawa Hospital, Department of Surgery, Ottawa, Canada, [6]St. Michael's Hospital, University of Toronto, Divison of Cardiology, Toronto, Canada, [7]The Ottawa Hospital, Division of Gastroenterology, Ottawa, Canada, [8]The Ottawa Hospital, Division of Neurology, Ottawa, Canada, [9]The Ottawa Hospital, Division of Hematology, Ottawa, Canada

Background: Management of life-threatening bleeding episodes in patients receiving direct oral anticoagulants (DOACs) is a significant clinical concern.

Aims: We aimed to assess clinicians' knowledge regarding the evaluation and management of DOAC-associated bleeding.

Methods: We conducted a multinational cross-sectional survey of physicians from a variety of disciplines. The 32-question survey was electronically administered (SurveyMonkey®) and distributed via email through several medical associations in Canada and the United States.

Results: A total of 518 physicians have completed the survey to date, with a completion rate of 91%. Most respondents were from either Canada (72%) or the US (15%) and were staff physicians (78%). The survey was completed by thrombosis specialists (14%), hematologists (13%), emergency physicians (32%), anesthesiologists (18%), general practitioners (4%), neurologists (3%), general surgeons (3%) and other specialties (13%). A majority of physicians (58%) stated that they did not feel confident in managing serious DOAC-associated bleeding complications. Most clinicians surveyed did not identify the correct laboratory investigation to detect or quantify individual DOACs in bleeding patients. Only 29% of physicians would use thrombin time to identify dabigatran, whereas 42% and 41% would use calibrated anti-Xa levels to identify rivaroxaban and apixaban, respectively. Similarly, only 37% of surveyed clinicians would use dilute thrombin time to quantify plasma concentrations of dabigatran. Table 1 indicates laboratory testing availability according to survey respondents. Participants' responses regarding the use of pro-hemostatic agents are illustrated in Figure 1.

TABLE 1 DOAC Laboratory Testing Availability

DOAC Laboratory Test	% Total Respondents Reporting Availability
Dilute Thrombin Time	17
Ecarin Clotting Time	7
Heparin Calibrated Anti-Xa Levels	41
DOAC Calibrated Anti-Xa Levels	15
Serum DOAC Levels	5
Do Not Know	34
None of the Above	24

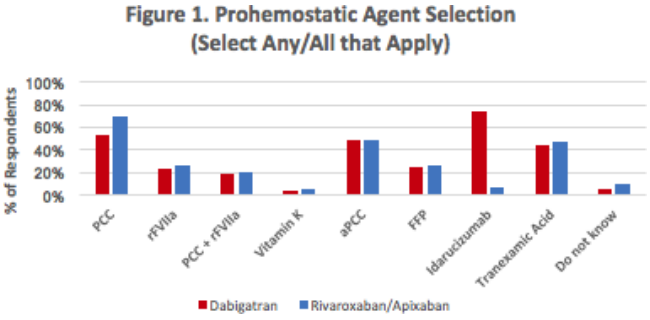

FIGURE 1 Prohemostatic Agent Selection

Conclusions: There appears to be important knowledge gaps regarding the assessment and management of DOAC-associated life-threatening bleeding in the majority of surveyed clinicians. Targeted educational initiatives regarding the management of DOAC-associated bleeding are warranted to enhance patient safety.

PB 473 | Apixaban in Mechanical Circulatory Support - Evaluation in a Mock Circulatory Loop with Human Blood

S. Rao, D. Connor, N. Kerr, J. Joseph, P. Jansz, C. Hayward

St Vincent's Hospital, Sydney, Australia

Background: In light of decreased intracranial haemorrhage with apixaban compared to warfarin in atrial fibrillation trials, we conducted an ex vivo study of thrombus formation in an ASTM 1841 hemocompatibility testing loop incorporating a continuous flow left ventricular assist device (HeartWare HVAD.

Aims: The aim of this study was to determine the effect of low and high dose apixiban on intra-pump thrombus formation.

Methods: Blood from volunteers were used in four experimental conditions: un-anticoagulated blood (control); blood from patients on warfarin; in vitro low dose apixaban (equivalent 2.5mg BID); and in vitro high dose apixaban (equivalent 5mg BID). Afterload, preload and loop temperature were controlled to physiological targets. The primary outcome was time to formation of intra-pump thrombosis based on 20% rise in power characteristics. A secondary outcome was changes in haemostasis over one hour of stable pump use as measured by microparticle activity (PPL). platelet aggregation (multiplate), rotational thromboelastometry and von Willebrand factor levels (CBA/Ag).

Results: A total of 10 runs were completed. Overall time to intra-pump thrombosis formation was prolonged in the anticoagulated runs when compared to control (83.1vs 70.6 mins). Low dose apixaban was comparable to warfarin (80.5mins vs 80.3), however high dose apixaban showed no evidence of thrombosis after 90mins. Baseline total clotting times were prolonged in the anticoagulation groups (control 91.2s, warfarin 120s, low dose apixaban 164.4s, high dose apixaban > 180s). The reduction in clotting times over one hour pump running was similar in the control, warfarin and low dose apixaban groups (44.3s vs 37.8s vs 45.8s).

Conclusions: In an in vitro setting, low dose apixaban provides similar anticoagulant property as warfarin in terms of prolongation of thrombosis formation. Higher dose apixaban may have lower pump thrombosis rates. Further studies in patient groups are needed before change in clinical practice.

PB 474 | Management of Major Bleeding and Outcomes in Patients Treated with DOACs: Results from the START SSC Event Register

Background: Management of major bleeding in patients treated with direct oral anticoagulants (DOAC) is still not well established.

Aims: START SSC Events, branch of the START register, aims to describe the management and outcomes of bleeding or recurrent thrombotic events during DOAC treatment in routine clinical practice. We present the results of the management of bleeding patients.

Methods: Adult patients with major bleeding (based on ISTH definition) during DOAC treatment for atrial fibrillation (AF) or venous thromboembolism (VTE) were enrolled. Baseline characteristics, laboratory results, site of bleeding, management strategies and outcomes at hospital discharge and after 6 months were recorded on a web based-form.

Results: Between January 2015 and December 2016, 173 patients on DOACs (25% on apixaban, 24% on dabigatran 50% on rivaroxaban, and 1% on edoxaban) were enrolled, 117 had major bleeding events. AF was the indication for treatment in 84%, 62% were males, median age was 79 years, median creatinine clearance was 59.5 mL/min. The site of bleeding was cerebral in 53 patients (15 fatal during hospitalization), gastrointestinal in 42 (2 fatal), and in other sites 22 (1 fatal). Bleeding occurred within the first 90 days of DOACs treatment in 45% of patients. Haemoglobin, PT, and aPTT were available in nearly 90% of cases while specific DOACs measurements in only 20%. Therapeutic strategies included surgery or invasive procedures in 17% of patients; red blood cells transfusion in 25%, prothrombin

complex concentrates in 23%, antifibrinolytic drugs in 7.6%, fresh frozen plasma in 2.1%; 3 patients on dabigatran were treated with idarucizumab. At 6-month follow-up, there were 16% deaths, 64% complete resolutions, and residual disability in 32% of patients with intracranial haemorrhage.

Conclusions: Our data confirm a high heterogeneity in the management of bleeding complications in patients treated with DOACs. Only rarely specific measurements of DOACs activity drove management strategies.

PB 475 | High Recanalization Rate in Patients with Proximal-vein Thrombosis Treated with the New Direct Oral Anticoagulants

San Giovanni-Addolorata, Department of Emergency, Rome, Italy, [8]Hospital of Feltre, Department of Medicine, Allergy Service, Feltre, Italy, [9]Le Scotte Hospital of Siena, Internal Medicine, Siena, Italy, [10]Hospital of Ravenna- Faenza, Department of Vascular Medicine, Ravenna, Italy, [11]G. D'Annunzio University, Chieti, Department of Medical, Oral and Biotechnological Science, Chieti, Italy, [12]University of Padua, Unit of Angiology, Department of Cardiovascular Sciences, Vascular Medicine Unit, Padua, Italy, [13]SS Giovanni e Paolo Hospital, Venice, Unit of Angiology, Internal Medicine, Venice, Italy, [14]Santa Maria della Misericordia Hospital, Department of Internal Medicine, Rovigo, Italy

Background: In patients with proximal deep venous thrombosis (DVT) of the lower extremities, the persistence of residual vein thrombosis (RVT) has been reported to increase the risk of subsequent complications. With the use of standard anticoagulant therapy (LMWH followed by vitamin K antagonists), the rate of RVT has consistently been reported to occur in approximately 50% of patients after 3 and 6 months.

Aims: In an Italian registry, we sought to investigate the rate of RVT in 352 consecutive outpatients with proximal DVT who were treated with the new oral anticoagulants (NOA). We compared this rate with a historical cohort of 1094 patients who had been treated with standard anticoagulation.

Methods: 282 patients had been treated with Rivaroxaban, 28 with Dabigatran and 42 with Apixaban. In each patient the common femoral vein at the groin and the popliteal vein at the popliteal fossa were scanned in transverse plane at 3 and/or 6 months after the acute event. Veins were assessed during compression, and RVT was defined as the persistence of thrombotic material resulting in a diameter of at least 4 mm.

Results: RVT was detected in 143 patients treated with NOA (41.2%) after three months and in 58 patients (21.1%) after six month; the corresponding in patients treated with standard anticoagulation was 52.3% and 54.5%, respectively. After adjusting for the baseline characteristics, the odds ratio of RVT in patients treated with the NOA as compare to those treated with conventional anticoagulation was 0.63 (95% CI 0.48 - 0.81) after three months and 0.17 (95% CI 0.11 -0.26) after six months.

Conclusions: Our study results show for the first time that in patients with proximal DVT treated with the NOA the persistence of ultrasound detectable RVT occurs less frequently than in patients treated with standard anticoagulation. Whether this observation has implications for the development of subsequent complications remains to be demonstrated.

PB 476 | Clot Waveform Analysis of Activated Partial Thromboplastin Time Measurement Curves Reveals How Direct Oral Anticoagulants Impact In Vitro Coagulation

Y. Fujimori[1], M. Wakui[2], H. Katagiri[1], Y. Kondo[1], S. Nakamura[1], N. Shimizu[1], M. Murata[2]

[1]Keio University Hospital, Central Clinical Laboratory, Tokyo, Japan, [2]Keio University School of Medicine, Department of Laboratory Medicine, Tokyo, Japan

Background: Clot waveform analysis (CWA) has been reported to extend the interpretation of activated partial thromboplastin time (APTT) measurement curves. The parameters are obtained from successive derivatives of the clotting reaction curve, dissecting the coagulation cascade pathway. The first, second, and third derivatives represent the thrombin activity for fibrin generation, the activated factor X (Xa) activity for thrombin generation, and the IXa activity for Xa generation, respectively.

Aims: To assess the in vitro effects of direct oral anticoagulants (DOACs), CWA was applied to the APTT assay of plasma samples spiked with each drug.

Methods: Pooled plasma samples from healthy volunteers were spiked with one of three Xa inhibitors, rivaroxaban, apixaban, and edoxaban, or a direct thrombin inhibitor (DTI), dabigatran. APTT was assayed using the Actin regent (SIEMENS) and the automated blood coagulation analyzer, CS-5100 (Sysmex). In addition to the four DOACs, another DTI, argatroban was subjected to analogous assays. For CWA, the first and second derivatives were automatically gained using the CS-5100 program. The third derivative was calculated using data from the CS-5100 analysis.

Results: All the maximum positive values in the successive derivatives were decreased dependently on the concentrations of each drug to a varying degree (Fig 1, 2). The patterns of decrease seemed to depend on whether the drug is a DTI or a Xa inhibitor. Moreover, the negative values in the second and third derivatives appeared putatively due to consumption of thrombin and factor Xa, respectively, to form complexes with plasma serine protease inhibitors. The maximum negative values decreased dependently on the concentrations of each drug

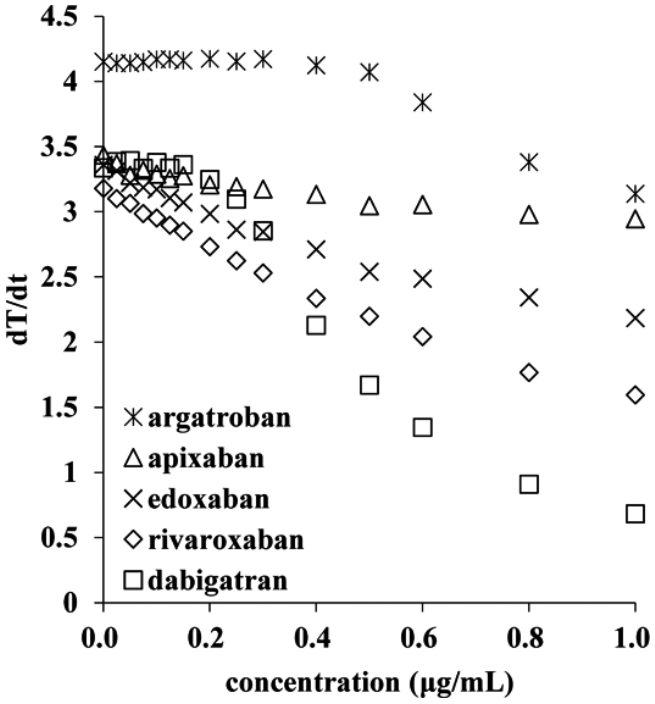

FIGURE 1 Maximum positive values of the first derivative of the clotting reaction curves were decreased dependently on the concentrations of each drug

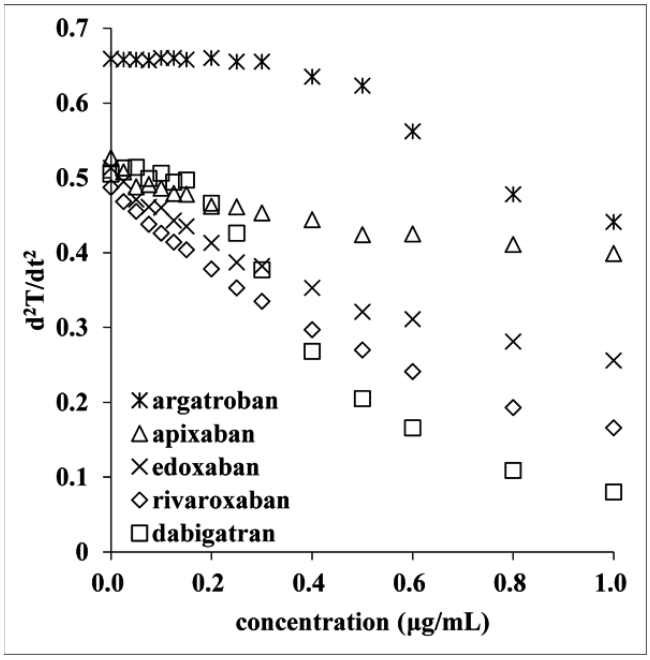

FIGURE 2 Maximum positive values of the second derivative of the clotting reaction curves were decreased dependently

were likely consistent with the suppressed generation of thrombin and factor Xa.

Conclusions: CWA revealed that the effects of DOACs involve not only direct inhibition of generation of thrombin or fibrin but also prevention of thrombin positive feedback.

PB 477 | Concentration Correlation of Direct Oral Anticoagulants as Measured by the TEG® 6s Oral Anticoagulant Assay

F. Zaman[1], B. Matthew[1], C. Lopez-Espina[1], M. Doubleday[2], A. Muresan[1]

[1]*Haemonetics Corporation, Rosemont, United States,* [2]*Haemonetics Corporation, R&D, Rosemont, United States*

Background: No fast, reliable point of care assay is currently available for measuring the anticoagulant effect of DOACs (Direct Oral Anticoagulants). Although DOACs do not require routine monitoring there can be situations where measurements may be necessary (e.g. perioperative management, patients with renal failure, thromboembolic or bleeding events, suspected overdose or lack of adherence).

Aims: This *In-vitro* study aimed to characterize the Oral Anticoagulant Assay (OAC; Haemonetics Corp, MA) as a new method to assess four currently available DOACs (dabigatran, rivaroxaban, apixaban and edoxaban).

Methods: After obtaining informed consent venous blood (in 3.2% citrate) from healthy volunteers (n≥ 4 for each DOAC) was analyzed with the fully automated OAC cartridge with an Ecarin based DTI channel and an HFXa based AFXA channel. Blood was spiked with increasing concentrations of a particular DOAC to achieve target levels. Concentrations were chosen to represent sub-therapeutic, therapeutic and in some cases supra-therapeutic concentrations of each DOAC according to published literature. Pearson's r was used to analyze correlation.

Results: A direct linear relationship was observed between the elongation of TEG®6s R-time and the spiked DOAC concentrations. DTI-R time was strongly correlated with dabigatran with Pearson coefficient of r=0.97 (0-300 ng/ml). A strong correlation was demonstrated between AFXA channel R-time and both rivaroxaban and apixaban (r=0.92; 0-300 ng/ml). Edoxaban showed a relatively weak correlation (r=0.52; 0-500 ng/ml). In edoxaban group response was highly donor dependent and interestingly in one donor no response was observed even at supra-therapeutic level indicating possible resistance.

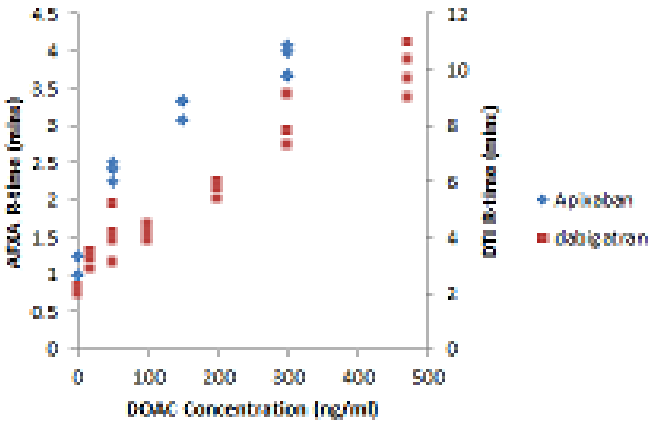

FIGURE 1 In- Vitro Apixaban and dabigatran Concnetration Correlation in blood from healthy volunteers (n=4)

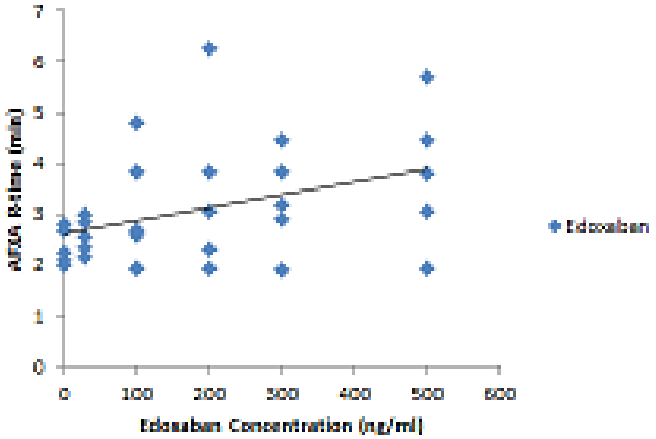

FIGURE 2 In-Vitro Edoxaban Concentration Correlation in blood from healthy volunteers (n=5)

Conclusions: A strong linear concentration response was observed for TEG® R time in this in-vitro study for all DOACs except edoxaban. As efficacy and safety of DOACs are correlated with drug concentrations in certain critical situations the TEG® 6s OAC Assay can be a valuable tool in such situations.

PB 478 | Self-poisoning with Direct Oral Anticoagulants: A Series of Five Cases Admitted to the Intensive Care Unit

A. Stepanian[1,2], A. Dragoni[1], I. Malissin[3], N. Deye[3], B. Joly[1,2], A. Hadj-Ali[1], J. Oliary[4], A. Veyradier[1,2], B. Mégarbane[3,5], V. Siguret[1,6]

[1]Hôpital Lariboisière (AP-HP) - Université Paris Diderot, Hématologie, Paris, France, [2]Institut Universitaire d'Hématologie, EA3518, Paris, France, [3]Hôpital Lariboisière (AP-HP) - Université Paris Diderot, Réanimation Médicale et Toxicologique, Paris, France, [4]Hôpital Lariboisière (AP-HP) - Université Paris Diderot, Pharmacie, Paris, France, [5]Université Paris Descartes, Sorbonne Paris Cité, UMR-S1144, Paris, France, [6]Université Paris Descartes, Sorbonne Paris Cité, UMR-S 1140, Paris, France

Background: There are limited reports of self-poisoning with direct oral anticoagulants (DOAC). Additionally specific monitoring of DOAC concentrations is rarely reported in the published series.

Aims: To describe the clinical features and management of DOAC-self-poisoned patients referred to intensive care unit (ICU).

Methods: We prospectively included all DOAC-self-poisoned patients referred to the intensive care unit of Lariboisière - F. Widal Hospital during a two-year period. Collected data included medical history, all ingested toxicants, clinical features, laboratory parameters, patients' management and outcome. DOAC anti-Xa or anti-IIa activities were measured using dedicated calibrators (Liquid Anti-Xa, Stago; Hemoclot-DTI, Hyphen).

Results: Five DOAC-self-poisoned patients with multi-drug ingestions including rivaroxaban (patients 1, 2, 3), apixaban (patient 4) and dabigatran (patient 5) were admitted to the ICU during 2 years (Figure 1). All patients except one were depressive or already committed suicide attempt. Clinical presentation was attributed to the co-ingested

Patient	1	2	3	4	5
Age / Gender	21 / Female	82 / Male	49 / Male	62 / Male	48 / Male
Body-weight	107 kg	70 kg	150 kg	112 kg	140 kg
Medical history	Depression and bipolar disorder	Previous suicide attempt / mixed anxiety-depressive disorder	None	Depressive disorder	Previous suicide attempt
Ingested DOAC	rivaroxaban	rivaroxaban	rivaroxaban	apixaban	dabigatran
Ingested dose	420 mg	210 mg	280 mg	230 mg	3000 to 4500 mg
Other co-ingested drugs	9 g valpromide 16 g paracetamol 80 mg propranolol	60 mg perindopril arginine/amlodipine 12.5 mg bisoprolol	6 g amiodarone 1.2 g propranolol	100 mg amlodipine 750 mg hydrochlorothiazide 520 mg bisoprolol 4 g paracetamol 400 mg atorvastatine 600 mg clomipramine 20 g potassium	5 pen insulin aspart > 2 sticker tramadol > 2 sticker perindopril arginine/amlodipine
Renal Function (Cockcroft formula)	192 mL/min	56 mL/min	192 mL/min	125 mL/min	305 mL/min
Clinical presentation	Bradycardia	Hypovolemic shock	Wrist bilateral phlebotomies and hypovolemic shock	Hypovolemic shock	None

FIGURE 1 Clinical and laboratory data in five DOAC self-poisoned patients.

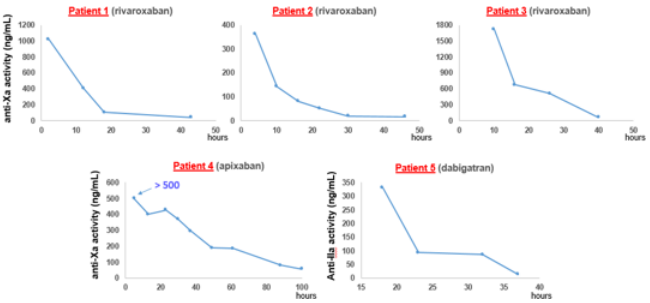

FIGURE 2 Monitoring of anti-Xa (rivaroxaban or apixaban) or anti-IIa (dabigatran) activities in the five self-poisoned patients. X-axis indicates the

drugs. None of the patients developed bleeding on admission and in the following days. Plasma DOAC concentrations on admission were up to 1800 ng/mL for rivaroxaban. Patient 3 admitted with wrist bilateral phlebotomies required stiches. Neither hemostatic treatment nor anti-Xa antidote was used. Activated charcoal was administered only in patient 2. In all these 5 patients, the renal function remained normal. Specific anti-Xa or anti-IIa activities were monitored until becoming undetectable (Figure 2).

Conclusions: Despite elevated serum DOAC concentrations, none of the 5 DOAC-poisoned patients presented bleedings. In these patients, normal renal function and absence of drug-drug interactions altering DOAC pharmacokinetics allowed the complete elimination of the toxicant between in less than 4 days.

PB 479 | New Insights in Interindividual Variability of Pharmacodynamic (PD) Response to Rivaroxaban through Thrombin Generation in the Presence of an Active Protein C Pathway: DRIVING Study Results in Healthy Volunteers

Background: DRIVING was a prospective study on interindividual variability to R exposure among 60 healthy volunteers (Gouin *et al*, *J Thromb Haemost* 2016).

Aims: The present study aims at assessing the PK-PD relationship of R, with thrombin generation (TG) as the PD parameter.

Methods: Blood was sampled at baseline and after a single 40-mg R dose over a 24h-period (11 time-points). TG in platelet poor plasma was studied with the fully automated system ST Genesia (Stago). It differs from the calibrated automated thrombogram system by a calibration performed in plasma with a known amount of human thrombin in buffered solution and AMC fluorophore. Three experimental conditions were used: intermediate (STG-DrugScreen) or low (STG-ThromboScreen, TS) tissue factor concentration, the latter with and without thrombomodulin (+TM/−TM, Stago).

Results: Endogenous thrombin potential (ETP), peak height (PH) and time to peak (TTP) are shown at baseline, Tmax and T24 along with R plasma concentrations (Figure 1).

Using TS, adding TM markedly reduced ETP and PH, especially at Tmax, without return to baseline at T24. The PK-PD relationship was modeled by an exponential, with a decay rate (k) presenting a large between-subject variability, both for ETP (k = 2.8×10^{-3} [−TM] *vs* 13.4×10^{-3} [+TM] (ng/mL)$^{1-}$; CV: 37 vs %25) and PH (k = 6.8×10^{-3} [−TM] *vs* 15.2×10^{-3} [+TM] (ng/mL)$^{1-}$; CV: 15 vs %24)(Figure 2).

Conclusions: Phenotyping TG with ST-Genesia allows a reliable assessment of the PD response after R intake. In addition to PK variability, a substantial between-subject variability of TG parameters was evidenced in presence of R. In subjects receiving R, the involvement of the inhibitory dynamic system of activated protein C, formed in presence of TM by thrombin still generated, is important to take into account, in contrast to what occurs in subjects under vitamin K antagonist therapy, whose proteins C and S are altered.

PB 480 | DTI/DXI Interferences with Global Coagulation Tests in Daily Care Emergency Admissions - Results of the Prospective Dresden NOAC Registry (NCT01588119)

L. Wunder, U. Hänsel, S. Hauswald-Dörschel, K. Daschkow, L. Tittl, J. Beyer-Westendorf

Universitätsklinikum Carl Gustav Carus, Dresden, Germany

Background: Emergency management of orally anticoagulated patients is challenging, also because type of anticoaguolant may be unknown and direct thrombin inhibitors (DTI) and direct FXa inhibitors (DXI) may or may not affect global coagulation tests such as prothrombin time (PT), international normalized ratio (INR) or activated thromboplastin time (aPTT), depending on the assay and the time between last drug intake and blood sampling.

Aims: To evaluate impact of the interferences of DTI/DXI with global coagulation tests.

Methods: DTI/DXI patients with emergency hospital admissions were identified in the prospective, non-interventional *Dresden NOAC Registry*. Impact of drug class and time between last intake and blood sampling on the admission laboratory testing (proportion of normal vs. abnormal PT, INR, aPTT) was evaluated.

Results: 237 emergency admissions (46 DTI cases; 191 DXI cases) into 36 different hospitals were identified. DOAC specific testing was performed in 9 DTI (8 thrombin time, 1 ecarin clotting time) and in 12 DXI cases (chromogenic aXa assays).

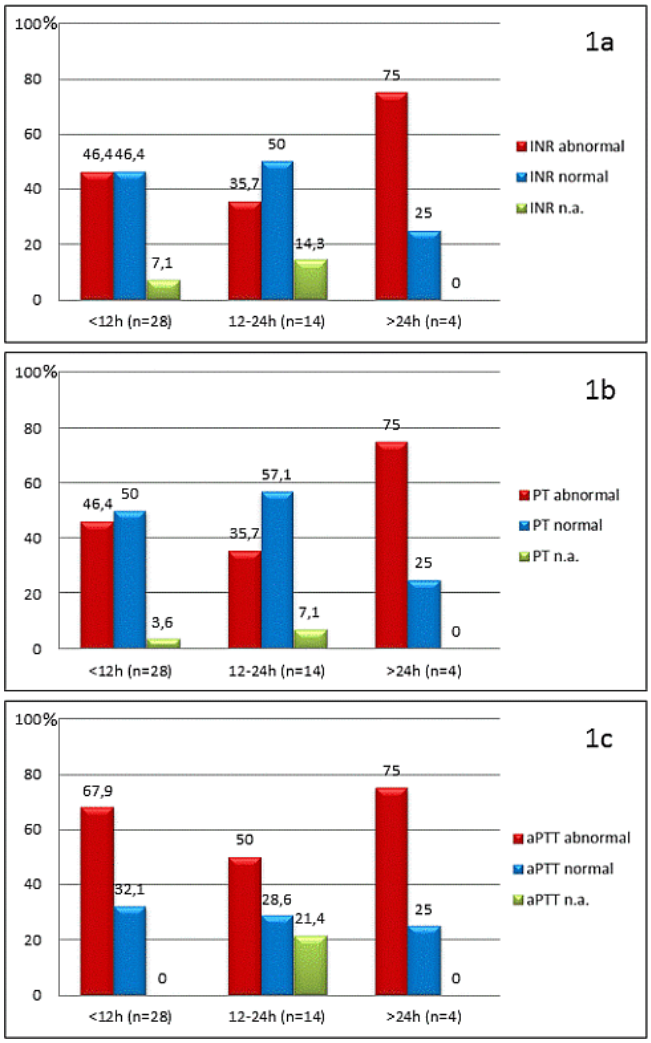

FIGURE 1 Effects of DTI intake on INR (1a), PT (1b), and aPTT (1c); n.a.=not available

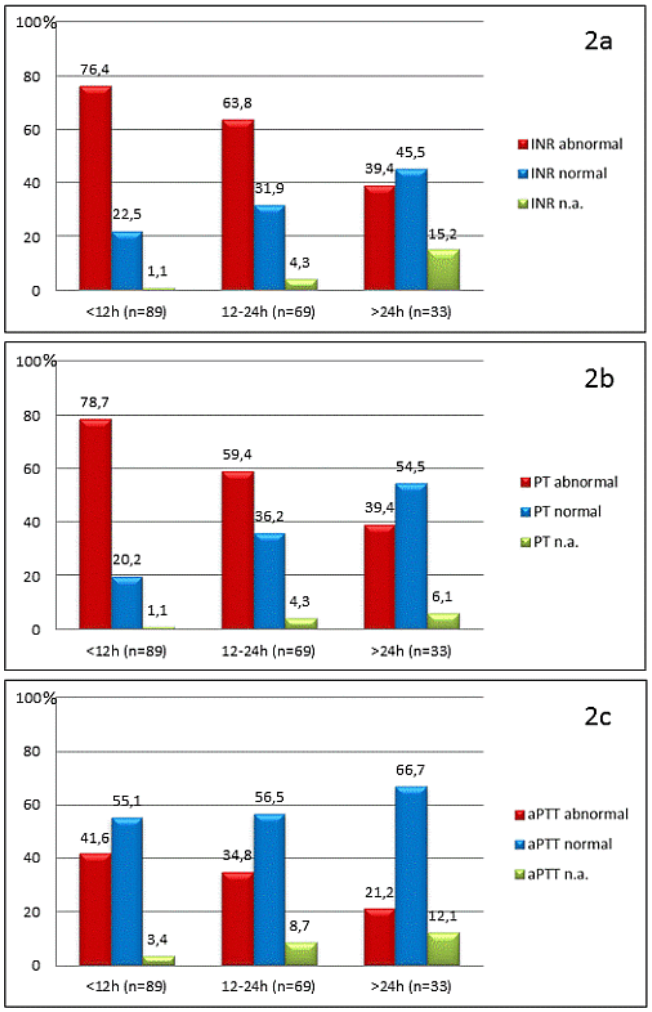

FIGURE 2 Effects of DXI intake on INR (2a), PT (2b), and aPTT (2c); n.a.=not available

Within 12 hours after last intake, only 46% of DTI recipients had abnormal INR or PT values but 67.9% had abnormal aPTT. These numbers decreased to 35.7% (PT and INR) and 50.0% (aPTT), if DTI was taken within 12-24h before blood sampling (figure 1 a-c).

In contrast, DXI recipients demonstrated abnormal INR or PT values in 76.4 and 78.6%, respectively, if last intake was < 12h before blood sampling, which decreased to 63.8 (INR) and 59.4% (PT) if DXI was taken within 12-24h and to 39.4%, if DXI before blood sampling (figure 2 a-c).

APTT was abnormal in 41.6% (< 12h); 34.8% (12-24h) and 21.2% (< 24h), respectively.

Conclusions: Within 12 hours after last intake, approximately 70-80% of DTI and DXI recipients demonstrate abnormal coagulation test results across a spectrum of assays, which may be helpful to identify unknown presence of DTI/DXI at high plasma concentrations. However, >12h after last intake, global coagulation tests are of little predictive value.

PB 481 | No Additional Diagnostic Value of Chest X-ray Prior to the YEARS Algorithm in the Diagnostic Management of Suspected Pulmonary Embolism

L.M. van der Pol[1,2], T. van der Hulle[1], C. Tromeur[1], L.J.M. Kroft[3], A. de Roos[3], L.M. Faber[4], A.T.A. Mairuhu[2], M.V. Huisman[1], F.A. Klok[1]

[1]Leiden University Medical Center, Department of Medicine - Thrombosis and Hemostasis, Leiden, The Netherlands, [2]HagaHospital, Department of Internal Medicine, The Hague, The Netherlands, [3]Leiden University Medical Center, Department of Radiology, Leiden, The Netherlands, [4]Red Cross Hospital, Department of Medicine, Beverwijk, The Netherlands

Background: The YEARS algorithm was designed to simplify the diagnostic process of suspected pulmonary embolism (PE) and to reduce the number of required CTPA-scans (*Figure 1*). A recent outcome study confirmed the safety and efficacy of YEARS (2016 ESC abstract 5727), with PE ruled out in 48% of patients without need for CTPA. Chest X-ray (CXR) is an important test in the initial evaluation of

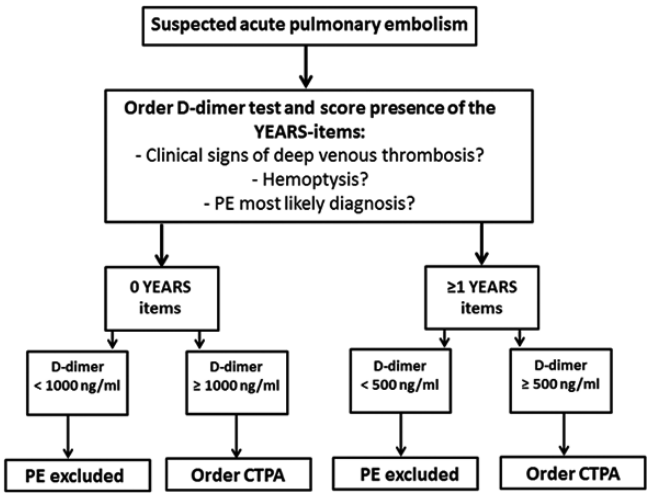

FIGURE 1 The YEARS algorithm

*Example: Assuming that the pre-test probability of PE is 28% in a certain patient with suspected PE and an indication for CTPA according to YEARS, the post-test probability of PE in case of a normal CXR result would be 28%*1.07 = 30%. The post-test probability of PE in this patient with any abnormality on CXR would be 28%*0.89 = 25%.*

	All patients (n=1473)		*Patients in whom CTPA was indicated according to the YEARS algorithm (n=763)*	
Results CXR	*Positive LR (95%CI)*	*Negative LR (95%CI)*	*Positive LR (95%CI)*	*Negative LR (95%CI)*
Normal CXR	0.86 (0.78-0.96)	1.39 (1.13-1.69)	1.07 (0.95-1.21)	0.89 (0.73-1.10)

Atelectasis	0.49 (0.06-3.75)	1.00 (0.99-1.02)	0.37 (0.05-2.96)	1.01 (0.99-1.02)

n.a. = not applicable

FIGURE 2 Overview of LRs and CXR results in two groups; all patients and patients in whom CTPA was indicated according to the YEARS algorithm

suspected acute cardiopulmonary disease and is cheaper and associated with less radiation exposure than CTPA.

Aims: To investigate whether CXR provides incremental diagnostic value to YEARS in patients with suspected PE, i.e. whether the post-test odds of PE after certain CXR findings would allow to change the decision of the algorithm to perform CTPA or not.

Methods: This post hoc analysis was assessed in 1473 consecutive patients with suspected PE who were managed according to YEARS and were also subjected to CXR as part of standard policy. The likelihood ratio's (LR) of 7 main CXR findings for a final diagnosis of PE were calculated.

Results: 214 patients were diagnosed with PE at baseline (15%), of which 137 had a normal CXR (64%). PE was ruled out in 1259 patients, with 7 thrombotic events during 3-month follow-up (0.5%), of whom 1069 had a normal CXR (72%), for an Odds Ratio of 1.60 (95%CI 1.18-2.18) compared to patients with PE. For the overall population, only the finding of a rib fracture or pneumothorax, present in 6 patients (0.4%), significantly changed (lowered) the post-test probability of PE (*Figure 2*). For patients with an indication for CTPA (PE prevalence 28%), only the CXR finding of a rib fracture, present in 2 patients (0.3%), lowered the post-test probability to such an extent that CTPA would no longer be required to rule out PE.

Conclusions: In our cohort of patients with suspected PE, CXR was more frequently abnormal in patients who were diagnosed with PE than in those in whom PE was ruled out. The incremental diagnostic value of CXR to the YEARS algorithm to rule out was limited.

PB 482 | Rivaroxaban Levels in Patients Plasmas Are Comparable by Measuring through Two Different Calibrators in Two Different Systems

M. Martinuzzo[1,2,3], R. Forastiero[3], C. Duboscq[4], M.S. Campana[5], M.S. López[5], L.H. Barrera[2,5], D. Penchasky[6], S. Viñuales[6], J. Ceresetto[4], J. Oyhamburu[1,2]

[1]Hospital Italiano de Buenos Aires, Laboratorio Central, Grupo Bioquímico, Buenos Aires, Argentina, [2]Instituto Universitario del Hospital Italiano, Bioquímica, Buenos Aires, Argentina, [3]Universidad Favaloro, Fisiología, Buenos Aires, Argentina, [4]Hospital Británico de Buenos Aires, Hematología, Buenos Aires, Argentina, [5]Hospital Italiano de Buenos Aires., Laboratorio Central, Grupo Bioquímico, Buenos Aires, Argentina, [6]Hospital Italiano de Buenos Aires, Hematología, Buenos Aires, Argentina

Background: Rivaroxaban (Riva) is used for thromboembolic prevention in patients with Atrial Fibrillation (AF) and in venous thromboembolism (VTE) treatment, without laboratory monitoring, but in particular situations measured plasma Riva levels is needed.

Aims:

A) To verify the analytical performance of HemosIL liquid anti Xa calibrated by Riva specific Calibrators in an ACL TOP coagulometer.

B) To compare the results with those obtained by STA-Liquid Anti Xa calibrated with specific RIVA calibrators in a TCoag Destiny Plus coagulometer,

C) to compare results obtained by calibrating each system with the other branch calibrator.

Methods: 53 samples drawn at any time (through or peak) from consecutive patients taking Riva because of AF or VTE were processed in three different centers. Riva was measured by HemosIL Liquid anti Xa in a ACLTOP 300 and STA liquid Anti Xa in a TCoag Destiny Plus

TABLE 1 Rivaroxaban methods comparison by using two different test systems and calibrators

Comparison of reagent-calibrator combinations	HemosIL-HemosIL vs STA-STA	HemosIL-HemosIL vs HemosIL-STA	STA-STA vs STA HemosIL
n	53	42	52
Slope (95%CI)	1.053 (0.961 to 1.142)	1,024 (0,953 to 1,096)	1,062 (0,985 to 1,139)
Y intercept (95%CI)	-3,87 (-19,94 to 12,19)	11,7 (-2,0 to 25,5)	-16,5 (-30,7 to -2,2)
R (Corr Coef)	0.953	0.976	0.967
BIAS %	2.85	10	-6.9

coagulometer. HemosIL Rivaroxaban and STA Rivaroxaban Calibrators and controls were used. Data Analysis: Precision and trueness were evaluated by EP15A3, linearity by EP6 and methods comparison by EP 9 CLSI protocols. Methods comparison statistics was performed by Deming regression and Bland Altman plots in EP evaluator software.

Results: Riva HemosIL showed CVr 2.18 and 1.32%, CVi 3.06 and 3.27% and BIAS 10.5 and 13.3% giving TE of 16.0 and 19.8% for Low and High Riva controls, respectively. Linearity was verified from 8.2 to 525 ng/mL Deming regression equations and BIAS % calculated by methods comparison are included in table.

Conclusions: The analytical performance of HemosIL anti Xa calibrated by specific calibrators is acceptable, with precision and trueness similar to that reported for low molecular weight heparin. The best method comparison results were obtained when each reagent is used in their specific system with their specific calibrators. However, both tests are robust and calibration procedure with both calibrators can be used showing comparable results.

PB 483 | Multicenter Observational Study to Evaluate TEG®6s Oral Anticoagulant (OAC) Assay in Apixaban-treated Patients

K. Bliden[1], F. Zaman[2], H. Taheri[1], L. Ilkhanoff[1], C. Sandesara[1], M. Blessy[2], U. Tantry[1], P. Gurbel[1]

[1]Inova Heart and Vascular Institute, Falls Church, United States, [2]Haemonetics Corporation, Rosemont, United States

Background: Detection of anticoagulant effects of NOACs and NOAC classification are important in situations such as trauma, stroke or emergent surgery where a major intervention may increase survival. Currently, no standardized point-of-care test is available to evaluate the anticoagulant effects of apixaban.

Aims: The aim of the study was to evaluate the anticoagulant effect of apixaban-treated patients and compare with results obtained from healthy volunteers by using the point-of-care TEG®6s Oral Anticoagulant (OAC) assay.

Methods: Healthy volunteers (n=27) and patients on apixaban (n=50) were enrolled across 5 sites. Protocol was approved by site IRBs and informed consent was obtained prior to blood draw. To ensure that a range of drug concentrations were captured, blood samples were obtained at non-trough (< 9hrs) and trough (9-12hrs) levels as indicated from last dose (2.5 or 5.0 mg BID). The viscoelastic OAC assay utilizes human Factor Xa and Ecarin as reagents for AFXA and DTI assays, respectively. Data derived from patients on apixaban were compared against the reference range (based on a separate healthy cohort; n=111) to determine sensitivity and specificity for detection.

Results: The majority of patients were prescribed apixaban for atrial fibrillation. Patients had significantly longer Reaction Time (R) by AFXA assay ($p < 0.001$) but not DTI assay ($p=0.55$) as compared to healthy volunteers. AFXA-R time >1.9 min indicated detection of anticoagulation effect with 96% sensitivity and 100% specificity (Fig A). A DTI R-time cut-off < 2.3 min classified an anti-Xa with 98% sensitivity

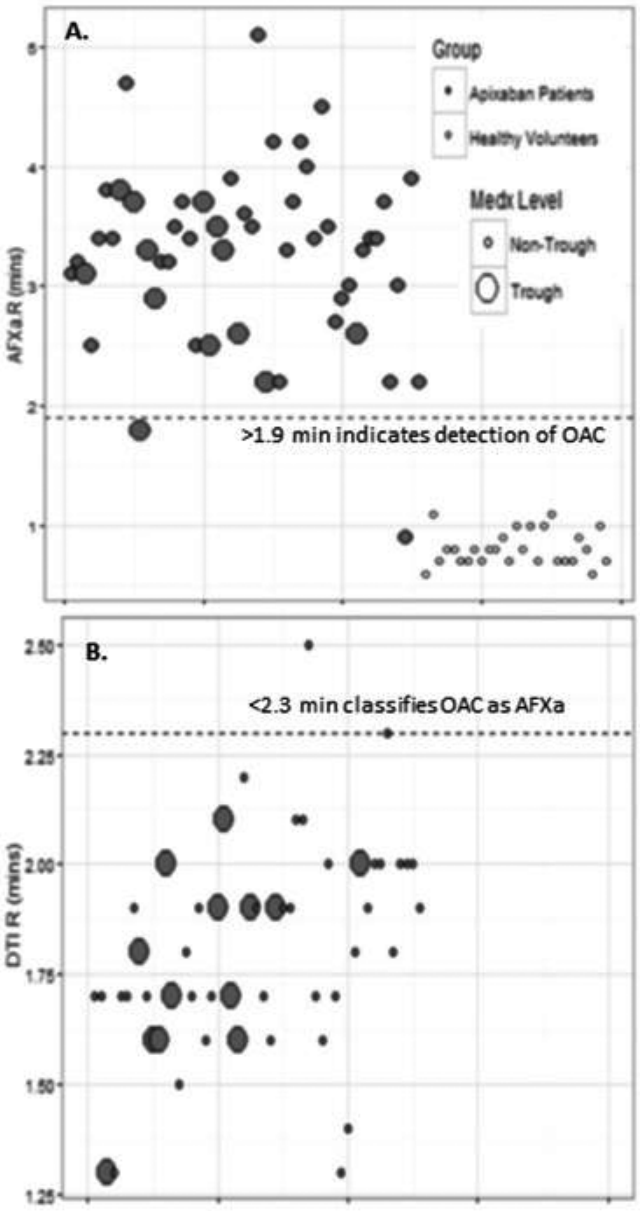

FIGURE 1

(Fig B). There was a large interindividual variability in anticoagulant effect that was not attributable to dose or trough measurements.

Conclusions: The automated TEG®6s device with its OAC assay may be an effective tool to rapidly identify anticoagulant effects in apixiban-treated patients and thus, facilitate care in emergent situations.

PB 484 | Management Strategies and Long-term Outcomes in Patients with Upper Extremity Deep Vein Thrombosis: Findings from the XALIA Study

W. Ageno[1], L.G. Mantovani[2], S. Haas[3], R. Kreutz[4], D. Monje[5], J. Schneider[6], M. van Eickels[6], M. Gebel[7], A.G.G. Turpie[8]

[1]University of Insubria, Department of Clinical and Experimental Medicine, Varese, Italy, [2]University of Milan Bicocca, CESP-Center for Public Health Research, Monza, Italy, [3]Formerly Technical University Munich, Munich, Germany, [4]Charité Universitaetsmedizin Berlin, Institute of Clinical Pharmacology and Toxicology, Berlin, Germany, [5]Bayer Vital GmbH, Leverkusen, Germany, [6]Bayer AG, Berlin, Germany, [7]Bayer AG, Wuppertal, Germany, [8]Hamilton Health Sciences, Medicine, Hamilton, Canada

Background: Upper extremity deep vein thrombosis (UEDVT) accounts for approximately 5-10% of venous thromboembolism (VTE) events. Evidence on the treatment and clinical history of UEDVT is either indirect or from small observational studies. No study has assessed the efficacy and safety of the non-vitamin K antagonist oral anticoagulants in patients with UEDVT.

Aims: To report the results of a subgroup analysis of patients with UEDVT from the XALIA study.

Methods: XALIA was a prospective, non-interventional study of rivaroxaban in the treatment of acute VTE. Patients aged ≥18 years scheduled to receive ≥3 months of anticoagulation with rivaroxaban or standard of care (SOC) were eligible. Baseline characteristics, management strategies and unadjusted incidence rates of recurrent VTE, major bleeding and all-cause mortality for patients with UEDVT were compared between treatment groups.

Results: Overall, 164 patients with UEDVT were enrolled; 61 (37.2%) received rivaroxaban and 103 (62.8%) received SOC. Mean age was 48.8 years in the rivaroxaban group and 53.9 years in the SOC group; 3 (4.9%) and 5 (4.9%) had creatinine clearance < 50 ml/min, 4 (6.6%) and 48 (46.6%) had cancer; and UEDVT was provoked by a transient risk factor in 16 (26.2%) and 54 (52.4%), respectively. Twelve (19.7%) patients in the rivaroxaban group and 51 (49.5%) in the SOC group were hospitalized (mean duration 4.9 and 9.1 days, respectively). Median treatment duration was 132 and 161 days, respectively. The annualized symptomatic recurrent VTE incidence was 0% and 6.95% (95% CI 1.89-17.8), major bleeding rates were 0% and 3.51% (0.42-12.67) and all-cause mortality was 0% and 15.4% (7.03-29.2), respectively.

Conclusions: In XALIA, most patients with UEDVT received SOC, and nearly half of the SOC group had cancer. Rivaroxaban-treated patients most frequently had unprovoked UEDVT and only a minority were hospitalized. In these patients, rivaroxaban appears to be a safe and effective treatment strategy.

PB 485 | Measurement of Apixaban and Rivaroxaban Levels in Real Life Clinical Practice: An Instrument to Improve Anticoagulation Management?

C. Kartsios, M. Kaparou, R. Payne, L. Philpotts, K. Beale, M. Fowler, A. Lokare, N. Smith

Birmingham Heartlands Hospital, Haematology, Birmingham, United Kingdom

Background: Rivaroxaban (R) and apixaban (A) are oral anticoagulants that function as direct anti-factor Xa inhibitors (DFXaI). Although routine monitoring is not required, knowledge of drug levels may be required in bleeding, thromboembolic events, procedures, extreme body weight, suspected non-compliance or overdose. Anti-Xa chromogenic assays have become recently available to determine plasma levels of DFXaI.

Aims: We analysed all DXaI plasma level requests received in our lab in 12 months. We recorded the clinical details and anticoagulation outcome for every patient (pt).

Methods: We utilised chromogenic anti-factor Xa assays (Technoclone®) to measure A and R levels. The expected mean plasma levels for A 2.5 mg bd were 21 (trough) and 62
(peak) ng/ml while for 5mg bd were 50 and 125ng/ml respectively (Frost, 2013). For R 20 mg od the expected peak levels were 223 (160-360) while the mean trough levels were 22 (4-96) ng/ml (Mueck, 2008). Pts were advised to take their tabs as usual.

Results: A total of 97 samples from 78 pts (M:44/F:34), median age:66 (32-98) years were recorded.
41 pts suffered from atrial fibrillation and 37 had DVT/PE. 29 pts were on A 2.5mg, 41 on A 5mg and
28 on R 20mg. The main reasons to request drug levels were: extreme body weight:17, gastric/bowel//pancreas pathology: 12, carbamazepine use: 11, chronic kidney disease(CKD): 10, clinician reassurance: 10, history of bleeding:9, recurrent DVT/pt compliance:6. Median drug levels for R were 47 (1,07-437,4) ng/ml, for A 2.5mg 93.74 (2.82-254.6) and for A 5mg they were 116.9 (5.39-442.68) ng/ml. Anticoagulation was changed in 8/78 pts (10%); it was stopped in 1 A pt with CKD, A was reduced in
3 pts; 1 on amiodarone, 1 with pancreatic cancer, 1 on carbamazepine. A was changed to other anticoagulant in 4 pts; 1 with new thrombosis, 1 with bleeding and 2 with drug interactions.

Conclusions: DFXaI are safe even in complex clinical scenarios like carbamazepine co-use or bowel pathologies. Lab testing would favor implementation of DOACs but its role remains to be defined.

PB 486 | Comparison of Bleeding and Thromboembolic Event Rates in Atrial Fibrillation Patients with Good and Poor Warfarin Control before and after Switching to Direct Oral Anticoagulants

B. Haymart[1], X. Kong[1], X. Gu[1], S. Almany[2], J. Kozlowski[3], G. Krol[4], M. McNamara[5], M. Dahu[5], E. Kline-Rogers[1], J. Froehlich[1], G. Barnes[1], S. Kaatz[4]

[1]University of Michigan, Ann Arbor, United States, [2]William Beaumont Hospital, Royal Oak, United States, [3]Cardiology and Vascular Associates, Commerce, United States, [4]Henry Ford Health System, Detroit, United States, [5]Spectrum Health, Grand Rapids, United States

Background: It is unclear which non-valvular atrial fibrillation (NVAF) patients would most clearly benefit from switching from warfarin to a direct oral anticoagulant (DOAC). There have been no randomized controlled trials to examine this common scenario, and providers have differing opinions.

TABLE 1 Event rates before and after switching to DOAC

	Good control before switch	Good control after switch	p-value	Poor control before switch	Poor control after switch	p-value
# total patients	119	119		71	71	
# patient years	275.1	213		116	82	
Median months of treatment per patient	22.8	18		13	12	
Mean/median TTR (%)	72/71	N/A		47/50	N/A	
Stroke/TIA (# per 100 pt-yr)	1.5	0.5	0.31	2.6	0	/
Bleeding requiring ED visit or hospitalization (# per 100 pt-yr)	9.8	3.3	0.006	7.8	2.4	0.08
Stroke/TIA or bleeding requiring ED visit or hospitalization (# per 100 pt-yr)	11.3	3.8	0.003	10.3	2.4	0.04

Aims: To examine outcomes in NVAF patients with good and poor INR control before and after switching from warfarin to a DOAC.

Methods: Since 2009, abstractors at 6 anticoagulation services have entered patient data into the Blue Cross Blue Shield of Michigan funded Michigan Anticoagulation Quality Improvement Initiative (MAQI^2) registry. NVAF patients with at least 6 months of warfarin treatment before switching to a DOAC were stratified into two groups according to INR control based on time in therapeutic range (TTR): good control (TTR ≥ 60%) and poor control (TTR < 60%). The composite rate of stroke/TIA or bleeding requiring ED visits or hospitalizations was calculated for both groups before and after switching to a DOAC. Comparisons were made using Poisson regression and Chi-square.

Results: A total of 190 patients were identified with 119 (63%) having good INR control and 71 (37%) having poor INR control. After switching to a DOAC, the composite event rate in patients with good control was reduced by 7.5 per 100 pt-yr (11.3 to 3.8, p=.003) while the composite event rate in patients with poor control was reduced by 7.9 per 100 pt-yr (10.3 to 2.4, p=.04) (Table 1). This represents similar relative composite event rate reductions (66% vs. 77%, p=0.21) in the good and poor INR control groups, respectively (Table 2).

TABLE 2 Relative percent event rate reduction after switching to DOAC

	Good control	Poor control	p-value
Stroke/TIA	67%	100%	0.01
Bleeding requiring ED visit or hospitalization	66%	69%	0.77
Stroke/TIA or bleeding requiring ED visit or hospitalization	66%	77%	0.21

Conclusions: NVAF patients with good and poor INR control from our cohort benefitted equally after switching from warfarin to a DOAC. Both groups experienced a significant reduction in rate of our composite outcome. Our results suggest that patients with both good and poor INR control may be appropriate candidates to switch to a DOAC.

PB 487 | Measurement of Direct Oral Anticoagulant Drug Levels Following Bariatric Surgery

E. Tseng[1], L. Sardo[2], J. Bayadinova[2], M. Crowther[1,3], D. Siegal[1,4]

[1]McMaster University, Hamilton, Canada, [2]St. Joseph's Healthcare Hamilton, Hamilton, Canada, [3]McMaster University, Department of Pathology and Molecular Medicine, Hamilton, Canada, [4]Population Health Research Institute, Hamilton, Canada

Background: Absorption of the direct oral anticoagulants (DOACs) occurs to a variable extent in the stomach and small intestine. While bariatric surgery may result in decreased drug absorption, there is limited data regarding its impact on the absorption of DOACs.

Aims: We evaluated peak plasma drug concentrations in a case series of patients receiving rivaroxaban or apixaban for atrial fibrillation or venous thromboembolism, following bariatric surgery.

Methods: Our institution is a regional bariatrics centre. All bariatric patients receiving DOACs are assessed post-operatively, and peak plasma DOAC concentrations routinely are evaluated 2 to 4 hours post-dose with validated assays. We performed a retrospective review of DOAC levels in bariatric patients receiving therapeutic dose DOACs at our centre between January 2015 and January 2017.

Results: 10 patients were identified who resumed a DOAC after bariatric surgery (7 rivaroxaban, 3 apixaban). Peak drug concentrations were measured at median (range) 7.0 days (0.0-29.0) after anticoagulant resumption. Mean body weight (SD) was 140.1 kg (23.2), mean body mass index was 47.9 kg/m^2 (5.5), and mean eGFR was 88.7 ml/min/1.73 m^2 (13.2). Among patients receiving rivaroxaban, mean peak concentration was 299.3 ng/ml (55.4; reference range 189-419). Among patients receiving apixaban, mean peak concentration was 132.7 ng/ml (26.4; 91-321). 6 patients demonstrated levels consistent with prior published ranges, while 3 were below published ranges. No thrombotic or bleeding events occurred during hospitalization.

Conclusions: This case series provides preliminary data suggesting that standard therapeutic doses of DOACs in morbidly obese patients after bariatric surgery may achieve peak anticoagulant levels within or close to prior published ranges. The pharmacokinetic properties

Sex	Surgery	Weight (kg)	eGFR	Anticoagulant	Peak (ng/ml)
F	SG	146.7	84.0	Riva. 20 mg OD	273
M	GB	141.0	78.0	Riva. 20 mg OD	363
F	SG	148.6	101.0	Riva. 20 mg OD	262

FIGURE 1 Patient Characteristics and Peak Direct Oral Anticoagulant Levels After Bariatric Surgery

of DOACs and clinical significance of these findings requires further evaluation in prospective studies in bariatrics and morbid obesity.

PB 488 | Use of a 4-factor Prothrombin Complex Concentrate for Management of Direct Xa Inhibitor-induced Major Bleeding

P. Dobesh[1], B. Trevarrow[1], P. Malinowski[1], K. Guiliano[1], C. Duncan[1], K. Gundabolu[2]

[1]*University of Nebraska Medical Center College of Pharmacy, Pharmacy Practice, Omaha, United States,* [2]*University of Nebraska Medical Center College of Medicine, Internal Medicine, Omaha, United States*

Background: While direct Xa inhibitors provide safety advantages over warfarin, concern still exists over the lack of a specific antidote for management of major bleeding events. Four factor prothrombin complex concentrate (4PCC) has demonstrated the ability to reverse coagulation parameters in healthy subjects, but efficacy and safety data are lacking in patients with bleeding events.

Aims: Assess the efficacy and safety of 4PCC in management of direct Xa inhibitor-induced major bleeding in real world practice.

Methods: This retrospective study included all patients who received 4PCC at our hospital for a major bleeding event on a direct Xa inhibitor from 11/14 to 10/16. Patients receiving other anticoagulants were excluded from the analysis. Patient demographics, medication use, laboratory values, and outcomes were collected from patient charts. All descriptive data are presented as mean ± standard deviation.

Results: We identified 23 patients who received 4PCC for management of direct Xa inhibitor-induced major bleeding, 65% of which were traumatic and 65% of which were cranial. Patients were 78% female, age 75±10 years, and weight 84.6±21.9 kg. Indications for a direct Xa inhibitor included atrial fibrillation (n=13) and venous thromboembolism (n=10). Patients were balanced between receiving apixaban (n=12) and rivaroxaban (n=11), with a HASBLED Score of 1.9±0.8. Nine patients were also on aspirin. The 4PCC dose was 3342±1474 U at 38.6±12.5 U/kg. 4PCC stopped bleeding in 15 patients, while 4 required surgery to stop bleeding. 4PCC stopped bleeding within 26.6±37.8 hours. Five patients also received PRBC and 4 received FFP and/or platelets. Five patients died during hospitalization (3 during acute bleeding event), and two thrombotic events occurred within the subsequent 30 days.

Conclusions: While 4PCC was not 100% successful, it did provide a rapid and safe strategy for management of a direct Xa inhibitor-induced major bleeding. More experience in non-cranial bleeding will be needed at our institution.

PB 489 | Is Rivaroxaban Associated with Headache and Dizziness? A Retrospective Study

S. Piran, S. Schulman

McMaster University, Department of Medicine, Division of Hematology and Thromboembolism, Hamilton, Canada

Background: Direct oral anticoagulants are effective in the prevention of stroke in atrial fibrillation and treatment of venous thromboembolism (VTE). Clinicians at different centers have made observations of headaches and dizziness being associated with rivaroxaban, which disappear upon switching to a different anticoagulant. However, these observations have not been reported in the literature.

Aims: To evaluate the incidence of headache and dizziness associated with rivaroxaban compared to a control group receiving apixaban.

Methods: A retrospective chart review was performed. We hypothesized that the incidence of headache and/or dizziness would be significantly higher in patients receiving rivaroxaban.

Results: A total of 491 patients were included in the rivaroxaban group and 397 in the apixaban group. The groups were similar with regards to gender but not for age (median age of 69 versus 78; $P < 0.001$). The most common indication for anticoagulation in the rivaroxaban group was treatment of VTE compared to management of atrial fibrillation in the apixaban group. The median duration of anticoagulation therapy was significantly longer for the apixaban group compared with the rivaroxaban group (19 months versus 11 months; $P < 0.001$). Number of patients who had headache was not different between the two groups, 3 (0.6%) versus 1 (0.25%). Two of the 3 patients on rivaroxaban and the patient on apixaban had resolution of headache after switching to a different anticoagulant. Number of patients who had dizziness was also not different, 4 (0.8%) versus 3 (0.75%). Two of the 4 patients on rivaroxaban and one patient on apixaban had resolution of dizziness after switching to a different anticoagulant.

Conclusions: Data from our study suggests that the incidence of headache and dizziness in patients receiving rivaroxaban was very low and not different from a control group of patients on apixaban. Switching

to a different anticoagulant resolved either symptom in most of the cases.

PB 490 | Adherence to Rivaroxaban, Dabigatran, and Apixaban for Stroke Prevention for Newly Diagnosed and Treatment Naïve Atrial Fibrillation Patients: 2013-2014

J. Brown[1], J. Talbert[2]

[1]University of Florida, Pharmaceutical Outcomes & Policy, Gainesville, United States, [2]University of Kentucky, Pharmaceutical Outcomes & Policy, Lexington, United States

Background: Few studies have assessed adherence to non-vitamin K, oral anticoagulants (DOACs), especially using contemporary data now that multiple DOACs are available.

Aims: This study compared adherence and treatment patterns among DOACs for stroke prevention in NVAF.

Methods: Incident, treatment-naïve NVAF patients were identified during 2013-2014 from a large claims database. Patients were included who initiated rivaroxaban, dabigatran, or apixaban within 30 days after diagnosis. Adherence to the index medication and adherence to any oral anticoagulant was assessed using the proportion of days covered (PDC) at 3, 6, and 9 months. The number of switches and gaps in therapy were also evaluated. Analyses were stratified by stroke risk scores and a logistic regression model was used to control for factors that may predict high adherence.

Results: Dabigatran had lower adherence (PDC=0.76, 0.64, 0.57) compared to rivaroxaban (PDC=0.83, 0.73, 0.66; p< 0.001) and apixaban (PDC=0.82, 0.72, 0.66; p< 0.001) at 3, 6, and 9 months of follow and twice the number of switches to either other anticoagulants or antiplatelet therapy. Adherence was higher overall as stroke risk increased and showed dabigatran had consistently lower adherence compared to the other DOACs. Adjusted analyses showed that increasing age and comorbid hypertension and diabetes were associated with higher adherence.

Conclusions: In this real-world analysis of adherence to DOACs, rivaroxaban and apixaban had favorable profiles compared to dabigatran and rivaroxaban appeared to have higher overall adherence among the DOACs. Clinicians and managed care organizations should consider the implications of lower adherence on clinical outcomes and quality assessment.

PB 491 | Determination of Rivaroxaban, Apixaban, Edoxaban and Dabigatran by Ultra-performance Liquid Chromatography-tandem Mass-Spectrometry and Chromogenic Assays from Urine Samples of Patients

R. Schreiner[1], S. Hetjens[2], C. Giese[3], H.-J. Roth[1], C. Weiss[2], R. Krämer[3], J. Harenberg[4,5]

[1]Medical Service Center Dr. Limbach and Colleagues, Heidelberg, Germany, [2]Medical Faculty Mannheim, Biometry and Statistics, Mannheim, Germany, [3]University of Heidelberg, Inorganic Chemical Institute, Heidelberg, Germany, [4]Medical Faculty Mannheim, Mannheim, Germany, [5]DOASENSE GmbH, Heidelberg, Germany

Background: The direct oral anticoagulants (DOAC) apixaban (A), edoxaban (E), rivaroxaban (R), and dabigatran (D) are excreted into the urine between 30% and 80%. Ultra-performance liquid chromatography tandem mass-spectrometry (UPLC-MS/MS) methods the reference procedure to quantify DOACs in plasma samples.

Aims: To develop an UPLC-MS/MS method for DOACs in urine and evaluate the analytical performance compared to chromogenic substrate (CS) assays from urine samples of patients treated with A, R and D.

Methods: Urine samples were analysed with ACQUITY H-Class UPLC System, Xevo TQ-S Mass spectrometer, ACQUITY UPLC CSH C18 Column (Waters) and Risperidon D4 as internal standard. Samples were eluted with gradients of ammoniumformiate pH 3.5 and methanol. Artificial urine was spiked up to 10,00ng/ml of DOACs to evaluate of the method. The method was validated using urine samples from patients (n=29 per group) treated with A (5mg bid), R (20mg od), D (110mg or 150mg bid) and controls. Modified Coamatic (Haemochrom) and S2238 CS assays were adopted to determine DOACs activity from patient's urine samples. Results of UPLC-MS/MS and CS assays were compared by statistical analysis.

Results: Linearity of he UPLC-MS/MS method was from 0 to 10,000ng/ml for A, E, R, and D, LLOD between 0.1 and 2.0ng/ml, LLOQ 0.4 and 3.6ng/ml, intra- and inter-assay coefficient of variation of 2% to 11% (n=8 determinations). Background noise of clinical samples of A, R and D corresponded to mean±sd: 5.3±6.7ng/ml, 0.4±0.2ng/ml, 1.2±0.2ng/ml (UPLC-MS/MS), 3.6±3.5ng/ml, 3.6±3.5ng/ml, and 1.2±1.2ng/ml (CS assays). The results from urine samples of DOAC patients and statistical analysis of the comparison of methods are given in the table.

Conclusions: UPLC-MS/MS is more precise than CS assays for determination of DOACs in urine. CS assay indicates the presence of active

TABLE 1 Concentrations of DOACs from patient's urine determined by UPLC-MS/MS and chromogenic substrate assays and statistical comparison of methods

	UPLC-MS/MS method . . . ng/ml . . . . . mean+/-sd	chromogenic substrate assay . . . . ng/ml . . . . . mean+/-sd	t-test . . . . . p value	Pearson coefficient of correlation . . . r value	Intraclass coefficient of correlation . . . r value	Maloney Rastogi test . . p value
Apixaban	1849+/-1420	1533+/-1624	0.4344	0.6956	0.6821	0.3387
Rivaroxaban	2829+/-1909	4148+/-1947	0.0117	0.7257	0.5925	0.8828
Dabigatran	5650+/-3698	5674+/-4532	0.9821	0.7868	0.7767	0.0901

metabolite/s of R in urine. UPLC-MS/MS may serve as gold standard method for development of a point of care test from urine samples of patients to determine DOACs in emergency medicine.

PB 492 | Length of Hospital Stays Following Acute Pulmonary Embolism in England: Observational Cohort Study Using the CPRD-HES Databases

R. Alikhan[1], M. Lumley[2], S. Lister[3], N. Hill[3], C. Lefevre[3]

[1]University Hospital of Wales, Haemophilia and Thrombosis Centre, Cardiff, United Kingdom, [2]Pfizer UK, Surrey, United Kingdom, [3]BMS UK, Middlesex, United Kingdom

Background: The development of low molecular weight heparin (LMWH) and more recently the DOACs has revolutionised the anticoagulation management of patients with DVT, such that outpatient management in the UK is accepted as the standard of care; this is not the case for PE. The newly updated 2017 British Thoracic Society (BTS) Guidelines for the management of PE recommend that patients with PE should receive a DOAC (Grade A recommendation) and those with a PESI score I/II, sPESI 0 or meeting the Hestia criteria should be considered for outpatient management (Grade B recommendation).

Aims: The aim of this study is to describe hospital admission patterns following the diagnosis of acute VTE in England.

Methods: We performed a retrospective cohort study of all VTE (DVT and PE) events identified in the UK Clinical Practice Research Database linked to Hospital Episode Statistics (CPRS-HES) from April 1st 2008 to March 31st 2012. VTE occurrence was defined by a VTE read code or ICD-10 code and matched to hospitalisation, measured in number of days.

Results: 11,353 VTE events were identified, 5114 (45%) PE and 6239 (55%) DVT. Of the 5114 PE episodes identified, 3021 (59%) resulted in hospitalisation. The median duration of hospitalisation for PE patients was 6 days, with an inter-quartile range of 3-10 days (Q1-Q3), compared to a median hospital stay for DVT patients < 1 day.

Conclusions: PE patients spend almost a week in hospital, whereas DVT patients are in general discharged the same day. The increasing availability, experience and confidence in the use of DOACs as well as the development of ambulatory PE pathways in line with the new UK BTS Guidelines, utilising risk assessments such as PESI and Hestia criteria, is likely to result in a paradigm shift in the management of PE patients in the UK with more patients being managed in the outpatient setting.

PB 493 | Early Uptake of Edoxaban: A Danish Nationwide Cohort Study

M. Hellfritzsch[1], E. Grove[2,3], A. Pottegård[1]

[1]University of Southern Denmark, Public Health, Clinical Pharmacology and Pharmacy, Odense, Denmark, [2]Aarhus University Hospital, Department of Cardiology, Aarhus, Denmark, [3]Aarhus University, Faculty of Health, Institute of Clinical Medicine, Aarhus, Denmark

Background: Edoxaban is the fourth direct oral anticoagulant (DOAC) to enter the market. In Europe, edoxaban is licensed for use in atrial fibrillation as well as treatment and prevention of pulmonary embolism and deep vein thrombosis. The place for edoxaban in a field with four highly similar drugs is not clear.

Aims: To describe the early uptake of edoxaban in the first six months after market entry in Denmark.

Methods: Using nationwide health registries, we identified new users of edoxaban (n=170) from June 6 (day of marketing) through November 2016. For comparison, we also identified new users of dabigatran (n=1,319), rivaroxaban (n=8,755), and apixaban (n=6,932). Users were compared according to the indication of use and described with regard to previous anticoagulant experience, comorbidity and comedication.

Results: The rate of edoxaban initiation increased to 1.2 per 100 000 person months in November, compared to 3.4, 33.9 and 26.2 for dabigatran, rivaroxaban, and apixaban, respectively.

Atrial fibrillation was the most common registered indication for edoxaban use (57%) as well as the other DOACs (38-51%). Overall, users of edoxaban were comparable to users of the other DOACs with regard to age, gender distribution and comorbidities. However, 85% of edoxaban users had previously received anticoagulant treatment

TABLE 1 Baseline characteristics of new users of direct oral anticoagulants (DOAC) in Denmark between June and November 2016

	Edoxaban (n=170)	Dabigatran (n=1,319)	Rivaroxaban (n=8,755)	Apixaban (n=6,932)
Age, median (IQR)	73 (69-81)	73 (68-81)	72 (63-80)	76 (68-83)
Male gender	92 (54%)	773 (59%)	4,804 (55%)	3,737 (54%)
Switching from warfarin	38 (22%)	235 (18%)	1,166 (13%)	1,009 (15%)
Switching from other DOAC	71 (42%)	281 (21%)	728 (8%)	907 (13%)
Indication: atrial fibrillation	97 (57%)	672 (51%)	3,398 (39%)	3,548 (51%)
Previous myocardial infarction	23 (14%)	79 (6%)	616 (7%)	604 (9%)
Previous bleeding event	25 (15%)	166 (13%)	909 (10%)	1,012 (15%)
Previous ischaemic stroke / transient ischemic attack	12 (7%)	149 (11%)	745 (9%)	1,002 (15%)
Use of low-dose aspirin	24 (14%)	270 (21%)	1,685 (19%)	1,632 (24%)

compared to 34-48% for users of the other DOACs. Further, edoxaban users generally had lower use of other medication.

Conclusions: While the use of edoxaban is still limited compared to other DOACs, its use is increasing. Edoxaban is primarily used in atrial fibrillation, and edoxaban users are often switchers from another oral anticoagulant. Continued monitoring of DOACs, including effectiveness and safety, is considered essential to the safe and rational use of these drugs. However, selective prescribing may be a challenge when comparing DOACs.

PB 494 | Fibrin Monomer Complex and Dilute Prothrombin Time as a Marker for Thrombotic Tendency in Anti-Xa DOAC Therapy

T. Suzuki[1,2], M. Ieko[2], S. Naito[3], M. Yoshida[3], D. Hatanaka[1], Y. Komiyama[1], T. Suetake[1], O. Kumano[1], N. Takahashi[2], I. Sakuma[4]

[1]Sysmex Corporation, Kobe, Japan, [2]Health Sciences University of Hokkaido, Department of Internal Medicine, Hokkaido, Japan, [3]Health Sciences University of Hokkaido, Department of Clinical Laboratory, Hokkaido, Japan, [4]Caress Sapporo Hokko Memorial Clinic, Cardiovascular Medicine, Hokkaido, Japan

Background: Direct oral anticoagulant targeted to factor Xa(Anti-Xa DOACs) such as Rivaroxaban, Apixaban and Edoxaban, a direct thrombin inhibitor, have been administered for prevention of cerebral embolism in patients with non-valvular atrial fibrillation (NVAF), and the monitoring is not required in general clinical setting. However, some evaluation criteria are needed to prevent major bleeding and/or other severe events.

Aims: In this study, we compared the anticoagulant effect of anti-Xa DOACs in patients with NVAF by dilute prothrombin time (dPT), fibrin monomer complex (FMC), D-dimer and general clotting assay.

Methods: Citrated plasma samples were obtained from Japanese patients (Pt) with NVAF receiving Rivaroxaban (n=593), Apixaban (n=471) and Edoxaban (n=310) therapy. Depending on clinical setting, they were classified into 4 groups: no particular event (N, n=1325), minor bleeding (B, n=36), major bleeding (n=0) and thrombus (T, n=13). Sample characteristics were classified according to blood collection time after ingestion: peak group is within 4 hours after ingestion, and others were trough group. Laboratory tests such as dPT (indicated by Ratio of Inhibited Thrombin Generation, RITG), FMC and D-dimer was determined by Sysmex CS series. Anti-Xa DOACs were determined with anti Xa Assay (Hyphen Biomed).

Results: In trough group, a significant difference was confirmed in PT-INR between N (1.21) and T (1.16), in RITG between N (15.7) and T (1.3) and between N (15.7) and B (34.2), and in FMC between N (3.1 ug/mL) and T (10.3 ug/mL), but no significant difference was confirmed in other items. In peak group, the significance was lower than trough group.

Conclusions: This study suggested that PT-INR, RITG and FMC were useful tool for understanding anticoagulant effect during oral anti Xa DOACs treatment. Especially, FMC measuring at trough might be a marker to judge thrombotic tendency, and also RITG measuring at trough might judge bleeding and thrombotic tendency.

PB 495 | Adherence to Rivaroxaban for the Management of Acute Venous Thromboembolism (VTE) - Early Results from the ‚Follow-up in Rivaroxaban Patients in Setting of Thromboembolism' (FIRST) Registry

V. Speed[1], V. Auyeung[2], J. Patel[3], L. Roberts[3], J. Czuprynska[3], J. Samuel[3], R. Patel[3], R. Arya[3]

[1]King's College Hospital, London, United Kingdom, [2]Institute of Pharmaceutical Science, King's College London, London, United Kingdom, [3]Kings College Hospital, London, United Kingdom

Background: Medication non- adherence is a global public health concern with 30-50% of medicines not taken as recommended. Those prescribing anticoagulants must consider these concerns with the

TABLE 1 Adherence screening questionnaire results from the FIRST Registry

Adherence Screening Questionnaire	1 month n= 95/104	End of treatment n= 102/104	p Value
Morisky Score - Mean (/4) (Only patients who answered all 4 questions included)	3.78	3.76	NS
	1 month questionnaire	End of treatment questionnaire	
Adherence Screening Questionnaire (Questions regarding patient beliefs taken from 16-item screening tool)	Responded no	Responded no	p Value
Do you feel that you need to take your rivaroxaban regularly? n (%)	1 (1)	7 (7)	≤ 0.05
When you feel better do you sometimes stop taking your rivaroxaban? n (%)	104 (99)	100 (95)	≤ 0.05
Do you only take your rivaroxaban when you feel you need to? n (%)	101 (96)	103 (98)	NS
Sometimes if you feel worse when you take your rivaroxaban, do you stop taking it? n (%)	104 (99)	104 (99)	NS
Sometimes do you stop taking your rivaroxaban so your body can take a break from its effects? n (%)	102 (97)	102 (97)	NS
Are you careless at times about taking your rivaroxaban? n (%)	92 (88)	98 (93)	NS

increased use of the direct oral anticoagulants, which require less clinician patient interface.

Aims: To evaluate patients adherence to rivaroxaban at the start and at the end of treatment for the management of acute VTE, and explore what factors cause patients concern about their treatment with rivaroxaban.

Methods: FIRST is a non-interventional, investigator led, multicentre registry investigating the incidence of long-term complications of VTE treated with rivaroxaban without bridging heparin in routine practice. Following written informed consent patients were administered an adherence screening questionnaire (16 items), including the 4-item Morisky Medication Adherence Scale, 1 month into rivaroxaban treatment and at the end of treatment.

Results: To date, 14 UK hospitals have recruited 600 patients. Results from the first 298 patients recruited and who have completed their treatment are presented. Reassuringly, results suggest that adherence to rivaroxaban is very high during the first month and does not decrease with time (Table 1). Whilst a quarter of patients reported being worried or concerned about their treatment, 29% at 1 month and 32% at the end of treatment, this did not impact on overall adherence. Most were worried about side-effects (25%) and the long-term effects rivaroxaban may have, with the latter increasing with time (11% versus 18% NS).

Conclusions: Adherence to rivaroxaban is high during the acute management of VTE, although we did find that some patient's beliefs about taking rivaroxaban, did change between one month and the end of treatment. Further results from FIRST will provide valuable information about these beliefs and their relationship with adherence, particularly when rivaroxaban is prescribed long-term during the secondary prevention phase.

PB 496 | Level of Fatigue after Initiation of Rivaroxaban for Treatment of Venous Thromboembolism

T.M. Karlsvik[1], K.K. Utne[1,2], T.L. Borgenvik[1], E. Førsund[1], C. Jørgensen[1], W. Ghanima[1,2]

[1]*Ostfold Hospital Trust, Department of Hematology, Grålum, Norway,* [2]*University of Oslo, Institute of Clinical Medicine, Oslo, Norway*

Background: Rivaroxaban, a direct oral Factor Xa inhibitor, was the first direct oral anticoagulant approved for treatment of venous thromboembolism (VTE). Clinical trials showed that rivaroxaban was non-inferior to conventional anticoagulation for VTE with regard to efficacy and safety. However, increased fatigue symptoms have been reported by some patients after the initiation of rivaroxaban in routine use, but data on this potential side-effect is currently non-existing.

Aims: The aim of this study was to assess fatigue levels before, during and after treatment with rivaroxaban.

Methods: Consecutive patients were recruited from the thrombosis clinic of Østfold Hospital, Norway after a diagnosis of VTE. Fatigue was assessed with the Fatigue Questionnaire (FQ), consisting of 11 questions with scores from 0 to 3 (Higher scores=higher level of fatigue). The FQ consists of 2 subdimensions (physical and mental fatigue), as well as a total sum score (total fatigue). Fatigue measurement was performed at baseline, after 3 weeks of treatment and 1 month after the discontinuation of rivaroxaban or at 6 months if treatment was continued beyond 6 months. Data were analyzed using descriptive analyses and the Mann-Whitney test. Ethics committee approved the study and informed consent was acquired from patients.

Results: Median age of 55 patients (35 males) was 57 years; 33 had DVT, 17 pulmonary embolism and 5 had both). Fatigue data from all timepoints were available in 30 patients. Table 1 summarizes the mean dimensional and total fatigue scores during the study period. There was no statistically significant change in physical, mental or total fatigue scores between baseline, 3 weeks and end of treatment or at 6 months.

TABLE 1 Mean (standard deviation) fatigue score for patients receiving rivaroxaban at baseline, 3 weeks and after the end of treatment period

Fatigue score	Baseline	3 weeks	4-6 months
Total fatigue	15.27 (4.21)	14.84 (3.24)	15.20 (4.61)
Physical fatigue	10.89 (3.49)	10.24 (2.71)	10.30 (3.47)
Mental fatigue	4.38 (1.39)	4.60 (1.29)	4.90 (1.61)

Conclusions: In this observational study we found no indication of increased fatigue at 3 weeks as compared to baseline in patients receiving rivaroxaban for VTE. We are, however, limited by small sample size, and further studies are needed to assess this.

PB 497 | The Combination of Rivaroxaban and Dabigatran Is Superior to Either Agent Alone in Suppressing Mechanical Heart Valve-induced Thrombin Generation

I. Jaffer[1], A. Stafford[2], J. Fredenburgh[2], R. Whitlock[3], J. Weitz[4]

[1]*McMaster University and Thrombosis and Atherosclerosis Research Institute, Surgery, Hamilton, Canada,* [2]*McMaster University and Thrombosis and Atherosclerosis Research Institute, Hamilton, Canada,* [3]*McMaster University and Population Health Research Institute, Surgery, Hamilton, Canada,* [4]*McMaster University and Thrombosis and Atherosclerosis Research Institute, Medicine, Biochemistry and Biomedical Sciences, Hamilton, Canada*

Background: Although direct oral anticoagulants (DOACs) are at least as effective as warfarin for stroke prevention in atrial fibrillation and treatment of venous thromboembolism, dabigatran is less effective than warfarin in patients with mechanical heart valves (MHVs). The utility of rivaroxaban in this setting is unknown.

Aims: Compare the capacities of rivaroxaban, dabigatran, or their combination with warfarin to suppress thrombin generation (TG) induced by components of MHVs.

Methods: TG was quantified in the absence or presence of valve leaflets or sewing ring segments (SRS). Studies were done in recalcified

human plasma containing added rivaroxaban and/or dabigatran at concentrations achievable with clinically available dosing regimens, or in plasma from patients on warfarin with varying international normalized ratio (INR) values.

Results: Mean endogenous thrombin potential (ETP) increased by 17%, 80%, and 52% (from a background of 4401 ± 192 nM·min) in the presence of leaflets, Dacron SRS, and Teflon SRS, respectively. At INR values above 2, warfarin reduced ETP below background levels. By contrast, concentrations of rivaroxaban and dabigatran required to reduce ETP to a similar extent as warfarin at an INR of 2 were 86 and 260 ng/mL, respectively; concentrations higher than those measured at trough with the currently approved dosing regimens. Whereas 50 ng/mL rivaroxaban or 100 ng/mL dabigatran on their own had little effect on leaflet induced ETP, when combined, ETP was significantly suppressed.

Conclusions: MHVs induce TG in concentrations that overwhelm dabigatran. Like dabigatran, rivaroxaban is less effective than warfarin in preventing TG in the presence of MHVs. These results suggest rivaroxaban is unlikely to be effective for patients with a MHV. Although rivaroxaban and dabigatran suppress TG induced by MHVs to a greater extent when combined than they do as monotherapy, the safety of such combinations is unknown.

PB 498 | Oral Rivaroxaban for the Treatment of Antiphospholipid Syndrome (APS)

Y. Du, X.-X. Yan, K. Sun, T.-Y. Lian, Z.-C. Jing

Peking Union Medical College and Chinese Academy of Medical Science, Thrombosis and Haemostasis Center, Fuwai Hospital, Beijing, China

Background: Rivaroxaban has been proposed as an effective and safety strategy for venous thromboembolism patients that could prevent symptomatic or fatal recurrence of VTE and prevent the major bleeding. But whether it is useful in patients with antiphospholipid syndrome (APS) is uncertain.

Aims: -

Methods: The historical cohort study in Fu Wai Hospital-The National Center of Cardiovascular Disease included 20 antiphospholipid syndrome patients between March 17, 2014, and June 26, 2016. All of them were treated with Rivaroxaban (15 mg twice daily for 3 weeks, followed by 20 mg once daily). We analysed the baseline characteristics and record recurrence of thrombotic events, Chronic thromboembolic pulmonary hypertension (CTEPH), bleeding event, and all-cause death. The thrombotic events and CTEPH diagnosis were confirmed by available clinical, laboratory, and imaging findings.

Results: Of 20 APS patients, 7 (35%) male and 13 female with 42 years old (15-84) as the median of age and the eldest was 84 years old. For the first thromboembolic event, 11(55%) were pulmonary embolism (PE), 8(40%) were deep venous thrombosis, 1(5%) were coronary heart disease. The median treatment time of Rivaroxaban is 14.5 months. During the follow-up, recurrence of thrombotic events was recorded in 4 patients (20%, 3 patients recur PE at the 6, 7 and 21 month respectively during the treatment of Rivaroxaban, 1 patient occur left atrial thrombus at the 22 month). 2 (10%) patients were confirmed as CTEPH during the long term follow up. 1(5%) patient occur major bleeding (hemoptysis), 5(25%) patients occurred non-major bleeding. No death occurred.

Conclusions: Patients with antiphospholipid syndrome (APS) is likely to happened recurrence thrombotic events, in our study, with the treatment of Rivaroxaban the thrombotic events recurrence rate was 20%, with only 1(5%) major bleeding happened. A fixed-dose regimen of rivaroxaban alone for the treatment of antiphospholipid syndrome (APS) had a potentially improved benefit-risk profile.

PB 499 | Improving Appropriate Use of NOACs: Success of Online CME

J. Spyropoulos[1], J. Marko[1], A. Spyropoulos[2]

[1]Medscape LLC, New York, United States, [2]Northwell Health, Medicine, New York, United States

Background: Anticoagulant therapy is often not appropriately initiated in patients with venous thromboembolism (VTE), resulting in poor patient outcomes.

Aims: To determine if an online continuing medical education (CME) intervention could improve knowledge and competence of cardiologists and hematologists/oncologists (hem/oncs) regarding appropriate use of non-vitamin K oral anticoagulants (NOACs).

Methods: An online CME activity was developed as a 15-minute video-based discussion on appropriate initiation of NOAC therapy in the setting of VTE. The effects of education were assessed using a linked pre-/post-assessment study design. For all questions combined, the McNemar's chi-square test was used to assess differences from pre- to post-assessment. P values are shown as a measure of significance; P values < .05 are statistically significant. Cramer's V was used to calculate the effect size (> 0.3 are large, 0.16-0.3 are medium, and < 0.16 are small).

Results: Comparisons of individually linked pre-assessment question responses to the respective post-assessment responses demonstrated statistically significant improvements for cardiologists (N = 31; P < .05; V=0.243) and hem/oncs (N=48; P< .05; V=0.186). An average of 42% of cardiologists and 47% of hem/oncs selected the best response on pre-assessment, which rose to an average of 67% on post-assessment for both specialty groups. Statistically significant relative improvements were observed (all P< .05):

A 74% improvement among hem/oncs (31% vs 54%) and a 72% improvement among cardiologists (32% vs 55%) in knowledge of strategies to improve adherence to NOAC therapy

A 55% improvement (42% vs 65%) among hem/oncs (42% vs 65%) in recognition of dosing regimens for the different NOACs

A 103% improvement for cardiologists (32% vs 65%) in selection of effective strategies to improve adherence to NOAC therapy

Conclusions: The significant improvements observed in this intervention demonstrate the benefits of using effective online CME to educate appropriate target audiences.

PB 500 | Influence of Anthropometric, Hematological and Biochemical Parameters on Plasma Levels of Direct Oral Anticoagulants

S. Lancellotti, M. Sacco, E. De Candia, R. De Cristofaro

Catholic University of the Sacred Heart School of Medicine, Institute of Internal Medicine, Department of Hematology-Oncology, Roma, Italy

Background: Direct oral anticoagulants (DOACs) were developed to overcome the limitations of the previous standard therapeutic approach with vitamin K antagonists. However, the influence of anthropometric biochemical and hematological parameters on levels of DOACs was investigated only in part.

Aims: The aim of this study concerns the influence of anthropometric, biochemical and hematological parameters on the plasma level of different DOACs.

Methods: Globally, 141 patients (M:F=60:81; median age= 76.5, IQR: 69-82) were studied: 21 on dabigatran (DBT), 66 on rivaroxaban (RVX) and 54 on apixaban (APX) therapy for AF and VTE. The dose and the precise time elapsed after dosing were recorded in all cases. PT, APTT, fibrinogen, blood count, hematocrit (Htc), AST, ALT and creatinine with BMI were also measured in all patients. Plasma level of DBT, RVX and APX was measured using a liquid anti-Xa assays on a STA Compact Max® instrument (Diagnostica Stago). Statistical analysis was performed with SPSS (v. 21) software.

Results: DBT concentration did not show any significant correlation with the above hematological, biochemical and anthropometric factors in univariate analysis. RVX showed an inverse correlation with the time elapsed after dosing (ρ= -0.751, p< 0.001), which remained also in multivariable regression analysis (p< 0.001 and p=0.028, respectively). Finally, APX level was inversely associated in bivariate non-parametric analysis only with Htc and Hb levels (ρ= -0.643, p= 0.018 and ρ= -0.637, p= 0.019, respectively). In multivariable analysis only Hb was inversely correlated with APX concentration
(ρ= -0.476, p=0.029).

Conclusions: These results showed that: a) DBT, RVX and APX can be safely prescribed in adult patients of any BMI ranging from 23 to 38; b) APX shows a strong negative correlation with Hb and Htc level, so that APX concentration increases by about 20 ng/ml as a function of a Hb decrease of about 1gr/dl and vice versa. Hence, Hb level should not be ignored when APX is prescribed.

PB 501 | Non Vitamin-k Oral Anticoagulants (NOAC) Dose Reduction and Adverse Outcomes - A Single Center Experience

A. Lubetsky[1,2], M. Misgav[3], S. Lalezari[3], J. Luboshitz[3], O. Salomon[4], G. Kenet[4]

[1]Institution of Thrombosis and Hemostasis, Sheba Medical Center, Tel Hashomer, Israel, [2]Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel, [3]Sheba Medical Center, Institute of Thrombosis and Hemostasis, Tel Hashomer, Israel, [4]Sheba Medical Center, Thrombosis and Hemostasis Unit, Ramat Gan, Israel

Background: NOACs have become the mainstay of therapy for patients with atrial fibrillation (AF) and venous thromboembolism (VTE). However, recommended doses are frequently reduced due to safety concerns leading potentially to reduced effectiveness and safety.

Aims: We aimed to test the effect of NOAC dose administered on effectiveness and safety in a cohort of consecutive patients admitted to our center due to recurrent thrombosis or major bleeding events.

Methods: Consecutive patients treated with either dabigatran, rivaroxaban or apixaban for atrial fibrillation or venous thromboembolism presenting to the ER with major bleeding or thrombotic episode (arterial or venous) between 01/01/2016 - 31/12/2016 formulated the study group. For each patient detailed medical and drug history, drug compliance, base line blood tests and NOAC blood level were carefully assessed. Adverse thrombotic and bleeding episodes were then related to NOAC doses. Dose reduction was considered adequate if 2/3 criteria (age>75, weight < 55 kg, CCT < 50 ml/m) were present.

Results: Thirty nine patients (23 M) with a mean age of 74 ± 14 were admitted during 2016 to various hospital wards because of thrombotic or bleeding events. Of the patients admitted 20 received apixaban (7 with reduced dose), 16 patients received rivaroxaban (5 reduced dose) and 3 patients received dabigatran (1 reduced dose). All 13 dose reductions were considered unjustified. In patients receiving adequate NOAC dose 15/26 (58%) and 11/26 (42%) had a thrombosis or bleeding episode, respectively, while most of the patients with reduced dose (11/13, 85%) had a thrombotic episode and 2/13 (15%) a bleeding episode (P=0.09).

Conclusions: In patients with AF or VTE treated with NOACs unjustified dose reductions was associated with increased rate of thrombosis. Dose reduction should be carefully assessed in these patients.

PB 502 | Reversal of Rivaroxaban Using Prothromplex Total, a 4-Factor Prothrombin Complex

H. Kaur[1], S.H. Yeang[2], E. See[2], D. Grant[1], C.W. Tan[1], W.H. Wong[1], D. Tan[1], H.J. Ng[1], L.H. Lee[1]

[1]Singapore General Hospital, Department of Haematology, Singapore, Singapore, [2]Singapore General Hospital, Department of Pharmacy, Singapore, Singapore

Background: The absence of approved specific antidote for reversal of rivaroxaban means that life-threatening bleeding events or reversal for emergency procedures are currently managed with 4-factor prothrombin complex (4F-PCC) in our hospital. A number of commercial preparations exist with variations in contents and limited data on individual efficacy.

Aims: To describe and review the efficacy and safety of a 4-factor prothrombin complex (4F-PCC) (Prothromplex Total, Shire) in reversing rivaroxaban in a series of patients.

Methods: Requests for 4F-PCC to reverse rivaroxaban were screened by haematologists and used as triggers to identify subjects over a 2-year period. Progress and outcomes data were then prospectively collected for analysis.

TABLE 1 Patient Characteristics

Patient	#1	#2	#3	#4	#5	#6	#7	#8
Age/sex	81/Female	81/Male	82/Female	65/Male	76/Female	80/Male	66/Female	64/Female
Creatinine clearance (ml/min)	54	65	36	NA	26	53	105	33
Rivaroxaban dose (mg/day)	15	20	15	20	15	15	20	15
Indication for anticoagulation	Atrial fibrillation	Atrial fibrillation	Atrial fibrillation	Atrial fibrillation	Atrial fibrillation	Atrial flutter	Deep vein thrombosis	Atrial flutter
Indication for reversal	Right frontal intra-parenchymal haematoma	Sub-dural haematoma	Sub-arachnoid haematoma	Haemopericardium, post-coronary angiogram	Urgent percutaneous nephrostomy	Basal ganglia haematoma	Tracheostomy Bleed	Massive Hemoptysis
Dose of 4F-PCC (U/kg)	40	47	46	49	30	45	40	66
Prothrombin Time (PT) (seconds) before 4F-PCC	11.4	14.3	19.2	NA	11.7	15.2	17.6	16.9
PT after 4F-PCC	10.5	10.5	12.2	NA	NA	NA	11.9	17.1
Bleeding post infusion	No	Yes (4 days later)	No	No	No	No	No	Yes

Results: Eight patients were given Prothromplex to reverse life-threatening bleed or for urgent procedure. Seven patients were on rivaroxaban for atrial fibrillation/flutter with one for deep vein thrombosis. The indications for reversal were intracranial haemorrhage (ICH)(n=4), haemopericardium post coronary angiogram(n=1), massive hemoptysis(n=1), tracheostomy bleed (n=1) and urgent percutaneous nephrostomy(n=1). Six patients received a single dose of Prothromplex 50 iu/kg rounded to the nearest vial (range 40-49 iu/kg). The patients undergoing percutaneous nephrostomy and massive hemoptysis received 30 iu/kg and 65 iu/kg respectively. There were two mortalities from septic shock (the patient with hemoptysis) and ICH. The first death was unrelated to bleeding while the second was contributed by delayed therapy. Prothromplex effectively controlled bleeding in 6 of 8 patients. There were no thrombotic events.

Conclusions: This data supports the utility of Prothromplex in the management of the majority of patients on rivaroxaban who suffer life-threatening bleeding episodes or require urgent interventional procedures. 50 iu/kg appears efficacious and safe although higher optimal dosing has not been ascertained.

PB 503 | Similar Rivaroxaban Plasma Concentrations Induce Different Anticoagulant Effects in Individual Obese Patients

D. Bertaggia Calderara[1], D. Kröll[2], C. Gerschheimer[1], N. Nicolas[1], G. Stirnimann[2], L. Alberio[1]

[1]*CHUV, University Hospital and Univeristy of Lausanne, Department of Hematology, Lausanne, Switzerland,* [2]*Inselspital, Bern University Hospital, and University of Bern, Department of Visceral Surgery and Medicine, Bern, Switzerland*

Background: Rivaroxaban (RVX), a direct inhibitor of factor Xa, has been developed to bypass the traditional anticoagulant limitations. RVX has predictable pharmacokinetics and pharmacodynamics, thus, there is no need for laboratory monitoring. However the "one dose fits all" concept based on randomized clinical trials might not be always adequate for individual patients in clinical practice.

Aims: To asses thrombin generation (TG) and spatial clot growth (SCG) at similar plasma concentration of RVX in:

1. different obese patients before bariatric surgery.
2. individual patients before and after surgery.

Methods: Citrate blood was collected during 24 hours from obese patients receiving a single dose of RVX (10 mg) before bariatric surgery

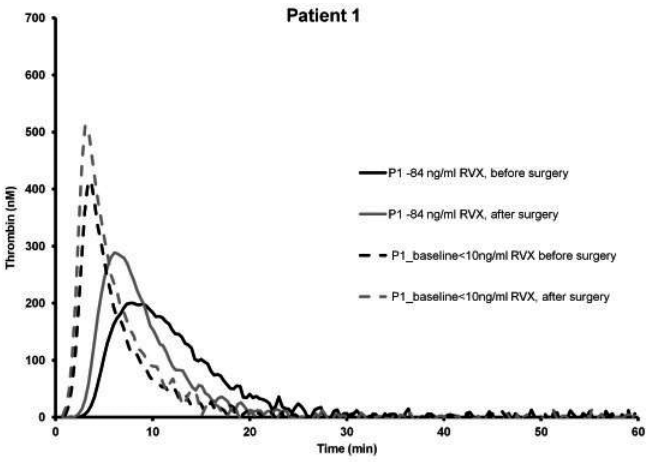

FIGURE 1 Thrombin generation profiles of Patient 1 before and after bariatric surgery

and on the third postoperative day. RVX plasma concentration was quantified with an anti-Xa chromogenic assay. RVX anticoagulant effect was assessed *ex-vivo* by monitoring tissue factor induced TG in platelet-poor-plasma (PPP) with calibrated automated thrombogram (CAT). TG and SCG were recorded with Thrombodynamics analyzer.

Results: Despite similar RVX-concentrations, patient TG and SCG profiles significantly differed. Large inter- and intra-individual variations were observed among patients (Figure 1).

At similar RVX concentrations, patients had higher thrombotic profiles after surgery. Despite RVX, spontaneous clots appeared in patient's plasma.

Conclusions: Obese patients show, in response to similar concentrations of RVX, inter-individual and intra-individual differences in TG inhibition. These differences reflect the variable anticoagulant effect in each individual. High prothrombotic tendency in individual obese patients is suggested by Thrombodynamics assay. The lower TG inhibition and increased SCG observed for the same patient after surgery might indicate that the preoperative RVX dose is less effective in providing a good prophylactic anticoagulation.

PB 504 | Reversal of Dabigatran in Emergency Situations

A. Fernandez, T. Arias, J. Zanabili

HUCA, Hematology, Oviedo, Spain

Background: In 2015, the Reverse AD study, a phase III trial that evaluated the efficacy and safety of Idarucizumab as a specific agent for the reversal of Dabigatran, were published. There is still little data on the use of Idarucizumab in real life.

Aims:

Methods: We retrospectively reviewed the patients who received Idarucizumab for the reversal of Dabigatran at our center to date.

Results: Case 1: Male of 81 years old, traumatic brain injury on August 3, 2016. HTA. Sigma adenocarcinoma pT3N0 (year 2012) Hepatic recurrence in (2015). Atrial flutter CHA2DS2Vasc 3, anticoagulated with Dabigatran 110mg c / 12h, last dose of Pradaxa at 14 h before. Weight 66.8 Kg. Normal neurological examination. Tests: EGF 80.9 ml / min, Coagulation: TP 11.8 sec, TTPa 29.7 sec. Ethanol in plasma 267 mg / dl. Anti-IIa (performed on the following day using admission sample) 8.87 ng / ml (28-155ng / ml) Cranial CT scan: Haemorrhage of 5 mm in right semioval center. An urgent reversal is performed with Idarucizumab 5 g and observation 36 h with good evolution.

Case 2: Male 65 years old, Hypertension. Atrial fibrillation and non-obstructive hypertrophic cardiomyopathy (MYBPC3 mutation Y749 C). Anticoagulated with Pradaxa 150 mg / 12 hours. Work accident: section of the deep flexor tendon of the 5th finger, of the superficial flexor tendon of the 5th finger and of the ulnar collateral nerve of the 5th finger. Requires urgent surgery. Last intake of dabigatran (21:00 hours of the previous day, 14 hours before). Weight 74kg. Test: Coagulation: TP 15.1 sec, TTPa 43.70 sec (R 1.46) Anti-IIa: 91.87 ng / ml (39.8-74.3 ng / ml) FGE: 59 mL / min. Idarucizumab was administered prior to surgery that was performed without incident and restart Pradaxa at 24 h.

Conclusions: Few cases of use of Idarucizumab in real life have been published. In our experience the treatment has been proven effective and safe. The anti-IIa measurement is not available in most centers. The use of Idarucizumab can be oriented with data from the coagulation study.

PB 505 | Can we Successfully Reverse a "Massive Overdose" of Dabigatran?

I. Freire, T. Gago, A.P. Azevedo

Centro Hospitalar de Lisboa Ocidental, Hemostasis, Lisboa (Lisbon), Portugal

Background: Dabigatran (Dab) is used in clinical practice for stroke prevention in atrial fibrillation. Specific antidotes for these new drugs are still under development. Idarucizumab is already approved by FDA in clinical practice as Dab inhibitor. Are the recommended doses enough to reverse the anticoagulant effect and clotting assays?

Aims: Present a clinical case where the recommended doses for Idarucizumab weren't enough for reversing the anticoagulant effect, and question if the results of RELY- ABLE and RE-VERSE AD trials cover overdoses of Dabigatran such as > 1000 ng/mL.

Methods: Clinical Case

Results: A 76 y/o female with clinical history of Pott's disease, hypertension, diverticulosis, iron deficiency *anemia*, atrial fibrillation (AF) medicated with Dab (110mg), was admitted at emergency care with vomits, nausea, melena, diffuse abdominal pain and no other relevant symptoms. Hgb-12.1g/dL, Leu-19x10^9/L (Neu-17x10^9), Plt-307x10^9/L, RPC-0.8mg/dL, aPTT>120", INR-8, eGFR-CKD-EPI=28 and normal liver function. Later she developed hypotension with renal function deterioration and active digestive bleeding, evolving to hypovolemic shock. Clotting assays revealed an aPTT and Thrombin Time > 120" and a diluted Thrombin Time (dTT) of 3374ng/mL. Clinical deterioration provoked her death on the 4th day. Although Idarucizumab administration, Dab levels were persistently high (1219ng/mL). The autopsy revealed that hypovolemic shock by a massive gastro-intestinal bleeding was the cause of death.

During hospitalization, besides Dab's withdraw, the therapy given was 4U PCC, 2 FFP and a pool of platelets, 5g Fbg, 2U rFVIIa and 2x5g Idarucizumab.

Conclusions: Two doses of Idarucizumab were not efficient on clinical outcome and did not reverse the clotting assays. Are we far from the ideal antidote? Is Idarucizumab able to reverse Dab's effect at a 1:1 stoichiometric ratio as known? Which Dab levels were assayed on trials? For ethical reasons managing massive overdose is limited on trials.

PB 506 | Routine Coagulation Tests for Assess Anticoagulant Activity of Direct Oral Anticoagulants

H. Cruz Gomes, L. Gonçalves, C. Monteiro, V. Cunha, M. Carvalho, C. Koch

Centro Hospitalar São João, Centre of Thrombosis and Hemostasis, Porto, Portugal

Background: Direct oral anticoagulants (DOACs) do not require routine monitoring, however, in certain clinical situations assessment of anticoagulant activity may be important. Assays for quantification of DOACs are not available in most hospitals. It is important to evaluate locally if routine coagulation tests, prothrombin time (PT) or activated partial thromboplastin time (aPTT) can be used to assess DOAC anticoagulation.
Aims: Assess the sensitivity of PT and aPTT to different DOACs, correlating the results with quantitative assays: ecarin chromogenic assay (ECA) for dabigatran and specific anti-Xa for apixaban and rivaroxaban.
Methods: Blood samples were collected from 72 patients under dabigatran, 25 under apixaban and 39 under rivaroxaban, admitted to our hospital.
For each sample a quantitative assay (ECA or specific anti-Xa), PT and aPTT were performed.
Results for each qualitative assay were correlated with plasma drug levels and the ‚misprediction percentage' (MP), that represents how often the coagulation test values were in the normal reference range while the drug concentration was in or above the therapeutic range, was calculated.
Results: We found the strongest correlation and the lowest MP with Dabigatran (aPTT: R^2=0,615, MP=6,0%; PT: R^2=0,519, MP=23,9%).
At higher levels of Dabigatran (ECA>260ng/mL), all samples showed aPTT and PT values above reference ranges. Under 260ng/mL, PT values were very variable but aPTT remained above reference range as of 57 patients with ECA>50ng/mL, only 1 presented normal aPTT.
Correlation between routine coagulation tests and Apixaban were not as strong as with Dabigatran (aPTT: R^2=0,382, MP=36,4%; PT: R^2=0,470, MP=40,9%).
The weakest correlations and highest MPs were found in Rivaroxaban samples (aPTT: R^2=0,205, MP=71,9%; PT: R^2=0,375, MP=65,6%).
Conclusions: Routine coagulation tests not always show the same ability to quantify drug effect as described in literature. These assays are generally insufficient for measuring Xa inhibitors activity.

PB 507 | Direct Oral Anticoagulants in the Treatment of Deep Vein Thrombosis: The Experience of a Hemostasis Unit

E. Papadakis[1], N. Petridis[2], A. Banti[1], V. Papadopoulos[3], S. Efremidou[3], A. Kioumi[3]

[1]Papageorgiou Hospital, Hemostasis Unit, Thessaloniki, Greece, [2]Papanikolaou General Hospital, Internal Medicine, Thessaloniki, Greece, [3]Papageorgiou Hospital, Hematology, Thessaloniki, Greece

Background: Direct Oral Anticoagulants (DOACs) are novel therapeutic agents for DVT. According to their clinical trials they are superior to AVK anticoagulants concerning safety and bleeding risk.
Aims: The objective is to present our clinical experience in the treatment of DVT with DOACs, regarding effectiveness, side effects, bleeding risk and post-thrombotic syndrome.
Methods: For a period of 47 months (2012-2016), 102 (50 male, 52 female) patients with median age 47 years (17-78), with a VTE diagnosis and indication for *indefinitetreatment* were assessed. They were treated with DOACs (rivaroxaban, dabigatran, apixaban) for a median treatment duration of 17 months (7-47). The study included patients who were anticoagulant naive and patients who had previously used a coumadin anticoagulant. Effectiveness and side effects of the treatment were assessed. Additionally, major and minor bleeding and the course of the post-thrombotic syndrome were evaluated using the 2015 ISTH bleeding definition recommendations and the Villalta score respectively.
Results: One patient presented acute coronary syndrome (0,98%). No patient experienced a recurrent VTE episode, 6 patients had minor bleeding (5,88%) and 2 developed major bleeding without fatal outcome. One patient complained of pruritus (0,98%) and one of headaches (0,98%), symptoms which were attributed to DOACs. The treatment had no effect in the vast majority of the patients (97,1%) regarding the post thrombotic syndrome. 5 patients had an aggravation of the post thrombotic syndrome (4,9%), of whom 4 had their treatment discontinued.
Conclusions: DOACs are the drug of choice for the treatment of DVT. The clinical experience of the Hemostasis Unit is consistent with the results of the clinical trials regarding their effectiveness and safety. Nevertheless, long-term clinical experience is required in order to establish these conclusions.

PB 508 | Reversal of Dabigatran with Idarucizumab in Five Patients Admitted to the Emergency Department of Centro Hospitalar São João, Porto

L. Gonçalves, M. Carvalho, F. Correia, G. Oliveira, C. Koch

Centro Hospitalar São João, Centre of Thrombosis and Hemostasis, Porto, Portugal

Background: Urgent reversal of direct oral anticoagulants (DOACs) is important when facing severe bleeding or emergency surgery. Idarucizumab, the specific reversal agent of dabigatran, is the only antidote for DOACs approved and available so far.
Aims: Presentation of 5 patients under dabigatran who needed urgent reversal with idarucizumab. Evaluation of anticoagulation parameters.
Methods: Five patients under dabigatran were admitted to emergency department. Three patients with severe bleeding events: 2 with intracraneal hemorrhages (ICH) after trauma, 1 with gastrointestinal bleeding (GIH) associated to angiodysplasia, anemia. Two patients needed urgent invasive procedures:
1 with sepsis needing an urological procedure, 1 with a severe compartment syndrome secondary to infection in the right arm. At admission all patients had prolonged activated partial thromboplastin time (aPTT) (>39 sec; N: 24,2-36,4 sec) and dabigatran concentrations within or above therapeutic range (>80 ng/ml), determined by ecarin chromogenic assay (ECA). Idarucizumab was administered: 2.5 g infusion, followed by 2.5 g 10 minutes later. ECA and aPTT were performed after the first and second vial.
Results: In blood samples collected 5 min after the first vial of idarucizumab, dabigatran concentration was not detectable (< 15 ng/mL

- detection limit of ECA) and aPTT was normal in all patients. Results were similar after the second vial. Patients with ICH completely recovered; dabigatran was restarted 2 weeks later. The patient with GIH did not need any further blood transfusion; anticoagulation was not restarted. Hemostasis was normal in the 2 patients submitted to invasive procedures; one patient died within 24 h due to her clinical condition.

Conclusions: Idarucizumab successfully reversed dabigatran effect in 5 patients. Our findings suggest the possibility of using a lower dose (2,5 g) of idarucizumab in selected patients (normal renal function and therapeutic concentrations of dabigatran) leading to a more cost-effective therapy.

PB 509 | Do All Patients Respond to Treatment with Direct Oral Anticoagulants?

J. Janukonyte, D. Svenstrup Moeller, G. Dahlmann Oddershede, J. Refsgaard

Viborg Regional Hospital, Viborg, Denmark

Background: Use of direct oral anticoagulants (DOACs) is increasing due to a wide therapeutic window, no requirements for laboratory monitoring and stable anticoagulation. Other advantages are little drug and dietary interaction, low bleeding rate and good compliance. However, variation of pharmacokinetic profiles, safety and efficacy still are important issues to be explored.

Aims: To present clinical cases, where a new thrombosis was diagnosed during the treatment with DOACs.

Methods: Review of medical records.

Results: Seven patients (4 women and 3 men, age 61-82 years, body mass index 25,3-39,9 kg/m^2) from our Patient Clinic of Department of Cardiology were included. Inclusion criteria: New thrombosis during treatment with DOACs and good compliance regarding intake of medicine. The patients were treated with standard dose of Rivaroxaban (5) and Apixaban (1). One patient initially was treated with Rivaroxaban and later with Apixaban. Their primary diagnosis was pulmonary embolism (PE) (5) or combination of deep vein thrombosis (DVT) and PE (2). Unprovoked thromboembolic event (TE) was seen in 2 patients and provoked in 5. Risk factors were: Surgery/immobilization, infection, atrial fibrillation and congenital thrombophilia. Thrombophilia testing was performed in 2 patients. Testing results were normal in one patient, whilst other patient had a combination of a heterozygous factor II and V gen mutation. All patients had normal liver function. 4 patients had normal (> 60 ml/min) estimated glomerular filtration rate (eGFR) , 2 patients had eGFR > 90 ml/min and one 58-60 ml/min. All patients were treated with DOAC as recommended at the time they were diagnosed with a new TE. No patients were treated with the drugs, which potentially could interact with DOACs.

Conclusions: Little is known about treatment failure of DOACs. Further clinical studies of different population, i.e obese, multimorbid patients and new possible mechanisms influencing action of DOACs could shed more light on DOAC's efficacy.

PB 510 | Measurement of Direct Factor Inhibitors Concentration in Practice Laboratory

T. Vavilova, A. Bekoeva, P. Zubkova, Y. Skorobogatova, I. Yurinok, E. Vasilieva

Federal Almazov North-West Medical Research Centre, Saint Petersburg, Russian Federation

Background: Direct coagulation factors inhibitors or new oral anticoagulants are include in modern recommendations and widely use in prevention and treatment of thromboembolic events in fixed doses. But the problem of objective assessment of individual action by laboratory methods in clinical practice is not solved.

Aims: To validate the dabigatran (Dabi) and rivaroxaban (Riva) concentration measurement on the base of diluted thrombin time and ati-Xa activity in practice laboratory.

Methods: 50 patients with non valvular atrial fibrillation - 10 patients received dabigatran (68 [60; 74] years old, in dose 150 mg bid and 40 patients received rivarixaban 20 mg od, 72 [65; 76] years old. Quik test (PT) and aPTT screening tests (STA Compact, Stago reagents) as well as diluted thrombin time (Hemoclot Thrombin Inhibitors) and anti-Xa activity (Biophen DiXaI), both HYPHEN BioMed, using Sysmex CS-2000i automated analyzer were measured 3 times per day - final concentration (FC, before 1-st dose), peak concentration (PC, 4 hours after drug intake) and through concentration (TC, 8 hours after intake).

Results: Prolongation of aPTT in Dabi was max at PC and TC points (x1,3-1,7 control values) on the background of considerably different concentrations from 8,5 to 165,0 ng/ml (min in FC, max in PC points). In Riva group aPTT was unexpectedly prolonged in PC point (x1,4), Quick test in PC point - 53,6±21,7%. Riva concentration in FC, PC and TC - 67,9±50,6 ng/ml, 235,7±101,3 ng/ml and 182,6±108,1 ng/ml, respectively. There were not major hemorrhages, but 10% minor bleedings in Dabi and 15% - in Riva group without correlation with PC or TC, probably because of small number of observation.

Conclusions: Anti-Xa activity and Hemoclot Thrombin Inhibitors measurement by HYPHEN BioMed Kits is simple and repeatable laboratory assay and may be validated in routine laboratory for emergency situations in patients, receiving direct factors inhibitors.

PB 1000 | The Prevalence of Concomitant Deep Vein Thrombosis, Symptomatic or Asymptomatic, in the Patients with Symptomatic Pulmonary Embolism

J. Hirmerova[1], J. Seidlerova[1], Z. Chudacek[2]

[1]*Faculty of Medicine in Pilsen, Charles University, 2nd Department of Internal Medicine, Pilsen, Czech Republic,* [2]*First Faculty of Medicine Charles University and General University Hospital in Prague, Department of Radiology, Prague, Czech Republic*

Background: The reported prevalence of concomitant deep vein thrombosis (DVT) in patients with pulmonary embolism (PE) is very

variable and the utility of routine venous compression ultrasound (CUS) is controversial.

Aims: To evaluate the prevalence of DVT in patients with symptomatic PE and to identify factors associated with the presence of DVT and with the symptomatic/asymptomatic character of DVT.

Methods: We conducted a single center retrospective study of prospectively collected data, including consecutive adult patients with objectively confirmed PE. The patients underwent clinical examination, complete CUS of both legs and were asked about medical history and risk factors for venous thromboembolism (VTE). For statistical analysis we used the t test and the chi-squared test.

Results: Of 428 patients with symptomatic PE (mean age 59±16.4 years; 52.3% men), DVT was found in 302 cases (70.6%), and proximal DVT in 202 (49.5%). Men had concomitant DVT significantly more often than women (79.5% versus 60.8%, P=0.02). DVT was asymptomatic in 173 patients (sensitivity of DVT symptoms 42.7%, specifity 93.7%). Patients with symptomatic DVT (compared to asymptomatic) were significantly younger (54.2 vs. 64.4 years, P< 0.0001) and had proximal location more frequently (78.3% vs. 64.2%, P=0.01). None of further considered factors (obesity, history of previous VTE, smoking, various risk factors) was associated with the presence/absence of symptomatic/asymptomatic DVT.

Conclusions: In patients with PE, the prevalence of concomitant DVT is quite high but clinical diagnosis is unreliable. In our group, the prevalence of concomitant DVT was significantly higher in men. Symptoms of DVT were more often present in younger patients or if thrombosis was proximal. Venous CUS may be helpful in PE diagnostic process, in risk stratification of PE or, potentially, for timely prevention of post-thrombotic syndrome. Criteria for proper ordering CUS in PE patients deserve further studies.

PB 1001 | Predicting Post-thrombotic Syndrome with Ultrasonographic Measurements after Proximal Deep Vein Thrombosis

C.E.A. Dronkers[1], G.C. Mol[2], G. Maraziti[3], M.A. van de Ree[4], M.V. Huisman[1], C. Becattini[3], F.A. Klok[1]

[1]Leiden University Medical Center, Department of Thrombosis and Hemostasis, Leiden, The Netherlands, [2]Meander Medical Center, Department of Internal and Vascular Medicine, Amersfoort, The Netherlands, [3]University of Perugia, Internal and Cardiovascular Medicine-Stroke Unit, Perugia, Italy, [4]Diakonessenhuis, Department of Internal Medicine, Utrecht, The Netherlands

Background: Post-Thrombotic syndrome (PTS) is a common and potential severe complication of deep venous thrombosis (DVT). Elastic compression stocking therapy may prevent PTS if worn on a daily basis, but stockings are cumbersome to apply and uncomfortable to wear. Hence, identification of predictors of PTS may help physicians to target PTS prevention in those patients with a high risk of PTS.

Aims: To identify ultrasonographic (US) parameters assessed during or after treatment of DVT of the leg, that predict post thrombotic syndrome.

Methods: Systematic review and meta-analysis. Databases were searched for prospective studies including consecutive patients with

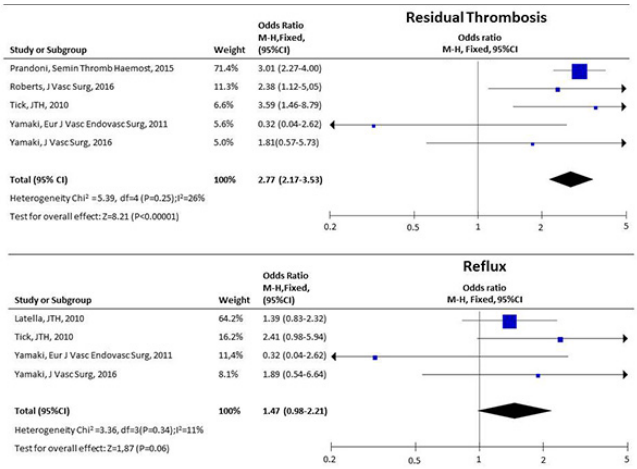

FIGURE 1 Forrest plot

DVT who received standardized treatment, had an ultrasonography during follow-up assessing findings consistent with vascular damage after DVT, and had a follow-up period of at least 6 months for the occurrence of PTS assessed by a standardized protocol.

Results: The literature search revealed 1156 studies of which 1068 were irrelevant after title and abstract screening by 2 independent reviewers. After full text screening of 88 studies, 6 relevant studies were included, with a total of 1550 analysed patients. All studies used different time points for US measurement with a range of 6 weeks to 6 months after DVT. The Villalta score or CEAP score were used for diagnosing PTS at 11 months to 6 years after DVT. Two US parameters proved to be predictive of PTS: reflux (retrograde flow >1 second after compression), for a pooled odds ratio (OR) of 1.5 (95%CI 0.98-2.2; figure 1); positive likelihood ratio (LR=+) of 1.7 (1.3-2.2); negative likelihood ratio (LR-) of 0.8 (0.7-0.9), and residual vein thrombosis, for a pooled OR of 2.8 (95%CI 2.2-3.5); LR+ of 1.8 (95%CI 1.6-2.1); LR- of 0.6 (0.5-0.7).

Conclusions: The US features reflux and residual thrombosis measured at least 6 weeks after DVT predict post-thrombotic syndrome and may be helpful in identifying patients with high risk that could benefit from compression therapy.

PB 1002 | Can Ultrasonographic and Laboratory Measurements One Year after Proximal Deep Vein Thrombosis Predict Post-thrombotic Syndrome?

G.C. Mol[1], C.E.A. Dronkers[2], M.A. van de Ree[3], F.A. Klok[2], M.V. Huisman[2]

[1]Meander Medical Center, Department of Internal and Vascular Medicine, Amersfoort, The Netherlands, [2]Leiden University Medical Center, Department of Thrombosis and Hemostasis, Leiden, The Netherlands, [3]Diakonessenhuis, Department of Internal Medicine, Utrecht, The Netherlands

Background: Elastic compression stockings (ECS) are constricting, itchy and difficult to apply but may prevent post-thrombotic syndrome

TABLE 1.]

Ultrasound and laboratory features	Continue ECS group OR (95% CI), p value	Stop ECS group OR (95% CI), p value	Whole group OR (95% CI), p value
Reflux	1.1 (0.5-2.5), 0.8	1.1 (0.6-2.1), 0.9	1.1 (0.7-1.9), 0.7
Residual thrombosis	1.0 (0.5-2.2), 0.9	1.2 (0.6-2.1), 0.7	1.1 (0.7-1.8), 0.6
Thrombus score>1	1.1 (0.5-2.3), 0.8	1.1 (0.6-2.1), 0.8	1.2 (0.7-1.8), 0.5
D-dimer>0.5 mg/L	1.0 (0.3-3.3), 1.0	1.0 (0.4-2.6), 0.9	1.1 (0.5-2.2), 0.9
High sensitive CRP>3 mg/L	1.6 (0.6-3.8), 1.0	1.7 (0.8-3.8), 0.2	1.6 (0.9-2.7), 0.1
Fibrinogen>4 g/L	4.4 (1.1-18), 0.04	0.9 (0.2-3.4), 0.8	1.9 (0.7-4.8), 1.3

(PTS), a potential severe complication of deep venous thrombosis (DVT). The ability to predict PTS may help clinical decision making with regard to the optimal duration to wear ECS after DVT.

Aims: To assess the predictive value of ultrasonography and laboratory parameters for PTS development in the Octavia study, which was a randomized controlled trial that randomized patients who were compliant to ECS after DVT and had not developed PTS after 1 year, to continue or discontinue ECS treatment [G.C. Mol et al, BMJ 2016].

Methods: At baseline (12 months after acute DVT), ultrasonography was performed in all 518 study patients to assess reflux (retrograde flow > 1 second after compression), the presence of residual thrombosis and the thrombus score (amount of vein segments with a residual thrombus). D-dimer, fibrinogen and high-sensitive CRP levels were determined post-hoc in 275 patients.

Results: 51 of 256 patients randomized to the stop-ECS group and 34 of 262 patients in the continue-ECS group developed PTS during follow-up. Reflux, residual thrombosis, and the thrombus score did not predict PTS in univariate analysis, nor did any of the markers except for fibrinogen in the continue-ECS group, for an OR of 4.4 (95%CI 1.1-18) with a threshold of >4.0 g/L.

Conclusions: In our cohort, US features and laboratory tests were not predictive of PTS, making it unlikely that these parameters are helpful in making management decisions.

PB 1003 | Patient-reported Reasons for and Predictors of Non-compliance with Elastic Compression Stockings in the SOX Trial

S.R. Kahn[1], A. Akaberi[2], J.-P. Galanaud[3], D. Morrison[1], S. Shapiro[1], for the SOX Trial Investigators

[1]*Jewish General Hospital, Centre for Clinical Epidemiology, Montreal, Canada,* [2]*Lady Davis Institute for Medical Research, Centre for Clinical Epidemiology, Montreal, Canada,* [3]*Montpellier University, Internal Medicine and Clinical Investigation Centre, Montpellier, France*

Background: Elastic compression stockings (ECS) are used to prevent and treat venous insufficiency. However, lack of compliance might be a limitation to achieving optimal effectiveness.

Aims: To describe patient-reported reasons for non-compliance with ECS and identify predictors of non-compliance in the SOX Trial population.

Methods: The multicenter randomized controlled SOX Trial compared active ECS (A-ECS) vs. placebo-ECS (P-ECS) to prevent post-thrombotic syndrome (PTS) after a first, symptomatic DVT (*Lancet* 2014). At each follow-up visit (1, 6, 12, 18 and 24 months), patients were asked how many days per week they wore study stockings and if not worn daily, to specify the reason. Compliance was defined as wearing ECS for 3 or more days per week. Potential predictors of ECS non-compliance were assessed in univariate and multivariate analyses.

Results: Of 776 study patients who had at least 1 follow-up visit, 61% were male, mean age was 55, mean BMI was 29. The reasons specified for non-daily use of study stockings at each visit fell into 3 main categories: 1) aversive aspects of ECS (uncomfortable, irritating, too hot, makes things worse, itchy, hard to put on, unaesthetic, don't help) in ~2/3 of patients, 2) patient behavior-related (too lazy, forgot, need a break) in ~1/3 of patients, and ‚other reason' in a minority of patients (see Figure). In multivariate analyses, predictors of ECS non-compliance were female sex (OR 1.4 [95% CI 1.1,1.9]) and smoker (OR 1.5 [1.05, 2.2]). Age, level of education, BMI, anatomical extent of DVT, Villalta score at baseline, and allocation to A-ECS vs. P-ECS did not predict non-compliance.

Conclusions: The most frequent reasons for non-daily use of ECS were aversive aspects of ECS. Females and smokers were significantly more likely to be non-compliant with ECS. Our results provide insight into why patients do not wear ECS, and suggest that improving the

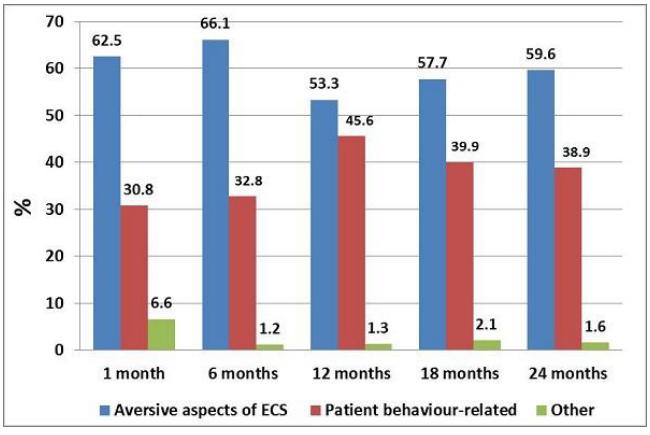

FIGURE 1 Reasons for non-daily use of ECS at each study visit

appeal and tolerability of ECS may have more impact than interventions to change patient behavior.

PB 1004 | External Validation of the Patient Reported Form of the Villalta Scale

K.K. Utne[1,2], A. Dahm[3], H.S. Wik[4], L.-P. Jelsness-Jørgensen[1,5], P.M. Sandset[2,4], W. Ghanima[1,2]

[1]Ostfold Hospital Trust, Department of Hematology, Grålum, Norway, [2]University of Oslo, Institute of Clinical Medicine, Oslo, Norway, [3]Akershus University Hospital, Department of Hematology, Akershus, Norway, [4]Oslo University Hospital, Department of Hematology, Oslo, Norway, [5]Østfold University College, Department of Health Science, Fredrikstad, Norway

Background: Post-thrombotic syndrome (PTS) is a long-term complication of deep vein thrombosis (DVT). The Villalta scale is the recommended tool for diagnosing PTS, but requires a clinician's assessment of clinical signs in addition to patient self-assessment of symptoms. In a previous study, we developed and validated a self-administered tool for patient reporting of symptoms and clinical signs of the Villalta scale (PRV) (Utne et al Thromb Haemost, 115 (2), 361-7).

Aims: To perform an external validation of PTS diagnosed by the PRV scale.

Methods: The validity of PRV was assessed in 175 patients (57% male) diagnosed with DVT between 2010 and 2014. Median time from DVT to inclusion was 24 months (interquartile range (IQR) 23-27). Patients were requested to complete the PRV form before a scheduled visit. PTS diagnosed by the original Villalta scale during the visit served as the reference method. PTS was diagnosed if Villalta score was >4. Regional etics committee approved the study.

Results: PTS was diagnosed in 73 (42%) patients according to the original Villalta scale and in 81 (46%) by PRV. There was a very good agreement between the 2 measurements (kappa 0.82, 95% CI 0.73-0.90). The sensitivity of PRV to detect PTS was 95% and the specificity was 88%.

TABLE 1 Agreement between original Villalta and Patient Reported Villalta scale

	Original Villalta scale	Patient Reporte Villalta Scale	Kappa (CI 95%)
Post-thrombotic syndrome	73 (42)	81 (46)	0.82 (0.73-0.90)
No post-thrombotic syndrome	102 (58)	94 (54)	

Conclusions: This study confirms that patient Reported Villalta Scale is a valid and sensitive tool for diagnosing PTS. The tool can be particularly useful in clinical research, making studies on PTS less resource demanding by reducing the need for in-person clinic visits.

PB 1005 | High Accuracy and Reproducibility of CT Right-to-left Ventricular Diameter Measurement by Non-radiologists in Patients with Acute Pulmonary Embolism

Y.M. Ende-Verhaar[1], I.C. Mos[1], L.J.M. Kroft[2], M.V. Huisman[1], F.A. Klok[1]

[1]LUMC, Thrombosis and Hemostasis, Leiden, The Netherlands, [2]LUMC, Radiology, Leiden, The Netherlands

Background: Right ventricular (RV) dysfunction caused by acute pulmonary embolism (PE) is associated with poor short and long-term prognosis, i.e. higher risk of PE-related mortality and chronic thromboembolic pulmonary hypertension. RV dysfunction can be easily assessed by calculating the right-to-left ventricle diameter (RV/LV) ratio on standard computed tomography pulmonary angiography (CTPA) images (*Figure 1*). It is unknown whether dedicated training is required to adequately measure RV/LV ratio.

Aims: To assess the accuracy and reproducibility of CT RV/LV ratio measurement by non-radiologist clinicians without dedicated training and expertise in CT reading.

Methods: CTPA images of 100 patients with PE were reviewed by three independent non-radiologist clinicians and one experienced thoracic radiologist, after 1-time clear instructions by the latter. The maximum diameters were evaluated in the axial view by measuring the distance between the ventricular endocardium and the interventricular septum, perpendicular to the long axis of the heart. RV dysfunction was defined as a ratio of ≥1. Interobserver accuracy and

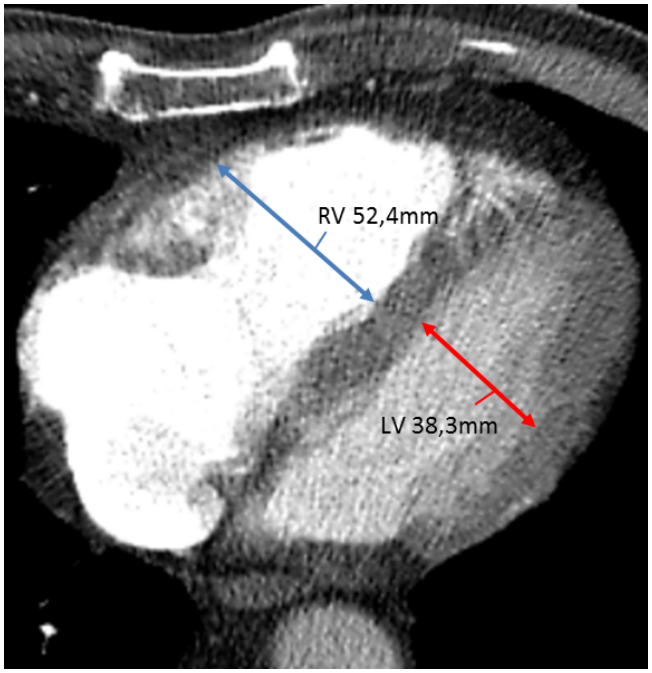

FIGURE 1 CTPA demonstrating the RV/LV ratio measurement in this patient was 1.4

reproducibility was determined using Kappa statistics, Bland-Altman analysis and Spearman´s rank correlation.

Results: The average interobserver difference in calculated RV/LV ratio's (±SD) between the three non-radiologist clinicians was very low: -0.01 (±0.11), 0.07 (±0.14) and 0.06 (±0.18) respectively, with an overall mean RV/LV ratio of 1.04. In line with this finding, Spearman´s rank correlation coefficient was 0.92, 0.88 and 0.85 indicating very good correlation (p< 0.01 for all). Furthermore, there was good agreement on the presence of a RV/LV ratio ≥1.0 compared to the ruling of the experienced radiologist, with kappa statistics ranging from 0.83-0.94.

Conclusions: After simple instruction, RV/LV ratio assessment on CTPA images by non-radiologist clinicians is accurate and reproducible, which may prove convenient in clinical practice.

PB 1006 | Nationwide Study on the Management and Outcomes of Patients with Superficial Vein Thrombosis under Real-life Conditions (INSIGHTS-SVT)

R. Bauersachs[1,2], H.E. Gerlach[3], U. Hoffmann[4], F. Langer[5], A. Heinken[6], E. Rabe[7], D. Pittrow[8], J. Klotsche[9], T. Noppeney[10]

[1]Klinikum Darmstadt, Klinik für Gefäßmedizin, Darmstadt, Germany, [2]University of Mainz, Center of Thrombosis and Haemostasis, Mainz, Germany, [3]Venen-Kompetenzzentrum, Mannheim, Germany, [4]LMU München, Sektion Angiologie, Med. Klinik und Poliklinik IV, München, Germany, [5]Universitätsklinikum, II. Medizinische Klinik und Poliklinik, Hubertus Wald Tumorzentrum, Universitäres Cancer Center Hamburg (UCCH), Hamburg, Germany, [6]Aspen Pharma, Medizinische Abteilung, München, Germany, [7]Dermatologische Klinik der Universität, Bonn, Germany, [8]Medical Faculty, Technical University of Dresden, Institute for Clinical Pharmacology, Dresden, Germany, [9]Deutsches Rheumaforschungszentrum, Epidemiologie, Berlin, Germany, [10]Gefäßzentrum, Medizinisches Versorgungszentrum, Nürnberg, Germany

Background: In Germany, representative and current data on the care situation and the outcomes of patients with acute superficial thrombosis (SVT) are missing.

Aims: The Investigating SIGnificant Health TrendS in the management of Superficial Vein Thrombosis study (INSIGHTS-SVT, registered at ClinTrials.gov NCT02699151) aims at closing this gap.

Methods: The study is observational, and physicians determine diagnostic procedures, treatment and the visit/contact schedule of their patients. Documentation about patient characteristics, diagnostics, comorbidities, and medical and non-medical treatment is collected at baseline, at approximately 10 days or approximately 45 days (depending on treatment), at 3 months and at 12 months. Patients are requested to fill in quality of life questionnaires (VEINES-QoI/Sym, EQ-5D-5L) at baseline and at 3 months, and report pain at every visit. The primary effectiveness outcome is the incidence of VTE at 3 months, the primary safety outcome is the combined incidence of major and clinically relevant bleeding events at 3 months. As quality measures, plausibility checks at data entry, queries based on statistical analyses, monitoring visits and adjudication procedures are applied.

Results: Results based on 709 patients are shown in the Table.

TABLE 1 Baseline characteristics (n= 709 patients)

Age, years	60.1 ± 14.7
Females, %	62.2
SVT in history, %	30.8
DVT/pulmonary embolism in history, %	15.1 / 2.8
Varicose veins, %	76.6
Known thrombophilia, %	5.4
Active cancer, %	2.3
SVT length of thrombus, cm	13.6
SVT distance form the saphenous femoral junction, cm	24.8
SVT in varicose veins, %	33.2

Conclusions: This large study provides a comprehensive picture on patients with SVT under clinical practice conditions in Germany.

PB 1007 | Post-Thrombotic Syndrome in Patients Treated with Rivaroxaban or Warfarin for Venous Thromboembolism

C.I. Coleman, T.J. Bunz

University of Connecticut School of Pharmacy, Storrs, United States

Background: Post-thrombotic syndrome (PTS) is a common complication of deep vein thrombosis (DVT)±pulmonary embolism (PE).

Aims: To assess the relative hazard of PTS in venous thromboembolism (VTE) patients treated with rivaroxaban or warfarin in routine practice.

Methods: Using US MarketScan claims from 1/2012-6/2015, we identified adults with a primary diagnosis code for VTE during a hospitalization/emergency department visit (index event) and newly-started on rivaroxaban or warfarin. Patients lacking at least 6-months of continuous medical and prescription benefits prior to (baseline period) and at least 4-months after the index VTE or with a claim for an anticoagulant at baseline were excluded. PTS was defined as a code for ≥1 extremity venous study along with code(s) for both pain and swelling of the limb within 7-days of each other; lower extremity varicose veins; post-phlebitic syndrome; or other disorder of the circulatory system ≥3-months after the index event. Differences in baseline characteristics between rivaroxaban and warfarin users were adjusted for using inverse probability of treatment weights based on propensity scores. Cox regression was performed and reported as hazard ratios (HRs) and 95% confidence intervals (CIs).

Results: In total, 10,463 rivaroxaban and 26,494 warfarin users were followed for a mean of 16±9 months. Duration of anticoagulation was similar between cohorts (mean=7-months). Rivaroxaban was associated with a significant 23% reduced hazard of PTS vs. warfarin (adjusted incidence rate difference=1.04 events/100 person-years). Reductions in PTS with rivaroxaban were consistent across subgroups (Figure 1) and when a ≥6-month post-index event gap was required before PTS diagnosis (HR=0.76, 95%CI=0.69, 0.85). (Figure 1) and when a ≥6-month post-index event gap was required before PTS diagnosis (HR=0.76, 95%CI=0.69, 0.85).

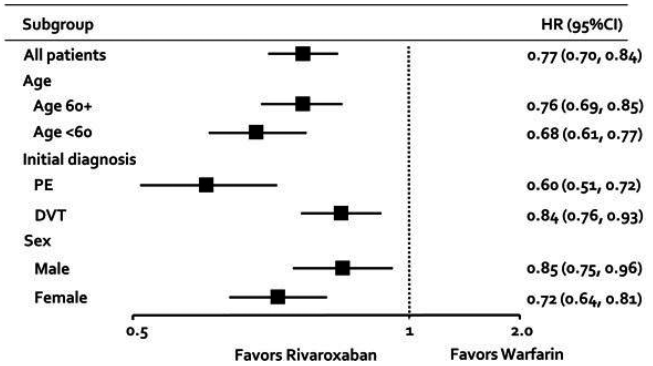

FIGURE 1 Development of Post-Thrombotic Syndrome in Patients Treated with Rivaroxaban or Warfarin for Venous Thromboembolism

Conclusions: We found rivaroxaban to be associated with less PTS vs. warfarin in VTE patients treated in routine clinical settings. Our results are consistent with those from the post-hoc PTS analysis of EINSTEIN-DVT trial.

PB 1009 | Possible Predictors of Long-term Dyspnea in Patients with Pulmonary Embolism - A Cross Sectional Study

M. Tavoly[1,2,3], H. Skuterud Wik[4], L.-P. Jelsness-Jørgensen[3,5], J. Ghanima[3], F.A. Klok[6], P.M. Sandset[1,4], W. Ghanima[1,3]

[1]University of Oslo, Institute of Clinical Medicine, Oslo, Norway, [2]Sahlgrenska University Hospital, Medicine, Gothenburg, Sweden, [3]Østfold Hospital Trust, Medicine, Grålum, Norway, [4]Oslo University Hospital Rikshospitalet, Haematology, Oslo, Norway, [5]Østfold University College, Health Science, Fredrikstad, Norway, [6]Leiden University Medical Center, Thrombosis and Hemostasis, Leiden, The Netherlands

Background: In recent studies on long-term complications after pulmonary embolism (PE), up to 50% of patients still complain of dyspnea, have physical deconditioning, and/or impaired health-related quality of life (HRQoL). The etiology of these findings is still not fully established.
Aims: To evaluate the main differences between patients reporting dyspnea versus those without dyspnea, with regard to the severity of PE, cardiopulmonary comorbidities, employment status, BMI, smoking, exercise intolerance and HRQoL.
Methods: 203 patients diagnosed with PE at Ostfold hospital, Norway, were identified from hospital registries. Eligible patients were scheduled for a study visit, including a functional capacity test (6-minute walking test, 6MWT). HRQoL was assessed using both generic and disease-specific questionnaires (EQ-5D-3L and PE-mb-QoL). The severity of PE was assessed with both the proximal extension of the emboli (Fredrikstad score) and pulmonary embolism severity index (PESI) score.
Results: 96 (47%) patients of whom 52% were males reported dyspnea. Median time from diagnosis was 3.6 years (IQR 1.9-6.5). The severity of PE measured by the proximal extension of the clot (2.89 vs 2.98; p=0.57) and PESI score (70 vs 75; p=0.12) at index was not different between the groups. Patients with dyspnea had significantly more comorbidities (16% vs 4%, OR 4.8, 95%CI 1.5-14.9) and higher BMI (29.5 vs 27.7; p< 0.05). Unemployment was significantly higher in the dyspnea group as well (33% vs 17%; p< 0.05). Smoking history did however not differ between the groups (45% vs 42%, OR 1.1, 95%CI 0.6-1.9). As expected patients without dyspnea performed better on 6MWT (488m vs 413m; p< 0.005) and had better both generic and disease-specific HRQoL results (p< 0.005).
Conclusions: In our cohort of PE patients, persistent dyspnea was associated with poorer exercise capacity and HRQoL. Moreover, patients with persistent dyspnea were more frequently unemployed. We did not identify PE specific variables predictive of persistent dyspnea.

PB 1010 | Reliability Testing of the CAPTSureTM Pediatric Post-thrombotic Syndrome Tool

M.L. Avila, C.M. Lumia, M.I. Montoya, J. Vincelli, S. Williams, L.R. Brandão

The Hospital for Sick Children, Department of Paediatrics, Toronto, Canada

Background: CAPTSure^{TM} is a new tool for diagnosis and severity rating of pediatric post-thrombotic syndrome, developed using an expert panel consensus method.
Aims: To test the inter- and intra-rater reliability of the clinician-reported (CR) and patient/proxy-reported (PR) elements of CAPTSure^{TM}, respectively.
Methods: Patients aged 0-18 yrs who sustained upper or lower extremity deep vein thrombosis (UE/LE DVT) were enrolled. All patients were assessed at least 6 months post-DVT by two raters to determine the reliability of the CR component of CAPTSure^{TM}. Patients/proxies completed an online version of CAPTSure^{TM} (symptoms questionnaire) at baseline and 2 weeks after. Ethics approval and participant consent were obtained.
Results: 47 of the planned 100 patients have been enrolled since November 2016. Median age at the time of study participation was 9 yrs (25th-75th percentile 4-13 yrs); 23 patients were males; 63% had sustained LE-DVT.
CR component: There was an 89% agreement for classification of collaterals; ulcers were not observed. The intraclass correlation coefficients (ICC) were 0.79 (95% CI 0.55-0.90), 0.49 (-0.10-0.76), and 0.86 (95% CI 0.65-0.95) for absolute thigh, calf, and arm circumference difference, respectively. The overall ICC for CR-CAPTSure^{TM} scores was 0.89 (95% CI 0.80-0.93).
PR component: Thus far, 24 participants completed their symptoms questionnaire a second time. The agreement for items of the PR component was as follows: skin redness and combined heaviness/tiredness/tightness 100%; heaviness 96%; paresthesia and endurance 92% and swollen limb 88%.
The overall agreement for pain was 89% (children 4-9 y.o: 88% agreement; children 10 y.o. and older: 91% agreement).
Conclusions: Preliminary results show good reliability of CR-CAPTSure^{TM} scores. Further testing is required in PR scores, since the low variability in the population thus far precluded estimation

of the ICC for PR-CAPTSure™ scores. Given our current recruitment rate, the study is expected to be completed in the next 4 months.

PB 1011 | Measuring Limb Edema in Children at Risk of Post Thrombotic Syndrome: Do I See what You Feel?

M.L. Avila, M.I. Montoya, J. Vincelli, S. Williams, C.M. Lumia, L.R. Brandão

The Hospital for Sick Children, Department of Paediatrics, Toronto, Canada

Background: Limb edema is the most common finding of post-thrombotic syndrome (PTS). Pediatric tools for PTS diagnosis measure both patient/proxy-reported and clinician-assessed limb edema. How closely related these approaches are remains unknown.

Aims: To evaluate the correlation between patient- and proxy-reported and clinician-assessed limb edema, and the correlation between different techniques that estimate limb edema in children at risk of PTS.

Methods: Limb circumference difference, limb volume ratio, bioimpedance spectroscopy (BIS, which measures extracellular fluid content), durometry (which measures skin resistance to indentation) and self- or proxy-reported swelling were measured in 140 children at risk of PTS [n=70 with upper extremity (UE) deep vein thrombosis (DVT),

TABLE 1 Correlations between items assessing upper extremity limb edema in children with deep vein thrombosis

	Swelling patient-reported n=27	Swelling proxy-reported n=43	Circ. difference n=70	BIS ratio n=70	Limb volume ratio n=70	Durometry n=11

BIS ratio n=70	0.42 (0.17 - 0.66; p=0.03)	0.15 (-0.14 - 0.34; p=0.34)	0.45 (0.24 - 0.62; p<0.001)	0.36 (0.14 - 0.55; p=0.002)	-	0.39 (0.17 - 0.57; p<0.001)	0.34 (-0.60 - 0.81; p=0.30)
Limb volume ratio n=70	0.01 (-0.33 - 0.41; p=0.94)	0.40 (0.24 - 0.59; p=0.006)	0.68 (0.53 - 0.79; p<0.001)	0.61 (0.44 - 0.74; p<0.001)	0.39 (0.17 - 0.57; p<0.001)	-	0.46 (-0.34 - 0.92; p=0.15)

n=70 with lower extremity (LE)-DVT]. Correlation between items was estimated using Pearson/Spearman correlation coefficient, as appropriate, for the UE and LE cohorts separately. Ethics approval/informed consents were obtained. This study was funded by PSI Foundation.

Results: Median age (25^{th}-75^{th} percentile) of recruited patients was 7 yrs (3-11) and 8.3 yrs (4-12) in the UE and LE-DVT group, respectively. In the UE-DVT group (Table 1), *proxy-reported* edema was weakly to moderately correlated with limb circumference difference (r=0.36, p=0.02) and with limb volume ratio (r=0.42, p=0.005), but not with BIS (r=0.21, p=0.18). No significant correlations for *patient-reported* edema and other items were found. In the LE-DVT group (Table 2), *proxy-reported* edema was moderately correlated with thigh circumference difference (r=0.49, p< 0.001) and limb volume ratio (r=0.40, p=0.006); *patient-reported* edema was correlated with BIS ratio (r=0.42, p=0.03). No significant correlations for durometry were found.

Conclusions: *Proxy-reported* edema best approximates the measurement of total limb size, whereas *patient-reported* edema measures a concept closer to limb fluid content. Edema as a sign and as a symptom seems to measure different aspects of PTS.

PB 1012 | Laboratory and Clinical Parameters at Diagnosis of Venous Thromboembolism (VTE) Are Not Associated to the Presence of Residual Vein Thrombosis (RVT)

S.M.S. Soares[1], F.M. Hasseman[2], A.V.C. Romano[1], L.F.B. Sckayer[1], F.A. Orsi[1], E.V. de Paula[1], J.M. Annichino-Bizzacchi[1]

[1]*University of Campinas - UNICAMP, Hematology and Hemotherapy Center, Campinas, Brazil,* [2]*University of Campinas - UNICAMP, Vascular Surgery, Campinas, Brazil*

Background: RVT is a complication of VTE and can be detected by Doppler ultrasound (US). The grayscale median (GSM) method can provide quantitative analysis of the echogenicity of US images.

Aims: The purpose of this study was to investigate the relation between clinical parameters, the presence of RVT and the impact of RVT on post-thrombotic syndrome (PTS), which are until now a matter of debate.

Methods: This is a cross-sectional study with patients with lower limb VTE treated at the outpatient clinic of Hemocentro of Campinas, UNICAMP, between January 2015 and November 2016. Cancer, dyslipidemia, high blood pressure, diabetes, body mass index, D-dimer, FVIII, and C-reactive protein, and antiphospholipid antibodies were evaluated at the end of anticoagulation. No patient presented hereditary thrombophilia. PTS and US analysis were performed with a median of 60 months after VTE. RVT was defined as ultrasound incompressibility of at least 4 mm in the common femoral and/or popliteal vein. RVT echogenicity was determined by GSM. The classification of PTS was performed according to Villalta scale. A hundred and twenty-nine patients were included, with a median of 60 months after the acute episode.

Results: Fifty-seven patients (44.5%) showed RVT. Considering that 19 patients were excluded from this analysis due to lack of PTS data, 64 (58.18%) presented PTS: 46.87% mild, 10.9% moderate and 42.18% severe. Table 1 and 2 show clinical and laboratory parameters according to the presence or absence of RVT. There was no statistically significant difference when the presence of RVT was associated to all parameters analyzed. Furthermore, data did not shows any association between the presence of RVT and PTS, independently of the Villalta classification. The analysis of US images by GSM demonstrated no difference according to PTS classification.

TABLE 1 Clinical data of patients with and without residual vein thrombosis

Clinical data	Patients without thrombus (N=72)	Patients with thrombus (N=57)	P value
Genre: Male/ Female	30.10/69.90	39.30/60.70	0.27
Locals of occurrence: Left lower limb / Right lower limb	61.60/34.20	64.30/32.10	0.94
Characterization: Spontaneous/ Induced	35.60/64.40	33.90/60.70	0.97
PTS: No/ Mild/ Moderate/ Severe	26/18/4/14	20/12/3/13	0.94
HAS: Without/with	41/31	30/22	0.93
Diabetes: Without/ with	61/11	46/10	0.69
Dyslipidemia: Without/ with	55/17	43/13	0.95
Cancer: Without/ with	69/3	51/1	0.48
SAF: negative/ positive	60/13	49/4	0.09

TABLE 2 Laboratory data

TEST	Percentiles without RVT	Percentiles with RVT
Reactive C-Protein (P=0.84)	25:0.22 50:0.63 75:2.26	25:0.28 50:0.64 75:2.05
FVIII (P=0.09)	25:119.61 50:168.35 75:211.70	25:153.97 50:193.90 75:216.62
Total Cholesterol (P=0.32)	25:161.50 50:187.00 75:228.00	25:170.00 50:197.00 75:225.00
LDL Cholesterol (P=0.76)	25:95.00 50:109.00 75:144.00	25:93.50 50:115.50 75:134.50
Triglycerides (P=0.48)	25:86.00 50:113.00 75:181.00	25:85.00 50:127.00 75:187.75

Conclusions: Among our patients, laboratory and clinical parameters at diagnosis of VTE are not associated to the presence of RVT, and the presence of RVT is not correlated to PTS.

PB 1013 | An Innovative Approach to an Age-old Problem: Piloting a Smart Compression Garment Device

M.L. Avila[1], K.L. Tam[2], T. Chau[2], M.I. Montoya[1], S. Stephens[1], C.M. Lumia[1], L.R. Brandão[1]

[1]The Hospital for Sick Children, Department of Paediatrics, Toronto, Canada, [2]Holland Bloorview Kids Rehabilitation Hospital, Bloorview Research Institute, Toronto, Canada

Background: The efficacy of compression garments in the treatment and prevention of post-thrombotic syndrome in adults and children is poorly understood, due in part to the lack of an objective method to quantify compliance with wearing these garments. Lack of compliance has surfaced as a reason for contradictory results in clinical trials.

Aims: To develop and test a prototype of a device designed to objectively measure compliance to wearing compression garments.

Methods: In collaboration with the Bloorview Research Institute, a prototype of compression garments that incorporates wearable technology was developed. The core concept behind the device is the detection and storage of changes in harmless electric signals triggered by small changes in muscular volume as a consequence of muscular contraction, paired with the signals obtained from a 2-axis accelerometer. Readings from these two systems are recorded every 5 minutes. We estimated the Pearson correlation between the readings of these two detection systems. Ethics approval/participant consent were obtained. The study was funded by an Innovation grant.

Results: Two patients have been enrolled so far. 3,725 data points were obtained from the first patient and first prototype; 479 of the readings showed changes indicative of use of the compression sleeve (40 hrs of use) with a clear transition between the baseline and stretched readings (Figure 1). The correlation for the thread and the axis parallel to the ground (Axis 1: forward acceleration) was 0.69 (95% CI 0.64-0.73), and for the thread and the perpendicular axis (Axis 2: downward acceleration) was 0.33 (95% CI 0.25-0.41). The feedback and data obtained from the first patient resulted in adjustments to the device. The next device iteration, which will be piloted by the second patient, is expected to enhance the acquisition of data in compliance.

Conclusions: The use of wearable technology to monitor compliance to compression garments, which will be instrumental for pediatric and adult patients, is feasible.

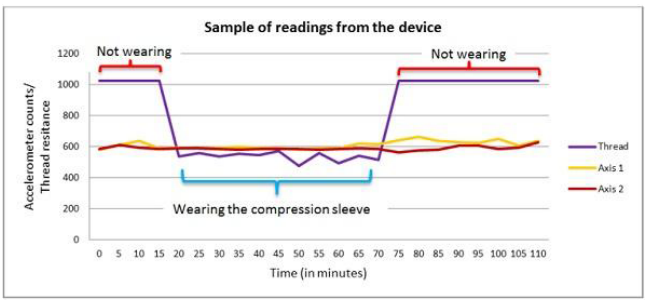

FIGURE 1 Sample of readings from the device

PB 1014 | Post-Pulmonary Embolism Syndrome Development among Patients who Needed Pulmonary Embolism Response Team Assessment

K. Smart[1], A. Ahsan[1], O. Iftikhar[2], A. Tafur[3]

[1]NorthShore University HealthSystem (University of Chicago Pritzker School of Medicine), Internal Medicine, Evanston, United States, [2]NorthShore University HealthSystem (University of Chicago Pritzker School of Medicine), Cardiology, Evanston, United States, [3]NorthShore University HealthSystem (University of Chicago Pritzker School of Medicine), Vascular Medicine, Evanston, United States

Background: Pulmonary Embolism Response Team (PERT) initiatives are increasingly implemented, with the premise of improved outcomes after expedited, multidisciplinary, expert approach to the patient with severe PE. There is however paucity of comparative outcome data. A growingly recognized PE outcome is post-PE syndrome, defined by persistently abnormal RV function, functional status, and quality of life among PE survivors.

Aims: To quantify the incidence of post-PE syndrome after PERT activation.

Methods: We initiated a PERT registry that includes initial activation and outpatient follow up data. A follow up ECHO was ordered on patients with persistent symptoms after 3 months. Patients were classified as post-PE syndrome if the imaging right ventricular systolic pressure (RVSP) increased. Continuous variables are reported as median and categorical as percentages. We used SPSS for analysis.

Results: A total of 58 patients required activation of PERT, age 70.5, most (65.5%) were female, PESI class III and 32.7% had cancer (Table 1). The RV was dilated by CT criteria in 48.9% of the patients and 40% had troponin elevation on presentation. PERT decided to do thrombolysis in 10%. A reported 8.5% of the patients died. Among survivors, 11% had an abnormal right ventricular systolic pressure per ECHO. Right heart ECHO variables are tabulated in Table 2. Positive troponin, increased RV/LV ratios, increased RVSP at diagnosis were not associated with post-PE syndrome incidence. Patients with PESI class V were more likely to have an abnormal ECHO at follow-up, but this result was not statistically significant (OR 2.1 95%CI 0.3-13.4).

TABLE 1 Basic demographics and clinical parameters from NorthShore's PERT registry. (N=58)

Median Age	70.5
Female	38/58 (65.5%)
Active Malignancy	19/58 (32.7%)
Concomitant DVT	37/58 (66.6%)
RV/LV ratio >1	23/58 (48.9%)
Troponin Elevation	22/58 (40%)
Pro-BNP / BNP Elevation	28/58 (68.2%)

TABLE 2 ECHO Variables (N=10)

Median RSVP at Diagnosis	30 mm Hg
RV Dilation at Diagnosis	5/10 (50%)
Median RSVP at Follow Up	40.5 mm Hg
RV Dilation at Follow Up	5/10 (50%)

Conclusions: PERT activation selects more complex patients with a high incidence of post-PE syndrome. Given our results, accounting for a 20-30% of post PE syndrome reported in the literature, we estimate that a 500 patient comparative trial may define if there is clinical utility of PERT initiatives, and is needed as to justify its growing acceptance.

PB 1015 | Patients Treated with Rivaroxaban Presented Low Prevalence of Post-thrombotic Syndrome

T. Ferreira, L.F. Bittar, S. Cares Huber, S. Soares, A.V. Calazans Romano Marina Pereira Colella, F. Andrade Orsi, E.V. de Paula, J.M. Annichino-Bizzacchi

Universidade Estadual de Campinas, Campinas, Brazil

Background: A Post-thrombotic syndrome (PTS) is a common complication of deep vein thrombosis (DVT) and is present in about 20-50% of patients after the thrombotic episode. Poorly quality treatment with warfarin is a risk factor for PTS. Direct oral non-vitamin K anticoagulants (DOACs) are increasingly used in the prevention of recurrent DVT and the occurrence of PTS with these novel medications is not well stablished.

Aims: To compare the prevalence of PTS in patients with previous DVT treated with rivaroxaban (RIVA) or enoxaparin/warfarin.

Methods: Patients with previous proximal lower limb DVT (Doppler), treated with RIVA (5.88±3.84 months) or warfarin (8.06±4.15 months) assisted at outpatient clinic of Hemocentro de Campinas (Brazil) from 2014-2017 were included. The classification of the PTS was performed (Villalta scale), 3 to 30 months after treatment.

Results: A total of 107 patients were included, 52 RIVA (26 F/26M, mean age of 48.26 y) and 55 warfarin (45F/10M, mean age of 41.85 y). The body mass index (BMI) >30 were 30.8% and 41.8%, respectively. There were 29 (55.8%) idiopathic and 23 (44.2%) provoked DVT and 21 (38.2%) idiopathic and 34 (61.8%) provoked for RIVA/warfarin, respectively. From patients treated with RIVA 29 (55.8%) did not develop PTS whereas 23 (44.2%) presented this diagnosis (38.5% mild, 3.8% moderate and 1.9% severe). In warfarin group 29 (52.7%) did not show PTS and 26 (47.3%) developed the syndrome (29.1% mild, 10.9% moderate and 7.3% severe). Patients treated with warfarin showed an increased prevalence of moderate/severe PTS (P=0.057). After adjusting for all different factors between the groups and considering only the risk of PTS moderate/severe, warfarin treatment showed a positive impact, but not significant (P=0.078). BMI was an independent risk factor for PTS (RR=1.11; 95 % CI: 1.01-1.22, P=0.028).

Conclusions: Rivaroxaban was associated with low prevalence of PTS, but other risk factors, specially BMI can have a higher impact in development of this syndrome.

PB 1016 | Non-invasive Detection of Fresh Deep Vein Thrombosis with Diffusion Weighted Magnetic Resonance Imaging

Y. Kuroiwa[1,2], A. Yamashita[2], T. Gi[2], Y. Konishi[3], T. Asanuma[3], T. Miyati[4], T. Imamura[5], Y. Asada[2]

[1]Koga General Hospital, Department of Radiological Technology, Miyazaki, Japan, [2]Faculty of Medicine, University of Miyazaki, Department of Pathology, Miyazaki, Japan, [3]Faculty of Veterinary Medicine, University of Miyazaki, Department of Radiology, Miyazaki, Japan, [4]Faculty of Health Sciences, Institute of Medical, Pharmaceutical and Health Sciences, Kanazawa University, Kanazawa, Japan, [5]Koga General Hospital, Department of Internal Medicine, Miyazaki, Japan

Background: It is important to detect fresh deep vein thrombosis (DVT) for the strategy of anti-thrombotic therapy. Diffusion weighted magnetic resonance (MR) imaging can visualize diffusion capacity of water molecules in the tissue, therefore, we hypothesized that the signal intensity on diffusion weighted MR imaging may reflect acuity of the DVT.

Aims: This study investigated whether diffusion weighted MR imaging can detect the thrombus in patients with DVT and define the thrombus age in a rabbit model of venous thrombus.

Methods: Diffusion weighted MR imaging was performed with a 1.5-T MR system in 8 patients with DVT, and we assessed signal intensity and apparent diffusion coefficient of the thrombi. Venous thrombus was induced in rabbit jugular vein by endothelial denudation and 10 minutes blood stasis with a balloon catheter. The thrombus was imaged with a 3.0-T MR system at 4 hours and at 1, 2 and 3 weeks, and the jugular veins were histologically assessed.

Results: All patients were detected DVT with diffusion weighted MR imaging, and the DVT showed high or mixed high and iso signal intensity on the diffusion sequence. The signal intensity and apparent diffusion coefficient at proximal portion of DVT were higher or smaller than those at distal portion, respectively. The rabbit venous thrombi showed time-dependent organizing reaction. The rabbit thrombi showed high signal intensity on diffusion weighted MR imaging at 4 hours, mixed high and iso signal intensity at 1 and 2 weeks, or mixed iso and low signal intensity at 3 weeks. The signal intensity was positively correlated with erythrocyte and fibrin contents, and negatively correlated with macrophage and collagen contents.

Conclusions: Diffusion weighted MR imaging can detect fresh DVT as a high signal intensity lesion in deep vein.

PB 1017 | Patients' Experience of Post-thrombotic Syndrome: A Qualitative Study with Focus Groups Aiming at a More Accurate Diagnosis

M. Engeseth[1,2], T.R. Enden[3], M.H. Andersen[4], P.M. Sandset[1,2,5], H.S. Wik[1]

[1]Oslo University Hospital, Department of Haematology, Oslo, Norway, [2]University of Oslo, Institute of Clinical Medicine, Oslo, Norway, [3]Oslo University Hospital, Department of Radiology, Oslo, Norway, [4]Oslo University Hospital, Division of

Cancer Medicine, Surgery and Transplantation, Oslo, Norway, [5]Oslo University Hospital, Research Institute of Internal Medicine, Oslo, Norway

Background: In clinical trials the Villalta scale is the recommended tool for diagnosing and grading post-thrombotic syndrome (PTS). However, limitations of the scale have been recognized. Additionally, it is our experience that the Villalta scale may have poor specificity and sensitivity in typical patients, and that diagnosis and grading of PTS can be improved.
Aims: We aimed to explore which complaints patients with chronic post-thrombotic problems of the lower limb experience, and relate these findings to the individual items of the Villalta scale.
Methods: We conducted a qualitative study with three focus group interviews with a total of 16 PTS patients within the southeastern Norway health region. The interviews were audio recorded before verbatim transcription and thematic analysis.
Results: Thematic analysis revealed four frequently occurring complaints not included in the Villalta scale: I) Venous claudication, II) symptoms related to a reduced cardiac preload, III) impaired plantar sensation, and IV) difficulty climbing stairs/walking uphill. PTS patients without ulcer did not report pain, but described discomfort, paresthesia and a burning sensation. As included in the Villalta scale, the patients experienced heaviness of the leg and pretibial edema. However, the typical worsening during the day and with prolonged standing, or relief by elevation of the leg is not included in the scale. The patients presented with various post-thrombotic skin changes, but most of them emphasized that these were not of importance. Nevertheless, skin changes constitute four out of the six clinical signs in the Villalta scale.
Conclusions: Our findings indicate that the Villalta scale does not capture some typical PTS complaints, and that some items of the scale are of less importance though weighed equally in the summary score. We conclude that a revision of the tool should be considered to improve the accuracy of PTS diagnosis and grading in clinical trials.

PB 1018 | Optimizing Treatment for Post-thrombotic Syndrome (PTS): A Systematic Review

S. Abegunde[1], I. Ajayi[2]

[1]National Orthopaedic Hospital, Lagos, Nigeria, [2]University of Benin, Benin-City, Nigeria

Background: Post thrombotic syndrome (PTS) is a burdensome and costly complication of deep venous thrombosis (DVT) that develops in 20-40% of patients within 1-2 years after DVT and is associated with reduction in the quality of life.
Aims: This review is aimed at examining the current best evidence regarding the optimal preventive and treatment strategies for PTS, particularly regarding the elastic compression stocking (ECS),catheter directed thrombolytic therapy(CDT), "venoactive" drugs and endovascular surgery.
Methods: The PUBMED, MEDLINE and the Cochrane Database of systematic reviews were searched for relevant reports of clinical trials and studies for the current best evidence regarding the efficacy of different approaches used in preventing and treating PTS. Studies were eligible for inclusion if they were randomized controlled trial(RCT) or observational studies in adult patients.
Results: We found 714 potentially eligible studies, including 27 RCTs. Most studies had small sample size (range:29-800) and there were variations in individual studies with respect to management protocols. Predominant risk factors for PTS include recurrent ipsilateral DVT, extensive DVT, sub-therapeutic INRs, obesity and advanced age. Systematic use of thromboprophylaxis in hgh- risk hospitalized patients, and the use of optimal anticoagulation of appropriate intensity and duration in the treatment of initial DVT was associated with effective prevention of PTS. Prolonged use of ECS in patients with established PTS led to reduced symptoms. Up-front CDT in conjunction with heparin to treat acute DVT in selected patients including those with low bleeding risk was associated with a significant relative reduction (P< 0.05) in the risk of PTS at 2 years Supervised exercise training was associated with reduced PTS symptoms.
Conclusions: Capitalizing on available strategies including patient and physician education, establishing hospital wide management protocols, and adherence to consensus guidelines, will ensure optimal management of PTS.

PB 1020 | Comparison of Trans-popliteal Reflux in the Limb with Deep Vein Thrombosis and the Limb without Thrombosis

L. Sarolo, G. Turatti, M. Milan, F. Bilora, P. Prandoni

University of Padua, Padua, Italy

Background: Chronic venous insufficiency (CVI) leads to various consequences, including pain, swelling, edema, skin changes and ulcerations. Venous reflux is the primary cause of CVI. In literature there are no much evidence on possible damages that thrombotic events may cause to the deep veins of the lower limbs.
Aims: The aim of our study was to determinate whether deep vein thrombosis (DVT) may be cause of incompetence of the venous valves and then of the venous reflux.
Methods: In order to test the plausibility of the association between DVT and the PVI, we assessed the rate of PVI in 59 consecutive outpatients with previous proximal DVT (32 males; mean age, 57 years), and compared it with that detectable in the otherwise unaffected contralateral leg of the same patients. The presence of a retrograde flow through the popliteal valve after a standardized compression of the mid thigh, persisting after repeating the manoeuvre with a tourniquet to prevent the influence of superficial vein reflux, was considered suggestive of valve incompetence.
Results: PVI was detected in 17 patients (28.9%), and involved the leg with previous DVT in 14 cases (82.3%), the contralateral leg in 2 (11.8%), and both legs in 1 patient (5.9%). The odds ratio (OR) of PVI in the legs with previous DVT as compared to the unaffected legs was 6.40 (95% CI, 1.7 to 23.5).
Conclusions: We conclude that after an episode of proximal DVT, trans-popliteal venous reflux is detectable in the leg with thrombosis much more frequently than in the otherwise healthy leg. Our study results makes it plausible the association between DVT and the subsequent development of PVI.

PB 1022 | Inferior Vena Cava Filters: Experience of 133 Patients in a Tertiary Referral Center

A. Riera-Mestre[1], J. Ribas Sola[2], E. Cuevas Sales[2], E. Alba Rey[3], E. Escalante Porrua[3], X. Corbella Virós[1], J. Dorca Sargatal[2]

[1]*Hospital Universitari de Bellvitge - IDIBELL, Internal Medicine, L'Hospitalet de Llobregat, Spain,* [2]*Hospital Universitari de Bellvitge - IDIBELL, Pneumology, L'Hospitalet de Llobregat, Spain,* [3]*Hospital Universitari de Bellvitge - IDIBELL, Interventional Radiology Unit, L'Hospitalet de Llobregat, Spain*

Background: Contraindication to anticoagulant therapy is the main indication for inferior vena cava filters (IVCF) insertion in patients with venous thromboembolism (VTE). An increased use of new retrievable IVCF, has been observed during the last years.

Aims: To analyze the indications for IVCF placement, clinical outcomes, retrieval rate, and causes of failed filter retrieval attempts.

Methods: From 2009 to 2015, clinical data of all consecutive patients who underwent IVCF insertion at our tertiary referral university hospital were retrospectively reviewed. The study was approved by our Clinical Research Ethics Committee. Quantitative variables are expressed as mean (standard deviation -SD-; range) and categorical variables, as percentages.

Results: In total, 133 patients underwent IVCF insertion (52.6% women), with a mean age of 62.5 (15.2; 21-93) years. Of them, 96 IVCF (72.2%) were

TABLE 2 Reasons for failure to filter removal (n=30)

Lack of planning / follow-up	13 (43.3%)
IVCF thrombosis	11 (36.7%)
Endothelial adhesion	4 (13.3%)
Residual DVT	1 (3.3%)
Patient decission	1 (3.3%)

retrievable and 37 (27.8%) permanent. There was an increasing trend in IVCF use during the study period (from 7 IVCF in 2009 to 38 in 2015). IVCF indications are shown in **Table 1.** Overall, 18 (13.5%) patients died during IVCF follow-up, 14 of them with a retrievable filter; however, no death was directly related to IVCF insertion. Among the 82 retrievable IVCF in patients who survived, successful retrieval attempt occurred in 52 (63.5%) patients, with a mean time since IVCF placement of 46.3 (23.8; 12-106) days. Reasons for failure to filter removal in the remainig 30 (36.5%) patients are shown in **Table 2.**

Conclusions: There was an increasing trend in IVCF placement, being most of them retrievable. The main IVCF indication was contraindication for anticoagulant therapy in patients with VTE. Retrievable filters could be effectively removed in almost 2 out of 3 of our IVCF patients. Lack of planning/follow-up and IVCF thrombosis were the main reasons to not remove retrievable IVCF. Applying an institutional monitoring protocol could optimize IVCF management for ensuring the filter is appropriately removed.

PB 1023 | Sex Specific Prevalence and Performance of Diagnostic Algorithms for Pulmonary Embolism

T.E. van Mens[1], L.M. van der Pol[2], N. van Es[3], I.M. Bistervels[3,4], A.T.A. Mairuhu[5], T. van der Hulle[2], F.A. Klok[2], M.V. Huisman[2], S. Middeldorp[3]

[1]*Academic Medical Center, Vascular Medicine, Amsterdam, The Netherlands,* [2]*Leiden University Medical Center, Department of Medicine - Thrombosis and Hemostasis, Leiden, The Netherlands,* [3]*Academic Medical Center, Department of Vascular Medicine, Amsterdam, The Netherlands,* [4]*Flevo Hospital, Department of Internal Medicine, Almere, The Netherlands,* [5]*HagaHospital, Department of Internal Medicine, The Hague, The Netherlands*

Background: In the recommended diagnostic algorithms of pulmonary embolism (PE), clinical prediction rules are combined with D-dimer levels to rule out PE, avoiding the need for imaging. It is unclear whether the performance of these algorithms is equal in both sexes.

Aims: To compare the performance of three algorithms for PE between women and men: the Wells rule with fixed (WELLS) or age adjusted (ADJUST) D-dimer cutoff and a novel algorithm (YEARS). We also investigated two subgroups: women under 50, who do not benefit from high efficiency of the ADJUST algorithm and in whom avoiding unnecessary imaging is especially important because of high radiation sensitivity of breast tissue; and women using estrogen, since estrogen use raises D-dimer levels, possibly affecting algorithm performance.

Methods: Individual patient data were obtained from six studies (ADJUST n=1; WELLS n=5) identified by a previous systematic review and from work awaiting publication (YEARS n=1). All studies prospectively enrolled consecutive patients with suspected acute PE. Main outcomes were efficiency (proportion of patients in which the algorithm ruled out PE without imaging) and failure rate (proportion of patients with VTE during 3-month follow-up, i.e. PE missed by algorithm). Prevalence of PE was a secondary outcome. Outcomes were estimated using (multilevel) logistic regression models.

Results: No sex differences in efficiency nor failure rate were observed in any of the algorithms (Table 1), overall and in patients under 50. Prevalence of PE was lower in women in all studies. Estrogen use, adjusted for age, was associated with a lower efficiency and a higher risk of PE (Table 2).

Conclusions: Despite lower prevalence of PE in women, the three diagnostic algorithms showed no sex differences in performance, which might suggest lower specificity in women. An explanation might be sought in estrogen use, which was associated with decreased efficiency, possibly reflecting (aside from a higher PE prevalence) effects on D-dimer levels.

TABLE 1 Primary analysis. Sex specific prevalence and performance of three diagnostic algorithms for PE

	Efficiency Women	Efficiency Men	Efficiency Odds ratio	Failure rate Women	Failure rate Men	Failure rate Odds ratio	Prevalence Women	Prevalence Men	Prevalence Odds ratio
YEARS n = 3465									
Women 52.3 ± 18.5 yrs Men 54.9 ± 17.5 yrs	48.6 %	43.8 %	1.1 (0.96-1.3)	0.64 %	0.50 %	1.1 (0.4-3.0)	11.8 %	16.8 %	0.66 (0.55-0.81)

PB 1024 | Clinical Course of Lemierre Syndrome: An Individual-Patient Data Meta-Analysis of 518 Subjects

S. Barco[1], F. Zane[2], C. Sacco[2], S. Granziera[3], S.V. Konstantinides[1,4], M. Di Nisio[5,6], A. Pecci[2], Lemierre Study Group

[1]*University Medical Center of the Johannes Gutenberg University Mainz, Center for Thrombosis and Hemostasis, Mainz, Germany,* [2]*University of Pavia, Department of Internal Medicine, Pavia, Italy,* [3]*University of Padua, Padova, Italy,* [4]*Democritus University of Thrace, Department of Cardiology, Komotini, Alexandroupolis, Greece,* [5]*University of Chieti, Chieti, Italy,* [6]*Academic Medical Center, University of Amsterdam, Vascular Medicine, Amsterdam, The Netherlands*

Background: Lemierre syndrome (LS) is a rare disease characterized by acute head/neck bacterial infections (often due to *Fusobacterium Necrophorum)*, neck vein thrombosis, and septic embolism. No large studies on LS have ever been performed due to its very low incidence (3 diagnoses of LS/1,000,000 person-years).

Aims: To investigate the risk of new thromboembolic events (thrombosis recurrence, extension, or new septic embolism), major bleeding, and in-hospital death.

Methods: Studies of subjects with an established diagnosis of LS were identified by a systematic search of Medline and Embase databases (2000-2016). Four investigators assessed the study eligibility, extracted data, and requested the authors of eligible articles to provide missing or additional information. Statistical analysis was based on individual-patient data (PROSPERO protocol ID: CRD42016052572).

Results: A total of 1,969 citations were identified, 467 articles included (case reports >90%), and data of 518 subjects extracted and evaluated for the present preliminary analysis of studies published between 2000 and 2015. The median age was 22 years, 56.6% were males, and jugular vein thrombosis was present in 74.9% of subjects. *Table 1* summarizes patients´ baseline characteristics and sites of thromboembolic complications detected at the time of LS diagnosis.

TABLE 1 Baseline characteristics of patients diagnosed with Lemierre syndrome and site of thromboembolic events at the time of diagnosis

Age (years), median (IQR)	22 (17-35)
Male sex, n (%)	293 (56.6)
Active cancer, n (%)	8 (1.5)
Isolation of Fusobacterium spp., n (%)	238 (45.9)
Jugular vein thrombosis, n (%)	388 (74.9)
Other neck/head vein thrombosis, n (%)	158 (30.5)
Septic pulmonary embolism, n (%)	330 (63.7)
Septic central nervous system embolism, n (%)	69 (13.3)
Septic abdominal embolism, n (%)	23 (4.4)
Septic embolism located at joints, bones, or muscles, n (%)	52 (10.0)

Initial parenteral anticoagulation was used in 243 (46.9%) subjects, of whom 90 were switched to an oral agent before discharge. Surgical treatment was performed in 201 (38.8%) subjects. During hospitalization, new thromboembolic events were reported in 35 (7.6% of valid entries; 95%CI 5.5-10.4), bleeding events in 13 (2.8; 95%CI 1.7-4.8), and death in 18 (3.6%; 95%CI 2.3-5.6) subjects.

Conclusions: LS affects young individuals and is still associated with significant in-hospital mortality rate. Although vein thrombosis is a key feature of the disease, anticoagulants are used in less than half of subjects. The risk of in-hospital recurrent thromboembolic and bleeding events appears high.

PB 1025 | Comparison of Pulmonary Embolism Severity Index Score and Hestia Criteria to Identify Pulmonary Embolism Patients for Outpatient Treatment

P. Nona[1], A. Tawney[1], D. Tirunagari[2], C. Klochko[3], S. Ahsan[4], V. Shah[1], S. Ellsworth[1], S. Kaatz[2]

[1]Henry Ford Hospital, Internal Medicine, Detroit, United States, [2]Henry Ford Hospital, Hospital Medicine, Detroit, United States, [3]Henry Ford Hospital, Radiology, Detroit, United States, [4]Henry Ford Hospital, Cardiology, Farmington Hills, United States

Background: Guidelines recommend out of hospital treatment of low risk pulmonary embolism (PE) if home circumstances are adequate. The Pulmonary Embolism Severity Index (PESI) score is a validated risk assessment model that predicts early mortality. The Hestia criteria is a list of conditions that preclude outpatient treatment. Which tool is best to guide treatment decisions is controversial.

Aims: To quantify agreement between low risk PESI scores and eligibility for outpatient treatment per Hestia criteria in PE patients.

Methods: Elements of the PESI score and Hestia criteria were abstracted from consecutive patients with confirmed PE from May 2015 to May 2016. PESI scores were classified as very low, low, intermediate, high and very high and dichotomized into low risk (very low and low) and high risk (intermediate, high and very high). Patients were deemed candidates for outpatient treatment if they had none of the 11 Hestia criteria.

Results: Of 367 patients, 164 (44.7%) had a low risk PESI score and 97 (26.4%) were candidates for outpatient treatment per Hestia criteria; 62 (16.8%) met both criteria. 168 (45.7%) had either a high PESI score or were precluded form outpatient treatment per Hestia. 35 (9.5%) patients were deemed candidates for outpatient treatment but had high mortality risk.

Conclusions: Only 16.8% of our patients were deemed to be candidates for outpatient PE treatment and had low mortality risk using standard risk assessment tools. Nearly half of our patients were at high risk for dying or did not meet published outpatient treatment criteria. Approximately 1 in 10 of all met Hestia criteria for outpatient treatment despite having a high mortality risk. Further research is needed to define the optimal candidate for out of hospital PE treatment.

TABLE 1 Comparison of PESI score and Hestia criteria

	Low risk PESI score	High risk PESI score	Total
Hestia candidate for outpatient treatment - yes	62	35	97
Hestia candidate for outpatient treatment - no	102	168	270
Total	164	203	367

PB 1026 | Clinical Courses of Portal Vein Thrombosis (PVT) in Children

P. Komvilaisak[1], S. Sutra[1], R. Komvilaisak[2], N. Tewattanarat[3], K. Wichajarn[1]

[1]Khon Kaen University, Department of Pediatrics, Faculty of Medicine, Muang, Thailand, [2]Khon Kaen University, Department of Obstetrics and Gynaecology, Faculty of Medicine, Muang, Thailand, [3]Khon Kaen University, Department of Radiology, Faculty of Medicine, Muang, Thailand

Background: PVT is defined as thrombus in the portal vein causing of total or partial obstruction. 5-10% of PVT can lead to portal hypertension (PH) with the devastating outcomes.

Aims: The retrospective descriptive study is to report clinical courses of PVT in children from 2006-2016 in Srinagarind Hospital, Khon Kaen, Thailand.

Methods: Data of children diagnosed with PVT including sex, location, risk factors, age of developing PH, clinical presentations, treatment of PVT, and follow-up time is reviewed.

Results: 17 cases diagnosed with PVT are M:F=11:6 with median follow-up time 1 year 9 months (2 months-17 years). 13 cases were diagnosed at median age at diagnosis 1.25 months (5 days- 9 years) and 4 cases were unknown age at diagnosis. Clinical manifestations include direct hyperbilirubinemia in 7, splenomegaly 5, bleeding from esophageal varices 4, thrombocytopenia 3, abdominal pain 2, pancytopenia and no symptom in each 1. The most common risk factor of developing PVT is umbilical catheterization in 9 followed by sepsis 5, unknown etiology 4, liver abscess 3, exchange transfusion 3 and post Kasai operation 1. 11 cases developed PT at median age 7 years 10 months (range from 1year 6months-18 years 3 months). The most common locations of PVT are found in main portal, left and right portal vein in 11 cases, 10 cases and 5 cases respectively. 6 cases received anticoagulation including low molecular weight heparin 5 cases and warfarin 1 case with response from no to complete recanalization.

Conclusions: Children with PVT might progress to PH during 8 years after PVT with poor outcome in spite of adequate preventive treatment. Children with risk factors of PVT should be warranted for follow-up Doppler abdominal ultrasound at least 8 years in order to early diagnosis and proper management for PH. Anticoagulant therapy is still debated in light of prevention of PH even though it might be rapid clot resolution. The future study in order to determine the role of anticoagulation to reduce PH should be performed.

PB 1027 | The Incidence and of Catheter-related-Thrombosis during Induction Chemotherapy and Follow-up in Chinese Acute Lymphocytic Leukemia Children

Y. Wei, R. Wu

Capital Medical University, China, Beijing, China

Background: As PICC is more widly used, catheter-related-thrombosis (CRT) has been a more common complication among children.

Aims: To investigate the current status of CRT of Chinese acute lymphocytic leukemia (ALL) children with PICC, and follow up the outcome of ALL children with CRT.

Methods: Collect the clinical data of the inpatients preliminarily diagnosed ALL in the Leukemia Ward of Beijing Children's Hospital with PICC from 1st March 2014 to 31st December 2014 prospectively, and follow up for the next 2 years.

Results:

① A total of 116 cases of children preliminarily diagnosed ALL with PICC were collected. Refer to the B-ultrasound on the 15th day after catheterization, the incidence of CRT is 28.4% (33/116 cases), all cases are symptom-free.

② On the 15th day after catheterization, it revealed significant statistical differences of D-Dimer between the two groups (P=0.001).

③ Multivariate Logistic regression analysis verified catheterization on right is a risk factor of CRT.

④ The B-ultrasound on the 33rd day after catheterization showed 73.1% of the cases had thrombosis reduced, 3.8% had thrombosis growth, 23.1% had no obvious change.

⑤ During the follow-up for 2 years, 61.5% of the cases had thrombosis reduce, 15.4% had thrombosis growth, 23.1% had no obvious change.

⑥ During the follow-up, there were 3 cases had leukemia relapse, and 2 of them had CRT growth or persistent existence.

Conclusions: CRT is a common catheter related complication among ALL children during induction chemotherapy, and CRT cases with symptoms are rare. Catheterization on right is a risk factor for CRT, and regular test of D-Dimer and B ultrasound contribute to detect CRT. Most of the CRT cases had thrombosis reduced without specific management. The growth or persistent existence of CRT may indicate poor prognosis of ALL, which is still need more clinical evidence to confirm.

PB 1028 | Behcet and Thrombosis in Children: Hacettepe Experience

S. Aytac, I. Altan, I. Yaman Bajin, M. Cetin, S. Ozen, F. Gumruk

Hacettepe University Faculty of Medicine, Ihsan Dogramacı Children's Hospital, Ankara, Turkey

Background: Behcet is a multisystemic-vasculitic inflammatory disorder associated with a significant mortality and morbidity in males with early age onset. It affects any type and size of vessels which was classified as ´variable´ vasculitis. Multiple thrombosis without a known underlying disorder in a young male adults is typical for Behcet´s disorder. The frequency of vasculary involvement is reported to be 5-20% in pediatric series.

Aims: Here, we retrospectively evaluate our Behcet cases with thrombosis to define their outcome and prognosis.

Methods: We searched our database which was include 560 pediatric patients with thrombosis and find 8 cases of Behcet´s disorder with a median age 15 year-old (range 11-21 years) at the time of thrombotic event.

Results: Localization of the trombosis were DVT(n=4), intracardiac(n=2), sinovenous(n=1), thrombophlebitis of the superficial veins(n=1) and from those patients 3 had simultaneously pulmonary thromboembolism (2 cases of 4 DVT and 1 case of 2 intracardiac thrombosis). Thrombosis is the first initial presentation in 3 of 8 patients and they further diagnosed as Behcet´s disorder. Thrombotic recurrence was observed in 5 of 8 cases. During the thrombotic event they all received antiplatelet and/or anticoagulation with or without immunosupressive treatment. Six out of 8 cases, thrombosis disappered within a median 6 years follow-up time (range1- 10 years) including 2 patients with a diagnose of pulmonary artery anevrysm/ pulmonary thromboembolism; one was successfully treated with pulmonary artery embolisation and the other was still on immunosuppressive treatment. On the other hand 2 patients with thrombosis have chronic thrombosis without any sequela.

Conclusions: Despite a reported high mortality rate in Behçet´s disease with intracardiac and pulmonary thrombosis, a limited number of pediatric cases reported in this study were all alive after a considerable follow-up time.

PB 1029 | Relevance of the Pulmonary Embolism with and without Cancer of for 3 Years in an Academic Medical Center

C. Yasuda[1], M. Shiina[2]

[1]*Japanese Foundation for Cancer Research Hospital, Department of Medical Safety Management, Tokyo, Japan,* [2]*Kinki University, Research Institute Traditional Asian Medicine, Osaka-Sayama, Japan*

Background: Pulmonary embolism is high mortality disease, though the incidence of cancer associated thrombosis is not enough to reveal in Japan. Our academic medical center has been going to perform the prophylaxis of venous thromboembolism since 14 years. We experienced 73 patients of pulmonary embolism for last 3 years.

Aims: We are evaluating the feature of these cases after prophylaxis, and assessing cancer associated thrombosis.

Methods: We analyzed the feature of recent incidence after prevention of venous thromboembolism with or without surgery and cancer in our hospital. Incidence of pulmonary embolism analyzed for three years from 2013 to 2015 in our hospital. We assessed the age, gender,

D-dimer, the period of onset, risk factor, associate with a malignant disease, symptomatic or asymptomatic, provoked or unprovoked, Trousseau syndrome, paradoxical cerebral infarction, the number of IVC filter insertion, existence of a chemotherapy and mortality, etc. Then we compared the feature of our research with the JAVA study in Japan.

Results: Average age is 64.9±14.8 years old, male and female ratio is 1:0.87, BMI is 23.4±4.34, and D-Dimer is 17.5±20.3 ng/ml. medical treatment of patient is 41(56.2%)cases and patients of peri-surgical period is 32 cases (43.8%), The specialty for medical treatment is Cardiology 29 cases(40%), surgery 12 cases (16%), Obstetrics and gynecology 6 cases (8%). Thrombosis with malignant disease is 30 cases (41.1%), history of venous thromboembolism is 7 cases (9.6%). The number of Trousseau syndrome is 4, paradoxical cerebral infarction case is 1 and death case is 2. The pathological examination of peri-surgical period patient's group is mainly detected the pathological finding of the adenocarcinoma.

Conclusions: The incidence of pulmonary embolism was clearly decreasing by performing of prevention of venous thromboembolism in our hospital. Here after, we consider to be increasing incidence which is important points to manage for prevention of VTE with cancer.

PB 1030 | Pulmonary Thromboembolism in Children: Tuberculosis May Be the Underlying Problem

M. Çetin[1], İ. Yaman Bajin[1], S. Aytaç[1], İ. Altan[1], E. Yalçın[2], A.B. Cengiz[3], F. Gümrük[1]

[1]*Hacettepe University, Department of Pediatrics, Division of Pediatric Hematology, Ankara, Turkey,* [2]*Hacettepe University, Department of Pediatrics, Division of Pediatric Pulmonology, Ankara, Turkey,* [3]*Hacettepe University, Department of Pediatrics, Division of Infectious Disease, Ankara, Turkey*

Background: Pulmonary thromboembolism (PE) is a rare entity among children compared with adults and unlike adults, in whom PE is idiopathic in almost one third of the patients, children with PE has an underlying identifiable risk factor 95% of the time. Tuberculosis is one of the rare causes of PE. Deep vein thrombosis (DVT) and PE in tuberculosis is implicated to the release of inflammatory cytokines, endothelial dysfunction, increased venous stasis, decreased synthesis of anti-coagulant proteins and increased fibrinogen levels.

Aims: Here we report a 14 years old girl diagnosed with PE and tuberculosis.

Methods: She was born as the first child of a healthy mother and father with no consanguinity. She was diagnosed and followed with the diagnosis of epilepsy and motor mental retardation since she was 11 months old. When she was 14 years old she admitted to hospital because of fever, weight loss and difficulty to breathe. Thorax computed tomography (CT) showed mediastinal and hiler lymph nodes, diffuse consolidation and cavitations in the parenchyma of the lung with thrombosis in the left lower pulmonary artery. Heparin infusion started immediately and the tuberculosis culture was positive in the bronchoalveolar lavage specimen.

Results: She dignosed with PE associated with tuberculosis since there was no other risk factors shown for thrombosis.

Conclusions: Tuberculosis should be kept in mind in children with tuberculosis especially in developing countries when there is no other risk factors shown.

PB 1031 | Inherited Prothrombotic Risk Factors in Turkish Children with Hereditary Anjioedema. Single Center Experience

T. Patiroglu[1], M. Cansever[2], A. Ozcan[1], F. Tahan[2], Y. Ozkul[3]

[1]*Erciyes University Medical Faculty, Pediatric Hematology and Oncology, Kayseri, Turkey,* [2]*Erciyes University Medical Faculty, Pediatric Allergy and Immunology, Kayseri, Turkey,* [3]*Erciyes University Medical Faculty, Medical Genetics, Kayseri, Turkey*

Background: Hereditary angioedema (HAE)is a rare diseases. If plasma C1 inhibitor(C1-INH) is deficient, complement, quinine-bradykinin, coagulation and fibrinolytic systems activate out of control and angioedema develops, tendency to thrombosis increases.

Aims: Treatment with danazol and antifibrinolytic drugs may also situmulate the thrombosis. Therefore, prothrombotic risk factors (PRF) are important in the patients with HAE. We also planned to investigate PRF in patients with HAE.

Methods: Ten patients who were followed up at the Department of Erciyes Pediatric Immunology and Allergy were included to the study. The type and frequency of attacks, use of prophylaxy and family-history of HAE were questioned. Factor V G1691A, prothrombin G20210A variant, methylenetetrahydrofolate reductase (MTHFR) and plasminogen activator inhibitor (PAI) mutations were investigated.

Results: Mean ages of patients were 151,90±48,21 months old and nine patients (90%) had family-history. The mean value of C4 level was 4,71±1,62 mg/dl, mean value of C1-INH level was 50,10±19,22 mg/L. Eight patients (80%) had reccurrent attack (ranges:once per 2 weeks-2 months). None of them received prophylactic treatment. One patient (10%) had heterozygous F V G1691A, another one had also heterozygous protrombin G20210A mutation. The heterozygous MTHFR mutation in seven patients (70%) and homozygous MTHFR mutation in two patients (20%) were identified respectively. Furthermore, four patients (40%) heterozygous PAI mutation, another one (%10) homozygous PAI mutation had respectively.

Conclusions: A case of HAE who had heterozygous F V leiden mutation and purpura fulminans was reported in the literature. In our study, there was no clinical evidence supporting thrombosis. Our patient with homozygous PAI mutation had an attack more frequently. In HAE, it's important to be known of PRF to estimate both frequency of attack and risk of thrombosis.

PB 1187 | Relation of Stroke and Bleeding Risk Profiles to Efficacy and Safety of Edoxaban for Cardioversion of Atrial Fibrillation: An Ancillary Analysis from the Edoxaban versus Warfarin in SubjectsUndeRgoing Cardioversion of Atrial Fibrillation (Ensure-AF) Study

G.Y. Lip[1,2], J.L. Merino[3], A.G. Dan[4], S. Themistoclakis[5], K.A. Ellenbogen[6], R. De Caterina[7], A. Goudev[8], J. Jin[9], M. Melino[10], S.M. Winters[11], B. Merkely[12], A. Goette[13,14]

[1]University of Birmingham, Institute of Cardiovascular Sciences, City Hospital, Birmingham, United Kingdom, [2]Aalborg Thrombosis Research Unit, Department of Clinical Medicine, Aalborg, Denmark, [3]Hospital Universitario La Paz, Universidad Europea, Arrhythmia and Robotic Electrophysiology Unit, Madrid, Spain, [4]University Hospital Colentina of Bucharest, Bucharest, Romania, [5]Dell'Angelo Hosiptal, Venice-Mestre, Italy, [6]Virginia Commonwealth University Medical Center, Richmond, United States, [7]Institute of Cardiology, 'G. d'Annunzio' University, Chieti, Italy, [8]Queen Giovanna University Hospital and Medical University-Sofia, Department of Cardiology, Sofia, Bulgaria, [9]Daiichi Sankyo Pharma Development, Biostatistics, Edison, United States, [10]Daiichi Sankyo Pharma Development, Clinical Development, Edison, United States, [11]Daiichi Sankyo, Inc, Global Medical Affairs, Parsippany, United States, [12]Semmelweis University Heart and Vascular Center, Budapest, Hungary, [13]St. Vincenz-Hospital, Cardiology and Intensive Care Medicine, Paderborn, Germany, [14]University Hospital Magdeburg, Working Group - Molecular Electrophysiology, Magdeburg, Germany

Background: In the ensure-AF study (NCT 02072434), the oral factor Xa inhibitor edoxaban was compared to enoxaparin-warfarin in patients undergoing electrical cardioversion of nonvalvular atrial fibrillation (AF). This trial showed comparable low rates of major and clinically relevant non-major (CRNM) bleeding and thromboembolism in the two treatment arms.

Aims: This ancillary analysis investigated differences in relation to stroke and bleeding risk profiles, based on the CHA_2DS_2-VASc and HAS-BLED scores, respectively.

Methods: This multicenter, PROBE evaluation trial compared edoxaban 60 mg QD with enoxaparin-warfarin in 2199 patients. The primary efficacy endpoint was the composite of stroke, systemic embolic event, myocardial infarction, and cardiovascular death from randomization until end of study and the primary safety endpoint was the composite of major and CRNM bleeding. Efficacy and safety outcomes were analysed in relation to CHA_2DS_2-VASc and HAS-BLED scores, respectively. Patients were followed for 28 days on study drug after cardioversion plus another 30 days to assess safety.

Results: 1095 patients were randomized to edoxaban and 1104 received enoxaparin-warfarin. Mean age was 64.3±10 years and 64.2±11 years, respectively. The mean CHA_2DS_2-VASc score was 2.6 (standard deviation [SD] 1.5 and 1.4, respectively) and the mean HAS-BLED score was 0.9 (SD 0.8) in both arms. Efficacy and safety events were low; with only 1 event in CHA_2DS_2-VASc score 0-2 patients. There were non-significant trends towards a lower Odds Ratio (OR) for the primary efficacy endpoint in patients at high risk (CHA_2DS_2-VASc score >2) and a trend for higher ORs with HAS-BLED 0-2 or ≥3 (Table). Mean time in therapeutic range was >67%, with no difference between stroke or bleeding risk strata.

Conclusions: In the ensure-AF study, edoxaban had comparable efficacy and safety to optimized usual anticoagulation with enoxaparin-warfarin and numerically lower primary efficacy endpoint events in those at high stroke risk.

PB 1188 | Anticoagulation Treatment Patterns of Venous Thromboembolism in GARFIELD-VTE Patients

S. Haas[1], A.G.G. Turpie[2], J.I. Weitz[3], W. Ageno[4], P. Angchaisuksiri[5], H. Bounameaux[6], S.Z. Goldhaber[7], S. Goto[8], G. Kayani[9], J. Dalsgaard Nielsen[10], S. Schellong[11], L.G. Mantovani[12], P. Prandoni[13], A.K. Kakkar[9,14]

TABLE 1 Outcomes by stroke and bleeding risk strata

	Total by Treatment No. of events / Total No. (%)			
Primary efficacy endpoint ITT Analysis Set Overall Treatment Period	Edoxaban (n=1095)	Warfarin-Enoxaparin (n=1104)	OR (95%CI)	Mean TiTR with warfarin-enoxaparin arm
CHA2DS2-VASc score				
0-1	0/252 (0%)	0/232 (0%)		71.8
2	1/305 (0.3%)	0/306 (0%)		71.0
>2	4/536 (0.7%)	11/560 (2.0%)	0.38 (0.09-1.28)	70.3
Primary safety endpoint Safety Analysis Set On Treatment Period	(n=1067)	(n=1082)		
HAS-BLED				
0-2	15/1041 (1.4%)	10/1049 (1.0%)	1.52 (0.63-3.80)	70.9
≥3	1/24 (4.2%)	1/32 (3.1%)	1.34 (0.02-109.16)	67.4

Copenhagen, Denmark, [11]Krankenhaus Dresden Friedrichstadt, Dresden, Germany, [12]University of Milano- Bicocca, Milan, Italy, [13]University of Padua, Padua, Italy, [14]University College London, London, United Kingdom

Background: Parenteral anticoagulation overlapping with vitamin K antagonists (VKA) has been the cornerstone of venous thromboembolism (VTE) treatment. With the recent introduction of four direct oral anticoagulants (DOACs), physicians now have broader treatment choices. The non-interventional global GARFIELD-VTE registry observes real-world treatment practices and provides a contemporary snapshot of current VTE treatment.

Aims: To describe interim data on the initial anticoagulation (AC) treatment of VTE patients prospectively enrolled at 361 sites in 28 countries from July, 2014 to September, 2016.

Methods: The study was approved be the individual ethics committees of each participating site and all patients provided written informed consent. Patients with documented initial AC therapy within ±2 weeks of diagnosis (n=8017) were stratified into four treatment groups:

1. parenteral AC alone,
2. parenteral AC followed by a VKA,
3. VKA alone, and
4. DOAC with or without a heparin lead-in.

Results: Differences in therapeutic approach were observed by geographical region, patient population and site of deep-vein thrombosis (DVT) (Table). As recommended by current guidelines, patients with active cancer and pregnant women were more likely to be treated with a parenteral AC alone. AC treatment was similar in patients with DVT and pulmonary embolism, but parenteral anticoagulant alone was more frequently used for upper than lower limb DVT. Furthermore, analyses of AC treatment patterns by geographical regions found that VKA alone was more frequently prescribed in countries outside Asia, Europe and North America (Table).

Conclusions: GARFIELD-VTE provides a global perspective on AC treatment patterns for VTE, which not only varies by patient population, but also by geographic region and site of DVT.

PB 1189 | Clinical Outcomes in Fragile Patient with Venous Thromboembolism

F. Moustafa[1], M. Giorgi Pierfranceschi[2], P. Di Micco[3], E. Bucherini[4], A. Lorenzo[5], A. Villalobos[6], J.A. Nieto[7], B. Valero[8], A.L. Samperiz[9], M. Monreal[10], RIETE Investigators

[1]CHU Clermont-Ferrand, Emergency Department, Clermont-Ferrand, France, [2]Val d'Arda Hospital, Emergency Department, Piacenza, Italy, [3]Ospedale Buonconsiglio Fatebenefratelli, Internal Medicine, Naples, Italy, [4]Azienda U.S.L. Di Ravenna - O.C. Di Faenza, Vascular Medicine, Ravena, Italy, [5]Hospital Universitario La paz , Internal Medicine, Madrid, Spain, [6]Hospital Regional Universitario de Málaga, Internal Medicine, Malaga, Spain, [7]Hospital General Virgen de la Luz, Internal Medicine, Cuenca, Spain, [8]Hospital General Universitario de Alicante, Internal Medicine, Alicante, Spain, [9]Hospital Reina Sofía, Internal Medicine, Tudela, Spain, [10]Hospital de Badalona Germans Trias i Pujol. Universidad Católica de Murcia, Internal Medicine, Barcelona, Spain

Background: Subgroup analyses from randomized trials suggested favorable results for the direct oral anticoagulants in fragile patients with venous thromboembolism (VTE). These findings, obtained from randomized trials with selected patients, have not been validated yet in real-life studies.

Aims: To compare the clinical characteristics, treatment and outcomes during the course of anticoagulation and after its discontinuation in fragile versus non-fragile patients with VTE.

Methods: Retrospective study using prospectively collected data from consecutive patients enrolled in RIETE registry (Registro Informatizado Enfermedad Trombo-Embolica, NCT02832245). Fragile patients were defined as those having creatinine clearance levels [CrCl] ≤50 mL/min, age ≥75 years or body weight ≤50 kg.

Results: From January 2013 to October 2016, 15079 patients were recruited. Of these, 6260 (42%) were fragile: 37% aged ≥75 years, 3.6% weighed ≤50 kg and 20% had CrCl levels ≤50 mL/min. During the course of anticoagulation (mean, 210 days), fragile patients had a lower rate of VTE recurrences (hazard ratio [HR]: 0.7; 95%CI: 0.5-0.8) and an over 2-fold higher rate of major bleeding (HR: 2.3; 95%CI: 1.8-2.8) or death (HR: 2.45; 95%CI: 2.2-2.75) than non-fragile. After discontinuing anticoagulation, fragile patients had a higher rate of VTE recurrences

TABLE 1 Treatment approach by geographic region, patient populations and site of DVT

		Parenteral alone	Parenteral+ VKA	VKA alone	DOACs ± Parenteral
Overall		17.6%	28.3%	3.7%	50.5%
Regions	Europe (n=4981)	17.3%	27.6%	2.7%	52.4%
	Asia (n=1116)	28.2%	23.0%	4.2%	44.5%
	North America (n=757)	16.4%	30.5%	2.2%	50.9%
	Other (n=1163)	9.2%	34.6%	8.3%	48.0%
Patient Populations	Active (n=710) / History (n=829) of cancer	64.2% / 36.1%	11.5% / 20.3%	1.4% / 2.8%	22.8% / 40.9%
	Pregnancy (n=115)	49.6%	23.5%	8.7%	18.3%
	Renal impairment (n=279)	21.1%	42.3%	7.2%	29.4%
Site of DVT	Upper (n=512) / Lower (n= 5500) limb	25.2% / 16.6%	22.5% / 28.9%	3.5% / 3.8%	48.8% / 51.6%

(HR: 1.59; 95%CI: 1.29-1.97), major bleeding (HR: 2.38; 95%CI: 1.09-5.33) and death (HR: 2.92; 95%CI: 2.37-3.61) than non-fragile.

TABLE 1 Clinical outcomes during and after discontinuing anticoagulant therapy

	Fragile		Non Fragile	
	N	Events per 100 patient-years	N	Events per 100 patient-years
During anticoagulant therapy	6260		8819	
Recurrent VTE	92	2.63 (2.13-3.21)	203	4.01 (3.49-4.59)
Major Bleeding	234	6.69 (5.87-7.59)	151	2.95 (2.51-3.45)
Death	783	22.1 (20.6-23.7)	465	9.02 (8.23-9.87)
After discontinuing Therapy	1848		2980	
Recurrent VTE	163	16.1 (13.7-18.7)	180	10.1 (8.71-11.7)
Major Bleeding	10	0.97 (0.49-1.73)	5	0.28 (0.10-0.62)
Death	233	22.7 (19.9-25.7)	139	7.75 (6.54-9.12)

Conclusions: In real life, 42% of VTE patients were fragile. During anticoagulation, they had fewer VTE recurrences and more major bleeds or deaths. After its discontinuation, they had more recurrences, bleeds and deaths.

PB 1190 | Comprehensive Characteristics of the Anticoagulant Activity in Relationship to the Plasma Concentration of Dabigatran

W.J. Comuth[1,2], L.Ø. Henriksen[3], D. van de Kerkhof[4], S. Husted[5,6], S.D. Kristensen[6,7], M.P.M. de Maat[8], A.-M.B. Münster[9]

[1]Hospital Unit West, Cardiology, Clinical Biochemistry, Herning, Denmark, [2]Aarhus University, Department of Biomedicine, Herning, Denmark, [3]Hospital Unit West, Clinical Biochemistry, Herning, Denmark, [4]Catharina Hospital, Clinical Biochemistry, Eindhoven, The Netherlands, [5]Hospital Unit West, Department of Medicine, Herning, Denmark, [6]Aarhus University, Aarhus, Denmark, [7]Aarhus University Hospital, Department of Cardiology, Aarhus, Denmark, [8]Erasmus Medical Center, Department of Hematology, Rotterdam, The Netherlands, [9]Hospital Unit West, Department of Clinical Biochemistry, Herning, Denmark

Background: Dabigatran can be detected by a variety of coagulation assays, which have yet to be validated in clinical settings. Important problems in diagnostics include: 1) Are the assays good reflections of the concentration? 2) Most of the currently available data are derived from studies with spiked plasma samples and does not necessarily reflect the *in vivo* effect in treated patients.

3) In clinical studies, it is optimal to perform analyses batchwise at the end of the study, to reduce analytical variation. This requires stability of samples during long-term storage at -80°C.

Aims: To evaluate:

1. The correlation between the plasma concentration (liquid chromatography-tandem mass spectrometry (LC-MS/MS)) and the anticoagulant effect of dabigatran
2. The difference in anticoagulant effect between plasma samples spiked with dabigatran and *ex vivo* samples from patients treated with dabigatran etexilate
3. Stability of these samples after long-term storage at -80°C

Methods: ROTEM®, ecarin chromogenic assay (ECA), a laboratory developed diluted thrombin time (LD-dTT) and LC-MS/MS were used to measure dabigatran in plasma from healthy donors spiked with dabigatran (0-1000 ng/mL) and in *ex vivo* samples from patients treated with dabigatran etexilate. Samples were frozen and stored at -80°C, then thawed at 1, 3, and 6 months and analyzed.

Results: EXTEM clotting time (CT), ECA and LD-dTT have very high correlation with dabigatran plasma concentrations. With the exception of clot formation times (CFT) and maximum clot firmness (MCF), there were no significant differences in results between spiked and patient samples (Figure 1). Samples were stable for at least 6 months at -80°C.

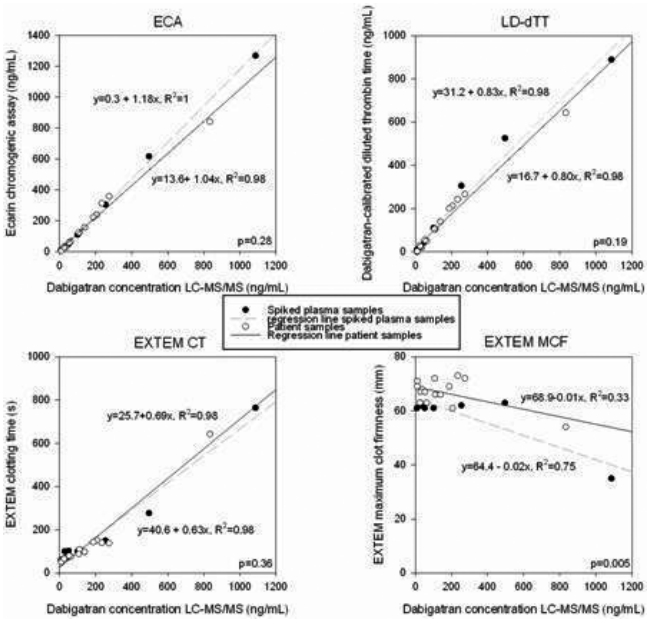

FIGURE 1 The relationship between plasma concentration and the anticoagulant effect of dabigatran. The p-value shown is for the difference between sp

Conclusions: EXTEM CT, ECA and LD-dTT are suitable for measuring the effect of dabigatran in treated patients. In general, results from spiked-plasma samples are similar to those of patient samples. Storage of plasma samples of dabigatran-treated patients for up to 6 months does not influence the measured levels.

PB 1191 | Menstrual Bleeding Patterns in Women Treated with Rivaroxaban: Data from the EINSTEIN CHOICE Trial

K. Boonyawat[1,2], A.W. Lensing[3], M.H. Prins[4], P. Prandoni[5], J.I. Weitz[6], M. Crowther[1]

[1]McMaster University, Hamilton, Canada, [2]Ramathibodi Hospital, Mahidol University, Bangkok, Thailand, [3]Bayer Healthcare, Wuppertal, Germany, [4]Maastricht University Medical Centre, Maastricht, The Netherlands, [5]University of Padua, Padua, Italy, [6]Thrombosis & Atherosclerosis Research Institute and McMaster University, Hamilton, Canada

Background: Recent evidence suggests that rivaroxaban increases menstrual bleeding. It is uncertain whether this effect is dose-dependent.

Aims:

1) To compare menstrual bleeding patterns in women receiving rivaroxaban 20 mg, 10 mg or aspirin in a large randomized trial.

2) To describe the frequency of changes in menstrual bleeding related-therapy in such women.

Methods: We prospectively collected data from women enrolled in the EINSTEIN CHOICE study who had menstrual bleeding. At each follow-up visit, data on last menstrual flow length and intensity (shorter/less than usual, as usual, or longer/more than usual) compared with those from before the start of antithrombotic therapy were recorded as were any actions taken to manage menstrual bleeding. Frequency was reported in percentage and differences between treatment groups were calculated.

Results: Information from 353 women was collected. Over the 5 follow-up visits, menstrual flow length increased in 12.6-18.4% of women given rivaroxaban 20 mg, in 6.0-12.8% given rivaroxaban 10 mg, and in 9.4-12.8% given aspirin. Menstrual flow intensity increased in 19.7-25.6% of women given rivaroxaban 20 mg, in 14.7-22.1% given rivaroxaban 10 mg, and in 13.4-20.6% given aspirin. The proportion of women with increased menstrual flow length and intensity was higher with 20 mg of rivaroxaban than with 10 mg of rivaroxaban or with aspirin. Women treated with 10 mg of rivaroxaban reported a mixed pattern of change in menstrual flow length and intensity compared with those receiving aspirin (Tables 1, 2). Few women required actions to manage menstrual bleeding.

Conclusions: Women treated with 20 mg rivaroxaban had increased menstrual flow length and intensity compared with those given 10 mg rivaroxaban or aspirin. Compared with aspirin, there was minimal difference in menstrual flow length and a mixed pattern of flow intensity with 10 mg of rivaroxaban.

TABLE 1 Comparison of menstrual flow length patterns across groups

Days of follow-up	Rivaroxaban 20 mg vs ASA 100 mg	Rivaroxaban 10 mg vs ASA 100 mg	Rivaroxaban 10 mg vs Rivaroxaban 20 mg
Day 30	=	---	----
Day 90	=	=	=
Day 180	++	-	--
Day 270	++++	=	----
Day 360	+++	---	----

= if difference between treatment groups is +/- 1 %, +/- if difference between treatment groups is >1% but <3 %, ++/-- if difference between treatment groups is ≥3 but <5 %, ++/-- if difference between treatment groups is ≥3 but <5 %, +++/--- if difference between treatment groups is ≥ 5 but <7%, ++++/---- if difference between treatment groups is ≥ 7%

TABLE 2 Comparison of patterns of menstrual flow intensity across groups

Day of follow-up	Rivaroxaban 20 mg vs ASA 100 mg	Rivaroxaban 10 mg vs ASA 100 mg	Rivaroxaban 10 mg vs Rivaroxaban 20 mg

PB 1192 | Absence of Interaction between Rivaroxaban, Tacrolimus and Everolimus in Renal Transplant Recipients Anticoagulated for Proximal Deep Vein Thrombosis or Atrial Fibrillation

G. Camporese[1], M.T. Sartori[2], D. Bernardi[3], F. Marchini[4], G. Avruscio[1]

[1]University Hospital of Padua, Department of Cardiac, Thoracic and Vascular Sciences; Unit of Angiology, Padua, Italy, [2]University Hospital of Padua, Department of Internal Medicine; Clinical Medicine I, Padua, Italy, [3]University Hospital of Padua, Department of Laboratory Medicine, Padua, Italy, [4]University Hospital of Padua, Division of Nephrology and Renal Transplantation, Padua, Italy

Background: No data is available on rivaroxaban use for the treatment of venous thromboembolism (VTE) or atrial fibrillation (AF) in renal transplant (RT) patients, not included in phase III clinical trials, and on its surmised interaction with some immunosuppressive drugs, such as tacrolimus or everolimus, which share the same metabolic pathways

Aims: To investigate a potential drug interaction in RT patients taking tacrolimus ± everolimus receiving concomitant rivaroxaban.

Methods: Five consecutive RT patients, 4 taking tacrolimus and 1 tacrolimus plus everolimus, were treated with rivaroxaban for acute VTE or AF. All patients had a stable renal function at baseline. Rivaroxaban was taken at 8.00 am, and tacrolimus and everolimus at 6.30 am. Blood samples were drawn during the first 2 weeks (days 1-5 and 8-12) both at 8.00 am and 12.00 am for Ctrough and Cpeak rivaroxaban assay, respectively (HemosIL Rivaroxaban on ACL TOP LAS 750 WERFEN-IL). Serum levels of tacrolimus, everolimus and creatinine were measured at the same time. Blood cell count, AST and ALT were determined on day 1 and 12. Both bleeding and thrombotic events were recorded.

Results: In all patients rivaroxaban levels showed a predictable trend according to its pharmacokinetics, both in samples at Ctrough (< 30-80 ug/L) and at Cpeak (54-449 ug/L). No significant variations were observed neither in tacrolimus levels (8.00 am: 2.78-9.33 ug/L; 12.00 am: 3.41-16.11 ug/L),nor in everolimus levels (8.00 am: 4.7-11.5 ug/L; 12.00 am: 8.3-17.3 ug/L), nor in creatinine levels between Ctrough and Cpeak measurements for each patient. No patient had bleeding or thrombotic events.

Conclusions: In RT recipients tacrolimus or everolimus does not seem to interact with rivaroxaban given for VTE or AF treatment. Both anticoagulant and immunosuppressive effects seem warranted, without any effect on the graft function, and with the expected antithrombotic effect without bleeding complications.

PB 1193 | Impact of Evolving ACCP Guidelines on Estimates of Venous Thromboembolism Risk in US Hospitals

W. Huang[1], A. Cohen[2], Z. Maksim[3], A. Wyman[1], F. Anderson[1]

[1]*University of Massachusetts Medical School, Surgery, Worcester, United States,*
[2]*Guy's, King's and St. Thomas's School of Medicine, London, United Kingdom,*
[3]*University of Massachusetts Medical School, Anesthesia, Worcester, United States*

Background: The annual number of US acute-care hospital discharges at risk of VTE and the impact of evolving American College of Chest Physicians (ACCP) Consensus guidelines on identification of patients at VTE risk are unknown.

Aims: To estimate the annual number of US acute-care hospital discharges at risk of VTE.

Methods: The Y2004, Y2008 and Y2012 ACCP guidelines for prevention of VTE were applied to Y2014 US hospital discharges using Clinical Classification System codes in the National Inpatient Sample, a database of acute-care hospital discharges from the US Agency for Health Care Quality and Research.

Results: Of 35.4 million discharges from US acute-care hospitals in Y2014, 11.7 million (33%) met the Y2012 ACCP criteria for VTE prophylaxis risk, including 4.4 of 7.5 million (59%) who underwent a surgical procedure. An additional 7.3 of the 20.8 million (35%) remaining eligible discharges met criteria for VTE prophylaxis based on medical risk factors. These data allow estimation of the annual number of US hospital discharges at risk for VTE by age group (Table 1). Estimated VTE risk in patients with medical risk factors decreased by 13% (from 8.4 to 7.3 million discharges) based on 2012 vs. 2008 ACCP criteria (Table 2).

TABLE 2 Number of Discharges from US Acute-Care Hospitals in Y2014 with ACCP Guideline-Defined Risk of VTE: Comparison of the three most recent guide

VTE Risk Population	ACCP-2004 Guidelines Discharges (N)	ACCP-2008 Guidelines Discharges (N)	ACCP-2012 Guidelines Discharges (N)
Major surgery	4,416,707	4,470,702	4,440,848
Major medical illness	8,377,923	8,451,433	7,300,447
Total	12,794,630	12,922,135	11,741,295

Conclusions: One-third of Y2014 US hospital discharges met Y2012 ACCP criteria for VTE prophylaxis. Compared with estimates based on the 2004 or 2008 guidelines, a modest decrease was observed when applying Y2012 ACCP guidelines to Y2014 NIS data. This decrease reflects the ACCP's decision to adopt quantitative risk scoring to identify non-surgical discharges at sufficient VTE risk to warrant prophylaxis. Further research is needed to validate quantitative in-hospital risk models in identifying high-risk patients with medical illnesses that can benefit from VTE prophylaxis, and to evaluate the potential impact of recent evidence for continuation of prophylaxis after hospital discharge in selected patients.

TABLE 1 VTE Risk Groups vs. Age Group for Y2014 US Hospital Discharges

VTE Risk Population	At risk per ACCP-2012 (N)	Age 18–39 years, N (%)	Age 40–59 years, N (%)	Age 60–74 years, N (%)	Age ≥75 years, N (%)
Major surgery	4,440,848	446,980 (10)	1,343,020 (30)	1,644,461 (37)	1,006,385 (23)
Medical illness	7,300,447	365,330 (5)	1,256,035 (17)	2,196,985 (31)	3,482,095 (48)
Total	11,741,447	812,310 (7)	2,599,055 (22)	3,841,446 (33)	4,488,480 (38)

PB 1194 | Healthcare Resource Use in the Non-interventional XALIA Study of Rivaroxaban versus Standard Anticoagulation for Deep Vein Thrombosis

L.G. Mantovani[1], S. Cano[2], M. Gebel[3], K. Sahin[4], K. Folkerts[5], S. Haas[6], R. Kreutz[7], D. Monje[8], J. Schneider[5], M. van Eickels[5], W. Ageno[9], A.G.G. Turpie[10]

[1]University of Milan Bicocca, CESP-Center for Public Health Research, Monza, Germany, [2]Modus Outcomes, Letchworth Garden City, United Kingdom, [3]Bayer AG, Wuppertal, Germany, [4]ClinStat GmbH, Cologne, Germany, [5]Bayer AG, Berlin, Germany, [6]Formerly Technical University Munich, Munich, Germany, [7]Charité Universitaetsmedizin Berlin, Institute of Clinical Pharmacology and Toxicology, Berlin, Germany, [8]Bayer Vital GmbH, Leverkusen, Germany, [9]University of Insubria, Department of Clinical and Experimental Medicine, Varese, Italy, [10]Hamilton Health Sciences, Medicine, Hamilton, Canada

Background: The phase III EINSTEIN DVT and EINSTEIN PE studies showed that rivaroxaban significantly reduced median hospital length of stay (LOS) compared with standard anticoagulation. The non-interventional XALIA study compared the safety and effectiveness of rivaroxaban to standard anticoagulation for treatment of venous thromboembolism (VTE) in routine clinical practice.

Aims: This XALIA substudy assessed the potential of rivaroxaban to reduce healthcare resource use, including hospital LOS and frequency of hospitalization.

Methods: Patients in XALIA aged ≥18 years scheduled to receive ≥3 months of anticoagulation for treatment of deep vein thrombosis (DVT) with rivaroxaban or standard anticoagulation were eligible. Treatment decisions were at the physician's discretion. Healthcare resource use, including hospital admission for the index DVT and initial LOS, was documented. The main analyses in this substudy used the Propensity score-matched (PMS) set of patients, with adjustment for the presence of cancer at baseline.

Results: In the safety population, 727/2619 (27.8%) rivaroxaban-treated patients were hospitalized for the index DVT, as were 1011/2149 (47.0%) of the standard anticoagulation group. In the PMS analysis, 1124 rivaroxaban-treated patients and 1124 standard anticoagulation-treated patients were included; baseline characteristics are in Table 1. In the PMS analysis, 433/1124 (38.5%) rivaroxaban-treated patients and 438/1124 (39.0%) standard anticoagulation-treated patients were hospitalized. For the index event, LOS in the PMS analysis was a least-squares mean of 2.6 days shorter with rivaroxaban vs standard anticoagulation (5.4 vs 8.0 days; geometric odds ratio=0.67 [95% CI 0.61-0.74, $p< 0.001$]).

Conclusions: In XALIA, hospital LOS was shorter with rivaroxaban than standard anticoagulation, consistent with phase III results. DVT treatment with rivaroxaban in routine clinical practice may reduce the cost per patient compared with standard anticoagulation.

TABLE 1 Baseline demographics and clinical characteristics (PMS analysis)

Characteristic N (%) unless stated	Rivaroxaban (N=1124)	Standard anticoagulation (N=1124)
Age, years, mean (SD)	60.8 (16.2)	61.2 (17.2)
Male sex	508 (45.2)	523 (46.5)
First available Creatinine Clearance <50 ml/min	64 (5.7)	82 (7.3)
DVT only	1008 (89.7)	1014 (90.2)
DVT with PE	116 (10.3)	110 (9.8)
Hospitalization for index VTE	433 (38.5)	438 (39.0)
Provoked VTE	368 (32.7)	390 (34.7)
Cancer at baseline	94 (8.4)	95 (8.5)
Previous major bleeding	23 (2.0)	24 (2.1)

PB 1195 | Oral Anticoagulation with Direct Thrombin Inhibitors Prevents the Early Events of Atrial Remodeling and the Thrombin-activated ErbB Signaling in a Rat Model of Atrial Dilation

C. Jumeau[1,2], F. Loisel[1], G. Dilanian[1], N. Mougenot[3], N. Villeneuve[2], S. Hatem[1], M. David-Dufilho[1]

[1]UMRS1166 Inserm-UPMC, Paris, France, [2]Servier Research Institute, Suresnes, France, [3]UMS 28, UPMC, Paris, France

Background: Oral anticoagulation is a key therapy in the prevention of thromboembolism associated with atrial fibrillation. We recently published that anticoagulation with direct thrombin inhibitors (DTIs) prevent dilation, interstitial fibrosis and myocardial hypertrophy of atria from rats with heart failure (Jumeau et al JACC-BTS 1 (5) 2016).

Aims: The current study investigates the action of DTIs on the early markers of extracellular matrix remodeling and the participation of epidermal growth factors/ErbB in thrombin signals.

Methods: Heart failure associated with atrial dilation is induced by myocardial infarction (MI) in 2-months old rats, treated with either vehicle or 25 mg/kg/d dabigatran or 6 mg/kg/d S35972 for 5, 30 or 60 days. Cultures of atrial explants and cardiac cells are performed. Plasma thrombogenic potential is measured by thrombography. Soluble biomarkers are quantified by ELISA, atrial mRNAs by RT-qPCR, ErbB activation by western blot.

Results: The endogenous thrombin potential of plasma is similar 5 and 30 days post-MI and decreases at 60 days to levels remaining higher than those of controls. It is associated with increased plasma thrombospondin-1 (TSP-1). DTIs prevent this rise in soluble TSP-1 and the induction of atrial mRNAs for TSP-1 and intercellular adhesion molecule-1 from 5 days post-MI. DTIs also block the induction of mRNAs for heparin-binding epidermal growth factor (HB-EGF) and neuregulin-1, which appears together with that of myocardial hypertrophic markers 60 days post-MI. Plasma HB-EGF levels, which result from the general circulation, are similar in rats

with dilated atria and controls. However, thrombin activates release of soluble HB-EGF and expression of remodeling markers in atrial explants. To note, recombinant rat HB-EGF activates ErbB4 receptors in atrial fibroblasts but do not induce hypertrophic markers in cardiomyocytes.

Conclusions: These results show early inhibition of atrial remodeling by DTIs and suggest a role for HB-EGF in atrial fibrosis.

PB 1196 | 6-months Outcomes of Patients: Results from GARFIELD-VTE

A.G.G. Turpie[1], S. Haas[2], J.I. Weitz[3], W. Ageno[4], P. Angchaisuksiri[5], H. Bounameaux[6], S.Z. Goldhaber[7], S. Goto[8], G. Kayani[9], J. Dalsgaard Nielsen[10], S. Schellong[11], L.G. Mantovani[12], P. Prandoni[13], A.K. Kakkar[9,14]

[1]McMaster University, Hamilton, Canada, [2]Technical University of Munich, Formerly Department of Medicine, Munich, Germany, [3]McMaster University and Thrombosis and Atherosclerosis Research Institute, Hamilton, Canada, [4]University of Insubria, Department of Clinical and Experimental Medicine, Varese, Italy, [5]Ramathibodi Hospital, Mahidol University, Department of Medicine, Bangkok, Thailand, [6]University Hospitals of Geneva, Faculty of Medicine, Geneva, Switzerland, [7]Harvard Medical School, Boston, United States, [8]Tokai University School of Medicine, Kanazawa, Japan, [9]Thrombosis Research Institute, London, United Kingdom, [10]Copenhagen University Hospital, Copenhagen, Denmark, [11]Krankenhaus Dresden Friedrichstadt, Dresden, Germany, [12]University of Milano-Bicocca, Milan, Italy, [13]University of Padua, Padua, Italy, [14]University College London, London, United Kingdom

Background: The Global Anticoagulant Registry in the FIELD - Venous Thromboembolism (GARFIELD-VTE; NCT02155491) is a global prospective observational study, which aims to capture the treatment patterns for acute VTE and the rate and nature of VTE recurrence, VTE complications, bleeding complications, and all-cause mortality over ≥3 years.

Aims: To determine the 6-month outcomes of patients enrolled from 396 sites in 28 countries from 2014-2016.

Methods: Interim data on 8842 with a confirmed diagnosis of VTE and 6-month follow-up data were analysed. Occurrences of major outcomes were estimated using person-time event rates (per 100 person-years). Rates and 95% confidence intervals were estimated using a Poisson model.

Results: Patients were recruited from Europe (59.3%), Asia (15.0%), North America (9.9%) and the rest of the world (15.7%). The median age was 60.1 y (interquartile range: 46.0-71.5). Over 6-months follow-up, the rates (95% CI) of all-cause mortality and first occurrence of major bleeding and VTE recurrence were: 11.1 (10.0; 12.3), 2.8 (2.3; 3.4), and 3.6 (3.0; 4.3) per 100 person-years, respectively. The rates of all three major outcome events were higher in the first month of follow-up (Table) than in the subsequent 5 months. Overall, 17% of bleeds were major, requiring transfusion in 16.2% of cases. Fatal bleeding occurred in 2.2% of patients with any bleeding event (n=502). The most common cause of death at 6 months was cancer in 50.9% of cases (of these, 14.6% were due to lung cancer; 9.3% to colorectal; 8.6% to pancreatic; and 8.6% to lymphoma). A further 5.1% of deaths were due to pulmonary embolism and 1.3% due to other VTE complications.

Conclusions: Death was the most frequent major adverse outcome in patients diagnosed with VTE; although half were cancer-related. The highest event rates for death and major bleeding occurred during the first month of follow-up.

TABLE 1 Event rates during the first and 6 months of follow-up

	Event rate per 100 person-years(95% CI)	
Follow-up	1-month	6-months
All-cause mortality	15.0 (12.3 to 18.2)	11.1 (10.0 to 12.3)
Major bleeds	5.8 (4.3 to 8.0)	2.8 (2.3 to 3.4)
Recurrent VTE	3.9 (2.7 to 5.7)	3.6 (3.0 to 4.3)

PB 1197 | Outcomes, Interventions and DOAC Plasma Concentration Assay Utility in DOAC-treated Patients Presenting with Major Haemorrhage or Thrombosis - Results from the Anticoagulant Reversal and Events Study Collaborative (ARES1)

R.I. Baker[1,2], J. Curnow[3], L. Young[4], S.R. McGregor[1,2], T. Brighton[5], P. Harper[6], J. Joseph[7], A. Hugman[8], G.V. D'Aulerio[1,2], A. Gallus[9], Thrombosis and Haemostasis Society of Australia and New Zealand

[1]Western Australian Centre for Thrombosis and Haemostasis, Murdoch University, Perth, Australia, [2]Perth Blood Institute, Perth, Australia, [3]Westmead Hospital, Sydney, Australia, [4]Auckland City Hospital, Auckland, New Zealand, [5]Prince of Wales Hospital, Sydney, Australia, [6]Palmerston North Hospital, Rosyln, New Zealand, [7]St Vincent's Hospital, Sydney, Australia, [8]St George Hospital, Sydney, Australia, [9]Flinders Medical Centre, Adelaide, Australia

Background: The ARES Collaborative is a large observational study in Australia and New Zealand of consecutive patients who present to hospital with haemorrhage, thromboembolism (TE) or requiring urgent anticoagulant reversal and are taking a DOAC (dabigatran, rivaroxaban, apixaban) or warfarin. The pilot study (ARES1) included case records from 287 presentations, of which 83 (28.9%) involved a DOAC.

Aims: To describe major haemorrhage (MH) and TE presentations in ARES1 amongst patients presenting on DOACs.

Methods: Demographics and site of bleed or thrombosis were reported. Outcomes assessed included interventions utilised, length of hospital stay, 30-day mortality and DOAC plasma concentration assessment within 24 hours of presentation.

Results: MH and TE accounted for 45.8% (38/83) and 14.5% (12/83) of DOAC case presentations, respectively. Most patients presenting with MH received a haemostatic agent (e.g. Prothrombinex-VF® 47.4%, FEIBA® 13.2%, FFP 26.3% and/or tranexamic acid 26.3%), however 28.9% did not receive a specific haemostatic agent.

57.9% (22/38) of patients presenting with MH and 33.3% (4/12) with TE had DOAC plasma concentrations assessed within 24 hours of

presentation. The median time from patient presentation to collection of a DOAC level was 2 hours. The majority (69.2%) of DOAC levels were within the expected on-therapy range for the respective drug. MH and TE were associated with an extended length of hospital stay (median: 6.5 days and 6 days) and a high all-cause mortality (18.4% and 8.3%), respectively.

Conclusions: MH or TE in patients taking DOACs are sentinel medical events with high 30-day mortality and prolonged hospitalisation. Most patients with MH had DOAC levels within the expected 'on-therapy' range, although a proportion had undetectable levels. Obtaining DOAC plasma levels may be critical to inform clinical management decisions in patients presenting with DOAC-related haemorrhage or thromboembolism, including the requirement for specific anticoagulant reversal agents.

PB 1198 | Direct Oral Anticoagulants in Patients with Venous Thromboembolism Usually Excluded for Clinical Trials

F. Moustafa[1], R. Pesavento[2], P. Di Micco[3], J. Gonzalez-Martinez[4], R. Quintavalla[5], L. Peris[6], J.A. Porras[7], N. Falvo[8], P. Banos[9], M. Monreal[10], RIETE investigators

[1]CHU Clermont-Ferrand, Urgences Adultes, Clermont-Ferrand, France, [2]University of Padua, Internal Medicine, Padua, Italy, [3]Ospedale Buonconsiglio Fatebenefratelli, Internal Medicine and Emergency Room, Naples, Italy, [4]ALTAHAIA, Xarxa Assistencial de Manresa, Internal Medicine, Barcelona, Spain, [5]Azienda Ospedaliera Universitaria, Medicine, Parma, Italy, [6]Consorcio Hospitalario Provincial de Castellón, Internal Medicine, Castellon, Spain, [7]Hospital Universitario Joan XXIII de Tarragona, Internal Medicine, Tarragona, Spain, [8]CHU de Dijon, Hôpital du Bocage, Internal Medicine, Dijon, France, [9]Hospital de Can Misses, Internal Medicine, Ibiza, Spain, [10]Hospital de Badalona Germans Trias i Pujol. Universidad Católica de Murcia, Internal Medicine, Barcelona, Spain

Background: Based on the results from randomized clinical trials, current guidelines recommend the use of the direct oral anticoagulants (DOACs) in patients with venous thromboembolism (VTE).

Aims: We aimed to assess the use of DOACs in VTE patients that would not have been eligible for these pivotal trials, and their efficacy and safety as well.

Methods: We conducted a retrospective study that used prospectively collected data from consecutive patients enrolled in the RIETE (Registro Informatizado Enfermedad Trombo Embólica, NCT02832245) database. We considered as exclusion criteria any of the following: metastatic cancer; creatinine clearance levels < 30 mL/min; platelet count < 100,000/μL; recent major bleeding; chronic liver failure and pregnancy.

Results: From January 2013 to December 2016, 18853 patients were recruited. Of these, 3578 (19%) had exclusion criteria: metastatic cancer 48%; renal insufficiency 29%; thrombocytopenia 13%; recent bleeding 11%; liver failure 7.5% and pregnancy 3.5%. During initial therapy, patients with exclusion criteria receiving rivaroxaban (n=104) had a lower rate of major bleeding than those (n=224) on unfractionated heparin (hazard ratio [HR]: 0.18; 95%CI: 0.03-0.64) and a non-significantly lower rate than those (n=3172) on low-molecular-weight heparin (LMWH) (HR: 0.39; 95%CI: 0.06-1.30). During long-term therapy, patients on rivaroxaban (n=151) had a lower rate of VTE recurrences (HR: 0.25; 95%CI: 0.04-0.84) and major bleeding (HR: 0.38; 95%CI: 0.12-0.93) than those on LMWH (n=2071) and a similar rate than those on vitamin K antagonists (n=939). There were too few patients (n=43) with exclusion criteria on apixaban to perform comparisons.

TABLE 1 VTE recurrences and major bleeding during initial and long term therapy for rivaroxaban

	N	VTE recurrences	Major bleeding
		Events per 100 patient-years (95%CI)	Events per 100 patient-years (95%CI)
Initial therapy	2229		
Exclusion criteria	104	-	4.60 (0.77-15.2)
No exclusion criteria	2125	1.96 (1.20-3.04)	1.85 (1.11-2.90)
Long-term therapy	2499		
Exclusion criteria	151	2.41 (0.40-7.96)	4.85 (1.54-11.7)
No exclusion criteria	2348	1.87 (1.22-2.76)	1.61 (1.01-2.45)

TABLE 2 VTE recurrences and major bleeding during initial and long term therapy for apixaban

	N	VTE recurrences	Major bleeding
		Events per 100 patient-years (95%CI)	Events per 100 patient-years (95%CI)
Initial therapy	123		
Exclusion criteria	11	-	-
No exclusion criteria	112	-	2.89 (0.14-14.2)
Long-term therapy	401		
Exclusion criteria	43	10.4 (1.75-34.4)	4.98 (0.25-24.6)
No exclusion criteria	358	0.65 (0.03-3.21)	3.30 (1.21-7.31)

Conclusions: In real life, 19% of VTE patients had exclusion criteria. Those receiving rivaroxaban had fewer bleeds than those on unfractionated heparin, and fewer VTE recurrences or bleeds than those on long-term LMWH.

PB 1199 | A New Method for Determining Concentrations of Direct Oral Anticoagulants

S. Bloemen[1,2], S. Zwaveling[1,2], J. Douxfils[3], T. Peters[1,2], R. Wagenvoord[1,2], H.C. Hemker[1,2], F. Mullier[3,4], B. de Laat[1,2], M. Roest[1,2], R. Kremers[1,2]

[1]Synapse Research Institute, CARIM, Maastricht University, Maastricht, The Netherlands, [2]CARIM, Maastricht University, Department of Biochemistry, Maastricht, The Netherlands, [3]Namur Research Institute for Life Sciences, University of Namur, Department of Pharmacy, Namur, Belgium, [4]Université Catholique de Louvain, CHU UCL Namur, Hematology Laboratory, Namur Thrombosis and Hemostasis Center, Yvoir, Belgium

Background: Direct oral anticoagulants (DOACs) are commonly provided without monitoring. However, reliable assays to measure DOAC levels and activity in emergency situations are needed. We developed a test based on the inhibition of $\alpha_2$macroglobulin-thrombin (α_2M-IIa) by dabigatran (DAB) and of α_2M-factor Xa (α_2M-Xa) by rivaroxaban (RIV), making it possible to evaluate both DOAC classes in combination with thrombin generation (TG).

Aims: To quantify DOAC levels and activity in plasma.

Methods: Consenting patients using RIV (n=50) and DAB (n=28) were included. TG was performed in platelet poor plasma (5 pM tissue factor), with idarucizumab in calibrator wells for DAB samples. The new DOAC assays measured the effect of diluted plasma samples on Z-Gly-Gly-Arg-AMC conversion by α_2M-Xa or α_2M-IIa. The slopes of these curves were compared to a reference curve with known DOAC concentrations. DOAC levels were also estimated by 'classical' assays. Spearman correlation coefficients were determined.

Results: A concentration of 30 nM α_2M-Xa or α_2M-IIa was optimal to measure 50-500 nM RIV/DAB and 90 nM α_2M-Xa or 70 nM α_2M-IIa, respectively were optimal for 500-1000 nM RIV/DAB (Fig.1).

The intra- and inter-assay CV were below 2.5 % and 5% (n=2). Both the RIV and DAB assay correlated with TG parameters. The RIV assay correlated with ‚classical' assays and had a very good correlation with Biophen DiXaI. The DAB assay did not correlate with hemoclot thrombin inhibitor (probably since DAB concentrations were too low), but showed variable correlation with the other assays (Table1).

Conclusions: The new DOAC assays show good correlations with other assays that were confirmed to accurately assess DOAC levels (particularly the RIV assay with the Biophen DiXaI, which had the best correlation with mass spectrometry). Our assay can simultaneously evaluate DOAC concentrations as well as the DOACs effect on thrombin generation, providing an overview of the anticoagulation status of a patient in relation to circulating DOAC levels.

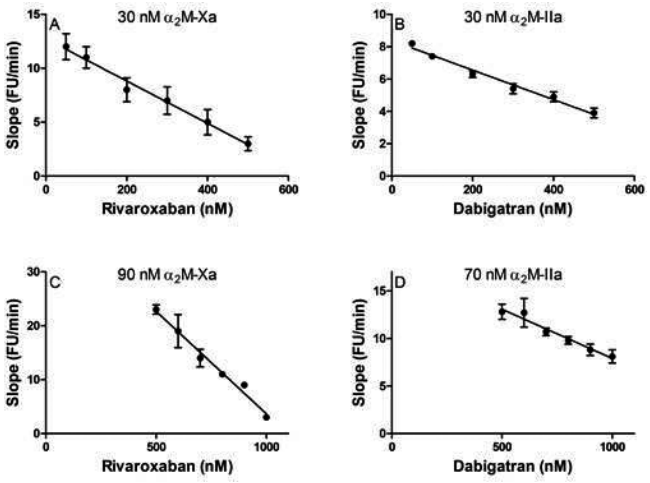

FIGURE 1 Dose-response of several DOAC concentrations at chosen α2M-Xa and α2M-IIa concentrations

TABLE 1 Correlation (Spearman) of rivaroxaban or dabigatran concentration (as determined by the new assay) with TG and other calibrated assays

	Assay	Correlation coefficient	p-value		Assay	Correlation coefficient	p-value
Rivaroxaban	Calibrated prothrombin time (ng/ml)	0.468	0.002	Dabigatran	Activated partial thromboplastin time (s)	0.581	0.002
	Dilute Russel viper venom time (s)	0.760	0.000		Dilute Russel viper venom time (s)	0.649	0.001
	Biophen DiXaI (ng/ml)	0.915	0.000		Hemoclot thrombin inhibitor (ng/ml)	0.391	0.097
	TG endogenous thrombin potential(nM.min)	-0.525	0.000		Ecarin chromogenic assay (ng/ml)	0.591	0.001
	TG Peak (nM)	-0.550	0.000		TG endogenous thrombin potential(nM.min)	-0.323	0.100
	TG lag time (min)	0.671	0.000		TG Peak (nM)	-0.354	0.201
	TG time-to-peak (min)	0.702	0.000		TG lag time (min)	0.423	0.028
					TG time-to-peak (min)	0.339	0.084

PB 1200 | Patients with Dabigatran Circulating Concentration above 200 ng/ml Have a Rebound after Neutralization by a Single Dose of Idarucizumab

N. Gendron[1,2], J. Gay[1], M. Lemoine[3], A. Lillo-Le Louët[3], D. Smadja[1,2]

[1]Hopital Européen Georges Pompidou, Hematology, Paris, France, [2]Université Paris Descartes, Sorbonne Paris Cité, UMR_S1140, Paris, France, [3]Hopital Européen Georges Pompidou, Regional Center of Pharmacovigilance, Paris, France

Background: Idarucizumab was recently approved for dabigatran reversal in emergent life-threatening bleeding episodes and urgent surgery or invasive procedure.

Aims: The aim of this study was to analyze all clinical and biological data available to date for idarucizumab use in real life.

Methods: From December 2015 through the February 1st 2017, a total of 27 cases related to the use of idarucizumab were published. One case was excluded because the patient received idarucizumab for dabigatran overdose without bleeding. Five cases were excluded because they were not published in English. Four cases that required idarucizumab before thrombolysis were published. We reported here 7 supplementary cases of idarucizumab use referred to our institution: 5 patients for serious bleeding and 2 who required urgent procedures. A total of 28 cases related to idarucizumab utilization were analyzed.

Results: Clinical characteristics of the 14 patients who received idarucizumab for serious bleeding and 10 patients for urgent procedures were similar to RE-VERSE AD according to age, indication of dabigatran and comorbidities. Bleeding cases had a median concentration of dabigatran lower in RE-VERSE AD Group A (84ng/ml, range 3-641) than in the reported cases (239ng/ml, range 50-3337). We also found a median concentration of dabigatran lower in RE-VERSE AD Group B (76 ng/ml, range 4-2880) than in the pre-surgical cases reported (192,5 ng/ml, range 84-1014). In all reported cases with dabigatran measure at baseline and after reversal, 60% of the patients had a rebound in circulating dabigatran concentration. The median dabigatran concentration at baseline was lower in patients without rebound (113.5, range: 50-176) than those with rebound (338 ng/mL, range; 209-3337). This rebound can appear from 7 hours to 2 days.

Conclusions: Our analysis demonstrates that a dabigatran concentration cut-off of 200ng/ml at baseline could predict the risk of rebound in patients who received a single injection of idarucizumab.

PB 1201 | Patient-reported Treatment Satisfaction with Oral Rivaroxaban: Results from the Non-interventional XALIA Study of Deep Vein Thrombosis

L.G. Mantovani[1], S. Cano[2], M. Gebel[3], K. Sahin[4], K. Folkerts[5], S. Haas[6], R. Kreutz[7], D. Monje[8], J. Schneider[5], M. van Eickels[5], W. Ageno[9], A.G.G. Turpie[10]

[1]University of Milan Bicocca, CESP-Center for Public Health Research, Monza, Italy, [2]Modus Outcomes, Letchworth Garden City, United Kingdom, [3]Bayer AG, Wuppertal, Germany, [4]ClinStat GmbH, Cologne, Germany, [5]Bayer AG, Berlin, Germany, [6]Formerly Technical University Munich, Munich, Germany, [7]Charité Universitaetsmedizin Berlin, Institute of Clinical Pharmacology and Toxicology, Berlin, Germany, [8]Bayer Vital GmbH, Leverkusen, Germany, [9]University of Insubria, Department of Clinical and Experimental Medicine, Varese, Italy, [10]Hamilton Health Sciences, Medicine, Hamilton, Canada

Background: For venous thromboembolism (VTE) treatment, patient satisfaction improved with rivaroxaban versus standard anticoagulation in the phase III EINSTEIN DVT and EINSTEIN PE trials.

Aims: This substudy of the prospective, non-interventional XALIA study of rivaroxaban for VTE treatment assessed if this also occurred in routine clinical practice.

Methods: Patients in XALIA who received rivaroxaban or standard anticoagulation treatment were eligible for inclusion in this substudy. Treatment decisions were at the physician's discretion. Patients completed the 17-item Anti-Clot Treatment Scale (ACTS; comprising a 12-item Burdens subscale, a 3-item Benefits subscale and two global items for the respective subscales) during follow-up. The propensity score-matched set was the main analysis set; the adjusted safety analysis set (ASAF) was used for confirmatory purposes. Analyses by follow-up visit and by subgroups, including age, sex and previous VTE, were also conducted.

Results: The main PMS-ACTS analysis included 458 rivaroxaban-treated patients and 434 standard anticoagulation-treated patients. Baseline demographic and clinical characteristics were similar across treatment arms. ACTS Burdens scores were superior (indicative of lower treatment burden) with rivaroxaban versus standard anticoagulation (least-squares mean [LSM] difference of 2.4±0.4 points; $p<0.0001$); ACTS Benefits scores were numerically higher with rivaroxaban (LSM difference of 0.2±0.1 points; $p=0.2$). Similar observations occurred across follow-up visits and subgroups. Results were confirmed in the ASAF-ACTS analysis.

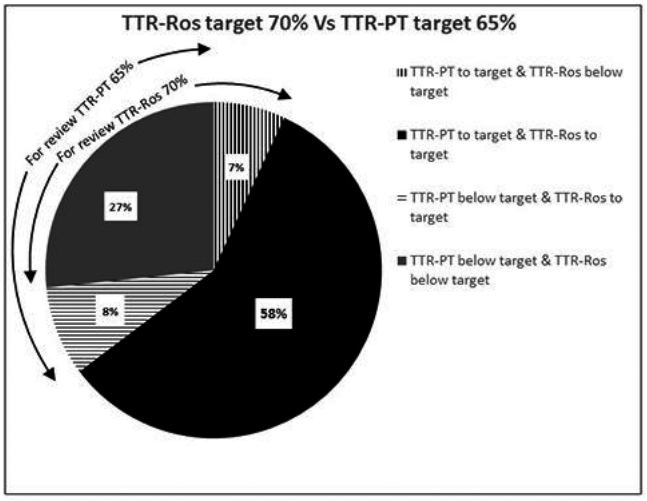
Conclusions: Patients who received rivaroxaban reported more favourable ACTS Burdens scores. ACTS Benefits scores numerically favoured rivaroxaban, although they were not statistically significant. The findings were observed across treatment visits and nearly all patient subgroups. Patient perception of rivaroxaban as less burdensome may positively affect treatment adherence and persistence.

PB 1202 | Comparison of Applying TTR Proportion of Tests and TTR Rosendaal to a Sample Population Attending a Warfarin Clinic

T. O Halloran[1], D. O Keeffe[2], O. Power[2], J. Conway[2], M. Watts[2]

[1]University of Limerick, Limerick, Ireland, [2]University Hospital Limerick, Limerick, Ireland

Background: Warfarin therapy is first line for long term anticoagulation but patients with labile INRs should be considered for DOAC (NICE, MMP Ireland). TTR, time in the therapeutic range, is used as a method to identify patients with poor INR control. NICE refers to two



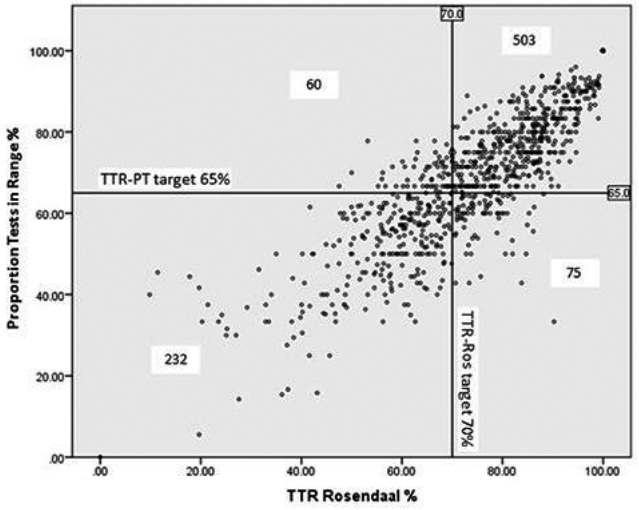


FIGURE 1 Patients considered for review using TTR-PT and TTR Rosendaal. Pie chart showing percentages and a scatter plot with the number in each quadrant

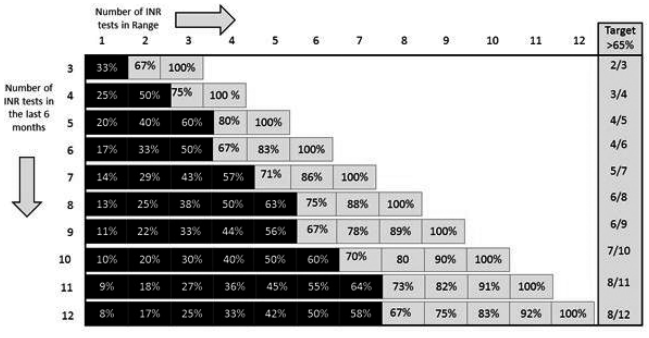

FIGURE 2 A look up chart to calculate TTR-PT with a target of 65%

methods to calculate TTR, Rosendaal and proportion of tests in range. While the Rosendaal method has been used extensively in research settings, it requires computer methods to calculate. The proportion of tests in range may be more practical clinically as it can be implemented by a lookup table or simple arithmetic and may be more easily understood by the patient.

Aims: To investigate the difference in patient selection, when TTR-Rosendaal and TTR proportion of tests in range, TTR-PT, are used on a population of patients attending the warfarin clinic at University Hospital Limerick.

Methods: A retrospective study of all INR tests performed by the clinic from June 2015 to July 2016 was conducted. 872 patients on long term anticoagulation (INR tests spanning greater than 4 months) were selected. TTRs were calculated, using a bespoke computer program, for all patients using the Rosendaal method and proportion of tests. Thresholds of TTR-Ros of 70% (MMP) and TTR-PT of 65% (NICE) were chosen to select patients for review. There is a mean difference, in our data, of 5.4(stdev 8.8) between TTR-Rosendaal and TTR-PT which was similar to that reported by Caldeira, 2015. SPSS was used to cross tabulate patients in each data set.

Results: 85% of the population are treated the same using either method (27% reviewed and 58% considered well controlled). 15% of the total population are treated differently.

Conclusions: The majority of patients are treated similarly when using TTR targets of 70%, Rosendaal, and 65% proportion of tests. TTR proportion of tests may be a more practical method to calculate TTR for patient selection for DOAC therapy.

PB 1203 | Relation between Use of Direct Oral Anticoagulants and Use of Proton Pump Inhibitors as Proxy for Gastric Complaints

G.D. van Ginkel-Zielinski[1], M. Teichert[2], F.A. Klok[3], F.R. Rosendaal[1], M.V. Huisman[3], S.C. Cannegieter[4], W.M. Lijfering[1]

[1]Leiden University Medical Center, Department of Clinical Epidemiology, Leiden, The Netherlands, [2]Leiden University Medical Center, Department of Clinical Pharmacy & Toxicology, Leiden, The Netherlands, [3]Leiden University Medical Center, Department of Thrombosis and Haemostasis, Leiden, The Netherlands, [4]Leiden University Medical Center, Department of Clinical Epidemiology and Department of Thrombosis and Haemostasis, Leiden, The Netherlands

Background: Dabigatran has been linked to gastrointestinal complaints, but it is unknown whether the risk of gastro-intestinal complaints is higher in dabigatran users as compared with other direct oral anticoagulants (DOACs).

Aims: To compare the association between different types of DOACs (dabigatran, apixaban or rivaroxaban) with new use of proton pump inhibitor (PPI) as a proxy for gastrointestinal complaints in patients with atrial fibrillation.

Methods: Observational study with an active-comparator, new user study design. Anonymised dispensing data from Community Pharmacies in The Netherlands were available for 2012-2016. Patients initiating DOAC after 31-03-2012 and without PPI use within the 180 days before start of DOAC were included. The final study sample included 8231 apixaban-, 20394 rivaroxaban- and 17781 dabigatran users. The incidence of PPI initiation was examined for the 3 groups.

TABLE 1 Baseline characteristics of AF* patients included in the study

	DOAC† n=46406(100%)	Apixaban n=8231(17.7%)	Rivaroxaban n=20394(43.9%)	Dabigatran n=17781(38.3%)
Mean age (range)	68 (14-103)	69 (18-100)	68 (14-103)	69 (16-102)
Men, n (%)	27444 (59.1%)	4827 (59.2%)	11709 (57.4%)	10863 (61.1%)
Socioeconomic class** <= 90, n (%)	41193 (89.3%)	7459 (91.1%)	17972 (88.7%)	15762 (89.2%)
Concomitant medication (%)	37349 (80.5%)	6820 (82.9%)	16101 (78.9%)	14428 (81.1%)
Previous VKA use (%)	3711 (8.0%)	1105 (13.4%)	1647 (8.1%)	959 (5.4%)
Previous PPI use††, n (%)	17853 (38.5%)	3334 (40.5%)	7680 (37.7%)	6839 (38.5%)

*AF atrial fibrillation † DOAC Direct Oral Anticoagulant **According to SCP †† PPI use more than 180 days before DOAC initiation

Sensitivity analysis was performed for subjects without PPI use for more than 180 days before start of DOAC. Cox regression models were adjusted for age, sex, previous vitamin K antagonist use, socio-economic status, and concomitant drug use.

Results: The 3 groups were similar with respect to age, sex, socio-economic status, and concomitant drug use (Table). The adjusted hazard ratio (aHR) of initiating PPI for rivaroxaban, as compared with apixaban use, was 0.95 (95% CI 0.89-1.02), and these patients (on rivaroxaban/apixaban) were subsequently taken together in one reference group. The aHR for initiating PPI was 1.14 (95% CI 1.09-1.19) in dabigatran users, compared with the reference group and 1.21 (95% CI 1.14-1.29) when patients with a history of PPI use were excluded. The cumulative incidence of PPI initiation was 20.8% at 12 months for dabigatran users, and 18.7% in the reference group, which yielded a number needed to harm of 48.

Conclusions: PPI initiation occurred more often in patients treated with dabigatran than in those treated with rivaroxaban/apixaban.

PB 1204 | Development and Characterization of Neutralizing Monoclonal Antibodies Targeting the Direct Oral Anticoagulant Apixaban

E. Maurer[1], S. Crosnier[1], C. Baltus[2], M.-C. Viaud-Massuard[3], M. Canton[1], P. Ohlmann[1]

[1]AGRO-BIO, R&D, La Ferté Saint-Aubin, France, [2]McSAF, UFR des Sciences Pharmaceutiques, University François Rabelais, Tours, France, [3]Université de Tours - UFR des Sciences Pharmaceutiques, UMR CNRS 7292 GICC Equipe 4 Innovation Moléculaire et Thérapeutique, Tours, France

Background: Direct oral anticoagulants (DOAC) are indicated for thromboembolism prevention and treatment. Dabigatran is a thrombin inhibitor while apixaban, rivaroxaban, edoxaban and betrixaban are factor Xa inhibitors. Novel clinical research tools are required to better understand the mechanisms of action of this new generation of therapeutical molecules.

Aims: The challenge was to generate high specificity and affinity monoclonal antibodies (Mabs) against a chemical structure such as apixaban.

Methods: Apixaban molecules are conjugated to carrier proteins to obtained enhanced immune response to such reputed hapten. Eighteen weeks after immunization spleen cells from mice presenting with the highest specific serum titers are isolated for fusion following clonogenic and non clonogenic methods. Specific binding of purified Mabs to apixaban is analyzed in a competition ELISA where antibodies are pre-incubated with apixaban before being added to hapten-carrier conjugate immobilized onto microtiter plates. Prothrombin time and FXa activity assays are performed on human citrated plasmas spiked with increasing apixaban concentrations in the presence and in the absence of the selected Mabs. Isotypes and affinity were also determined.

Results: We have generated 23 clones, all secreting IgG1 isotype Mabs specific for apixaban. All Mabs presented with a total absence of reactivity against the other "xabans" as tested by ELISA. Moreover our anti-apixaban Mabs are able to neutralize the in vitro apixaban anticoagulant effect on prothrombin time (Neoplastine CI Stago) and on STA®-Liquid FXa assay (Stago) at a Mab-apixaban molecular ratio of 10:1 and 5:1, respectively.

Conclusions: We therefore report the development of various Mabs specific to apixaban and able to neutralize the anticoagulant effect of the drug. These Mabs could be very useful in diagnostic applications. Further steps are being undertaken to develop recombinant monoclonal antibodies for extended applications in clinical research and pharmacodynamic studies.

PB 1205 | Pulmonary Embolism Rule-out Criteria (PERC) Has No Added Value to the YEARS Algorithm to Rule out Pulmonary Embolism

L.M. van der Pol[1,2], T. van der Hulle[1], A.T.A. Mairuhu[2], M.V. Huisman[1], F.A. Klok[1]

[1]Leiden University Medical Center, Department of Medicine - Thrombosis and Hemostasis, Leiden, The Netherlands, [2]HagaHospital, Department of Internal Medicine, The Hague, The Netherlands

Background: The YEARS algorithm was designed to simplify the diagnostic work-up of pulmonary embolism (PE) and reduce the number of required CT-scans (*Figure 1*). A recent outcome study confirmed

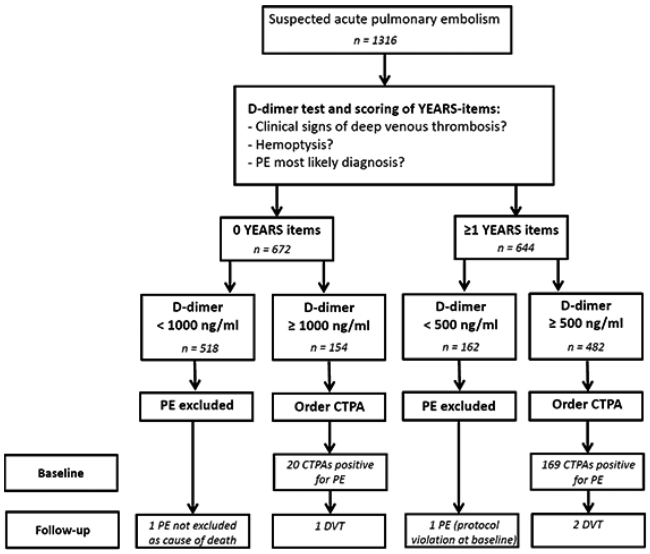

FIGURE 1 Flowchart of the YEARS algorithm with results at baseline and during follow-up of the study patients. * CTPA = computed tomography pulmonary

the safety and efficacy of YEARS (2016 ESC abstract 5727). The PE rule-out criteria (PERC) were created to exclude PE without further testing (*Table 1*). A diagnostic strategy combining both scores might save additional CT-scans, but they have never been evaluated in conjunction.

Aims: To determine the safety and efficacy of combining YEARS and PERC in a single diagnostic strategy for suspected PE.

Methods: The PERC rule was assessed in 1316 consecutive patients with suspected PE who were managed according to YEARS. We calculated the negative predictive value and number of ‚saved' CT-scans for the scenario that PE would have been ruled out without CT in the absence of all PERC items.

Results: Using the YEARS algorithm, PE was diagnosed in 189 patients (14%), 679 patients (52%) were managed without CT and the 3-month rate of VTE in patients in whom PE was ruled out was 0.38%. Only 6 of 154 patients (3.9%; 95%CI 1.4-8.2) with no YEARS items who were referred for CT would have been PERC negative, of whom none were diagnosed with PE at baseline or during follow-up (0%; 95%CI 0-64). Applying PERC in these selected patients with no YEARS-items would have led to a 0.89% absolute reduction in the number of CT-scans at baseline (0.41-1.9) without safety issues. Of the 482 patients with one or more YEARS items who were referred for CT, 51 would have been PERC negative (11%, 8.1-14), of whom 12 were diagnosed with PE, for a failure rate of 24% (14-37). Lastly, both patients managed without CT who suffered PE during follow-up were PERC negative.

Conclusions: Since combining YEARS with PERC would have yielded only a modest improvement of efficiency in patients with 0 YEARS items and an unacceptable failure rate in patients with ≥1 YEARS items, applying PERC before the YEARS algorithm cannot be recommended.

TABLE 1 The Pulmonary Embolism Rule-Out criteria (PERC)

Age ≥ 50 years
Heartrate ≥ 100 beats per minute
SO2 < 95%
Hemoptysis
Exogenous estrogen use
Trauma or surgery within four weeks
Unilateral leg swelling
Prior history of venous thrombo-embolism
The PERC rule is negative when none of above items are met - if negative acute PE is ruled out

PB 1206 | Evaluation of Different Coagulation Laboratory Methods to Monitor Apixaban, Rivaroxaban and Dabigatran Treatment

A. Rasmuson[1], M. Berndtsson[1,2], L. Söderblom[1], M. Skeppholm[3,4], R.E. Malmström[5,6], J.P. Antovic[1,2]

[1]Karolinska University Hospital, Department of Clinical Chemistry, Stockholm, Sweden, [2]Karolinska Institutet, Department of Coagulation Research, Institute for Molecular Medicine and Surgery, Stockholm, Sweden, [3]Danderyd Hospital, Department of Clinical Sciences, Stockholm, Sweden, [4]Karolinska Institutet, Division of Cardiovascular Medicine, Stockholm, Sweden, [5]Karolinska Institutet, Department of Medicine, Stockholm, Sweden, [6]Karolinska University Hospital, Clinical Pharmacology, Stockholm, Sweden

Background: Apixaban (API), rivaroxaban (RIV) and dabigatran (DAB) are direct oral anticoagulants (DOACs) for which routine laboratory monitoring is not recommended. However, in certain clinical situations rapid measurements of these drugs are desirable.

Aims: To test different combinations of reagents and analyzers for assessment of DOACs in clinical samples against liquid chromatography-tandem mass spectrometry (LC-MS/MS).

Methods: Plasma DAB (n=26), API (n=30) and RIV (n=36) concentration was determined by LC-MS/MS. In addition, four different analyzers CS-2100i, CS-5100, STA R Max and ACL TOP 750, in combination with various reagents (see table), were used for indirect concentration estimations.

Results: A wide range of API, RIV and DAB concentrations were determined by LC-MS/MS (2-372, 3-664 and 3-358 mg/L respectively). Pearson correlation and % bias between LC-MS/MS results and coagulation methods are shown in the table.

Conclusions: It seems that the majority of investigated combinations of coagulation analyzers and reagents for indirect determination of DOACs may be used in routine laboratory but significant bias may be observed with low values (< 50 mg/L), and therefore those results should be cautiously interpreted. It seems that Biophen® Heparin Anti-Xa on CS-5100 or STA R Max is the most reliable for anti-Xa inhibitors, while STA-ECA on STA R Max is the most appropriate for DAB. Our results

TABLE 1 Comparison of LC-MS/MS results for API, RIV and DAB with various indirect methods

Reagent	Analyzer	Apixaban R2 (high/low*)	Apixaban % Bias (high/low*)	Rivaroxaban R2 (high/low*)	Rivaroxaban % Bias (high/low*)	Dabigatran R2 (high/low*)	Dabigatran % Bias (high/low*)
STA®-Liquid-Anti-Xa	CS-2100i	0.99/0.90	15.9/46.8	0.94/0.88	25.0/39.8		
STA®-Liquid-Anti-Xa	STA R Max	0.99/0.94	-24.2/-48.2	0.95/0.91	-35.8/-46.1		
Biophen® Heparin Anti-Xa	CS-5100	0.99/0.98	-8.2/-15.0	0.99/0.87	-8.09/-7.91		
Biophen® Heparin Anti-Xa	STA R Max	0.99/0.97	-10.5/-15.2	1.00/0.93	-7,3/-9,1		
HemosIL® Liquid Anti-Xa	ACL TOP 750			0.99/0.86	73,3/99,4		
Biophen® HTI (clot)	CS-2100i					0.94/0.14	46.5/89.8
Biophen® DTI (chrom)	CS-5100					0.99/0.58	-14.2/-12.3
STA®-ECA (clot)	STA R Max					0.99/0.80	2.8/3.3
HemosIL® DTI (chrom)	ACL TOP 750					0.97/0.79	11.9/10.1

*Below 50 mg/L

indicate that the widely used method for indirect DAB determination, Biophen® HTI, probably should not be used at least for CS-2100i.

PB 1207 | Effect of Rivaroxaban on Expression of Monocyte Platelet Aggregates and P Selectin in Patients with Atrial Fibrillation

R.C.F. Duarte[1], E.L. Figueiredo[2], L.G. Freitas[3], E. Reis[4], C.N. Ferreira[5], F.F.M. Campos[1], M.G. Carvalho[1]

[1]Faculty of Pharmacy - Federal University of Minas Gerais, Department of Clinical and Toxicological Analysis, Belo Horizonte, Brazil, [2]Lifecenter Hospital, Belo Horizonte, Brazil, [3]Faculty of Pharmacy - Federal University of Minas Gerais, Belo Horizonte, Brazil, [4]Institute of Exact Sciences - Federal University of Minas Gerais, Department of Statistics, Belo Horizonte, Brazil, [5]Federal University of Minas Gerais, Technical College, Belo Horizonte, Brazil

Background: Patients with atrial fibrillation (AF) are at an increased risk of developing stroke and thromboembolism due to arrhythmia and hyperactivation of both platelets and coagulation. Activated platelets exposes on its surface glycoproteins such as P-selectin and interact with leukocytes. Binding of P-selectin to PSLG-1 expressed on monocytes mediates the formation of platelet monocyte aggregates (PMA), which contributes to inflammation and thrombogenesis. In addition, platelets activate factor (F) X to FXa on their surfaces leading to thrombin generation and further platelet activation by thrombin. Rivaroxaban is an oral direct FXa inhibitor used for prevention of thrombomembolic events in AF.

Aims: To determine the effect of rivaroxaban on the expression of P-selectin and PMA in patients with AF.

Methods: In blood samples from 74 participants, including patients using rivaroxaban (n = 33), and individuals without AF (control group, n= 41) were determined, by flow cytometry, the levels of P-selectin (CD62P+) and PMA (CD14+/ CD51/61+). Plasma levels of rivaroxaban were determined by using a chromogenic assay. Data were analyzed by Mann Whitney test and $p < 0.005$ was considered significant.

Results: The medium plasma levels of rivaroxaban in AF patients were 115.15 ng/ml. Use of rivaroxaban significantly reduced the levels of P-selectin and PMA (Table 1 and Figure 1).

TABLE 1 Levels of platelet monocyte aggregates (PMA) and P-Selectin in patients using rivaroxaban and in control group

Parameters	Rivaroxaban	Control	p Value
PMA % (± IQR)	1.85 (2.550)	3.90 (4.050)	0.000
P-Selectin % (± IQR)	1.82 (1.610)	2.73 (2.080)	0.023

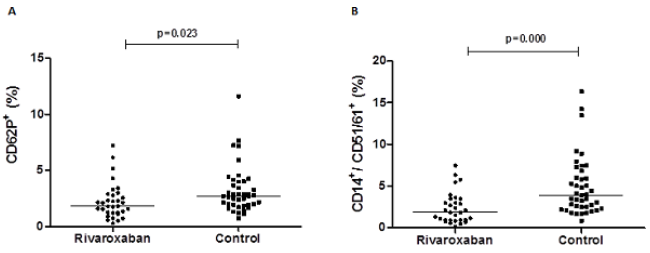

FIGURE 1 Levels of P selectin -CD62P+ (A) and platelet monocyte aggregates-CD14+/ CD51/61+ (B) in patients on rivaroxaban compared to control group

Conclusions: Rivaroxaban reduced platelet activation and its interaction with monocytes, which may contribute to decrease the inflammatory and hypercoagulable state in patients with AF.

Support: CAPES, CNPQ and FAPEMIG.

PB 1208 | Gastrointestinal Bleeding in Patients on Warfarin and Direct Oral Anticoagulant Therapy: An Observational Study in a District General Hospital

A. McSorley, C. Dinning, M.D. Creagh, J. Blundell

Royal Cornwall Hospitals NHS Trust, Haematology, Truro, United Kingdom

Background: Gastrointestinal (GI) bleeding is a recognised complication of anticoagulation. Increasingly anticoagulated patients take Direct Oral Anticoagulants (DOACs) rather than Warfarin. Locally in September 2016 there were 11,678 prescriptions for Warfarin and 6,368 for a DOAC, compared to 3804 for DOACs in July 2015. Some clinical trials report increased GI bleeding on DOACs. This is consistent with our gastrointestinal physicians' anecdotal experience.

Aims: To determine the real world safety of DOAC's compared with Warfarin with respect to GI bleeding.

Methods: A systematic review of anticoagulated patients referred to the ‚Endoscopy Upper/Lower GI Request Service' between August 2015 and July 2016 was undertaken using the hospital computer system.

Results: 70 bleed events were identified, 34 on Warfarin (48.6%) and 36 (51.4%) on a DOAC. The patients in both groups had similar Charleston Index co-morbidity scores, renal function and transfusion requirements. In the Warfarin group, 8.8% of bleeds occurred within 40 days of commencing anticoagulation compared with 30.6% on a DOAC. Bleeding on Warfarin most frequently occurred secondary to gastric ulceration whereas patients anticoagulated with a DOAC had more non-specific gastric bleeding. Fewer patients (23.3%) on DOACS compared to warfarin (36.4%) remained in hospital more than 7 days.

Conclusions: The number of DOAC related GI bleeds in our local population is consistent with the rates reported in the respective clinical trials; however bleeding on DOAC's appeared to occur sooner and was less associated with a defined anatomical gastric lesion. This may make bleeding in this cohort more difficult to predict. Patients must be carefully selected and counselled about the risk of early bleeding on DOACs. There may be a role for nurse led DOAC clinics and perhaps some place for monitoring of the DOAC effect in patients at the start of treatment.

PB 1209 | Select-d Trial Qualitative Sub-study: Patient and Carer Experience of Anticoagulation for Cancer-Associated Thrombosis

A. Hutchinson[1], S. Rees[2], K. Date[1], A. Young[2], A. Maraveyas[1], M.J. Johnson[1]

[1]University of Hull, Hull York Medical School, Hull, United Kingdom, [2]University of Warwick, Warwick Medical School, Coventry, United Kingdom

Background: Cancer patients have a 4-7 greater risk of venous thromboembolism (VTE) than the general population. VTE is the commonest cause of death during chemotherapy. Current treatment for cancer-associated thrombosis (CAT) is at least six months' low-molecular-weight heparin (LMWH). The Anticoagulation Therapy in SELECTeD Cancer Patients at Risk of Recurrence of Venous Thromboembolism (select-d) trial is a randomised, multi-centre pilot study of dalteparin (a LMWH) *vs* rivaroxaban (a direct oral anticoagulant [DOAC]) to assess VTE recurrence and optimal duration.

Aims: This qualitative sub-study explored patient/carer experience of CAT and its treatment.

Methods: Semi-structured face-to-face or phone interviews were conducted with a purposive sample of select-d participants +/- carer. Interviewers used a topic guide to explore experience of CAT and anticoagulant use. Interviews were audio-recorded and transcribed. Data were analysed using Framework Analysis and NVivo software.

Results: 37 patients and nine carers were interviewed (8 to 62 minutes long). Three main themes were identified: VTE and cancer; VTE treatment and cancer; and balancing risks and benefits. Some patients were shocked by the CAT, but others felt it was relatively insignificant in the context of cancer. Most patients were unaware of the risk of VTE. Most saw DOAC tablets as easier than injections (LWMH), but some preferred injection. There were unwanted effects with LMWH, but in the context of cancer, these were acceptable. Whilst most were happy to follow medical advice, others weighed preference on the basis of effectiveness.

Conclusions: Most patients found tablets were more convenient, but LMWH was acceptable in the context of cancer and its treatment despite the side-effects. Patients' lack of awareness of CAT is concerning. Cancer patients should be informed of VTE risk and symptoms to enable prompt help-seeking. DOACs could provide a welcome choice for patients preferring tablets. Study funded by Bayer.

PB 1210 | TRAP-induced Platelet Aggregation is Reduced in Patients Receiving Dabigatran

J. Sokol[1], F. Nehaj[2], M. Mokan[2], J. Ivankova[1], J. Stasko[1]

[1]Jessenius Faculty of Medicine in Martin, Comenius University in Bratislava, Department of Hematology and Transfusion Medicine, Martin, Slovakia, [2]Jessenius Faculty of Medicine in Martin, Comenius University in Bratislava, First Department of Internal Medicine, Martin, Slovakia

Background: The availability of direct oral anticoagulants has caused a paradigm shift in thrombosis management. The direct thrombin inhibitor dabigatran seems to obstruct tenase complex by inhibiting thrombin generated in the initial phase and feedback to the amplification phase of cell-based coagulation reactions. However, it is still not fully understood if and how dabigatran impact platelet function.

Aims: This observational study aimed to assess in vitro platelet function in patients with atrial fibrillation receiving dabigatran.

Methods: Light transmission aggregometry (LTA) was performed using the international protocol for the laboratory investigation of platelet function. The antecubital venous blood was collected into tubes containing 3.2% buffered sodium citrate (anticoagulant-blood ratio 1:9) to assess platelet aggregation. Platelet aggregability was tested with platelet-rich plasma using platelet aggregometry (PACKS-4 aggregometer, Helena Laboratories, USA). Blood samples were stimulated with thrombin receptor agonist peptide - TRAP (32 μmoL).

Results: Twenty-eight patients with non-valvular atrial fibrillation were enrolled. The mean age was 71.57 ± 9.75 years (range 50-87 years), 16 patients were woman and the mean CHA_2DS_2VASc score was 3.93 ± 1.41. All patients began treatment with dabigatran as initial anticoagulant treatment. The minimum term use of dabigatran was 18 days. Dabigatran doses were 110 mg (57.14%) or 150 mg (42.86%) twice daily. The mean dabigatran concentration in sample 1 was 90.56 ± 77.61 ng/mL and in sample 2 was 143.27 ± 103.62 ng/mL. TRAP-induced platelet aggregation was analysed independently of concomitant treatment. As shown in Figure 1, the TRAP-induced platelet aggregation by LTA was significantly reduced in sample 2 compared with sample 1 (79.39% ± 13.38% vs. 90.14% ± 10.5%; p=0.000).
Conclusions: The TRAP-induced platelet aggregation was reduced in cardiovascular patients two hours after receiving dabigatran.

PB 1211 | An Oral Factor Xa Inhibitor Edoxaban Ameliorates Neointima Formation Following Vascular Injury in ApoE KO Mice

Y. Morishima, Y. Honda

Daiichi Sankyo Co., Ltd., Tokyo, Japan

Background: Vascular injury activates the coagulation cascade. Coagulation factor Xa and thrombin have been implicated in proliferation of vascular smooth muscle cells and neointima formation after vascular injury.
Aims: The aim of this study was to determine the effect of edoxaban on neointima formation following the carotid artery injury by ferric chloride in ApoE knockout (KO) mice.
Methods: Vascular injury was induced by the application of 10% ferric chloride to the carotid artery for 3 min in ApoE KO mice. After vascular injury, all animals were fed with high-cholesterol diets for 6 weeks. Edoxaban at 15 mg/kg was orally administered to the mice 1 hour before (n = 10) and 1 hour after (n = 9) ferric chloride injury, and thereafter 10 mg/kg edoxaban was orally administered b.i.d. for 6 weeks. As a control (n = 10), 0.5% methylcellulose was administered. Thrombus formation and neointima formation were evaluated.
Results: Ferric chloride injury of the common carotid arteries of ApoE KO mice induced thrombus formation. Thereafter, feeding with high-cholesterol diets for 6 weeks promoted neointima formation that contained smooth muscle cells, foam cells, and cholesterin crystals. Treatment with 15 mg/kg edoxaban before vascular injury almost completely inhibited thrombus formation, and chronic administration of 10 mg/kg edoxaban b.i.d significantly suppressed neointima formation. In the mice treated with edoxaban after vascular injury, there was wide interindividual variability. In some mice (4 out of 9) the neointima formation was inhibited like in edoxaban-pretreated mice, but not in the other mice. There was no statistical difference compared with control.
Conclusions: This study demonstrated that inhibition of the coagulation cascade with edoxaban ameliorated neointima formation caused by ferric chloride injury and feeding with high-cholesterol diets in ApoE KO mice. This suggests that factor Xa has a crucial role in the formation of neointima following vascular injury.

PB 1212 | Thrombelastography (TEG) for Assessing Dabigatran Reversal in a Preclinical Trauma Model

M. Honickel, N. Akman, O. Grottke

RWTH Aachen University Hospital, Department of Anesthesiology, Aachen, Germany

Background: Currently, no approved point of care test for assessing direct oral anticoagulants (DOAC) is available. For the TEG device, a DOAC specific cartridge has been developed, using ecarin to detect dabigatran (DTI channel).
Aims: We used TEG in a trauma model to assess dabigatran and evaluate the efficacy of intravenous (IV) and intraosseous (IO) Idarucizumab (IDA), an approved reversal agent for dabigatran.
Methods: After ethical approval, 21 pigs received oral dabigatran etexilate and a dabigatran infusion followed by standardized trauma (blunt liver injury, femur fracture). 15 min after trauma, animals randomly received 1) IO Ringer's solution (control), 2) IO IDA, or 3) IV IDA (both 60 mg/kg). Animals were observed for 240 min or until death. Levels of dabigatran (dTT), TEG variables and blood loss (BL) were recorded. ANOVA (mean±SD) and Pearson's r were used.
Results: IO or IV IDA resulted in a 4-fold decrease in BL as compared to controls (Fig. 1). Dabigatran levels before trauma were comparable in all groups (583±139 ng/mL). A strong correlation between dabigatran levels and DTI R-time was present before trauma and after IO and IV IDA (R^2=0.90 and 0.89; Fig. 2). 15 min after IO and IV IDA, DTI R-time returned to baseline, with corresponding low dabigatran levels (0-28 ng/mL). Dabigatran levels recurred 120 min after trauma in both groups as shown by TEG, most likely caused by redistribution (1). In controls no significant correlation between DTI R-time and dabigatran levels after trauma was measured (R^2< 0.01).

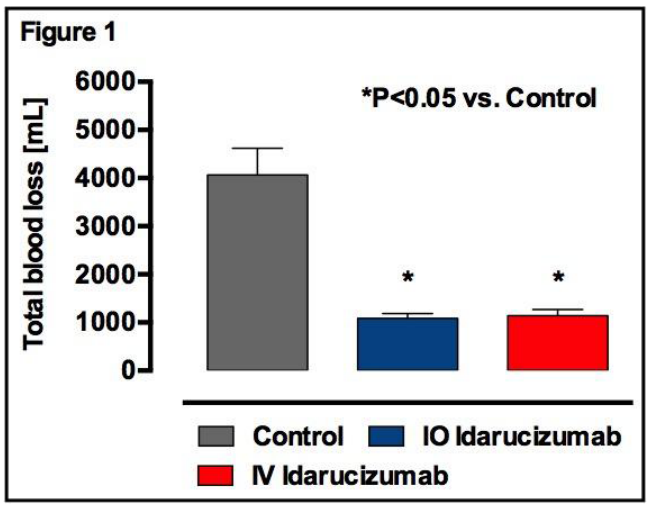

FIGURE 1 Total blood loss [mL]

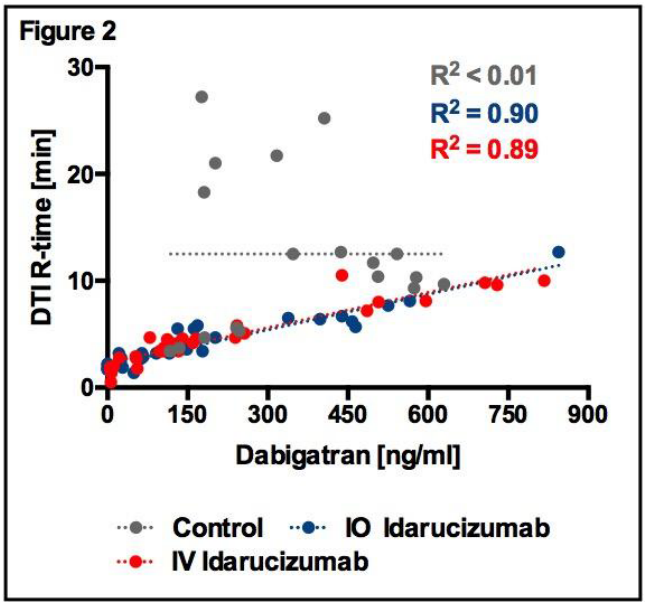

FIGURE 2 Correlation between DTI R-time [min] and Dabigatran [ng/mL

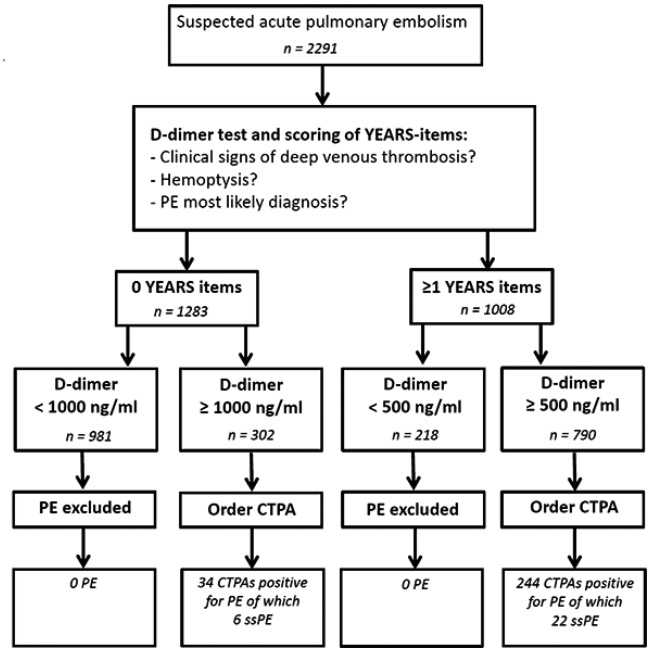

FIGURE 1 The YEARS algorithm

Conclusions: In this model, TEG was useful to assess dabigatran anticoagulation before trauma and after its reversal by IDA, as shown by strong correlations between TEG and dabigatran levels. Since TEG depends on viscoelastic quality of the clot, in controls continuous bleeding with very low coagulation factor levels was probably responsible for the poor correlation between dabigatran levels and TEG.

PB 1213 | Lower Prevalence of Isolated Subsegmental Pulmonary Embolism in the YEARS Diagnostic Algorithm Compared with the Conventional Algorithm for Suspected Pulmonary Embolism

L.M. van der Pol[1,2], T. van der Hulle[1], P.L. den Exter[1], J.M. van Werkhoven[3], T.E. van Mens[4], I.M. Bistervels[4,5], M. ten Wolde[5], A.T.A. Mairuhu[2], S. Middeldorp[4], M.V. Huisman[1], F.A. Klok[1]

[1]Leiden University Medical Center, Department of Medicine - Thrombosis and Hemostasis, Leiden, The Netherlands, [2]HagaHospital, Department of Internal Medicine, The Hague, The Netherlands, [3]HagaHospital, Department of Radiology, The Hague, The Netherlands, [4]Amsterdam Medical Center, Department of Vascular Medicine, Amsterdam, The Netherlands, [5]Flevo Hospital, Department of Medicine, Almere, The Netherlands

Background: The rate of isolated subsegmental pulmonary embolism (ssPE) has doubled with advances in computed tomography pulmonary angiography (CTPA) technology. The clinical relevance, i.e. the need to treat these small emboli is debated. The YEARS algorithm was designed to simplify the diagnostic work-up of PE (*Figure 1*). A recent outcome study confirmed the safety and efficacy of YEARS (2016 ESC abstract 5727). We hypothesized that this reduction for CTPA may have led to a reduction in the number of isolated ssPE diagnoses.

Aims: To investigate the prevalence of isolated ssPE in patients managed according to YEARS.

Methods: Data were collected from 2291 consecutive patients with suspected PE who were managed according to YEARS, and compared to historical data from the Christopher study, where 3306 patients were managed according to the Wells rule and a conventional D-dimer threshold of 500 ng/ml. The location and involved arteries were assessed by two reviewers.

Results: In the YEARS cohort, 10% of all PE were isolated ssPE (prevalence of all PE 12%), 51% of entire cohort were managed without CTPA. In the Christopher cohort, 17% of all PE were isolated ssPE (prevalence of all PE 20%), 32% were managed without CTPA. The prevalence of isolated ssPE was significantly lower in the YEARS cohort (absolute difference 7.2%, 95%CI 2.3-11; Odds Ratio 0.54, 95%CI 0.35-0.84). The 3-month venous thrombo-embolism rate in untreated patients was comparable: 0.35% (95%CI 0.18-0.69) in YEARS versus 0.73% (0.49-1.1) in the Christopher study.

Conclusions: The prevalence of isolated ssPE diagnoses is lower in the YEARS algorithm compared to the Christopher study for suspected PE, without compromising the safety of the algorithm. This is likely a consequence of the lower sensitivity of YEARS for ssPE due to the significant reduction in the number of necessary CTPA examinations.

PB 1214 | Renal Clearance is Able to Predict Drug Discontinuation in Patients with Atrial Fibrilation Treated with Direct Oral Anticogulants

B. Navarro-Almenzar, J.J. Cerezo-Manchado, A. Maritnez-Marin, E. Fernandez, M. Moya-Arnau, F. Garcia-Candel, N. Marin, D. Iyu, V. Cabañes, M. Berenguer, S. Eduardo, R. Perez-Lopez, F. Labbadia, M. Blanquer, A.M. Garcia-Hernandez, D. Sanchez, J. Sanchez-Garcia, N. Garcia-Iniesta, F. Iniesta, J.M. Moraleda

University Hospital Virgen de la Arrixaca, IMIB-Arrixaca, Murcia University, Murcia, Spain

Background: DOACs are useful in prevention of thromboembolic events for patients with atrial fibrillation. However these drugs are no exempt of some discontinuation problems.

Aims: The objective of this study was analyze what factors could predict the discontinuation of the therapy at the beginning of the treatment.

Methods: A retrospective study was conducted of patients who were treated with DOACS in our unit from 2011-2016. Patients were followed until discontinuation drug or to the last follow. The main variables investigated were the percentage of patients discontinued the drug, and the main reason to this outcome: Exitus relate or non-related, major bleedings, thromboembolic events. Statistical analyzes were performed using SPSS 21.0 (SPSS Inc.,Chicago,IL). All the confidence interval was at 95%.

Results: A total of 514 patients were finally included with a mean age of 74(73-75) years old. Gender was female in 301(58.6%) patients. The mean of CHA2DS2-VASc and HAS-BLED was 3,9(3.8-4.1) and 2.5(2.4-2.6) points respectively. Mean follow-up was 1,2(1.0-1.3) years. Eighty two patients discontinue with the treatment until the last follow-up (15%) being the first reason exitus 33(6%). Only one patient has an exitus related with drug intake(0,19%). We analyzed what factors could predict drug discontinuation in our patients. We saw that only age and renal clearance was able to predict discontinuation $p< 0.001$ and $p = 0.02$ respectively. In multivariate analyze we showed that patients with a renal clearance between 30-50 or < 30 milliliter/minute has 4.2(1,5-11) and 3.0(1.0-9.0) times more risk of discontinuation , respectively, than patients with more than 50 milliliter/minute. Age maintained a p value less than 0.05 in multivariate study.

Conclusions: Renal clearance, that has been related with others important outcomes in oral anticoagulation treatment for AF, could be an important factor to predict drug discontinuation and be included in future predictive scales.

PB 1215 | What's the Optimal Cut-off Value of the Prothrombin Time (PT) Assay for Determining Overdose Status of Rivaroxaban?

B. Kim[1], S. Jang[2], Y.-U. Cho[2], C.-J. Park[2]

[1]*Soonchunhyang University Cheonan Hospital, Laboratory Medicine, Cheonan-si, Korea, Republic of,* [2]*University of Ulsan College of Medicine and Asan Medical Center, Laboratory Medicine, Seoul, Korea, Republic of*

Background: The plasma concentration of rivaroxaban (RIV) should be known in specific clinical situations. However, the anti-factor Xa assays may not be readily available. The PT assay is simple and widely available, therefore could be a good candidate for predicting plasma RIV level.

Aims: The aim of this study is to establish the cut-off clotting time and INR of the PT assay for estimation of overdose status of RIV.

Methods: Normal pooled plasma (NPP) was prepared from 337 healthy individuals. PT assay was performed using Thromborel® S reagent with the CA-7000 coagulometer. We applicated Clinical and Laboratory Standard Institute (CLSI) EP12-A2 guideline. We set the arbitrary cut-off plasma RIV level at 275 ng/mL and the RIV-spiked NPP at 275 ng/mL was analyzed in 40 replicates to validate whether the C50 (the concentration near the cutoff that yield 50% positive results and 50% negative results) is plausible. The RIV-spiked NPPs with final concentrations of 200, 250, 275, 300, 325, and 350 ng/mL were analyzed with 20 replicates to determine cut-off value. After setting a cut-off, an imprecision study was performed using RIV-spiked NPP at 220, 247.5, 261.25, 275, 288.75, 302.5, and 330 ng/mL. They analyzed in 60 replicates to determine whether or not a particular concentration range bounds the C5-C95 interval (the range of RIV concentrations around the cut-off). The results at concentrations outside this interval are consistently negative or consistently positive.

Results: The optimal cut-off clotting time and INR value to determine RIV overdose were 13.45 and 1.19. The prepared C50 (275 ng/mL) was plausible. In the imprecision study, there is 92.5% confidence that samples with RIV level ≤247.50 ng/mL or ≥288.75 ng/mL can be expected to yield consistent results with the current PT measurement system.

Conclusions: PT test with a reliable cutoff for screening of overdose status of RIV could help physicians to determine treatment strategies in clinical settings.

PB 1216 | DOAC Reversal with Low (< 20 Units/kg) or Moderate Dose (≥20 Units/kg) FEIBA in the Urgent Management of Major Bleeding

W. Dager, A. Roberts

University of California, Davis Medical Center, Pharmacy, Sacramento, United States

Background: Management of acute, major or life threatening bleeding in the presence of direct acting oral anticoagulants (DOAC) is unclear. Emergent hemostasis using concentrated clotting factors including prothrombin complex concentrates (PCC) or activated prothrombin complex concentrates (aPCC) have been explored in-vitro/ex-vivo in non-bleeding patients and case reports/small series with bleeding patients. The ideal PCC and dose is unclear, and their use has an associated risk for thrombotic events (TE). At our institution, acute major bleeding the presence of DOACs is managed with the aPCC FEIBA.

Early experience demonstrated a profound, rapid effect with doses around 8 units/kg, leading to an initial low dose (LD) with the option to titrate to effect with additional FEIBA. Moderate doses (MD) of 25-50 units/kg are considered in intracranial hemorrhage (ICH) or eminent life threatening massive bleeds.

Aims: Describe a FEIBA dosing strategy for major DOAC bleeding.

Methods: A single center retrospective analysis of consecutive DOAC patients who received aPCC. Assessed outcomes included the dose administered, post administration bleeding, new TE, or survival to discharge.

Results: 54 patients; apixaban (n=18), dabigatran (n=13) and rivaroxaban (n=23) received LD (< 20 units/kg) aPCC (mean 10±3.5 units/kg; n=32) or MD (mean 24±2.4units/kg;n=22). CNS bleeds occurred in 20 patients. 9 patients expired prior to discharge. One TE occurred with MD. Follow-up CT exams for ICH, endoscopy/colonoscopy, or interventional radiology exams did not reveal any clinically concerning active bleeding or hematoma expansion except one HD patient where CT showed slight worsening of massive multifocal ICH.

Conclusions: LD aPCC titration strategy using an option to repeat, and MD aPCC, depending on the urgency of the situation, may be a management strategy for major DOAC bleeding events. More data and experiences however are needed to determine the best approach to emergently manage major/life threatening bleeding events with DOAC therapy.

PB 1217 | Treatment Effect Estimates for Extended Treatment of VTE Using Network Meta-analysis from Clinical Trials with Rivaroxaban, Aspirin or Placebo

Á.F. Pap[1], A.W.A. Lensing[1], M.H. Prins[2], P. Prandoni[3], U. Krahn[1]

[1]Bayer AG, Wuppertal, Germany, [2]University of Maastricht, Department of Epidemiology and Technology Assessment, Maastricht, The Netherlands, [3]University of Padua, Department of Cardiothoracic & Vascular Sciences, Padua, Italy

Background: Four contemporary randomized trials evaluated continued antithrombotic therapy with either rivaroxaban, aspirin or placebo in patients with VTE who had completed 6-12 months of anticoagulation: EINSTEIN EXTENSION (rivaroxaban 20 mg vs. placebo; randomized: 1197), EINSTEIN CHOICE (rivaroxaban 20 mg and 10 mg vs. aspirin 100 mg; randomized: 3396), ASPIRE and WARFASA (both compared aspirin 100 mg vs. placebo; randomized: 822 and 403). None of the studies assessed all 4 treatment groups directly.

Aims: To provide hazard ratio estimates for recurrent VTE for each pairwise comparison between the treatment groups based on the evidence from the 4 trials taking into account direct and indirect comparisons.

Methods: Network meta-analysis is a method in which multiple treatments are compared using information from both direct comparisons of treatments within randomized trials and indirect comparisons across trials based on a common treatment group(s). In all 4 trials, extended treatment of VTE was investigated after completion of 6-12 months of anticoagulant treatment and all studies reported hazard ratios for recurrent VTE. Trial estimates of ASPIRE and WARFASA were combined into a single hazard-ratio by conventional meta-analysis. Hazard ratios from the whole network were calculated based on the assumption of a consistent network of treatment effects.

Results: Table 1 shows the results from the analyses from the studies and the results from the network meta-Analysis.

TABLE 1

Comparison	Hazard ratios (95% CI) within study (direct comparisons)	Hazard ratios (95% CI) from the network meta-analysis
Rivaroxaban 10 mg vs. placebo	NA	0.17 (0.09-0.32)
Rivaroxaban 20 mg vs. placebo	0.18 (0.09-0.39)	0.21 (0.13-0.34)
ASA 100 mg vs. Placebo (ASPIRE and WARFASA combined)	0.67 (0.51-0.90)	0.66 (0.50-0.87)
Rivaroxaban 10 mg vs. ASA 100 mg	0.26 (0.14-0.47)	0.25 (0.14-0.46)
Rivaroxaban 20 mg vs. ASA 100 mg	0.34 (0.20-0.59)	0.32 (0.20-0.50)
Rivaroxaban 10 mg vs. Rivaroxaban 20 mg	0.75 (0.36-1.54)	0.79 (0.40-1.56)

Conclusions: We found no evidence of treatment effect heterogeneity between ASPIRE and WARFASA (ASA 100 mg vs. placebo) or inconsistency between direct and indirect evidence in the entire network. From the network it was possible to obtain an indirect estimate for the comparison rivaroxaban 10 mg vs placebo. The treatment group comparisons obtained from network meta-analysis were consistent with the direct estimates from the studies and generally resulted in slightly narrower confidence intervals due to the information gained from the network.

PB 1218 | Is LMWH-calibrated Anti-Xa Assay Useful to Estimate Apixaban Concentration in Patients Undergoing Apixaban Treatment?

M.D.L. Herrera[1], A. Scazziota[1], A. Grinspon[1], S. Aguirre[1], R. Raimondi[1], A. Brodsky[1], S. Pons[1], V. Monserrat[2]

[1]Universidad de Buenos Aires. Facultad de Farmacia y Bioquimica, Bioquímica Clinica, Buenos Aires, Argentina, [2]Universidad de Buenos Aires, Buenos Aires, Argentina

Background: Therapy with Apixaban, a direct oral anticoagulant, is given at fixed doses without laboratory-guided adjustment, but in

particular situations it´s necessary to be measured. Chromogenic anti-factor Xa activity (aXa) using Apixaban calibrator is the preferred clinical assay. In developing countries, commercial calibrators are not always affordable, so the challenge was to use LMWH calibrators for this purpose.

Aims: To determine in patients receiving Apixaban:
a) correlation between aXa, expressed in ng/mL (aXaA), and aXa in IU/mL (aXaIU), using Apixaban and LMWH calibrators respectively,
b) influence of Apixaban on routine coagulation tests.

Methods: 10 patients taking 2.5 or 5 mg of Apixaban twice, had two blood samples taken: at peak and at trough. Plasmas were tested for PT, APTT, dRVVT and aXa (Liquid anti-Xa) using Apixaban and LMWH commercial calibrators employing the STA®-Compact Max analyzer. aXaA precision was evaluated at two levels: 90 and 228 ng/mL, intra-assay CV was 9.17% and 3.85% respectively and inter-assay CV 7.20% and 3.98%. Statistical analysis was performed with ANOVA test, correlation and linear regression with Barlett sphericity.

Results: We found a statistically significant correlation (r:0.96) between aXaA compared to aXaIU, stronger at trough (r=0.99) than at peak (r:0.96). aXaIU and aXaA assays showed a linearity up to 177 and up to 500 ng/mL of Apixaban, respectively. PT and APTT were insensitive to Apixaban neither at through nor at peak. By contrast, both dRVVT screen and confirm, were prolonged at minimal concentration of Apixaban.

Conclusions: We have shown a strong correlation between plasma Apixaban concentration and aXa activity using LMWH calibrators available in most clinical laboratories, providing a reliable assessment of Apixaban. Nevertheless, significant limitation exists using this method because therapeutic range for Apixaban exceeds that for LMWH. dRVVT could only be used to rule out significant levels of Apixaban.

PB 1219 | Calibrated Automated Thrombogram II: A New Thrombin Generation Test Able to Measure in the Presence of a Direct Thrombin Inhibitor

P.L.A. Giesen[1], A.J.W. Gulpen[2], R. van Oerle[2], H. ten Cate[2], H.M. Spronk[2]

[1]Thrombinoscope BV, Maastricht, The Netherlands, [2]Maastricht University / Cardiovascular Research Institute Maastricht (CARIM), Internal Medicine and Biochemistry, Maastricht, The Netherlands

Background: Thrombin generation (TG) assessed by the Calibrated Automated Thrombogram (CAT-I) reflects the overall capability of plasma to generate thrombin and is a sensitive method for assessment of a persons' coagulation profile. However, proper measurement of the thrombin calibrator in the presence of direct thrombin inhibitors is impossible due to the inhibition of calibrator by the anticoagulant.

Aims: To develop a modified TG assay (CAT-II) with an alternative calibration approach insensitive for patients receiving thrombin inhibitors.

Methods: TG was assessed by means of the CAT method as previously described. In CAT-I each measurement was calibrated against the fluorescence curve obtained in the same plasma to which calibrator was added. In the CAT-II method calibration was performed by one single measurement applying a standard concentration of thrombin in buffer to correct for substrate consumption. Correction for the color of the plasma was obtained by addition of 7-Amino-4-methylcoumarin (AMC) to every individual assessed plasma.

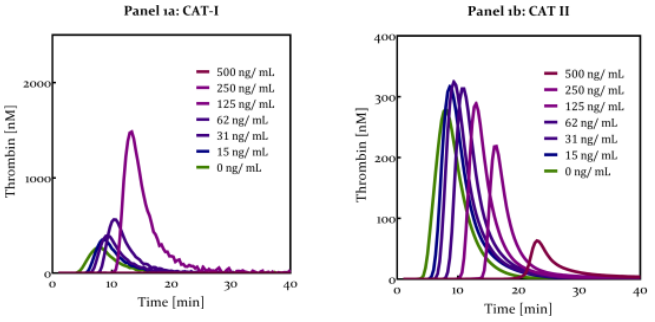

FIGURE 1 Thrombin generation curves in CAT-1 (a) and CAT-II (b) method in direct thrombin inhibitor plasma

Results: Because of inhibition of the calibrator in CAT-I by the direct thrombin inhibitor dabigatran, plasma thrombin generation is overestimated, resulting in elevated ETP and peak thrombin values with increasing dabigatran dosage (Figure 1a). Through calibration according to the CAT-II method, expected inhibition of thrombin generation was obtained with increasing levels of dabigatran (Figure 1b). In healthy individuals both methods showed good coefficients of variation (Table 1).

TABLE 1 Coefficient of variability of TG parameters in blanco measurements in CAT-I and CAT-II

TG parameter	Intra-Assay %CV CAT -I (5 pM TF)	Intra-Assay %CV CAT-II (5 pM TF)
Lag Time (min)	2.43	1.84
Peak Height(nM)	2.69	3.61
ETP (nM.min)	3.83	4.87
Velocity Index (nM/min)	5.07	5.8

Conclusions: Alternative calibration applied in the CAT-II method corrected for interference of direct thrombin inhibitors with the calibrator in CAT-I, which results in overestimated and unrealistic thrombin generations. Thrombin generation assessed by the CAT-II method in plasmas of healthy volunteers was comparable to data obtained by the CAT-I assay.

PB 1220 | Inability of Idarucizumab 5gm to Completely Reverse Excessively High Dabigatran Concentrations

W. Dager, A. Roberts

University of California, Davis Medical Center, Pharmacy, Sacramento, United States

Background: Idarucizumab 5gms is a recently approved antidote that rapidly reverses the effects of dabigatran with full reversal is

suggested in 99% of patients. Occasionally, patients may present with excessively high levels where it is unclear if there is a maximal dabigatran concentration fully reversed with 5gm's of idarucizumab. Measurement of dabigatran concentrations using ecarin clotting assay are utilized to assess the amount of dabigatran present during acute reversal management.

Aims: To report 2 cases of partial reversal of excessive dabigatran concentrations with 5 gm's of idarucizumab 5gm.

Methods: Case report.

Results:

Case 1: A patient admitted for pulmonary issues but eventually required emergent surgery with a pre-operative INR of 13.2 and dabigatran level of 1360 ng/ml. 2 hours later the INR was 1.93 and dabigatran level 447ng/ml.

Case 2: A patient with an initial elevated dabigatran level of 2250ng/ml (INR > 12) that dropped to 1140ng/ml one hour after Idarucizumab was administered. Hemodialysis was initiated to remove dabigatran and subsequently stopped with a post rebound dabigatran concentration of 692ng/ml noted 2 hours prior to the second Idarucizumab dose which was administered 14 hours after the first dose. The dabigatran concentration 7 hours later (and 21 hours after the initial dose) was 552ng/ml and 465ng/ml an additional 7 hours later.

Conclusions: A 5gm idarucizumab dose appears to reverse approximately 900-1100ng/ml of dabigatran. In the setting of major bleeding or need for an emergent procedure and very high dabigatran levels, additional idarucizumab may be necessary for full neutralization. In case two, the limited drop in the dabigatran concentration may in part may have been driven by a rebound in the dabigatran level after the initial dose. Further assessments are necessary to fully understand the approach to reversing very high levels of dabigatran.

PB 1221 | The Direct Rivaroxaban: Direct Measurement of Plasma Rivaroxaban Concentration through Prothrombin Time (PT) Assay

B. Kim[1], S. Jang[2], Y.-U. Cho[2], C.-J. Park[2]

[1]Soonchunhyang University Cheonan Hospital, Laboratory Medicine, Cheonan-si, Korea, Republic of, [2]University of Ulsan College of Medicine and Asan Medical Center, Laboratory Medicine, Seoul, Korea, Republic of

Background: The plasma concentration of rivaroxaban (RIV) should be monitored in specific clinical situations. However, the anti-factor Xa assays may not be readily available. The PT assay is simple and widely available, therefore could be a good candidate for measuring plasma RIV level.

Aims: The aim of this study is to develop a direct RIV measuring method with PT assay using RIV-specific calibrators, and diluted RIV-spiked normal pooled plasma (NPP).

Methods: Thromborel®S and CA-7000 coagulometer were used to PT assay. The RIV-specific commercial calibrator and RIV-spiked NPP samples (0 to 500 ng/mL) were analyzed. In addition, control material and multicalibrator spiked with RIV 0, 100, 250, and 500 ng/mL were analyzed. We calculated and compared the slopes of the calibration line and regression line of RIV-spiked plasma, control materials, and multicalibrator. To identify the effect of factor X level in relation to sensitivity for RIV, functional factor X assay was performed. The PT assay with multiple diluted NPP was performed, then comparing the change of sensitivity for RIV.

Results: The sensitivity of Thromborel®S (0.0095) for RIV in RIV-spiked NPP samples was lower than RIV-specific calibrators (0.0241). As the target INR was increase, the sensitivities for RIV in the RIV-spiked control and multicalibrator increased. The lower the factor Xa level is, the sensitivity for RIV increases. The sensitivity for RIV increased as more dilution of NPP was made (0.7-fold dilution: 0.0208, and 0.6-fold dilution: 0.0250) and the sensitivity of diluted NPP at 0.6 fold was almost same as that of the RIV-specific calibrator.

Conclusions: The direct calculation of plasma concentration of RIV using PT assay with a commercial RIV-specific calibrator material could be possible, with increase of reagent sensitivity through adequate dilution of patient plasma samples. The dilute PT assay is suggested as a simple and rapid method for evaluating the anticoagulant activity of RIV.

PB 1222 | Management of Pulmonary Embolism in a Short Stay Medical Unit: A Cohort Study

M. Donadini[1], A. Squizzato[2], M. Caprioli[2], N. Macchi[2], W. Ageno[2]

[1]ASST Sette Laghi, Clinical Medicine, Varese, Italy, [2]University of Insubria, Varese, Italy

Background: Low risk pulmonary embolism (PE) could be treated in hospital or even entirely at home, when home circumstance are adequate. However, the length of hospital stay (LOS) for PE remains long in the Italian setting (mean 11.5 days, Ministry of Health reports, 2010).

Aims: Our objective was to evaluate the management and outcome of haemodinamically stable PE patients admitted to a short stay medical unit (SSMU).

Methods: We conducted a cohort study enrolling consecutive patients diagnosed with acute PE, admitted to the SSMU and then followed at Thrombosis Center of the Ospedale di Circolo (Varese) from May 2014 to December 2016. The outcomes were LOS, symptomatic recurrent venous thromboembolism (VTE), major bleeding and mortality during hospital observation and at 1 month. The study was approved by the insitutional ethics committee.

Results: 100 patients were enrolled, with a mean age of 67.5 years (standard deviation-SD-17.5), 41% were males. According to the pulmonary embolism severity index (PESI) 37 patiens (37%) were classified at low risk of adverse outcome. Overall, the mean LOS was 5.7 days (SD 4.3). In particular, 77% of patients were discharged home

after a mean LOS of 4.5 days (SD 1.7), whereas 23% of patients were transferred to other wards, for a mean LOS of 10.0 days (SD 7.0).

Overall, 50% of patients received direct oral anticoagulants, 20% low molecular weight heparin (LMWH) with warfarin, 29% LMWH alone, 1% fibrinolysis.

During the hospital stay, no patients experienced recurrent VTE, 2 patients (2%) experienced major bleeding and 2 patients died (2%) At 30 days, one patient had recurrent VTE, whereas 2 additional patients died. All those patients were high-risk PESI and had been transferred from SSMU to other wards.

Conclusions: A reduction of LOS, as compared with the national mean, was obtained by admitting PE patients to a SSMU, with follow-up at the thrombosis center. A short hospital stay seems safe for haemodinamically stable PE patients, especially those classified at low risk by PESI.

PB 1223 | The Safety of a Nurse Led Pathway to Transition Patients with Acute Venous Thromboembolism (VTE), Treated with Rivaroxaban, into the Community

T. Indran[1], A. Cummins[1], H. Tran[1,2,3], S. Brown[1,2], A. Bennett[1,3], E. Wood[1,4], Z. McQuilton[1,4], N. Chan[1,5], S. Chunilal[1,2]

[1]Monash Medical Center, Haematology, Melbourne, Australia, [2]Monash University, Haematology, Melbourne, Australia, [3]Australian Centre for Blood Diseases, Monash University, Melbourne, Australia, [4]Monash University, Department of Epidemiology Preventive Medicine, Melbourne, Australia, [5]McMaster University, Haematology, Hamilton, Canada

Background: Rivaroxaban is effective treatment for patients with VTE, but the appropriate clinical monitoring of these patients after discharge is uncertain.

Aims: To audit the safety of a nurse led pathway to monitor patients with acute VTE. treated with Rivaroxaban

Methods: Prospective audit of patients treated with Rivaroxaban for acute VTE at Monash Health over 12 months. A VTE nurse identified patients at discharge then reviewed their files for suitability to receive Rivaroxaban. Patients were followed with telephone calls and text messaging and email, until clinic review. Using set criteria the nurse to identified patients at risk of major bleeding or recurrent VTE.

Outcomes:

1) The proportion of patients requiring pre-emptive intervention to prevent major bleeding or recurrent VTE.

2) Rates of major bleeding and recurrence during anticoagulation (6 weeks to 90 days).

Results: 180 patients with VTE prescribed rivaroxaban were identified. 5 patients did not come onto the pathway and 3 patients declined and 1 patient was lost to follow-up.171patients were managed on the pathway. Their average age was 54 years and 52% were male. 102 patients had pulmonary embolus (PE), 63 patients had deep vein thrombosis (29 proximal and 34 distal) and 6 patients had other VTE. Pre-emptive action was required in 11 %(95% Confidence intervals (CI) 7-17%) of patients, 5 % (95%CI2-10%) to prevent major bleeding and 6 % (95%CI 3-10%) to prevent recurrence. No 0% (95%CI: 0 to 2%) major bleeding occurred but 2 patients (1.5%(95%CI 1-4%)had possible recurrences.

Conclusions: Our nurse led pathway identified 11% of patients at risk of recurrence or major bleeding needing timely preventative physician interventions. The safety of this simple nurse led pathway is validated by the low rate of actual major bleeding 0% and recurrent VTE 1.2%.

PB 1224 | Performance of a Chromogenic Assay for the Measurement of Edoxaban Concentration in Plasma

C. Hamon[1], C. Godefroy[1], A. Barthod-Malat[2]

[1]CH Marne la Vallée, Jossigny, France, [2]Stago, Asnières sur Seine, France

Background: Edoxaban is an oral direct Factor Xa inhibitor used at fixed daily dosages. Edoxaban has been approved by regulatory authorities for use as a direct oral anticoagulant (DOAC) without the need for routine blood monitoring. Nevertheless, the quantification of edoxaban plasma anti-Xa activity may be desired, or necessary, in specific clinical situations including emergency surgery or severe active bleeding. A chromogenic assay has been developed to provide rapid and automated measurements of edoxaban activity in plasma.

Aims: The purpose of this study was to assess the performance of this assay in comparison to results obtained by the reference standard of liquid chromatography-mass spectrometry (LCMS).

Methods: 65 plasma samples were obtained from clinical studies sponsored by Daiichi-Sankyo (DSI). The chromogenic assay for edoxaban quantitation in plasma was performed using proper assay methodology, calibrators and quality controls. The results obtained from the chromogenic assay were compared to LCMS measurements performed by the DSI reference site.

Results: Samples in the method comparison showed LCMS results ranging from 19 to 408 ng/mL *versus* 25 to 393 ng/mL for anti-Xa results. The correlation between the chromogenic Anti-Xa assay and LCMS was excellent (r^2 = 0.99). Inter-laboratory coefficient of variation (CV) were determined for two edoxaban levels: 7.06% and 2.92% for edoxaban level equivalent to 42 ng/mL and 103 ng/mL respectively.

Conclusions: The comparison between the chromogenic assay for measuring edoxaban plasma concentration and the LCMS method demonstrates excellent overall correlation between both methodologies. The rapid and automated chromogenic assay permits haemostasis laboratories the ability to quickly measure edoxaban plasma concentrations which may be useful in serious or emergency patient situations.

PB 1225 | The Perioperative Anticoagulant Use Surgery Evaluation (PAUSE) Study

J. Douketis[1], A. Spyropoulos[2], S. Bates[1], M. Blostein[3], J. Caprini[4], M. Carrier[5], J. Duncan[1], P.L. Gross[1], J. Kassis[6], S. Kowalski[7], A. Lee[8], G. Le Gal[9], G. Le Templier[10], E. MacKay[11], S. Shivakumar[12], V. Shah[13], F. Spencer[1], S. Solymoss[3], S. Syed[1], A. Tafur[14], C. Wu[15], E. Yeo[16], S. Schulman[1]

[1]McMaster University, Hamilton, Canada, [2]Northwell Health at Lenox Hill Hospital, New York, United States, [3]McGill University, Montreal, Canada, [4]NorthShore University Health Systems, Evanston, United States, [5]University of Ottawa, Ottawa Hospital Research Institute, Ottawa, Canada, [6]Hôpital Maisonneuve Rosemont, Montreal, Canada, [7]University of Manitoba, Winnipeg, Canada, [8]University of British Columbia, Vancouver, Canada, [9]Institut de Recherche de l'Hôpital Montfort, Ottawa, Canada, [10]University of Sherbrooke, Sherbrooke, Canada, [11]University of Calgary, Calgary, Canada, [12]Dalhousie University, Halifax, Canada, [13]Henry Ford Hospital, Detroit, United States, [14]Northshore University Health Systems, Evanston, United States, [15]University of Alberta, Edmonton, Canada, [16]University of Toronto, Toronto, Canada

Background: The optimal perioperative management of patients who are receiving direct oral anticoagulants (DOACs) is uncertain. The ongoing PAUSE Study is recruiting patients with atrial fibrillation (AF) who are taking a DOAC (dabigatran, rivaroxaban or apixaban) and require an elective surgery/procedure to demonstrate the safety of a perioperative standardized DOAC interruption protocol. This protocol, adjusted by type of DOAC, renal function and related bleed risk (see figure), aims to demonstrate acceptably low rates of perioperative major bleeding (MB) and arterial thromboembolism (ATE). This study aims to recruit 3,300 patients (1,100 for each DOAC), of whom 1/3 will have a high bleed risk surgery/procedure.

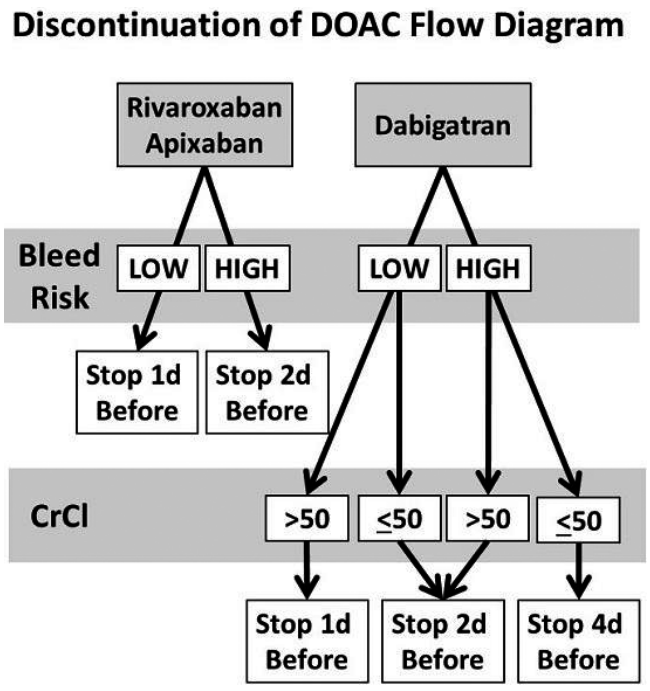

FIGURE 1 Standardized DOAC preoperative interruption protocol (Based on DOAC type, risk of bleed and CrCl)

Aims: To review the recruitment profile of the first 1,500 patients recruited into PAUSE to assess the distribution among the 3 DOACs and bleed risk classification. Should the target recruitment in one DOAC cohort and/or high bleed risk procedure categories be under-represented, selective recruitment may be implemented.

Methods: This international, observational, prospective cohort study, with 3 parallel cohorts for each DOAC, at ~20 centres expects to recruit 3,300 AF patients receiving a DOAC and having an elective surgery will be recruited for the study in a non-selective manner. The first 1,500 patient recruitment profile will be reviewed to evaluate whether current recruitment practices are favorable to meeting target recruitment.

Results: To date, 1,500 patients have been recruited into PAUSE over a 2-year period with 32.7% of patients having a high bleeding risk surgery/procedure. There are 28.3% of patients in the dabigatran, 35.5% of patients in the rivaroxaban, and 36.2% of patients in the apixaban cohorts.

TABLE 1 PAUSE Study Recruitment Profile - Type of DOAC and Surgery/Procedure Bleed Risk

Type of DOAC	Patients having HIGH RISK for BLEED procedures	Patients having LOW RISK For Bleed procedures	Total Recruited
Dabigatran	145	279	424
Rivaroxaban	167	366	533
Apixaban	179	364	543
Total	491	1009	1500

Conclusions: The PAUSE Study recruitment, to date, demonstrates symmetric patient recruitment in the 3 DOAC cohorts and has attained the targeted proportion of patients having a high bleeding risk surgery/procedure. Selective recruitment is not required.

PB 1226 | Assay Availability for Measurement the Anticoagulant Effect of Direct and Indirect Xa Inhibitors

S. Platton, M. Dave

Barts Health NHS Trust, London, United Kingdom

Background: Although routine coagulation monitoring of the direct oral anticoagulants is unnecessary, there is an urgent need for readily and rapidly available tests to measure them. This need will increase with the introduction of reversal agents such as idarucizumab for dabigatran and andexanet alfa for rivaroxaban, apixaban, and edoxaban. Idarucizumab is already licensed and andexanet is undergoing regulatory review and could be approved later this year.

Aims: There have been recent calls for the urgent adoption in the hospital setting of assays that can accurately and rapidly determine the concentration of these drugs. We describe how rapid access to assays based on anti-Xa activity has been achieved in two of our hospitals.

Methods: Our laboratories validated the Hyphen Biomed [Hyphen] LRT reagent against the Hyphen Heparin 6 reagent for the indirect-Xa inhibitors, and against the Hyphen DiXaI reagent for rivaroxaban. New assays were created for apixaban and edoxaban using the Hyphen LRT reagent. Calibrators and controls for all assays were from Hyphen, except for edoxaban, where they were obtained from Diagnostica Stago.
Results: All assays comply with the requirements of ISO15189, except edoxaban where no inter-laboratory comparisons are yet available.
Conclusions: Through the use of a single reagent set with different calibration curves for each drug, training for staff on all shifts is achievable. The stability of the liquid reagents on board the analyser also means that reagents can be left on the analyser; when a request is received, relevant controls are run and the assay is performed. In this way assays are available immediately for heparin (low molecular weight and unfractionated), rivaroxaban, apixaban, edoxaban, danaparoid and fondaparinux with less than one hour turnaround time. Hospital laboratories should consider the use of liquid reagents for anti-Xa activity assays in order to enable rapid evaluation of all direct and indirect Xa inhibitors using commercially available calibrators and controls.

PB 1227 | Evaluation of Prescribing Practices and Medication Persistence in Patients Initiated on Direct Oral Anticoagulant Therapy at a Tertiary Care Academic Medical Center

B. Lai[1], E. Peterson[1], P. Klem[2], G. Woodhouse[2], E. Fields[2], T. Trujillo[1], K. Hassell[3], C. Thienelt[3]

[1]University of Colorado Skaggs School of Pharmacy and Pharmaceutical Sciences, Pharmacy, Aurora, United States, [2]University of Colorado Health, Pharmacy, Aurora, United States, [3]University of Colorado Health, Hematology, Aurora, United States

Background: Direct oral anticoagulants (DOACs) are preferred over warfarin due to favorable efficacy and safety comparisons as well as patient convenience. However, concerns remain over gaps in appropriate prescribing and reduced medication persistence resulting in suboptimal outcomes.
Aims: To assess the appropriateness of DOAC prescribing and medication persistence in patients following discharge.
Methods: A retrospective analysis of patients initiated on a DOAC during hospitalization between January 1, 2016 to October 31, 2016 was conducted. Data was abstracted from the EMR in order to evaluate clinical outcomes and medication persistence at 1 month and 3 months post-discharge.
Results: A total of 281 patients were identified. Primary indications were treatment of acute VTE (63%) and atrial fibrillation (26%). Rivaroxaban was used in 77% of the patients and apixaban 19%. Based on current dosing recommendations, 14 patients (5%) received incorrect initial dosing. The most common error was providing induction doses of a DOAC when an acute VTE was not present (8/14 patients). At 1 month, 29% of patients were lost to follow up. Only 142 patients (50%) had follow-up documentation in the EMR regarding anticoagulation therapy in the first 3 months. In patients with documented follow-up, 96% remained on therapy for a minimum of 1 month. Major adverse events occurred in 11 patients
(7 hemorrhagic, 3 thromboembolic, 1 other) which led to 7 or 11 patients discontinuing therapy. Of the documented patients, 88% remained on DOAC therapy at 3 months.
Conclusions: Our results demonstrate concerns regarding medication persistence with a high percentage of patients newly started on DOAC therapy being lost to follow-up within 1 month and a small but significant percentage of inappropriate dosing. Clinical outcomes may be adversely affected by these factors. These results support the concept that follow up with an anticoagulation clinic can aid in the transition of care and appropriate use for patients newly started on DOAC therapy.

PB 1228 | Selection of Long-term Anticoagulation Therapy after Acute Pulmonary Embolism in Real Life

V. Ģībietis, D. Kigitoviča, B. Vītola, S. Strautmane, A. Skride

Riga Stradiņš University, Riga, Latvia

Background: In patients with acute pulmonary embolism (APE), two classes of oral anticoagulants are recommended for long-term treatment - vitamin K antagonists (VKAs) and direct oral anticoagulants (DOACs). Clinical trials indicate that DOACs are non-inferior and possibly safer than VKAs (ESC Guidelines, 2014).
Aims: To assess the factors for long-term oral anticoagulant class selection after APE in real-life practice.
Methods: The prospective cohort study included 147 consecutive patients from a single centre from June 2014 till October 2016 presenting with symptomatic APE. Statistical analyses were conducted using SPSS 23.0. Pearson's chi-square test, Student's t-test or Mann-Whitney U test were used.
Results: 136 patients survived until discharge. As their long-term treatment 134 received oral anticoagulants. DOACs were prescribed to 92 (68.7%) and VKAs to 42 (31.3%). Statistically significant factors in favour of VKA selection were gender (male: 54.8% in VKA group vs 35.9% in DAOC group, p=0.040), chronic heart failure (59.5% vs 39.1%, p=0.028), chronic lung disease (23.8% vs 7.6%, p=0.009), creatinine clearance (CrCl, Cockcroft-Gault) < 60 mL/min (39.0% vs 22.2%, p=0.046). However, in favour of DOACs were higher body-mass index (BMI) (kg/m2, median (IQR): 26.8 (24.4-30.4) vs 29.5 (25.7-34.6), p=0.016) and presence of transient risk factors for venous thromboembolism (recent surgery, immobility, hormonal therapy, recent travel) (16.3% vs 38.0%, p=0.011).
Higher Charlson Comorbidity Index (CCI) values were more present in VKA group (mean (SD): 4.8 (2.3) vs 3.7 (2.8), p=0.029). Presence of cancer was similar between both groups.
Conclusions: Male gender, chronic heart failure, chronic lung disease, CrCl < 60 mL/min, and overall higher burden of comorbidities (CCI)

are associated with preference of VKAs for long-term treatment of APE in real-life practice. Patients with higher BMI and transient risk factors more often receive DOACs.

PB 1229 | Impact Analysis of Prognostic Stratification for Pulmonary Embolism: The iAPP Study

M. Donadini[1], W. Ageno[2], M. Cei[3], F. Dentali[2], P. Fenu[3], N. Mumoli[4], F. Pomero[5], R. Re[6], G. Palmiero[7], L. Spadafora[5], D. Aujesky[8], A. Squizzato[2]

[1]ASST Sette Laghi, Clinical Medicine, Varese, Italy, [2]University of Insubria, Varese, Italy, [3]Azienda USL6 Livorno - Presidio Ospedaliero di Cecina, Cecina, Italy, [4]Azienda USL6 Livorno - Presidio Ospedaliero di Livorno, Livorno, Italy, [5]Azienda Ospedaliera Santa Croce e Carle, Cuneo, Italy, [6]Azienda Ospedaliera ‚Maggiore della Carità', Novara, Italy, [7]Azienda USL12 Viareggio - Ospedale Versilia, Viareggio, Italy, [8]Bern University Hospital, Bern, Switzerland

Background: Pulmonary Embolism Severity Index (PESI) is an extensively validated prognostic score on the risk of adverse outcomes after acute pulmonary embolism (PE). However, there is no evidence that adopting PESI changes physicians behaviour, improves patients outcomes and/or reduces costs.

Aims: To demonstrate that the use of PESI will help physicians to correctly identify PE patients at low-risk of adverse outcomes, thus discharging them earlier and reducing the length of hospital stay (LOS).

Methods: The iAPP study (Impact Analysis of Prognostic Stratification for Pulmonary Embolism) is a multicenter randomized controlled trial, enrolling consecutive adult outpatients with an objective diagnosis of acute PE. Within 48 hours from diagnosis, treating physicians are centrally randomized, for every patients, to stratify PE prognosis by formally calculating PESI and reporting it in the clinical record form or to routine practice. Randomization is stratified by the intented treatment choice.

The primary outcome is the median LOS. Secondary efficacy outcomes include the proportion of patients undergoing complete home-treatment, post-discharge visits to emergency department or hospital re-admissions. Safety outcomes include mortality, PE complications, hospital-acquired infections or iatrogenic complications.

To find a statistically significant difference ($p< 0.05$) between the median LOS of the two groups, with an α error of 0.05 and a statistical power of 80%, 220 patients for each group need to be enrolled. The study was approved by the ethics committee of the participating centers. ClinicalTrials.gov identifier NCT03002467.

Results: The study is ongoing. Enrollment started in September 2016 and thirty patients from five active centers were enrolled until January 2017. We estimate that 2 years are necessary to reach the sample size.

Conclusions: The iAPP study is expected to provide information on the impact of PESI in clinical practice, in terms of changing physicians behaviour on the duration of hospitalization.

PB 1230 | Do the Direct Oral Anticoagulants (Doacs) Make Managing Anticoagulant Therapy during the Peri-operative Period Easier?

K. Kittoe, J. Patel, R. Arya

King's College Hospital, Haematology, London, United Kingdom

Background: The introduction of the DOACs into clinical practice is leading to significant number of patients being prescribed these agents. With their increased use, all too often, anticoagulation services are being asked to manage these agents during the peri-operative period.

Aims: To describe how many patients prescribed DOACs were referred to the anticoagulation service at King's College Hospital, London between April 2016 - December 2016, whether patients required bridging with low molecular weight heparin (LMWH), and what the outcomes were for the patients evaluated.

Methods: All patients referred to the service for peri-operative management advice had a proforma plan completed. This contained amongst other things, indication for use, DOAC prescribed, renal function, when to stop and re-start the DOAC, along with if any patients required bridging with LMWH therapy when the DOAC was stopped. These proformas were retrieved and reviewed retrospectively, following which the outcomes from the medical notes and patients were collated.

Results: During the evaluation time period 28 patients were referred; 16 males, average age 65.68 (SD 14) years of age. The hospital guidelines on managing DOAC therapy were followed in 100% of cases. One patient experienced a minor bleed and a further patient had to be taken back to theatre, following the development of a haematoma. None of the DOAC patients required bridging therapy with LMWH. During the same period, 36 warfarin patients were referred to our service for peri-operative advice, of which 17 patients required enoxaparin bridging therapy.

Conclusions: Managing DOACs during the peri-operative period is much less resource intensive, compared to warfarin therapy, with benefits observed on clinic personnel time saved.

PB 1231 | Limits of Sensitized Rotational Thromboelastometry for Rivaroxaban and Apixaban Detection

C. Pailleret Ringuier[1,2], G. Jourdi[1], V. Siguret[1,3], I. Gouin-Thibault[1], S. Gandrille[1,4], A. Stepanian[3,5], J.-L. Golmard[6], P. Gaussem[1,4], C.-M. Samama[1,2], B. Le Bonniec[1]

[1]Faculté de Pharmacie, Université Paris Descartes, UMR_S 1140, Paris, France, [2]Hôpital Cochin, APHP, Anaesthesia and Intensive Care, Paris, France, [3]Hôpital Lariboisière, APHP, Hematology, Paris, France, [4]Hôpital Européen Georges Pompidou, APHP, Hematology, Paris, France, [5]Hôpital Saint Louis, EA 3518, Paris, France, [6]Université Pierre et Marie Curie, Biostatistic, Paris, France

Background: Direct oral factor Xa (FXa) inhibitors are increasingly used for the prevention and treatment of thromboembolic diseases.

Their detection may be essential in emergency situation involving invasive procedure, bleeding, or before thrombolysis in acute ischaemic stroke. Target-specific assays (anti-Xa) quantifying the drugs in plasma are out of reach in emergency.

Aims: Rotational thromboelastometry (ROTEM) is performed with whole blood and available in a number of operating rooms and intensive care or emergency units but the marketed ROTEM assay only detects high amounts of inhibitors. Since thrombin generation assay and clot waveform analysis are adequately sensitive to FXa inhibitors, we investigated the potential of ROTEM.

Methods: We first verified that sensitized ROTEM has the potential to detect low level of FXa inhibitors in platelet poor plasma. We studied the interferences of platelet count, fibrinogen level, and haematocrit on inhibitor detection. We tested whole blood spiked with FXa inhibitors from healthy volunteers. Finally we evaluated the method with whole blood from 66 patients.

Results: We established that, independently, neither platelets nor fibrinogen or haematocrit preclude FXa inhibitor detection. We established what would be the lowest amount of FXa inhibitor detected in whole blood taking into account the inherent variability of samples having haematocrit comprised between 30 and 60%. Regrettably sensitized ROTEM failed to safely detect FXa inhibitors in patients.

Conclusions: Study suggests that in real life conditions sensitized ROTEM is not relevant in clinical practice for emergency FXa inhibitor detection.

PB 1232 | Choice of Anticoagulation in the Obese

G. McCaughan[1,2], H. Crowther[3,4], J. Curnow[3,4]

[1]ICPMR, Westmead Hospital, Sydney, Australia, [2]University of Sydney, Sydney Medical School, Sydney, Australia, [3]Western Sydney Local Health District, Department of Haematology, Sydney, Australia, [4]Sydney Centres for Thrombosis and Haemostasis, Sydney, Australia

Background: The optimal anticoagulation strategy in the obese is unclear. There is limited available data to guide the use of direct oral anticoagulants (DOACs) and low molecular weight heparin (LMWH) in this patient group.

Aims: Examine anticoagulant choice, drug specific anti-Xa levels and clinical outcomes in this group.

Methods: We identified patients with venothromboembolism (VTE) and weight >120kg or BMI >40kg/m^2 attending Western Sydney Haematology Services in 2016. We collected demographic data, weight, height, indication, anticoagulant choice, drug monitoring, dose adjustments and clinical outcomes.

Results: We identified 21 VTE patients with a median weight of 136kg (range 119-208). 8 were given DOACs as initial anticoagulant (5 rivaroxaban, 3 apixaban) and 7 subsequently received DOACs during follow-up. Anti-Xa levels on rivaroxaban 20mg daily were: peak 65-96ng/ml (n=3) and trough 13-32ng/ml (n=2). Anti-Xa levels on apixaban 5mg BD were: peak 97-141ng/ml (n=3) and trough 39-48ng/ml (n=2). 10 patients received protracted enoxaparin therapy monitored by Anti-Xa levels (n=8) and 4 required dose adjustments. Median dose to achieve therapeutic Anti-Xa (0.6-1.2U/ml) was 0.87mg/kg (range 0.66-1.1). 3 patients had recurrent thromboses while anticoagulated, 2 on rivaroxaban (troughs 13ng/ml and 23ng/ml) and 1 when warfarised previously. Bleeding complications occurred in 1 on enoxaparin and 2 on rivaroxaban (menorrhagia).

Conclusions: There is limited data on the appropriate use of LMWH and DOACs in obese patients. Although measurement of DOAC drug levels in obese patients has been recommended by ISTH, there is limited data available on clinical correlates of DOAC drug levels or therapeutic ranges. Compared with available published DOAC ranges, peak levels appear to be reduced in the obese population, however trough levels appear appropriate. The clinical significance of this is yet to be determined. We have commenced a multi-centre prospective registry of obese patients requiring anticoagulation.

PB 1233 | Antithrombotic Effects of Edoxaban, a Direct Factor Xa Inhibitor, and Antiplatelet Agents and their Combination Effects on Stent Thrombosis in Rats

Y. Morishima, C. Kamisato, Y. Honda

Daiichi Sankyo Co., Ltd., Tokyo, Japan

Background: Stent thrombosis is an uncommon but serious complication after percutaneous coronary intervention and femoropopliteal endovascular intervention in patients with peripheral artery disease.

Aims: The aim of this study was to determine the antithrombotic effects of a direct factor Xa inhibitor edoxaban alone or in combination with antiplatelet agents in a rat model of stent thrombosis.

Methods: Bare metal stents (4 per rat) were inserted in an ex vivo arterio-venous shunt in rats. Stent thrombosis was induced by exposing to arterial blood for 30 min. Protein content of the thrombus was measured. Edoxaban and antiplatelet agents (aspirin, clopidogrel, and ticagrelor) were orally administered 30 min and 2 hours before the stent exposure to blood, respectively. As a control, 0.5% methylcellulose was administered.

Results: In this rat stent thrombosis model, edoxaban (0.3 - 3 mg/kg), aspirin (1 - 100 mg/kg), clopidogrel (1 - 30 mg/kg), and ticagrelor (0.3 - 3 mg/kg) exerted significant and dose-dependent antithrombotic effects. The maximum inhibition by each compound was 86% (3 mg/kg edoxaban), 83% (100 mg/kg aspirin), 94% (30 mg/kg clopidogrel), and 89% (3 mg/kg ticagrelor). The combination of submaximum doses of edoxaban and aspirin or edoxaban and clopidogrel significantly potentiated the antithrombotic effects compared with these drugs alone.

Conclusions: This study demonstrated that a direct factor Xa inhibitor, edoxaban, significantly and dose-dependently inhibited the formation of stent thrombosis in a rat model. The effect of edoxaban was comparable to that of antiplatelet agents, aspirin, clopidogrel,

and ticagrelor. The concomitant use of edoxaban and antiplatelet agents exerted the combination effects. These results suggest that edoxaban alone and in combination therapies with edoxaban plus aspirin and edoxaban plus clopidogrel are promising options for prevention of stent thrombosis.

PB 1234 | Dental Extractions on NOACs withouTStopping Therapy (DENTST) Study: Interim Analysis

Y. Brennan[1], Y. Gu[2], E.J. Favaloro[3], H. Crowther[1], E. Kelly[4], H. Zoellner[4], M. Schifter[2], J. Curnow[1]

[1]*Westmead Hospital, Department of Haematology, Sydney, Australia,* [2]*Westmead Hospital, Department of Oral Medicine, Oral Pathology and Special Needs Dentistry, Sydney, Australia,* [3]*Westmead Hospital, Diagnostic Haemostasis Laboratory, Pathology West, Sydney, Australia,* [4]*The University of Sydney, Sydney, Australia*

Background: International guidelines recommend warfarin be continued for dental extractions, as bleeding rates are not high; instead, discontinuation can result in venous thromboembolism (VTE). There is currently no published data from clinical trials to guide the management of patients on new oral anticoagulants (NOACs) requiring dental intervention.

Aims: To determine the safety of performing dental extractions on patients taking NOACs. Secondary aims are to identify factors associated with increased bleeding risk and to determine if there is a safe lower limit of NOAC drug level below which dental extractions may be safely performed.

Methods: This is a prospective cohort study with 3 groups: patients on NOAC, warfarin, or no anticoagulant. The study has local ethics approval and informed consent is obtained. Participants do not withhold their anticoagulant. Blood tests are measured immediately prior to extraction. After extraction, Surgicel is placed in the socket, the socket then sutured and pressure applied with gauze. The gauze is weighed before and after haemostasis is achieved, and blood loss estimated by laboratory analysis. Bleeding complications are assessed at 48 hours and 7 days.

Results: Recruitment commenced in February 2016 with a target completion of November 2018. Data from 41 participants available at the time of abstract submission is summarised in tables 1 and 2. There have been 2 episodes of clinically relevant non-major bleeding: both were delayed bleeding requiring unanticipated dental review in patients on warfarin with therapeutic INRs. The difference in weight of gauze appears to indicate that patients on NOACs bleed less than warfarin. Interim blood loss analysis suggests this is typically low and not clinically significant.

TABLE 2 Anticoagulant drug levels

Oral anticoagulant	Warfarin	Apixaban	Dabigatran	Rivaroxaban
Assay	INR	Anti-Xa	Dilute thrombin time	Anti-Xa
Median drug level (range)	2.2 (2.0-2.4)	136.1 ng/ml (37.3-238.7)	122.3 ng/ml (68.5-188.1)	137.0 ng/ml (11.0-487.0)

Conclusions: Interim results suggest that bleeding outcomes in patients on NOACs are comparable and perhaps less than patients on warfarin. NOAC interruption may be unnecessary for dental extractions.

PB 1235 | Patients on a Fixed Dose of DOAC: What Percentage is in the Therapeutic Window?

H.C. Hemker[1,2], S. Bloemen[1,2], R. Kremers[1,2], H. Kelchtermans[1,2], J. Douxfils[3], F. Mullier[3,4], B. de Laat[1,2]

[1]*CARIM, Maastricht University, Synapse Research Institute, Maastricht, The Netherlands,* [2]*CARIM, Maastricht University, Department of Biochemistry, Maastricht, The Netherlands,* [3]*Namur Research Institute for Life Sciences, University of Namur, Department of Pharmacy, Namur, Belgium,* [4]*Université Catholique de Louvain, CHU UCL Namur, Hematology Laboratory, Namur Thrombosis and Hemostasis Center, Yvoir, Belgium*

Background: Adequate antithrombotic medication ideally modulates the function of the clotting system to a certain therapeutic window (TW) to minimize thrombotic recurrence while maintaining adequate hemostasis, i.e. prevent bleeding. For anti-vitamin K (AVK) treatment

TABLE 1 Patient details and outcomes

Oral anticoagulant	Warfarin	All NOACs	Apixaban	Dabigatran	Rivaroxaban	No anticoagulant
Patient number	6	22	12	4	6	13
Total number of teeth extracted	10	48	17	15	16	27
Total number of roots extracted	15	67	27	18	22	48
Any bleeding	3 (50%)	5 (23%)	3 (25%)	1 (25%)	1 (17%)	1 (8%)
Major bleeding episodes	0	0	0	0	0	0
Clinically relevant non-major bleeding episodes	2 (33%)	0	0	0	0	0
Minor bleeding episodes	1 (17%)	5 (23%)	3 (25%)	1 (25%)	1 (17%)	1 (8%)
Difference in weight of gauze per tooth (grams)	3.24	2.00	2.91	1.80	1.29	1.82
Difference in weight of gauze per root (grams)	2.16	1.42	1.83	1.50	0.94	1.03

the TW is roughly an international normalized ratio (INR) of 2-4. For heparins and direct oral anticoagulants (DOACs), the TW is unknown. Therefore, their dosage can only be based on the outcome of clinical trials using standard dosages.

Ample evidence exists that the thrombin generating capacity (TGC) of plasma, measured as the area under the thrombin generation curve (Endogenous Thrombin Potential, ETP) is an adequate surrogate parameter for both thrombotic- and bleeding tendency. An INR of 2-4 corresponds to a TGC of 33-66% of the normal mean, and TGC < 30% is the clinical limit of a bleeding phenotype in congenital bleeding disorders. We therefore assume 66%>TG>33% as a tentative TW for all anticoagulant treatment.

Aims: To estimate the amount of patients on DOACs within the TW.

Methods: Plasmas from 60 healthy volunteers were spiked with low molecular weight heparin (LMWH), unfractionated heparin (UFH) or DOACs at concentrations that inhibit TGC in pooled normal plasma by 40%. In plasma of 48 patients on rivaroxaban samples were harvested 2±0.6 h after intake. The concentration of the drug was measured by its inhibition of factor Xa activity and the ETP was assessed by Calibrated Automated Thrombinography.

Results: The individual response of normal plasmas to an IC40 concentration of heparin and DOACs proved to be highly variable (Table).

TABLE 1

	Normal plasma	N	CV (%)	Above TW	Below TW
Spiked Plasma	None	60	18.0	99	0
	UFH	60	27.8	14	9
	LMWH	50	29.0	15	10
	DOAC-IIa	40	23.9	10	6
	DOAC-Xa	40	21.5	10	5
Patient Samples	DOAC-Xa	22	27.0	14	9

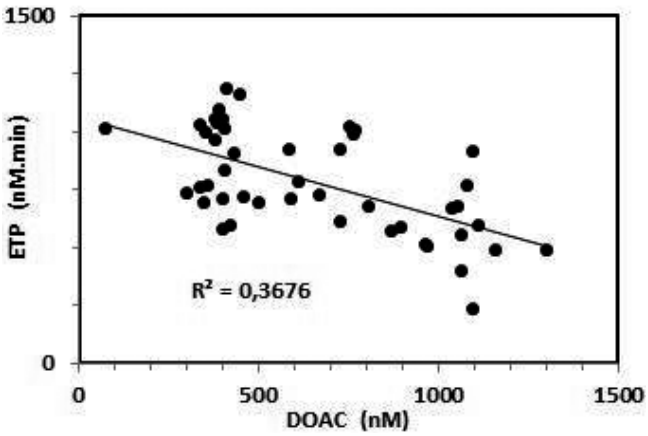

FIGURE 1

The level of the direct anti-Xa inhibitor measured in patient samples had a CV of 46% and a poor correlation was found between inhibition of ETP and the DOAC levels (Fig. 1).

Conclusions: Inter-individual variation of both pharmacokinetics and pharmacodynamics of the tested DOACs is so high that maintenance within the TW is only possible by personalized dosage guided by the effect of the drug on the TGC.

PB 1236 | Comparing the Performance of Different Assays for Monitoring Dabigatran Plasma Concentrations in Real-practice

L. Gonçalves, M. Carvalho, V. Cunha, C. Monteiro, C. Koch

Centro Hospitalar São João, Centre of Thrombosis and Hemostasis, Porto, Portugal

Background: Patients under therapeutic doses of dabigatran, a direct thrombin inhibitor, do not require routine coagulation monitoring. However, it may be important in certain clinical situations to assess anticoagulant activity. Most guidelines recommend to perform activated partial thromboplastin time (APTT) and thrombin time as screening assays, and dilute thrombin time (dTT) or ecarin chromogenic assays (ECA) to determine dabigatran plasma concentration.

Aims: Compare the results obtained with ECA, used in our laboratory, and two dTT assays, and correlate ECA with APTT. This will enable us to choose the best test for our hospital.

Methods: Blood samples were collected from 18 patients taking therapeutic doses of dabigatran, admitted to our emergency room. Plasma dabigatran concentrations were determined with STA®-ECA II (Diagnostica Stago) and compared with 2 methods of dilute thrombin time: Hemoclot® Thrombin Inhibitor (Hyphen Biomed) and a dilute thrombin time assay based on STA®-Thrombin. APTT was determined with Pathromtin® SL (Siemens). All tests were performed on STA-R® Max coagulation analyser (Diagnostica Stago).

Results: ECA showed high correlation with dTT assays, across a broad range of dabigatran levels. The correlation between ECA and Hemoclot® was very strong (R=0,980; R^2=0,960), as well as between ECA and dTT based on STA®-Thrombin (R=0,994; R^2=0,987). Both dTT assays values were similar, with excellent correlation (R=0,994; R^2=0,989). The correlation between ECA and APPT was strong (R=0,814; R^2=0,663). ECA showed to be more sensitive and useful for detecting very low dabigatran levels (limit detection level: 15 ng/ml) than dTT assays (limit detection level: 50 ng/ml).

Conclusions: This study showed that dTT and ECA accurately identify a broad range of dabigatran levels. The lower limit detected by ECA is 15 ng/ml, which can be important for patient needing high-risk surgery. Facing these results we decide to maintain ECA as the quantitative test for dabigatran in our hospital.

PB 1237 | Total Thrombus-formation Analysis System (T-TAS) as a Potential Tool for Assessing Comprehensive Hemostatic Function in Patients Taking Dabigatran

T. Ito[1], T. Nagasato[1,2], T. Nakashima[3], H. Matsuoka[3], K. Hosokawa[2], I. Maruyama[1]

[1]*Kagoshima University, Kagoshima, Japan,* [2]*Fujimori Kogyo Co., Ltd., Yokohama, Japan,* [3]*Kagoshima Medical Center, Kagoshima, Japan*

Background: Patients with non-valvular atrial fibrillation (NVAF) have an increased risk of stroke. To reduce this risk, patients with NVAF are recommended to take anticoagulants. Among these, direct oral anticoagulants (DOACs) are now widely used. DOACs are used as fixed doses without laboratory monitoring, however, it is still possible that some monitoring tools may be useful for identifying patients with high risk of bleeding complications. Recently, we have developed a flow channel-based total thrombus-formation analysis system (T-TAS®) that quantitatively analyzes the process of mixed thrombus formation involving platelets and fibrin.

Aims: In this study we analyzed correlation and discrepancy between conventional coagulation tests and T-TAS.

Methods: Blood samples were taken from patients with NVAF before initial dabigatran dosing (baseline), 2 hours after initial dosing (2h post-dose) and before the day 7 dosing. Dabigatran levels were measured by diluted thrombin time (Hemoclot®), and thrombotic abilities were measured by T-TAS and conventional coagulation tests.

Results: A total of 19 cases were evaluated in this study. Dabigatran levels on 2h post-dose correlated with the PT ratio to baseline (R=0.667), the APTT ratio to baseline (R=0.829), and the T-TAS occlusion time ratio to baseline (R=0.899). A part of patients showed discrepancy between T-TAS occlusion time and APTT, and elder patients exhibited this tendency.

Conclusions: T-TAS is a novel tool that reflects the anticoagulant activity of dabigatran. This tool may provide additional information as to comprehensive hemostatic function in patients taking dabigatran. Further studies are needed to elucidate whether T-TAS is useful for identifying patients with high risk of bleeding complications.

PB 1238 | Evaluation of Dabigatran Concentrations in Patients Plasma. Comparison of Four Commercially Available Assays

P. Toulon[1], N. DePooter[2], A. Appert-Flory[1], D. Jambou[1], F. Fischer[1]

[1]*CHU Pasteur, Hematology, Nice, France,* [2]*CH Grasse, Hematology, Grasse, France*

Background: Dabigatran is a new direct oral anticoagulant that inhibits specifically thrombin. It achieves strong anticoagulation that is more predictable than warfarin. Even though the routine monitoring of dabigatran is not recommended, there are circumstances in which the evaluation of its plasma level could be valuable such as emergent surgery, and occurrence of bleeding episode in one of the treated patients.

Aims: To evaluate the clinical performances of four commercially available assays for dabigatran in clinical materials.

Methods: We evaluated 145 plasma samples obtained from 108 patients. Indication of blood collection was emergent surgery, routine purpose, and bleeding complications including one episode that required the use of the antidote idarucizumab. Dabiigatran levels were measured using three clotting assays: the DG DTI assay performed on the QSmart analyzer, the HemosIL Direct Thrombin Inhibitor Assay and the Hemoclot Thrombin Inhibitors, the two latter were performed on the ACL TOP 700 analyzer, and one chromogenic assay (STA-ECAII assay) performed on the STAR Max analyzer. Assays were calibrated using the specific lyophilized calibration plasmas obtained from the reagent manufacturer, and the same applied for the control plasmas.

Results: The within-run and between-run precisions evaluated using control lyophilized samples, in the low and high ranges of concentrations, were below 10% for the four assays. Plasma dabigatran levels were measured in the range from below the detection limit of the techniques to 1250 ng/mL. The correlation coefficients between test results obtained using the four methods were above 0.98 in all cases with mean bias, calculated according to Bland-Altman, below 7.0%.

Conclusions: Test results obtained using the four evaluated assays for dabigatran are in good concordance, and their performances allow their use in clinical routine to evaluate the drug concentration in the plasma from treated patients.

PB 1239 | Comparison of the LMWH Tinzaparin and the Direct Inhibitors of Factor Xa and Thrombin on the Kinetics and Qualitative Characteristics of Blood Clot. An in vitro Thromboelastometric Study

S. Salta[1,2], C. Soulier[2], P. Van Dreden[3], L. Papageorgiou[1,2], A. Larsen[1], I. Elalamy[1,2], G. Gerotziafas[1,4]

[1]*Cancer Biology and Therapeutics, Centre de Recherche Saint-Antoine, Institut National de la Santé et de la Recherche Médicale (INSERM) U 938 and Université Pierre et Marie Curie (UPMC), Sorbonne Universities, Paris, France,* [2]*Service d'Hématologie Biologique, Hôpital Tenon, Hôpitaux Universitaires Est Parisien, Assistance Publique Hôpitaux de Paris, Paris, France,* [3]*Clinical Research, Diagnostica Stago, Gennevilliers, France,* [4]*Service d'Hématologie Biologique, Hôpital Tenon, Hôpitaux Universitaires de l'Est Parisien, Assistance Publique Hôpitaux de Paris, Paris, France*

Background: Fibrin clot structure and firmness are major determinants for thrombus early lysis in patients with venous thromboembolism (VTE).

Aims: The comparison of the effect of tinzaparin, rivaroxaban and dabigatran on the clot formation kinetics and quality.

Methods: Citrated whole blood samples from healthy volunteers were spiked with clinically relevant concentrations of rivaroxaban or dabigatran (10 to 500 ng/ml) or tinzaparin (0.05 to 0.8 anti-Xa IU/ml). Combination of rivaroxaban and dabigatran at clinically relevant concentrations were used. Whole blood thromboelastometry, triggered by low tissue factor concentrations (5 pM) was assessed with

TABLE 1 Patient characteristics, management of bleeding and biological measurements for major bleeding events

Gender, age (years)	CLcr (ml/min)	DOAC (dosage, indication)	Time after last intake (hours)	Site of bleeding	DOAC plasma concentrations (ng/ml)	Management	Length of stay (days)	Outcome at 90 days
F, 70	Unknown	Rivaroxaban 15 mg OD, SPAF	22	GI bleeding	Biophen DiXaI: 237.5	RBC (3 units)*	Unknown	Unknown
F, 87	48	Rivaroxaban 20 mg OD, VTE	38	GI bleeding	Biophen DiXaI: 70.8	RBC (2 units)*	3	Alive
F, 67	53	Rivaroxaban 20 mg OD, SPAF	27	GI bleeding	Biophen DiXaI Low: 58.3	RBC (3 units)*	1	Alive
F, 74	73	Apixaban 5 mg BID, SPAF	5	IC bleeding	Biophen DiXaI: 298.0	-	9	Alive
F, 77	61	Rivaroxaban 15 mg OD, SPAF	27	IC bleeding	Biophen DiXaI: 139.4	PCC 2500 IU (40 IU/kg)	43	Alive
F, 76	33	Dabigatran etexilate 110 mg BID, SPAF	53	GI bleeding	HTI Low: 19.0	RBC (1 unit)	34	Alive
F, 90	60	Rivaroxaban 15 mg OD, SPAF	27	IC bleeding	Biophen DiXaI: 86.5	-	1	Alive

* Transfusion before blood sampling. BID: twice daily, CLcr: creatinine clearance (according to Cockroft-Gault equation), Biophen DiXaI: Biophen® Direct Factor Xa Inhibitors, GI: gastrointestinal, HTI: Hemoclot Thrombin Inhibitor®, IC: intracranial, OD: once daily, PCC: prothrombin complex concentrates, RBC: red blood cells, SPAF: stroke prevention in atrial fibrillation, VTE: venous thromboembolism

the ROTEM®; Clotting Time (CT), Clot Formation Time (CFT), α-angle, Maximum Clot Firmness (MCF) were analyzed.

Results: Rivaroxaban and dabigatran, prolonged the CT but did not significantly alter the CFT, the α-angle and the MCF. At equivalent gravimetric concentrations dabigatran effect was more pronounced compared to rivaroxaban. When the two agents were combined no amplificatory effect on CT was observed. The α-angle and MCF were not significantly affected. Tinzaparin induced a significant prolongation of CT and CFT and reduced the α-angle and MCF values as compared to the control. Tinzaparin impact was significantly more potent than the DOAC combination used even at the higher studied concentrations.

Conclusions: When coagulation is triggered by physiologically relevant concentrations of TF, rivaroxaban and dabigatran prolong the CT, did not alter fibrin polymerization kinetics nor clot firmness. The combination of rivaroxaban and dabigatran did not alter clot formation process suggesting that the important effect of tinzaparin on clot formation quality is not linked to its anti-Xa or anti-IIa activity association but most probably is related to a direct interference with fibrin network and others antithrombin dependent inhibitory effects.

PB 1240 | Measurement of Direct Oral Anticoagulants Levels in Patients Admitted for Bleeding Events: A Prospective Study

A.-L. Sennesael[1,2], A.-S. Larock[3], J. Douxfils[2], J.-M. Dogné[2], A. Spinewine[1,3], F. Mullier[4]

[1]*Université Catholique de Louvain, Louvain Drug Research Institute, Clinical Pharmacy Research Group, Brussels, Belgium,* [2]*University of Namur, Department of Pharmacy, Namur Thrombosis and Hemostasis Center (NTHC), Namur Research Institute for LIfe Sciences (NARILIS), Namur, Belgium,* [3]*Université Catholique de Louvain, CHU UCL Namur, Department of Pharmacy, NTHC, Yvoir, Belgium,* [4]*Université Catholique de Louvain, CHU UCL Namur, Hematology Laboratory, NTHC, Yvoir, Belgium*

Background: Although direct oral anticoagulants (DOAC) do not require close laboratory monitoring, their measurement remains useful in specific clinical situations. A therapeutic range has not been defined yet, but DOAC plasma concentrations were shown to correlate with bleeding outcomes.

Aims: To describe DOAC plasma concentrations in patients with bleeding events, in relation to clinical and medication data.

Methods: As part of a prospective observational study conducted in the emergency departments of 2 hospitals, we collected 14 plasma samples from DOAC-treated patients admitted for bleeding events. Routine clotting assays were performed as well as specific assays using CE approved procedures (calibrated chromogenic anti-Xa assays for apixaban and rivaroxaban and diluted thrombin time and ecarin chromogenic assay for dabigatran). Clinical data were collected on admission, at discharge and at 90 days. Bleeding severity was assessed using ISTH definition. The study was approved by the Ethics Committees.

Results: Patients (median age 75 years) were mainly treated with rivaroxaban (10/14), for stroke prevention in atrial fibrillation (10/14). The most frequent site of bleeding was gastrointestinal (6/14). Seven bleedings were major (table 1).

Conclusions: A large range of DOAC plasma concentrations was observed, with above on-therapy levels estimated in around half of patients admitted for bleeding events. Among the factors contributing to bleeding, potential drug interactions are frequent in anticoagulated patients and should be screened.

PB 1241 | Direct Oral Anticoagulants for Pulmonary Embolism in Patients Initially Admitted to Sub Intensive Care Unit for Intermediate High Risk Index Event

D. Arioli[1], M. Casella[2], M. Calzolari[3], A. Casali[1], L. Morini[4], M.C. Leone[1], M. Granito[1], A. Ghirarduzzi[4], G. Tortorella[3], E.A. Negri[4]

[1]*Arcispedale Santa Maria Nuova, Thrombosis and Hemostasis Centre Internal Medicine, Reggio Emilia, Italy,* [2]*Arcispedale Santa Maria Nuova, Reggio Emilia, Italy,* [3]*Arcispedale Santa Maria Nuova, Cardiology, Reggio Emilia, Italy,* [4]*Arcispedale Santa Maria Nuova, Internal Medicine, Reggio Emilia, Italy*

Background: Pulmonary Embolism (PE) is a potential life-threating cardiovascular emergency with an early mortality rate varying up to 25% depending on the severity of presentation.

DOACs (Direct Oral Anticoagulants) have been developed to address limitations associated with traditional anticoagulant therapy. Anyway due to the scarce representation of intermediate high risk patients in clinical study, parenteral anticogaulants overlapping with oral vitamin k antagonists, still represent the mainstay of treatment in many Sub Intensive Care Unit (SICU).

Aims: The aim of our pivotal register is to obtain a reliable estimate of the risks and benefits of DOACs treatment in PE patients initially admitted to SICU.

Methods: Consecutive patients admitted for intermediate high risk PE to the two SICU of our hospital in the last 24 months were retrospectively evaluated. For patients who started DOAC, informations on recurrent venous thromboembolic and major bleeding events were collected at discharge and at the 3rd and 6th month follow up visits.

Results: 7 of the 77 patients admitted to the two SICU died during hospital stay (9.1% mortality). To 55 of the remaining 70 patients (78.6%) DOAC was prescribed after a period of parenteral therapy variable from 0 to 24 days (median 3 days). Moreover 7 patients (12.8%) were thrombolysed before starting any other therapy.

At the time of the index event the mean age was 70.1 (SD±16.5) while the median PESI (Pulmonary Embolism Severity Index) scored 104.0 (range 24-181) and signs of ventricular dysfunction on an imaging test were present in 40 patients (72.7%).

Of the 55 patients discharged on DOAC, 37 started Rivaroxaban, 17 Apixaban and 1 Dabigatran: up to February 1st 2017 no recurrent venous thromboembolic and 2 major bleeding events were observed in the 6 months period of active therapy.

Conclusions: DOACs appear to be a reasonable alternative for patients admitted to SICU for intermediate high risk PE after an initially favorable evolution.

PB 1242 | Oral Anticoagulant Associated Bleeding Events - A Single Centre Experience

S. McNeill[1], J. Tan[2], S. MacBride-Stewart[3], L. Green[2,4,5], P. MacCallum[2,4], C. Bagot[1], R.C. Tait[1]

[1]*Glasgow Royal Infirmary, Glasgow, United Kingdom,* [2]*Barts and the London School of Medicine and Dentistry, London, United Kingdom,* [3]*NHS Greater Glasgow and Clyde, Prescribing and Pharmacy Support Unit, Glasgow, United Kingdom,* [4]*Barts Health NHS Trust, London, United Kingdom,* [5]*NHS Blood and Transplant, London, United Kingdom*

Background: We report our single centre experience of patients presenting with major bleeding whilst on an oral anticoagulant (OAC: warfarin or DOAC) and their clinical outcomes, reported to the ORANGE registry.

Aims: Based on primary care OAC prescription data, as a denominator, we aimed to determine the incidence of major bleeding in real-life terms.

Methods: During a 32 month observation period (2013-2016) we documented 186 major bleeding events - defined as bleeding leading to hospitalisation and one or more of the following: death, transfusion of ≥ 2 units red blood cells, drop in haemoglobin of ≥ 20g/L, bleeding into a critical organ, administration of plasma or coagulation factor based therapies.

Results: Based on prescription data during the study period, those prescribed an OAC rose from 1.44% to 2.0% of our hospital catchment population (circa. 320,000) with those receiving a DOAC increasing from 6.2% to 38.7%. The total number of anticoagulated patient years was calculated as 14,921y. Of the 186 patients who developed major bleeds the median age was 78y with 53% female. The overall OAC-associated bleed rate was 1.25%/y. Table 1 details bleed characteristics by OAC type and incidence rates (bleeds/100 patient years), with 95% CI calculated by Fisher's exact test. No bleeds were recorded during 150 patient years dabigatran treatment. The majority of bleeds on rivaroxaban and apixaban (87% and 66% respectively) were encountered within the first year of therapy with that agent, compared with 10% for warfarin. We observed significantly lower overall and gastrointestinal bleed rates with apixaban compared with warfarin and a similar non-significant trend for intracranial bleeds and 30-day post bleed mortality.

Conclusions: Despite the small cohort size, this real-world data is consistent with results from clinical trials reporting a lower incidence of bleeding events with apixaban, but not with rivaroxaban, when compared to warfarin.

TABLE 1 Bleeding rates by OAC

	Warfarin	Rivaroxaban	Apixaban	All OACs
Patient years f/u	11461	1196	2114	14921
Bleeds: n, incidence [95% CI]	162, 1.41 [1.20-1.65]	15, 1.25 [0.702-2.069]	9, 0.43 [0.195-0.808]	186, 1.25 [1.074-1.439]
Intracranial bleed: n, incidence [95% CI]	69, 0.60 [0.468-0.762]	5, 0.42 [0.136-0.976]	6, 0.28 [0.104-0.618]	80, 0.54 [0.425-0.667]
GI bleed: n, incidence [95% CI]	63, 0.55 [0.422-0.703]	6, 0.50 [0.184-1.092]	3, 0.14 [0.029-0.415]	72, 0.48 [0.378-0.608]
30d mortality: n, incidence [95% CI]	34, 0.30 [0.205-0.415]	4, 0.33 [0.091-0.856]	1, 0.05 [0.012-0.264]	39, 0.26 [0.186-0.357]

PB 1243 | Influence of Direct Oral Anticoagulants in Fibrinolysis Testing

M. Pereira, R. Matos, E. Cruz, S. Morais

Centro Hospitalar do Porto (CHP), Setor de Trombose e Hemostase, Hematologia Clínica, Porto, Portugal

Background: The effect of Direct Oral Anticoagulants (DOACs) on routine tests of haemostasis is now well known; the effect on special tests (factor assays or thrombophilia testing) begins to be reported. However, there are few studies on the effect of DOACs on fibrinolysis tests.

Aims: Evaluate the influence of the direct thrombin inhibitors and direct FXa inhibitors, on fibrinolysis.

Methods: We have studied plasma samples from 16 patients on dabigatran, 17 on rivaroxaban and 22 on apixaban: TAFI, PAI-1, Plasminogen (PLG), antiplasmin (AP) activity and FXIII antigen were evaluated. The DOAC concentration was determined in all samples. All the reagents were supplied by Stago (France) and run on a STA Compact Max.

Results:

Dabigatran: 8 samples had concentration < 50ng/mL (4 below detection limit) and 8 above 50ng/mL. TAFI level was low (median 54%) in 10 samples but showed no correlation with Dabigatran level (p< 0.2). FXIII was not analysed.

Rivaroxaban: 12 samples had concentration < 90 ng/mL and 5 above; 1 sample had TAFI level 52% and 2 with low FXIII.

Apixaban: 5 samples with level below 90 ng/mL, and 16 with level >90ng/mL; 4 samples had low FXIII. None of the parameters presented significant correlation with the DOAC concentration. All samples had normal PLG, AP levels, except for one sample with dabigatran with undetectable PAI-1.

Conclusions: There was a marked decrease on TAFI from patients on dabigatran, not observed on patients taking rivaroxaban or apixaban. Correlation between dabigatran concentrations and the decrease on TAFI was not found, however the number of samples analysed was low. These results reflect the inhibition of thrombin that is the activator of TAFI and acts directly on its regulation. The other parameters studied seems not to be affected by DOAC.

PB 1837 | Natriuretic Peptides for Detection of Heart Failure in Patients with Atrial Fibrillation? An IPD Analysis of Opportunistic Screening Studies from the Community

S. van Doorn[1], G.-J. Geersing[1], R.F. Kievit[1], Y. van Mourik[1], L.C. Bertens[1], E.E.S. van Riet[1], L.J.M. Boonman-Winter[2], K.G.M. Moons[1], A.W. Hoes[1], F.H. Rutten[1]

[1]University Medical Center Utrecht, Julius Center for Health Sciences and Primary Care, Utrecht, The Netherlands, [2]Amphia Hospital, Breda, The Netherlands

Background: Heart failure (HF) increases the risk of atrial fibrillation (AF), and the vice versa. Early detection of concurrent heart failure in patients with AF has important clinical consequences. However, both diseases share similar symptomatology and elevated natriuretic peptide levels, making it difficult to identify AF patients in need for additional diagnostic testing for heart failure, in particular for primary care physicians.

Aims: To assess the diagnostic value of amino-terminal pro B-type natriuretic peptide (NTproBNP) for uncovering heart failure in patients with atrial fibrillation.

Methods: Individual patient data from four opportunistic HF screening studies in older high-risk persons from the open population (≥60 years and type 2 diabetes, ≥65 years and chronic obstructive pulmonary disease, ≥65 years and shortness of breath, and ≥65 years and multimorbidity) were used. All participants underwent an extensive clinical assessment, blood testing, electrocardiography, and echocardiography. Presence or absence of HF was established by an expert panel following the criteria of the European Society of Cardiology on HF. We used a two-stage mixed effects regression meta-analysis to calculate discrimination; efficiency; the proportion of missed cases; and sensitivity, specificity and predicted values.

Results: In 1,941 individuals with median age 72 (IQR 67-78) years and 49.7% male, 196 (10.1%) cases had atrial fibrillation. Heart failure was uncovered in 82 (43%) patients with AF. Median NTproBNP levels of AF patients with and without uncovered HF were 744 pg/mL and 211 pg/mL, respectively. Fourty-three (21.9%) AF patients had NTproBNP value below 125 pg/mL. At this recommended exclusionary cut-point, the sensitivity was 93%, specificity 36%, and the positive value and negative predictive value 52% and 87%, respectively.

Conclusions: In older high-risk AF patients from the community the prevalence of unrecognized HF is very high (42.5%), and straightforward echocardiography should be considered.

PB 1838 | Direct Oral Anticoagulants (DOAC) vs Low Molecular Weight Heparin (LMWH) as Anticoagulant Therapy in Patients with Non-valvular Atrial Fibrillation (NVAF) and Concomitant Active Cancer

A. Varela-Magallon[1], P. Olivera[1], G. Oristrell[2], J. Limeres[2], E. Johansson[1], T. Canals[1], V. Pons[1], F. Bosch[1], A. Santamaria[1]

TABLE 1 Demographic characteristics

Demographic characteristics	DOAC (n=96)	LMWH (n=55)	p value
Gender (male)	52 (54.1%)	30 (54.5%)	0,964
Age (years)	78,73 ± 1,5	74,88 ± 1,94	0,002
Median CHA2DS2-VASc (Median HAS-BLED)	4 (3)	4 (2)	
Arterial hypertension	78 (81.2%)	42 (76.3%)	0,483
Diabetes mellitus	30 (31.2%)	16 (29%)	0,780
Cardiac failure	31 (32.2%)	20 (36.3%)	0,613
Myocardial ischemia	13 (13.5%)	9 (16.3%)	0,643
Vasculopathy	5 (5.2%)	5 (9%)	0,387
Previous stroke	14 (14.5%)	6 (10.90%)	0,506

TABLE 2 Cancer subtypes and chemotherapy agents

Cancer subtypes	DOAC (n=96)	LMWH (n=55)	p value	Chemotherapy agents	DOAC (n=52)	LMWH (n=40)	p value
Breast cancer	16 (16.6%)	10 (18.1%)	0.814	Antimitotic agents	3 (5.7%)	10 (25%)	0.011
Prostate cancer	11 (11.4%)	3 (5.4%)	0.178	Antimetabolite agents	9 (17.3%)	12 (30%)	0.155
Lung cancer	6 (6.2%)	11 (20%)	0.020	Hormonotherapy	21 (40.3%)	4 (10%)	0.0002
Digestive tract cancer	15 (15.6%)	9 (16.3%)	0.905	Alkylating agents	3 (5.7%)	4 (10%)	0.461
Urothelial cancer	8 (8.3%)	4 (7.2%)	0.813	Platinum based agents	2 (3.8%)	5 (12.5%)	0.140
Lymphoproliferative syndromes	17 (17.7%)	8 (14.5%)	0.606	Tyrosine kinase inhibitors	13 (25%)	6 (15%)	0.225
Plasmatic cell disorders	7 (7.2%)	5 (9%)	0.701	Monoclonals antibodies	17 (32.6%)	19 (47.5%)	0.147
Others	26 (27%)	12 (21.8%)	0.463	Immunomodulation inhibitors	2 (3.8%)	9 (22.5%)	0.008
				Others	10 (19.2%)	12 (30%)	0.235

Background: Appropriate anticoagulation management of NVAF in active cancer is of growing clinical concern, especially in those receiving chemo-immunotherapy where LMWH are still recommended despite that there is no indication for primary prevention of stroke in patients with NVAF. Nowadays, DOAC are broadly used for primary prevention of stroke. However there is no data about active cancer patients with NVAF who need a personalised approach.

Aims: To assess the safety and effectiveness in both cohorts according to DOAC or LMWH treatment and to determine the rate of anticoagulant-associated clinically relevant bleeding-free survival in our unit.

Methods: We consecutively included patients with active cancer and NVAF treated with DOAC or LMWH (2011-2016). Demographic, laboratory, cancer diagnosis, and NVAF diagnosis data were collected. All active cancers were included. Pharmacological interactions check-up was performed prior election of treatment. Bleeding events were classified according to ISTH criteria.

Results: Among 151 patients, 96 (63.6%) were treated with DOAC (10 Dabigatran, 34 Rivaroxaban, 40 Apixaban and 12 Edoxaban) and 55 (36.4%) with LMWH. Mean follow-up (FU) were 10.8 and 8.5 months (DOAC vs LMWH,p:0.56). Demographic characteristics and cancer subtypes and drugs are summarised in tables 1 and 2, respectively.

Patients undergoing chemotherapy were 54% vs 73% (DOAC vs LMWH,p:0.01). Most frequent previous anticoagulant treatment was acenocumarol (DOAC 54% vs LMWH 51%,p:0.69). During FU, no stroke was reported and 9 (9.3%) vs 7 (12.7%) major bleeding events (DOAC vs LMWH,p:0.53) occurred. Bleeding-free survival rates were not statistically different between both cohorts. There were 2 thromboembolic events in the LMWH group. All reported mortality was disease-related.

Conclusions: The safety and effectiveness of DOAC treatment for NVAF in patients with active cancer have a similar profile to LMWH. Anticoagulation units play a crucial role in offering the best personalised therapy.

PB 1839 | Thrombin Generation and International Normalized Ratio in Patients with Atrial Fibrillation Using Rivaroxaban or Warfarin

R.C.F. Duarte[1], D.R.A. Rios[2], S.M. Rezende[3], L.L. Jardim[3], J.R.S. Caiaffa[4], F.R. Silveira[5], E. Reis[6], C.N. Ferreira[7], F.F.M. Campos[8], M.G. Carvalho[8]

[1]Federal University of Minas Gerais, Department of Clinical and Toxicological Analysis, Belo Horizonte, Brazil, [2]Federal University of São João del-Rei, Divinópolis, Brazil, [3]Faculty of Medicine - Federal University of Minas Gerais, Belo Horizonte, Brazil, [4]Hospital Governador Israel Pinheiro (IPSEMG), Belo Horizonte, Brazil, [5]Semper Hospital, Belo Horizonte, Brazil, [6]Institute of Exact Sciences - Federal University of Minas Gerais, Department of Statistics, Belo Horizonte, Brazil, [7]Technical College of Federal University of Minas Gerais, Belo Horizonte, Brazil, [8]Faculty of Pharmacy - Federal University of Minas Gerais, Department of Clinical and Toxicological Analysis, Belo Horizonte, Brazil

Background: Atrial fibrillation (AF) is the most common cardiac arrhythmia and predisposes patients to an increased risk of stroke. So, one of the main strategies for the treatment of AF is the use of oral anticoagulant, rivaroxaban or warfarin for prevention of stroke and systemic embolism. International normalized ratio (INR) has been traditionally used for control doses of warfarin. Thrombin is the central enzyme in blood coagulation and an increased *ex-vivo* thrombin generation (TG) can be considered a marker of thrombogenic potential in plasma.

Aims: To evaluate the effect of warfarin and rivaroxaban on the hemostatic system by using TG assays and its correlation with INR, in patients with non-valvular AF.

Methods: TG using calibrated automated thrombogram (CAT) system was performed in plasma samples from patients using rivaroxaban (n= 36) or warfarin (n= 37), and in individuals without AF (control group, n= 41 for rivaroxaban and n= 36 for warfarin). The medium plasma levels of rivaroxaban were 115.15 ng/ml. TG tests were performed using 10 pM of tissue factor and prothrombin time/INR was performed according to conventional methodology. Mann-Whitney and Spearman tests were used.

Results: Use of rivaroxaban (Table 1) and warfarin (Table 2) reduced endogenous thrombin potential (ETP) and peak and prolonged lag time, compared to controls. A significant inverse relationship between INR and ETP (r= -0.739, p=0.000) and peak (r= -0.758, p=0.000) and a positive correlation for lagtime (r= 0.482, p=0.003) were found in patients using warfarin. For patients on rivaroxaban, no correlation between TG and INR was found.

TABLE 1 Parameters of thrombin generation in patients using rivaroxaban compared to control group

Parameters	Rivaroxaban	Control	p value
Lagtime_(min) (± IQR)	3.13 (1.670)	1.33 (0.665)	0.000
ETP_(nM•min) (± IQR)	1227.5 (356.4)	1606.0 (409.5)	0.000
Peak_(nM) (± IQR)	158.6 (95.9)	386.8 (102.1)	0.000
ttPeak_(min) (± IQR)	7.30 (3.912)	3.33 (0.985)	0.000

TABLE 2 Parameters of thrombin generation in patients using warfarin compared to control group

Parameters	Warfarin	Control	p value
Lagtime_(min) (± IQR)	2.93 (1.800)	1.64 (0.7075)	0.000
ETP_(nM•min) (± IQR)	598.8 (310.1)	1577.4 (490.3)	0.000
Peak_(nM) (± IQR)	114.95 (78.4)	379.6 (127.9)	0.000
ttPeak_(min) (± IQR)	5.00 (2.490)	3.50 (1.330)	0.000

Conclusions: Warfarin and rivaroxaban provided effective anticoagulation measured by TG. As expect, INR correlated with TG parameters only in patients under warfarin therapy. Contrarily, in patients using rivaroxaban, INR was not sensitive for assessing anticoagulation status.

Support: CNPq, CAPES. and FAPEMIG

PB 1840 | Variation of Renal Function during Treatment with Direct Oral Anticoagulants and Risk of Major Bleeding in Patients with Non-balvular Atrial Fibrillation

M. Giustozzi[1], C. Becattini[1], M.G. Ranalli[2], G. Bogliari[1], F. Cianella[1], G. Agnelli[1], M.C. Vedovati[1]

[1]University of Perugia, Internal and Cardiovascular Medicine - Stroke Unit, Perugia, Italy, [2]University of Perugia, Dept. of Political Science, Statistics Section, Perugia, Italy

Background: Chronic kidney disease is a risk factor for major bleeding in patients with atrial fibrillation (AF) on treatment with warfarin.

Aims: To assess the effect of variations of creatinine clearance on the risk for major bleeding (MB) during treatment with direct anticoagulants (DOACs) in patients with non-valvular AF.

Methods: Consecutive AF patients were prospectively followed since they received the first DOACs prescription. Periodic assessments of creatinine clearance (by means of both the Cockcroft-Gault and Chronic Kidney Disease Epidemiology Collaboration equations) were performed and the incidence of MB recorded. A joint survival model was used to estimate the association between variation of creatinine clearance and the risk for MB.

Results: During a mean follow-up of 575 days in 449 patients, 44 MBs were observed (6.1% patient-year). Variations lower than 30% in creatinine clearance were common, regardless of baseline values. Decreases in creatinine clearance greater than 30% were more common in patients with baseline values lower than 60 ml/min and rarely occurred in patients with baseline values higher than 90 ml/min.

Variation of creatinine clearance over time was inversely and independently associated with the risk for MB; in particular, every 1 ml/min decrease in creatinine clearance was associated with 2% increase in the risk for major bleeding (HR 0.98, 95% CI 0.97-0.99; p< 0.001). No association was found between diabetes, chronic heart failure or treatment with different DOACs and the risk for major bleeding.

Conclusions: Variation of renal function over time is associated with the risk for major bleeding in AF patients treated with DOACs. Identification of patients and intervening clinical settings likely to be associated with variation in renal function is essential to reduce the risk of major bleeding associated with DOACs and to make this treatment further safe.

PB 1841 | Global Public Awareness about Atrial Fibrillation

A. Wendelboe[1], P. Angchaisuksiri[2], A. Blanco[3], H. Ddungu[4], J. Dvorak[1], B. Hunt[5], E. Hylek[6], A. Kakkar[7], S. Konstantinides[8], M. McCumber[1], C. McLintock[9], T. Urano[10], H. Buller[11], J. Weitz[12], G. Raskob[1]

[1]University of Oklahoma Health Sciences Center, Biostatistics and Epidemiology, Oklahoma City, United States, [2]Mahidol University, Medicine, Bangkok, Thailand, [3]Academia Nacional de Medicina, Haemostasis Division, Buenos Aires, Argentina, [4]Uganda Cancer Institute, Kampala, Uganda, [5]King's College Hospital NHS Foundation Trust, London, United Kingdom, [6]Boston University School of Medicine, Boston, United States, [7]Thrombosis Research Institute, London, United Kingdom, [8]Johannes Gutenberg University of Mainz, Center for Thrombosis and Hemostasis, Mainz, Germany, [9]Auckland City Hospital, Medicine, Auckland, New Zealand, [10]Hamamatsu University School of Medicine, Medical Physiology, Hamamatsu, Japan, [11]Academic Medical Center, University of Amsterdam, Vascular Medicine, Amsterdam, The Netherlands, [12]McMaster University, Medicine, Hamilton, Canada

Background: Atrial fibrillation (AF) is an important cause of ischemic stroke that often remains undetected until stroke occurs. Awareness of the risk factors and symptoms of AF is important because effective stroke prevention in such patients is available. However, the extent of public awareness of AF is uncertain.

Aims: Compare global awareness of AF with awareness of other thrombotic and non-thrombotic disorders.

Methods: In collaboration with Ipsos-Reid, we conducted an internet-based survey from Sep 22 to Oct 13, 2016 in 10 countries: Argentina, Australia, Canada, Germany, Japan, Thailand, Netherlands, Uganda, United Kingdom, and United States. Participants were selected from

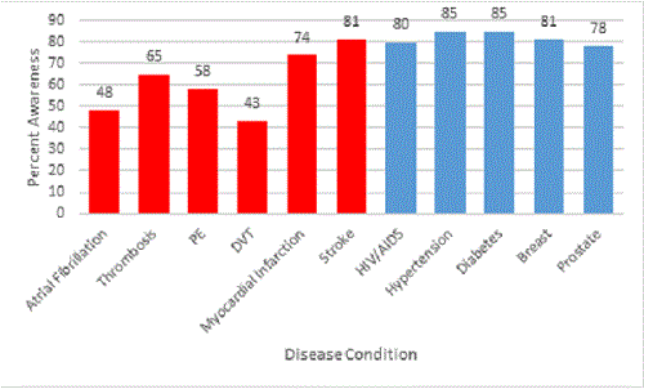

FIGURE Average overall awareness of selected health conditions. Thrombosis-related conditions are in red, whereas non-thrombotic conditions are in blue

survey panels in weighted, age-stratified categories (40-60, 61-74, and ≥75 years). The survey included 11 questions about demographics and AF awareness and took ≤5 minutes to complete. Awareness of other thrombotic disorders (thrombosis, pulmonary embolism, deep-vein thrombosis, heart attack and stroke) and non-thrombotic disorders (hypertension, HIV/AIDS, diabetes, breast cancer, and prostate cancer) was also assessed. Proportions and 95% confidence intervals (CI) were calculated.

Results: In a total of 6,312 participants, overall awareness of AF was 48% (95% CI 46%-50%), which was lower than all other thrombotic and non-thrombotic disorders except deep-vein thrombosis (43%, 95% CI: 41%-45%) (Figure). Across countries, AF awareness ranged from 25% to 69%; US-specific awareness was 67% (95% CI 62%-72%). Knowledge of AF risk factors ranged from 8%-52% (Table) and awareness AF leads to stroke was 36%-46%. Among those reporting awareness of AF, 82% correctly identified palpitations as an AF symptom.

Conclusions: Global awareness of AF is low. Although US awareness was higher than that in most other countries, possibly reflecting direct-to-patient marketing, awareness about AF was lower than that of other disorders. Increased awareness of AF is essential to reduce the burden of stroke.

TABLE 1 Distribution of participants' recognition of risk factors for atrial fibrillation

Risk Factors	%	95% CI
High blood pressure	52	50, 53
Smokin	46	44, 47
Obesity	43	41, 45
Heart failure	37	35, 38
Drinking too much alcohol	31	29, 32
Age over 75 years	27	26, 29
Diabetes	20	18, 21
Hyperactive thyroid	9	8, 10
Asthma	8	7, 9

PB 1842 | VKA Treatment and Bleeding Rate of Patients Aged Older than 90 Years: Results from a Prospective Multicentre START Register Study

D. Poli[1], E. Antonucci[2], S. Fumagalli[1], L. Migliaccio[2], F. Marongiu[3], A. Tripodi[4], V. Pengo[5], S. Testa[6], G. Palareti[2]

[1]Azienda Ospedaliera Universitaria Careggi, Firenze, Italy, [2]Fondazione Arianna Anticoagulazione, Bologna, Italy, [3]Università degli Studi di Cagliari, Cagliari, Italy, [4]Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy, [5]Thoracic and Vascular Sciences, University of Padua, Department of Cardiac, Padova, Italy, [6]Hospital of Cremona, Cremona, Italy

Background: Oral anticoagulant therapy (OAT) is increasingly used for prevention of stroke in atrial fibrillation (AF). Bleeds are the major concern for prescription, especially in very old patients.

Aims: We evaluate the history of patients aged≥90 years (yrs) enrolled in the multicentre prospective observational START Register to evaluate the quality of anticoagulation and the incidence of bleedings.

Methods: Patients' demographic and clinical data were collected as electronic file in anonymous form in the web site of START-Register (ClinTrials Gov Identifier: NCT02219984). The study included 4579 AF patients naïve to anticoagulation. In this study the analysis is limited to183 patients aged ≥90 yrs (97 starting treatment a≥90 yrs, 86 patients became ≥90 yrs during follow-up). The overall exposure to anticoagulants for each patient was calculated in relation to aging, before and after his/her 90th birthday. Patients characteristics and incidence of bleeds were recorded.

Results: Clinical characteristics of patients are listed in table 1. The total follow-up was 183 patients-yrs(pt-yrs), 119 patients were females(65%) 141 (77%) were treated with vitamin K antagonist (VKA) and 43 (23%) with direct oral anticoagulants (DOACs). We recorded 8 major bleedings (rate 4.37x100 pt/yrs), 6 bleeds occurred among VKAs patients (rate 4.42 x100 pt/yrs) and 2 among DOACs patients (rate 4.24); 3/8 were cerebral (rate 1.64 x x100 pt/yrs) 2 occurred in VKAs patients and 1 in DOACS patients.

TABLE 1 Patient's chracteristics

	N (%)
Heart failure	47 (25.7)
Hypertension	157 (85.8)
Diabetes mellitus	27 (14.8)
Previous Stroke/TIA	34 (18.6)
Coronary artery disease	26 (14.2)
CHA2DS2VASc score (mean±SD)	4.5±1.2
HAS-BLED (mean±SD)	2.9±0.9
Time in Therapeutic Range (IQR) (%)	56 (37-75)
Antiplatelet treatment	17 (9.3)

Conclusions: In this group of AF patients aged ≥90 yrs on anticoagulation for stroke prevention the rate of bleedings is elevated both on VKAs and on DOACs, suggesting a careful evaluation of clinical benefit of OAT in very advanced age.

PB 1843 | Low Performance of the CHA2DS2-VASc Rule for Predicting Stroke Risk in Atrial Fibrillation Patients: A Systematic Review and Meta-analysis

S. van Doorn, T.P.A. Debray, F. Kaasenbrood, A.W. Hoes, F.H. Rutten, K.G.M. Moons, G.-J. Geersing

University Medical Center Utrecht, Julius Center for Health Sciences and Primary Care, Utrecht, The Netherlands

Background: The CHA2DS2-VASc decision rule is widely recommended for estimating stroke risk in patients with atrial fibrillation (AF). It has seen a rapid introduction into practice guidelines, though subsequent validation studies show ambiguous and conflicting results.
Aims: To
1) review existing studies validating CHA2DS2-VASc in AF patients not (yet) anticoagulated,
2) meta-analyze estimates of stroke risk per score, and
3) explore sources of heterogeneity across the validation studies.
Methods: We performed a systematic literature review and random effects meta-analysis of studies externally validating CHA2DS2-VASc in AF patients not on anticoagulants. To explore between-study heterogeneity in stroke risk, we stratified studies to the clinical setting in which patient enrollment started, and performed meta-regression.
Results: In total 16 studies were evaluated with over one million person-years of follow-up. In studies recruiting AF patients in hospitals, stroke risk for a score of zero, one and two were 0.4% (approximate 95% prediction interval (PI) 0.03 to 2.3%), 1.2% (95% PI 0.1 - 3.5%) and 2.2% (95% PI 0.4 - 5.7%), respectively. This was consistently higher than studies recruiting patients from the open general population, with risks of 0.2% (95% PI 0.03 - 1.2%), 0.6% (0.04 - 1.8%) and 1.5% (95% PI 0.2 - 4.4%) for score zero to two respectively. As an illustration of heterogeneity, our findings implicate that for a CHA2DS2-VASc score of 1 there is still a probability of 36% to 83% that patients have a stroke risk below 1% per year; the commonly used threshold below which the benefits of anticoagulant treatment do not outweigh its bleeding risks. Heterogeneity could not be fully explained by meta-regression.
Conclusions: The CHA2DS2-VASc score is unable to accurately predict stroke risk in patients with AF. Therefore its current role in contemporary practice guidelines could be questioned.

PB 1844 | Improving Appropriate Use of NOACs in AF: Success of Online CME

J. Spyropoulos

Medscape LLC, New York, United States

Background: Evidence-based anticoagulant therapy is the cornerstone of stroke prevention in atrial fibrillation (SPAF); however, patients are often inappropriately treated, resulting in morbidity and mortality that might otherwise be preventable.
Aims: Determine whether a video-based online continuing medical education (CME) activity can improve the knowledge and competence of cardiologists and primary care physicians (PCPs) regarding understanding and appropriate use of non-vitamin K antagonist oral anticoagulants (NOACs) in management of SPAF.
Methods: An online CME activity was developed as a 25-minute roundtable discussion with 3 leading experts on the role of NOACs in the setting of SPAF. The effects of education were assessed using a linked pre-assessment/post-assessment study design. For all questions combined, the McNemar's chi-square test was used to assess differences from pre- to post-assessment. *P* values are shown as a measure of significance; *P* values < .05 are statistically significant. Cramer's V was used to calculate the effect size (> 0.3 are large, 0.16-0.3 are medium, and < 0.16 are small).
Results: Comparison of individually linked pre-assessment question responses to the respective post-assessment question responses demonstrates statistically significant improvements for both cardiologists (n = 184; *P*< .05; V=0.2) and PCPs (n=250; *P*< .05; V=0.243). Following the education, 15% of cardiologists and 33% of PCPs selected that they had improved confidence in prescribing NOACs for a newly diagnosed patient with AF at risk for stroke.
Conclusions: The significant improvements observed for thislonline CME roundtable discussion demonstrate the benefits of educating the large target audience base. This assessment of physicians' knowledge identified education gaps that support the need to develop additional CME activities on SPAF management, including appropriate use of NOACs to optimize safety while preventing further strokes.

TABLE 1 Percentage of Participants With Correct Response by Question (Pre- and Post-Assessment Questions)

	Cardiologists (n=184)	Cardiologists (n=184)	PCPs (n=250)	PCPs (n=250)
Topic	Relative percent change; P value	Pre-assessment vs Post- assessment	Relative percent change; P value	Pre-assessment vs Post- assessment
Real-world evidence for NOACs on major bleeding/mortality	68%; <0.05	17% vs 28%	162%; <0.05	12% vs 30%
TTR data from the real-world setting for patients on VKA therapy	67%; <0.05	27% vs 45%	65%; <0.05	29% vs 48%
Stroke reduction efficacy of NOACs based on real-world registries	96%; <0.05	28% vs 55%	153%; <0.05	20% vs 50%

PB 1845 | Optimisation of Anticoagulation Therapy for Stroke Prevention in Atrial Fibrillation Using a Virtual Clinic Model

A. Brown[1], R. Byrne[1], H. William[2], N. Hamedi[2], A. Hodgkinson[3]

[1]King's College Hospital NHS Foundation Trust, London, United Kingdom, [2]NHS Southwark and Lambeth Clinical Commisioning Groups, London, United Kingdom, [3]NHS Lambeth Clinical Commisioning Group, London, United Kingdom

Background: Atrial fibrillation (AF) is the leading and most preventable cause of embolic stroke. Anticoagulation is the current gold standard for the prevention of strokes in patients with AF with $CHA_2DS_2VASc \geq 2$. Quality and Outcome Framework (QOF) data for two Clinical Commissioning Groups (CCGs) in London revealed that of 2493 patients with AF and $CHADS_2$ score ≥ 2, only 1546 (62%) were anticoagulated. In the cohort of 947 high risk patients who were not anticoagulated the CCGs could expect to see 48 strokes per annum, up to 33 of which could be prevented by oral anticoagulation.

Aims:

- To ensure all patient considered at risk are offered appropriate anticoagulant therapy
- To identify reasons why patients who are at risk are not being prescribed anticoagulation
- To educate practice staff on the use of stroke risk assessment tools, bleeding risk assessment tools and the role of anticoagulation in stroke prevention in AF

Methods: Specialist pharmacist led virtual clinics were conducted with general practitioners at each practice. GP engagement was secured through the GP delivery scheme/prescribing incentive scheme. Patients with a CHA_2DS_2VASc score ≥ 2 who were not currently anticoagulated were identified and reviewed and an action plan for each patient was agreed and documented.

Results: Data from the two CCGs (Jan 2017) shows that 83% and 78% of AF patients are now anticoagulated, an increase from 73% and 72% respectively prior to the virtual clinics.

1292 patients were initiated on anticoagulation equating to the prevention of approximately 43 strokes.

The following were identified as barriers to anticoagulation:

- Misconception of bleeding risk vs stroke risk for certain patient groups
- Lack of review for patients who had historically refused warfarin
- Housebound patients unable to attend anticoagulation clinics for initiation

Conclusions: The use of specialist pharmacist-led virtual clinics led to a significant increase in the proportion of AF patients with a $CHA_2DS_2VASc \geq 2$ being appropriately anticoagulated.

PB 1846 | Evaluation of Antithrombotic Management in Patients with Atrial Fibrillation at a Tertiary Care Academic Medical Center

S. Bhatt[1,2], M. Adra[3], J. Lacoste[1], E. Seoane-Vazquez[1]

[1]MCPHS University, Department of Pharmacy, Boston, United States, [2]Beth Israel Deaconess Medical Center, Boston, United States, [3]Beth Israel Deaconess Medical Center, Pharmacy, Boston, United States

Background: Atrial fibrillation (AF) affects an estimated 5 million people in the United States. Oral anticoagulation (OAC) is the preferred therapy for reducing the risk of stroke, however several studies demonstrate that the prescribing rates of OAC in these patients have remained lower than anticipated, especially in those who are at high risk for stroke.

Aims: To assess the antithrombotic management of AF patients in an academic medical center and its concordance with recommended evidence-based practices, and to explore potentials barriers to prescribing OAC.

Methods: Retrospective data analysis of 1198 patients with atrial fibrillation admitted between June 1 - December 31, 2015. Patients charts were reviewed for documented comorbidities to calculate risk of stroke using the CHADSVASC score, to evaluate OAC agent prescribed, and documented reasons for not prescribing OAC in eligible patients.

Results: OAC was prescribed in 759 (63%) eligible patients, 175 (14.6%) had documented reasons for not using OAC, and 264 (22.0%) were candidates for OAC without a documented reason. Physician specialty in cardiology and CHA2DS2-VASc score were positively associated with antithrombotic prescribing. Conversely, age, female gender and HAS-BLED score were negatively associated with antithrombotic prescribing. History of bleeding, fall risk, and patients declining therapy were the most common documented reasons for not prescribing OAC.

Conclusions: OAC use in eligible patients with AF remains suboptimal. Further research is needed to address barriers to prescribing OAC is patients who are candidates and would benefit from such therapies.

TABLE 1 Agreed patient recommendations from virtual clinics (n = 1348)

Referral for consideration of anticoagulation	Anticoagulation contraindicated	Anticoagulation not indicated	Referral for confirmation of diagnosis	Anticoagulation declined-review yearly	Other (e.g. Left Atrial Appendage Occlusion Device, patient uncontactable)
455 (33.8%)	111 (8.2%)	525 (38.9%)	79 (5.9%)	80 (5.9%)	98 (7.3%)

PB 1847 | Recent Years Trends in Real-life Antithrombotic Therapy for In- and Out-patients with Atrial Fibrillation in Moscow

A. Melekhov, G. Gendlin, E. Dadashova, E. Alekseeva, I. Zaigraev, I. Nikitin

Russian National Research Medical University, Internal Diseases, 2, Moscow, Russian Federation

Background: Stroke prevention strategy in atrial fibrillation (AF) patients had changed past decade. Registries are the useful instruments for study how it´ve changed their real-life management.

Aims: To investigate a real-life use of antithrombotic drugs in AF patients.

Methods: The registry of 1624 in- and out-patients with AF, observed in 2 hospitals and 3 out-patient clinics of Moscow at 2009-2015.

Results: 99,1% of patients had indications for tromboembolic events prophilaxis with anticoagulants. HAS-BLED score median was 2,0 (2,0-3,0).

Retrospective analysis showed, that 9,0% of out-patients've took warfarin (66,7% of them had INR values available, 30,9% of them had INR target rate); 3,4% - new oral anticoagulants (NOACs), 17,7% - antiplatelets (AP). 33,2% of in-patients were prescribed warfarin (42,0% of them had INR data available, 39,7% of them achieved INR target rate); 1,9% - NOACs, 42,6% - AP. So only 5,3% of out-patients and 7,4% of in-patients have got adequate thromboprophylaxis.

388 patients hospitalized in 2014-2015 with AF were observed prospective. Before hospital admission 14,7% of them took warfarin (47% of them had INR data available, 44,4% of them had target rate); 11,9% - NOACs, 26% - AP (so adequate thromboprophylaxis have got 14,9% of patients). At discharge 78,6% of patients were prescribed warfarin (82% of them had INR data, 31,8% of them - at target rate), 7,5% - NOACs, 4,1% - AP (adequate stroke prevention have got 28,1% of patients). 84,6% of patients were recommended NOACs as warfarin alternative. In 13 (10-14) months after discharge telephone contacts with 176 of these patients were obtained. 25,6% of interviewed patients continued to use warfarin, 33,5% - NOACs, 34,1% - AP.

Conclusions: Warfarin and NOACs use in Moscow at 2009-2015 increased (but remains low), of AP - decreased. Financial reasons limitate NOACs further growth and warfarin reduce. So the greatest effort required for improving monitoring of warfarin treatment by INR, especially in out-patient clinics.

PB 1848 | Should we Abandon the APTT for Monitoring the Anticoagulant Effect of Unfractionated Heparin?

D. Jayakody Arachchillage[1,2], F. Kamani[1], S. Deplano[1], S. Fox[1], M. Mcevoy[1], L. Tillyer[1], M. Laffan[2]

[1]Royal Brompton Hospital, London, United Kingdom, [2]Imperial College London, London, United Kingdom

Background: The activated partial thromboplastin time (APTT) is commonly used to monitor unfractionated heparin (UFH) but may not accurately measure anticoagulation. The anti-Xa assay is less prone to confounding factors and may be a better assay for this purpose.

Aims: To determine the relationship between anti-Xa activity and APTT in patients on intensive care.

Methods: Anti-Xa (chromogenic Liquid anti-Xa assay), and APTT (SynthASil,HemosIL®), [IL] were performed in parallel on 3543 samples from 475 patients (infants [n= 165], children 1-16 years [n= 60] and adults [n= 250]) receiving UFH in intensive care units in a single centre over 6 months. Patients with coagulation factor deficiencies and lupus anticoagulant were excluded.

Results: Table 1 shows anti-Xa levels and corresponding APTT values. Samples with anti-Xa activity within the therapeutic range (0.3-0.7IU/mL) had a wide range of APTT: (mean 62, range 29-250 s). The correlation between APTT and anti-Xa was poor in all 3 age groups; r values and 95% confidence intervals (CI) were 0.29(0.16-0.41), 0.38(0.20-0.52) and 0.34(0.29-0.39) for infants, children and adults respectively. For infants with anti-Xa of 0.3-0.7IU/mL; 10 (5%), 60 (31%) and 123 (64%) had an APTT in the sub-therapeutic, therapeutic (60-100s) and supra-therapeutic ranges respectively. Children had the highest concordance (48%) between anti-Xa of 0-3-0.7 and APTT values of 60-100s.

Adults with anti-Xa of 0.3-0.7 IU/ml but sub-therapeutic APTT had significantly higher fibrinogen levels: mean [CI] 4.5g/l [2.8-7.5] compared to those with therapeutic range APTT; 3.5 [1.5-5.5] and supra-therapeutic APTT; 3.3 [1.0-5.5], (p=0.02).

TABLE 1 Anti-Xa levels and corresponding APTT values

	Anti-Xa IU/mL	No.(%) of samples in the sub-therapeutic range (APTT <60s)	No.(%) of samples in the therapeutic range (APTT 60-100s)	No.(%) of samples in the supra-therapeutic range (APTT >100s)	Total
Infants (<1year)	<0.3	85(34%)	100(40%)	64(26%)	249
	0.3-0.7	10(5%)	60(31%)	123(64%)	193
	>0.7	2(12%)	4(23%)	11(65%)	17
Children (1-15 years)	<0.3	98(76%)	23(18%)	8(6%)	129
	0.3-0.7	20(17%)	55(48%)	40(35%)	115
	>0.7	2(20%)	3(30%)	5(50%)	10
Adults (16-88 years)	<0.3	1370(84%)	251(15%)	17(1%)	1638
	0.3-0.7	640(56%)	432(38%)	64(6%)	1136
	>0.7	12(21%)	23(41%)	21(38%)	56

Conclusions: There is a poor correlation between anti-Xa and APTT in all age groups. The majority of samples from infants with anti-Xa of 0.3- 0.7IU/ml had a supra-therapeutic APTT, whereas adults tended to have a sub-therapeutic APTT. These results confirm the limitation of APTT in monitoring UFH. Some of the variation in adults may be accounted for by fibrinogen level.

PB 1849 | Evaluation of the 4T Score and Rapid Anti PF4/Heparin Antibodies Detection for Heparin Induced Trombocytopenia (HIT) Diagnosis in Clinical Practice. A Multicenter Study

M.J. Villagra Iturre[1], N. Schütz[2], V. Otero[2], M.E. Ariscancella[3,4], A. Rossi[5], C. Fondevila[6], L.H. Barrera[7], M.S. Lopez[8], J. Oyhamburu[7], S. Viñuales[2], D. Penchasky[2], J. Arbelbide[2], M.E. Martinuzzo[7]

[1]Hospital Italiano de Buenos Aires, Hematología, Buenos Aires, Argentina, [2]Hospital Italiano de Buenos Aires - Instituto Universitario del Hospital Italiano, Hematologia, Buenos Aires, Argentina, [3]Instituto Cardiovascular de Bs. As., Hematología, Buenos Aires, Argentina, [4]Hospital Universitario Austral, Hematologia, Pilar, Argentina, [5]Fundacion Favaloro Hospital Universitario, Hematologia, Buenos Aires, Argentina, [6]Sanatorio Bazterrica, Hematologia, Buenos Aires, Argentina, [7]Hospital Italiano de Buenos Aires - Instituto Universitario del Hospital Italiano, Laboratorio Central, Buenos Aires, Argentina, [8]Hospital Italiano de Buenos Aires, Laboratorio Central, Buenos Aires, Argentina

Background: Incidence of HIT is 1-5% in patients receiving heparins, and 30 to 50% of them develop venous or arterial thrombosis. The 4T score (4Ts) is used as a clinical pretest score.

Aims: To perform an external validation of 4Ts in patients with HIT suspiction, b) To evaluate patients' characteristics, c) To evaluate factors associated to HIT development

Methods: An observational transversal cohort multicenter study was performed. We included 204 consecutive patients (>18 years old) with anti PF4/Heparin Antibodies (APF4/HEP) test requested from January 2014 and December 2016. APF4/HEP were measured by an immunoturbidimétric assay (HemosIL HIT AB Instrumentation Laboratory), Patients risk was categorized as low, moderate and high according to the 4Ts blinded calculated by independent hematologists upon clinical records. Descriptive statistics, chi2, t test as well as ROC curves were calculated by using Stata13 program.

Results: Characteristics of the 175 patients finally included (29 were excluded because of no HIT suspicion or scarce clinical data) are summarized in table 1.

TABLE 1 Clinical characteristic of patients with and whitout APF4/HEP

Characteristic	APF4/HEP + (n = 28)	APF4/HEP - (n = 147)	OR (95%CI)	p value
Age Median (range)	64 (18-84)	65 (18-90)		0,84
Sex (F/M)	11/17	72/75		0,34
Type of inpatient acceptance	clinical 19 (68%) surgical 9 (32%)	clinical 105 (72%) surgical 40 (28%		0,62
Oncological patients, n (%)	8 (29%)	42 (29%)		1
Inpatients area	clinical 16 (57%) // ICU 9 (32%) // CCU 3 (11%)	clinical 90 (61%) // ICU 22 (15%) // CCU 33 (22%)		0,11
Type of Heparin	UFH 17 (61%) // LMWH 10 (36%)	UFH 51 (35%) // LMWH 96 (65%)		0,002
Trombosis, n (%), OR (CI 95)	Stroke 4 (14%) // AMI 1 (4%)// VTE 10 (36%)	Stroke 1 (0,68%)// AMI 0// VTE 27 (18%)	Stroke 24(2-254)// VTE 2,47 (1-6)	<0.001// 0,021 // 0,022
4Ts	Low 3 (11%)// Intermediate 14 (50%)// High 11 (39%)	Low 65 (44%)// intrmediate 73 (50%)// High 9 (6%)		<0.001

APF4/HEP were more associated to UFH than LMWH, and thrombosis was more prevalent in the group with APF4/HEP positive (VTE and Stroke).

APF4/HEP positive prevalence according 4Ts was 3/68 [4,4% (IC95 0-12)] for low risk; 14/87 [16% (IC95 9-25)] for intermediate risk and 11/20 [55% (IC95 32-77) for high risk, p 0.000].

ROC AUC for 4Ts: 0,75 (0.65 a 0.86). Sensitivity and specificity were 90% and 44% for a 4Ts of 4; 39% and 94% for a 4Ts of 6. Positive predicting value for an intermediate or high 4Ts were 0,24 (IC95 0,16-0,33) and 0,55 (IC95 0,32-0,76). Negative predicting value of low 4Ts was 0.96 (IC95 0.87-0.99).

Conclusions: 4Ts was a good pretest tool to select patients to be studied and safely excluding patients with 4Ts ≤ 3. Performing a rapid test in patient with intermediate and high risk to exclude HIT diagnosis seems to be useful to avoid stop heparin and start other antithrombotic therapy particularly in critically ill patients.

PB 1850 | Risk of Thromboembolic Disease in Renal Transplant Patients

V. Privitera[1], N. Schutz[1], S. Viñuales[1], V. Otero[2], D. Penchasky[1], N. Imperiali[3]

[1]Hospital Italiano de Buenos Aires - Instituto Universitario del Hospital Italiano, Hematology, Buenos Aires, Argentina, [2]Hospital Italiano de Buenos Aires - Instituto Universitario del Hospital Italiano, Ciudad Autonoma de Buenos Aires, Argentina, [3]Hospital Italiano de Buenos Aires - Instituto Universitario del Hospital Italiano, Nephrology, Buenos Aires, Argentina

Background: Venous thromboembolic disease (VTE) is a complication in renal transplant (Tx) recipients and a source of morbi-mortality.

Aims: To evaluate incidence and prevalence of VTE; and risk factors associated with thrombosis after renal tx

Methods: Retrospective cohort study including all patients(px) with renal Tx at our institution between Jan 2010-Jan 2016. A nested case control study was performed to identify transient risk factors. Primary endpoint: diagnosis of VTE or venous graft thrombosis from time of Tx till death, second renal Tx or loss to follow up. Per institutional protocol px received prophylaxis with unfractionated heparin 5.000-10.000 units/day beginning 12-24 hours after Tx; continued with enoxaparin 20mg/day once creatinine < 2mg/dl for 3 months; then low dose aspirin for one year. Study was approved by IRB. Descriptive statistics, t test and chi2 and multivariate analysis with logistic regression were performed (Stata 13 software)

Results: We included 181 patients. Prevalence of VTE was 15%, most during first 3 months of Tx (32% in first month). Lower limb DVT was the most frequent event (82%), 65% of them homolateral to transplanted kidney. Factors associated with increased risk of VTE in univariate analysis are listed in Table 1.

TABLE 1 Factors associated with increased risk of thrombosis in univariate analysis

Variable	OR (CI 95%)	p Value
Age > 50 years	3,9 (2-9)	0,0009
Personal History of DVT	4,7 (2-13)	0,0013
Elevated FVIII	3,87 (1-11)	0,0060
Hyperhomocysteinemia	2,6 (1-6)	0,0195
LAC	0,58 (0,2-2)	0,3444
Reoperations	6,43 (2-25)	0,0019
1-2 Thrombotic risk factors	6,15(1-47)	0,082
3 o > Thrombotic risk factors	16,1(1,6-156)	0,017

Hemoglobin level and creatinine clearance were lower in case group vs control group. Use of mycophenolate was associated with lower incidence of VTE (0 vs 21% p=0.011). In multivariate analysis age over 50, personal history of VTE and number of thrombophilic risk factors were statistically significant.

Conclusions: Age over 50y, personal history of VTE and more than one laboratory-measured thromboembolic risk factor identifies px at increased risk of VTE after renal tx. Individualized VTE risk factor assessment and differentiated prophylaxis strategies should be considered for these px, in order to optimize outcomes.

PB 1851 | Validation of Risk Assessment Models for Venous Thrombosis in Hospitalized Medical Patients

B. Nemeth[1,2], M. Cobben[1], W. Lijfering[1,3], S. Cannegieter[1,3]

[1]Leiden University Medical Center, Clinical Epidemiology, Leiden, The Netherlands, [2]Leiden University Medical Center, Orthopaedic Surgery, Leiden, The Netherlands, [3]Leiden University Medical Center, Internal Medicine, Section of Thrombosis and Haemostasis, Leiden, The Netherlands

Background: Medical patients are at risk for developing venous thrombosis (VT). However, regardless of current evidence, international guidelines differ on thromboprophylaxis regimens for medical patients. Consequently, many hospitals create their own thromboprophylaxis policy. To assist in these decisions, risk assessment models (RAMs) have been developed to predict the risk for VT. Of all RAMs currently available, only a few have been externally validated, all showing moderate discrimination.

Aims: Our objective was to externally validate all developed RAMs till date, in one dataset of medical patients.

Methods: A literature search was performed to find all eligible RAMs. We used data from a large population based case-control study (MEGA) into aetiology of a first VT (4956 cases with VT and 6297 controls without). To identify hospitalized medical patients, the MEGA study has been linked to the Central Bureau for Statistics database of the Netherlands with information on all hospital admissions. Written informed consent

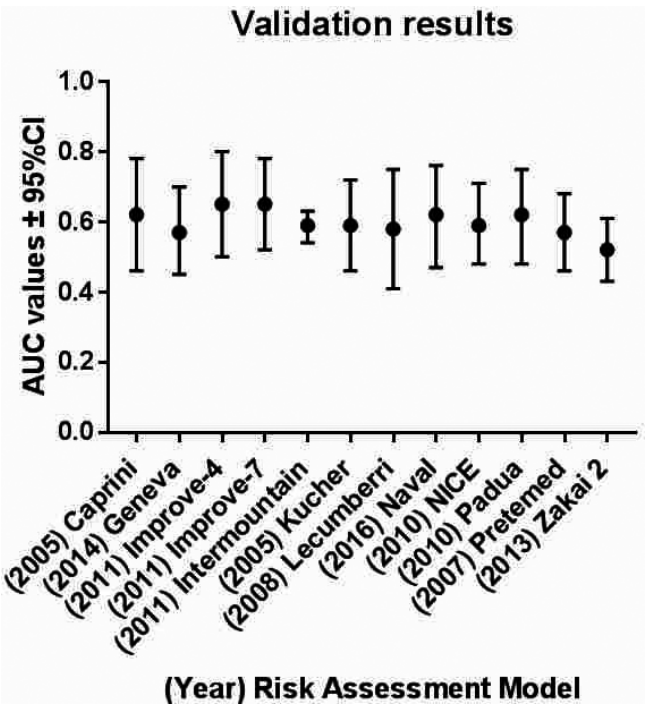

FIGURE 1 Validation results of the performance of all Risk Assessment Models for VT in hospitalized medical patients

was obtained for all participants. 516 cases and 40 controls met the inclusion criteria (medical patient, hospitalized for at least one day within three months before VT/control date, no surgery). The discriminative performance of each RAM was assessed by calculating the c-statistic, sensitivity and specificity and negative and positive predictive values.

Results: The literature search provided 12 RAMs. None showed good discrimination (Fig 1. Area Under the Curve range 0.52-0.65) or a high sensitivity with a high specificity. The negative predictive value was high in all RAMs (range 98.8-99.4%) and the positive predictive value low (range 1.2-3.4%), meaning that in those who had a positive screening test, the probability of getting VT was at best 3.4%.

Conclusions: The discriminative performance of currently available RAMs in medical patients to predict VT seems limited. Our results underline the importance for the development of a new and better RAM for medical patients at risk for VT.

PB 1852 | In ECMO Patients Anticoagulated with Heparin the Dose-response Relationship Disappears when the Dose is Adjusted by ACT but it is Preserved with Anti-Xa Activity

F. Guerrero[1], J.M. Conil[2], A. Jacquemin[2], C. Delmas[2], T. Seguin[2], B. Marcheix[3], V. Memier[1], N. Savy[4], B. Georges[2]

[1]CHU de Toulouse, Hematology Laboratory, Toulouse, France, [2]CHU de Toulouse, Intensive Care, Toulouse, France, [3]CHU de Toulouse, Cardiac Surgery, Toulouse, France, [4]Université Paul Sabatier, Institut de Mathematiques de Toulouse, Toulouse, France

Background: Extra-corporeal membrane oxygenation (ECMO) has become standard supportive therapy during critical cardio-respiratory situations. Anticoagulation is mandatory to prevent obstruction of the circuit. The optimal heparin infusion rate is estimated for each patient according to a dose-response relationship that is usually measured with the activated clotting time (ACT).

Aims: To test if ACT gives a wrong estimate of the dose-response relationship compared to anti-Xa activity during ECMO.

Methods: We performed a prospective cohort study on 65 consecutive patients treated with ECMO and unfractionated heparin between January 2014 and April 2015 in the intensive care unit of the Rangueil University Hospital in Toulouse, France. ACT was measured with Hemocron®Low Range for a target 180-220 sec. Anti-Xa activity was measured for a target 0.2-0.4 UI/ml (verified for a range 0.3-0.7 UI/ml) with STA-Liquid anti-Xa on the STAR® coagulometer. We studied the dose-response relationship over time with a generalized mixed effects model. The study protocol was approved by our institutional ethics and research committee (n°11-0214).

Results: ACT results are independent (p=0.55) of the daily amount of heparin administered (IU/kg/day) while anti-Xa activity results show a clear quadratic dose-response relationship (p< 0.001).

ACT does not predict the risk of overdosage (p=0.82) while anti-Xa activity shows that this risk diminishes over time (p< 0.001) and directly relates to heparin (p=0.05). The risk of underdosage is less pronounced with ACT than with anti-Xa activity (table 1).

TABLE 1 Effect of ACT and anti-Xa activity on the risks of over and under dosage during heparin treatment

Risk	Test	Risk factor	OR	95% confidence interval	p-value
Overdosage	Anti-Xa activity	Time (12h periods)	0.65	0.57-0.74	<0.0001
Overdosage	Anti-Xa activity	Heparin dose (IU/kg/day)	1.001	1.000-1.003	0.05
Overdosage	ACT	Time (12h periods)	0.99	0.91-1.08	0.823
Overdosage	ACT	Heparin dose (IU/kg/day)	1.00	0.999-1.001	0.956
Underdosage	Anti-Xa activity	Time (12h periods)	1.12	1.03-1.21	0.006
Underdosage	Anti-Xa activity	Heparin dose (IU/kg/day)	0.997	0.996-0.998	<0.0001
Underdosage	ACT	Time (12h periods)	1.02	0.94-1.11	0.562
Underdosage	ACT	Heparin dose (IU/kg/day)	0.999	0.997-1.000	0.039

Conclusions: This study confirms that ACT gives a wrong estimate of the dose-response relationship during ECMO and challenges this test as the reference method for adjusting heparin infusion rates.

These results should be confirmed by independent studies. If this is the case, a dose response study that considers the risks of thrombosis and bleeding using anti-Xa activity for dose adjustments needs to be performed.

PB 1853 | AVAIL-MoNa-Study: Audit of Venous Thromboembolism Evaluation and Management Thromboprophylaxis in Moroccan Hospitals - National Level

Hospital, Rabat, Morocco, [16]Mohammed V Hospital, Anesthesia Reanimation, Meknes, Morocco, [17]Hopital Mohammed V, Tanger, Morocco, [18]Hassan II Hospital, Anesthesia Reanimation, Agadir, Morocco, [19]Mohammed V Hospital, Traumatology Orthopedics, Meknes, Morocco, [20]Mohammed VI University for Health Sciences, Casablanca, Morocco, [21]Faculty of Medicine, Oujda, Morocco

Background: Venous thromboembolism (VTE) is a common clinical problem that is associated with substantial morbidity and mortality.
Aims: The aim of this study was to describe the clinical practice in VTE prophylaxis in university and peripheral hospitals in Morocco.
Methods: This was a national, cross sectional, multicenter, observational study assessing the management ofthe VTE risk in selected Moroccan hospitals (4 university hospitals and 3 peripheral hospitals). The thromboembolic risk of the patients selected was assessed according to the American College of Chest Physicians guidelines.
Results: A total of 1318 patients were analyzed: 467 (35.5%) medical and 851 (64.5%) surgical. Mean age of the patients was 52.6±16.5 years and 52.7% were female. 51.1% of the patients had at least one risk factor for VTE and 10.3% had two risk factors according to ACCP guidelines. Medical patients were more likely to present risk factors than surgical patients (53.6% vs 50.7%, respectively). A total of 54.8% patients without contraindication to thrombophylaxis were considered to be at risk of VTE according to ACCP guidelines and were eligible for thrombophylaxis. Thrombophylaxis was prescribed to 66.8% of these patients. On the other hand, TP was prescribed for 42.9% of patients who according to recommendations should not receive it. In total, treatment prescription was concordant with the recommendations for 62.4% of the patients and not concordant for 37.6% of them. The concordance between the recommended and the prescribed prophylaxis was poor for the total population (kappa = 0.239; p < 0.001) as well as when considering surgical and medical patients alone (kappa=0.318 for medical patients and 0.147 for surgical patients; p < 0.001).
Conclusions: New strategies are required toaddress TP appropriately in hospitalized patients, including simpler assessment of the risk of VTE, at least in hospitals where complex strategies based on computerized reminders and alerts are not implementable.

PB 1854 | A Post Hoc Analysis of Dalteparin versus Vitamin K Antagonist (VKA) for the Treatment of Cancer-associated Venous Thromboembolism (VTE) in High-risk Patients with Metastatic Disease and Recent Antineoplastic Treatment

S. Woodruff[1], A. Lee[2,3,4], M. Carrier[5], G. Feugère[6], P. Abreu[1], J. Heissler[1]

[1]Pfizer inc., New York, United States, [2]University of British Columbia, Vancouver, Canada, [3]Vancouver Coastal Health, Vancouver, Canada, [4]British Columbia Cancer Agency, Vancouver, Canada, [5]University of Ottawa, Ottawa, Canada, [6]Pfizer Canada Inc, Kirkland, Canada

Background: Cancer-associated VTE is associated with higher rates of recurrent VTE (rVTE) and bleeding events than seen in non-cancer patients. Variation in risk for rVTE and bleeding also exists between subgroups of cancer patients. Discriminating between low- and high-risk cancer patients is crucial to optimize the risk-benefit of patient-centered care, especially in the era of direct oral anticoagulants.
Aims: This exploratory, hypothesis generating analysis aimed to help improve the treatment of cancer-associated VTE in high-risk patients with metastatic disease and recent antineoplastic treatment.
Methods: This post hoc analysis used data from the pivotal CLOT study to compare the efficacy and safety of dalteparin vs. VKA for the treatment of cancer-associated VTE in patients with metastatic disease and recent antineoplastic treatment (chemotherapy, radiation, and/or surgery within prior 6 months) at baseline. Significance was set at 5%. No multiplicity adjustments were made. Patients gave informed consent; local independent ethics committees/review boards reviewed the study.
Results: 15/171 (8.8%) dalteparin patients and 35/177 (19.8%) VKA patients experienced ≥1 symptomatic rVTE (p=0.0048). In these patients, 25/171 (14.6%) dalteparin patients and 30/174 (17.2%) VKA patients experienced ≥1 any bleeding episode (p=0.4315); 11/171 (6.4%) dalteparin patients and 3/174 (1.7%) VKA patients experienced ≥1 major bleeding episode (p=0.0498). Most major bleeds occurred during the first month of treatment: 8/11 (72.7%) dalteparin; 1/3 (33.3%) VKA. Overall 6-month mortality was 162/348 (46.6%): 82/171 (48.0%) dalteparin; 80/177 (45.2%) VKA.
Conclusions: High-risk cancer patients with metastatic disease and recent antineoplastic treatment showed a 58% relative risk reduction of rVTE when treated with dalteparin vs. VKA. Dalteparin was associated with a small, but statistically significant increase in the incidence of ≥ 1 major bleeding events in these patients.

PB 1855 | Tinzaparin for the Treatment of Superficial Vein Thrombosis of the Lower Limbs

K. Nikolakopoulos, C. Papageorgopoulou, S. Kakkos, A. Kouri, S. Papadoulas, I. Ntouvas, G. Lampropoulos, I. Tsolakis

University Hospital of Patras, Vascular Surgery, Patras, Greece

Background: The optimum duration of anticoagulation to treat superficial vein thrombosis (SVT) of the lower limbs is a matter of debate.
Aims: To investigate the optimum duration of treatment with tinzaparin in patients with lower limb SVT.
Methods: Consecutive patients with SVT were treated with subcutaneous tinzaparin (Innohep™, LEOPharma A/S, Ballerup, Denmark). Those with thrombi measuring less than 5 cm on Duplex or reaching the saphenofemoral junction (last 3 cm of the great saphenous vein) were excluded. The composite primary endpoint of the study was recurrent thrombosis, defined as occurrence of clinically evident SVT recurrence, deep-vein thrombosis or pulmonary embolism. Patients were stratified into three groups by the duration of treatment: group 1 (≤30 days) and group 2 (31-60 days), which run in parallel and patients received mostly an intermediate or therapeutic dose and also a subsequent group 3 where patients received an intermediate dose

(131iu/Kg) for 90 days. Duration of follow-up was 120 days after initiation of treatment.

Results: A total of 147 patients (101 females and 46 males) with a median age of 58.2 years were studied (group 1, n=60, group 2, n=38 and group 3, n=49). Recurrent thrombosis occurred in 15/147 patients (10.2%), including 10 cases of recurrent SVT, four cases of deep-vein thrombosis and one case of pulmonary embolism. Recurrent thrombosis rates were significantly lower in group 3 (0%) compared to groups 1 (18.3%) and 2 (10.5%) (Table and Figure). Similar results were obtained for recurrent SVT only.

TABLE 1 Recurrence-free rate in relation to treatment duration

	30-day event-free rate (%±s.e.)	60-day event-free rate (%±s.e.)	90-day event-free rate (%±s.e.)	120-day event-free rate (%±s.e.)	p value
Group 1 (N=60)	93.3±0.032	85.0±0.046	81.7±0.05	81.7±0.05	0.002
Group 2 (N=38)	100±0.0	97.4±0.026	89.5±0.05	89.5±0.05	0.021
Group 3 (N=48)	100±0.0	100±0.0	100±0.0	100±0.0	REF

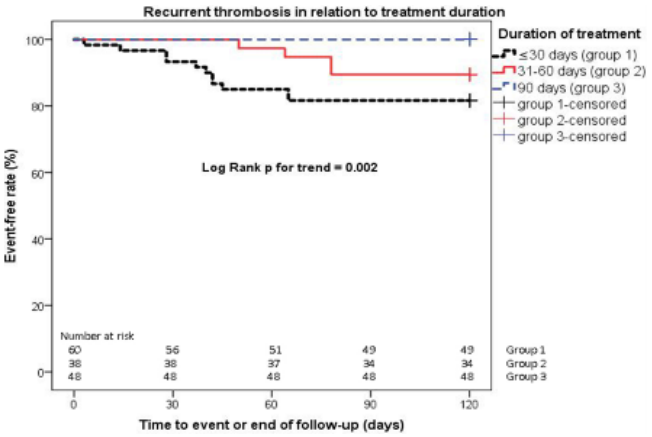

FIGURE 1 Recurrent thrombosis in relation to treatment duration

Conclusions: The incidence of recurrent thrombosis in patients with SVT of the lower limbs is high for the first three months and as a result treatment of shorter duration is inadequate. Future randomized trials should compare firstly the effectiveness of tinzaparin administered for the three-month risk period identified by our study against a 30-45 day regimen per current recommendations, and secondly the optimum dose of tinzaparin.

PB 1856 | Structural and Haemostatic Features of Pharmaceutical Heparins from Different Animal Sources: Challenges to Define Thresholds Separating Distinct Drugs

M.S. Pereira, A.M.F. Tovar, G.R.C. Santos, N. Capille, B.F. Glauser, E. Vilanova, P.A.S. Mourão

Universidade Federal do Rio de Janeiro, Instituto de Bioquímica Médica Leopoldo de Meis, Rio de Janeiro, Brazil

Background: Heparin is widely employed in medicine as anticoagulant and antithrombotic agent. Its use is essential for procedures of extracorporeal circulation during cardiovascular surgeries and hemodialysis. The tissue sources used for preparation of pharmaceutical-grade heparins have changed over time, from dog liver, where heparin was originally described, to bovine liver, then to bovine lung and, lastly, to porcine intestinal mucosa, which is currently the most commonly used source. The current production of heparin mostly based on a single animal source raises a "supply insecurity", which lead the FDA - USA to evaluate the reintroduction of lung or intestine bovine heparins.

Aims: The objective of the present study was to investigate if heparins obtained from different sources are distinct drugs and which are the analytical thresholds separating these distinct heparins.

Methods: We performed herein a systematic analysis on the physicochemical properties, disaccharide composition, in vitro anticoagulant potency and in vivo antithrombotic and bleeding effects of several batches of pharmaceutical grade heparins obtained from porcine intestine, bovine intestine and bovine lung.

Results: Each of these three heparin types unambiguously presented differences in their chemical structures, physicochemical properties and/or haemostatic effects. We also prepared derivatives of these heparins with similar molecular weight differing exclusively in their disaccharide composition. The derivatives from porcine intestinal and bovine lung heparins were structurally more similar with each other and hence presented close anticoagulant activities whereas the derivative from bovine intestinal heparin had a higher proportion of 6-desulfated α-glucosamine units and about half anticoagulant activity.

Conclusions: Our findings reasonably indicate that pharmaceutical preparations of heparin from different animal sources constitute distinct drugs, thus requiring specific regulatory rules and therapeutic evaluations.

PB 1857 | The Effect of Prolongation of Initial Enoxaparin Therapy to One Month on the Risk of VTE Recurrences and the Recanalization of Deep Veins

N. Vorobyeva[1], O. Ermolina[2], T. Balakhonova[2], A. Kirienko[3], E. Panchenko[2]

[1]Pirogov Russian National Research Medical University of Ministry of Healthcare of the Russian Federation, Russian Gerontology Clinical Research Center, Moscow, Russian Federation, [2]Russian Cardiology Research and Production Center, Moscow, Russian Federation, [3]Pirogov Russian National Research Medical University of Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

Background: Standard therapy of VTE pts consists of at least 5 days initial therapy with parenteral anticoagulants followed by long-term oral anticoagulants therapy. Prolongation of LMWH therapy over 5 days is an alternative treatment, which can be recommended in VTE pts with cancer only. Need of prolongation of initial LMWH therapy in all VTE pts is not yet clear.

Aims: To determine the effect of prolongation of initial enoxaparin (En) therapy to 1 month on the risk of VTE recurrence and recanalization of deep veins.

Methods: Sixty-four pts (38 men, age 54±14 yrs.) with deep vein thrombosis (DVT) and/or pulmonary embolism (PE) were studied. First group pts (n=32) received UFH for at least 5 days followed by long-term warfarin (W) therapy (INR 2,0-3,0). Second group pts (n=32) received En (1 mg/kg twice daily) for 30 days and then long-term W therapy (INR 2,0-3,0). Compression ultrasonography was performed at baseline and after 1, 3, 6, and 12 months. We analyzed the presence or absence of signs of occlusive thrombosis in deep veins. Follow-up period was 12 months. Endpoints were DVT/PE recurrences.

Results: In all pts, the rate of DVT recurrence during 12 months was 14%. There were no PE recurrences. The rate of DVT recurrence was significantly lower in En group (3,1% vs 25%; p=0,026). Univariate Cox regression showed that prolongation of En therapy to 1 month significantly decreases the risk of DVT recurrence during 12 months (HR 0,12; 95% CI 0,02-0,99; p=0,049). The Kaplan-Meier curve showed that pts received En had lower cumulative risk of DVT recurrence (chi-square = 5,6; p (log rank test) = 0,018). Univariate Cox regression also showed that prolongation of En therapy increases the probability of recanalization of occlusive thrombosed veins during 12 months (HR 2,52; 95% CI 1,06-5,97; p=0,036).

Conclusions: Our pilot study showed that prolongation of initial En therapy to 1 month decreases the risk of DVT recurrence and increases the probability of recanalization of occlusive thrombosed veins during 12 months.

PB 1858 | Validation of the Pulmonary Embolism Severity Index (PESI) and Simplified PESI in Asian Patients with Acute Pulmonary Embolism

W.Y. Jen[1], P. Kojodjojo[2], H.E.E. Lee[3], Y.H. Lee[3], Y.P. Ren[3], T.J.S. Tan[3], Y. Song[3], T. Zhang[3], L. Teo[4], Y.L. Chee[1]

[1]National University Cancer Institute, Division of Haematology, Singapore, [2]National University Heart Centre, Department of Cardiology, Singapore, Singapore, [3]National University of Singapore, Singapore, Singapore, [4]National University Hospital, Department of Diagnostic Imaging, Singapore, Singapore

Background: Pulmonary embolism (PE) is common, with mortality ranging from 2% to 95%. The Pulmonary Embolism Severity Index (PESI) and simplified PESI (sPESI) are risk stratification tools developed to predict mortality in outpatients presenting with PE and identify a low risk group that can potentially be treated without hospitalisation. Both PESI and sPESI have been extensively validated in Caucasians, but limited data exists about their validity in Asians.

Aims: To assess the validity of the PESI and sPESI scores in an Asian population.

Methods: Consecutive outpatients presenting with acute PE to our institution and diagnosed by computed tomographic pulmonary angiogram (CTPA) from 2013 to 2016 were recruited. Clinical characteristics and outcomes were extracted from a comprehensive electronic patient records system. For each patient, the PESI and sPESI were calculated, and patients were stratified into class I-V for PESI and low or high risk groups for sPESI respectively. The primary end-point was 30-day all-cause mortality. Area under the receiver operating curves (ROC) was used to assess the performance of these scores. This study was approved by our institutional ethics review board.

Results: 119 patients (mean age 58±16 years, 46.2% males) were recruited. 30-day mortality data are shown in Table 1. Overall mortality was 6.7%. ROC curves are shown in Figure 1. The area under the ROC curve was 0.87 (95% CI 0.79-0.95) for the PESI and 0.69 (95% CI 0.48-0.90) for the sPESI scores. The negative predictive value for 30-day mortality was 100% and 95.8% for the PESI class I/II and sPESI low risk groups respectively.

TABLE 1 30-day all-cause mortality data for patients stratified by PESI class and sPESI risk

PESI Class	Number Dead	Number Alive	Total	30-Day All-Cause Mortality (%)
Class I (low risk)	0	21	21 (17.6%)	0
Class II (low risk)	0	21	21 (17.6%)	0
Class III (high risk)	0	28	28 (23.5%)	0
Class IV (high risk)	2	18	20 (16.8%)	10
Class V (high risk)	6	23	29 (24.4%)	20.7
Total / Overall	8	111	119	6.7
Simplified PESI				
Low Risk	1	23	24 (20.2%)	4.2
High Risk	7	88	95 (79.8%)	7.4

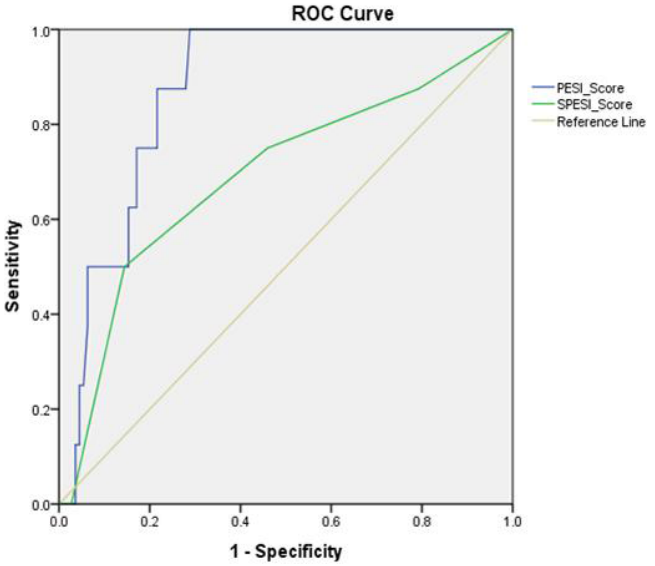

FIGURE 1 ROC curves for PESI and sPESI scores and 30-day all-cause mortality

Conclusions: The PESI score accurately predicts 30-day mortality in Asian patients, but sPESI, whilst easier to apply, is less discriminatory. The negative predictive value for overall 30-day mortality in class I/II PESI was 100% and reliably identifies low risk PE patients that may be treated safely in the outpatient setting.

PB 1859 | Help the Aged? Are we Failing to Protect Patients with Dementia from the Risks of Developing Hospital Associated Venous Thrombo-Embolism?

A. McSorley[1], M.D. Creagh[1], A. Mabin[2], S. Gupta[3]

[1]*Royal Cornwall Hospitals NHS Trust, Haematology, Truro, United Kingdom,* [2]*University of Exeter Medical School & Peninsula College of Medicine & Dentistry, Truro, United Kingdom,* [3]*Royal Cornwall Hospitals NHS Trust, Emergency Medicine, Truro, United Kingdom*

Background: In 2016 dementia became the leading cause of death in the UK. Increasing age in the UK population is predicted to raise the number of hospital inpatients with dementia. Hospital associated Venous Thrombo-Embolism (VTE) has been reported at a district general hospital in patients with dementia declining Low Molecular Weight Heparin (LMWH) thrombo-prophylaxis.

Aims: To determine if patients with a diagnosis of dementia miss more doses of appropriately prescribed LMWH prophylaxis compared to those without dementia and if this is a result of patients declining medication.

Methods: A retrospective audit of adult patients admitted to an acute hospital between March and May 2016 identified 189 study patients by a standard dementia screen. Electronic Prescribing (EPMA) requires VTE risk assessment and records prescribing decisions, analysis of which determined the total number of doses of LMWH prophylaxis prescribed, missed and declined by patients. A control group (n=177) of similar sex, age and hospital length of stay was studied along with the number of prescribed and missed doses of LMWH prophylaxis for the hospital population over the same time period.

Results: Patients with dementia missed 167 (9.0%) doses of prescribed LMWH prophylaxis compared to 76 (4.2%) in the control group. Of the missed doses in the study group 115 (6.2%) were recorded as declined, statistically more than both the control (1.8%) and the hospital population as a whole (4.0%). 12.7% of study group patients assessed as at risk of VTE were not prescribed any prophylaxis compared to 5.4% of all hospital patients.

TABLE 1 Prescribed and missed doses of LMWH VTE prophylaxis

	Study Group (n=189)	Control Group (n=177)	Hospital Population
Prescribed Doses of LMWH prophylaxis	1854	1789	29,049
Total Missed doses	167 (9.0%)	76 (4.2%)	1817 (6.3%)
Declined Doses	115 (6.2%)	32 (1.8%)	1171 (4.0%)
Mean Age	85.4	83.5	n/a
Mean Length of Hospital Stay (days)	10.3	10.6	n/a
Female %	50.2	55.6	n/a

Conclusions: Following admission to hospital patients with dementia identified as at risk of VTE are less likely to be prescribed prophylaxis. When LMWH prophylaxis is correctly prescribed for these patients most missed doses are due to the patient declining. These factors may contribute to failure of VTE prevention strategies and a greater risk of hospital associated VTE, prompting the need to consider alternative care pathways.

PB 1860 | The Efficacy and Safety of Anticoagulations in Cerebral Vein Thrombosis: A Systematic Review and Meta-analysis

B. Al Rawahi[1], M. Almegren[2], M. Carrier[3]

[1]*Sultan Qaboos University Hospital, Haematology, Al-Khoud, Oman,* [2]*Al Imam Mohammad Ibn Saud Islamic University, Medicine, Riyadh, Saudi Arabia,* [3]*Ottawa Hospital Research Institute at the University of Ottawa, Hematology, Ottawa, Canada*

Background: Anticoagulation with unfractionated heparin (UFH) or low molecular weight heparin (LMWH) is the mainstay of treatment of acute cerebral vein thrombosis (CVT) patients with or without intracranial hemorrhage (ICH).

Aims: We conducted a systematic review and meta-analysis to determine the efficacy and safety of LMWH compared to UFH in the acute treatment of CVT.

Methods: An electronic search of MEDLINE and Google Scholar was performed. Randomized controlled trials (RCT) reporting on the efficacy and safety of anticoagulation for acute treatment of CVT were

included. Outcomes of interest included mortality, disability, new ICH and pulmonary embolism (PE).

Results: Overall, 4 RCT were included in the meta-analysis. Two trials compared anticoagulation (one trial UFH and one trial LMWH) to placebo. The use of anticoagulation therapy was associated with an odd ratio (OR) for mortality and disability of 0.31 (95% confidence interval (CI) 0.07 to 1.45) and 0.3 (95% CI 0.09 to 1.01), respectively. Three new ICH were observed among patients receiving placebo and no patient had a PE complication. The other two trials compared LMWH to UFH. LMWH was associated with an OR for mortality and disability of 0.21 (95% CI 0.02 to 2.44) and 0.5 (95% CI 0.11 to 2.23), respectively. There were no new events of ICH or PE in these trials. Combining the result from all the 3 RCT that assessed LMWH showed that LMWH was associated with lower mortality (OR 0.25 (95% CI 0.07 to 0.85)). The OR for disability was 0.46 (95% CI 0.16 to 1.32).

Conclusions: In this study, LMWH treatment for CVT appeared to be safe and effective for the management of CVT.

PB 1861 | Study of Bioaccumulation of Tinzaparin in Renally Impaired Patients when Given at Prophylactic Dose: The STRIP Study

D. Projean[1], S. Lalonde[2], J. Morin[2], E. Nogues[2], A. Séguin[2], A. Vincent[2], V. Masson[1], J.-P. Lafrance[1,3], J. Fafard[1], J. Kassis[1,3], M. Lordkipanidzé[2,4]

[1]CIUSSS de l'Est-de-l'Ile de Montréal: Installation Hôpital Maisonneuve Rosemont, Montreal, Canada, [2]Université de Montréal, Faculty of Pharmacy, Montreal, Canada, [3]Université de Montréal, Faculty of Medicine, Montreal, Canada, [4]Montreal Heart Institute, Research Center, Montreal, Canada

Background: Hospitalized patients with severe chronic kidney disease (CKD) are among the highest risk patients for venous thromboembolism (VTE). Although low-molecular-weight heparins (LMWH) are effective and safe for VTE prophylaxis, LMWH are rarely used in this population because of concerns about bioaccumulation leading to increased risk of bleeding.

Aims: To assess whether bioaccumulation occurs after repeated daily subcutaneous administration of prophylactic doses of tinzaparin in patients with severe CKD.

Methods: Patients with severe CKD (defined by an estimated glomerular filtration rate (eGFR) between 6 and 30 ml/min/1.73 m2) were included in this prospective single-center observational cohort study. Informed consent was obtained for all subjects and the study was approved by the local Research Ethic Board and Health Canada. Tinzaparin was injected s.c. once daily as per local guidance for medical thromboprophylaxis. The dose used was 3500 IU or 4500 UI, depending on patient's body mass index. Peak anti-Xa activity blood levels (anti-Xa) were measured 4 hours after injection on day 2 (or 3), 5 and 8. A through anti-Xa was obtained before the dose injected on day 5. Primary outcome was the comparison of peak anti-Xa on day 2/3 and day 5.

Results: 28 patients with a mean (SD) eGFR of 17.6 ml/min/1.73m2 (6.6) were enrolled; 14 patients were excluded because they were discharged before testing or their treatment/sampling was interrupted (n = 10) or their eGFR rose above 30 ml/min/1.73m^2 (n = 4). Of the remaining 14 patients, none had quantifiable through anti-Xa (< 0.10 IU/ml). Overall peak anti-Xa levels ranged from < 0.1 to 0.33 UI/ml. There was no significant increase in anti-Xa levels over time (Figure), supporting an absence of tinzaparin bioaccumulation. No thrombotic or bleeding adverse events were documented during the study period.

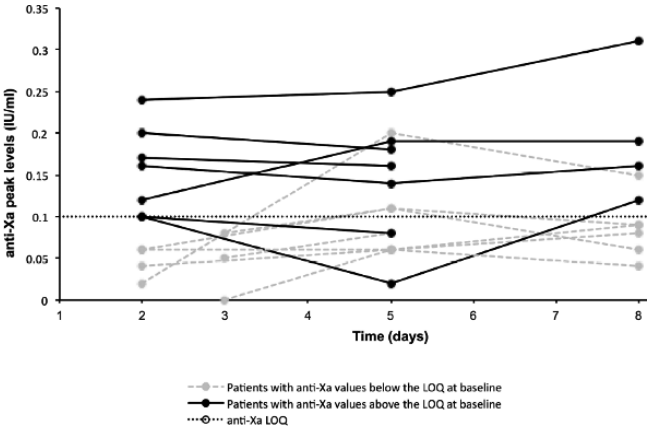

FIGURE 1 Time course of anti-Xa peak levels (UI/ml) in patients (n=14) with severe CKD

Conclusions: This study shows that prophylactic administration of tinzaparin in patients with severe CKD does not result in bioaccumulation.

PB 1862 | Thromboembolic Events Following Splenectomy: Risk Factors, Prevention, Management and Outcomes

A. Rottenstreich[1], G. Kleinstern[2], G. Spectre[3], N. Da'as[4], E. Ziv[3], Y. Kalish[1]

[1]Hadassah Hebrew University Medical Center, Jerusalem, Israel, [2]Braun School of Public Health and Community Medicine, Jerusalem, Israel, [3]Rabin Medical Center, Petah Tikva, Israel, [4]Saare Zedek Medical Center, Jerusalem, Israel

Background: Thromboembolic events following splenectomy are not uncommon. However, the role of thromboprophylaxis and risk factors for thrombosis, as well as the clinical course and outcomes are not well characterized.

Aims: To investigate the risk factors, incidence, clinical presentation, management and outcomes of thrombotic events following splenectomy.

Methods: A retrospective review of individuals who underwent splenectomy between January 2006 and December 2015.

Results: Overall, 297 patients underwent splenectomy [open splenectomy (n=199), laparoscopic splenectomy (n=98)]. Mechanical (thigh-length pneumatic compression stockings) and pharmacologic thrombo-prophylaxis (40 mg enoxaparin daily, starting 12 hours after surgery until discharge) was provided for all patients. One hundred

and sixteen patients (39%) also received an extended course of enoxaparin for 2-4 weeks after discharge. Twenty-three patients (7.7%) experienced thrombotic complications following splenectomy, including 16 cases (5.4%) of portal-splenic mesenteric venous thrombosis (PSMVT), 5 (1.7%) pulmonary embolism and 2 (0.7%) deep vein thrombosis. Longer operative time (mean operative time of 369 vs. 273 minutes, P=0.02) was independently associated with thrombosis. Post-splenectomy thrombocytosis was not associated with thrombosis (P=0.41). The overall thrombosis rate was significantly lower in patients who received an extended course of anticoagulation following splenectomy (3.4% vs. 10.5%, P=0.02). Complete resolution of PSMVT was observed in most cases (n=13, 81.3%) with no *recurrent thrombosis during a mean follow up of* 33±24 months.

Conclusions: Thromboembolic complications, mainly PSMVT, are common following splenectomy. Longer operative time was associated with thrombosis. As significantly lower rates of thrombosis were found in patients who received an extended course of anticoagulation, we support its use for at least two weeks after discharge.

PB 1863 | Low and High Responders to Unfractionated Heparin Can Be Distinguished in Vitro by Inhibition of Thrombin Generation

L.N. van der Vorm[1,2,3], H. de Haan[3], D. Huskens[1,2], J.A. Remijn[3], B. de Laat[1,2,3]

[1]*Synapse Research Institute, CARIM, Maastricht University, Maastricht, The Netherlands,* [2]*CARIM, Maastricht University, Department of Biochemistry, Maastricht, The Netherlands,* [3]*Gelre Hospitals, Department of Clinical Chemistry and Hematology, Apeldoorn, The Netherlands*

Background: Unfractionated heparin (UFH) is the parenteral anticoagulant of choice in the critical care setting. Proper selection of an initial dose of UFH is important. However, the anticoagulant response varies widely and some patients present with heparin resistance, defined as an inadequate responsiveness to standard doses of heparin.

Aims: We aimed to assess whether the *in vitro* response to UFH measured by thrombin generation can be predicted by (a combination of) biological parameters.

Methods: Thrombin generation was determined in platelet-poor plasma from 91 healthy subjects spiked with 0.07 IU/mL UFH. The variability (%CV) of the inhibitory effect of UFH within the population was calculated. Responsiveness to UFH was expressed as the sum of the inhibition (%) of the peak and endogenous thrombin potential (ETP). Antithrombin (AT) activity was determined as described by Kremers et al. (2015).

Results: The CVs of the % inhibition of ETP and peak height by UFH were 48% and 56%, respectively. Interestingly, instead of a normal bell-shaped distribution, two partly overlapping populations of low- and high responders to UFH could be distinguished in the frequency distribution graph.

In the low-responder group there were significantly more women (p = 0.0328), who were older (p=0.0022) and had lower AT activity (p=0.0023). Mixing equal volumes of plasma from low and high responders resulted in correction of the low response to the theoretical average in most but not all cases.

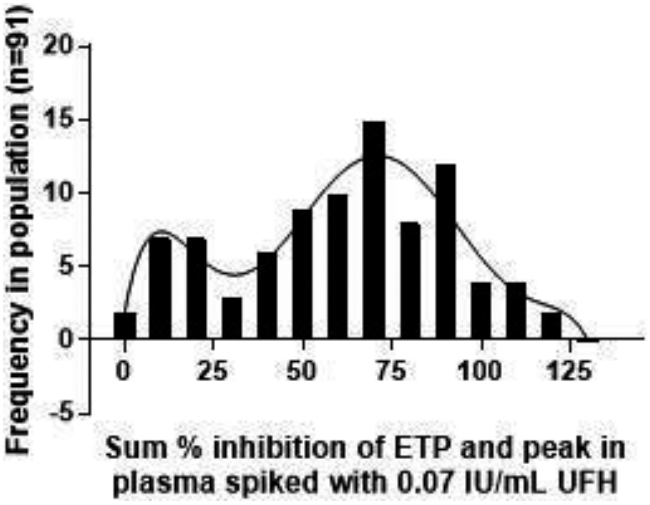

FIGURE 1 Frequency distribution of TG inhibition by UFH

Conclusions: Addition of a fixed concentration of UFH causes a highly variable inter-individual inhibition of TG. Two populations of low- and high responders to UFH can be distinguished based on TG parameters, with significant differences in age, sex and AT activity. Whereas correction of a low response upon mixing with high responders' plasma may be attributed to AT deficiency, an additional, currently unknown cause underlies heparin resistance in plasma that does not correct upon mixing.

PB 1864 | Should Anticoagulation Therapy for Cancer Associated Pulmonary Embolism (PE) Be Modified in Individuals with Brain Metastasis or Thrombocytopenia?

K. Musgrave[1,2], L. Stuart[2], J. Hanley[2], P. Kesteven[2], J. Simpson[1]

[1]*Newcastle University, Newcastle upon Tyne, United Kingdom,* [2]*Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom*

Background: There is little guidance for managing cancer associated pulmonary embolism (PE).

Aims: Cases of cancer associated PE were reviewed at a UK teaching hospital, to compare rates of mortality and intracranial bleeding (ICH) in those with brain metastasis or thrombocytopenia (platelets< $100x10^9$/L).

Methods: Cases were retrieved from a PE database between July 2012-July 2013 and electronic medical records reviewed. Groups were compared using the chi-squared test.

Results: There were 135 cases, 63 (47%) male with a median age of 68 years. The most common primary cancer sites were: lung, 28 cases; oesophagus, 12; prostate, 9; and colorectal, 9. A primary brain malignancy was present in 3. 78 (58%) had metastatic disease at PE diagnosis and the overall mortality 12 months post PE was 84% (114).

Anticoagulation was given to 124 (95%); 113 with tinzaparin. In 5 cases the anticoagulant was unrecorded. 6 were not anticoagulated: 2 required multiple procedures, 1 presented with an ICH, 1 died prior to anticoagulation and in 2 cases there was no reason recorded. 92 received long-term anticoagulation; 23 stopped following a median duration of 6 months (range 5-36) and in 9 cases the duration was unrecorded.

17 (13%) had brain metastasis, either at PE diagnosis (14) or following anticoagulation (3). Two ICHs occurred, one within a brain metastasis and one prior to anticoagulation in a case with a primary brain malignancy (14% vs. 0% p = 0.012). There was no significant difference in mortality 12 months post PE (93% vs. 83%, p = 0.694).

Thrombocytopenia was present in 19 cases (14%) in the 3 months prior to the PE. Only 1 case was not anticoagulated, this was due to the need for recurrent procedures. No ICH occurred in this group and the mortality rate 12 months post PE was similar to those without thrombocytopenia (95% vs. 82% p=0.306).

Rate of recurrence was 3% (4), none of which were thrombocytopenic or had brain metastasis.

Conclusions: There appears to be an association between brain metastasis and ICH.

PB 1865 | Comparison of the Injection Site Reactions Elicited by Two Subcutaneously Injected Heparins, Nadroparin Calcium and Enoxaparin Sodium

J.J. van Tonder[1], S. Mathijs[2], J.M. Dippenaar[3], O. Greeff[2]

[1]*Triclinium Clinical Development, Scientific Affairs, Centurion, South Africa,* [2]*University of Pretoria, Pharmacology, Pretoria, South Africa,* [3]*University of Pretoria, Oral and Dental Health Hospital, Pretoria, South Africa*

Background: Subcutaneous administration of low-molecular-weight heparins (LMWHs) often causes problems such as pain at the injection site. This can lead to problems with treatment compliance. The vital need for anticoagulation treatment compliance to prevent the high risk of morbidity and mortality prompted the primary objective of this clinical trial.

Aims: The primary objective was to assess local administration site signs of intolerability, specifically pain intensity, after a single subcutaneous injection of two widely used LMWHs, nadroparin calcium and enoxaparin sodium. Secondary objectives included monitoring safety, as well as changes in physical examination and laboratory findings.

Methods: A five-week double-blind, randomised, placebo-controlled, single-centre, phase IV clinical trial was conducted in 15 healthy volunteers. The trial was conducted according to the Declaration of Helsinki and international and local guidelines on good clinical practice. The trial was approved by an independent research ethics committee and individual informed consent was obtained prior to the commencement of any trial-related procedures. Perceived pain was assessed using a visual analogue scale (VAS) and an 11-point numeric rating scale (NRS). Measurements were taken at 1, 3, 5, 10, 15 and 20 min post-administration.

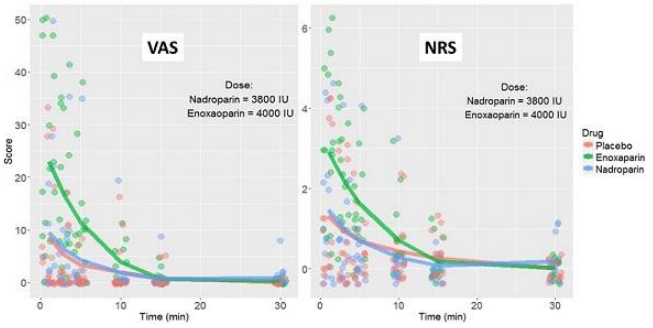

FIGURE 1 Individual and mean pain scores following study drug administration

Results: Enoxaparin administration was significantly more painful, compared to either placebo or nadroparin administration. Compared to placebo, enoxaparin was also associated with a significantly greater burning sensation. Statistically, no distinction could be made between the study drugs with respect to perceived pruritus.

Conclusions: Administration of LMWHs in the form of nadroparin, as compared to enoxaparin, results in less subjective pain experienced by participants, which may improve compliance to anticoagulation treatment utilised to prevent the high risk of morbidity and mortality.

PB 1866 | The Incidence of Adverse Events in Patients Treated with Therapeutic Dose Enoxaparin in Relation to Body Mass Index

R.M.M. Al-Shehristani

Univeristy of Kerbala, Karbala, Iraq

Background: Low Molecular Weight Heparin (LMWH) has widely replaced its parent and oldest anticoagulant compound "Heparin" due to its numerous advantages. However, LMWH are not devoid of adverse effects which may be serious. Since the therapeutic dose of LMWH "*Enoxaparin*" is determined by a weight-based regimen, the incidence of adverse events may be increased when using higher doses.

Aims: To assess the incidence of adverse events in acutely thrombosed patients treated with therapeutic dose Enoxaparin in relation to Body Mass Index (BMI).

Methods: A prospective study conducted through a 6 months period in 2014 including 181 patients (98 males, 83 females) with acute thrombotic disorders (i.e. acute venous thromboembolism, acute coronary syndrome excluding those received thrombolytic, and acute cardiac thromboembolism) admitted to the coronary care unit in Al-Hussein Medical city in Karbala-Iraq. All patients had normal renal functions and were received weight-based LMWH in the form of *Enoxaparin*. They were subdivided according to their BMI into 3 groups; normal, overweight and obese. Any evidence of adverse events were followed and recorded. Statistical analysis was done using Fisher exact test.

Results: Bleeding was the most common adverse event occur in 15 out of 181 patients (8.3%), categorized as Major Bleeding comprising 2.2% overall, occur in 2% of normal BMI, 1.6% of overweight, & 2.9%

of obese patients, and Minor Bleeding comprising 6.1% overall, occur in 5.9% of normal BMI, 6.5% of overweight, & 5.8% of obese patients. No death was reported related to bleeding. Other adverse events were thrombocytopenia in 2.6%, and fever in 1.1% overall.

TABLE 1 Incidence of Adverse Events in Relation to Body Mass Index (BMI)

Adverse Events	BMI <25 N=51	BMI 25-<30 N=61	BMI ≥30 N=69	P-value
Major Bleedings	1 (2.0%)	1 (1.6%)	2 (2.9%)	0.97
Minor Bleedings	3 (5.9%)	4 (6.5%)	4 (5.8%)	0.96
Thrombocytopenia	1 (2.0%)	2 (3.2%)	2 (2.9%)	0.92
Fever	1 (2.0%)	0 (0%)	1 (1.4%)	0.63
Death related to Bleeding	0 (0%)	0 (0%)	0 (0%)	1.0
Death related to Thrombosis	2 (3.9%)	2 (3.3%)	2 (2.9%)	0.95

Conclusions: The incidence of bleeding and other adverse events was not found to be increased in relation to BMI when using weight-based therapeutic dose *Enoxaparin*, which may indicate the rationale use of this regimen in patients with acute thrombotic disorders.

PB 1867 | Management of Venous Thromboembolism in Patients with Glioma

M. Almegren[1], C. De Wit[2], M. Carrier[2]

[1]*Al Imam Mohammad Ibn Saud Islamic University, Riyadh, Saudi Arabia,* [2]*Ottawa Hospital Research Institute at the University of Ottawa, Ottawa, Canada*

Background: Venous thromboembolism (VTE) is a common complication among patients with glioma. However, data on the safety of therapeutic doses of anticoagulation is scarce in this patient population.

Aims: The purpose of this study is to evaluate the risk of intracranial hemorrhage (ICH) in glioma patients receiving therapeutic anticoagulation for VTE treatment.

Methods: We conducted a case-control study including glioma patients with and without acute VTE from Jan 2010 to March 2015. Controls were matched based on age, gender and tumor grade.

Results: 569 patients with glioma were identified, 76 (13.3%) developed acute VTE. Of the 70 patients treated with full dose anticoagulant therapy, 14 (20%) patients had a major bleeding including 11 (15.7%) ICH. The odds ratio for ICH in patients with glioma and VTE who were treated with anticoagulation compared to the control group was 7.5 (95% CI, 1.6-34.9) P=0.01. Overall survival was similar for VTE and control group (36 vs. 42 months, P= 0.93).

Conclusions: Therapeutic anticoagulation is associated with a 7-fold increase risk of ICH in glioma patients. Data emerging from this study support the need for high quality studies to evaluate the risk of ICH in patients with glioma and VTE.

PB 1868 | Resistance of Liquid Anti-Xa Assay (IL) to Platelet Factor 4 Interference

J. Gabbeta[1], V. Krougliak[1], C. Kung[1], R. Bottenus[1], M. Triscott[2]

[1]*Instrumentation Laboratory, R&D, Orangeburg, United States,* [2]*Instrumentation Laboratory, R&D, Bedford, United States*

Background: Platelet Factor 4 (PF4) can bind to both unfractionated and low-molecular weight heparins (UFH and LMWH), thereby neutralizing heparin activity. Low levels of PF4 (~0.005 µg/mL) usually present in plasma have a negligible effect on anti-Factor Xa (Xa) assays, however, improper plasma sample preparation can lead to platelet activation and release of high levels of PF4. Such PF4 levels in plasma samples have the potential to interfere with anti-Xa assays causing erroneous results and increased risk of patient mismanagement.

Aims: This study evaluates PF4 interference on heparin measurements made with the Liquid Anti-Xa Assay (Instrumentation Laboratory (IL)), a global assay for both UFH and LMWH.

Methods: Heparinized plasma samples (UFH or LMWH) ranging from 0 - 2 IU/mL were prepared by spiking UFH or LMWH international standards into normal plasma. Various concentrations (0 - 2 µg/mL) of PF4 were added to these samples, which were analyzed using the Liquid Anti-Xa kit (IL) on an automated coagulation analyzer (IL). The heparin recoveries for samples with and without PF4 were compared to assess the inhibitory effect of PF4 on the assay results.

Results: All UFH and LMWH samples activities covering the heparin concentration range of 0.2 - 2 IU/mL were resistant (decrease in activity <10%) to the presence of PF4 up to 0.2 µg/mL and 0.5 µg/mL respectively, which is 40 and 100 fold higher than normal PF4 levels. Sample recoveries with UFH or LMWH concentration of 0.6 IU/mL and higher were resistant to PF4 concentrations up to 0.5 µg/mL or 1.0 µg/mL, respectively. At PF4 concentrations of 0.5 µg/mL or higher, UFH and LMWH sample activities at ~0.2 IU/mL were the most affected with a change in heparin activity >10%.

Conclusions: Our results demonstrate that the Liquid Anti-Xa Assay (IL) is insensitive to PF4 presence up to 0.2 µg/mL or 0.5 µg/mL in UFH or LMWH plasma samples respectively, which is 40 or 100 fold higher than normal PF4 levels.

PB 1869 | A Matched Case-control Study to Determine Early Post-operative Haematological Complications after Renal Transplantation in Chronic Renal Failure Patients Receiving Therapeutic Anticoagulation

E. Meeks[1], E. Thompson[1], P. Goldsmith[1,2], J. Sexton[3,4], S. Mehra[5]

[1]*Royal Liverpool University Hospital, Transplant Surgery, Liverpool, United Kingdom,* [2]*University of Liverpool, Infection and Global Health, Liverpool, United Kingdom,* [3]*Royal Liverpool University Hospital, Pharmacy, Liverpool, United Kingdom,* [4]*Liverpool John Moores University, School of Pharmacy and Biomolecular Sciences, Liverpool, United Kingdom,* [5]*Royal Liverpool University Hospital, Liverpool, United Kingdom*

Background: Chronic Renal Failure (CRF) patients often have associated pro-thrombotic conditions requiring the use of anticoagulation peri- and post-operatively after renal transplantation. This can lead to early haematological complications in this group of patients who also have platelet dysfunction.

Aims: To determine the haematological complications and outcomes after renal transplantation in chronic renal failure patients with therapeutic anticoagulation compared to their matched controls.

Methods: Twenty-two renal transplant cases on therapeutic anticoagulation were analysed and matched with 22 controls (renal transplants without therapeutic anticoagulation) to determine the risk of haematological complications including, bleeding, re-explorations, upper gastro-intestinal (UGI) bleeding, and deep vein thrombosis (DVT). Controls were matched on gender, age, induction agent, pre-transplant dialysis and donor factors (type, gender and age).

Results: Although there was no observed increased risk of bleeding complications in the anticoagulated group (5 versus 3, p=0.70), all 5 cases returned to theatre compared to 0 controls (p=0.024). The rate of delayed graft (kidney) function was significantly greater in the study group (p=0.011). However, renal function at 3,6 and 12 months was comparable between the 2 groups, as was the incidence of DVT, UGI bleed, blood transfusion and mean length of stay.

TABLE 1 Complications, function and graft loss between cases and controls

Characteristic	Cases (n=22)	Controls (n=22)	Significance
Haematological Complications (%):	6 (27)	3 (14)	P=0.47
Return to theatre (%):	5 (22)	0 (0)	P=0.024
Blood transfusion (%):	5 (22)	2 (9)	P=0.187
Graft loss (%):	2 (9)	0 (0)	P=0.244
eGFR: 3 Months (mean, variance); 6 Months (mean, variance); 12 Months (mean, variance):	(45.62, 354.95); (48.35, 305.50); (51.88, 405.36)	(44.27, 173.54) (43.35, 223.50) (44.63, 194.58)	P=0.39; P=0.17; P=0.11
Mean length of Stay:	13.8	14.5	P=0.403
Primary Function (%):	14 (62)	21 (95)	P=0.011

Conclusions: This study demonstrates an increased risk of post-operative bleeding requiring surgical intervention in CRF patients on therapeutic anticoagulation, resulting in delayed graft function. Thus, careful postoperative monitoring of anticoagulation in this group of patients with platelet dysfunction is advised to minimise the post-operative comorbidity.

PB 1870 | Factors Associated with Thromboembolic Events Following Cytoreductive Surgery and Hyperthermic Intraperitoneal Chemotherapy

A. Rottenstreich[1], Y. Kalish[1], G. Kleinstern[2], A. Ben Yaacov[3], J. Dux[3], A. Nissan[4]

[1]Hadassah Hebrew University Medical Center, Jerusalem, Israel, [2]Braun School of Public Health and Community Medicine, Jerusalem, Israel, [3]Chaim Sheba Medical Center, Ramat Gan, Israel, [4]Chaim Sheba Medical Center, Jerusalem, Israel

Background: Cytoreductive surgery with hyperthermic intraperitoneal chemotherapy (CRS/HIPEC) is an effective treatment for selected patients with peritoneal surface malignancies. Little is known about the prevalence and risk factors associated with thrombosis following CRS/HIPEC.

Aims: To investigate the risk factors, incidence and the role of thromboprophylaxis in the development of thrombosis following CRS/HIPEC.

Methods: We retrospectively reviewed data from a prospectively collected database on patients with CRS/HIPEC.

Results: Overall, 192 patients underwent CRS/HIPEC between 2007-2016. Mechanical (thigh-length pneumatic compression stockings) and pharmacologic thrombo-prophylaxis (40 mg enoxaparin daily, starting 12 hours before surgery until discharge) was provided for all patients. One hundred and sixteen patients (60.4%) also received an extended course of enoxaparin for 2-4 weeks after discharge. Twenty-six patients experienced thrombotic complications (13.5%) including portal-splenic-mesenteric venous thrombosis (n=11, 5.7%), pulmonary embolism (n=10, 5.2%) and deep vein thrombosis (n=5, 2.6%). Most of them (n=21, 80.8%) occurred after hospital discharge. Univariate analysis identified Peritoneal Cancer Index, intraoperative transfusion requirement, operative blood loss, operative time, length of hospital and intensive care unit stay and lack of administration of anticoagulation at discharge as significantly associated with thrombosis. By multivariate analysis only the lack of anticoagulation at discharge remained significantly associated with thrombosis [odds ratio (95% CI): 9.24 (3.03, 28.16), P=0.0001]. Complete resolution of thrombosis was observed in all cases with no recurrent thrombosis during a mean follow up of 21±23 months.

Conclusions: Thromboembolic complications are common following CRS/HIPEC. As significantly lower rates of thrombosis were found in patients who received an extended course of anticoagulation, we support its use for at least two weeks after discharge.

PB 1871 | Clinical Course of Patients Presenting with Acute Superficial Vein Thrombosis: A Post-hoc Analysis of the ICARO Study on 488 Patients

F. Dentali[1], S. Barco[2], F. Pomero[3], M.N.D. Di Minno[4], G. Barillari[5], M.S. Napolitano[6], W. Ageno[1]

[1]*Insubria University, Clinical Medicine, Varese, Italy,* [2]*Johannes Gutenberg University, Center for Thrombosis and Hemostasis, Mainz, Germany,* [3]*Cuneo Hospital, Clinical Medicine, Cuneo, Italy,* [4]*Federico II University, Department of Advanced Biomedical Sciences, Naples, Italy,* [5]*University Hospital of Udine, Center for Hemorrhagic and Thrombotic Diseases, Udine, Italy,* [6]*University of Palermo, Hematoloy Unit & Thrombosis and Hemostasis Reference Regional Cente, Palermo, Italy*

Background: Superficial vein thrombosis (SVT) is frequently occurring, but only limited follow-up data from adequately sized cohort studies are available.

Aims: To estimate the risk of recurrence, major bleeding, and death in patients presenting with SVT.

Methods: ICARO was designed as a multicenter, retrospective cohort study for the derivation of a clinical score to rule out the concomitance of deep vein thrombosis (DVT) in patients presenting with SVT (N=494). For the present post-hoc analysis, 488 patients with more than 30 days of follow-up were included.

Results: Median age was 56 years (25-75 percentile 42-70) and 309 (63.3%) were women. Concomitant DVT was found in 77 (15.8%) patients at baseline. The most common site of thrombosis was the internal saphenous vein (n=316 [64.8%]), involving the crosse in 43. Anticoagulation was administered to 89.3% of patients with a median duration of 42 days (30 and 182 days in patients without or with concomitant DVT, respectively). Total follow-up was 1768 and 650 patient-years for the outcomes of death and recurrence/bleeding events, respectively. SVT and VTE recurrence occurred in 107 (21.9%) and 64 (13.1%) patients (of whom 15 with pulmonary embolism), major bleeding in 13 (2.7%), and death in 31 (6.4%) patients. Overall annual rates (95% Confidence Intervals) were 16.5% (13.5-19.9) for SVT and 9.8% (7.6-12.5) for VTE recurrence, 2.0% (1.0-3.4) for major bleeding, and 1.7% (1.2-2.5) for all-cause death. In a multivariable Cox regression model fit with age, sex, unprovoked nature of SVT, concomitant DVT, and anticoagulation, only anticoagulant discontinuation was associated with either SVT or VTE recurrence (aHR 4.6 [1.6-13.5]).

Conclusions: SVT and VTE recurrence in this population is not negligible.

PB 1872 | The Assessment of Safe Prescribing and Cost-effectiveness of Low Molecular Weight Heparin (LMWH) Treatment

J.K. Chahal[1], C.Y. Zhang[1,2], V. Vakulenko[1,2], P.K. MacCallum[3,4], S. Antoniou[1]

[1]*Barts Heart Centre, Department of Pharmacy, Barts Health NHS Trust, London, United Kingdom,* [2]*Purdue University, College of Pharmacy, West Lafayette, United States,* [3]*Barts Health NHS Trust, Department of Haematology, London, United Kingdom,* [4]*Queen Mary University of London, Barts and The London School of Medicine and Dentistry, London, United Kingdom*

Background: In an era of numerous anticoagulants being available, the low molecular weight heparins (LMWHs) retain a significant role in the treatment and prevention of thrombosis. However, LMWH use is not risk averse as demonstrated in the CRUASADE study where 42% of patients receiving weight and renal-based antithrombotics were given doses outside the recommended range. Alternatively, the direct oral anticoagulants (DOACs) are simpler to dose and offer a better patient experience.

Aims: For LMWH treatment:

· Assess dosing according to patients' weight and renal function.

· Economic analysis on the number of patients eligible for DOAC therapy.

Methods: Patients on LMWH (licensed and off-label use) were analyzed across Barts Health NHS Trust, UK. The data collected prospectively were; patient demographics, weight, renal function, co-morbidities, LMWH dosing, indication and duration within a 2-week study period August - September 2016. For DOAC eligibility, the LMWH cost comparison was based on the use of rivaroxaban for non-valvular atrial fibrillation (AF) and edoxaban for venous thromboembolism (VTE).

Results: A total of 162 patients were on treatment dose LMWH, of which 53 (33%) and 6 (4%) patients were dosed inappropriately according to their weight and renal function respectively. Fifty-six (35%) patients were eligible to switch to a DOAC, 40 (71%) with VTE and 16 (29%) with AF. For these eligible patients, the LMWH cost £1,120.06 in comparison to £401.60 if DOACs were prescribed, equating to potential savings of £718.46 over a 10-day period. Extrapolated over a year, this would produce approximately £26,000 savings.

Conclusions: Though adverse events were not observed during this study, approximately a third of patients were at risk due to inappropriate LMWH dosing. Replacement by DOACs can introduce safer anticoagulation therapy by eliminating weight based dosing and produce significant savings.

PB 1873 | Sustained Anticoagulant Effect and High Inter-individual Variability of Treatment with Rivaroxaban. An ex vivo Analysis of Thrombin Generation and Thromboelastometry

S. Salta[1], P. Van Dreden[2], E. Lefkou[1], H. Ketatni[3], A. Khaterchi[3], L. Papageorgiou[1,3], I. Elalamy[1,3], G. Gerotziafas[3,4]

[1]*Cancer Biology and Therapeutics, Centre de Recherche Saint-Antoine, Institut National de la Santé et de la Recherche Médicale (INSERM) U 938 and Université Pierre et Marie Curie (UPMC), Sorbonne Universities, Paris, France,* [2]*Clinical Research, Diagnostica Stago, Gennevilliers, France,* [3]*Service d'Hématologie Biologique, Hôpital Tenon, Hôpitaux Universitaires Est Parisien, Assistance Publique Hôpitaux de Paris, Paris, France,* [4]*Cancer Biology and Therapeutics, Centre de Recherche Saint-Antoine, Institut National de la Santé et de la Recherche Médicale (INSERM) U 938 and Université Pierre et Marie Curie (UPMC), Sorbonne Universitie, Paris, France*

Background: Rivaroxaban, 20 mg orally administered daily, is widely used for secondary prevention of venous thromboembolism (VTE) without the need for routine laboratory monitoring.

Aims: In patients treated for secondary prevention of VTE, we evaluated ex vivo the anticoagulant potency of rivaroxaban treatment at different times after drug intake.

Methods: 97 patients (39 males, 58 females; median age: 59 years) with idiopathic VTE were treated with rivaroxaban (20 mg/day) for a period longer than 6 months and compared to 30 controls age and sex-matched. Rivaroxaban concentrations (STA®-Liquid Anti-Xa), thrombin generation (PPP-reagent 5 pM TF; calibrated automated thrombogram, Stago France) and whole blood thromboelastometry (5 pM tissue factor; ROTEM® Werfen) were assessed. The interval between drug intake and blood sampling was registered.

Results: Treatment with rivaroxaban significantly inhibited thrombin generation (TG) and prolonged clotting time (CT): 93% of patients had TG inferior to the lower normal limit and 77% had CT longer than the upper normal limit. This effect in both assays, was not correlated to its plasma concentrations, it was significant from the 1st hour after drug intake and persisted at similar levels during the daily therapeutic cycle even at low concentrations (30 ng/ml). Rivaroxaban had no effect on clot firmness. The inter-individual coefficient of variation of rivaroxaban concentrations and TG/ROTEM alterations after drug intake ranged from 50% to 100%.

Conclusions: Once daily administration of rivaroxaban induces sustained daily anticoagulant effect, detected by TG and ROTEM assays, with no significant changes related to drug concentration reduction. This profile could explain the wide therapeutic window and the favorable benefit risk ratio of the treatment with rivaroxaban. Due to the high variability the identification of patients with extreme values of TG could be useful strategy for treatment optimization on individual basis.

PB 1874 | Comparison of UFH and Enoxaparin Originated from Bovine, Ovine and Porcine Mucosa with Functional Coagulation Assays

G. Gerotziafas[1,2], P. Van Dreden[3], W. Jeske[4], J. Walenga[4], D. Hoppensteadt[4], M. Grusse[3], A. Larsen[2], I. Elalamy[1,2], Y. Yao[4], J. Fareed[4]

[1]Service d'Hématologie Biologique Hôpital Tenon, Hôpitaux Universitaires Est Parisien, Assistance Publique Hôpitaux de Paris, Paris, France, [2]Cancer Biology and Therapeutics, INSERM U 938, Institut Universitaire de Cancérologie (IUC), Université Pierre et Marie Curie (UPMC), Sorbonne Universities, Faculté de Médecine Pierre et Marie Curie, Paris, France, [3]Clinical Research, Diagnostica Stago, Gennevilliers, France, [4]Cardiovascular Institute Loyola University Chicago, Chicago, United States

Background: Pharmaceutical heparin is a linear glycosaminoglycan with an average mass between 10 and 20 kDa extracted from porcine intestine. Other sources such as bovine or ovine intestine are being examined as potential substitutes in order to diversify the heparin supply.

Aims: The present in vitro study examines bovine, ovine and porcine unfractionated heparin (UFH) and respective low molecular weight heparin enoxaparin and compares these to the commercially available heparins.

Methods: Platelet poor plasma (PPP) from 5 healthy volunteers were spiked with increasing concentrations (from 1 to 10 µg/ml) of UFH or enoxaparin of bovine, ovine or porcine origin. The specific anti-Xa activity was measured in PPP (using the STA-Liquid anti-Xa assay) and thrombin generation (TG) was assessed with PPP-reagent 5TF®/Calibrated Automated Thrombogram (CAT®; Stago, France). TG was also triggered in PPP in the presence of pancreatic cancer cells BXPC3 (Rousseau, et al Thromb Res 2015;136:1273-9). The activated partial thromboplastin clotting time (aPTT) was measured with the conventional assays on the STA-R® instrument.

Results: The anti-Xa activity/µg, the concentrations prolonging 2-fold the aPTT, and the IC50% for ETP and MRI from the TG test of the studied preparations of UFH and enoxaparin are shown in Table 1. The studied preparations of UFH and enoxaparin at the concentration of 0.3 anti-Xa IU/ml inhibited 50% TG induced by the BXPC3 cancer cells.

Conclusions: Enoxaparin and UFH prepared from raw material of different species showed similar anti-Xa activity when compared on gravimetrically equivalent units (anti-Xa IU/µg). Enoxaparin and UFH prepared from bovine raw material was slightly less potent on the inhibition of TG as compared to those prepared from ovine or porcine raw material. These data confirm the possibility to use alternative sources of raw material for the preparation of enoxaparin or UFH providing that the purification and depolymerisation methods are not modified.

TABLE 1 Comparison of the UFH and enoxaparin from different origin on the basis of their anti-Xa activity and on their potential to double the aPTT

	Bovine Enoxaparine	Ovine Enoxaparine	Porcine Enoxaparine	Bovine UFH	Ovine UFH	Porcine UFH
anti-Xa IU/µg	0,08	0.12	0.10	0.10	0.21	0.12
aPTT x 2	8 µg/ml	8 µg/ml	8 µg/ml	1.9 µg/ml	1 µg/ml	1.6 µg/ml
IC50 MRI	3 µg/ml	2 µg/ml	2 µg/ml	0.9 µg/ml	0.8 µg/ml	0.8 µg/ml
IC50 ETP	4.1 µg/ml	3 µg/ml	3 µg/ml	1.2 µg/ml	1 µg/ml	1 µg/ml

PB 1875 | Efficacy and Safety of Pharmacological Thromboprophylactic Agents for the Prevention of Venous Thromboembolism after Major Abdominal Surgery: A Systematic Review and Meta-Analysis

B. Al Rawahi[1], G. Le Gal[2], R. Auer[3], M. Carrier[2]

[1]Sultan Qaboos university, Haematology, Al-Khoud, Oman, [2]Ottawa Hospital Research Institute at the University of Ottawa, Hematology, Ottawa, Canada, [3]Ottawa Hospital Research Institute at the University of Ottawa, Surgery, Ottawa, Canada

Background: Patients undergoing major abdominal surgery are at high risk for developing venous thromboembolism (VTE) in the post-operative period. However, the ideal agent, dose and duration of thromboprophylaxis remain unclear.

Aims: We conducted a systematic review and meta-analysis to determine the efficacy and safety of pharmacological thromboprophylaxis after major abdominal surgery.

Methods: An electronic search of the following databases was performed: MEDLINE, EMBASE and CENTRAL. Randomized controlled trials (RCT) and prospective cohort studies reporting on the efficacy and safety of different pharmacological thromboprophylactic agents after major abdominal surgery were included. Pooled proportions of VTE and major bleeding complications in the post-operative period were generated for 6 different regimens of pharmacological thromboprophylaxis: fondaparinux; high and low prophylactic doses of low molecular weight (LMWH) and unfractionated heparin (UFH); placebo or observation; and non-pharmacological thromboprophylaxis.

Results: Our literature search study identified 1,569 records. A total of 166 articles were identified as potentially eligible and after review, 87 articles (71 RCTs and 16 prospective cohorts) were included in the pooled analysis. The pooled outcome rates according to each prophylaxis regimen are depicted in table 1.

Conclusions: In this study, there was no difference in the pooled proportion of post-operative VTE between pharmacological thromboprophylaxis and observation or placebo. The pooled proportion of post-operative major bleeding events was higher in patients receiving high dose LMWH.

PB 1876 | Comparative Anticoagulant Effects of Recombinant Thrombomodulin, Antithrombin, and Unfractionated Heparin, Hematological Implications

Z. Siddiqui[1], P. Aggarwal[1], O. Iqbal[1], D. Hoppensteadt[1], M. Lewis[1], S. Abro[2], K. Tsuruta[3], J. Fareed[1]

[1]Loyola University Medical Center, Pathology, Maywood, United States, [2]Loyola University Medical Center, Maywood, United States, [3]Asahi Kasei Pharma America Corporation, Waltham, United States

Background: Unfractionated heparin (UFH), antithrombin (AT), and recombinant thrombomodulin (RT) are all anticoagulant/antithrombotic agents. Currently, a recombinant and soluble version of human thrombomodulin, ART-123 (Recomodulin ©) is undergoing clinical trials for treatment of sepsis-associated coagulopathy.

Aims: The purpose of this study is to compare the anticoagulant and platelet modulatory effects of RT, UFH, and AT.

Methods: Porcine UFH was obtained from Medefil Inc. (Glendale Heights, IL), AT from Baxter Healthcare Corporation (Deerfield, IL), and RT from Asahi Kasei Pharma (Tokyo, Japan). The effects of RT, AT, and UFH at 0-5 μg/mL on glass ACT and thromboelastography (TEG) were measured. PT, APTT, and TT were measured in citrated whole blood and retrieved plasma. The effect of these drugs on agonist induced platelet aggregation (arachidonic acid, ADP, collagen, thrombin, and epinephrine) was measured in platelet rich plasma from healthy donors.

Results: In contrast to AT and UFH, RT showed no anticoagulant effects in TEG and ACT at 1.25 μg/mL. At higher concentrations of up to 5.0 μg/mL, RT was a much weaker anticoagulant. In the clotting assays, all agents produced anticoagulant effects in the following order: UFH > AT > RT. UFH mildly increased aggregation with some agonists. AT and RT did not produce any effects at concentrations of up to 5 U/ml and 10 μg/ml, respectively, for all of the agonists except thrombin.

Conclusions: This study shows that RT is a much weaker anticoagulant compared to UFH and AT, and at therapeutic concentrations, it does not produce measurable anticoagulant effects. The circulating levels of RT for the management of sepsis-associated coagulopathy range from 0.5-1.5 μg/mL. At supratherapeutic concentrations of

TABLE 1 Pooled outcome rates according to each prophylaxis regimen

Intervention	Fondaparinux	LMWH high dose	UFH high dose	LMWH low dose	UFH low dose	Placebo
Overall VTE(number of studies)	1.23 (4)	4.39 (27)	10.1 (14)	3.36 (19)	7.97 (13)	8.64 (12)

PB 1877 | Nuts and Bolts of Running a Pulmonary Embolism Response Team: Results from an Organizational Survey of the National PERT™ Consortium Members

G. Barnes[1], J. Giri[2], D.M. Courtney[3], S. Naydenov[4], T. Wood[5], R. Rosovsky[6], K. Rosenfield[6], C. Kabrhel[6], National PERT Consortium Research Committee

[1]Univeristy of Michigan, Ann Arbor, United States, [2]University of Pennsylvania, Philidelphia, United States, [3]Northwestern University, Chicago, United States, [4]St. Louis University, St. Louis, United States, [5]Lancaster General Hospital, Lancaster, United States, [6]Massachusetts General Hospital, Boston, United States

Background: Pulmonary Embolism Response Teams (PERT) are developing rapidly to operationalize multi-disciplinary care for acute pulmonary embolism patients. However, core components of PERT necessary for newly developing programs have not been defined.

Aims: To describe core components of established PERT programs and to understand variation in program structure.

Methods: An online organizational survey of active National PERT™ Consortium members was performed between April and June 2016. Analysis, including descriptive statistics and Kruskal-Wallis tests, was performed on centers self-reporting a fully operational PERT program.

Results: The survey response rate was 80%. Of the 31 institutions that responded (71% academic), 19 had fully functioning PERT programs. These programs were run by steering committees (17, 89%) more often than individual physicians (2, 11%). Most PERT programs involved 3-5 different specialties (14, 74%, Figure), which did not vary based on hospital size or academic affiliation.

Multidisciplinary discussions occurred via phone or conference call (12, 67%) with a minority of these utilizing "virtual meeting" software (2, 17%). Guidelines for appropriate activations were provided at 16 (84%) hospitals. Most PERT programs offered around-the-clock catheter-based or surgical care (17, 89%). Outpatient follow up usually occurred in personal physician clinics (15, 79%) or dedicated PERT clinics (9, 47%), which were only available at academic institutions.

Conclusions: PERT programs can be implemented, with similar structures, at small and large, community and academic medical centers. While all PERT programs incorporate team-based multidisciplinary care into their core structure, several different models exist with varying personnel and resource utilization. Understanding how different PERT programs impact clinical care remains to be investigated.

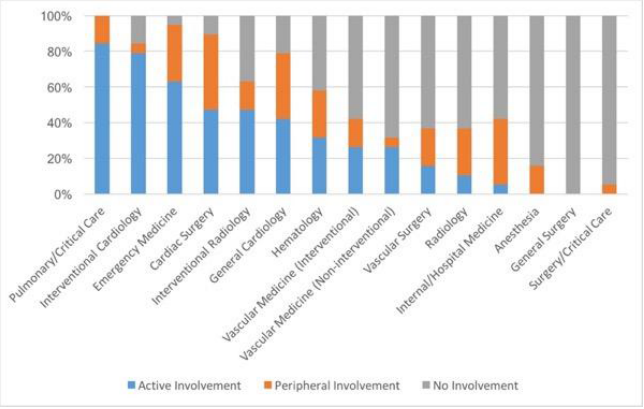

FIGURE 1 Specialty Involvement in Pulmonary Embolism Response Teams

PB 1878 | Long Term Anticoagulant Treatment Management in Patients with Portal Vein Thrombosis at High Bleeding Risk

M. Napolitano[1], S. Mancuso[2], S. Raso[3], M.R. Lanza Cariccio[4], M.F. Mansueto[4], S. Siragusa[1]

[1]Università degli Studi di Palermo, Reference Regional Center for Thrombosis and Hemostasis, Palermo, Italy, [2]Università degli Studi di Palermo, Hematology Unit, Palermo, Italy, [3]Università degli Studi di Palermo, Reference Regional Center for Thormbosis and Hemostasis, Plaermo, Italy, [4]Università degli Studi di Palermo, Palermo, Italy

Background: Portal vein thrombosis (PVT) is quite common in patients with liver cirrhosis or hepatocellular malignancy. Prospective registries report that up half of the patients with PVT secondary to liver disease do not receive any anticoagulant treatment mainly due to thrombocytopenia and esophageal varices (EV).

Aims: To evaluate the safety and acceptability of long-term anticoagulant treatment with Low Molecular Weight Heparin (LMWH) in patients with PVT secondary to liver disease.

Methods: Patients with liver disease referred to our Center, from January 2011 to June 2016, for concomitant PVT and a high bleeding risk secondary to EV and thrombocytopenia are included in the current analysis. LMWH was tapered to patient's platelet (PLT) count: full dosage for PLT above 50.000/, reduced dosage (75%) for PLT below 50000/μL but above 30000/μL. Prolonged anticoagulant treatment was deemed necessary based on concomitant risk factors or thrombosis recurrences. LMWH discontinuation was patient driven. All subjects underwent a monthly clinical and laboratory follow-up. Compliance to therapy was based on clinical evaluation and answers to a specific questionnaire.

Results: Overall, 20 Caucasian patients with PVT secondary to liver cirrhosis (n=13) or carcinoma (n=7) were included in the current analysis, 11 women, 9 males (mean age: 65.2;range, 56-71 years). All patients had at least grade II esophageal varices associated with moderate to severe thrombocytopenia (mean PLT count: 42 x 10^3/L; range 35-68 x10^3/L). Mean anticoagulant treatment duration was 16 months (range: 12-30 months).Treatment was well tolerated without any major bleeding or premature discontinuation. Four patients complained easy bruising. Compliance to LMWH treatment was good, short-term treatment discontinuation (one day off therapy, every 3 days) was however reported in 5 patients.

Conclusions: In our case cohort, LMWH treatment for PVT was well tolerated in patients with liver disease under regular clinical and laboratory follow-up.

PB 1879 | Antikoagulant Effects of New Vegetable Heparinoid

M. Lyapina[1], M. Grigorjeva[2]

[1]*Lomonosov Moscow State University, Biology, Lab. Blood Coagulation, Moscow, Russian Federation,* [2]*Lomonosov Moscow State University, Moscow, Russian Federation*

Background: Anticoagulant action of some plants is known. Plants of peonies family at which roots there are heparinoid are of special interest.
Aims: To show influence of extracts from roots of peony (P.lactiflora) containing a heparinoid on parameters of coagulant and anticoagulant systems of blood at their single intraperitoneal administration in rats organism.
Methods: Experiments are made on laboratory white rats according to ethical principles of the Helsinki Declaration. Extract from peonies (EP) in a dose of 1 mg/kg was entered intraperitoneal to each experienced rat. A control animal entered in the same way saline. The blood on analyses was taken from a vein jugularis 1 and 5 h after introduction. In a blood plasma determined anticoagulating activity by tests of activated partial thromboplastin time (APTT), prothrombin time (PT), thrombin time (TT) and fibrindepolimerizing activity (FDPA) and activity of the tissue plasminogen activator (t-PA).
Results: The increase of anticoagulating activity of a blood plasma due to elongation of APTT and PT for 80-68% respectively is established 1 h after EP introductions, at this TT practically didn´t change. During this period FDPA and t-PA raised in rats plasma for 110%-45% respectively in comparison with control. Increased anticoagulating activity due to elongation of APTT and PT for 73 and 70% respectively remained 5 h after introduction of the EP. In addition this TT remained within control. At the same time rising of FDPA for 91% and t-PA for 38% was observed.
Conclusions: So, administration of the extract from P.lactiflora causes hypocoagulation due to decrease transformations of a fibrinogen to fibrin. We concluded that the submitted results indicate prospects of study of new heparinoid from peonies as vegetable agent for pharmacological correction of the increased level of blood coagulation.

PB 1880 | Establishing the Heparin Therapeutic Range Using aPTT and Anti-Xa Measurements for Monitoring Unfractionated Heparin Therapy

A. Rashid, B. Moiz, N. Kazmi, B. Rizvi

Aga Khan University Hospital, Karachi, Pakistan

Background: The activated partial thromboplastin time (aPTT) test has been used to monitor UFH therapy, but its results can be affected by numerous patient related and laboratory test related variables. The heparin responsiveness of aPTT reagents may change from lot to lot and among different reagents used on different instrument platforms. Each laboratory must set up its own heparin therapeutic range (HTR) to standardized interpretation of aPTT results in the context of heparin therapy.
Aims: To establish an aPTT heparin therapeutic range (HTR) corresponding to therapeutic anti-Xa levels for continuous intravenous UFH administration, and used appropriate monitoring to determine if an adequate dose of UFH was applied.
Methods: A total of 30 ex vivo samples were obtained from 16 patients with a variety of thromboembolisms. All patients received intravenous UFH therapy and were enrolled from June to July 2016 at Aga Khan University Hospital. All laboratory protocols were in accordance with the Clinical and Laboratory Standards Institute guidelines and the College of American Pathologist requirements for aPTT HTR. Ethical exemption was sought from institutional ethical review committee.
Results: An aPTT range of 47 to 65 second corresponded to anti-Xa levels of 0.3 IU/mL to 0.7 IU/mL for HTR under our laboratory conditions. Based on their anti-Xa levels, blood specimen distribution were as follows: less than 0.3 IU/mL, 13%; 0.3–0.7 IU/mL (therapeutic range), 50%; and more than 0.7 IU/mL, 33%. No evidence of recurring thromboembolism was observed.
Conclusions: Although aPTT HTR determination and standardization is laborious but is a good alternative for monitoring of UFH therapy where anti-Xa assay is not available or is not cost-effective.

PB 1881 | Patients Are More Adherent to Treatment with LMWH Nadroparin than Enoxaparin for Cancer Related Venous Thromboembolism

S. van der Wall[1], F. Klok[1], P. den Exter[1], D. Barrios[2], R. Morillo[2], S. Cannegieter[3], D. Jimenez[2], M. Huisman[1]

[1]*Leiden University Medical Center, Thrombosis & Hemostasis, Leiden, The Netherlands,* [2]*Ramon y Cajal Hospital IRYCIS, Madrid, Spain,* [3]*Leiden University Medical Center, Epidemiology, Leiden, The Netherlands*

Background: Current guidelines recommend low-molecular-weight-heparins (LMWH) monotherapy for 3 to 6 months as first-line treatment for cancer-associated venous thromboembolism (VTE). In clinical practice nadroparin and enoxaparin are common agents used. However, differences in therapy adherence between these LMWHs have never been reported.
Aims: To compare adherence to nadroparin and enoxaparin in patients with cancer-associated VTE.
Methods: Consecutive patients with active cancer and objectively confirmed VTE , treated at three Dutch hospitals and one Spanish hospital, were included and followed during LMWH therapy with a maximum of 180 days. Cumulative incidences of discontinuation of both LMWHs were estimated and compared according to the Kaplan-Meier method, applying a competing risk analysis to correct for mortality.

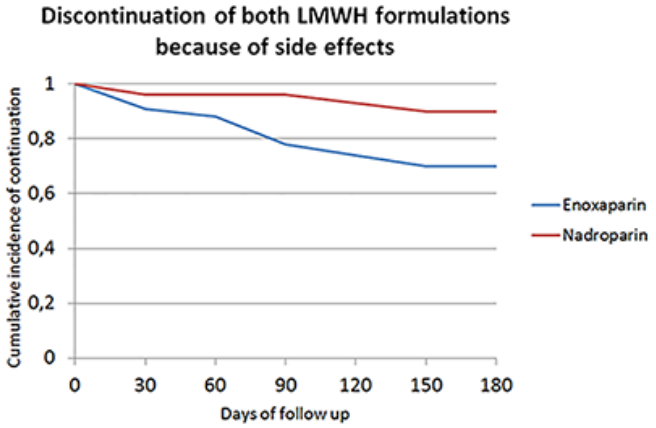

FIGURE 1 Discontinuation of both LMWH formulations because of side effects

Results: 372 patients were analysed during LMWH treatment, of whom 284 patients (76%) were treated with enoxaparin and 88 (24%) with nadroparin. The overall cumulative incidence of discontinuation of enoxaparin and nadroparin treatment because of side effects was 30% (95%CI 24-36) and 10% (95%CI 2.7-17) respectively (*Figure 1*). Competing risk analysis revealed a higher number of patients discontinuing enoxaparin because of side effects (Hazard Ratio: 3.4, 95%CI 2.6-4.2). Unacceptable pain at the injection site was the most common reason of discontinuation in patients using enoxaparin, occurring in 32 patients, while it occurred in one patient using nadroparin.

Conclusions: This analysis reveals that enoxaparin was associated with a higher risk of discontinuation because of side effects compared to nadroparin. Although this was a non-randomised comparison, our findings are relevant for choice of LMWH when treating cancer-associated VTE.

PB 1882 | Prevalence of FOXD1 Mutations in Primigravidae with Pregnancy Loss

J.-C. Gris, E. Mercier, S. Bouvier, E. Cochery-Nouvellon, G. Lissalde-Lavigne

University Hospital, Haematology, Nîmes, France

Background: Mutations of the transcription factor gene *FOXD1* impairing the activation of the promotor of the placental growth factor gene *PGF* are associated with recurrent pregnancy loss (Open Biol. 2016 Oct;6(10). pii: 160109) but their prevalence is not documented in other pregnancy loss phenotypes.

Aims: Assess the rate of the 3 non-synonymous *FOXD1* sequence variants [c.1285_1286InsGCCGCG (p.Ins429AlaAla); c .1067 C>G (p.Ala356Gly) ; c.1092C>G (p.Ile364Met)] in primigravida with pregnancy loss (PwPL).

Methods: We tested DNAs from the 6,992 women included in the matched case-control study nested into the NOHA-First cohort (J Thromb Haemost 2005;3(10): 2178-84). *FOXD1* coding region was sequenced as described.

Results: None of the 3 *FOXD1* mutations was evidenced in the 3,496 controls of the NOHA-First study. A total of 53 patients were found positive for the *FOXD1* mutations: 19 of the 412 PwPL before 10 weeks of pregnancy (4.6%; OR 81 [18.7-347], p< 0.0001) and 34 of the 2,705 PwPL from the 10th week (1.26%; OR 22 [5.3-91, p< 0.0001]). In this latter group, all losses in mutated women hapened before 12 weeks (2.9% of the 1,191 PwPL during weeks 10-11). The association with FOXD1 mutations in FV Leiden negative and positive women was 45/6746 (0.67%) *vs.* 8/246 (3.25%, p=0.0007), it was 48/6804(0.7%) *vs.* 5/188 (2.66%, p=0.0115) in *F2* 20210A negative and positive women.

Conclusions: *FOXD1* mutations impairing *PGF* transcription are significantly found in primigravida with pregnancy loss before 12 weeks, mainly in women with embryonic loss, and are significantly associated with the FV Leiden and the *F2* 20210A polymorphisms. The progressive description of causal mutations associated with pregnancy failure could gradually lead to a better understanding of the risk of pregnancy loss associated with thrombophilia.

PB 1883 | Prothrombin Fragment F1+2 (F1F2) in Pregnancy Is Associated with a History of Venous Thromboembolism (VTE) and Thrombophilia

R.B. Zotz[1,2], R.E. Scharf[2], A. Gerhardt[2,3]

[1]Institute for Laboratory Medicine, Blood Coagulation and Transfusion Medicine (LBT), Duesseldorf, Germany, [2]Heinrich Heine University Medical Center, Department of Hemostasis, Hemotherapy and Transfusion Medicine, Duesseldorf, Germany, [3]Blutgerinnung Ulm, Department of Hemostasis and Transfusion Medicine, Ulm, Germany

Background: Since the positive predictive value of factor V Leiden (FVL) and other genetic risk determinants for a pregnancy-associated VTE is low, additional indicators of hypercoagulability are needed to identify women at risk of VTE during pregnancy. An increased level of F1F2 is a potential indicator of hypercoagulation in normal pregnancy.

Aims: We hypothesized that women with previous VTE and FVL or prothrombin G20210A mutation (PTM) are at a higher hypercoagulable state during pregnancy than women without prior thrombotic complications and without genetic thrombophilic risk factors.

Methods: In a prospective study, we determined F1F2 over pregnancy (818 measurements) among 131 women with previous VTE, 109 women with previous fetal loss (1 late or 3 early fetal losses), 51 women with previous severe preeclampsia, and 93 healthy pregnant women. Evaluation of thrombophilia included FVL and PTM. The F1F2 levels were statistically analyzed over the course of pregnancy using a multivariate mixed model.

Results: Among women with a previous history of VTE, F1F2 values were significantly higher during the course of pregnancy than among pregnant women without VTE (p< 0.0001) (p=0.63 for preeclampsia vs. no preeclampsia, p=0.40 for fetal loss vs. no fetal loss). The results were adjusted for the physiological increase of F1F2 over pregnancy (p< 0.0001) and independent of heparin prophylaxis (F1F2 reduced

in women using heparin, p=0.004). In addition, FVL (p=0.004) and PTM (p=0.011) were independently associated with increased levels of F1F2.

Conclusions: Increased F1F2 in pregnancy are associated with thrombophilic risk factors (FVL and PTM) and a history of VTE. Determination of indicators of hypercoagulation such as F1F2 can represent a supplementary approach to identifying women at risk of VTE during pregnancy, independent of known and unknown risk determinants of VTE.

PB 1884 | Recurrent Venous Thromboembolism (VTE) in Pregnancy in Women with a History of First Venous Thromboembolism

A. Gerhardt[1,2], R.E. Scharf[2], R.B. Zotz[2,3]

[1]*Blutgerinnung Ulm, Department of Hemostasis and Transfusion Medicine, Ulm, Germany,* [2]*Heinrich Heine University Medical Center, Department of Hemostasis, Hemotherapy and Transfusion Medicine, Duesseldorf, Germany,* [3]*Institute for Laboratory Medicine, Blood Coagulation and Transfusion Medicine (LBT), Duesseldorf, Germany*

Background: There are insufficient data on the risk of recurrent VTE in pregnany.

Aims: To evaluate the risk of recurrent pregnancy-associated VTE in women with a single previous episode of VTE and a subsequent pregnancy without heparin prophylaxis.

Methods: We included in the study 142 women with at least one pregnancy without heparin prophylaxis after a first VTE. Evaluation of thrombophilia comprised factor V Leiden, prothrombin G20210A mutation, and deficiencies of antithrombin, protein C or protein S.

Results: Nine of 142 women without heparin prophylaxis (6.3%) had an antepartum recurrence of VTE. Among the 66 women with evidence of thrombophilia and a first episode of VTE associated with a temporary risk factor, 4 (6.06%) had an antepartum recurrence of VTE (first trimenon n=1, second trimenon n=2, third trimenon n=1) (first VTE on oral contraceptives (OC) n=3, during surgery n=1). There was no recurrence in the women with thrombophilia and a first episode of idiopathic VTE (n=8). Among the 61 women who had no evidence of thrombophilia and a first episode of VTE associated with a temporary risk factor, 4 women (6.56%) (first trimenon n=2, second trimenon n=1, third trimenon n=1) (first VTE on OC n=1, during immobilization n=1, during surgery n=2), and among 7 women with no evidence of thrombophilia and a first idiopathic VTE, 1 woman (14.3%) had an antepartum recurrence (first trimenon).

In the postpartum period, 11 VTE occurred after live birth in 142 women (7.75%). The first episode of VTE in all these women was associated with a temporary risk factor. 7 of these 11 women showed evidence of thrombophilia.

Conclusions: In addition to guideline-recommended postpartum heparin prophylaxis, our data also support routine antepartum prophylaxis in women whose previous episode of thrombosis was associated with a transient risk factor not related to pregnancy or use of estrogen, regardless of the presence of thrombophilia and starting in the first trimenon.

PB 1885 | Incidence and Risk Factors of Pregnancy-associated Venous Thromboembolism in Singhealth, a Major Healthcare Cluster in Singapore

S.L. Jaya-Bodestyne[1], S.Y. Tan[2], C.K. Ng[2], T.C. Tan[3], L.K. Tan[2], J.C. Allen[1], Y. Yang[2], S.X.S. Tan[4], L.H. Lee[2]

[1]*Duke-NUS Medical School, Singapore, Singapore,* [2]*Singapore General Hospital, Singapore, Singapore,* [3]*KK Women's and Children's Hospital, Singapore, Singapore,* [4]*Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore*

Background: Pregnancy-associated venous thromboembolism (VTE), which includes deep venous thrombosis (DVT) and pulmonary embolism (PE), although uncommon, is associated with high maternal mortality and morbidity. Generally thought to be more common in Caucasians than in Asians, recent studies show that the incidence of pregnancy-associated VTE in the Asian population has been on the rise and is approaching that of Western populations (0.71-1.99 per 1000 deliveries).

Aims: To evaluate the incidence and risk factors of pregnancy-associated VTE in the SingHealth cluster.

Methods: Medical records of women from KK Women's and Children's Hospital and Singapore General Hospital with pregnancy-associated VTE that occurred between 2004 and 2015 were retrospectively reviewed. VTE cases diagnosed during pregnancy or within 6 weeks postpartum and confirmed on imaging were analysed for risk factors and timing of thromboembolism.

Results: Among 156,862 deliveries there were 73 cases of VTE, with an overall incidence of 0.465 per 1000 deliveries. 2 cases (2.7%) resulted in maternal death. There were 62 cases of DVT (0.395 per 1000 deliveries) and 13 cases of PE (0.083 per 1000 deliveries), of which 2 were concurrent DVT and PE. 43.5% of DVT cases were diagnosed in the first trimester, and 71.0% were in the left lower limb. Majority of PE cases were diagnosed in the first week postpartum (61.5%) with Malay ethnicity associated with increased risk (OR 3.85, 95% CI 1.00, 14.93; p=0.050). Increased risk of VTE was associated with caesarean section (OR 3.19, 95% CI 1.40, 7.27; p=0.006).

TABLE 1 Timing of pregnancy-associated venous thromboembolism

Stage of pregnancy	DVT	PE	Both	VTE (%)
1st trimester	27	0	0	27 (37.0%)
2nd trimester	13	1	0	14 (19.2%)
3rd trimester	7	2	0	9 (12.3%)
Week 1 postpartum	6	8	0	14 (19.2%)
Week 2 postpartum	3	0	2	5 (6.8%)
Week 3 postpartum	2	0	0	2 (2.7%)
Week 4 postpartum	1	0	0	1 (1.4%)
Week 5 postpartum	1	0	0	1 (1.4%)
Week 6 postpartum	0	0	0	0 (0.0%)

TABLE 2 Sites of pregnancy-associated deep venous thrombosis

Sites of DVT	Number of cases (n=62)	Proportion of cases (%)
Left leg (total/proximal/distal/both)	44/28/11/5	71.0/45.2/17.7/8.1
Right leg (total/proximal/distal/both)	13/10/1/2	21.0/16.1/1.6/3.2
Both legs (total/proximal/distal/both)	3/1/1/1	4.8/1.6/1.6/1.6
Left brachial vein	1	1.6
Mesenteric veins	1	1.6

Conclusions: Incident prevalence of pregnancy-associated VTE in Singapore´s multi-racial Asian population appears lower than what is generally reported in Western populations. Caesarean section and Malay ethnicity were found to be significant risk factors for VTE and PE, respectively. Women in these categories should be considered as candidates for thromboprophylaxis.

PB 1886 | The Features of Pregnancy Management in Paroxysmal Nocturnal Hemoglobinuria

M. Vinogradova[1], A. Kulagin[2], T. Kirsanova[1], R. Shmakov[3]

[1]Federal Scientific Centre for Obstetrics, Gynecology and Perinatology, Hematology, Moscow, Russian Federation, [2]Pavlov First Saint Petersburg State Medical University, Hematology, Saint Petersburg, Russian Federation, [3]Federal Scientific Centre for Obstetrics, Gynecology and Perinatology, Obstetrics, Moscow, Russian Federation

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a life-threatening disorder with a high risk of thrombosis due to chronic complement-mediated hemolysis. The management of PNH during pregnancy recently has been challenging because of frequent severe maternal and fetal complications. The combination of targeted therapy with eculizumab and anticoagulants radically changed the prognosis in PNH and made it possible not only to increase the survival rate, but also to improve the quality of life.

Aims: to analyze the pregnancy outcomes depending on the therapeutic approach.

Methods: From 1999 to 2016 we have analyzed 29 pregnancies in PNH patients. 15 patients from 2013 exposed to eculizumab during pregnancy with anticoagulants (group 1). Other women (group 2) received only symptomatic therapy (anticoagulation with low molecular weight heparin in intermediate or therapeutic doses. The median age at the start of pregnancy - 25 years (21-34). 21,4% patients registered venous thromboembolism before conception.

Results: Clinical manifestations of hemolysis significantly regressed during eculizumab treatment: normalization of LDH was registered in 71,4% patients. Without eculizumab LDH level increased in all pregnant patients. No thrombotic events during pregnancy and postpartum have been observed. Pregnancy complications were less frequent with eculizumab: abortion threat 40% vs 85,7%, fetal growth retardation syndrome 6,7% vs 21,4%, preeclampsia 6,7% vs 14,3%. Pregnancies resulted in the birth in 100% patients exposed eculizumab and 42,9% on supportive treatment.

Conclusions: Pregnancy in PNH with symptomatic treatment with a high probability ends adversely. The risk of complications during pregnancy and postpartum in PNH may be minimized by applying the management algorithm with eculizumab and anticoagulation treatment. We can conclude that pregnancy outcomes in PNH patients with eculizumab are better than with symptomatic therapy only.

PB 1887 | High Levels of Complement C3 Increases the Risk for Postnatal Venous Thrombosis

A.E.A. Dahm[1,2], E.M. Jacobsen[3], A.F. Jacobsen[4], H. Skuterud Wik[3], P.M. Sandset[4]

[1]Akershus University Hospital, Hematology, Lørenskog, Norway, [2]University of Oslo, Oslo, Norway, [3]Oslo University Hospital, Oslo, Norway, [4]Oslo University Hospital and University of Oslo, Oslo, Norway

Background: Venous thrombosis (VT) is one of the most serious complications to pregnancy in developed countries. The complement system is part of the innate immune system. It has been suggested that the complement system and the coagulation system cross-talks and high levels of C3 is associated with VT.

Aims: To investigate complement C3 in blood as a risk factor for pregnancy related VT.

Methods: We investigated women in the Norwegian VIP study which is a population based case-control study of VT in pregnancy or within 3 months post partum (cases, n=313) and women without pregnancy related VT (controls, n=353). Informed consent was obtained from all women and the study was approved by the regional medical ethics committee. C3 was analyzed in blood by Behring Nephelometer II (BN II) by immunonephelometry using antisera to Human Complement C3c (Siemens Healthcare Diagnostics, Deerfield, IL, USA). C3 levels above the 90th percentile in the controls was investigated as a risk factor for pregnancy related VT. Antenatal and postnatal VT were analyzed separately. Odds ratios were calculated with logistic regression.

Results: We first investigated determinants of C3 levels in the control women without pregnancy related VT. We found that C3 levels were strongly correlated with body mass index (BMI, r = 0.60) and C-reactive protein (CRP, r = 0.70), but not with smoking.

C3 in blood above the 90th percentile (1.33 g/L) was not associated with antenatal VT, odds ratio 0.87 (95% confidence interval (CI) 0.43-1.7). Adjustment for high CRP and BMI > 25 with multiple logistic regression did not change the odds ratio.

C3 in blood above the 90th percentile increased the risk for postnatal VT, odds ratio 3.0 (95% CI 1.8-5.0). After adjustment for BMI >25, the odds ratio was 2.0 (1.1-4.0). Adjustment for high CRP did not change the odds ratio for postnatal VT.

Conclusions: C3 levels above the 90th percentile increases the risk for postnatal VT, but not for antenatal VT.

PB 1888 | Risk of Venous Thromboembolism in Unsuccessful ART Cycles: An Italian Cohort Study

M. Villani[1], D. Colaizzo[1], F. Cappucci[1], P. Totaro[2], G. Favuzzi[1], M. Margaglione[3], E. Grandone[1]

[1]*I.R.C.C.S. ‚Casa Sollievo della Sofferenza', Atherosclerosis and Thrombosis Unit, San Giovanni Rotondo, Italy,* [2]*Centro PMA ‚Casa di Cura Santa Maria', Bari, Italy,* [3]*University of Foggia, Medical Genetics, Foggia, Italy*

Background: Assisted reproductive technologies (ART) have been associated with an increased risk of venous thromboembolism (VTE). In recent studies, it has been reported a 5-fold increased risk in pregnancies after ART as compared to that observed in spontaneous ones (8.5 ‰ vs 1.8 ‰). On the other hand, little is known about the VTE risk in unsuccessful ART cycles.

Aims: To assess

1) the absolute risk of VTE in unsuccessful ART cycles,

2) the weight of all known risk factors,

3) the potential benefit of antithrombotic prophylaxis.

Methods: This observational study was based on a cohort of 998 women approaching ART between April 2002 and July 2011, consecutively referred by local Fertility Clinics to our Unit. All women were investigated for the presence of inherited (Factor V Leiden, prothrombin 20210A mutation, deficiencies in protein S and C and antithrombin) and acquired (antiphospholipid antibodies - aPL) thrombophilias. Clinical information were collected during office visits and/or by phone interviews. Women undergone at least 1 unsuccessful ART cycle (negative pregnancy test) and with a negative personal history for VTE were selected.

Results: Among 671 women undergone ART, 512 experienced at least 1 unsuccessful ART cycle for a total of 1518 failed attempts. VTE was observed in 2 out of 1518 (1.3‰) unsuccessful cycles. Both cases, isolated pulmonary embolism, occurred in absence of antithrombotic prophylaxis: the first one in an overweight (BMI: 26) and aPL-positive woman, the second one in a 45 years old overweight (BMI: 31) woman; both cycles were complicated by OHSS.

Conclusions: In women undergone unsuccessful ART cycles we found a lower VTE incidence than that previously reported in women after successful cycles (1.3‰ vs 8.5 ‰). However, both the recorded events are potentially life-threatening. Antithrombotic prophylaxis could be efficacious in the prevention of ART-related VTE. Further studies on the potential benefit of thromboprophylaxis are needed.

PB 1889 | M2 Haplotype in Annexin A5 Gene and Antiphospholipid Antibodies: Possible Relationship and Clinical Impact in a General Obstetric Population

M. Villani[1], E. Chinni[1], G.L. Tiscia[1], F. Cappucci[1], L. Fischetti[1], M. Margaglione[2], E. Grandone[1]

[1]*I.R.C.C.S. ‚Casa Sollievo della Sofferenza', Atherosclerosis and Thrombosis Unit, San Giovanni Rotondo (Foggia), Italy,* [2]*University of Foggia, Medical Genetics, Foggia, Italy*

Background: M2 haplotype in the Annexin 5 (ANXA5) gene has been associated with the occurrence of gestational vascular complications. More recently, in M2 carriers a higher susceptibility to develop antiphospholipid antibodies (aPL) has been suggested.

Aims: To prospectively evaluate, in general obstetric population, the possible relationship between the M2 haplotype and aPL, and M2 haplotype and/or aPL and obstetric outcomes.

Methods: From an initial cohort of 3097 pregnant women consecutively admitted to 14 obstetric and gynaecology wards of the Campania region (Italy) during a 15-month period (November 2000 - January 2002), 1286 samples were analysed for the presence of both anticardiolipin and anti β2-Glycoprotein I antibodies; samples with available DNA (n= 606) were also investigated for the M2 haplotype.

Results: Overall, 233/1286 (18.1%) women showed the presence of aPL. Among them, 26 (11.1%) experienced a pregnancy loss in the current pregnancy, 201 (86.3%) gave birth to live-born babies (p: ns vs those w/o aPL). M2 haplotype was identified in 140 (23.1%) out of 606 women with DNA available: 20/140 (14.3%) M2 carriers and 97/466 (20.8%) non-carriers tested positive for aPL, respectively (p: ns). 22/227 (9.7%) M2 and/or aPL carriers, and 31/359 (8.6%) non aPL and/or M2 carriers suffered from obstetric complications (p: ns).

Conclusions: In general obstetric population, no relationship between M2 haplotype and presence of aPL was found. Furthermore, neither the M2 haplotype nor aPL were associated with adverse obstetric outcomes. Therefore, in low-risk pregnant women the routine investigation of M2 haplotype and/or aPL is not justified.

PB 1890 | Recurrent Miscarriage Predictive Capacity Using Thrombo inCode - Recurrent Miscarriage

J.A. Páramo[1], J. Bellver[2], P. Llamas[3], S. Cabanillas[2], R. Lecumberri[1], P. Alamá[2], A. García-Raso[3], A. Alfonso[2], V.H. Gómez[2], C. Miranda[3], C. Díaz[4], K. Guillén[5], S. Pich[5], I. Ortega[5], E. Salas[5]

[1]*Clínica Universitaria de Navarra, Hematology, Pamplona, Spain,* [2]*Valencian Infertility Institute, Human Reproduction Unit, Valencia, Spain,* [3]*Hospital Universitario Fundación Jiménez Díaz, Hematology, Madrid, Spain,* [4]*Hospital Universitario y Politécnico La Fe, Obstetrics and Gynecology Service, Valencia, Spain,* [5]*Gendiag.exe, S.L, Esplugues Llobregat, Spain*

Background: Recurrent miscarriage (RM) is a clinical problem affecting 1-5% of couples of reproductive age. The contribution of thrombophilia to RM is disputed. This controversy is partly due to low

sensitivity of the genetic variants currently used to evaluate hereditary thrombophilia: the Leiden mutation (identified as rs6025) in the coagulation factor 5 (F5L) gene and mutation G20210A (identified as rs1799963) in the prothrombin (PT) gene.

Aims: Our objective was to determine whether a wider algorithm that includes clinic and genetic variants associated with thrombophilia could be more useful in the prediction for RM than FVL and PT alone.

Methods: A prospective case-control study was carried out. The study included 184 cases of idiopathic early (less than 20 weeks) recurrent miscarriages (not advanced maternal age, normal paternal karyotypes, uterus without disorders, absence of antiphospholipid syndrome or endocrinopathy, obesity or chronic systemic diseases) and 183 healthy women with at least one pregnancy to term and no previous miscarriage. Informed consent was obtained from all of the participants and the studies were approved by the Institutional medical ethics committees. Two algorithms were analysed in each study (see table1).

TABLE 1 Parameters included in 'TiC-recurrent miscarriages' and 'F5L-PT'

TiC-recurrent miscarriages	F5L-PT
F5-Leiden-rs6025	F5-Leiden-rs6025
PT-rs1799963	PT-rs1799963
F5-Hong Kong-rs118203906	
F5-Cambridge-rs118203905	
F12-rs1801020	
F13-rs5985	
Serpin-C1-rs121909548, Serpin-A10-rs2232698	
AB0-rs8176719, rs8176750, rs7853989,rs8176743	
Age, Gender, Body Mass Index, Smoking and Family history of VTE	

The predictive capacity was determined by AUC, sensitivity, specificity, -LHR and +LHR and diagnostic odds ratio (DOR).

Results: F5L-PT showed a non-significant AUC 0.50 [0.449-0.553]. TiC-RM showed a significant AUC 0.77 , 95%CI [0.722-0.818], with a good sensitivity (73%) and specificity (70%), +LHR was 2.43 and -LR was 0.39. The DOR was 6.3.

Conclusions: TiC-RM proved to better predict patients who would suffer thrombophilia related-RM than the classic F5L and PT algorithm.

PB 1891 | Effect of Blood Loss during Caesarean Section on Coagulation

C. Thomassen[1], T. Hackeng[1], S. Costa[2], E. Stickeler[3], S. Tchaikovski[3]

[1]*University of Maastricht, Cardiovascular Research Institute Maastricht, Maastricht, The Netherlands,* [2]*University of Magdeburg, Magdeburg, The Netherlands,* [3]*University of Aachen, Aachen, Germany*

Background: Venous thrombosis and pulmonary embolism are the leading causes of the maternal morbidity and mortality. The risk of thrombosis is even higher postpartum further increasing following caesarean section and blood loss.

Aims: To study the mechanisms of the prothrombotic state development due to an increased blood loss during caesarean section.

Methods: The endogenous thrombin potential (ETP) and the function of anticoagulant pathways were evaluated via calibrated automated thrombography in the pre- und postoperative plasma samples of 50 pregnant women (age 30,7±4,4 years, 38,5±0,7 weeks of gestation), who underwent a primary caesarean section at the University Clinic of Magdeburg. The blood loss was subjectively und objectively evaluated (weighting of surgical towels and aspirator content and „one-compartmental biometric method") and correlated with the changes in the coagulation system.

Results: Blood loss led to a minor decrease in the ETP: ΔETP -4% (95%CI:-4%;-2%) immediately after a caesarean section and -5% (95%CI:-7%;-2%) in 6 hours postoperatively. In contrast, the ETP in the presence of APC significantly increased immediately after surgery ΔETP_{+APC} 54% (95%CI:28%;80%) and 6 hours postoperatively: 96% (95%CI:48%;144%). The changes both in the ETP and ETP_{+APC} gradually changed in the groups with < 10%; 10-20%, >20% of Hb-decrease. Objective methods of the blood loss evaluation correlated well between each other (Pearson coefficient=0,56), but not with the subjective method.

Conclusions: A mild postoperative ETP decrease reflects a reduction or normalisation of antepartum elevated coagulation factors. The ETP_{+APC} increase indicates an impairment of the anticoagulant pathways' function (protein S, tissue factor pathway inhibitor und APC) that were already decreased in the pregnancy. This results in a simultaneous pronounced deficiency of several anticoagulant proteins, which can explain an increased thrombosis risk following a caesarean section with an increased blood loss.

PB 1892 | Assessment of Peripartum Management in a Population at High Risk for Venous Thromboembolism

C. Berens[1], A. Esser[1], J. Nadal[2], J. Oldenburg[1], B. Pötzsch[1], H. Rühl[1]

[1]*University Hospital Bonn, Experimental Hematology and Transfusion Medicine, Bonn, Germany,* [2]*University Hospital Bonn, Medical Biometry, Informatics and Epidemiology, Bonn, Germany*

Background: Women with a history of VTE or hereditary risk factors are at an increased risk for venous thromboembolism (VTE) in pregnancy. While risks and benefits of anticoagulant treatment have been well studied in this population, less is known about its impact on peripartum management.

Aims: To assess obstetric and anesthesiological management of delivery in women with a history of thrombosis and/or hereditary risk factors for VTE.

Methods: The medical charts of women who delivered at the University Hospital Bonn were reviewed. Women fulfilling the aforementioned inclusion criteria were matched with women without a history or known hereditary risk factors for VTE, who did not receive anticoagulants. Matching criteria were age, gestational age at delivery, and date of delivery.

Results: 114 women were included. 62 of them had a history of thrombosis, thereof 13 in the current pregnancy. In 72 women, hereditary risk factors for VTE were present, including factor V Leiden (n=45), prothrombin G20210 (n=15), and inhibitor deficiencies (n=15). In 42 women with a history of VTE no hereditary risk factors were identified. 90 women received heparin once daily and 13 twice daily. With 50.9% a significantly lower rate of spinal and epidural anesthesia was observed in comparison to the controls (66.7%, p=0.011%). The rates of caesarean section (41.2% vs 47.4% in the control group), vacuum extraction (6.1% vs 7.9%), and vaginal delivery (52.6% vs 44.7%) did not differ significantly. Median (interquartile range) blood loss at delivery was 300 (225-500) ml in comparison to 400 (250-500) ml in the control group. A statistically significant difference between both groups regarding bleeding complications was not observed.

Conclusions: Our data demonstrate that bleeding complications at birth does not occur frequently in women at high thrombotic risk, despite a high rate of anticoagulant treatment. A higher proportion of women with anticoagulant treatment in pregnancy might be eligible for spinal and epidural anesthesia.

PB 1893 | Role of ADAMTS-13 Activity and Inhibitor Monitoring during Pregnancy in Women with History of Severe Preeclampsia

V. Bitsadze, S. Akinshina, A. Makatsariya

I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

Background: The term „thrombotic microangiopathy“ (TMA) brings together clinical conditions of heterogeneous nature characterized by arteriolar and capillary thrombosis with the development of hemolytic anemia, thrombocytopenia and ischemic damages leading to multiple organ failure. Thrombotic thrombocytopenic purpura (TTP) is related to more than 70 mutations of ADAMTS-13. TTP may also be due to decreased activity of ADAMTS 13 under the influence of antibodies (e.g., in patients with antiphospholipid syndrome). Recently it was shown that pregnancy is one of the main initiating agent for development of TTP.

Aims: We studied the role of ADAMTS-13 defects in pathogenesis of severe preeclampsia.

Methods: 128 patients with severe preeclampsia were tested for genetic thrombophilia, antiphospholipid antibodies and elevated homocysteine level. In 60 cases we tested activity of ADAMTS-13 and antibodies titer to ADAMTS-13.

Results: Thrombophilia was detected in 100% women with 2 and more recurrent preeclampsia and in 60% primagravida with preeclampsia. We determined ADAMTS-13 inhibitor in high titer in 11 patients. The basic therapy during pregnancy was low molecular weight heparin guided by D-dimer, serial plasmapheresis in women with low ADAMTS-13 activity, antibodies to ADAMTS-13 and progressive thrombocytopenia. 5 patients with preeclampsia and ADAMTS-13 inhibitor were delivered after 37 weeks, all babies were alive. 4 patients were delivered prematurely with 2 fetal losses.

Conclusions: Severe obstetric complications may be considered as a distinct form of thrombotic microangiopathy, including HELLP-syndrome and severe preeclampsia.

PB 1894 | Assessment of Annexin A5 and Annexin A2 Levels as Biomarkers for Pre-eclampsia: A Pilot Study

M. Abd El-Latif[1], H. Azzam[1], M. Othman[2,3], O. Warda[4], S. El-Sharawy[1], H. Ghoneim[1]

[1]Mansoura University, Clinical Pathology Department, Mansoura, Egypt, [2]Queen's University, Biomedical and Molecular Medicine, Kingston, Canada, [3]St Lawrence College, School of Baccalaureate Nursing, Kingston, Canada, [4]Mansoura University, Gynaecology and Obstetrics Department, Mansoura, Egypt

Background: Dysregulated placental function due to fibrin deposition and microthrombi has been implicated in the pathogenesis of pre-eclampsia (PE). Deficient anticoagulant activity of annexin A5 and deficient profibrinolytic activity of annexin A2 have been linked to increased risk for thrombotic events. The identification of biomarkers that can predict incidence and severity of pre-eclampsia would support improved therapies to prevent adverse maternal and fetal outcomes.

Aims: To assess serum levels of annexin A5 and annexin A2 in a cohort of pre-eclampsia patients and investigate their role as biomarkers for the development of the disease.

Methods: We examined a total of 80 women; 40 with healthy pregnancy and 40 with pre-eclampsia of varying severities. Women were subjected to full clinical assessment, ultrasonography, and laboratory testing including complete blood picture, liver and kidney function tests and serum and urine proteins. Serum Annexin A5 and annexin A2 were analyzed using enzyme-linked immunosorbent assay.

Results: Serum annexin A2 but not annexin A5 was significantly reduced (P=0.03) in women with PE (total and severe cases) when compared to those with normal pregnancy. The ROC analysis of annexin A2 level for the prediction of development of PE showed an area under the curve of 0.64 (P=0.03), and the best cut-off value was 0.89 ng/mL with a sensitivity of 70% and a specificity of 70%. Univariate analysis showed higher systolic and diastolic BP, proteinuria, lower platelet count and annexin A2 (< 0.89ng/ml) was associated with significantly higher risk to develop PE.

Conclusions: Based on this pilot study, serum annexin A2 levels may be a useful biomarker for pre-eclampsia. However, a larger study is required to further support this conclusion.

PB 1895 | Attenuated Thrombin Generation and Enhanced Fibrinolytic Activity in Early Onset Preeclampsia

K. Egan[1], H. O'Connor[2,3], C. Monteith[2,3], K. Parmar[4], B. Kevane[1,5], E. Tully[2,3], F. Malone[2,3], E. Dunne[3], D. Kenny[3], P. Maguire[6], P. Szklanna[6], S. Allen[1], N. Mc Callion[2,3], B.J. Hunt[4], F. Ni Ainle[1,2,5]

[1]*University College Dublin, School of Medicine and Medical Science, Dublin, Ireland,* [2]*Rotunda Hospital, Dublin, Ireland,* [3]*Royal College of Surgeons in Ireland, Dublin, Ireland,* [4]*Guy's and St Thomas' Hospitals, King's College, London, United Kingdom,* [5]*Mater Misericordiae University Hospital, Department of Haematology, Dublin, Ireland,* [6]*University College Dublin, Conway Institute, Dublin, Ireland*

Background: Preeclampsia is a complication of pregnancy with potentially life-threatening consequences for both mother and baby. Early onset preeclampsia (EOP; onset < 34 gestational weeks) is associated with greater maternal and fetal risks than late onset preeclampsia. The risk of venous thromboembolism is increased, particularly in severe preeclampsia. Consequently, mothers may be considered for thromboprophylaxis. However, risk assessment is complicated by competing bleeding risks such as placental abruption, post-partum haemorrhage, or renal impairment.

Aims: To characterise haemostasis in EOP patients to better understand parameters that may modulate thrombotic and bleeding risk in EOP.

Methods: The study was approved by the relevant ethics committee and written informed consent was obtained. Blood samples were collected from pregnant women with EOP (n=26) and matched pregnant controls (n=20). Patients with multiorgan involvement were characterised as severe cases (n=12). Plasma thrombin generation was measured by calibrated automated thrombography. Coagulation activation, fibrinolytic, and platelet activation biomarkers were measured by ELISA.

Results: Compared to controls, EOP patients have reduced Tissue factor-dependent thrombin generation (Peak thrombin (IIa); 150±80 vs. 205±69nM IIa, p< 0.05), which is more pronounced in severe EOP (136±102nM IIa, p< 0.05). There were increased levels of tissue plasminogen activator in EOP (6919±3116 vs. 1767±733ng/ml, p< 0.0001), particularly in severe EOP (8665±2296ng/ml, p< 0.0001) and reduced Plasminogen Activator Inhibitor-2 levels (122±64 vs. 169±17ng/ml, p< 0.05). Consistent with enhanced fibrinolytic activity, there was a trend towards increased D-Dimer levels in EOP (4.6±2.1 vs. 4.1±1.9µg/ml), particularly in severe EOP (5.6± 2.2µg/ml). There was no significant difference in platelet activation markers (soluble GPVI, platelet factor 4, CXCL7) in EOP and controls.

Conclusions: EOP is characterised by decreased thrombin generation and enhanced fibrinolytic activity.

PB 1896 | Management of Venous Thromboembolism in Women during Pregnancy and Puerperium (SAVE): A cross-sectional registry in Africa, Eurasia, Middle East and South Asia

J.-C. Gris[1], J. Aoun[2], SAVE Study Group

[1]*University Hospital, Haematology, Nîmes, France,* [2]*SANOFI, Paris, France*

Background: The modality of VTE prophylaxis during pregnancy and puerperium is not well documented outside Western countries.

Aims: Assess physician's VTE risk management and its adequacy with ACCP / RCOG guidelines.

Methods: International, observational, cross-sectional multicentre study across 18 countries (Dec2014-Oct2015). Consecutive women visiting for first prenatal consultation or any other consultation during pregnancy or puerperium were enrolled. VTE or antithrombotics led to exclusion. Assessments were made based on Investigator's questionnaires and CRFs. The quality control and validation of data was performed independently from investigators by a contract research organisation.

Results: The majority of women at risk received prophylaxis globally and similarly across regions except South Asia, where 23% women did not receive the prophylaxis as per guidelines. Thromboprophylaxis was prescribed in 47.7% of the patients, rarely in South Asian patients, commonly in African and Middle Eastern women, very often in Eurasian women. Lower rates of thromboprophylaxis during puerperium were observed in Eurasia and South Asia, higher in Africa. This was performed during pregnancy by pharmacological treatments (42.4%: LMWH in 73.5%, aspirin in 46.3%), mechanical treatments (11.5%) or both (46.2%) with heterogeneities across regions. A similar pattern was evidenced during puerperium. Prophylaxis in women at risk was rarer in Blacks and South Asians than in Caucasians. Assisted reproduction technology and Caesarean section were key factors determining prophylaxis, with heterogeneities across regions. Absence of available proof was frequently evoked for not prescribing. More than 80% of physicians declared following the guidelines.

Conclusions: The SAVE registry shows that consulting physicians manage at risk women with appropriate prophylaxis. However, discrepancies observed between the regions warrants further efforts to improve implementation of the guidelines.

PB 1897 | Genetic Variants Associated with Thrombophilia and Gestational Complications in an Argentinian Cohort

G. de Larrañaga[1], F. Aranda[1], S. Udry[2], M. Moiana[1], A. Lucero[1], V. Lara[1], O. Latino[2], S. Perés[1]

[1]*Hospital of Infectious Diseases F. J. Muñiz, Hemostasis and Thrombosis Laboratory, Buenos Aires, Argentina,* [2]*Hospital Carlos G Durand, Section of Autoimmune Diseases, Thrombophilia and Pregnancy, Buenos Aires, Argentina*

Background: Factor V Leiden (FVL) and Prothrombin 20210A (II20210A) have been recognized as risk factors for recurrent

pregnancy loss (RPL) by impairing normal placental vascular function. Other genetic variants as Fibrinogen-γ´10034T (FGG10034T) and Factor XI 7872C (FXI7872C) have been associated with a higher risk of venous thrombosis but their role in RPL is unknown.

Aims: The aim of this study was to analyze the association of FVL, II20210A, FGG10034T and FXI7872C with: 1) the risk and timing of RPL and 2) the risk of suffering other obstetric complications: intrauterine growth restriction (IUGR), placental abruption and preeclampsia, among Argentine women.

Methods: We performed a case-control study including 247 Argentine women (cases) with idiopathic RPL and 100 fertile controls (women in post-fertile age with ≥2 successful pregnancies and had never experienced any obstetric complication). Cases were stratified in early, n=87 (≥ 2 idiopathic consecutive failed pregnancies < 10th week) and late losses, n=155 (>10th week). FVL, II20210A, FGG10034T and FXI7872C were genotyped both in RPL and control groups.

Results: No differences were found in the distribution of the four genetic variants either among RPL (Figure 1), early or late losses groups vs controls, respectively (p>0.05).

Similarly, no differences were observed in its distributions when we analyzed RPL patients stratified according to obstetric complications (p>0.05), except for the FVL carriage in patients with IUGR vs controls (11.8%, 4/34 vs 2%, 2/100; p=0.017). FVL would be associated, independently from other inherited and acquired thrombophilia, with a higher risk of IUGR [OR=7.11 (1.24-40.93), p=0.028] (Figure 2)

Conclusions: Our results highlight the importance of FVL in obstetric complications, particularly with IUGR, and makes it a suitable candidate to be further evaluated in future investigations. This is the first study that analyzes the potential impact of the genetic variants FGG 10034T and Factor XI 7872C on RPL.

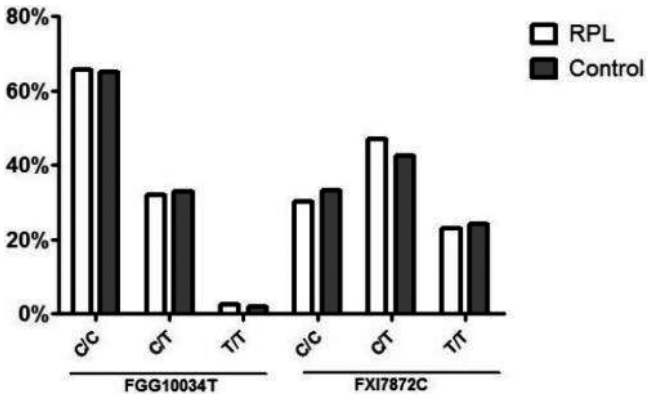

FIGURE 1 Genotype frequencies of FGG10034T and FXI7872C among patients with recurrent pregnancy loss (RPL) and controls

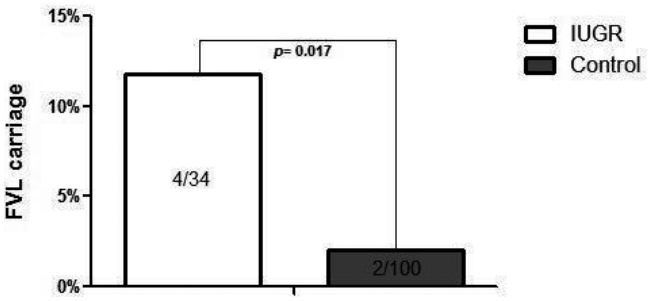

FIGURE 2 Distribution of FVL carriage in patients with intrauterine growth restriction (IUGR) and controls

PB 1898 | Risk Factors for Venous Thromboembolism and Pregnancy Outcomes in Women with Pelvic Vein Thrombosis during Pregnancy - A Retrospective Study from a Stockholm Cohort, Ranging from 2000 to 2014

R. Chaireti[1,2], S. Lundgren Hinnerdal[3], K. Bremme[3]

[1]Karolinska Institutet, Department of Molecular Medicine and Surgery, Stockholm, Sweden, [2]Karolinska University Hospital, Department of Hematology, Stockholm, Sweden, [3]Karolinska Institutet, Department of Women´s and Children´s Health, Stockholm, Sweden

Background: Pelvic vein thrombosis is rare outside of pregnancy and pelvic surgery. The recommended anticoagulant treatment is low molecular weight heparin. There is a lack of studies specifically on risk factors for antenatal pelvic vein thrombosis and the safety and efficacy of the administered treatment.

Aims: To document risk factors for antenatal pelvic vein thrombosis, evaluate maternal and foetal outcomes and pregnancy complications.

Methods: The medical records of 39 women who developed antenatal pelvic vein thrombosis and were treated at the Karolinska University Hospital during 2000-2014 were reviewed. The incidence of bleeding complications was used to evaluate safety and the number of recurrent thromboses was used to study efficacy.

Results: The majority of the women were nulliparous (82.1%) and had blood group A (74.4%) and half of them had thrombophilia (51.3%). One third (33.3%) suffered postpartum haemorrhage (PPH, ≥500ml) and 5.1% had severe PPH (≥1000 ml). No patient experienced recurrent thrombosis. One child (2.5%) was born small for gestational age and one patient (2.6%) was diagnosed with preeclampsia.

Conclusions: Nulliparity and blood group A were overrepresented in this cohort, as previously reported for patients with thrombosis. The anticoagulant treatment is effective in preventing recurrent thrombosis, but is appears to entail a somewhat increased risk for non-severe bleeding complications. No increased risk for maternal and foetal complications was observed. Studies on larger cohorts are needed in order to confirm these findings.

PB 1899 | Maternal Carriage of the Annexin A5 M2 Haplotype is Associated with a Higher Risk of Suffering from Gestational Vascular Complications

F. Aranda[1], S. Udry[2], S. Perés[1], L.C. Amshoff[3], N. Bogdanova[3], P. Wieacker[3], M. Moiana[1], J.O. Latino[2], G. de Larrañaga[1], A. Markoff[3]

[1]*Hospital of Infectious Diseases F. J. Muñiz, Hemostasis and Thrombosis Laboratory, Ciudad Autónoma de Buenos Aires, Argentina,* [2]*Hospital Carlos G. Durand, Section of Autoimmune Diseases, Thrombophilia and Pregnancy, Ciudad Autónoma de Buenos Aires, Argentina,* [3]*Institute of Human Genetics, University Clinic Muenster, Muenster, Germany*

Background: Annexin A5 (ANXA5) is a protein abundantly expressed in normal placenta where it was proposed to exert an anticoagulant function. The carriage of the ANXA5 M2 promoter haplotype results in a reduced expression of placental ANXA5 and was associated with an increased risk of Recurrent Pregnancy Loss (RPL) and other placental-mediated pregnancy complications (PMPC), in different European and Asian populations.

Aims: Our aim was to assess the association between maternal carriage of the ANXA5 M2 haplotype and: a) the risk of RPL, b) its influence on the timing of the losses and c) the risk of suffering other PMPC, for the first time in a Latin America population.

Methods: The case-control study included 229 women with RPL and 100 parous controls without pregnancy complications. Moreover, patients were stratified according to: a) the timing of miscarriages: early (< 10 weeks), late (≥10 weeks) and fetal losses (≥20 weeks) and b) having suffered or not these PMPC complications: intra uterine growth restriction (IUGR) and/or pre-eclampsia (PE).

The proximal core promoter region of the *ANXA5* gene was analyzed by amplicon sequencing in all subjects. Differences in the maternal *M2/ANXA5* carriage rate between groups were assessed using the chi-square test. The *odds ratio* (OR) was estimated by binary logistic regression adjusted for potential confounding variables.

Results: An association between maternal carriage of *M2/ANXA5* with predisposition to RPL only, or with the timing of pregnancy losses could not be confirmed. However, the results indicated that it would be associated (OR=2.38; 95%CI 1.04 to 5.45) with a higher risk of suffering IUGR and/or PE, not limited to miscarriage.

Conclusions: The maternal carriage of the ANXA5 M2 haplotype would be partly responsible for the onset of IUGR and/or PE, probably through reducing ANXA5 placental expression. This could be of direct relevance as *M2/ANXA5* might be considered in the diagnostic work-up as a prognostic marker of these gestational vascular complications.

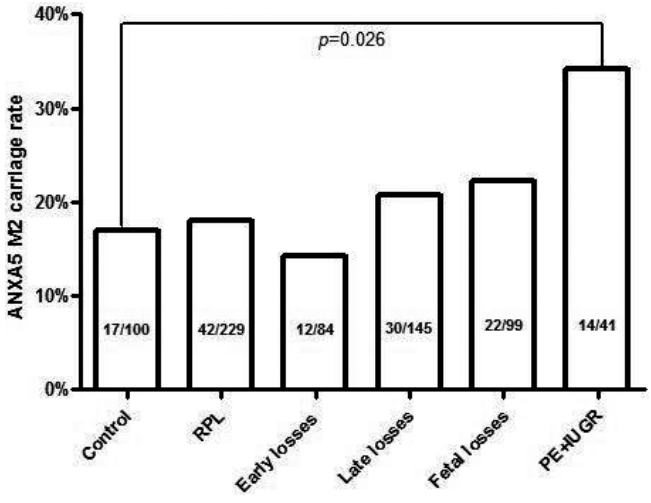

FIGURE 1 Maternal carriage of the ANXA5 M2 haplotype among RPL, PMCP and control groups

PB 1900 | Pregnancy-associated Hemolytic Uremic Syndrome as a Cause of Maternal Mortality

T. Kirsanova, M. Vinogradova

Federal Scientific Centre for Obstetrics, Gynecology and Perinatology, Moscow, Russian Federation

Background: Pregnancy-associated hemolytic uremic syndrome (P-aHUS) is a severe disorder with a high risk of maternal and fetal morbidity and mortality, defined by the occurrence of comlement-mediated thrombotic microangiopathy (TMA) without ADAMTS13 deficiency. Triggered by pregnancy and another complement-amplifying conditions women develop the syndrome, leading to a disastrous hemolytic disease characterized by diffuse endothelial damage and platelet consumption.

Aims: The evaluation of outcomes depending on the therapeutic approach.

Methods: We present the retrospective analysis of 31 P-aHUS cases.

Results: Pregnancy complications included mild preeclampsia (61%), anthenatal fetal death (32%), 32% of patients were urgency delivered (27-37 weeks). Massive uterine bleeding required hysterectomy occured in 23,2%. Acute kidney injury registered in 100% patients, neurological symptoms had 61%, respiratory distress syndrome- 55%, dilated cardiomyopathy- 16,7%. 61,3% required hemodialysis, 51,8%- respiratory care. All of them underwent plasma exchange and received low molecular weight heparin, 45,1% treated with eculizimab (but a full course was not held anyone). All of patients who died had 2 “waves” of TMA: first wave have damaged 2-5 organs without any proved infections, but treated with combination of antibiotics.Second TMA wave was fatal due to superimposed septic disorders, resistant to antibiotic therapy. Patients on eculizumab treatment had more severe disease at debut with shorter history of aHUS and responded well to eculizumab. 6 other patients died from 2-7 days.

Overall outcomes were poor: died 32%, reached the end stage renal disease by 1 month 19%. Survival on eculizumab treatment was 71,4%, without it - 64,7%.

Conclusions: P-aHUS is a life-threatening disorder associated with a significant maternal morbidity and mortality. Timely diagnosis and effective approaches including early prescribed targeted therapy can improve the survival rate and pregnancy outcomes.

PB 1901 | The Role of Acquired von Willebrand Syndrome in Bleeding during Pregnancy and Cesarean Section in Patients with Hereditary Connective Tissue Diseases (Marfan Syndrome, Ehlers-Danlos Syndrome, Hereditary Hemorrhagic Telangictasia)

L. Radetskaya[1], A. Makatsariya[2], O. Kaplina[1]

[1]*I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation,* [2]*I.M. Sechenov First Moscow State Medical University, Нахабино, Russian Federation*

Background: The term of acquired von Willebrand syndrome(AVWS)is now accepted for patients with predominant underlining diseases that lead to defective von Willebrand factor(VWF). In recent years there has been a progressive increase of publications concerning patients with defective VWF in whom the family history and the late onset of bleeding symptoms speak against an inherited forms. The inherited connective tissue diseases is a group of diseases with connective tissue deficiency various localizations. All of this patients have bleeding symptoms due to the connective tissue deficiency in vascular wall. Pregnancy and delivery in such patients are complicated by repeated bleeding and massive hemorrhage. We supposed that AVWS can play an important role in bleeding symptoms in patients with hereditary connective tissue diseases together with deficiency of vascular wall.

Aims: To evaluate the role of AVWS in bleeding symptoms during pregnancy and cesarean section in patients with hereditary connective tissue diseases.

Methods: We describe our experience in diagnosing AVWS in56 pregnant women with confirmed diagnosis of hereditary connective tissue diseases(23with Marfan syndrome, 22 with Ehlers-Danlos syndrome, 11with hereditary hemorrhagic telangictasia (HHT) over more than 8 years.

Results: All pregnant patients had bleeding various localizations. Marfan patients also had cardiovascular complications:18women developed increasing of mitral regurgitation, 10 aortic insufficiency, 13 mitral valve insufficiency. 1 patient with Marfan syndrome was died due to aortic dissection in 45 day after delivery. Cesarean section was performed in 53. AVWS was established in18 patients with hereditary connective tissue diseases.

Conclusions: AVWS can play an important role in bleeding symptoms during pregnancy and cesarean section in patients with hereditary connective tissue diseases together with deficiency of vascular wall. Patients with hereditary connective tissue diseases require the multidisciplinary care and repeated testing for AVWS.

PB 1902 | Impact of Blood Hypercoagulability on in vitro Fertilization Outcomes: A Prospective Longitudinal Observational Study

P. Van Dreden[1], E. Lefkou[2], E. Mathieu d'Argent[3], M. Grusse[1], M. Comtet[3], R. Sangare[4], H. Ketatni[5], A. Larsen[6], I. Elalamy[2,6], G. Gerotziafas[4,6]

[1]*Diagnostica Stago, Clinical Research Department, Gennevilliers, France,* [2]*Hôpital Tenon, Hôpitaux Universitaires Est Parisien, Assistance Publique Hôpitaux de Paris, Service d'Hématologie Biologique, Paris, France,* [3]*Hôpital Tenon, Hôpitaux Universitaires Est Parisien, Assistance Publique Hôpitaux de Paris, Department of Obstetrics and Gynecology, Paris, France,* [4]*Hôpital Tenon, Hôpitaux Universitaires de l'Est Parisien, Assistance Publique Hôpitaux de Paris, Service d'Hématologie Biologique, Paris, France,* [5]*Hôpital Tenon Hôpitaux Universitaires de l'Est Parisien, Assistance Publique Hôpitaux de Paris, Service d'Hématologie Biologique, Paris, France,* [6]*Centre de Recherche Saint-Antoine, Institut National de la Santé et de la Recherche Médicale (INSERM) U 938 and Université Pierre et Marie Curie (UPMC), Sorbonne Universities, Cancer Biology and Therapeutics, Paris, France*

Background: Blood coagulation is crucial in the implantation process and its alteration may be related to in vitro fertilization (IVF) failure.

Aims: We conducted a prospective observational longitudinal study in women eligible for IVF to explore the association between coagulation alterations with the IVF outcome and to identify the biomarkers of hypercoagulability which are related with this outcome.

Methods: 38 women eligible for IVF (IVF-group) and 30 healthy, age-matched women (control group). In the IVF-group blood was collected at baseline, 5-8 days after gonadotropin-releasing hormone agonist (GnRH) administration, before human recombinant chorion gonadotrophin administration and two weeks after hCG injection. Pregnancy was monitored by measurement of βHCG performed 15 days after embryo transfer. Thrombin generation (TG), whole blood thromboelastometry (ROTEM®), procoagulant phospholipid clotting time (PPL), thrombomodulin (TMa), Tissue factor activity (TFa), factor VIII (FVIII), factor von Willebrand (FvW), D-Dimers and fibrinogen were assessed at each time point.

Results: Positive IVF occurred in 15 women (40%). At baseline, the IVF-group showed significantly increased TG, TFa and TMa and significantly shorter PPL versus the control group. After initiation of hormone treatment TG was significantly higher in the IVF-positive group as compared to the IVF-negative. At all studied points, the PPL was significantly shorter and the levels of TFa were significantly higher in the IVF-negative group compared to the IVF-positive one. The D-Dimers were higher in the IVF negative as compared to IVF positive group. Multivariate analysis retained the PPL and MRI of TG as predictors for the IVF outcome.

Conclusions: The diagnosis of women with hypercoagulability and their stratification to risk of IVF failure using a model based on the PPL and TG is a feasible strategy for the optimisation of IVF efficiency that needs to be validated in prospective trials.

PB 1903 | Women with Homozygous AT Deficiency Type II Heparin Binding Site (HBS) Are at High Risk of Pregnancy Loss and Pregnancy Complications

J. Kraft[1], R. Sunder-Plassmann[2], P. Quehenberger[2], G. Tews[3], M. Langer[4], I. Pabinger[1]

[1]Medical University of Vienna, Department of Medicine I, Clinical Division of Hematology and Hemostaseology, Vienna, Austria, [2]Medical University of Vienna, Department of Laboratory Medicine, Division of Medical and Chemical Laboratory Diagnostics, Vienna, Austria, [3]IVF- and Kinderwunschinstitut, Wels, Austria, [4]Medical University of Vienna, Department of Obstetrics and Fetomaternal Medicine, Vienna, Austria

Background: Homozygous antithrombin (AT) deficiency type II HBS is a very rare and severe thrombophilia. Data regarding outcome and therapy of pregnancies in such women are scarce.

Aims: To get a better insight into pregnancy outcome and to identify suitable management procedures.

Methods: After institutional ethical approval a retrospective, descriptive investigation on the obstetric history of women with this thrombophilia was conducted.

Results: Eight women with homozygous AT deficiency type II HBS and at least one pregnancy were identified, each had the mutation c.391C>T p.Leu131Phe in the AT gene (SERPINC1). AT activity levels ranged between 12% and 32%, patients were between 13 and 23 years at first venous thromboembolism (table 1).

TABLE 1 Patient characteristics and first thrombotic events before their first pregnancy

Patient	First thrombotic event	Age at first TE	Age at diagnosis	AT activitiy Level
1	Unprovoked DVT right leg	13	18	12%
2	Provoked DVT right leg and pelvic veins	20	20	13%
3	Provoked DVT left leg	23	23	16%
4	Unprovoked DVT right leg and pelvic veins	16	23	22%
5	Povoked DVT right leg and pelvic veins	18	29	20%
6	No thrombotic events	n/a	35	32 %
7	Unprovoked DVT right leg	23	23	17%
8	Provoked PE	18	22	31%

Overall, the women reported 23 pregnancies between the years 1989 and 2013. One pregnancy was excluded, since it ended by induced abortion. Only seven out of the 22 pregnancies were successful with a live infant, however, all of them were born preterm. Patients suffered seven early pregnancy losses and eight intrauterine fetal deaths. The treatment regimes were widely spread, not least due to the rareness of the disease and thereof resulting lack of experience. The following regimens (figure 1) were used: low molecular weight heparin, intermittent AT concentrates, or a combination of both, or treatment with vitamin K antagonists (VKA). We found no clear association between treatment protocols and outcome. No anticoagulation was given during eight pregnancies and all of those ended in pregnancy loss.

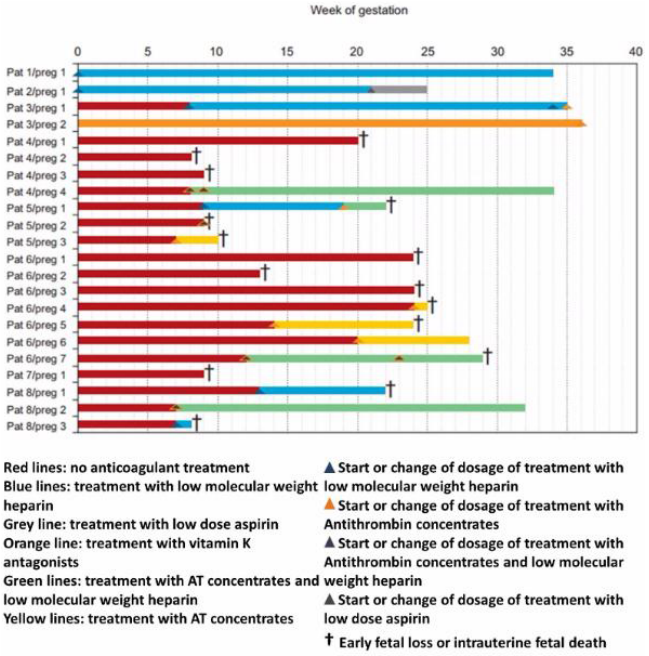

FIGURE 1 Treatment during pregnancy and pregnancy outcome

Conclusions: This rare thrombophilia is associated with a very high risk of pregnancy loss and preterm delivery. Anticoagulation and even AT replacement were only partially successful. VKA might be more effective, but the teratogenic effect has to be kept in mind. We surmise that women with homozygous AT deficiency type II HBS need a rigorous and preferably heparin-independent anticoagulation or intensified AT replacement.

PB 1904 | Use of Intravenous Immunoglobulin in the Antenatal Management of Haemolytic Disease of the Fetus and Newborn (HDFN): A Case Series from the East Midlands, United Kingdom

G. Swallow[1], B. Myers[2], J. Davis[3], A. Dillon[3], E. Millen[4], A. Mahendru[5]

[1]Nottingam University Hospital NHS Trust, Haematology, Nottingham, United Kingdom, [2]University Hospitals of Leicester NHS Trust, Haematology, Leicester, United Kingdom, [3]Nottingham University Hospital NHS Trust, Haematology, Nottingham, United Kingdom, [4]University Hospitals of Leicester NHS Trust, Haematology, Nottingham, United Kingdom, [5]Nottingam University Hospital NHS Trust, Obstetrics and Gynaecology, Nottingham, United Kingdom

TABLE 1 Antibody level, antenatal intervention, gestation at delivery and treatment in the neonate for the twocomparable pregnancies in our cases

Patient	Antibody	Booking and (peak) antibody level non IVIG treated	Booking and (peak) antibody level IVIG treated	Gestation IVIG commenced (weeks) in treated pregnancy	Gestation IUT commenced (weeks) non IVIG treated	Gestation IUT commenced (weeks)IVIG treated	Gestation at delivery (Weeks) non IVIG treated	Gestation at delivery (Weeks) IVIG treated
1	anti D (IU/ml)	5 (468)	18.5 (161)	14	28	31	34+4	34+2
2	anti D (IU/ml)	73 (83.1)	264 (264)	14	18	20	34	IUFD 21+4
3	anti D (IU/ml)	7 (23.6)	25.6 (25.6)	15	33+4	not required	33+5	35
4	anti D (IU/ml)	2.3 (29.3)	15.4 (unable to quantify anti C+G)	18	not required	32+2	35+5	34+4
5	anti D (IU/ml)	8 (24)	35 (35)	14 (1 dose)	not required	22+2	36	34+6
6	anti D (IU/ml)	8 (unable to quantify anti C+G)	554 (554)	16	not required	Not required (IUFD 19+6)	34	NA
7	anti K (titre)	1024 (2000)	8000 (8000)	16	26+6	28+2	IUFD 29	31+1
8	anti K (titre)	none detected	256 (2000)	17	not required	34+1	42	34
9	anti K (titre)	1024 (1024)	2048 (2048)	16	Early miscarriage	18+4	Early miscarriage	33

Background: Red cell alloimmunisation complicates approximately 3% of pregnancies. Standard of care involves fetal monitoring and intervention with intrauterine transfusion (IUT) if signs of anaemia develop; this is associated with significant risks. Administration of maternal intravenous immunoglobulin (IVIG) has been proposed as an alternative treatment option to delay the onset of fetal anaemia and is appealing in its non-invasive nature. There are no randomized controlled trials to support the use of IVIG however case series suggest potential benefit.
Aims: We report a retrospective case series of 9 patients with antenatal HDFN managed with IVIG between 2013 and 2017.
Methods: All women had a history of severe antenatal HDFN and/or significant red cell antibody titres in early pregnancy. Each pregnancy where IVIG was administered was compared to a pregnancy in the same woman without IVIG.
Results:
All women had at least 1 comparable pregnancy. IVIG 1g/kg was given weekly from a median of 16 weeks gestation. IVIG was stopped in 1 case due to asceptic meningitis. 3 women had IUFD; 2 in IVIG treated pregnancies. Of the 8 pregnancies where IVIG was continued; 4 women had IUT in a comparable pregnancy. IUT was commenced at later gestation in the IVIG treated pregnancy in all 4 patients; 1 did not require any IUT at all. 1 woman delivered at a later gestation than the pregnancy without IVIG. 2 women delivered earlier and 4 women had either a miscarriage or IUFD in the comparable pregnancy. There was no difference in treatment required in the neonates.
Conclusions: The aim of giving IVIG was to delay IUT until a later gestation, thus reducing the risk to the fetus. This was achieved in all 4 patients who had required IUT in a comparable pregnancy. This is particularly encouraging as IUT is often required at earlier gestation in subsequent pregnancies. This is a small case series and there is a clear need for further research in this area as randomized controlled trial data to support this management strategy is lacking.

PB 1905 | Genetic Hypofibrinolysis, Fetal Loss Syndrome and Pro-inflammatory Status in Women with Metabolic Syndrome

T. Pshenichnikova, E. Perederyaeva

I.M. Sechenov First Moscow State Medical University, Department of Obstetric and Gynecology, Moscow, Russian Federation

Background: Currently the metabolic syndrome (MS) is the most complex medical and social problem. The pregnant patients with MS are at higher risk of developing fetal loss syndrome, intrauterine growth retardation, preeclampsia and other obstetric complications. MS is also associated with at higher risk of thrombosis.
Aims: To determine the possible role of thrombophilic and pro-inflammatory status in the pathogenesis of fetal loss syndrome in women with metabolic syndrome.
Methods: The study involved 90 women aged from 21 to 43 years with the MS and fetal loss syndrome in history. In the history of women missed abortion, fetal death, spontaneous abortions, the failure of IVF were found in 80%, 55.6%,68.9%, 57.8% of cases respectively. The women were examined for pro-inflammatory cytokines genes polymorphisms and hereditary thrombophilia.
Results: The multigenic defects were verified in 100% of cases. The feature of multigenic defects is that the 4G/5G polymorphism of plasminogen activator inhibitor-1gene, the polymorphism in the tissue-type plasminogen activator I/D gene, in the angiotensin-converting

enzyme I/D gene, in the fibrinogen 455G/A gene were found in 85,6%, 58,9%, 45,6%, 47,8%, respectively. The polymorphisms IL-1β -31T/C gene, the polymorphisms IL-6 -174 G/C gene, the polymorphisms tumor necrosis factor-α -308G/A gene were found in 41,1%, 45,6%, 47,8% respectively.

Conclusions: The genetic assay demonstrates the presence of genetic hypofibrinolysis in patient with MS. We suggest the genetic hypofibrinolysis combined with pro-inflammatory status leads to impaired invasion cytotrophoblast and impaired placental development which ultimately leads to the development of obstetric complications, including the fetal loss syndrome.

PB 1906 | Venous Thromboembolism in Women Undergoing Assisted Reproduction: Data from RIETE

E. Grandone[1], M. Villani[1], D. Colaizzo[1], C. Fernández-Capitán[2], J. Del Toro[3], V. Rosa[4], A. Bura-Riviere[5], I. Quere[6], P. Di Micco[7], A. Blanco-Molina[8], M. Monreal[9], RIETE Investigators

[1]IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy, [2]Hospital Universitario La Paz, Department of Internal Medicine, Madrid, Spain, [3]Hospital General Universitario Gregorio Marañón, Department of Internal Medicine, Madrid, Spain, [4]Hospital Universitario Virgen de Arrixaca, Department of Internal Medicine, Murcia, Spain, [5]Hôpital de Rangueil, Department of Vascular Medicine, Toulouse, France, [6]Hôpital Saint Eloi, Department of Vascular Medicine, Montpellier, France, [7]Ospedale Fatebenefratelli, Department of Internal Medicine, Napoli, Italy, [8]Hospital Universitario Reina Sofía, Department of Internal Medicine, Córdoba, Spain, [9]Hospital Universitario Germans Trias i Pujol de Badalona, Universidad Católica de Murcia, Department of Internal Medicine, Barcelona, Spain

Background: Assisted Reproductive Technologies (ART), increasingly used in western Countries, have been reported to have an increased risk of venous thrombosis. However, the magnitude, duration and the impact of risk factors are poorly known.

Aims: To investigate the incidence, clinical features and risk factors of ART-related events.

Methods: d.Among 63,749 patients so far included in the RIETE registry, we analysed events occurred in the 6,313 fertile-age women: 35 of them were referred as ART-related VTE. The risk factors, localization of thrombosis, the duration of therapy, second recurrent VTE, were assesse.

Results: No difference between the study group and that of 6,278 fertile-age women with VTE outside ART as far as age, BMI, smoking habits, co-morbidities, previous VTE, and thrombophilia (when available) are concerned. Among 35 women (mean age: 35.7+/-5.6) suffering from an ART- related VTE, 21 had a deep vein thrombosis (DVT) at lower limbs, 5 DVT at upper extremities, 15 pulmonary embolism (in 6 cases associated with DVT). In 30 out 35 women an embryo-transfer was performed with 17 following pregnancies. Overall, at least one risk factor (BMI>30, age >39 yrs, known thrombophilia, Ovarian Hyper-Stimulation Syndrome) was present in 19 (54.3%) women. Treatment was performed by low-molecular-weight heparins in 24 cases and vitamin K antagonists in 10 cases, while direct oral anticoagulants were used in 1 case. Overall, the duration of treatment was 224 days (median, range: 12-2119) with a higher duration in isolated PE (n= 273, range 145-1088). 3 (8.6%) women had VTE in spite of thromboprophylaxis No recurrence was observed at 90 days.

Conclusions: These preliminary data indicate that VTE may occur in the context of an ART attempt in unfrequent sites and mostly in the presence of risk factors. Noteworhy, a high number of PE is observed. A possible resistance to prophylactic doses of heparin is documented by the occurrence of VTE in spite of the prevention by heparin.

PB 1907 | Outcomes of Threatened Abortions Following Anticoagulation Treatment to Prevent Recurrent Pregnancy Loss

A. Rottenstreich[1], G. Kleinstern[2], H. Amsalem[3], Y. Kalish[1]

[1]Hadassah Hebrew University Medical Center, Hematology, Jerusalem, Israel, [2]Braun School of Public Health and Community Medicine, Faculty of Medicine, Jerusalem, Israel, [3]Hadassah Hebrew University Medical Center, Obstetrics and Gynecology, Israel

Background: Prophylactic dose of low-molecular weight heparin (LMWH) is often prescribed to women with unexplained recurrent pregnancy loss (RPL) despite questionable benefit. Management and outcomes of threatened abortion during treatment with ongoing anticoagulant therapy in these patients has not been established.

Aims: To determine the outcome of threatened abortion in women treated by ongoing LMWH therapy due to RPL.

Methods: A retrospective review of all patients with RPL who experienced threatened abortion while on LMWH therapy between 2000-2016 in two university hospitals.

Results: Data of 114 women with ≥2 consecutive early miscarriages who experienced threatened abortion while on LMWH therapy were analyzed. All patients received enoxaparin at a dose of 40 mg. Fetal cardiac activity was demonstrated in all patients. The median age of the cohort was 33 years. Overall, 74 (64.9%) women had ≥3 previous miscarriages. Thrombophilia was present in 38 (33.3%) women, including 11 (9.6%) with antiphospholipid syndrome (APLS). The overall live birth rate was 58.8% (67/114). Live birth rates were 87.2% (41/47 patients) and 38.8% (26/67 patients) among those who discontinued versus those who continued LMWH therapy, respectively (P< 0.0001). Among the 11 patients with APLS, 10 experienced live birth, 8 of them continued LMWH and 2 discontinued it. In multivariate analysis, discontinuation of LMWH was the only significant predictor of live birth outcome (odds ratio [95% CI]: 10.78 (4.01, 28.93), P< 0.0001). Thrombophilia (P=0.61), presence of subchorionic hematoma (0.69), and severity of bleeding (P=0.33) were not found to be associated with live birth outcomes.

Conclusions: We found the continuation of LMWH therapy following threatened abortion in patients with RPL to be negatively associated with live birth rates. Therefore, we support its discontinuation in this setting. Since LMWH continuation resulted in a relatively high live birth rate among APLS patients, we advocate against its withdrawal in this subset of patients.

PB 1908 | OTTILIA and FIRST: Preliminary Data from Two Ongoing International Registries on Foeto-maternal Prognosis in Women with Recurrent Reproductive Failures after Spontaneous or Assisted Conception

M. Villani[1], G. Larciprete[2], M. Kovac[3], I. Martinelli[4], E. Tamborini Permunian[5], R. Cacciola[6], G. Lo Pinto[7], E. Bucherini[8], V. De Stefano[9], C. Lodigiani[10], T. Bartolotti[11], P. Background: There is uncertainty about the best management of pregnant women with previous recurrent pregnancy loss or recurrent implantation failures after assisted reproductive technologies (ART).

Aims: To investigate factors affecting reproductive outcomes and assess the best clinical management strategies of women with recurrent otherwise unexplained implantation/pregnancy failures after spontaneous or assisted conception.

Methods: OTTILIA and FIRST are two prospective, observational, multicenter studies.

Inclusion criteria OTTILIA (ClinicalTrials.gov: NCT 02385461): Pregnant women with recurrent pregnancy loss (≥3 or 2 in the presence of at least 1 normal fetal karyotype) or at least 1 intrauterine foetal death (a loss after 20 weeks of a morphologically normal fetus).

Inclusion criteria FIRST (NCT 02685800): ART attempt after ≥2 implantation failures/losses of clinical pregnancies after ART. Baseline characteristics, past and current obstetric history (including antithrombotic prophylaxis) of study women, are obtained during routine clinical follow-up or telephone interviews and recorded into a dedicated database. All women are followed until 4 weeks after the delivery or pregnancy test after ART procedure.

Results: To date, 166 and 57 women (median age: 36 and 37, range: 21-47 and 24-49 years) have been enrolled in OTTILIA and FIRST registers, respectively. Enrolment period, participating centers and management of index- pregnancies/ART cycles are shown in Table 1. Outcome is available in 169 pregnancies (4 were lost to follow-up, 20 are ongoing) and 49 ART cycles (8 are ongoing).

TABLE 1 Panel a. OTTILIA Register (Starting date: February 1, 2012; Participating centers: 10)

Index-pregnancies (n= 193)	No prophylaxis	ASA	LMWH	ASA+LMWH
Pregnancies in FVL heterozygotes, n (%) (n= 36)	1 (2.8)	3 (8.3)	26 (72.2)	6 (16.7)
Pregnancies in PTm heterozygotes, n (%) (n= 29)	1 (3.5)	0	25 (86.2)	3 (10.3)
Pregnancies in carriers of severe thrombophilias, n (%) (n= 13)	0	0	6 (46.2)	7 (53.8)
Pregnancies in non carriers, n (%) (n= 115)	40 (34.8)	19 (16.5)	39 (33.9)	17 (14.8)

TABLE 1 Panel b. FIRST Register (Starting date: October 1, 2015; Participating centers: 4)

Index-ART cycles (n= 57)	No prophylaxis	ASA	LMWH	ASA+LMWH
ART cycles in FVL heterozygotes, n (%) (n= 1)	0	0	1 (100)	0
ART cycles in PTm heterozygotes, n (%) (n= 2)	1 (50)	0	1 (50)	0
ART cycles in carriers of severe thrombophilias, n (%) (n= 1)	0	0	1 (100)	0
ART cycles in non carriers, n (%) (n= 53)	39 (73.6)	3 (5.7)	6 (11.3)	5 (9.4)

ASA: low-dose aspirin; LMWH: low-molecular-weight heparin; FVL: factor V Leiden; PTm: prothrombin 20210A mutation; Severe thrombophilias: homozygosis for FVL or PTm, double mutation, FVL or PTm and/or natural anticoagulants deficiency.

Conclusions: In both the cohorts, antithrombotic prophylaxis is mostly prescribed in women carrying thrombophilias. A larger sample size is required to better evaluate variables affecting outcome and clinical strategies to improve foeto-maternal prognosis.

PB 1909 | Efficacy and Safety of Treatment with High Dose Thromboprophylaxis in Pregnant Women - A Retrospective Study from a Stockholm Cohort, Ranging from 2004 to 2014

R. Chaireti[1,2], A. Lannemyr[3], L. Thyni[3], K. Bremme[3]

[1]Karolinska Institutet, Department of Molecular Medicine and Surgery, Stockholm, Sweden, [2]Karolinska University Hospital, Department of Hematology, Stockholm, Sweden, [3]Karolinska Institutet, Department of Women´s and Children´s Health, Stockholm, Sweden

Background: Pregnant women who have a very high risk of developing pregnancy related venous thromboembolism (VTE) should be treated with high-dose thromboprophylaxis (low molecular weight heparin). The efficacy and safety of the treatment have been evaluated mostly in mixed cohorts (high and normal dose thromboprophylaxis).

Aims: To evaluate the safety and efficacy of high dose thromboprophylaxis in pregnant women with high risk for VTE.

Methods: The cohort of the study consisted of 40 women treated with high dose thromboprophylaxis during pregnancy because of previous VTE or thrombophilia. Maternal medical records were reviewed in order to evaluate the efficacy of the treatment through the incidence of recurrent VTE and the safety of the treatment by recording bleeding complications and obstetric outcomes.

Results: The incidence of VTE and bleeding complications during pregnancy was 2,5% (n=1) and 10% (n=4), respectively. Postpartum haemorrhage (PPH) ≥500ml occurred in 30% of the patients (n=12) whereas PPH≥1000ml was recorded in 4,8% (n=3). The incidence of preterm births was 12,5% (n=5) and 12,5% (n=5) of the children were born small for gestational age (SGA).

Conclusions: High-dose low molecular weight heparin is an effective prophylaxis for pregnant patients with high risk of developing VTE, but the treatment may entail a somewhat increased risk of PPH, preterm birth and SGA. Larger studies in this population are required in order to confirm these findings.

PB 1910 | Thromboelastography Analysis of Haemostasis in Pre-eclamptic, Hypertensive and Normotensive Pregnant and Non-Pregnant Women

E. Murray[1], M. Murphy[1], G.N. Smith[2], C.H. Graham[1], M. Othman[1,3]

[1]Queen's University, Biomedical and Molecular Sciences, Kingston, Canada, [2]Queen's University, Obstetrics and Gynaecology, Kingston, Canada, [3]St Lawrence College, School of Baccalaureate Nursing, Kingston, Canada

Background: Pregnancy is a physiological hypercoagulable state. Hypertensive disorders of pregnancy such as pre-clampsia (PE) are often associated with coagulopathy. Of women who develop severe PE, 20% develop HELLP syndrome and/or DIC with subsequent severe maternal and fetal complications. Standard laboratory tests are useful guides to haemostatic function, however, they are plasma based and thus ignore the dynamic interaction between platelets, coagulation and fibrinolytic factors, as well as their inhibitors, and fail to reflect elements related to the quality of the formed clot. Thromboelastography (TEG) shows the dynamic viscoelastic properties of whole-blood during coagulation and fibrinolysis and is used as a point-of-care monitoring tool.

Aims: To investigate the differences in coagulation status found in non-pregnant state, normotensive pregnancy, gestational hypertension and pre-eclampsia.

Methods: Citrated whole-blood samples were collected from twenty one normotensive women during the third trimester of pregnancy, six pre-eclamptic women prior to delivery and at six weeks and six months post-partum, six women with gestational hypertension as well as fifteen non-pregnant controls. Using thromboelastography and standard laboratory tests, haemostatic functions were evaluated in at delivery and post-partum.

Results: TEG identified increased whole-blood coagulability in PE women at delivery, demonstrating its increased sensitivity over standard laboratory tests at identifying haemostatic alterations associated with PE. Haemostatic alterations were normalized by six weeks post-partum.

Conclusions: These results provide evidence supporting the use of TEG as a sensitive laboratory test in evaluating haemostasis in pregnant and non-pregnant women.

PB 1911 | Pregnancy Loss in APA-positive Women

D. Khizroeva, N. Makatsariya, N. Stuleva, N. Khamani

I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

Background: As it is known the pregnancy loss is a marker and the most striking manifestation of APS. Pregnant women with APA circulation has a potential risk of placental insufficiency and IUGR development. We evaluated the importance of different antiphospholipid antibodies in patinets with fetal loss syndrome history.

Aims: The evaluation of APA profile in patients with fetal loss syndrome.

Methods: We have investigated anticardiolipin, anti-annexin V, anti-b2-GPI, anti-prothrombin antibodies using ELISA method and LA circulation in 146 women with history of recurrent miscarriage and 60 age matched healthy pregnant women. The study included 74 first trimester pregnant women (I group) and 72 second and third trimesters women (II group) who had a history of unexplained recurrent miscarriage.

Results: 34,2% women were diagnosed APS. LA circulation - 14%, anticardiolipin - 31,5%, anti-annexin V - 31%, anti-b2-GPI - 22,6, anti-prothrombin - 10,3%. Combination of LA, anti-b2-GPI, anticardiolipin was in 12,1%, LA, anti-annexin V and anti-b2-GPI - in 13,7%, anti-prothrombin and anti-b2-GP I - in 8,9%, LA, annexin V and b2-GPI - in 7,9% and was associated with more severe complications. All APS patients received anticoagulant therapy. In women treated before the

pregnancy early miscarriage in the next pregnancy occurred in 1,6%. There was no antenatal death or stillbirth. In II group the frequency of obstetric complications was higher compared with women of I group ($p<0.05$) but still significantly lower compared their history without therapy.

Conclusions: 34% fetal loss cases in our investigattion are associated with antiphospholipid syndrome. The combination of various antibodies at the same time in women with more severe obstetric history demonstrates the diagnostic value of the determination of different groups of APA.

PB 1912 | Obesity and Thromboembolic Risk during Hospitalization in Pregnancy: Preliminary Results

V. Barros[1], A.M. Igai[2], M.R. Bortolotto[2], R. Francisco[2], M. Zugaib[2]

[1]*Clinics Hospital, University of Sao Paulo, Obstetrics and Gynecology, Sao Paulo, Brazil,* [2]*Hospital das Clinicas, Universidade de Sao Paulo, Obstetrics and Gynecology, Sao Paulo, Brazil*

Background: Worldwide there has been a dramatic increase in the prevalence of overweight (body mass index [BMI, calculated as weight (kg)/[height (m)]2] 25 and higher) and obesity (BMI 30 and higher). BMI 40 and higher (severe obesity) is considered a moderate/high risk for venous thromboembolism (VTE)during hospitalization in pregnancy.

Aims: The goal of this study was to apply a thromboprophylaxis protocol with a VTE risk score for hospitalized pregnant women. The analysis of patients with severe obesity was performed.

Methods: This was a longitudinal, interventional and prospective study of hospitalized pregnant women (n= 4126) in a tertiary hospital. The patients were classified according to the grade of obesity. The patients with severe obesity were compared with the remaining group. Patients were classified as low risk or high risk (score ≥ 3) according to a VTE risk score. The high-risk group received thromboprophylaxis with low-molecular-weight heparin (LMWH) unless the patient had a contraindication for anticoagulation, such as active bleeding or a high bleeding risk. The collected data were descriptively analysed to identify the profile of pregnant women with severe obesity using percentages and absolute values. One patient could have undergone more than one evaluation.

Results: The data of 218 cases with BMI ≥ 40 were descriptively analysed: 26 (12%) were already on anticoagulation. The others 191 (170 patients) were scored: 101(52.9%) were considered high risk. The main associated risk factors in this calculation were: age above 35 y or 40y (respectively 45% and 12.9%) and multiparity (n=43-42%). The type of evaluation was: 157 (82.1%) postpartum (c-section n=95-60.5% of the deliveries). One patient presented postpartum haemorrhage due to uterine atony(0.5%) and no patient presented adverse effects of anticoagulation.

Conclusions: In pregnant women with severe obesity more than half of the patients scored high risk for VTE and the main factors associated were maternal age and multiparity.

PB 1913 | Management of a Pregnant Patient with Antithrombin Deficiency and Acute Venous Thromboembolism

J. Hews-Girard[1], L. Skeith[2], N. Rydz[3]

[1]*University of Calgary, Foothills Hospital, Southern Alberta Rare Blood and Bleeding Disorder Comprehensive Care Program, Calgary, Canada,* [2]*University of Ottawa, Division of Hematology, Department of Medicine, Ottawa, Canada,* [3]*University of Calgary, Foothills Hospital, Division of Hematology, Department of Medicine, Calgary, Canada*

Background: In women with past unprovoked or estrogen-associated venous thromboembolism (VTE), antepartum and postpartum

TABLE 1 Antithrombin and Anticoagulant Dosing and Trough Levels

Timeline	Antithrombin dosing	Anticoagulant dosing	Trough levels, AT antigen (U/mL)	Trough levels, AT chromogenic (U/mL)
At presentation (5 weeks gestation)		Tinzaparin (175 units/kg)	0.33	0.19
Late 1st trimester	Bolus 4000U then daily 3000-2000U	Unfractionated heparin infusion for 3 days. Enoxaparin 80mg (1mg/kg) Q12H started day 4	0.85	0.76
Early 2nd trimester	3000U MWF	Enoxaparin 80 mg sc Q12H	0.81	0.77
2nd trimester	2000U MWF	Enoxaparin increase to 90 mg sc Q12H based on anti-Xa level	0.63	0.55
3rd trimester	1000U q2d	Enoxaparin 90 mg sc Q12H	0.54	0.45
Admission for induction of labor	Bolus 3000U then 2000U daily	Held for 24h prior to induction. Enoxaparin 40 mg sc given 4h postpartum, and 90mg sc q12h on post-partum day 1	0.83	0.87

low-molecular-weight heparin (LMWH) is recommended to prevent VTE recurrence. Antithrombin (AT) deficiency is a rare, hereditary thrombophilia that increases the risk of VTE during pregnancy. The management of pregnant patients with AT deficiency and acute or past VTE and the role of AT concentrate replacement remains unclear.

Aims: To describe management of a woman with severe AT deficiency and history of recurrent VTE who developed a VTE in early pregnancy despite therapeutic LMWH.

Methods: A 31 year old woman with Type 1 AT deficiency (baseline antigen 0.42U/mL, chromogenic 0.45U/mL) and history of recurrent VTE was switched from warfarin to therapeutic Tinzaparin (175 units/kg) after confirmation of pregnancy. One month later she presented with new left leg symptoms and shortness of breath; Doppler ultrasound confirmed evidence of progressive thrombus involving the femoral vein. She was started on intravenous unfractionated heparin and received AT concentrate (Antithrombin III NF, Baxalta) for 5 consecutive days, followed by 3 times/week for one month to achieve AT trough levels of 80%. Once stable, she was switched to enoxaparin 1 mg/kg twice daily with anti-Xa level monitoring. After the 1st month of treatment the target AT trough level was reduced to 50%. After delivery, the patient remained on therapeutic-dose enoxaparin and AT replacement until transitioned to warfarin.

Results:

Conclusions: This case highlights the potential role of AT concentrate in pregnant women with AT deficiency and acute VTE. While our protocol was effective, it was not without significant medicalization of the pregnancy, patient distress and use of hospital and national blood bank resources. This area would benefit from the development of a prospective registry of pregnant patients with AT deficiency with VTE.

PB 1914 | Prevalence of FOXD1 Mutations in the Obstetric Antiphospholipid Syndrome

J.-C. Gris, E. Mercier, S. Bouvier, E. Cochery-Nouvellon, G. Lissalde-Lavigne

University Hospital, Haematology, Nîmes, France

Background: Mutations of the transcription factor gene *FOXD1* impairing the activation of the promotor of the placental growth factor gene *PGF* are associated with recurrent pregnancy loss PL (Open Biol. 2016 Oct;6(10). pii: 160109): their prevalence is not documented in other PL phenotypes.

Aims: Assess the rate of 3 non-synonymous *FOXD1* sequence variants [c.1285_1286InsGCCGCG (p.Ins429AlaAla); c .1067 C>G (p.Ala356Gly) ; c.1092C>G (p.Ile364Met)] in the obstetric antiphopholipid syndrome (oAPS).

Methods: We tested DNAs from the 1,552 women included into the NOH-APS cohort (Blood 2012; 119(11):2624-32). *FOXD1* coding region was sequenced as described.

Results: *FOXD1* mutations were detected in 25 women from the NOH-APS, thrombophilia-negative control group (3.14%): in 20/483 with 3 embryonic PLs before 10 weeks (4.14%) and in 5/313 with one foetal death (1.60%, all before 12 weeks). They were also defected in 10 women positive for the FV Leiden or the *F2* 20210A polymorphisms (3.58%): in 6 /93 with recurrent embryonic PLs (6.45%) and in 4 /186 with one foetal death (2.15%, all before 12 weeks). They were finally detected in 13 of the oAPS women (2.51%): in 10/206 with 3 embryonic PLs (4.85%) and in 3/311 women with one foetal death (0.96%, all before 12 weeks). All foetal losses in mutated women occurred before 12 weeks. The rate of mutated women was not different between the 3 groups with recurrent embryonic PLs (p=0.603) or with one foetal loss (p=0.557). oAPS women positive for FOXD1 mutations were only positive for anticardiolipin IgM.

Conclusions: *FOXD1* mutations impairing *PGF* transcription are mainly found in women with recurrent embryonic losses before 10 weeks, to a lesser extent in case of a foetal loss before 12 weeks. *FOXD1* mutations in oAPS women only positive for anticardiolipin IgM questions the clinical relevance of this traditional APS marker. The progressive description of causal mutations for miscarriages could gradually lead to restricting the perimeter of oAPS.

PB 1915 | Management of Pregnancy in Cobalamin C Defect Causing Homocystinuria and Methylmalonic Aciduria

E. Grandone[1], M. Villani[1], G. Vecchione[1], A. Leccese[2], R. Santacroce[3], P. Martinelli[4], G.M. Maruotti[4], L. Fischetti[1], G. Corso[3], M. Margaglione[3]

[1]IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy, [2]Universty of Foggia, Foggia, Italy, [3]University of Foggia, Foggia, Italy, [4]University of Neaples ‚Federico II', Napoli, Italy

Background: Cobalamin C (CblC) defects are rare inherited autosomal recessive disorders of vitamin B12 metabolism with high levels of plasma homcysteine and high methylmalonic urine/plasma levels. Late-onset is rarer than the early-onset disease. We describe a 34 yrs-old Caucasian woman, referred because of a 20th week pregnancy loss of a morphologically normal intrauterine growth restricted foetus.

Aims: To describe management of pregnancy in late-onset cblC defect.

Methods: Patient underwent thrombophilia screening; homocysteine and methylmalonic acid plasma levels were measured by mass spectrometry.DNA was extracted and a Whole Exome Sequencing (WES) performed.

Results: Thrombophilia screening showed 100 microM of plasma homocysteine (tHcy). At that time, she was on calcium folinate, 15 mg/day.She was delivered at term and was in apparently good health until 20 yrs, when she showed a normocitic anemia (Hb: 8.2 g/dL), elevated inflammatory markers (ESR 55), and an impaired renal function (serum creatinine: 1.9 mg/dL). Urinalysis revealed proteinuria (150 mg/L) and micro-hematuria. Neurological examination was normal. A renal biopsy revealed thrombotic microangiopathy with predominant lesions in the glomerulus and minimal lesions in the arterioles. WES showed a

compound heterozygosity for p. Tyr130His and p.Tyr222Stop in the MMACHC gene (Methylmalonic Aciduria type C and Homocystinuria; OMIM *609831). Plasma concentration of methylmalonic acid was 1,09 micromol/L (reference value: 0-0,7). Hydroxocobalamin injection, 2 mg/week i.m., normalized tHcy plasma levels and restored anemia and renal function. Pregnancy was then started and low-molecular weigh heparin at prophylactic doses prescribed in addition to hydroxocobalamin until 4 weeks post-partum. After an uneventful pregnancy, a male baby weighing 2420 gr (Apgar 1' 8, 10': 9) was delivered at 39 weeks.

Conclusions: This is the first case of pregnancy described in a CblC defect. We show that a successful pregnancy is possible in this rare form of homocystinuria.

PB 1916 | Clinical Value of Antiphospholipid Antibodies Assesment in Women Undergoing IVF with History with IVF Failure

D. Khizroeva, N. Stuleva, N. Makatsariya, N. Khamani

I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

Background: antiphospholipid antibodies have a very multifaced effect on the hemostasis system, harming all its defensive units: endothelial barrier, function of natural anticoagulant, an endogenous fibrinolysis, activating platelet hemostasis and associating with a variety of obstetric complications and infertility. But what is the frequency of circulating aPL in women with IVF failure, and is AFA connected with the worst reproductive outcome?

Aims: To study the effect of AFA on the outcomes of assisted reproductive technologies.

Methods: we examined 387 women between 23 and 45 ages in the IVF program - 238 women with IVF failure (one of the more failed tries of IVF, the number of tries being between 1 and 9) (I group) and 149 women with a pregnancy after the IVF program (II group). The comparison group consisted of 80 women pregnant after IVF (male factor). The control group consisted of 80 pregnant women with physiological pregnancy.

Results: in I group APA circulation (IgG/IgM) was revealed in 42%. Among them antibodies to cardiolipin=8.9%, annexin V=24.7%, b2-glycoprotein I=31%, prothrombin — 13.5%. In II group — APA=19%, cardiolipin=4.5%, annexin V=10%, b2-glycoprotein I=15%, prothrombin — 8%.

Conclusions: we consider a circulation of APA as a temporary contraindication for assisted reproductive technologies program. APA should be considered as an important risk factor of IVF failures. Patients who are involved with ART prior to initiation of an IVF cycle should be tested for the presence of APA. A complete panel of antibodies is necessary for diagnostic of implantation failures associated with APS.

PB 1917 | Antiphospholipid Antibodies in Women with of Severe Preeclampsia

D. Khizroeva, V. Bitsadze, N. Makatsariya

I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

Background: in the management of pregnant women with APS, its possible to face other obstetric problems, like preterm birth and prematurity,IFGR and hypertensive disorders in the form of pre-eclampsia. Placental dysfunction - is the central mechanism for the development of pre-eclampsia. One of the main targets of AFA during pregnancy is the placenta.

Aims: The evaluation of spectrum of antiphospholipid antibodies (APA) in women with the history of severe preeclampsia (SP).

Methods: ELIZA-method was used to measure IgM/IgA APA screen anti-b2-GP I,antiannexinV, antiprothrombin in 125 women with severe preeclampsia. Control group was consisted of 60 health women.

Results: APA circulation in patients with history of severe preeclampsia was found in 32%. It is interesting that antibodies to b2-GPI were prevailed (31,6%).Antibodies to cardiolipin and antibodies to APA subgroups were respectively 21%and 17%. Lupus anticoagulant circulation was in15,7%. Antiannexin V-in5,2%, antiprothrombin-5,2%. Combination of LA,anti-b2-GPI, anticardiolipin was in 12,1%,LA,anti-annexin V and anti-b2-GPI - in 13,7%,anti-prothrombin and anti-b2-GP I - in 8,9%, LA, annexin V and b2-GPI-in7,9%.The worst clinical picture was observed in women with combination of different APA. Further we managed the next pregnancy in 54of these 125 examined women. Most of them (39) were observed from the fertile cycle. 15 other women admitted already being pregnant. All patients were re-examined for APA circulation. In 3 cases we observed the development of preeclampsia and in 1 case - repeated severe preeclampsia in women who applied in III trimester of pregnancy. All women received anticoagulant therapy. No case of severe preeclampsia development in patients with anticoagulant therapy started from the fertile cycle or I trimester of pregnancy.

Conclusions: The presence of history of preeclampsia is the indication for the APA-testing and the beginning of the anticoagulant therapy from the moment of preparing for pregnancy.

PB 1918 | The Clinical Significance of Determining the Activity and Inhibitor of Adamts-13 in the Management of Pregnant Women with Severe Preeclampsia and Thrombotic Microangiopathy History

A. Makatsariya, V. Bitsadze, D. Khizroeva

I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

Background: Thrombotic microangiopathy is one of the most difficult occurring thrombotic complications characterized by microvascular lesions of various organs and accompanied by thrombocytopenia and hemolytic anemia. One of the key triggers to the appearance of

thrombotic microangiopathy is pregnancy. ADAMTS-13 deficiency is a hallmark of thrombotic thrombocytopenic purpura, which allows to differentiate the pathology from other thrombotic microangiopathy.

Aims: The evaluation of ADAMTS-13 in women with the history of severe preeclampsia (SP).

Methods: We have examined 68 patients with severe preeclampsia history, including early (before 34 weeks of pregnancy), fetal death. Pregnancy has been interrupted due to multiple organ failure. All women were screened for the presence of lupus anticoagulant, antiphospholipid syndrome, ADAMTS-13 (activity and inhibitor circulation).

Results: On the basis of a high level of antibodies to ADAMTS-13 in 11 patients was suspected acquired form of thrombotic microangiopathy. Almost half of them (6) was found high titer antibodies against b2-glycoprotein I. Subsequently, 7 of them are planned for the next pregnancy. Prevention conducted LMWH, aspirin and in 3 cases dipyridamole also in connection with resistance to aspirin. Dynamic control of activity and ADAMTS-13 inhibitor was conducted. At 34-35 weeks of pregnancy in all the marked growth inhibitor and enzyme activity drop to 10%, which was the reason for a surgical delivery.

Conclusions: The presence of history of preeclampsia and especially with thrombocytopenia is the indication not onle for the APA-testing but for the evaluation of ADAMTS-13 level of activity and the presence of antibodies and the beginning of the anticoagulant therapy from the moment of preparing for pregnancy.

PB 1919 | Different Approaches of Thromboprophylaxis during Pregnancy in the Routine Clinical Practice. Results from the TEAM Project

A. Santamaria[1], E. Marti[2], TEAM Project of the SETH

[1]*Hospital Universitario Vall d´Hebron, Haemostais and Thrombosis Unit, Barcelona, Spain,* [2]*Hospital Clinic Valenica, Valencia, Spain*

Background: Limited data on the magnitude of the thrombosis risk associated with heritable thrombophilias and the interaction of risk factors have impeded the development of evidence-based risk stratification to guide thromboprophylaxis. Consequently, there is a lack of consensus on thromboprophylaxis in national and international guidelines.

Aims: To analyse the clinical management and clinical outcomes of antithrombotic treatment during pregnancy in the TEAM project.

Methods: rom 2010 until 2016 we performed an international observational multicentric study that prospectively included 312 women.

Results: The motive of thromboprophylaxis was 40% previous history of depp venous thrombosis and 23.4% asymptomatic thrombophilia, 14% received no thromboprophylaxis. In 60% od women, they started treatment in the first trimester. Thromboprophylactic doses were used in 79.1 %, intermediate in 15.4 % and 11,4% therapeutic doses. In 60% of cases thrombophilia was positive, most of them had FVL mutation . In terms of safety and efectiviness of treament , minor bleeding was 3 gcases, , 2 of them under theraputic dosages and one under prophylactic dosages and one case of major bleeding not related to treatment with prophylactic dosages. One woman with previous history of thrombosis and a combined deficiency (heterozygous for factor V Leiden and protein S deficiency) under theraupetic dosages of LMWH developed a proximal deep venous thrombosis.

When we analysed the type of treatment depending of the presence of known thrombophilia , the use of LMWH was higher (p=0.04) in women with known thrombophilia. (more than 90%).

Conclusions: Our results shown that more than 90% of woman without thrombophilia received different schemes of thromboprohylaxis. In women with previous thrombosis the tendency was to use therapeutic dosages, and in the majority of cases they started the first trimester. The different approaches of thromboprohylaxis reflect the need of further studies.

PB 1920 | In the TEAM PROJECT, the Management of Placental-mediated Pregnancy Complication (PMC) Reflects a Real Gap between Evidence-based Guidelines and Routine Clinical Practice

A. Santamaria[1], E. Marti[2], on behalf of the TEAM Porject form the SETH

[1]*Hospital Vall d´Hebron, Amparosantamaria, Spain,* [2]*Hospital Clinic Valencia, Valencia, Spain*

Background: In PMC, evidence-based guidelines are based on studies with controversial results or expert opinion, in this context, the implementation of those guidelines are quite different among physicians.

Aims: To analyze if the management of PMC followed evidence-based guidelines, and also the prevalence of thrombophilia and clinical management of thromboprophylaxis in women with previous PMC in agreement with guidelines or not.

Methods: From 2010 until 2015, we performed an international observational multicentric study that prospectively included 646 women with PMC.

Results: Women had pregnancy loss (50%), foetal death (25%), intrauterine growth restriction (6%) and 20% pre-eclampsia A thrombophilia test was indicated in more than 82.6%. The presence of factor V Leiden and antiphospholipids were the most frequent defect observed. The AAF were performed in less than 70% .In 260 women with previous PMC were referred to establish treatment or not, 10% did not receive any treatment and 46.8% received LMWH +AAS. Most of the women (88.7%) received treatment and recurrence was observed in 14% of women.

Conclusions: Our results reflect that despite guidelines, the thrombophilia test is performed and that most of women with a negative thrombophilia test are treated in subsequents pregnancies. Also that the presence of AAF are not performed in all women against the recommendations of guidelines.It implies an urgent need to perform an international project in order to establish and establish guidelines that cover all the uncertainties in this area.

PB 1921 | Risk Assessment of Venous Thromboembolism in Women Furing Pregnancy and Puerperium (SAVE): A Cross-Sectional Registry in Africa, Eurasia, Middle East and South Asia

J.-C. Gris[1], J. Aoun[2], SAVE study group

[1]University Hospital, Nîmes, Haematology, Nîmes, France, [2]SANOFI, Paris, France

Background: The clinical burden of VTE risk during pregnancy and puerperium is not well documented outside Western countries.

Aims: Assess the rate of women at risk of VTE during pregnancy/puerperium in Africa, Eurasia, Middle-East and South Asia.

Methods: International, observational, cross-sectional multicentre study across 18 countries (December 2014-October 2015). Physicians were randomly contacted from a list of private/public practitioners provided by each country. Consecutive women visiting for first prenatal consultation or any other consultation during pregnancy or puerperium were enrolled (30 patients per site). Prior VTE / ongoing antithrombotic therapy led to exclusion. Assessments were built on the identification of predefined VTE risk factors, based on Case Report Forms. The quality control and validation of data was performed independently from investigators by a contract research organisation.

Results: 181 physicians participated in the study. 4,010 women were included and eligible for the study. Majority of the women were pregnant (90.1%), in their last trimester (38.1%) and were enrolled during a routine visit to the physician (81.9%). Half (51.4%) of the women during pregnancy and post-partum were at risk of VTE. In Eurasia, the majority of the women (90%) were considered at risk while fewer women were at risk in South Asia (19.9%). South Asia had a high percentage of women considered at mild risk of VTE (73.5%), while Africa and MiddleEast followed the trend observed globally, with approximately half of the women being at mild risk of VTE and the other half at moderate and high-risk of VTE. Eurasia had the highest percentage of women at high-risk (20.2% vs. 1.5% [South Asia] to 12.9% [global]).

Conclusions: A high proportion of women consulted during pregnancy and puerperium are assessed for their VTE risk and are considered at risk . Differences and discrepancies observed across regions show that further efforts would be needed to promote and apply a uniform VTE risk evaluation.

PB 1922 | Evaluation of Venous Thromboembolism Risk and Adequacy of Prophylaxis in High Risk Pregnancy in Saudi Arabia (The Saudi Arabian Pregnancy Venous Thromboembolism Registry)

S. Abu-Harbesh[1], H. Yousef[1], F. Al-Qahtani[2], M. Kolkailah[3], The Saudi Arabian Pregnancy Venous ThromboEmbolism Registry

[1]Security Forces Hospital, Internal Medicine, Hematology Division, Riyadh, Saudi Arabia, [2]King Saud University College of Medicine, Internal Medicine, Hematology Division, Riyadh, Saudi Arabia, [3]Khamis Mushait Military Hospital, Obstetrics and Gynecology, Khamis Mushait, Saudi Arabia

Background: Pregnant women with inherited and acquired thrombophilias have an increased risk of venous thromboembolism (VTE) and adverse obstetric complications.

For these women, VTE and adverse obstetrical complications may occur during any trimester of pregnancy.

Various pharmacologic interventions have been used in high-risk pregnancies to decrease the likelihood of VTE or adverse obstetrical outcomes.

Aims: To identify high risk conditions in pregnant patients that put the patient at risk of thromboembolism in the outpatient settings. To determine the proportion of at-risk patients who receive effective types of prophylaxis. To determine types of anticoagulant used in the population under study. Drug related side effects: bleeding, local reactions and thrombocytopenia.

Methods: Retrospective analysis of 326 patient had been received anticoagulants during pregnancy from three participating hospitals in Saudi Arabia.

After approval from the research committee in each institute data had been collected and stored electronically.

Results: Recurrent fetal loss is the most frequent induction for anticoagulation followed by previous thromboembolic events. Antiphospholipid antibodys were the most frequent hypercoagulopathy condition.

Enoxaparin was the most frequent used anticoagulant followed by aspirin. Adverse events ranged from Post-partum hemorrhage experienced by 2 subjects (0.61%) DVT, Heparin allergy, thrombocytopenia and other site hemorrhage experienced each by one patient (0.31%).

Neonatal abnormalities (10.12% of the study population) and were mainly underweight and two neonatal death. Protein S deficiency is the most frequent inherited thrombophilia.

Conclusions: Deferent anticoagulations used to prevent recurrent fetal loss with small risk of complication. Inherited thrombophilia are very rare as cause for fetal loss.

PB 1923 | Ischemic-stroke due to an Embolic Thrombus in Carotid Artery in Recent Postpartum: Case Report and Review of the Literature

C. Borim, V. Barros, R. Francisco, M. Zugaib

Hospital das Clinicas, Universidade de Sao Paulo, Obstetrics and Gynecology, Sao Paulo, Brazil

Background: The risk of stroke and other postpartum cerebrovascular disease (CVD) occurring after hospital discharge for labor and delivery is uncertain.

Aims: Description of an ischemic stroke that occurred in the puerperium and was successfully treated with thrombolysis.

Methods: Case report.

Results: A 35-year-old postpartum multiparous woman at the 15th day after a c-section was referred with a history of 3 hours of decreased motion, weakness and sensibility on the left side of her body,

preceded by scintillating scotomas. She had a history of pre-eclampsia in her last pregnancy and dyslipidemia. National Institutes of Health Stroke Scale (NIHSS) score at presentation was 12. Physical examination revealed left hemiparesis (brachial and facial predominantly), associated with hemispatial neglect on the same side. CT angiogram of head and neck vessels exhibited a sudden occlusion in the territory of right middle cerebral artery, and an image suggestive of a thrombus at the emergence of the right internal carotid artery, about 2 cm long, resulting in stenosis of approximately 70% of the lumen. Thrombolysis was performed using a recombinant tissue plasminogen activator (rt-PA) roughly 3 hours within the onset of the symptoms. One day after the thrombolysis, a magnetic resonance angiography (MRA) was performed, displaying several areas without diffusion. It was also seen a filling defect on the proximal segment of right carotid artery, extending by approximately 1.7 cm, without significant stenosis, being suggestive of an embolus. A transesophageal echocardiogram was made to look for sources of emboli. After administration of saline water solution microbubbles were detected at the left chambers, compatible with an extra-cardiac shunt. The patient was discharged on low-molecular weight heparin, with no sequelae.

Conclusions: Intravenous thrombolytic therapy improves independent survival in patients with acute ischemic stroke and is perfectly feasible in the puerperium.

PB 1924 | Hypodysfibrinogenemia: AChallenge in Maternity Ward - Course of Pregnancy and a Literature Review

J.M. Teliga-Czajkowska[1], A. Sikorska[2], B. Ceglarek[2], K. Bykowska[3], B. Baran[3], E. Dmoch-Gajzlerska[1], K. Czajkowski[4]

[1]Medical University of Warsaw, Department of Obstetrics and Gynecology Didactics, Warsaw, Poland, [2]Institute of Hematology and Transfusion Medicine, Department of Hemostatic Disorders and Internal Medicine, Warsaw, Poland, [3]Institute of Hematology and Transfusion Medicine, Department of Hemostasis and Metabolic Disorders, Warsaw, Poland, [4]Medical University of Warsaw, 2nd Dept. Clinic of Obstetrics and Gynecology, Warsaw, Poland

Background: Reduced fibrinogen level in the presence of a normal fibrinogen antigen is suggestive of hypodysfibrinogenemia. This medical condition is characterized by prolonged Thrombin Clotting Time, a prolonged Reptilase Time and Turbidity tests measuring the rate of polymerization. In the number of over 150 mutations, approximately 25% present hemorrhagic symptoms and 1/5 - are associated with thrombosis. Women suffer from abnormal pregnacy outcome (APO); they have a history of frequent miscarriages and stillbirths. Although the major bleeding risk related to fibrinogen levels below 2.0 g/l is widely recognized by obstetricians, the hazard of thrombosis is underestimated. The possible mechanisms for thrombosis are: excessive levels of free thrombin due to poor thrombin binding, decreased binding of plasminogen and disorganized fibrin structure which impairs fibrinolysis.

Aims: To highlight the need for dual treatment of hypofibrinogenic pregnant patient

Methods: A case report and literature review

Results: A 32 year old patient with hypodysfibrinogenemia. During first pregnacy the fibrinogen level was within the 0.8-1.1 g/l range. There were strong indications for C-section as there was strong suspicion of fetal hypofibrinogenemia. Before the procedure 1g of fibrinogen was administered as supplementation. Further fibrinogen supplementation was mandatory in the puerperium to maintain the recommended fibrinogen level. The anticoagulant prophylaxis was administered for two weeks. No hypofibrinogenemia was observed in the healthy infant (1.48-1.98 g/l).

Conclusions: Rare coagulation disorders require close cooperation between medical specialists in order to avoid complications during pregancy, labour and puerperium. Delivery should take place in special perinatal care units and close surveillance in the neonatal period is highly advisable.

PB 1926 | Perinatal Outcomes in Women whith History of Ischemic Stroke

A. Makatsariya, S. Akinshina, V. Bitsadze, D. Khizroeva, V. Nemirovski

I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

Background: Pregnancy-related stroke is a rare event, however, when it occurs, may be life threatening and there may be implications for management of the patient and delivery.

Aims: to evaluate the role of thrombophilia in pathogenesis of ischemic stoke, the effectiveness of pathogenetic prophylactic strategy during pregnancy and outcomes for mother and fetus.

Methods: in our Moscow city maternity hospital N67, specialized in cardiology, we studied 59 women with history of ischemic stroke (32±5,5 years). In 22 pts stroke occurred during current pregnancy. Other 37 pts were included in the prospective study. 20 pts were followed prospectively (group I) in preconception period and during pregnancy (low molecular weight heparin (LMWH) guided by D-dimer, aspirin). In 17 pts (group II) therapy was started in II-III trimester. Control group included 60 pts with normal pregnancy. All women were screened for genetic thrombophilia, antiphospholipid antibodies (APA) and hyperhomocysteinemia.

Results: Stroke was associated with severe medical conditions: hypertension (27,1%), metabolic syndrome (37,3%), rheumatic diseases (16,7%), prosthetic valves (6,8%), past history of thromboembolic complications (21,7%), oral contraceptive use (3,4%). 40,9% pts had a family history of thromboembolic complications ($p < 0,001$ vs 13,3% in the control group). We noted a very high rate of obstetric complications in the past in parous women (n=31) with history of stroke (69,4% vs 11,5% in the control group, $p < 0,001$), including fetal loss syndrome (33,3% vs 0%) and placental obstetric complications (preeclampsia, placental abruption, intrauterine growth restriction [IUGR]) (38,7% vs 11,5%, $p < 0,05$).

Conclusions: Thrombophilia might be the main pathogenic mechanism of obstetrics complications and ischemic stroke in women of childbirth

age. Preconception treatment with LMWH and pathogenetic therapy during pregnancy guided by thrombophilia markers allows preventing pregnancy complications and recurrent thrombosis.

PB 1927 | Pregnancy Complications in Women with Thrombophilia and their Future Pregnancy Outcome after Anti-coagulant Treatment

N. Dally[1], G. Jiries[2], Y. Zivony[3], B. Eshel[3], M. Kashlikov[1]

[1]Ziv Medical Center affiliated to Bar-Ilan University Faculty of Medicine, Hematology Institute & Blood Bank, Safed, Israel, [2]Bar-Ilan University, Faculty of Medicine, Hematology Institute, Safed, Israel, [3]Ziv Medical Center affiliated to Bar-Ilan University Faculty of Medicine, Hematology Institute, Laboratories, Safed, Israel

Background: Pregnant women with hereditary thrombophilia are prone to pregnancy complications, including early and late abortions. Treatment with prophylactic dose Low Molecular Weight Heparin (LMWH) may have a protective effect in consecutive future pregnancies, on pregnant women with hereditary thrombophilia, and placenta mediated pregnancy complications in previous pregnancies.

Aims: To evaluate the efficacy of prophylactic dose LMWH in preventing pregnancy complications including abortions, in pregnant women with established thrombophilia and pregnancy complications in previous pregnancies.

Methods: A retrospective analysis was performed in Hematology outpatient clinic at Ziv Medical Center in Safed, between the years 2008-2014.Records of 41 pregnant women with established thrombophilia and pregnancy complications in previous pregnancies were analysed. The study was approved by the local ethics committee.

Results: The overall rate of live birth improved with Low dose LMWH (1.1±1.4 to 1.2±1.9), and there was an impressive reduction in early abortions (24/41 to 7/41, P< 0.001) but less effect on late abortions (5/41 to 2/41, P=0.152). The incidence of pre-eclampsia and intra-uterine growth restriction was similar, but there was a trend towards reduction in Intra-uterine fetal death (IUFD) rates (6/41 to 3/41, P=0.358). Figure number 1.

Conclusions: Pregnant women with hereditary thrombophilia associated with pregnancy complications in previous pregnancies, may benefit from low dose LMWH leading to lower rates of early abortions and IUFD in consecutive pregnancies, but a larger cohort of patients is needed in order to strengthen this observation.

PB 1928 | What is the Actual Role of Antiphospholipid Antibodies in Obstetric Morbidity?

L. Costa[1], R. Oliveira[1], N. Pinho[1], N. Seidi[1], F. Leite[1], E. Cruz[1], J. Braga[2], S. Morais[1]

[1]Centro Hospitalar do Porto, Thrombosis & Hemostasis Unit - Clinical Hematology, Porto, Portugal, [2]Centro Hospitalar do Porto, Department of Obstetrics, Centro Materno-Infantil do Norte, Porto, Portugal

Background: The known association between obstetric morbidity (OM) and antiphospholipid antibodies (aPL) led to the inclusion of OM as clinical criteria in the antiphospholipid syndrome (APS) definition. However, decades and countless studies later, there is still lack of qualified evidence to support this association. Different clinical and / or laboratorial criteria led to inconsistent results.

Previously in 2014, we found 22 (10.6%) out of 208 women with OM, with APS criteria.

Aims: Confirm if the 22 women who presented positivity for aPL accomplished clinical and laboratorial criteria for obstetric APS; surveillance of thrombotic events (TE) and pregnancy outcomes after the initial evaluation; correlate different aPL profiles (single, double or triple positivity) with distinct clinical profiles.

Methods: We reviewed data concerning the 22 women with OM who fulfilled clinical criteria for APS, clinical and laboratorial data.

Results: Only 6/22 women with aPL presented laboratorial criteria of APS (2.9% of 208 women). None of them had recurrent early miscarriages (REM). Table 1 describes aPL profiles and OM. Table 2 describes patients' outcomes. Concerning the remaining 16/22 women, 1 was lost to follow-up, 8 presented weak LA and 7 presented ACA and aß2GPI in low titers, not confirmed in a second sample.

TABLE 1 Characterization of women who accomplished clinical and laboratorial criteria of obstetric APS

Number of women (n=6)	
aPL profile	
5	Triple positivity*
1	LA alone‡
Obstetric morbidity	
0	REM (0/100)
2	fetal death (6.7%; 2/30)
4	pre-eclampsia/ HELLP syndrome (7.3%; 4/55)
0	placental insufficiency (0/23)

*Triple positivity accomplishes positivity for lupus anticoagulant (LA), anticardiolipin antibodies (ACA) and anti-ß2-glicoprotein I (aß2GPI); ‡LA: Lupus Anticoagulant

TABLE 2 Events during follow-up of of women who accomplished clinical and laboratorial criteria of obstetric APS

Number of women (n=6)	
2	successful pregnancies under LMWH#+AAS§
1	3 unsuccessful gestations despite LMWH#+AAS§
3	did not conceive again
0	thrombotic events

§AAS: acetylsalicylic acid; #LMWH: low molecular weight heparin

Conclusions: Despite the assumed association between aPL and REM, our data conflict with it, which is in line with recent reports by others. Triple positivity was previously identified as a risk factor for thrombosis and seems also to be a risk for pregnancy failure. Our results disfavor APS as a major cause of OM.

PB 1929 | Low Molecular Weight Heparin for Women with Pathologic Evidence of Placental Malperfusion

A. Gomez-Arteaga, M.T. DeSancho

Weill Cornell Medicine, NewYork-Presbyterian Hospital, New York, United States

Background: Placental-mediated pregnancy complications including pre-eclampsia, stillborn, intrauterine growth restriction (IUGR) and placental abruption are related to thrombosis in the placental blood vessels. There are conflicting reports regarding the benefit of heparin or low molecular weight heparin (LMWH) in preventing the development of thrombosis within the placenta in patients at high-risk of placental malperfusion (Dodd JM et al. The Cochrane database of systematic reviews. 2013) (Rodger MA et al. Lancet 2014)(Rodger MA et al. Lancet 2016).

Aims: To determine if using LMWH improves outcomes in subsequent pregnancies in women with prior history of pathologic placental malperfusion.

Methods: We retrospectively identified women referred to our hematology clinic from July 2006 to December 2016 with history of pathologic placental malperfusion that were managed with LMWH in a subsequent pregnancy. We obtained demographics, presence of inherited thrombophilia, complications and outcomes. Patients with antiphospholipid antibodies or other reasons for anticoagulation were excluded. The primary outcome was subsequent live births.

Results: There were 15 women with pathologic evidence of placental malperfusion (Table 1).

TABLE 1 Baseline Characteristics of the women N=11

Age in years (mean and range)	29 (27-39)
Race White	8
Black	1
Hispanic	1
Asian	1
Thrombophilia: Factor II G20210A Heterozygote	5
Factor V Leiden Heterozygote	3
Protein S deficiency type 1	1
Protein S deficiency type 3	1
No thrombophilia	1

Four were excluded as 3 did not become pregnant and one is currently pregnant. Most women were Caucasian and the most common thrombophilia was heterozygosity for factor II G20210A variant. Previous adverse outcomes, treatment and subsequent outcomes are described in Table 2.

TABLE 2 Type of Initial Complication, Treatment and Outcome

Previous Adverse Pregnancy Outcome	Treatment in a Follow up Pregnancy	Outcome
IUGR = 4	LMWH	IUGR = 2
Stillbirth = 3	LMWH	Stillbirth = 0
Preeclampsia = 5	LMWH	Preeclampsia = 0
Abruptio = 3	LMWH	Abruptio = 0

There were 14 subsequent pregnancies (three patients had two successive pregnancies). All received LMWH during pregnancy. Although all pregnancies ended in live births, two women experienced IUGR. One was a heterozygote carrier for the factor IIG20210A and the other had no thrombophilia. There were no venous thromboembolisms or major bleeding events.

Conclusions: The use of LMWH appears to be beneficial in a subgroup of women with pathologic placental malperfusion, most of whom have an underlying inherited thrombophilia.

PB 1930 | Pregnancy and Perinatal Outcomes in Women with History of Venous Thromboembolism

A. Makatsariya, S. Akinshina, V. Bitsadze, D. Khizroeva

I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

Background: Despite intensive research, thromboembolism still accounts for significant maternal.

Aims: to determine thrombophilia in patients with thromboembolism during pregnancy and to evaluate the efficiency of antithrombotic prophylaxis in patients with thrombophilia for prevention of recurrent thromboembolism.

Methods: GroupI:n= 87(28,7±4,2 years),subgroup I (n=68)women with history of thromboembolism, subgroup II(n=19) women with thromboembolism during current pregnancy, group II(control) - healthy pregnant women(n=60) were screened for genetic thrombophilia and antiphospholipid antibodies (APA). Subgroup I received prophylaxis with low molecular weight heparin (LMWH)+/- aspirin(50-100 mg/day) in preconception period, during pregnancy and at least 6 weeks postpartum.

Results: In group I 54% had familial history of venous thromboembolism, and 67,8% had personal history of pregnancy complications (fetal loss syndrome, preeclampsia, placental abruption) (p< 0,05 vs. control). In the group I thrombophilia was detected in 92,6%: FV Leiden (22% +/-), prothrombin G20210A (13,2% +/-), multigenic fibrinolytic defects (63,2%); APA (48,5%), hyperhomocysteinemia (44%)
(p< 0,001 vs. control). In 7 of 30 tested pts (23,3%) we found decreased ADAMTS-13 activity with inhibitor. Recurrent thrombosis occurred in 1 woman from subgroup I before the start of LMWH and

in 5 pts from subgroup II (26,3%) (p=0,091). In subgroup I no one had severe obstetrics complications. All pts were delivered at term and all babies were alive. In subgroup II moderate to severe obstetrics complications were noted: preeclampsia, IUGR grade I-III, critical maternal-placental-fetal blood flow disturbances (43,7%). Preterm delivery was required in 43,7% pts from subgroup II.

Conclusions: LMWH was effective for prevention of recurrent thromboembolism and obstetric complications.Women with personal or family history of thromboembolism or with history of obstetric complications should be screened for thrombophilia, including ADAMTS-13 activity with inhibitor.

PB 2138 | Evaluation of a Novel Short-acting Direct Dual FXa/FIIa Inhibitor for its Use in Acute Anticoagulation

S. Heitmeier, S. Allerheiligen, J. Strassburger, A. Buchmueller, C. Gerdes, M.J. Gnoth, B. Riedl, V. Laux

BAYER AG, Wuppertal, Germany

Background: Acute treatment of thrombotic events requires strong anticoagulation with good efficacy/safety profile and control of therapy.

Aims: Our aim was to identify and evaluate small molecules, which directly inhibit FXa and thrombin and ensure controllability by a short half-life and reliable pharmacodynamics.

Methods: BAY-878 was chemically synthesized and tested in various fluorogenic assay formats in buffer and plasma, as well as standard clotting tests in plasma and whole blood. It was evaluated in models of arterial, venous and systemic thrombosis, including an arterio-venous shunt model (vs. bivalirudin) and LPS infusion models (vs. Heparin) in rat.

Results: BAY-878 is a small molecule, which inhibited both, FXa and thrombin ($IC_{50\ 1}$nM/2.2nM) directly and reversibly with a fast binding kinetic, without inhibiting other proteases tested. In plasma it blocked both enzymes equi-potently (IC_{50}30 nM/35 nM) and prolonged the clotting times in plasma (PT/aPTT, EC_{200}0.2 µM) and whole blood without dependency on or consumption of antithrombin. Added after the trigger, BAY-878 reduced increases in thrombin activity, blocked clot-bound FXa and thrombin and improved clot lysis by inhibiting TAFIa generation. When infused in rat in an AV-shunt model BAY-878 was more efficacious in thrombus reduction than bivalirudin (EC_{50} 0.3 vs. 0.8µM) with less blood loss at comparable efficacies, which may be linked to a lower inhibition rate of each of the enzymes compared to the single thrombin inhibition of bivalirudin.

In rat models with LPS infusion, BAY-878 led to a reduction in platelet drop, TAT, IL-6, AST and LDH under prophylactic and treatment conditions, which was not observed with UFH.

Pharmacokinetic experiments in rats revealed a short half-life (< 10 min) with a good pharmacodynamic correlation and a low renal exretion rate.

Conclusions: BAY-878 is a direct dual FXa/thrombin inhibitor for parenteral use, which has the potential to improve the treatment of life-threatening acute coagulation disorders, like ACS and DIC.

PB 2139 | Discovery of ONO-5450598, a Highly Orally Bioavailable Small Molecule Factor XIa Inhibitor: The Pharmacokinetic and Pharmacological Profiles

S. Kouyama, T. Ono, T. Hagio, S. Sakimoto, H. Miyata, M. Tanaka, T. Kouda, N. Nakanishi, K. Tanaka, D. Yanagida, M. Sakai, H. Matsuya, A. Imagawa, Y. Hirota, K. Kawabata, H. Habashita

ONO PHARMACEUTICAL CO., LTD., Osaka, Japan

Background: In ISTH2015, we reported that ONO-7750512 as a small molecule factor XIa (FXIa) inhibitor has an oral bioavailability (BA) of 22% in rats and has potent antithrombotic efficacy without a prolonged bleeding time in animal models. Recently, we have found a new small molecule FXIa inhibitor ONO-5450598, which is equivalent to ONO-7750512 in terms of the potent antithrombotic efficacy without a prolonged bleeding time and has even higher oral BA.

Aims: To elucidate the *in vitro* pharmacological profile and to investigate the oral BA in various animal species and the *in vivo* antithrombotic and hemorrhagic effects of ONO-5450598 in monkeys.

Methods: Effects of ONO-5450598 against human coagulation and fibrinolytic factors were evaluated by *in vitro* enzyme assays. *In vitro* anticoagulation activities of ONO-5450598 were assessed as PT and APTT in humans and animals. To determine the oral BA, ONO-5450598 was orally or intravenously administered to rats, dogs, and monkeys. The antithrombotic effect of ONO-5450598 was assessed in a monkey arteriovenous (AV) shunt model. The hemorrhagic effect was assessed in a monkey nail-cut bleeding model.

Results: ONO-5450598 inhibited human FXIa activity with a Ki value of 2.0 nmol/L with 5000-fold selectivity over other coagulation and fibrinolytic factors. An *in vitro* plasma assessment revealed that ONO-5450598 doubled the APTT at < 1 µmol/L without PT prolongation even at 33 µmol/L in humans and monkeys. The oral BA of ONO-5450598 was 81% in monkeys, 88% in dogs, and 59% in rats. In a monkey AV shunt model, ONO-5450598 significantly inhibited thrombus formation at a dose higher than 0.0971 mg/kg/h, i.v. (plasma concentration: ≥0.41 µmol/L). In a monkey model of nail-cut bleeding, ONO-5450598 did not prolong the bleeding time even at 30 mg/kg, p.o. (plasma concentration: 13 µmol/L).

Conclusions: We identified ONO-5450598 as a selective human FXIa inhibitor with high oral BA and potent antithrombotic efficacy without the increased risk of bleeding.

PB 2140 | Discovery and Profiling of BAY-224 - A Novel Active Site Inhibitor of Thrombin for Oral Treatment of Thrombosis

S. Heitmeier, S. Allerheiligen, K.M. Gericke, A. Tersteegen, M.V. Schmidt, J. Strassburger, A. Buchmueller, C. Gerdes, P. Ellinghaus, B. Riedl, V. Laux

BAYER AG, Wuppertal, Germany

TABLE 1

	Population-based estimates of incidence				VTE as a hospital discharge diagnosis		
Types of Studies	Annual incidences of VTE	Retrospective cohort studies of specific disorders, injuries	Post-surgical VTE rates	Pregnancy-related VTE rates	Prevalence of VTE among all hospital inpatients	Prevalence of VTE in medical inpatients	Prevalence of VTE among surgical inpatients
	Korea 13.8 per 100,000	PE significantly higher in patients with autoimmune and chronic inflammatory disorders	Total Hip Arthroplasty -0.15 - 1.35%,	0.82 per 10 000 deliveries over the five year period from Korea	wide range	High risk medical and stroke -- 0.2 - 0.9%	Major trauma- 0.39%
	Taiwan 15.9 per 100,000	Higher DVT/VTE incidence in spinal cord injury	Total Knee Arthroplasty-0.22 - 1.2%,		11 to 65 per 10,000 for DVT,	Chronic liver disease - 1.6%	General, gastric and bowel surgery - 0.23 - 0.24% Colorectal surgery - 0.85%
	Hong Kong 19.9 per 100,000	Higher DVT/VTE incidence in organophosphate toxicity, carbon monoxide poisoning	Hip fracture Surgery-1.60%		2.5 to 23 per 10,000 for PE		Hong Kong - 0.17% (1998), 0.76%(1999) and 0.69%(2000)
		Higher DVT/VTE incidence in schizophrenia, sleep disorders, hormone replacement therapy and type 2 diabetes mellitus	Cancer surgery-0.67%		11 to 88 per 10,000 for VTE.		Mainland China - HFS -0.66% THR and TKR - 1.0 - 1.85%

Background: Thrombosis is a major underlying pathologic mechanism of severe diseases with thrombin as a key player.
Aims: Our aims were to identify and evaluate novel thrombin Inhibitors with an improved profile either alone or in combinations
Methods: A novel assay detecting fibrinogen turnover was used to screen for chemical lead structures. The optimized compound BAY-224 was characterized in fluorogenic assays and standard clotting tests. Clot lysis was measured turbidimetrically. Thrombin generated in situ in plasma was used as trigger for cytokine mRNA expression in HUVEC measured by RT-PCR.
BAY-224 was tested in various thrombosis models, including a venous reperfusion model (V. jugularis) in rabbit. The Pharmacokinetic (PK) profile was determined after administration in rat.
Results: BAY-224 is a direct, reversible inhibitor (IC_{50}0.71nM) with a different kon-/koff-profile compared to dabigatran and a high potency in plasma (IC_{50} 2nM). The clotting times in human plasma were prolonged (aPTT, EC_{200}0.7µM). BAY-224 had a stronger impact on peak height (IC_{50}0.43 µM) than lag time in the thrombin generation assay without rebound signs. BAY-224 inhibited clot-bound thrombin (IC_{50}100nM), accelerated clot lysis and reduced the induction of inflammatory cytokine mRNA expression in HUVEC.
BAY-224 showed antithrombotic effects in arterial, venous and systemic thrombosis models with an improved bleeding profile vs. dabigatran alone or in combination with FXa Inhibitors. In a rabbit venous reperfusion model, BAY-224 accelerated strongly the reperfusion of the V. jugularis.
The PK profile is compatible with oral administration without the need of a prodrug approach. BAY-224 has a low renal excretion rate.
Conclusions: BAY-224 is an active site inhibitor of thrombin with a slower, but longer binding to the target, strong adjuvant effects on clot lysis and an improved bleeding profile. Without prodrug approach it offers the potential for oral treatment and low risk for accumulation in renal insufficiency.

PB 2141 | Incidence of Venous Thromboembolism in Asian Populations: A Systematic Review

L.H. Lee[1], W. Chen[2], J. Rauvl[3], C.-C. Wu[4], A. Gallus[5]

[1]Singapore General Hospital, Haematology, Singapore, Singapore, [2]China-Japan Friendship Hospital, Beijing, China, [3]Fortis Hospital, Sahibzada Ajit Singh Nagar, India, [4]National Taiwan University Hospital, Taipei, Taiwan, Republic of China, [5]Flinders University, Flinders, Australia

Background: Despite the marked recent increase in the number of publications describing the incidence of venous thromboembolism (VTE) in Asia, there remains a lack of consensus on the true risks, and trends over time, to inform appropriate clinical practice.
Aims: To examine the evidence through systematic literature review on the burden of disease from symptomatic VTE in Asia.
Methods: Databases were searched for publications from Asia on VTE, deep vein thrombosis (DVT) or pulmonary embolism (PE) between January 1995 and February 2016. Review of eligible studies was conducted independently by two reviewers. Publications were excluded for the following reasons: small sample size; letter to the editor or literature review without new data; lack of denominator value therefore no incidence reported or calculable; survey based studies with poor response rates; duplicated data; described mainly non-symptomatic/sub-clinical disease diagnosed on screening; incidence

estimate extrapolated from < 90% of the population of interest; the report concerned predisposition for PE in people with a DVT; or VTE was not a main study outcome of interest.

Results: 1,095 studies were identified of which 72 were eligible for full text review and data extraction. Data were grouped into categories including post-surgical, non-surgical, chronic conditions, medical subgroups and cancer. Notable findings include the strong associations of increasing VTE risk with advancing age, strong emphasis on cancer associated VTE and the rising trend of VTE rates across Asia. The abbreviated findings are summarised in the table.

Conclusions: Population-wide incidence estimates were about 15-20% of the levels recorded in Western countries but have clearly increased over time. It is anticipated that this synthesis of evidence on the incidence of VTE and predisposing factors will assist with refining and updating Asian VTE-related guidelines and increase awareness about the importance of VTE in Asian populations.

PB 2142 | Thrombin Exosite 1 Inhibition with JNJ-375 Causes Anti-coagulation and Inhibits Thrombus Formation in a Human Translational Model of Thrombosis

S. Wilson[1], T. Connolly[2], G. Peters[2], A. Gosh[3], M. Johnson[3], D. Newby[1]

[1]*University of Edinburgh, Department of Cardiovascular Sciences, Edinburgh, United Kingdom,* [2]*Janssen R&D, Springhouse, United States,* [3]*Janssen R&D, Raritan, United States*

Background: JNJ-375 is a novel first-in-class anticoagulant that binds to the exosite 1 region of thrombin, whilst leaving the catalytic activity of the protease unaffected. It is derived from an anti-thrombin IgA paraprotein identified in a patient with elevated coagulation tests but without a history of bleeding episodes. Results from animal models of thrombosis suggest that selective exosite 1 inhibition may have advantages over current anticoagulants in widening the therapeutic window between anti-thrombotic and bleeding effects.

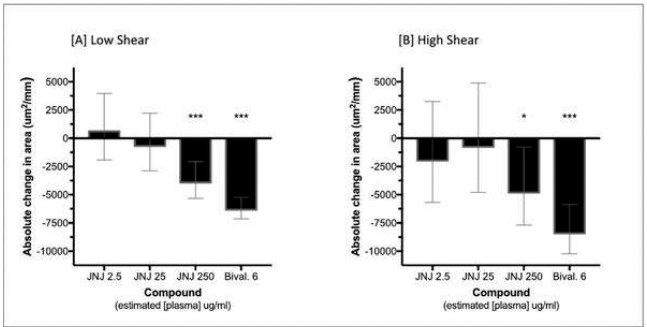

Figure 1.
The effect of study compound on *ex vivo* total thrombus formation at [A] low shear stress (212 s^{-1}) and [B] high shear stress (1690 s^{-1}) as compared to placebo. Data shown are adjusted mean absolute difference (um^2/mm) compared to placebo ± 95% confidence intervals; *p ≤0.05, **p ≤0.01, ***p ≤0.001. Abbreviations used: JNJ, JNJ-375.

FIGURE 1 The effect of study compound on ex vivo thrombus formation

Aims: To assess the anticoagulant and antithrombotic effects of JNJ-375 in an *ex vivo* human translational model of thrombosis.

Methods: Fifteen healthy volunteers participated in a double-blind randomized crossover. The effect of JNJ-64179375 (2.5, 25 and 250 µg/mL), bivalirudin (6 µg/mL; positive control) and matched placebo on coagulation assays and thrombus formation were determined using an *ex vivo* perfusion model of thrombosis.

Results: JNJ-375 produced concentration-dependent prolongation of all blood coagulation tests (correlations: r=0.98 for prothrombin time; r=0.87 for activated partial thromboplastin time; r=0.91 for thrombin time (TT), p< 0.001 for all), with TT the most sensitive to the anticoagulant effect. Compared to placebo, JNJ-375 (2.5, 25 and 250 mg/mL) reduced mean total thrombus area by -6.4% (95% CI: -41.3. 20.0; p=0.67), 7.1% (-23.0, 30.0; p=0.60) and 40.8% (21.5, 55.4; p< 0.001) at low shear and by 13.5% (-22.2, 38.8; p=0.40), 5.2% (-33.4, 32.7; p=0.75) and 32.9% (5.4, 52.5; p=0.02) at high shear stress respectively (Fig. 1).

Conclusions: In a human translational model of thrombosis, JNJ-375 produced concentration-dependent prolongation of coagulation time, and reduced *ex vivo* thrombus formation under conditions of both venous and arterial flow. Our results suggest that JNJ-375 may have a favourable anticoagulant and antithrombotic profile, and that further investigation in clinical trials is warranted.

PB 2143 | Vena Cava Filter Retrieval Rates and Factors Associated with Retrieval in the United States

J. Brown[1], V. Adams[2], J. Talbert[3]

[1]*University of Florida, Pharmaceutical Outcomes & Policy, Gainesville, United States,* [2]*University of Kentucky, Pharmacy Practice and Science, Lexington, United States,* [3]*University of Kentucky, Pharmaceutical Outcomes & Policy, Lexington, United States*

Background: The United States uses 20-40 times more inferior vena cava filters (IVCFs) than European countries. Retrieval of IVCFs is important for the safety of these devices as complications increase with longer dwell times, but is low in the U.S.

Aims: To assess IVCF retrieval rates and patient demographic and clinical factors associated with retrieval in a national cohort.

Methods: A retrospective cohort of patient receiving IVCFs was identified from a healthcare claims database. The indication for IVCF placement was identified as pulmonary embolism (PE) with or without deep vein thrombosis (DVT), DVT only, or prophylactic). Patient demographic and clinical characteristics were included in proportional hazard regression models to find associations with early (90-day) and one-year IVCF retrieval. Initiation of anticoagulation and the correlation between time-to-retrieval and time-to-initiation of anticoagulation was observed.

Results: Of 54,766 patients receiving an IVCF, 36.9% had PE, 43.9% had DVT only, and 19.2% had no apparent VTE present. Over the one-year of follow-up, the cumulative incidence of VCF retrieval was 18.4%, which differed based on indication, age, and several other key patient factors. Retrieval increased over time from a low of 14.0% in 2010 up to approximately 24% in 2014.

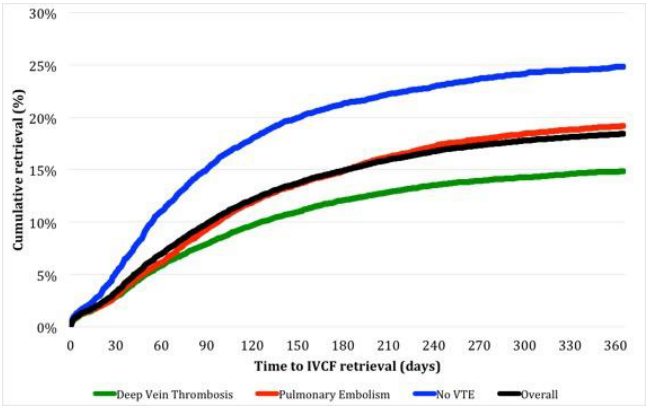

FIGURE 1 Cumulative incidence of vena cava filter retrieval

In adjusted time-to-event models, increasing age, differing regions, and some comorbidities were associated with poorer retrieval rates. Initiation of anticoagulation was poorly correlated with retrieval, with anticoagulation preceding retrieval by a median of 51 days while those without retrieval had a median of 278 days of exposure to anticoagulation.

Conclusions: IVCF retrieval increased over the study period but remained suboptimal. Improving retrieval rates can improve patient outcomes, prevent complications, and supplement clinic revenue. IVCF retrieval should be a priority for quality improvement initiatives at the institutional and national level.

PB 2144 | Dabigatran Neutralizing Antibody, Idarucizumab, Exhibits Procoagulant and Platelet Activation Responses in Whole Blood

Z. Siddiqui[1], O. Iqbal[1], D. Hoppensteadt[1], M. Lewis[1], R. Rege[1], S. Abro[1], E. Ramacciotti[1], I. Elalamy[2], J. Fareed[1]

[1]*Loyola University Medical Center, Pathology, Maywood, United States,* [2]*Hôpital Tenon, Service d'Hématologie Biologique, Paris, France*

Background: Idarucizumab is a humanized monoclonal antibody fragment that is clinically available to neutralize Dabigatran. There is currently limited data on its effects on the blood coagulation and platelet activation profiles.

Aims: The purpose of this study is to determine its effect on blood coagulation and platelet activation.

Methods: Idarucizumab was purchased as a 50 mg/mL solution from Loyola University Hospital Pharmacy. Synthetic dabigatran was obtained from Sellec Chemical (Houston, TX). Whole blood from healthy volunteers was collected for TEG and ACT analysis. Citrated whole blood was used for the preparation of platelet rich plasma (PRP) which was used in platelet aggregation studies. Arachidonic acid, ADP, epinephrine, thrombin, and collagen were used as agonists.

Whole blood was supplemented with Idarucizumab at 0-10 mg/mL and studied in a Haemoscope 500 TEG instrument. The ACT studies were carried out in celite tubes in a concentration range of 0-5 mg/mL. The agonist-induced platelet aggregation and HIT antibody mediated platelet aggregation profiles were studied after pre incubating PRP with Idarucizumab at a concentration of 1.0 mg/mL.

Results: Idarucizumab produced a dose-dependent hypercoagulable effect in the TEG profile, reducing R time by 35% and max amplitude by 45%. At high concentrations, Idarucizumab significantly affected clot retraction. Idarucizumab at 5 mg/mL reduced the ACT by 6%. Idarucizumab variably augmented the different agonist mediated platelet aggregation profiles. Idarucizumab at 1.0 mg/mL increased HIT antibody mediated platelet aggregation by almost 20%.

Conclusions: These studies show that Idarucizumab produces mild procoagulant effects as studied by TEG and ACT. It also augments the platelet aggregation profile by various agonists including Anti-heparin platelet factor IV antibodies. These procoagulant effects of Idarucizumab may contribute to potential hypercoagulable/prothrombotic events associated with its use and warrants further investigations.

PB 2145 | ONO-5450598, an Orally Available Small-molecule Inhibitor of Activated Blood Coagulation Factor XI, Inhibits Arterial Thrombus Formation without Increasing Bleeding when Used in Combination with Clopidogrel in Rabbits

T. Ono, S. Kouyama, T. Hagio, H. Miyata, S. Sakimoto, M. Tanaka, T. Koda, N. Nakanishi, K. Tanaka, D. Yanagida, M. Sakai, H. Matsuya, A. Imagawa, Y. Hirota, K. Kawabata, H. Habashita

ONO PHARMACEUTICAL CO., LTD, Osaka, Japan

Background: Both platelet aggregation and blood coagulation are involved in arterial thrombus formation. Therefore, a combination of antiplatelet and anticoagulant drugs is desired for prevention of arterial thrombosis. However, this combination therapy is known to increase the risk of bleeding. Our nonclinical studies have revealed that ONO-5450598, an orally available inhibitor of activated blood coagulation factor XI (FXIa), is lower in bleeding risk than existing anticoagulant drugs.

Aims: Combined effects of ONO-5450598 and clopidogrel were evaluated in rabbit arterial thrombosis and bleeding models to explore the possibility of whether ONO-5450598 can be a novel anticoagulant without increasing the risk of bleeding even when used in combination with antiplatelet drugs.

Methods: Clopidogrel was orally administered to rabbits at a dose of 3 mg/kg once daily for 3 days. On Day 3 of clopidogrel treatment, ONO-5450598 or rivaroxaban (an inhibitor of activated blood coagulation factor X) was orally administered. Time to occlusion (TTO) of the vessel was measured in a ferric chloride-induced carotid artery thrombosis model. Blood loss volume (BL) was measured in an abdominal incision bleeding model. In addition, activated partial thromboplastin time (APTT) and prothrombin time (PT) were measured.

Results: When administered in combination with clopidogrel, 10 mg/kg ONO-5450598 prolonged TTO without increasing BL compared with clopidogrel alone, whereas 3 mg/kg rivaroxaban prolonged TTO and increased BL. ONO-5450598 prolonged APTT by approximately 2-fold from baseline without PT prolongation while rivaroxaban prolonged both APTT and PT by approximately 1.4- and 1.3-fold, respectively.

Conclusions: ONO-5450598 is expected to be a novel oral anticoagulant without increasing the risk of bleeding even when used in combination with antiplatelet drugs.

PB 2147 | Inter-individual Variation in Plasma Levels of Direct Oral Anticoagulants in Patients with Non-valvular Atrial Fibrillation

I. Paskaleva, E. Doncheva, D. Dineva

National Heart Hospital, Laboratory Diagnostics, Sofia, Bulgaria

Background: Inter-individual variation in plasma drug levels of direct oral anticoagulants (DOAC) among patients raised the question of whether some patients may be at increased risk of bleeding events or treatment failure.

Aims: To evaluate inter-individual variability in patients with non-valvular atrial fibrillation (NVAF) on dabigatran, rivaroxaban or apixaban in the anticoagulation unit.

Methods: A total of 65 patients were enrolled, of which 30 were on dabigatran (taking 150 mg or 110 mg twice-daily, respectively), 20 on apixaban (taking 5mg or 2.5 mg twice-daily) and 15 on rivaroxaban (taking 20 mg once-daily). Blood was taken at trough level for dabigatran or apixaban and at peak level for rivaroxaban within the first 3 month of treatment. Diluted-thrombin time (DTI) was performed with Hemoclot (Hyphen BioMed) for dabigatran. Anti-FXa measurments for apixaban and for rivaroxaban were calibrated with Hyphen DiXal (Hyphen BioMed).

Results: The mean value for dabigatran 150mg 2x/daily was 86 ng/ml (30 - 182) with CV 55% and for 110mg 2x/daily was 107 ng/ml (43 - 162) with CV 44 % at trough . For apixaban 5 mg twice-daily the mean value was 77 ng/ml (36 - 122) with CV 44 % and for 2.5 mg twice-daily 51 ng/ml (20 - 75) with CV 43% at trough. The mean peak value for 20 mg rivaroxaban was 195 ng/ml (96 - 346) with CV 40% . Two patients with overweight had dabigatran levels below the lower limit (< 30 ng/ml) and one with obesity on apixabane also had levels below 20 ng/ml. The measurements of rivaroxaban at trough level was difficult because most of them are below the lower limit of detection.

Conclusions: The drug concentration levels varied in the range of six times among the patients for dabigatran on 150mg 2x/daily and about four times for apixaban on 5 mg 2 x/daily at trough. We found below on-therapy levels of DOAC in patients with overweight.

PB 2148 | Idarucizumab, a Specific Antidote for Dabigatran, Cross-reacts with Melagatran and May also Interact with other Benzamidine-containing Compounds

J. Fareed[1], L. Reikensmeyer[1], A. Walborn[2], D. Hoppensteadt[1], J. Walenga[3], E. Ramacciotti[1], S. Abro[1], W. Jeske[3], B. Lewis[4], O. Bouchard[1], I. Elalamy[5]

[1]Loyola University Medical Center, Pathology, Maywood, United States, [2]Loyola University Medical Center, Pharmacology, Maywood, United States, [3]Loyola University Medical Center, Thoracic and Cardiovascular Surgery, Maywood, United States, [4]Loyola University Medical Center, Cardiology, Maywood, United States, [5]Loyola University Medical Center, Service d'Hématologie Biologique Hôpital Tenon, Paris, France

Background: Dabigatran etexilate is used to prevent embolic stroke is patients with atrial fibrillation. Idarucizumab is an anti-dabigatran Fab fragment that binds to the benzamidine group on dabigatran and inhibits its anti-thrombin activity.

Aims: To determine the relative specificity antidote for benzamidine as a sole antidote for dabigatran.

Methods: Several of the anti-thrombin agents (argatroban, melagatran, hirudin, and bivalirudin, human antithrombin, thrombomodulin, heparin cofactor II, and heparin-AT complex and anti-factor Xa (rivaroxaban, apixaban and DX-9065a) agents were supplemented to citrated plasma at concentrations ranging from 0.1 to 100 µg/mL. Idarucizumab was added to each mixture at a concentration of 1 mg/mL and anticoagulant activity was assessed using PT, aPTT, thrombin time and chromogenic anti-IIa/Xa and flurometric thrombin generation assays.

Results: Idarucizumab itself did not produce any effect on whole blood or plasma clotting profile at concentrations of < 1.0mg/ml. The antibody showed strong specificity for the inhibition of dabigatran and did not affect the anticoagulant and other effects of the other synthetic and natural thrombin and FXa inhibitors with the exception of melagatran. The prolongation of the PT, APTT and thrombin time by melagatran was completely inhibited by idarucizumab. Idarucizumab more effectively inhibited the prolongation of thrombin time by dabigatran than the prolongation induced by melagatran.

Conclusions: The cross-reactivity of idarucizumab with melagatran may result from the presence of a common benzamidine. Since the benzamidine is present in a number of serine protease inhibitors as well as drugs such as pentamidine, propamidine and dibromopropamidine. These observations suggest that simultaneous administration of idarucizumab may compromise the pharmacodynamics profile of benzamidine derived drugs such as the anti-malarials, anti-psychotic, anti-fungal and other compounds.

PB 2149 | Influence of Dabigatran on Rotational Thromboelastometry

M. Bozic Mijovski[1], N. Vene[1], N. Snoj[2], P. Gradisek[3], A. Mavri[1]

[1]University Medical Centre Ljubljana, Department of Vascular Diseases, Ljubljana, Slovenia, [2]University Medical Centre Ljubljana, Clinical Institute of Clinical Chemistry and Biochemistry, Ljubljana, Slovenia, [3]University Medical Centre Ljubljana, Clinical Department of Anaesthesiology and Intensive Therapy, Ljubljana, Slovenia

Background: Rotational thromboelastometry (ROTEM®), that provides a point-of-care analysis of the viscoelastic properties of clot formation and dissolution, is widely implemented in the management of bleeding and coagulopathy. It is affected by anticoagulant drugs, such as warfarin and heparin.

Aims: We aimed to assess the effect of dabigatran on different ROTEM® parameters.

Methods: Ninety seven patients, 42 women and 55 men, on average 72±10 years old were included in the study after signing informed consent. From each patient blood was collected and time of last drug ingestion was carefully recorded. In whole blood ROTEM® assays EXTEM, INTEM, FIBTEM and APTEM were performed on ROTEM® delta analyzer (all Tem International GmbH, Germany) within one hour of blood collection and the following parameters were recorded: clotting time (CT), clot formation time (CFT), alpha angle, amplitude at 10 minutes (A10) and maximum clot firmness (MCF). Plasma dabigatran levels were measured with dilute thrombin time (dTT) with Test Thrombin Reagent on CS2100i analyzer (both Siemens, Germany) and ranged from 8 to 466 ug/L 10 minutes and up to 16 hours after the last drug intake covering both trough and peak levels.

Results: Dabigatran concentration significantly correlated with the CT of EXTEM, INTEM, FIBTEM and APTEM assay (correlation coefficients 0.79, 0.64, 0.80 and 0.75, respectively, all $p \leq 0.001$). APTEM was the most sensitive ROTEM® assay with 81/97 (83 %) CT results above the upper reference value compared to EXTEM (68 %), INTEM (65 %) or FIBTEM (63 %). A statistically significant but weaker correlation was observed between dabigatran and A10 and MCF within all the assays, but the majority of the MCF results were within the reference range. CFT and alpha angle were not affected by dabigatran of any ROTEM® assay.

Conclusions: Dabigatran prolonged CT of all ROTEM® assays: EXTEM, INTEM, FIBTEM and APTEM in a dose-dependent manner and could, therefore, be useful in emergency situations when high dabigatran levels are suspected.

PB 2150 | Direct Oral Anticoagulants for Thromboprophylaxis in Orthopedic Surgery in the Real World: A Systematic Review of Population Based Studies

F. Al-Ani[1], A. Garcia-Horton[1], A. Lazo-Langner[1,2]

[1]Western University, Medicine, London, Canada, [2]Western University, Epidemiology and Biostatistics, London, Canada

Background: Safety and efficacy of direct oral anticoagulants (DOACS) has been established in randomized trials but an increasing number of „real world" data outside clinical trials has become available after approval.

Aims: To assess the efficacy and safety of DOACS in population-based studies in the context of thromboprophylaxis in orthopedic surgery (OS).

Methods: We conducted a systematic review of observational studies assessing DOACs (dabigatran, rivaroxaban and apixaban) in patients with OS. Efficacy outcomes included VTE, and safety outcomes included major bleeding (MB) (as defined by investigators), gastrointestinal (GI), central nervous system (CNS) bleeding, and bleeding-related deaths. We conducted a meta-analysis of pooled incidence rates (IR) proportions using both fixed and random effects models. Given the non-randomized nature of the studies we did not conduct a meta-analysis of effect sizes.

Results: Ten studies were included: 9 assessed rivaroxaban and 1 dabigatran. 6 studies were prospective and 4 retrospective cohorts. Most studies used low molecular weight heparin (LMWH) as comparator and included patients with total hip and knee arthroplasty. The meta-analysis included rivaroxaban studies with available information. The Results of the meta-analysis of proportions is shown in table 1.

Bleeding related mortality was low in both rivaroxaban and LMWH patients. In a sensitivity analysis by funding source, no difference in estimated pooled estimates of VTE and MB were observed between industry and non-industry funded studies.

Conclusions: Rivaroxaban is effective and safe in orthopedic surgery in "real-world" observational studies, similar to RCTs. Observational data for other agents is currently limited.

TABLE 1 Evaluable patients and pooled proportions of VTE and MB

Outcome	Drug	n/N	Fixed Effects Model		Random Effects Model	
			Pooled proportion (%)	95% CI	Pooled proportion (%)	95% CI
VTE	Rivaroxaban	227/27,158	0.8	0.73-0.95	1.6	1.39-1.79
	LMWH	435/25,409	1.7	1.55-1.87	2.9	2.72-3.16
MB	Rivaroxaban	192/27,130	0.7	0.61-0.81	2.2	2.04-2.46
	LMWH	333/25,409	1.3	1.17-1.45	2.6	0.38-2.82

PB 2151 | Heparin Calibrated Anti-Xa Assays for the Measurement of Low Levels of Direct Factor Xa Inhibitors

L. Sabor[1], M. Raphaël[2], J.-M. Dogné[2], F. Mullier[2], J. Douxfils[2]

[1]CHU UCL Namur, Namur Thrombosis and Hemostasis Center (NTHC), Université Catholique de Louvain, Hematology Laboratory, Yvoir, Belgium, [2]University of Namur, Namur Thrombosis and Hemostasis Center (NTHC), Department of Pharmacy, Namur, Belgium

Background: Apixaban, edoxaban and rivaroxaban do not require frequent monitoring but an assessment of the intensity of anticoagulation may be required in emergent or elective surgery. Some experts reported that anti-Xa activity below 0.1 IU/mL using heparin calibrated chromogenic assays may assert the absence of clinically relevant (i.e. < 30 or < 50 ng/mL depending on the clinical situation) direct factor Xa levels. However, it is not clear if difference in response will depend on the anti-Xa agent and also on the chromogenic anti-Xa kit used to assess the anti-Xa activity.

Aims: To assess if a cut-off of 0.1 UI anti-Xa/mL is able to exclude apixaban, rivaroxaban or edoxaban concentration < 30 ng/mL or < 50 ng/mL using different heparin calibrated chromogenic anti-Xa kits.

Methods: Apixaban, edoxaban and rivaroxaban were added to normal pooled plasma at increasing concentrations ranging from 0 to 500 ng/mL. Anti-Xa activities were measured using

(1) STA®-Liquid Anti-Xa (STA®LAX) on a STA-R Evolution Coagulometer,

(2) Biophen®Heparin LRT (BP®LRT) on a STA-R Evolution coagulometer and

(3) HemosIL®-Liquid Anti-Xa (IL®LAX) on a ACL-TOP 700 according to manufacturer recommendations.

Results: At 30 ng/mL of rivaroxaban, BP®LRT, STA®LAX and IL®LAX provided anti-Xa results >0.1 IU/mL. At 30 ng/mL of apixaban or edoxaban, BP®LRT and IL®LAX were below the cut-off but the STA®LAX was not. At a concentration of 50 ng/mL, only edoxaban with the BP®LRT kit showed an anti-Xa activity < 0.1 UI/mL.

Conclusions: Low (< 0.1 IU/mL) anti-Xa activity is not safe to exclude clinically relevant direct factor Xa levels and should be avoided. It can only inform if the drug is present or not. Chromogenic anti-Xa assays calibrated against the appropriate agent and using the appropriate procedure remains the more accurate method to assess accurately low levels of direct FXa inhibitors.

TABLE 1 Anti-Xa activities using STA®LAX on a STA-R Evolution Coagulometer, BP®LRT on a STA-R Evolution coagulometer and (3) IL®LAX on a ACL-TOP 700

concentration (ng/mL)	anticoagulant	STA®LAX (UI/mL)	BP®LRT (UI/mL)	IL®LAX(UI/mL)
30	Rivavoxaban	0,19	0,12	0,08
30	Apixaban	0,09	0,03	0,04
30	Endoxaban	0,07	0,02	0,02
50	Rivavoxaban	0,45	0,34	0,16
50	Apixaban	0,17	0,10	0,07
50	Endoxaban	0,13	0,06	0,04

PB 2152 | Efficacy of a Novel Contact Pathway Inhibitor, Ir-CPI, on in vitro Clotting Induced by PCI Catheter Segment

J. Douxfils[1], D. Gheldof[1], S. Derochette[2], J. Tassignon[2], C. Meinguet[2], M. Guyaux[2], J.-M. Dogné[1], E. Godfroid[2]

[1]University of Namur, Pharmacy, Namur, Belgium, [2]Bioxodes, Marche-en-Famenne, Belgium

Background: Ir-CPI, a protein derived from the tick *Ixodes ricinus* salivary, is a serine protease inhibitor of both factor XIa (FXIa) and FXIIa. In patients undergoing percutaneous coronary intervention (PCI), catheter thrombosis may occur as catheters trigger activation of FXII/FXI.

Aims: The aim of this study was to evaluate the effect of Ir-CPI on in vitro clotting induced by PCI catheter segment.

Methods: Catheter segments were pressed flat, shaped into rings and placed around the perimeter of wells (96-well plate), leaving the center of the well unobstructed. To the wells were added serial dilution of Ir-CPI (until 10 µM) with normal pooled plasma (NPP) or plasmas deficient in FXI or FXII. After incubation at 37°C and addition of a $CaCl_2$ solution, clot formation was assessed by monitoring absorbance at 340nm. Time to reach one-half maximal absorbance (IC50) was defined as the clotting time. Thrombin generation test (TGT) was also assessed using catheter segment as trigger of the process. Positive inhibitory controls were used (fondaparinux, enoxaparin).

Results: Presence of the catheter reduced the clotting time of NPP; an effect reversed by the addition of Ir-CPI. At high concentrations (≥ 5µM), Ir-CPI allowed to overpass the clotting time without catheter. On TGT (Fig 1), catheter segments decreased lag time and time

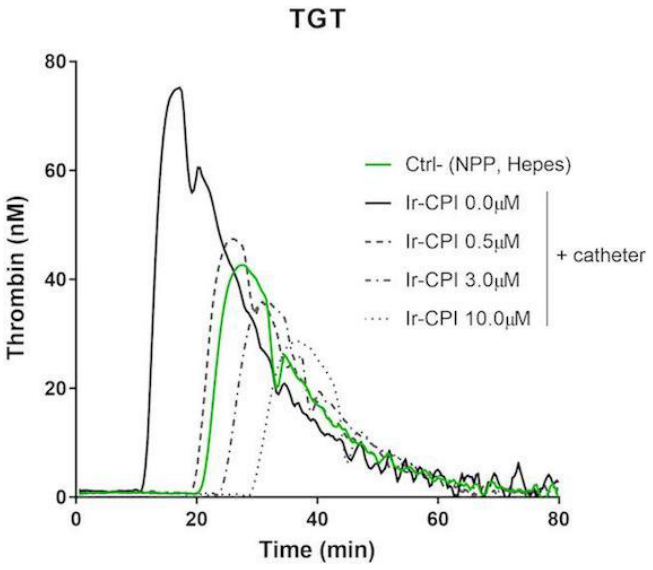

FIGURE 1 Effect of Ir-CPI on Thrombin Generation Time (TGT) in NPP exposed to PCI catheter segments

to peak while the endogenous thrombin potential (ETP) and the peak were increased. The presence of Ir-CPI allowed the restoration of baseline value, i.e. value of the NPP without exposition to catheter segments, in a concentration-dependent manner.

When clotting was triggered with FXII deficient plasma, we confirmed that catheter thrombosis is linked to FXI activation and that clotting can be abrogated with 3µM of Ir-CPI.

Conclusions: Ir-CPI can be used to inhibit the clotting induced by catheter segments and achieve antithrombotic effect. Ir-CPI is a promising agent with a better safety profile than heparins to face the problem of catheter thrombosis during PCI procedures.

PB 2153 | New Parenteral Poly (2-(acrylamide)-2-methylpropanesulfonic Acid) - Based Anticoagulants (NPACs): Efficacy and Safety Studies in Rats

B. Kalaska[1], K. Kaminski[2], J. Miklosz[1], S.-I. Yusa[3], K. Nakai[3], K. Szczubialka[2], D. Pawlak[1], M. Nowakowska[2], A. Mogielnicki[1]

[1]Medical University of Bialystok, Department of Pharmacodynamics, Bialystok, Poland, [2]Jagiellonian University, Faculty of Chemistry, Krakow, Poland, [3]University of Hyogo, Department of Applied Chemistry, Hyogo, Japan

Background: Unfractionated heparin (UFH) remains an indispensable parenteral drug inhibiting blood coagulation. The biologic variability, immunogenicity, unpredictable anticoagulation, and narrow therapeutic range limit its utility. Other parenteral anticoagulants lack of an efficient antidote. We recently presented a novel agent neutralizing all parental anticoagulants (Trans Res 2016). There is still a need for synthetic UFH alternative with the available safe antidote and without unacceptable adverse effects.

Aims: The aim of the present study was to develop a novel, safe, and easily synthesized poly (2-(acrylamide)-2-methylpropanesulfonic acid) (PAMPS)-based parenteral anticoagulants.

Methods: We synthesized, purified and characterized 4 novel PAMPS-based polymers named by us as new parenteral anticoagulants (NPAC1, NPAC2, NPAC3, and NPAC4) and PAMPS. Then, we screened polymers for potential anticoagulant and antiplatelet activity using the *in vitro* assays. Finally, we examined efficacy and safety of the most active polymers in male Wistar rats. We assessed aPTT, PT, anti-factor Xa activity, calcium concentration, and platelet aggregation as efficacy endpoints and cardiorespiratory and hematological parameters as safety measures.

Results: We found that all synthesized PAMPS-based polymers and PAMPS dose-dependently prolonged aPTT and PT and decreased platelet aggregation *in vitro*. The effect of NPAC1 on aPTT and PT was the weakest. Thus, we discontinued studying of this polymer. NPAC2 and NPAC4 significantly increased the anti-fXa activity. *In vivo*, all polymers significantly prolonged aPTT and PT. NPAC4 and PAMPS decreased, NPAC3 increased, whereas NPAC2 did not alter platelet aggregation. Unlike NPAC2 and NPAC3, NPAC4 and PAMPS caused unacceptable cardiorespiratory and/or hematological complications in rats (Table 1).

Conclusions: Documented efficacy and safety of NPAC2 in rats makes this polymer a promising candidate for a novel parenteral anticoagulant.

Funding: National Science Centre, 2016/21/B/ST5/00837.

PB 2154 | INR Might Be a Useful Predictor for Upcoming Minor to Major Bleedings in Patients Treated with NOAC

P. Bhardwaj, L.B. Petersen, T.S. Binko, T.B.S. Jørgensen, M.L. Nepper, A.M.K. Andersen, J.R. Petersen, G. Gleerup Fornitz

Amager Hospital, Copenhagen University Hospital, Research Centre of Cardiology, Copenhagen, Denmark

Background: Patients treated with Novel Oral Anticoagulants (NOAC) are not required to be monitored laboratory, as no qualitative tests or therapeutic intervals are recommended today. Despite favorable pharmacokinetic properties, bleeding events are some of the few complications to the treatment. As there are no recommended global anticoagulation tests, prediction of these complications is today not possible.

TABLE 1 In vivo efficacy and safety of new parenteral anticoagulants (NPACs)

	Vehicle	NPAC2	NPAC3	NPAC4	PAMPS
aPTT (seconds)	25.7±4.9	94.1±21.9***	82.9±27.8***	113.3±24.8***	109.9±23.4***
PT (seconds)	10.8±0.5	13.5±0.9***	12.6±1.0***	114.5±1.2***	14.6±1.5***
Platelet aggregation - maximal extension (Ω)	12 (8.5-13)	11 (5.5-13.5)	14 (13-19)**	4 (2.5-6)**	4 (0.5-6.5)**
Platelet aggregation - slope	6 (4.5-7)	6 (3-8)	8 (6-10)*	3 (2-4)***	3 (2-4.5)**
Platelet aggregation - lag time (seconds)	72 (64-89)	71 (69-89)	67 (35-74)	119 (74-196)**	106 (79-297)**
Platelet aggregation - area under the curve	39 (26-41)	34 (19-43)	49 (41-63)**	11 (5-20)**	12 (1-19)**
Blood platelets (10^3/mm^3)	666±65	654±68	666±46	562±103*	497±79***
Cardiorespiratory complications	-	-	-	Cardiac and respiratory arrest	Cardiac and respiratory arrest

Results are shown as mean±SD or as median with lower and upper limits.*P<0.05, **P<0.01, ***P<0.001 vs. vehicle, unpaired Student t test or Mann-Whitney test, n=6-11.

Aims: To explore if International Normalized Ratio (INR) assay could be used as a predictor for bleeding events in patients treated with NOAC.

Methods: Medical records of 243 patients were systematically reviewed retrospectively up to 30 months, with focus on minor and major bleedings defined using International Society on Thrombosis and Haemostasis (ISTH) criteria. Furthermore, INR elevation and fall in hemoglobin were assessed.

Patients treated with either Apixaban, Dabigatran or Rivaroxaban in recommended doses, due to either Non-Valvular Atrial Fibrillation (NVAF) or Venous Thromboembolism (VTE), were randomly selected.

Results: A peak of INR ≥ 1.5 was statistically significant associated with an increased risk of minor and major bleeding events.

There was a significant statistic correlation between INR elevations and bleeding events in the Apixaban treated patients (P-value: 0.025), and the same pattern was seen in the Dabigatran treated patients (P-value: 0.038), and also in the Rivaroxaban treated patients (P-value: 0.045). (**Table 1**)

TABLE 1 Minor to major bleeding incidents and INR correlation at peak INR > 1.5

	Bleeding and INR elevation	No bleeding but INR elevation	P-value
Apixaban	27.3%	9.7%	0.025
Dabigatran	36%	12.5%	0.038
Rivaroxaban	48.6%	25.7%	0.045

Conclusions: Patients with INR elevation ≥1.5 had a statistically significant higher risk of bleeding and/or development of anemia compared to patients with lower elevation or normal INR. This study therefore suggests that the low cost assay INR could be a predictor for upcoming bleeding events in patients treated with NOAC, but further prospective exploration will be needed.

PB 2155 | Correlation between Thromboelastometry and HPLC-MS/MS for Rivaroxaban Monitoring

V. Aranda[1], D. Priscilla[1], M. Colombini[1], M. Claudio[1], M. Cristovão[1], F. Carlos[1], J. Guerra[2]

[1]*Hospital Israelita Albert Einstein, São Paulo, Brazil,* [2]*Hospital Israelita Albert Einstein, laboratory, São Paulo, Brazil*

Background: Rivaroxaban acts as a direct factor Xa inhibitor. Although the absence of drug monitoring requirement, it is important to have a clotting assay that correlates plasma drug levels and hemorrhagic risk.

Aims: Evaluate the impact of rivaroxaban dosage and their correlation with plasma concentration quantified by chromatographic assay with mass spectrometric and Rotational thrombelastometry (ROTEM®).

Methods: We evaluated 46 patients treated with rivaroxaban: 13 with 10mg daily (OD), 16 with 15mg OD, nine with 20mg OD, and eight with 15mg twice a day (BID). Blood was collected 2h before (trough) and 2h after drug intake (peak). Non activated TEM was employed for: clotting time (CT), Clot Formation Time (CFT), Alpha angle, Amplitude after 5 minutes (A5), Amplitude after 10 minutes (A10) and Maximum Clot Firmness (MCF).

Results: There were significant difference between trough and peak response to CT, CFT and alpha angle parameters for 15 and 20 mg OD. For 10 mg OD it was possible to differentiate trough from peak in CT parameter. The A5 trough and peak were different only for 15 mg OD. For A10 parameter it was possible to differentiate trough and peak only in 20 mg OD. The comparison of HPLC-MS/MS and TEM, shows: a significant correlation at peak time between plasma concentration of rivaroxaban and CT (r=0.7879; p< 0.0001), CFT (r=0.7843; p< 0.0001), alpha angle (r= -0.7713; p< 0.0001), A5 (r= -0.7630; p< 0.0001) and A10 (r= -0.6800; p< 0.0001). No correlation was observed between the MCF and the plasma concentration of the drug in trough and peak times.

Conclusions: CT, CFT and alpha angle parameters show a statistically significant measured after 2h when compared to trough time, in a dose-dependent way. The ROTEM limitations in response to rivaroxaban in trough time present some advantages that can detect rivaroxaban effects quickly.

PB 2156 | Comparative Studies on the Anticoagulant Actions of Recombinant Thrombomodulin and Heparin and their Neutralization by FEIBA as Measured by Thromboelastography

P. Aggarwal[1], Z. Siddiqui[1], O. Iqbal[1], W. Jeske[2], D. Hoppensteadt[1], K. Tsuruta[3], J. Fareed[1]

[1]*Loyola University Medical Center, Pathology, Maywood, United States,* [2]*Loyola University Medical Center, Thoracic and Cardiovascular Surgery, Maywood, United States,* [3]*Asahi Kasei Pharma America Corporation, Waltham, United States*

Background: rTM (recombinant Thrombomodulin) is currently developed for various clinical indications and reduces thrombogenesis without increasing bleeding risk.

Aims: The purpose of this study is to compare the anticoagulant effects related to bleeding risk of rTM and Unfractionated Heparin (UH) at various levels and their neutralization by FEIBA.

Methods: Citrated Whole Blood samples were supplemented with rTM or UH in a concentration range of 0-10µg/ml (n=10). TEG analysis was performed on a Haemoscope 5000 instrument and the R time, K Time, MA and Angle were measured. The relative neutralization profiles of UH and rTM by FEIBA at 1 and 0.1 U/ml were also studied.

Results: rTM exhibited much weaker anticoagulant effects compared to UH. At 1µg/ml rTM did not produce any anticoagulant effects. At levels greater than 2.5µg/ml and up to 10µg/ml, rTM produced a concentration dependent and relatively weak anticoagulant effect.

UH was a much stronger anticoagulant and completely inhibited clot formation for the duration of TEG analysis at concentrations greater than 2.5µg/ml. FEIBA at 1U/ml completely neutralized the anticoagulant effect of rTM at 10µg/ml and UH at 0.5µg/ml. FEIBA at 0.1U/ml neutralized the anticoagulant effects of rTM at 10µg/ml completely, but only partially neutralized the anticoagulant effects of Heparin at 0.5µg/ml.

Conclusions: These studies suggest that rTM is a relatively weaker anticoagulant in comparison to UH. The expected concentration of rTM in its given indications is between 0.5-1.5µg/ml. At these concentrations, this agent is not expected to produce any anticoagulant effects. In contrast UH, at therapeutic concentrations of 1-2µg/ml produces strong anticoagulant effect. These TEG studies indicate that rTM is an antithrombotic agent mediating its effects via multiple mechanisms whereas heparins primarily produce anticoagulant effects. Supratherapeutic levels of thrombomodulin and heparin are neutralizable by FEIBA.

PB 2157 | Diclofenac for the Treatment of Acute Symptomatic Intermediate-risk Pulmonary Embolism

D. Jimenez[1], R. Nieto[1], J. Corres[1], C. Fernandez-Golfin[1], J.L. Zamorano[1], D. Barrios[2], R. Morillo[2], E. Barbero[2], M. Huisman[3], J. Kline[4], R. Yusen[5]

[1]Hospital Ramon y Cajal, Madrid, Spain, [2]Ramon y Cajal Hospital IRYCIS, Madrid, Spain, [3]Leiden University Medical Center, Leiden, The Netherlands, [4]Carolinas Medical Center, Indianapolis, United States, [5]Washington University Medical Center, Saint Louis, United States

Background: The inflammatory response induced by acute pulmonary embolism (**PE**) might contribute to the development of right ventricular (**RV**) dysfunction.

Aims: We conducted a double-blind, randomized, placebo-controlled pilot trial to investigate whether diclofenac improves RV dysfunction in intermediate-risk PE patients.

Methods: This single center study only enrolled patients who had acute symptomatic PE, echocardiographic RV dysfunction, and a lack of systemic hypotension. Patients were randomized 1:1 to receive intravenous diclofenac (two doses of 75 mg in the first 24 hours after PE diagnosis) or matching placebo in addition to standard anticoagulant therapy. The primary and secondary efficacy outcomes were persistence of RV dysfunction at 48 hours and at 7 days after randomization, respectively. The primary safety outcome was major bleeding within 7 days after randomization.

Results: The trial was stopped prematurely due to low recruitment. We randomly assigned 34 patients who had intermediate-risk PE to receive diclofenac (17) or placebo (17). In intention-to-treat analyses, rates of persistent RV dysfunction at 48 hours were 59% (95% confidence interval [**CI**], 33-82%) in the diclofenac group and 76% (95% CI, 50-93%) in the placebo group (absolute risk difference (**ARD**), -17 percentage points; 95% CI, -47 to +17). By day 7, diclofenac and placebo groups had similar RV dysfunction rates (35% in both arms). Major bleeding occurred in none of patients in the diclofenac group and in 5.9% of patient in the heparin group (ARD, -5.9 percentage points; 95% CI, -31 to +18). The randomized groups has similar rates of other adverse events.

Conclusions: This trial did not detect a significantly lower rate of RV dysfunction at 48 hours and at 7 days due to the addition of diclofenac to anticoagulation in patients who had acute symptomatic intermediate-risk PE. The diclofenac and placebo treatment groups had similar rates of adverse outcomes.

PB 2158 | Anticoagulant and Antiaggregation Effect of New Aminoestrogen

M. Flores-Garcia[1], E.C. Uribe-Lezama[1], J.M. Fernández-González[2], R. Botello-Maraver[3], M.A. Candia-Ramírez[4], O. Zepeda-García[5], E. Flores-C[2], L.R. Sosa-Flores[6], E. Pinzón-Estrada[4], A. De la Peña-Díaz[1,4]

[1]Instituto Nacional de Cardiología Ignacio Chávez, Biología Molecular, CDMX, Mexico, [2]Universidad Nacional Autónoma de México, Instituto de Química, CDMX, Mexico, [3]Instituto Politécnico Nacional, Escuela Superior de Medicina, CDMX, Mexico, [4]Universidad Nacional Autónoma de México, Facultad de Medicina, CDMX, Mexico, [5]Universidad Autónoma Metropolitana Xochimilco, CDMX, Mexico, [6]Universidad Nacional Autónoma de México, Farmacología, CDMX, Mexico

Background: The estrogens are involved in the regulation of many physiological functions, through estrogen receptor. Selective estrogen ligands are highly promising targets for different treatments. However, synthetic estrogens have side effects (e.g. increasing the risk of thrombosis). We are interested in developing drugs called aminoestrogens, with antithrombotic activity. We designed and synthesized two original compounds: N-[3-hydroxy-1,3,5(10)-estratrien-17beta-il]-4-metoxibencilamine and N-[3-hydroxy-1,3,5(10)-estratrien-17beta-il]-3,4,5-trimetoxifeniletilamine, Moame and Treoame respectively. Obtained by reaction of estrone with 3,4,5-trimethoxyphenylethylamine and 4-methoxybenzylamine followed by reduction with sodium borohydride.

Aims: Determining the anticoagulant and antiaggregant effect of two new aminoestrogens and compared with the aminoestrogen Tyrame.

Methods: The compounds were synthesized at UNAM. Male adult CD1 mice were kept under controlled conditions. After 24h of pretreatment (0.3-10mg/100g body weight compounds or DMSO (control), sc), we measured the blood clotting time with 25uL of a whole blood sample, obtained of the dorsal vein of the mice. The blood was made alternately flow by gravity between two marks in a capillary tube. We record the time until the blood is clot and stops to flow in the capillary tube. For platelet aggregation, a sample of blood (anticoagulated) was obtained under anesthesia and centrifuged. We added 10uM ADP or 1ug/mL collagen and PRP to a well of half-area 96-well plates that was at 37°C for 5min shaking and the absorbance was measured at 595nm. The result obtained with mice treated with DMSO was consider 100% of aggregation, using PPP wells as reference.

The protocol followed all the ethical and legal regulations outlined for animal experiments and was approved by the ethical institutional committee.

Results: The results are shown on table 1.

TABLE 1 IC50 of amynoestrogens

	IC 50 Moame (μM)	IC 50 Treoame (μM)	IC 50 Tyrame (μM)
Cotting time (seconds)	0.29	0.7	0.045
ADP induced platelet aggregation (%)	3.26	25.83	0.009
Collagen induced platelet aggregation (%)	9.59	5.77	7.66

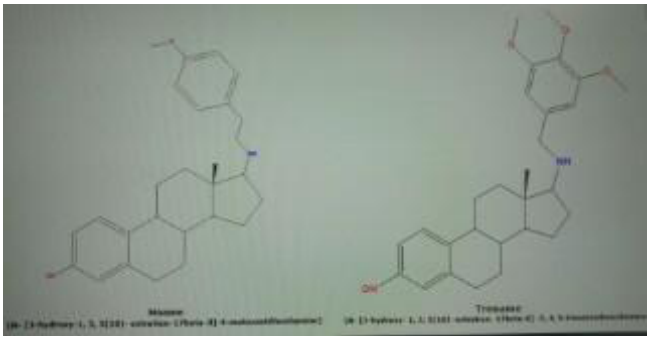

FIGURE 1 Molecular estructure of new amynoestrogens

Conclusions: The three aminoestrogens have anticoagulant and antiaggregant effect. Tyrame is the most potent.

PB 2159 | Anticoagulant Actions of Recombinant Thrombomodulin and Heparin and their Neutralization by FEIBA

M. Lewis[1], P. Aggarwal[2], Z. Siddiqui[1], O. Iqbal[1], W. Jeske[3], D. Hoppensteadt[1], K. Tsuruta[4], J. Fareed[1]

[1]Loyola University Medical Center, Pathology, Maywood, United States, [2]Loyola University Medical Center, Maywood, United States, [3]Loyola University Medical Center, Thoracic and Cardiovascular Surgery, Maywood, United States, [4]Asahi Kasei Pharma America Corporation, Waltham, United States

Background: Thromboelastographic (TEG) analysis represents a global approach to monitor the clotability of the native whole blood. This method provides an integrated hemostatic profile including both the cellular and humoral phases. rTM (recombinant Thrombomodulin) is currently developed for various clinical indications and exerts multiple actions on blood and its components to reduce thrombogenesis without increasing a bleeding risk. This is in contrast to heparins which mediate their actions accompanied by some bleeding risk. FEIBA (Factor VII Inhibitor Bypass Activity) contains non activated factors II, IX and X and activated factor VII and has been used in the management of bleeding in hemophilia patients.

Aims: The purpose of this study is to compare the anticoagulant effects related to bleeding risk of rTM and Unfractionated Heparin (UH) at various levels and their neutralization by FEIBA.

Methods: Citrated Whole Blood samples were supplemented with rTM or UH in a concentration range of 0-10ug/ml (n=10). TEG analysis was performed on a TEG 5000 system in which the clotting was initiated by reclacification of the whole blood and set parameters as R time, K time, MA and Angle were measured. The relative neutralization profiles of the UH and rTM by FEIBA at 1 and 0.1 U/ml were also investigated. All results were analyzed in terms of Means Values Standard Deviation.

Results: At 1ug/ml rTM did not produce any anticoagulant effects as evident by TEG profile. At > 2.5ug/ml, rTM produced a concentration dependent anticoagulant effect which altered the TEG profile. UH produced relatively stronger anticoagulant effects and at a concentration > 2.5ug/ml, totally inhibited the clot formation. At higher levels, UH produced strong effects, rTM at 10ug/ml produced weaker effects. FEIBA at 1U/ml neutralized the anticoagulant effect of rTM at 10ug/ml and UH at 0.5ug/ml.

Conclusions: These studies suggest that rTM is a relatively weaker anticoagulant in comparison to UH which are neutralized by relatively lower dosages of FEIBA.

PB 2160 | Sulodexide Efficiently Inhibits Thrombin Generation and Clot Formation via the Anti-Xa and Anti-IIa Activity. An in vitro Comparison with the LMWH Enoxaparin and UFH

G. Gerotziafas[1,2], P. Van Dreden[3], S. Salta[1,2], L. Papageorgiou[1], W. Jeske[4], J. Walenga[4], D. Hoppensteadt[4], M. Grusse[3], A. Larsen[1], I. Elalamy[1,2], A. Nicolaides[5], J. Fareed[4]

[1]Cancer Biology and Therapeutics, INSERM U 938, Institut Universitaire de Cancérologie (IUC), Université Pierre et Marie Curie (UPMC), Sorbonne Universities, Faculté de Médecine Pierre et Marie Curie, Paris, France, [2]Service d'Hématologie Biologique Hôpital Tenon, Hôpitaux Universitaires Est Parisien, Assistance Publique Hôpitaux de Paris, Paris, France, [3]Clinical Research, Diagnostica Stago, Gennevilliers, France, [4]Cardiovascular Institute Loyola University Chicago, Chicago, United States, [5]University of Nicosia Medical School, Nicosia, Cyprus

Background: Sulodexide is an orally active natural glycosaminoglycan composed of two entities, a fast-moving heparin fraction and a dermatan sulfate (20%). Recent phase III clinical trial data showed that oral treatment with sulodexide has a favorable risk/benefit profile when administered for long-term secondary prevention of VTE. However, the mechanism of the antithrombotic action of sulodexide remains unclear.

Aims: The effect of sulodexide, enoxaparin and unfractionated heparin (UFH) on thrombin generation (TG), clot formation kinetics and quality were compared.

Methods: Platelet poor plasma (PPP) from 5 healthy volunteers was spiked with increasing concentrations (up 10 µg/ml) of sulodexide, enoxaparin or UFH. The anti-Xa activity was measured in PPP (using the STA-Liquid anti-Xa assay) and TG was assessed with PPP-reagent 5TF®/Calibrated Automated Thrombogram (CAT®; Stago, France). For the TG test, ETP (Endogenous Thrombin Potential) and MRI were recorded. Whole blood thromboelastometry, triggered by low tissue factor concentrations (5 pM) was assessed with the ROTEM®; Clotting Time (CT), Clot Formation Time (CFT), α-angle, Maximum Clot Firmness (MCF) were analyzed. The activated partial thromboplastin clotting time (aPTT) and the thrombin time (TT) were measured.
Results: Sulodexide is a potent inhibitor of TG, delays clot formation and decreases clot firmness. The anti-Xa activity/µg, the concentrations of sulodexide, enoxaparin and UFH prolonging 2-fold the aPTT, TT, CT, CFT, and the IC50% for α-angle, MCF, ETP, MRI are shown in Table 1.

TABLE 1 In vitro comparison of the effect of sulodexide, enoxaparin and UFH on apt, TT, thrombin generation and clot formation kinetics and quality

n=5	Sulodexide	Enoxaparin	UFH
anti-Xa activity (IU/µg)	0.08	0.12	0.12
aPTT x 2 (µg/ml)	3.3	8.0	1.6
TT x 2 (µg/ml)	1.20	3.1	0.6
IC50 MRI (µg/ml)	0.80	2.0	0.8
IC50 ETP (µg/ml)	1.0	3.1	1.0
CTx2 (µg/ml)	1.8	5.8	1.0
CFTx2 (µg/ml)	1.0	4.1	1.0
IC50 α-angle (µg/ml)	3	>6	1.5
IC50 MCF (µg/ml)	3.5	-	3.3

Conclusions: Sulodexide as compared to enoxaparin and UFH, possesses 40% less anti-Xa activity per µg. The effect on aPTT and TT reveals that sulodexide has more anti-IIa activity than LMWH and about 50% less than the UFH. The inhibitory potency of sulodexide on TG and clot formation, which is the result of the synergistic action of the anti-Xa and anti-IIa activities, is in a range between UFH and enoxaparin.

PB 2161 | Porcine and Ovine Mucosal Heparins and Their Depolymerized Derivatives are Comparable in Contrast to Their Bovine Equivalents

W. Jeske[1], O. Bouchard[2], M. Lewis[2], D. Hoppensteadt[2], P. Maia[2], A. Silva de Castro[2], E. Kumar[2], N. Guler[2], D. Kahn[2], J. Walenga[3], J. Fareed[2]

[1]Loyola University Medical Center, Thoracic and Cardiovascular Surgery, Maywood, United States, [2]Loyola University Medical Center, Pathology, Maywood, United States, [3]Loyola University Medical Center, Thoraciv and Cardiovascular Medicine, Maywood, United States

Background: The currently used unfractionated heparin (UFH) and low molecular weight heparins (LMWH) are mostly derived from Porcine mucosal tissue. Recently bovine and ovine heparins have also become available.
Aims: The purpose of this study is to compare multiple individual batches of UFH obtained from Bovine, Ovine, and Porcine origin and their depolymerized product obtained by benzylation followed by alkaline hydrolysis representing enoxaparins.
Methods: The molecular profile of the heparins and enoxaparins from various sources were determined using the size exclusion method. The anticoagulant potency was measured using clot based methods such as aPTT and Thrombin Time whereas the USP potency in terms of anti-Xa and anti-IIa activities were measured using a commercial kit (Hyphen Biomedical, Ohio, USA). The relative interaction of the heparins and enoxaparins with heparin induced thrombocytopenia (HIT) antibody induced aggregation of platelets were investigated using aggregometry.
Results: The molecular profiles of the Bovine, ovine, and porcine heparins and enoxaparins were almost comparable and ranged from 15-18 kDa. The global anticoagulant and amidolytic protease assays for the bovine heparin were consistently lower than porcine and ovine samples. The USP potency of 28 batches of porcine ranged from 170-200 U/mg, whereas the 21 batches of ovine heparins exhibited comparable potencies in the range of 160-210 U/mL and 24 batches of bovine heparin ranged from 110-140 U/mg. The ovine and porcine enoxaparin exhibited comparable potencies which ranged from 94-110 U/mg whereas bovine enoxaparin was slightly lower, ranging from 80-87 U/mg.
Conclusions: These studies show that UFHs from various origin exhibit comparable molecular profiles. While the porcine and ovine heparins exhibit similar biological potencies, the bovine heparin was weaker. The enoxaparins derived from these species exhibit similar molecular profiles, however, in functional assays, they showed weaker potency.

NURSES AND ALLIED HEALTH

PB 1051 | Remote ‚Bridging Clinics' Maximise Efficiency and Patient Satisfaction in the Perioperative Management of Anticoagulation

S. Brookman

King's College Hospital NHS Foundation Trust, London, United Kingdom

Background: King's Thrombosis Centre receives approximately 130 referrals per annum for perioperative management of anticoagulation. The workload is largely nurse-led using local guidelines supported by Consultant Haematologists. In 2015 we changed our guidance to incorporate recommendations from the ‚BRIDGE' study, which results in fewer patients requiring bridging but referrals continued to increase. Patients were previously booked into a dedicated outpatient clinic to

formulate perioperative management plans. A virtual ‚bridging clinic' was introduced to reduce the need for patients to attend in person, with allocated telephone slots offering the opportunity to have a discussion and formulate a plan. Patients identified as needing face-to-face input were seen in the dedicated outpatient clinic.

Aims: The virtual clinic was created to reduce the number of hospital visits for patients, improve patient experience and promote efficiency in the anticoagulation clinic.

Methods: A virtual clinic was introduced in 2015 where a telephone appointment at a specified time and date was arranged with an anticoagulation clinical nurse specialist (CNS). During the consultation, discussion and blood result review took place as per the outpatient clinic and a perioperative management plan was devised. Data were collected prospectively on 61 patients who were reviewed in the virtual clinic from June 2015 to October 2016. Patient feedback was sought at the end of the consultation.

Results: By allocating virtual clinic slots instead of actual clinic slots, 82% of outpatient visits were avoided. This improved workload efficiency by increasing productivity. 100% of patients confirmed they were satisfied with the process and preferred a virtual clinic.

Conclusions: Perioperative anticoagulation advice is an integral part of the CNS workload and demand for this service increasing. It is important for the correct advice to be given in a timely manner and can be achieved via a virtual telephone clinic, with improved patient satisfaction.

PB 1052 | Expanding the Role of the Anticoagulation Nurse

S. Rivera, E. Gee

King's College Hospital NHS Foundation Trust, London, United Kingdom

Background: As the number of patients on DOACs (Direct Oral Anticoagulants) continues to increase, anticoagulation clinics face increased pressure to cope with this demand. The roles of all members of the multidisciplinary team including nurses should be enhanced to run the DOAC clinics effectively.

Aims: To help develop a new care model for anticoagulation by expanding the role of the anticoagulation nurse within nurse-led DOAC follow up clinics.

Methods: The training process comprises several stages. Nurses are trained by working closely with an anticoagulation specialist pharmacist. Training included familiarization with the relevant clinical trials and summaries of product characteristics. Experience and knowledge is gained by screening referrals and identifying if the DOAC is prescribed appropriately according to its license. Nurses then observe the pharmacist or doctor in clinic. They then undertake clinics under supervision of the pharmacist until adjudged competent to run the clinic independently.

The patient pathway was established and communicated to all stakeholders. A referral to the DOAC clinic initiates this pathway. Referrals get screened and discussed in the multidisciplinary team meeting to triage the patient to see a doctor, pharmacist, or nurse according to the complexity of the case. The plan for the patient is devised including blood tests, referrals to other specialist teams, or further review if needed.

Results: By undergoing structured training from a pharmacist in addition to supervision by a haematologist, the nurse-led DOAC follow up clinic successfully delivers a high quality service compliant with local and national guidelines.

Conclusions: Structured training on DOACs and coordinated patient pathways will help expand the role of the anticoagulation nurse and enable provision of an efficient, safe and cost effective service. Patients are seen by skilled and competent clinicians not limited to the doctor or pharmacist thereby reducing waiting times as well.

PB 1053 | Nurse-led Clinic Initiative for Patients Commencing Direct Oral Anticoagulants (DOACs) in the National Coagulation Centre, Dublin, Ireland

L. Solomon, M. Blake, R. Diaz, N. Flynn, V. Graham, J. Benson, A. O Sullivan, N. O Connell

St James's Hospital, National Coagulation Centre, Dublin, Ireland

Background: An increasing number of patients are commenced on DOACs, as an alternative to warfarin. Inorder to optimise patient safety, it is necessary to provide standardised, comprehensive followup and education for these patients. A nurse-led clinic was set-up as part of the existing anticoagulation service. The governance of the clinic is overseen by a Coagulation Consultant Haematologist.

Aims:

· To standardise care for patients on DOACs in accordance with the local SOP.

. To provide comprehensive education for patients on DOAC.

· To monitor renal prolife and dose adjust if needed.

Methods: An electronic referral system was set-up for referrals from both outpatient and inpatients commencing on DOAC within the hospital. The patients are booked for a group education session within two weeks followed by a review in the nurse-led clinic in 3 months. During the group education sessions patients receive information on the medication, indications, duration, side-effects and complications and follow-up care. The review clinic includes a detailed history on bleeding history, missed doses, concomitant medication along with a brief discussion reminding patients of the risks associated with anticoagulation. The patients creatinine clearance is monitored to ensure appropriate dosage of anticoagulation.

Results: To date, a total of 135 patients have attended the DOAC education session and 90 patients have been reviewed in the nurse-led clinic. Early contact between patients and the anti-coagulation nurse has enabled identification of early complications and clarification of treatment plans.

Conclusions: A nurse-led DOAC clinic is a new initiative which has been operational since May 2016. Considering the limited safety network for patients on DOAC in comparison with VKA-anticoagulants, a nurse-led clinic plays a oivitol role in improving anticoagulation care.

Patient education, monitoring and followup has optimised patient safety for those on DOAC.

PB 1054 | Haemorrheologic and Fibrinolytic Activities of Sickle Cell Subjects in Steady and Crisis States in Abuja Metropolis, Nigeria

D.C. Okpokam[1], G. Izuwa[2], J. Akpotuzor[1], P. Akpan[1]

[1]*University of Calabar, Medical Laboratory Science, Calabar, Nigeria,* [2]*Federal Staff Clinic, Medical Laboratory Science, Abuja, Nigeria*

Background: Sickle cell disease (SCD) is a common term for a group of haemoglobinopathies characterized by sickle cell anaemia, sickle beta thalassemia syndromes and other haemoglobinopathies in which haemoglobin S (HbS) is in association with abnormal haemoglobin.
Aims: This study was designed to evaluate the haemoglobin, platelet count, plasma viscosity, fibrinogen and euglobulin lysis time test values of Sickle Cell subjects in steady and crisis states that can be used in monitory the progress of sickle cell anaemia (SCA) patients treatment.
Methods: The study included 50 sickle cell (HbSS) subjects attending Federal Staff Hospital in Abuja metropolis, 40 were Sickle cell patients (HbSS) in steady state while 10 were sickle cell patients (HbSS) in crisis state. Haemoglobin electrophoresis was performed on cellulose acetate strip at alkaline pH 8.6 on all subjects. Euglobulin lysis time was determined using Haugie's method; fibrinogen level was estimated based on Clauss technique; plasma viscosity was determined using Reid and Ugwu method, while haemoglobin and platelet count were determined using Abacus Junior Haematology Analyzer. It was analysed statistically by using student's t-test, analysis of variance and Chi Square tests by statistical software SPSS version 16.0.
Results: There was a significant increase ($P < 0.05$) in the mean value of FIB 6.5±0.37 and significant decrease in PLT count 199±61.4 while no significant difference was seen in the mean values of ELT, RPV and Hb levels in sickle cell anaemia subjects in crisis state when compared to those in steady state. The mean ages in years of all subjects studied were 8.23±1.24 and 8.37±1.22 for HbSS in steady state and 7.68±1.18 HbSS in crisis. No significant difference was observed based on age
Conclusions: Fibrinogen concentration is shown in this study to be higher in crisis state than in steady state. Therefore, fibrinogen assay can be use as a tool to assess and monitor the progress of sickle cell anaemia patient especially those in crisis state.

PB 1055 | Social Work Research and Funding Opportunities: The Canadian Experience Claude Bartholomew, St. Paul´s Hospital, Vancouver, Canada Neale Smith, University of British Columbia

C. Bartholomew[1], N. Smith[2]

[1]*St Paul's Hospital, Hemophilia, Vancouver, Canada,* [2]*University of British Columbia, Clinical Epidemiology & Evaluation, Vancouver, Canada*

Background: Practice-based evidence is a component of social workers' knowledge base and is essential for providing best care to patients in both community and hospital settings. According to the Society for Social Work and Research, from 1994-2014, social work produced the fewest researchers and doctoral scholars among peer disciplines. We need additional ways to encourage knowledge development. Our aim is to understand the current capacity of social workers in practice contexts throughout Canada - i.e., providing primary patient care services and supports -- to initiate, participate in, and publish research.
Aims: We will describe the extent to which Canadian social workers currently direct or participate in research. Individual-level barriers to this include comfort with subjects like research design or data analysis. Organizational barriers include the scarcity of psychosocial grants, and lack of protected time to engage in research. To address such challenges, better understanding of funding options for research, evaluation and training purposes is needed. In Canada, sources for social work-led research funding can include foundation-based research, private-public partnerships, industry grant requests, academic grants, and individual hospital research. Relevance, availability, advantages and limitations of these different opportunities is discussed.
Methods: To be presented
Results: NA
Conclusions: An absence of social work perspectives eliminates important forms of practice-based evidence, to the detriment of patient care and frustration of professionals' career aims. By utilizing one or more forms of possible funding, we can elevate the participation of social workers in the research realm. For instance, having social work organizations lead in initiating projects and opportunities for skill development. Our aim is to give individuals and organizations a blueprint to increase the body of social work research and enabling potential participants to be successful, through identifying and accessing funding sources.

PB 1056 | Scapular Injection of Low Molecular Weight Heparin in Neonates Receiving Treatment for Thormobosis

R. Goldsmith[1], K. Hamilton[1], B. Paes[2], A. Chan[1]

[1]*McMaster Childrens Hospital, Hamilton, Canada,* [2]*McMaster University, Hamilton, Canada*

Background: Low molecular weight heparin (LMWH) is used for treatment of various thromboembolic events such as deep vein thrombosis, cerebral sinovenous thrombosis and renal vein thrombosis in neonates. To be quickly absorbed, LMWH must be injected into fat below the skin, typically, into the arm or leg. One of the primary concerns regarding administration of subcutaneous injections is the small amount of subcutaneous fat on the body of a premature neonate, especially the arm and leg. Therefore other sites of administering subcutaneous injections, such as the scapular region, need to be investigated.
Aims: The aim of the trial is to assess parent satisfaction, efficacy and bleeding following the use of scapular injection of LMWH in neonates.

Methods: This is a non randomized, prospective, pilot, cohort study of 5-10 neonates with diagnosed thrombosis who require LMWH for treatment. All patients will be treated using the current standard of LMWH administration (1.5-2.0 mg/kg of LMWH) to achieve a therapeutic anti-Xa level between 0.5-1.0 U/ml. Premature and term neonates aged < 28 days corrected age, with non cerebral thrombosis diagnosed by imaging will be included. Neonates on ventilators or those with physical deformities/anomalies at the injection site will be excluded. Parent satisfaction will be ranked using a Likert scale and will range from 1 (unsatisfied) to 5 (extremely satisfied). Efficacy will be determined by the achievement and maintenance of a therapeutic anti Xa level (0.5-1.0 U/ml) throughout the course of injections. Adverse events such as bleeding or bruising at the injections sites, or palpable areas of firmness at the injection site will be closely monitored and recorded for all study participants. The trial has been approved by the Hamilton Integrated Research Ethics Board.

Results: The study is ready to be implemented pending nursing education.

Conclusions: Conclusions will be made pending results of the trial.

PB 1057 | Empowering a Link Practitioner Network to Enhance Venous Thromboembolism (VTE) Prevention and Anti-coagulation Care

R. Greenall, E. Gee, L. Bonner, C. Doyle, G. Mulla

King's College Hospital NHS Foundation Trust, Haematology, London, United Kingdom

Background: A link practitioner;

· Acts as a role model and clinical leader for VTE prevention and anti-coagulation.

· Updates their multidisciplinary team on any new evidence and changes to guidelines.

· Conducts audit and quality improvement cycles and sharing best practice.

Aims: The aim of the link practitioner network is to increase the availability of expert knowledge at a clinical level and proactively drive quality improvement. A nurse, midwife or healthcare assistant can act as a link.

Methods: Link practitioners receive extra training in VTE prevention and anti-coagulation in their clinical area so that their role is suited to their context. Bi-monthly update meetings bring links together to share best practices and challenges.

Being motivated to extend their role and promote patient safety is a key requirement for the recruitment of a link. In return their involvement in audit and quality improvement places them in a good position when it comes to career progression. Learning gained can be demonstrated for purposes of re-validation with their relevant professional body.

Support from managers is also vital in the success of the network. Most managers have allocated two staff members to the role so that continuity of expertise is available across shifts.

The network is facilitated by the VTE prevention nurse specialist. Time required is approximately two days a month which includes organizing meetings, feeding back audit results, meeting links in their clinical area and facilitating improvement projects.

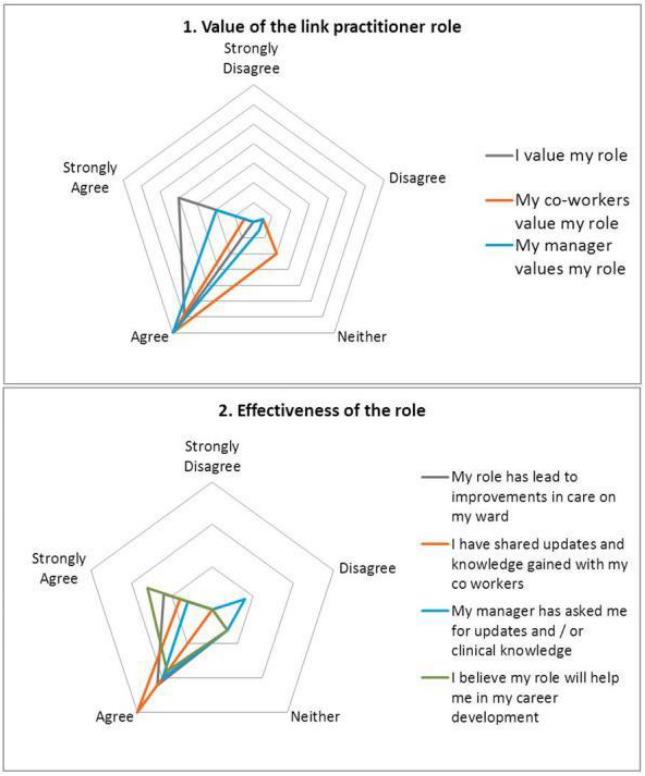

FIGURE 1 Graphs 1 and 2

Results: Graphs 1 and 2 show responses from the link network on the value they perceive it to provide.

Conclusions: There are many factors involved in VTE prevention and anti-coagulation care. These self-reported results show that the link practitioner network has a valuable contribution to improving care.

PB 1059 | Has the Introduction of the Direct Oral Anticoagulants (DOACs) Made Any Difference to Telephone Calls to A Secondary Care Led Anticoagulant Clinic?

S. Bond, S. Rhodes

Great Western Hospital, Anticogaulant Clinic, Wiltshire, United Kingdom

Background: The local secondary care led Anticoagulant Clinic manages all patients within the surrounding community receiving any oral anticoagulant. In 2010 we audited telephone calls to our clinic ansaphone over a 4 week period and we received 747 messages. This was an average of 37.4 messages per day and we had 3,900 registered patients (all taking warfarin).

Aims: The clinic now has 4,700 patients registered and 41% of these are now on a DOAC. The aim of re-auditing telephone calls was to determine whether the content of the phone calls has been influenced by the change in prescribing of oral anticoagulants.

Methods: We audited calls to the clinic ansaphone by retrospectively categorising messages received and logged by the clinic messaging service over a 4 week period in October 2016.

Results: In total we had 631 calls over the 4 week period. This equated to 31.55 calls per day.

We analysed the reason that patients were contacting us. In 2010 the most common reason to contact the clinic was patients leaving a home test INR results (18% of all calls). In 2017 this was still the most common reason to call us and now represented 46% of all calls to the clinic. The next most common reasons to contact us were calls from the hospital wards regarding planned discharges or for inpatient advice (6%) and for queries regarding peri-operative advice (6%). Calls relating to warfarin dose query dramatically reduced from 105 to 26 and change in INR retest date from 37 to 19.

Queries regarding DOACs were low, with only 21 calls in total and represented just 3.3% of calls to our clinic.

Messages left relating to bleeding were low in 2010 (1.3%) and was again low in 2016 with 8 patients (1.3%) contacted the clinic regarding bleeding on warfarin and 3 (0.48%) on a DOAC (1.75% in total)

Conclusions: It is clear that the implementation of DOACs has influenced the type of calls received by the Anticoagulant Clinic. There were far fewer calls relating to queries such as: change in INR retest date and query re dose of warfarin.

PB 1061 | When the Absence of Prophylaxis in Patients with Hemophilia, Surgery is Inevitable

L. Rakic

Clinical Center of Serbia, Belgrade, Serbia

Background: People with hemophilia due to the deficit of coagulation factors often bleed into joints, and the most common companion in their lives is hemophilic arthropathy. Lifetime propensity to, leads to passivity and different levels of disability, depending on the degree of factor deficiency which is is a major social problem. Abundant bleeding in males occur as a result of blood coagulation disorders and it can be: spontaneous and in minor injuries or interventions. As a standard for surgical procedures, compensation of the missing factor is 100% necessary. In the care and treatment of patients, where the complex surgical interventions are planned, nurse participation and a multidisciplinary approach are indispensable.

Aims: Emphasize the importance of a multidisciplinary approach, with special attention to the work of nurses, when complex procedure of knee joint replacement in patients with hemophilia is planned.

Methods: Case report.

Results: The use of prophylactic treatment has improved chances of reaching adulthood without the development of arthropathies. Patients who did not received prophylaxis in childhood are now adults with problems such as different levels of disability, or most commonly Haemophilus arthopathies.

Conclusions: In order to prevent potential bleeding, compensation of the missing factor is necessary before every minor or major surgical intervention.

Together with hemostatic screening and observation of hematologist, participation of trained hematology nurse, along with other members of the multidisciplinary team is essential.

Skill for specific application of coagulation factors as well as for specific care and health education of patients, nurses acquire through continuous education and work in the hematology team.

PATHOGENESIS OF THROMBOEMBOLISM

PB 614 | Efficacy of Dabigatran Etexilate in a Cancer Associated Thrombosis Murine Model

Y. Kassim[1], C. Lemarie[1], J. Van Ryn[2], M. Blostein[3]

[1]Lady Davis Institute for Medical Research, Montreal, Canada, [2]Boehringer Ingelheim, Ingelheim am Rhein, Germany, [3]Lady Davis Institute – Jewish General Hospital, Montreal, Canada

Background: Recurrent venous thromboembolism (VTE) is a common complication of cancer. Bleeding is particularly problematic due to the use of anticoagulants and the frequent need for surgical interventions. The treatment of cancer-associated thrombosis (CAT) consists primarily of low molecular weight heparin (LMWH) given parentally. Recently, direct oral anticoagulants (DOACs) have become available. DOACs require less dose adjustment and are given orally. A recent metanalysis of cancer patients treated with DOACs for VTE demonstrate that DOACs were as effective and safe as warfarin for use in cancer patients. However, no studies have directly studied DOACs in cancer patients with VTE nor compared DOACs with LMWH with selective inclusion of cancer patients only.

Aims: Compare the efficacy of dabigatran and LMWH in CAT and VTE murine models.

Methods: Thrombus formation is induced in the inferior vena cava (IVC) by partial flow restriction in wild type mice. For the CAT model, mice are injected with murine B lymphoma cells (Eμ-Myc cells). After 6 days, thrombosis is then induced as described above. Treatment with either dalteparin (200 IU/kg/day subcutaneously) or with dabigatran (45 mg/kg) by oral gavage is started 24h after thrombosis induction.

Results: Both dalteparin and dabigatran are effective in reducing the size of the thrombus in our VTE and CAT murine models. In our VTE model, dalteparin reduces thrombus size by 32% as compared to 18% for dabigatran, whereas, in our CAT model, dalteparin reduces thrombus size only 11% as compared to 24.9% with dabigatran.

Conclusions: Our data suggest that dalteparin is more effective when compared to dabigatran in VTE whereas dabigatran is superior in CAT. As a proof of principle, the above described models can be further employed to study the pathophysiology of VTE and CAT and provide biologic plausibility for pursuing further studies for using NOACs, specifically, dabigatran, in CAT.

PB 615 | Incidence of Venous Thromboembolism in Cancer Survivors: The Scandinavian Thrombosis and Cancer (STAC) Cohort

I.L. Gade[1], S.K. Brakkan[2,3], I.A. Naess[4], J.-B. Hansen[2,3], F.R. Rosendaal[5], S.C. Cannegieter[5,6], K. Overvad[7,8], H. Jensvoll[3], J. Hammarstrom[9], O.V. Gran[2], H.H. Eriksen[10], S.R. Kristensen[1,11], M.T. Severinsen[1,12]

Jebsen Thrombosis Research and Expertise Centre (TREC), Department of Clinical Medicine, Tromso, Norway, [3]University Hospital of North Norway, Division of Internal Medicine, Tromso, Norway, [4]Trondheim University Hospital, Department of Hematology, Trondheim, Norway, [5]Leiden University Medical Center, Department of Clinical Epidemiology, Leiden, The Netherlands, [6]Leiden University Medical Center, Department of Thrombosis and Hemostasis, Leiden, The Netherlands, [7]Aarhus University, Department of Public Health, Section for Epidemiology, Aarhus, Denmark, [8]Aalborg University Hospital, Department of Cardiology, Aalborg, Denmark, [9]Norwegian University of Science and Technology, Department of Cancer Research and Molecular Medicine, Trondheim, Norway, [10]Aalborg University Hospital, Unit of Clinical Biostatistics and Bioinformatics, Aalborg, Denmark, [11]Aalborg University Hospital, Department of Clinical Biochemistry, Aalborg, Denmark, [12]Aalborg University Hospital, Department of Hematology, Aalborg, Denmark

Background: Cancer patients have increased risk of venous thromboembolism (VTE). The risk is highest shortly after diagnosis and decreases afterwards. Few studies have investigated whether the incidence of VTE reaches that of the general population in long-term cancer survivors.

Aims: To compare the incidence of VTE in long-term cancer survivors with a matched control group in a population based cohort study.

Methods: The STAC cohort includes person-time data of 144,952 Danes and Norwegians. Informed consent at study enrollment between 1993 and 1997 permitted linkage to medical databases by the unique personal civil registration number. The Danish and Norwegian National Cancer Registers provide data of cancer diagnoses coded with the ICD-10 system. Incident symptomatic VTEs during follow-up until 2012 were objectively confirmed. All cancer-exposed subjects (excluding non-melanoma skin cancers), and five age-, sex- and nationality-matched controls, free of cancer at index date, were included in the study. Study entry was date of cancer diagnosis, and time since cancer diagnosis/index date was the time axis. We calculated incidence rates (IR) of VTE occurring later than five years after cancer diagnosis and compared the incidence of VTE in cancer-survivors to controls by incidence rate ratios (IRR).

Results: Of 14.272 diagnosed with overt cancer, 3.298 were alive five years after cancer diagnosis. Among these, 63 VTEs were observed later than five years since cancer diagnosis (IR 4.7 pr. 1000 p-y, 95% CI 3.7 - 6.1), which was higher than in the control group (IRR 1.4, 95% CI 1.1 - 1.9). Relative risks of VTE later than five years after cancer diagnosis varied with cancer type; from IRR 3.0 (95% CI 1.3 to 6.7) in hematologic malignancies to IRR 0.8 (95% CI 0.4 to 1.8) in colorectal cancer.

Conclusions: The incidence of VTEs more than five years after cancer diagnosis remains slightly elevated relative to the general population, but varies by cancer type.

PB 616 | Incidence of Occult Cancer in the Year Following a Second Unprovoked Venous Thromboembolism Event

A. Delluc[1], S. Rezig[1], J.-C. Ianotto[2], C. Tromeur[1], M. Gouillou[3], F. Couturaud[1], K. Lacut[3], D. Mottier[3]

[1]Brest University Hospital, EA 3878 GETBO - Internal Medicine, Brest, France, [2]Brest University Hospital, EA 3878 GETBO - Hematology, Brest, France, [3]Brest University Hospital, INSERM CIC 1412, Brest, France

Background: Between 3.2% and 10.0% of patients presenting with unprovoked venous thromboembolism (VTE) will be subsequently diagnosed with cancer, with the highest risk in the first year after the diagnosis of VTE. Several subgroups of patients with unprovoked VTE might benefit from systematic cancer screening, such as those with a previous unprovoked VTE event.

Aims: The aim of this study was to determine the one-year incidence of cancer following a second unprovoked VTE event.

Methods: The EDITH cohort is a cohort of patients followed at the Brest University Hospital for an objectively proven, symptomatic, deep vein thrombosis of the lower limbs and/or pulmonary embolism. For this analysis we used data from patients who experienced two unprovoked symptomatic VTE events. We selected only patients for whom time spanned between the first and recurrent VTE event was less than 2 years.

Results: Between May 1st, 2000 and December 31st, 2013, 201 patients with two documented symptomatic unprovoked VTE events that occurred in a 2-year's time were included in the EDITH cohort. Patients' mean age was 66.5±16.3 years, 101 (50.2%) were men. Of the 201 VTE recurrences, 21 (10.4%) occurred on therapeutic anticoagulation. In total, 15 cancers were diagnosed in the year following the second unprovoked VTE event (7.46% of the study sample): one cancer was patent at the time of the second VTE event, 8 were diagnosed to the 21 patients on therapeutic anticoagulation at the time of VTE recurrence (cumulative incidence: 30.77% (95% CI 15.06-56.36)), and 6 were diagnosed to the 180 patients off anticoagulation at the time of VTE recurrence (cumulative incidence: 4.69% (95% CI 2.43-9.35)) (p< 0.001 by log-rank test).

Conclusions: In this hospital-based cohort, the 1-year incidence of occult cancer in patients with a second unprovoked VTE event was low suggesting systematic cancer screening should not be performed. However, this incidence was high when VTE recurs on full anticoagulation.

PB 617 | Risk Factors of Occult Malignancy in Patients with Unprovoked Venous Thromboembolism: Results from the MVTEP Study

P. Robin[1], P.-Y. Le Roux[1], C. Tromeur[2], B. Planquette[3], N. Prévot-Bitot[4], C. Lavigne[5], J. Pastre[3], A. Merah[6], G. Le Gal[2,7], P.-Y. Salaun[1], MVTEP Study Group

[1]Centre Hospitalo-Universitaire de Brest, Université de Bretagne Occidentale, Service de Médecine Nucléaire, EA 3878 (GETBO) IFR 148, Brest, France, [2]Centre Hospitalo-Universitaire de Brest, Université de Bretagne Occidentale, Département de Médecine Interne et Pneumologie, EA 3878, CIC INSERM 1412, Brest, France, [3]Hôpital Européen Georges Pompidou, AP-HP; Université Paris Descartes, Sorbonne Paris Cité, Service de Pneumologie, INSERM UMR-S 1140, Paris, France, [4]Centre Hospitalo-Universitaire de Saint-Etienne, Université Jean Monnet, Service de Médecine Nucléaire, Inserm U1059, Saint-Etienne, France, [5]Centre Hospitalo-Universitaire d'Angers, Département de Médecine Interne et Maladies Vasculaires, Angers, France, [6]Centre Hospitalo-Universitaire de Saint-Etienne, Service de Médecine Vasculaire et Thérapeutique, Inserm CIC 1408, Saint-Etienne, France, [7]Ottawa Hospital Research Institute at the University of Ottawa, Department of Medicine, Ottawa, Canada

Background: Venous thromboembolism (VTE) can occur as the first manifestation of an underlying occult malignancy. It remains unclear whether or not a better selection of high risk patients might lead to more efficient occult cancer screening strategies.

Aims: To assess the predictors of occult malignancy diagnosis in a population of patients with unprovoked VTE.

Methods: Univariate analyses were performed to assess the effect of candidate predictors on occult cancer detection in patients enrolled in a prospective, multicenter, randomized, controlled study (MVTEP study) whose primary aim was to compare a limited screening strategy with a strategy combining limited screening and FDG PET/CT in patients with unprovoked VTE.

Results: Between March 3, 2009, and August 18, 2012, 399 patients were included. Five patients withdrew consent and refused the use of their data, and no VTE was confirmed in 2 patients who were excluded from this analysis. A total of 25 (6.4%) out of the 392 analysed patients received a new diagnosis of malignancy during the 2-years follow-up. Age > 50 years (p=0.01), male gender (p=0.04), leukocytes count (p=0.01), and platelets count (p=0.03) were associated with occult cancer detection. Previous VTE and current smoker status were not associated with occult cancer diagnosis (p>0.05).

Conclusions: Demographic characteristics (age and sex), and laboratory tests (leukocytes and platelets) may be predictors of occult cancer detection in patients with unprovoked VTE.

PB 618 | Impact of Tumor Grade on the Risk of Venous Thromboembolism in Cancer; the Scandinavian Thrombosis and Cancer (STAC) Cohort

I.L. Gade[1], S.K. Brakkan[2,3], I.A. Naess[4], J.-B. Hansen[2,3], F.R. Rosendaal[5], S.C. Cannegieter[5,6], K. Overvad[7,8], H. Jensvoll[3], J. Hammarstrom[9], O.V. Gran[2], H.H. Eriksen[10], S.R. Kristensen[1,11], M.T. Severinsen[1,12]

[1]Aalborg University, Department of Clinical Medicine, Aalborg, Denmark, [2]UiT The Arctic University of Norway, K.G. Jebsen Thrombosis Research and Expertise Centre (TREC), Department of Clinical Medicine, Tromso, Norway, [3]University Hospital of North Norway, Division of Internal Medicine, Tromso, Norway, [4]Trondheim University Hospital, Department of Hematology, Trondheim, Norway, [5]Leiden University Medical Center, Department of Clinical Epidemiology, Leiden, The Netherlands, [6]Leiden University Medical Center, Department of Thrombosis and Hemostasis, Leiden, The Netherlands, [7]Aarhus University, Department of Public Health, Section for Epidemiology, Aarhus, Denmark, [8]Aalborg University Hospital, Department of Cardiology, Aalborg, Denmark, [9]Norwegian University of Science and Technology, Department of Cancer Research and Molecular Medicine, Trondheim, Norway, [10]Aalborg University Hospital, Unit of Clinical Biostatistics and Bioinformatics, Aalborg, Denmark, [11]Aalborg University Hospital, Department of Clinical Biochemistry, Aalborg, Denmark, [12]Aalborg University Hospital, Department of Hematology, Aalborg, Denmark

Background: Cancer is associated with an increased risk of venous thromboembolism (VTE). The risk differs between cancer types, possibly partly with tumor grade. Tumor grade is associated with aggressiveness, and therefore the risk of VTE should be investigated in frameworks that treat death as a competing event.

Aims: To investigate the association between tumor grade and risk of VTE in a population based cohort; the Scandinavian Thrombosis and Cancer (STAC) Cohort.

Methods: The STAC cohort consists of data from three large population based cohort studies. Enrolment ran from 1993 through 1997. 144,952 participants free of previous cancer and VTE were followed prospectively; date of last follow-up for VTE was December 31, 2012. Information on tumor grade was obtained from the Norwegian Cancer Registry and the Danish National Pathology Registry, respectively providing the sixth digit of the ICD-O-3 code and SNOMED codes. Cancers were divided into low grade or high grade. Cumulative incidence (CI) of patients with VTE, treating death as competing event expressed risk of VTE. Cancer stage, age and sex were included as possible confounders in the Fine-Gray regression model, low grade was reference. Time since cancer diagnosis was used as time axis.

Results: Excluding subjects with VTE before cancer and haematological malignancies left 13,140 with a diagnosis of cancer, 29% had low grade tumors, 18% had high grade tumors. In 54% information on grade was not available from the registers. In total, 416 VTEs were observed during follow-up. The risk was highest in high grade tumors, 5-year CI 4.2 (3.4-5.1) versus 2.5 (2.0-3.1) in low grade tumors (figure 1).

The crude sub-distributional hazard ratio (SHR) for VTE in high grade was 1.5 (1.2 to 2.0), adjusted SHR in high grade tumors was 1.3 (1.0 to 1.8), this association was, however, not uniform in analysis stratified by cancer types.

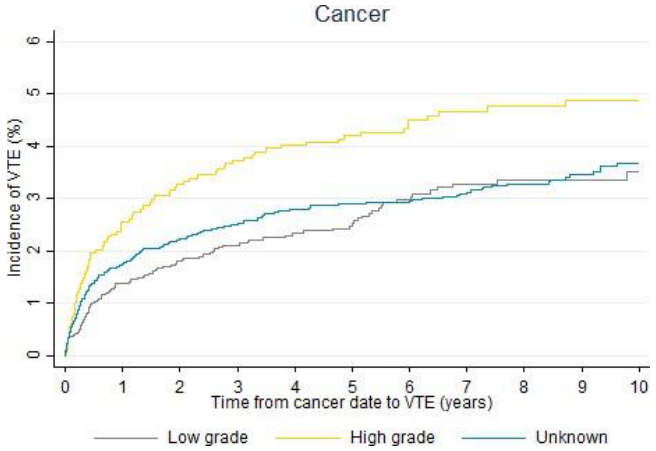

FIGURE 1 Cumulative Incidence of VTE in cancer

Conclusions: High grade tumors are in general associated with a higher risk of VTE than low grade tumors.

PB 619 | Thromboembolic Events in Cancer Patients on Active Treatment with Cisplatin-based Chemotherapy; Another Look!

H. Abdel-Razeq[1], A. Mansour[2], A. Alshwayat[1], H. Abdulelah[1], M. Ibrahim[1], M. Abu Nasser[1], A. Rabhaiah[3], R. Alfar[1], A. Abufara[1], A. Ibrahim[2], M. Ma'koseh[1], Y. Ismael[4]

[1]King Hussein Cancer Center, Internal Medicine, Amman, Jordan, [2]King Hussein Cancer Center, Radiology, Amman, Jordan, [3]King Hussein Cancer Center, Pharmacy, Amman, Jordan, [4]King Hussein Cancer Center, Radiation Oncology, Amman, Jordan

Background: The risk of thromboembolic events (TEE) is higher among cancer patients; especially so in patients undergoing chemotherapy. Cisplatin-based regimens has been widely used and claimed to be associated with high TEE, beyond what is usually seen in clinical practice.

Aims: In this study we report on the incidence of TEE in patients on active cisplatin-based chemotherapy and its relation to variables like primary tumor, disease stage and Khorana risk score.

Methods: Medical records and hospital database were searched for all adult patients treated with any cisplatin-based regimen for any kind of cancer. Thrombosis was considered cisplatin-related if diagnosed any time after the first dose and up to 4 weeks after the last. Khorana risk assessment model was performed on all.

Results: Between 2007 and 2015, a total of 1677 patients (65.5% males, median age: 50 years) treated with cisplatin-based regimens were identified. Head & neck (22.9%), lung (22.2%), lymphoma and gastric (11.4% each) were the commonest primary tumors. Thromboembolic events were reported in 110 (6.6%); highest in patients with gastric cancer (20.9%) and lowest in head & neck cancers (2.3%). Thrombosis included DVT in 69 (62.7%), PE in 18 (16.9%) and arterial thrombosis in 17 (15.6%). Majority (69.1%) of the patients had stage IV disease and only 10% had stage I or II.

High Khorana risk score, stage IV disease and gastric as the primary tumor but not age, sex or type of cisplatin combination regimen were associated with significantly higher rates of TEE.

Further analysis highlighting the role of mean cumulative cisplatin dose, presence of central venous catheters and other risk factors will be presented.

Conclusions: TEE events among cancer patients on active cisplatin-based chemotherapy are not as common as previously reported. However, higher TEE rates were encountered in patients with gastric cancer, stage IV disease and in those with high Khorana risk score which may justify a recommendation to offer such patients thrombosis prophylaxis.

PB 620 | Low Discriminating Power of the Modified Ottawa VTE Risk Score in a Cohort of Patients with Cancer from The RIETE Registry

A. Alatri[1], L. Mazzolai[1], C. Font[2], A. Tafur[3], R. Valle[4], M. Monreal[5], RIETE Investigators

[1]CHUV, Lausanne University Hospital, Division of Angiology, Lausanne, Switzerland, [2]Hospital Clínic de Barcelona, Institut Clinic de Malalties Hemato-Oncològiques (ICMHO), Barcelona, Spain, [3]NorthShore University Health Systems, Department of Medicine - Cardiology-Vascular Section, Evanston, United States, [4]Hospital Sierrallana, Department of Internal Medicine, Santander, Spain, [5]Hospital Universitario Germans Trias i Pujol de Badalona, Department of Internal Medicine, Barcelona, Spain

Background: Treatment of patients with cancer-associated venous thromboembolism (VTE) remains a major challenge. The modified Ottawa score is a clinical prediction rule evaluating the risk of VTE recurrences during the first six months of anticoagulant treatment in patients with cancer-related VTE.

Aims: We aimed to validate the Ottawa score using data from the RIETE (Registro Informatizado Enfermedad TromboEmbolica) registry.

Methods: We assessed the prognostic value of the modified Ottawa score in predicting the likelihood of VTE recurrences and overall mortality during the first six months of anticoagulant treatment.

Results: A total of 11,123 cancer patients with VTE were included in the analysis. According to modified Ottawa score, 2,343 (21%) were categorized at low risk for VTE recurrences, 4,525 (41%) at intermediate risk, and 4,255 (38%) at high risk. Overall, 477 episodes of VTE recurrences were recorded during the course of anticoagulant therapy, with an incidence rate for low, intermediate, and high risk groups of 6.88% (95% CI 5.31-8.77), 11.8% (95% CI 10.1-13.6), and 21.3% (95% CI 18.8-24.1) patient-years, respectively. Overall mortality had an incidence rate of 21.1% (95% CI 18.2-24.3), 79.4% (95% CI: 74.9-84.1), and 134.7% (95% CI: 128.3-141.4) patient-years, respectively. The accuracy and discriminating power of the modified Ottawa score for VTE recurrence was modest, with low sensitivity and specificity and a C-statistics of 0.58 (95% CI: 0.56-0.61). Similar results were obtained for overall mortality with low sensitivity and specificity and a C-statistic slightly better (0.65; 95%CI: 0.64-0.66).

Conclusions: Our analysis showed that the modified Ottawa score is not able to accurately predict VTE recurrence and overall mortality among patients with cancer-associated thrombosis, thus hindering its use in clinical practice. It is time to define a new score including other clinical predictors.

PB 621 | End of Life Management of Venous Thromboembolism in Metastatic Cancer: Current Practice, Place of Death and Complications

S. Banerjee[1], N. Pease[2], S. Noble[3]

[1]*Cardiff University, Cardiff, United Kingdom,* [2]*Velindre Cancer Centre, Palliative Medicine, Cardiff, United Kingdom,* [3]*Cardiff University, Palliative and Supportive Care, Newport, United Kingdom*

Background: Guidelines recommend cancer associated thrombosis (CAT) is treated with low molecular weight heparin (LMWH) for three to six months. Indefinite anticoagulation should be considered for patents with ongoing active/ metastatic cancer. There are no data on the management of CAT at the end of life and no guidance when to stop anticoagulation as death approaches.

Aims: To review current practice at the end of life care for advanced cancer patients who have been anticoagulated on LMWH for venous thromboembolism (VTE).

Methods: Prospective data was collected on patients attending a regional CAT service and cross-referenced with death notifications. Hospital, hospice and community patient's healthcare records were reviewed to evaluate end of life care within the context of VTE management.

Results: 214 patients with metastatic cancer and a history of VTE died over a 2-year period. 98 (46%) died at home, 59 (27%) in a hospice, 53 (25%) in acute hospital and 4 (2%) in a community hospital.

Of these 108 (50%) continued LMWH until death, 23 (11%) up to 7 days prior to death, 23 (11%), 1 week to 1 month 29 (13.5%), over one month 40 (18%).

Clinically relevant non-major (CRNM) bleeding occurred in 9/ 131 (7%) of the patients who continued LMWH to death or 7 days up to death.

Conclusions: The majority of CAT patients with metastatic disease remain anticoagulated up to or within days of death. Whilst symptoms of pulmonary emboli are controlled as death approaches, this comes with a 7% incidence of CRNM bleeding.

PB 622 | Outcomes of Extended Anticoagulant Treatment of Venous Thromboembolism in Patients with Cancer

M. Stalc[1], U. Cvajnar[2], A. Mavri[2]

[1]*University Medical Centre Ljubljana, Department for Nuclear Medicine, Ljubljana, Slovenia,* [2]*University Medical Centre Ljubljana, Department of Vascular Diseases, Ljubljana, Slovenia*

Background: Venous thromboembolism (VTE) is a common complication in patients with cancer. The optimal duration of anticoagulant therapy in cancer-associated thrombosis is not known, but anticoagulation beyond 3 months should be considered for those with active cancer and/or those receiving anticancer treatment. Data on extended anticoagulant therapy in cancer patients with VTE is scarce.

Aims: To establish safety and efficacy of extended outpatient treatment of cancer patients with VTE.

Methods: Anticoagulant treatment was assessed in 290 consecutive ambulatory treated cancer patients (age 68 ± 12 years, 134 (46%) women) with objectively confirmed VTE one month, six months and two years after VTE diagnosis. Bleeding events (major and minor), recurrent VTE events and death were identified by reviewing patients´ medical charts and the data from the anticoagulant therapy management computer program.

Results: Low molecular weight heparin (LMWH) was used for long-term treatment (6 months) in 243 (83%) patients. Vitamin K antagonists (VKA) were used in 130 (64%) and LMWH in 44 (22%) patients for extended treatment. Proportion of all complications during anticoagulant therapy is shown in figure 1. The majority of bleeding and recurrent VTE events occurred during the first 3 months of therapy with LMWH and in the first year of therapy with VKA. Stage of cancer was the only independent prognostic factor for developing a recurrent VTE (p< 0,01). In the two-year period 55% of patients died. In 87% the cause of death was cancer. Bleeding event was fatal for 4 (3 on LMWH, 1 on VKA) patients and pulmonary embolism was fatal for 4 (2 on LMWH, 2 on VKA) patients while receiving anticoagulant therapy. Survival rate was lower in patients who suffered recurrent VTE on VKA.

Conclusions: The risk of bleeding and VTE recurrence is the highest in the first months of anticoagulant therapy in cancer patients. In patients without complications, carefully monitored extended outpatient therapy seems to be beneficial.

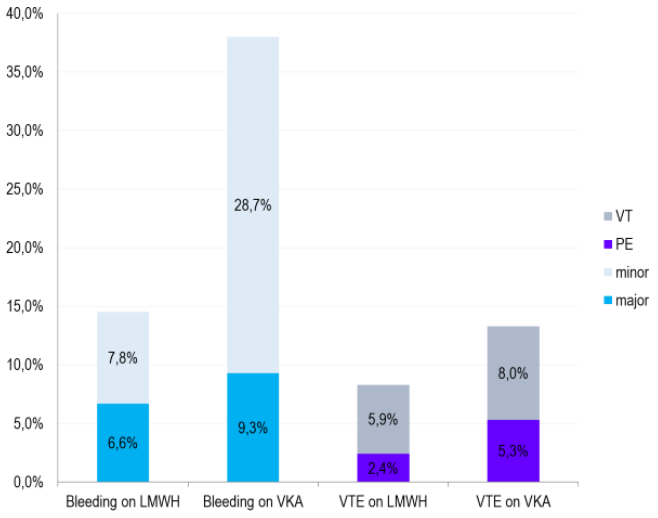

FIGURE 1 Proportion of complications during the two-year follow up (VT-vein thrombosis, PE-pulmonary embolism)

PB 623 | Joint Effects of Body Height and Cancer on the Risk of Incident Venous Thromboembolism: The Tromsø Study

H. Skille[1], O.V. Gran[1], B. Paulsen[1], S.K. Braekkan[1,2], J.-B. Hansen[1,2]

[1]UiT - The Arctic University of Norway, K. G. Jebsen TREC - Thrombosis Research and Expertise Center, Tromsø, Norway, [2]University Hospital of North Norway, Division of Internal Medicine, Tromsø, Norway

Background: Tall stature is associated with risk of both venous thromboembolism (VTE) and cancer, and VTE is a common complication in patients with malignancy. No previous study has investigated the joint effects of body height and cancer on the risk of VTE.

Aims: To study the joint effects of body height and cancer on the risk of incident VTE using a large population-based cohort.

Methods: Subjects (n=30 405) were recruited from the forth (1994-95) fifth (2001-02) and sixth (2007-08) surveys of the Tromsø Study. Validated VTE events and cancer diagnoses were registered until December 31, 2012. VTEs occurring 6 months before to 2 years after a cancer diagnosis were defined as cancer-related. Cox regression was used to determine age- and sex adjusted hazard ratios (HR) for VTE by cancer status and quartiles (Q) of height (Q1: ≤163cm, Q2: 163.1-170cm, Q3: 170.1-177cm, Q4: 177.1-207cm).

Results: There were 2981 incident cancer diagnoses and 658 VTE events, of which 175 were cancer-related, during a median follow-up of 17.5 years. The risk of VTE increased across quartiles of body height (p for trend < 0.001) with a 2-fold higher risk (HR 2.1, 95% CI 1.4-3.0) in Q4 compared to Q1. A similar trend was observed for VTE in cancer (HR Q4 vs. Q1: 1.6 95% CI 0.9-2.9). In subjects with cancer, the VTE risk increased from 17-fold (HR 17.7, 95% CI 13.0-24.0) in Q1 to 26-fold (HR 26.0, 95% CI 17.1-39.5) in Q4, when compared to non-cancer subjects in Q1.

Conclusions: Our findings demonstrated a dose-response relationship between body height and VTE in the general population and in cancer patients, suggesting a joint effect of malignancy and tall stature on the risk of VTE.

PB 624 | Patients with Cancer-associated Thrombosis Benefit from Anticoagulant Treatment Beyond 6 Months

I.T. Wilts[1], J. Trujillo-Santos[2], P.W. Kamphuisen[3,4], L. Hernández-Blasco[5,6,7], M. Lumbierres[8], M.D.C. Díaz-Pedroche[9], M.A. Lorente[10], J.B. López-Sáez[11], M. Ciammaichella[12], M. Monreal[13,14], the RIETE Investigators

[1]University Medical Center Groningen, Department of Internal Medicine, Division of Vascular Medicine, Groningen, The Netherlands, [2]Hospital General Universitario Santa Lucía, Department of Internal Medicine, Murcia, Spain, [3]University Medical Center Groningen, Department of Internal Medicine, division of Vascular Medicine, Groningen, The Netherlands, [4]Tergooi Hospital, Department of Internal Medicine, Hilversum, The Netherlands, [5]Alicante University General Hospital, Department of Pneumonology, Alicante, Spain, [6]Miguel Hernandez University, Department of Clinical Medicine, Alicante, Spain, [7]ISABIAL-FISABIO, Alicante, Spain, [8]Hospital Universitari Arnau de Vilanova, Department of Pneumonology, Lleida, Spain, [9]Hospital Universitario 12 de Octubre, Department of Internal Medicine, Madrid, Spain, [10]Hospital Vega Baja de Orihuela, Department of Internal Medicine, Alicante, Spain, [11]Hospital Universitario de Puerto Real, Department of Internal Medicine, Cádiz, Spain, [12]Ospedale St. John, Department of Emergency Internal Medicine, Rome, Italy, [13]Hospital Universitari Germans Trias i Pujol de Badalona, Department of Internal Medicine, Barcelona, Spain, [14]Universidad Católica de Murcia, Murcia, Spain

Background: Guidelines recommend treatment with low-molecular-weight heparin (LMWH) for 3-6 months in patients with cancer-associated thrombosis (CAT), and prolonged treatment during active cancer. Data on safety and efficacy of anticoagulant therapy beyond 6 months in CAT is scarce.

Aims: To compare the incidence of recurrent VTE, bleeding and death after 6 months between patients with CAT treated for 180±30 days and those treated >210 days.

Methods: We included patients with active cancer enrolled in the RIETE registry between January 2009 and January 2016. RIETE is an international prospective registry of patients with symptomatic acute VTE, approved by a medical ethics committee. All patients provided informed consent. Patients treated with anticoagulants for 180±30 days were compared to those treated >210 days using propensity score matching. Follow-up started after cessation of treatment in the group treated for 180±30 days, and after 180 days of treatment in the other group.

Results: A total of 3,240 patients were included, of which 598 (18.5%) treated for 180±30 days. The distribution of cancer types differed, with higher numbers of breast and prostatic cancer in the prolonged treatment group. Metastatic disease was equally present (37% vs. 39%).

Initial treatment consisted mostly of LMWH (92-97%). LMWH was also preferred for longterm treatment (54-66%).

During follow-up (median 174 and 130 days, respectively) , the rates of recurrent VTE and death were higher in the patients treated for 180±30 days. The rate of bleeding was higher in the patients with prolonged treatment. After propensity score matching (including 2,727 patients in a 4:1 ratio), the hazard ratios for recurrent VTE and death favoured prolonged treatment (HR for recurrent VTE 0.20 (0.11-0.35) and death 0.68 (0.53-0.89)). The HR for major bleeding was 1.93 (0.64-5.82).

Conclusions: After 180 days of anticoagulant therapy, patients with prolonged treatment had lower risk of recurrent VTE and death as compared to patients treated for 180±30 days.

PB 625 | Impact of Time Since Diagnosis and Mortality Rate on Cancer-associated Venous Thromboembolism in a General Population - The Scandinavian Thrombosis and Cancer (STAC) Cohort

K. Blix[1,2], M.T. Severinsen[3,4], S.C. Cannegieter[5], H. Jensvoll[1,2], K. Overvad[6,7], O.V. Gran[1,2], J. Hammerstrøm[8], A. Tjønneland[9], I.A. Naess[8], F.R. Rosendaal[1,5], S.R. Kristensen[3,10], S.K. Braekkan[1,2], J.-B. Hansen[1,2]

Background: Venous thromboembolism (VTE) is a common complication in cancer patients, and it has been suggested that aggressive cancers such as pancreatic, lung and brain cancers harbor the highest risk of VTE. However, competing risk by death may result in overestimation of VTE risk in cancers with high mortality.

Aims: To estimate the risk of VTE by cancer sites, accounting for the differential mortality between cancers.

Methods: The Scandinavian Thrombosis and Cancer (STAC) cohort is a merging of three Scandinavian population-based cohorts (n=144,952). Subjects were included in 1993-1997 and followed up to 2007-2012. We assessed incidence rates, cause-specific hazard ratios (HR) and sub-distribution hazard ratios (SHR, i.e. accounting for competing risk by death) for all cancers combined and by cancer sites according to time-intervals since cancer diagnosis.

Results: During follow-up, 14,272 subjects developed cancer and 567 of these had a cancer-related VTE. In cause-specific analyses, the risk of VTE was highest in the first 6 months after cancer diagnosis (HR 17.5, 95% CI 15.1-20.3), and declined rapidly thereafter. However, when mortality was taken into account, the risk were similar in the period 6 months before (SHR 4.8, 95% CI 3.6-6.4) and 6 months after (SHR 4.6, 95% CI 3.9-5.4) cancer diagnosis. Cancers with a high mortality rate had a high cause-specific HR of VTE, but in competing risk analyses the range of the 2-year cumulative incidences of VTE for all cancer sites was substantially narrowed (from 1-10% in conventional analyses to 1-4% in competing risk analyses).

Conclusions: The risk of VTE by different cancer sites was substantially influenced by the mortality rate and the time since cancer diagnosis. Our findings may suggest that the cancer itself is a major contributor to VTE risk and that competing risk by death should be taken into account when predicting VTE risk in cancer.

PB 626 | Quality of Life Related to Health in Cancer Associated Thrombosis. Pilot of Qca Study

Hospital Universitario Virgen de Valme, Seville, Spain, [11]Medical Oncology, Virgen del Rocio Hospital, Seville, Spain, [12]Medical Oncology, H. U. Puerto Real, Cadiz, Spain, [13]Medical Oncology, Grupo de Trabajo Cáncer y Trombosis SEOM Hospital General Universitario Gregorio Marañón, Madrid, Spain

Background: Venous thromboembolism (VTE) is a disease with high morbidity and mortality, but there is little evidence about health-related quality of life (HRQL) in oncological patients.

Aims: Our objective was to evaluate the HRQL in cancer associated thrombosis (CAT) and compare with controls (cancer without thrombosis).

Methods: Prospective, multicenter, national, case-control study. Cases: patient with symptomatic acute CAT. Controls: patient with cancer without VTE. All patients were given EQ-5D-3L questionnaire and an integrated system for assessing the health-related quality of life of cancer patients (EORTC QLQ-C30 questionnaire). In CAT, questionnaires were passed 1 month after VTE.

Results: From January 2014 to January 2017, 261 patients were evaluated in 13 hospitals, of which 209 (80%) completed the questionnaires. The mean age was 60 +/- 14 years, with 59% of men. We analysed 161 controls and 99 cases, and 63% deep vein thrombosis, 25% pulmonary embolism and 12% both. The most frequent tumour locations were: lung (30%), lymphoma (20%), gynaecological (14%), pancreas (8%) and gastric (6%). Sixty per cent had metastases and 87% presented ECOG 0-1. Except for the Anxiety/Depression subscale, cases (CAT patients) had substantially lower QoL than controls. In the EORTC QLQ-C30 questionnaire, the cases presented, statistically significant, worse Global Health Status (median: 50 vs. 67), Physical Function (median: 67 vs. 87), Role Function (58 vs. 83), Fatigue (50 vs. 33) and Pain (33 vs. 17) than controls.

Conclusions: In oncological patients, the presence of VTE had a negative impact in HRQL, even 1 month after thromboembolic event.

PB 627 | Differential Impact of Triggers on the Risk of Venous Thromboembolism in Subjects with and without Cancer - Results from a Population-based Case-crossover Study

O.V. Gran[1], H. Skille[1], B. Paulsen[1], T. Isaksen[1,2], S.K. Braekkan[1,2], J.-B. Hansen[1,2]

[1]UiT - The Arctic University of Norway, K.G. Jebsen Thrombosis Research and Expertise Center, Tromsø, Norway, [2]University Hospital of North Norway, Division of Internal Medicine, Tromsø, Norway

Background: Cancer is a strong risk factor for venous thromboembolism (VTE). Recent work has demonstrated that the risk of VTE immediately before and after cancer diagnosis is equal when competing risk by death is taken into account. This suggests that cancer itself, rather than it´s treatment (e.g. surgery) and complications (e.g. immobilization), plays a greater role on VTE risk.

Aims: To investigate the impact of various VTE-triggers in subjects without and with cancer.

Methods: We conducted a large case-crossover study of VTE patients (n=707) recruited from the general population (The Tromsø study). All hospitalizations and triggers were registered within each subject during the last 90-day period before the VTE diagnosis and in four preceding 90-day comparison periods. A 90-day washout period between the comparison- and VTE-periods was used to avoid potential carry-over effects. Conditional logistic regression was used to obtain odds ratios (ORs) for each trigger by cancer status. Each patient served as their own control allowing for within-subject adjustment for fixed covariates.

Results: There were 172 (24.3%) patients with cancer. When comparing the VTE-period to the control periods, the impact of various triggers was greater in non-cancer than in cancer. Triggers such as major surgery (OR 12.3, 95% CI 7.9-19.1 vs. OR 0.8, 95% CI 0.4-1.6), immobilization (OR 69.4, 95% CI 41.9-114.8 vs. OR 22.1, 95% CI 10.0-48.8), infection (OR 25.4, 95% CI 17.3-37.3 vs. OR 10.9, 95% CI 5.9-20.1), central venous catheters (OR 22.4, 95% CI 7.7-64.9 vs. OR 11.0, 95% CI 4.0-30.1) and transfusions (OR 16.4, 95% CI 7.6-35.4 vs. OR 9.9, 95% CI 4.4-22.3) had greater impact on the VTE risk in non-cancer compared to cancer patients, respectively.

Conclusions: We found that established triggers for VTE had a stronger impact on the VTE risk in non-cancer than in cancer patients. Our findings reinforce the concept that cancer itself outweighs the impact of traditional triggers on the VTE risk in cancer.

PB 628 | Venous Thromboembolism in Patients with Lymphoma

S. Phusanti, P. Angchaisuksiri

Ramathibodi Hospital, Mahidol University, Medicine, Bangkok, Thailand

Background: There is limited data regarding the prevalence and risk factors of VTE in Asian patients with lymphoma.

Aims: To determine the prevalence, the predictive factors, and the clinical outcomes of VTE among Thai patients with lymphoma.

Methods: We reviewed a cohort of 1,769 lymphoma patients diagnosed according to the World Health Organization classification and treated at Ramathibodi Hospital, Bangkok, Thailand between October 2005 and September 2015.

Results: The prevalence of VTE was 5.1% (91 patients). The most common site of VTE was deep vein thrombosis of leg (53.9%). In 41 patients (45.1%), thrombosis occurred during treatment or up to 3 months after completion of therapy whereas in 35 patients (38.4%) thrombosis was diagnosed prior to therapy. Median time from lymphoma diagnosis to VTE occurrence was 38 days. Of patients with VTE vs those without VTE, 51.6% vs 50.2%, respectively, were female (p=0.83) and the mean age was 61±15 vs 55±19 years (p=0.01), respectively. Type of lymphoma in corresponding groups included B-cell Non-Hodgkin lymphoma (NHL) (93.4% vs 76.6%), T-cell NHL (5.5% vs 9.6%) and Hodgkin disease (HD) (1.1% vs 9.0%), p≤0.01. In the multivariate analysis, relapsed disease, poor performance status, bulky mass ≥10 cm and pre-chemotherapy platelet count ≥350 x 10^9/L were independently predictive factors of VTE (Table)

TABLE 1 Logistic regression analysis of predictive factors of VTE in lymphoma patients

Variables	Univariate analysis		Multivariate analysis	
	OR (95%CI)	P value	OR (95%CI)	P value
Age >60 years	1.6 (1.0-2.4)	0.03	1.6 (0.9-3.0)	0.11
B-cell type NHL	4.3 (1.9-10.0)	<0.01	2.7 (0.9-7.3)	0.06
Relapsed disease	2.6 (1.7-4.0)	<0.01	3.4 (1.9-6.2)	<0.01
B-symptoms	1.8 (1.1-2.8)	<0.01	1.5 (0.8-2.9)	0.22
Poor performance status (ECOG ≥2)	1.9 (1.1-3.2)	0.01	2.1 (1.0-4.1)	0.04
Extranodal involvement >1 sites	1.9 (1.2-3.0)	<0.01	1.1 (0.5-2.0)	0.87
Bulky disease (Maximum diameter ≥10 cm)	2.9 (1.8-4.8)	<0.01	2.8 (1.5-5.2)	<0.01
Prechemotherapy platelet count ≥350 x 10^9/L	1.8 (1.1-3.0)	0.03	2.2 (1.1-4.1)	0.02

whereas high international prognostic index (IPI) score >3 (OR 1.5) and Khorana score ≥3 (OR 1.2) were not. The mortality rate in the patients with VTE and without VTE was 25.3% and 11.2%, respectively and the two-year overall survival was 65.9% vs 85.5%, respectively (p< 0.01).

Conclusions: The prevalence of VTE in Thai patients with lymphoma is not low. Relapsed disease, poor performance status, bulky mass, and elevated pre-chemotherapy platelet count are independent predictive factors of VTE. Khorana score is not predictive for VTE in Thai

patients. Predictive risk score for Thai patients with lymphoma will be further developed.

PB 629 | Cancer Associated Thrombosis in Cancer Patients Receiving Chemotherapy or Hormonal Therapy in an Ambulatory Setting

S. Rhodes[1], S. Bond[1], L. Moore[2], F. Rozycki[1], S. Abrook[2]

[1]Great Western Hospital, Anticoagulant Clinic, Swindon, United Kingdom, [2]Great Western Hospital, Cancer Services, Swindon, United Kingdom

Background: Venous thromboembolism (VTE) represents one of the most important causes of morbidity and mortality in cancer patients. Patients with the highest 1-year incidence rate are those with advanced disease of the brain, lung, uterus, bladder, pancreas, stomach and kidney.

While receiving chemotherapy, cancer patients have a 7-fold risk of developing VTE as compared with other patients without cancer. Chemotherapy can increase the risk of VTE by four mechanisms: acute damage to vessel walls, non-acute damage of the epithelium, a decrease in natural anticoagulant inhibitors (reduced levels of protein C, S and anti-thrombin 111) and platelet activation.

Aims: To identify if a specific cancer type or particular chemotherapy drug or regime predisposed patients to developing VTE.

Methods: We observed patients presenting with a confirmed VTE and a diagnosis of cancer between February 2013 and December 2016 who received either chemotherapy or hormonal therapy in an ambulatory setting.

Results: In total there were 111 VTE events (1.2%) out of total of 9332 patients being treated for cancer.The type of cancer with the highest number of VTE events was colorectal (27/111 VTE events) but in terms of the % incidence relating to total numbers of cancer patients receiving treatment the highest incidence of VTE was seen in patients with brain tumours (3/55 - 5.45%).

Of the 233 chemotherapy agents administered, Alkylating agents represented 36.5% of the drugs administered which had an association with VTE.

Diagnosis of VTE varied with Pulmonary Embolism (PE) representing 69/111 (62%), Proximal DVT 18/111 (16.2%) and distal DVT 23/111 (20.7%).

Mortality rate was 66/111 patients (59.4%) with 18/66 deceased within 1 month of diagnosis of VTE.

Conclusions: In our experience incidence of cancer associated VTE was low. Brain tumour and the use of alkylating agents had the highest associated risk of VTE. Poor prognosis of VTE and cancer may reflect both a combination of fatal complications (PE) and higher disease aggressiveness.

TABLE 1 VTE events per cancer diagnosis from February 2013 to December 2016

Cancer Type	Number of VTE events	Total number of patients treated	% incidence of VTE
Colorectal	27	853	3.16
Breast	18	1220	1.48
Haematological	16	550	2.91
Lung	14	542	2.58
Urological	11	1289	0.85
Gynaecological	11	358	3.07
Upper GI	11	492	2.23
Brain	3	55	5.45
Total	111	9332	1.19

PB 630 | Long-term Impact on Mortality of Isolated Superficial Vein Thrombosis in Patients with Active Cancer

J.-P. Galanaud[1], H. Rerrisse[2], M.A. Sevestre[3], G. Pernod[2], S. Kahn[4], I. Quéré[5], J.-L. Bosson[2]

[1]Montpellier University Hospital, Internal Medicine, Montpellier Cedex 5, France, [2]Grenoble University Hospital, Grenoble, France, [3]Amiens University Hospital, Amiens, France, [4]McGill University, Montreal, Canada, [5]Montpellier University, Montpellier, France

Background: Cancer patients who develop venous thromboembolism (VTE) are at higher risk of death than cancer patients without VTE. However, the impact of isolated superficial venous thrombosis (iSVT) (i.e. without concomitant deep vein thrombosis or pulmonary embolism) on the prognosis of cancer patients is unknown.

Aims: To determine the impact on mortality at 3 years of iSVT in patients with active cancer.

Methods: Using data from the OPTIMEV prospective, multicentre, observational study, we compared at 3 years the incidence of death in 34 patients with cancer-related iSVT to 68 cancer patients with

TABLE 1 Comparison of incidence of death during 3-years follow-up between different study populations

	Incidence %PY [95%CI], (n)	Crude Hazard Ratio HR [95% CI]	Adjusted Hazard Ratio aHR [95% CI]
Cancer-related iSVT	23.2 [14.2 - 37.9] (16)	Ref	Ref
iSVT without cancer	1.3 [0.5 - 3.6] (4)	0.1 [0.0 - 0.2]	0.1 [0.0 - 0.2]
Cancer without VTE	27.1 [20.6 - 35.8] (50)	1.1 [0.6 - 2.0]	1.0 [0.6 - 1.8]
Cancer-related proximal DVT	42.2 [31.2 - 57.1] (42)	1.7 [0.9 - 3.0]	1.5 [0.8 - 2.6]
Varicose veins status	-	-	0.6 [0.4 - 1.0]

isolated proximal DVT (matched 1:2 on age and sex), to 102 patients with iSVT without cancer (matched 1:3 on age and sex), and to 102 patients with cancer but without VTE (matched 1:3 on age and sex). All VTE events were confirmed by objective tests and all iSVT patients underwent a systematic whole leg compression ultrasound to exclude concomitant DVT. Survival analysis was conducted using Cox proportional hazards model with populations and varicose veins status as covariates.

Results: Patients with cancer-related iSVT had a significantly higher risk of death than patients with iSVT without cancer (23.2% per patient-year (PY) vs. 1.3% PY, p< 0.001), a lower risk of death than patients with proximal DVT (42.2%PY, p=0.2) and a similar risk of death than patients with cancer but without VTE (27.1%PY, p=0.9) (Table 1). Presence of varicose veins on physical exam was associated with a statistically significant lower risk of death (p=0.05). When restricting our analysis to patients without a history of VTE, results remained similar in magnitude.

Conclusions: Unlike for DVT or PE, occurrence of iSVT does not seem to strongly influence the prognosis of patients with active cancer in terms of death. However, this reassuring result needs to be confirmed by larger studies and does not apply to cancer patients whose iSVT occurred in non-varicose veins. In this latter case iSVT can constitute a marker of cancer severity.

PB 631 | Prediction of Venous Thromboembolism in Newly Diagnosed Patients Treated for Lymphoid Malignancies - Validation of the Khorana Risk Score among Patients with Diffuse Large B-cell Lymphoma and Hodgkin Lymphoma

J. Rupa-Matysek, L. Gil, M. Kaźmierczak, M. Barańska, M. Komarnicki

Poznan University of Medical Sciences, Department of Haematology and Bone Marrow Transplantation, Poznan, Poland

Background: The utility of the venous thromboembolism (VTE)-risk assessment model developed by Khorana known as the Khorana Risk Score (KRS) in patients with the most frequent subtypes of lymphoma receiving outpatient chemotherapy is unknown.

Aims: We evaluated the association of KRS with VTE in patients treated for diffuse large B-cell lymphoma (DLBCL) and Hodgkin lymphoma (HL).

Methods: Retrospective analyses were performed on 428 adult patients (median age 50, 51% females), of whom 241 were newly diagnosed diffuse large B-cell lymphoma (DLBCL) and 187 had Hodgkin lymphoma (HL). No patients received thromboprophylaxis. There was no routine screening for VTE.

TABLE 1 Comparison of patients' characteristics with/or without VTE

	Overall population n=428	VTE group during follow-up n=64	Non-VTE group during follow-up n=364	p value
Median age, range years	50 (18-98)	49 (22-81)	50 (18-98)	0.9698
Gender, male n (%)	209 (49%)	34 (53%)	175 (48%)	0.4562
Type of lymphoma: DLBCL	241 (56%)	45 (70%)	196 (54%)	0.0143
Stage IV of the disease	218 (51%)	38 (59%)	180 (49%)	0.1430
Presence of constitutional symptoms	258 (60%)	23 (36%)	41 (64%)	0.5025
Poor Prognostic Group (score ≥ 3 IPI/IPS)	178 (42%)	34 (53%)	144 (40%)	0.0423
High Khorana Risk Score	64 (15%)	11 (17%)	53 (15%)	0.5868
Death	56 (13%)	17 (27%)	39 (11%)	0.0005

TABLE 2 Comparison of patients' characteristics in the high or intermediate groups of the Khorana Risk Score

	Overall population n=428	High risk group n=64	Intermediate risk group n=364	p value
Median age, range years	50 (18-98)	40 (19-79)	52 (18-98)	0.0706
Gender, male n (%)	209 (49%)	28 (44%)	181 (50%)	0.3778
Type of lymphoma: DLBCL	241 (56%)	25 (39%)	216 (59%)	0.0026
Stage IV of the disease	218 (51%)	34 (53%)	184 (51%)	0.7039
Presence of constitutional symptoms	258 (60%)	49 (77%)	209 (57%)	0.0039
Poor Prognostic Group (score ≥ 3 IPI/IPS)	178 (42%)	41 (64%)	137 (38%)	<0.0001
Presence of VTE	64 (15%)	11 (17%)	53% (15%)	0.5868
VTE within 6 months after diagnosis	35 (8%)	5 (45%)	30 (57%)	0.4490
Death	56 (13%)	11 (17%)	45 (12)	0.2912

Results: During a median follow-up of 37 months (25th-75th percentile 16-57), 64 (15%) patients developed VTE and 56 (13%) died. Most of the thrombotic events (55%) occurred within 6 months after diagnosis. In comparison to the HL group, patients with DLBCL were older and more patients were in advanced stage (p< 0.001).

45 patients of the 241 (19%) treated for DLBCL developed VTE compared to 19 patients of the 187 HL patients (10%, p=0.0143), Table 1. Analysis of the risk of thrombosis, according to the Khorana model, showed an intermediate risk in 364 patients (85%, 1-2 points) and a high risk in 64 patients (15%, ≥3 points), Table 2.

More patients with HL were in the high-risk group of KRS (score ≥3), in comparison to the DLBCL group (39 vs. 25, p=0.0026). Eleven patients of the 64 (17%) from the high KRS group developed VTE compared to fifty-three patients of the 364 patients (57%) from the intermediate group (p=0.5868). In our patients, the KRS did not adequately stratify or predict VTE (PPV 15%, NPV 82% and C statistic 0.51).

In Kaplan-Meier analysis of VTE-free survival rates, no difference was found between patients in the high KRS and in the intermediate KRS group (log rank test 0.12, p=0.9079).

Conclusions: In this cohort of patients with lymphoid malignancies, the KRS did not adequately stratify or predict VTE events in patients at higher risk of VTE.

PB 632 | High Real-life Incidence of Venous Thromboembolism in Multiple Myeloma: A Need for More Effective Thromboprophylaxis at a Lower Thrombosis Risk Threshold

E. De Waal[1,2], M. Hoogendoorn[2], L. Snetselaar[1], R. Tjeerdsma[2], H. Kluin-Nelemans[1], E. Vellenga[1], K. Meijer[1,3]

[1]*University Medical Center Groningen, Hematology, Groningen, The Netherlands,* [2]*Medical Center Leeuwarden, Hematology, Leeuwarden, The Netherlands,* [3]*University Medical Center Groningen, Groningen, The Netherlands*

Background: Thromboprophylaxis is frequently used during the treatment of multiple myeloma (MM), dependent on the regimen applied. Despite prophylaxis, MM is often complicated by venous thromboembolism (VTE). However, the rate in published studies does not exceed 5-10%.

Aims: To determine real-life incidence of VTE in newly diagnosed MM patients treated with different anti-myeloma regimes.

Methods: We used two databases that prospectively registered consecutive patients with newly diagnosed MM: one covered all four hospitals in the province Friesland, the second the University Medical Centre Groningen, the reference centre for the northern part of the Netherlands. Data on treatment regimens, thromboprophylaxis and VTE were retrospectively collected. Dutch law does not require ethical review for chart review studies.

Results: Between 2002 and 2012, 521 patients were included. 57% were male, median age was 66 yrs (range 31-92). Initial treatment was immunomodulatory drugs (IMID)- (49%), proteasome inhibitors (PI)- (13%), vincristine, adriamycine and dexamethasone (VAD)-based (11%) or other, including expectative policy (26%). 37% underwent autologous stem cell transplantation. Thromboprophylaxis was prescribed to 63% in IMiD, 23% in PI and 15% in VAD-based group. VTE was diagnosed in 15% at a median of 91 days (range 0-2026) after diagnosis.

VTE risk was not associated with initial treatment: 16% in IMID, 13% in PI and 18% in VAD-based group. Similarly, VTE risk was equal for no thromboprophylaxis (13%), aspirin (19%) and low molecular weight heparin (21%). Data were similar for both databases.

Conclusions: VTE risk in real-life MM treatment is unacceptably high at 15%, with similar rates in all first line treatment regimens and for both aspirin and LMWH. This could be explained by physicians tailoring prophylaxis to VTE risk. A possible option to reduce VTE risk is to lower the threshold for higher intensity thromboprophylaxis.

PB 633 | The Procoagulant Fingerprint of Breast Cancer Cells Varies in Function of Their Aggressiveness and the Tissue Factor Expression

A. Camara[1], M. Sabah[1], E. Mbemba[1], A. Rousseau[2], P. Van Dreden[2], H. Mokrani[3], A. Khaterchi[3], A. Larsen[1], I. Elalamy[1,3], G. Gerotziafas[1,4]

[1]*INSERM U 938, Faculté de Médecine Pierre et Marie Curie, Université Paris VI, Paris, France,* [2]*Clinical Research, Diagnostica Stago, Gennevilliers, France,* [3]*Service d'Hématologie Biologique Hôpital Tenon, Hôpitaux Universitaires de l'Est Parisien, Assistance Publique Hôpitaux de Paris, Paris, France,* [4]*Service d'Hématologie Biologique, Hôpital Tenon, Hôpitaux Universitaires de l'Est Parisien, Assistance Publique Hôpitaux de Paris, Paris, France*

Background: Blood hypercoagulability is a common systemic alteration in patients with cancer and varies according to the histological type of cancer. Tissue factor (TF) is a key actor in cancer-induced hypercoagulability. We previously showed that contact of breast cancer cells line MCF7 enhances thrombin generation (TG).

Aims: To identify the procoagulant „fingerprint" of breast cancer cells of various degrees of aggressiveness.

Methods: Adhesive cell cultures of MCF7, MCF7-ShWisp2, BT-20 cancer cells lines and HUVEC (control) were analyzed for TF expression by flow cytometry and western blot assay using anti human TF murine IgG1 monoclonal antibody (ref 4503; American Diagnostics; USA). Studied cells were put in contact with normal platelet poor plasma (PPP ; Diagnostica Stago, Asnières, France) and TG was triggered with CaCl2 addition and measured with the Calibrated Automated Thrombogram assay (Diagnostica Stago, Asnieres France) as previously described (1).

Results: *MCF7-ShWisp2* and BT-20 cells expressed higher amounts of TF as compared to MCF7 and HUVEC. The MCF7-ShWisp2 and BT-20 cells significantly accelerated the initiation and propagation phases of TG and slightly increased the Peak and the ETP as compared to MCF7. The MCF7 cells enhanced TG as compared to HUVEC profile. Analytical data are depicted in Table 1.

Conclusions: The procoagulant „fingerprint" of breast cancer cells varies in function of their histological phenotype. The more aggressive

TABLE 1 Effect of breast cancer cells on TG of normal human plasma. Values are means±sd. (*<0.05 versus HUVEC; +<0.05 versus MCF7 or MDA-MB-231)

	MCF7-ShWisp2	BT-20	MCF7	HUVEC

Jebsen Thrombosis Reaserch and Expertice Center (TREC), Tromsø, Norway, [2]Aalborg University Hospital, Department of Hematology, Aalborg, Denmark, [3]Aalborg University, Department of Clinical Medicine, Aalborg, Denmark, [4]Norwegian University of Science and Technology, Department of Cancer Research and Molecular Medicine, Trondheim, Norway, [5]University Hospital of North Norway, Division of Internal Medicine, Tromsø, Norway, [6]Aalborg University Hospital, Department of Clinical Biochemistry, Aalborg, Denmark, [7]Leiden University Medical Center, Department of Clinical Epidemiology, Leiden, The Netherlands, [8]Danish Cancer Society Research Center, Diet, Genes and Environment, Copenhagen, Denmark, [9]Leiden University Medical Center, Department of Thrombosis and Hemostasis, Leiden, The Netherlands, [10]Aalborg University Hospital, Department of Cardiology, Aalborg, Denmark, [11]Aarhus University, Department of Public Health, Section for Epidemiology, Aarhus, Denmark, [12]Trondheim University Hospital, Department of Hematology, Trondheim, Norway

Background: Smoking is a well-established risk factor for cancer. Conflicting results have been reported on the association between smoking and risk of venous thromboembolism (VTE). In studies reporting a relationship between smoking and VTE, the association appeared to be mediated by smoking-related diseases (i.e. cancer). No study has investigated the joint effects of smoking and cancer on the risk of VTE.

Aims: To investigate the joint effect of smoking status and cancer on risk of VTE using a large population-based cohort.

Methods: The Scandinavian Thrombosis and Cancer (STAC) cohort is a merging of three population-based cohorts (Tromsø study, Danish Diet Cancer and Health Study and Nord-Trøndelag Health Study). Subjects (n=144 952) were included in 1993-97 and followed up to 2007-12. Former smokers were excluded (n=35 890). VTEs occurring from 6 months before to 2 years after a cancer diagnosis were defined as cancer-related. Smoking habits were registered by self-administrated questionnaires at baseline. Age- and sex- adjusted Cox regression was used to obtain hazard ratios (HR) for VTE across cancer- and smoking status. Rothmans synergy index ($S= (RR_{A+B+}-1)/(RR_{A+B-}-1)+(RR_{A-B+}-1)$) was used to assess the presence of synergism between smoking and cancer.

Results: There were 10 815 incident cancer diagnoses and 1 611 VTEs, of which 275 were cancer-related, during a median of 11 years of follow-up. There were 48 341 current smokers, of which 5948 developed cancer. In cancer-free subjects, smoking was not associated with VTE (HR 1.0, 95% CI 0.9-1.1). In cancer patients, however, the risk increased from 6-fold (HR 6.6, 95%, CI 5.4-8.0) in never smokers to 9-fold (HR 9.3, 95% CI 7.8-11.0) among smokers, when compared to non-smoking cancer-free subjects. Active cancer and smoking demonstrated a synergistic effect on VTE-risk
(S=1.5, 95% CI 1.1-1.9).

Conclusions: Our findings showed that smoking in combination with cancer yielded a modest synergistic effect on the risk of VTE.

PB 635 | The Impact of Traditional Triggers on the Risk of Venous Thromboembolism in Cancer - Results from a Population-based Case-crossover Study

O.V. Gran[1], B. Paulsen[1], H. Skille[1], T. Isaksen[1,2], S.K. Braekkan[1,2], J.-B. Hansen[1,2]

[1]UiT - The Arctic University of Norway, K.G. Jebsen Thrombosis Research and Expertise Center, Tromsø, Norway, [2]University Hospital of North Norway, Division of Internal Medicine, Tromsø, Norway

Background: Cancer is a well known risk factor for venous thromboembolism (VTE). Although several patient-, cancer- and treatment-related risk factors for VTE have been identified, the relative magnitude of these triggers of VTE risk in cancer is not well defined.

Aims: To investigate the impact of various VTE-triggers in subjects with cancer.

Methods: From a case-crossover study of VTE patients (n=707) recruited from the general population (The Tromsø study), VTE-patients with a history of cancer longer than six months prior to VTE were selected (n=96). All hospitalizations and triggers were registered within each subject during the last 90-day period before the VTE diagnosis and in up to four preceding 90-day comparison periods (n=332). A 90-day washout period between the comparison- and VTE-periods was used to avoid potential carry-over effects. Conditional logistic regression was used to obtain odds ratios (ORs) for each trigger. Each patient served as their own control allowing for within-subject adjustment for fixed covariates.

Results: When comparing the VTE-period to the control periods, immobilization (OR 22.1, 95% CI 10.0-48.8), infection (OR 10.9, 95% CI 5.9-20.1), central venous catheters (OR 11.0, 95% CI 4.0-30.1), chemotherapy (OR 4.4, 95% CI 2.2-8.8) and radiotherapy (OR 4.3, 95% CI 2.0-9.4) had the greatest impact on VTE in cancer, while surgery (OR 0.8, 95% CI 0.4-1.5) had no significant effect. The impact of radiotherapy came predominately from palliative (OR 10.4, 95% CI 3.4-31.7), rather than therapeutic radiotherapy (OR 0.9, 95% CI 0.2-4.5).

Conclusions: Our results imply that VTE-triggers related to cancer and its complications (i.e. immobilization, infection) generally have a greater impact on VTE than factors related to cancer treatment (i.e. surgery, radiotherapy, chemotherapy).

PB 636 | Impact of a Novel Version 2.0 of an Electronic Alert System for Venous Thromboembolism (VTE) Prevention in Hospitalised Cancer Patients

R. Figueroa[1], A. Alfonso[1], S. Villar[1], N. Martínez-Calle[1], M. Marcos[1], J. López-Picazo[1], I. Gil-Bazo[1], A. García-Mouriz[1], J. Páramo[1], J. Hermida[2], R. Lecumberri[1]

[1]Clinica Universidad de Navarra, Pamplona, Spain, [2]CIMA-University of Navarra, Pamplona, Spain

Background: Hospitalised cancer patients have high VTE risk. Prophylaxis with Low Molecular Weight Heparin (LMWH) is widely recommended, although underuse is a problem worldwide. Electronic alerts (e-alerts) are effective tools to increase its prescription.

Aims: To evaluate the impact of a new version (v2.0) of our e-alert system for VTE prevention compared with the initial software.

Methods: Prospective study including consecutive adult cancer patients admitted at our centre. During the first period (April 2014-June 2015) the initial e-alert system remained operative. During the second phase (July 2015-December 2016) the v2.0 was active. The v2.0 software interrogated physicians about reasons for not using prophylaxis. Patients were followed for 30 days after discharge. Approval by institutional ethics committee was obtained.

Results: 1128 patients were included, 767 patients in the first period and 461 in the second (Table 1). E-alerts v2.0 associated with an increase of the use of LMWH prophylaxis during hospitalisation (65.1% vs 72.2%; p=0.007). However, this improvement did not result in a reduction of VTE during admission or follow-up (2.5% vs 2.6%). 80% of VTE events occurred despite LMWH use. Major bleeding was similar (3.2% vs 3.4%), while mortality was higher in Group 2 (10.1% vs 15.6%; p=0.016), probably due to a higher proportion of patients with advanced disease. The main reason for not prescribing LMWH prophylaxis was bleeding risk, but in 17% of cases physicians did not consider the patient to have high VTE risk.

Conclusions: The new e-alert system further increases the use of VTE prophylaxis in hospitalised cancer patients, although this was not associated with a reduction of the incidence of VTE. A relevant number of VTE events occurs despite prophylaxis with standard LMWH. Identification of risk factors for thromboprophylaxis failure is needed.

PB 637 | Platelet-related Thrombin Generation in Adult Survivors of Childhood Cancer

M. Panova-Noeva[1,2], F. Haydl[1], M. Nagler[2,3], S. Eckerle[4], M. Michler-Abo Mustafa[1], M. Paul[1], D. Laubert-Reh[2,3], H.M. Spronk[5], H. Merzenich[6], J. Faber[4], K.J. Lackner[2,7], H. ten Cate[5], P.S. Wild[1,2,3]

[1]University Medical Center of the Johannes Gutenberg-University Mainz, Center for Thrombosis and Hemostasis (CTH), Mainz, Germany, [2]University Medical Center of the Johannes Gutenberg-University Mainz, Center for Translational Vascular Biology (CTVB), Mainz, Germany, [3]University Medical Center of the Johannes Gutenberg-University Mainz, Preventive Cardiology and Preventive Medicine, Center for Cardiology, Mainz, Germany, [4]University Medical Center of the Johannes Gutenberg-University Mainz, Pediatric Hematology / Oncology / Hemostaseology, Center for Childhood and Adolescence Medicine, Mainz, Germany, [5]Maastricht University Medical Center, Cardiovascular Research Institute Maastricht (CARIM), Maastricht, The Netherlands, [6]University Medical Center of the Johannes Gutenberg-University Mainz, Institute of Medical Biostatistics, Epidemiology and Informatics (IMBEI), Mainz, Germany, [7]University Medical Center of the Johannes Gutenberg-University Mainz, Institute for Clinical Chemistry and Laboratory Medicine, Mainz, Germany

Background: Adult survivors of childhood or adolescent cancer have significant long term morbidity related to their cancer therapy. Vascular conditions including premature atherosclerosis, hypertension, arterial and venous thrombosis are commonly described in these subjects.

Aims: This study aims to characterize thrombin generation (TG) in presence of platelets, as an assay of global hyper- or hypo-coagulability, in individuals from the Cardiac and Vascular late sequelae in long-term survivors of childhood cancer (CVSS) study.

Methods: TG, investigated in platelet rich plasma (PRP) at 1pM TF, was available in 200 individuals from the CVSS and in 407 individuals from the population-based Gutenberg Health study (GHS), as a control group. Lag time, endogenous thrombin potential (ETP) and TG peak were the analysed parameters of a TG curve.

Results: TG lag time was shorter (p=0.00056) and TG peak was higher (p=0.0027) in cancer survivors compared to GHS individuals. Cancer survivors with any cardiovascular risk factor (CVRF) presented with shorter lag time and higher TG peak compared to GHS individuals with any CVRF. The multivariable linear regression analysis adjusted for age, sex and CVRFs showed that female sex (beta estimate, ß: 193.3

[95%CI: 113.9; 272.7], p< 0.001), obesity (ß: 162.1 [64.7; 259.5], p=0.0013) diabetes (ß: 470.3 [98.5; 842.1], p=0.014) and particularly hypertension (ß: 174.6 [80.6; 268.5], p< 0.001) were associated with higher ETP in cancer survivors.

Conclusions: Cancer survivors presented with higher TG potential in comparison to population sample. Survivors with CVRFs had a worse TG profile compared to the control group with CVRFs. Hypertension in survivors was strongly associated with higher TG potential, independent of age, sex and traditional CVRFs. These results substantiate an interaction between cancer (treatment), CVRF like hypertension, and hypercoagulability that may be pathophysiologically relevant.

PB 639 | Clinical History of Thrombosis before Diagnosis of Overt Myeloproliferative Neoplasms in Triple Negative Patients

M. Napolitano, S. Siragusa, S. Mancuso, M. Santoro, F. Di Piazza, A. Perez, A. Russo, V. Accurso

Università degli Studi di Palermo, Palermo, Italy

Background: Thromboses are the most important preventable risk factors for morbidity and mortality in chronic myeloproliferative neoplasms (MPN).

Aims: To analyze the prevalence of thrombotic events in the past clinical history of patients with a diagnosis of MPN,even in absence of blood cells count abnormalities leading to hematology consult at the time of thrombosis diagnosis.

Methods: We here performed a retrospective cross sectional study of patients with a diagnosis of Philadelphia negative MPN and a prior history of thrombosis, analyzed from electronic charts. Available thrombophilia screening included the following assays: PT, aPTT, antithrombin, protein C and protein S, coagulation Factor VIII, anticardiolipin antibodies, Lupus Anticoagulant. Coagulation Factor VIII levels > 150IU/dL were considered elevated. These tests are part of a routine work-up in our institution. The local institutional review board approved the protocol and written informed consent was obtained from all patients.

Results: Among a cohort of 260 patients with MPNs (78PV, 102ET, 80 MF), forty four were found triple negative for JAK-2, calreticulin and MPL gene mutations. Sixty-nine (26.54%) patients (29F, 40M) had a personal past clinical history of arterial or venous thrombosis. Among patients with thrombosis, 13(18.8%) cases (11 ET, 2MF) were triple negative (median age:60 years). Most events, in particular in triple negative patients, occurred within 18 months before overt .MPN. At the time of thrombosis diagnosis, only a minority of patients showed blood tests abnormalities suggestive of MPN or indicating hematological consultation.History of thrombosis had a strong positive correlation with higher risk stages of MPN.

Conclusions: We here report the occurrence of ischemic and thromboembolic events in 20% cases of triple negative MPNs. Further evidences are needed to support the development of risk stratification scores or the detection of early molecular markers in diagnosis of MPNs.

PB 640 | Importance of the Association Cancer Cells and Microparticles on the Hypercoagulable Power of Cancer

A. Rousseau[1], R. Amrane[2,3], P. Van Dreden[1], A. Larsen[2], I. Elalamy[2,3], G. Gerotziafas[2,3]

[1]Clinical Research, Diagnostica Stago, Gennevilliers, France, [2]INSERM U 938, Faculté de Médecine Pierre et Marie Curie, Université Paris VI, Paris, France, [3]Service d'Hématologie Biologique, Hôpital Tenon, Hôpitaux Universitaires de l'Est Parisien, Assistance Publique Hôpitaux de Paris, Paris, France

Background: The hypercoagulable state of malignancy occurs due to the ability of tumor cells to activate the coagulation system. The prominent role is attributed to exposure of tissue factor (TF) and procoagulant phospholipids (PPL) by the tumor cell. We recently showed that contact of human plasma with pancreas adenocarcinoma cells (BXPC3) or breast cancer cells (MCF7) enhances thrombin generation (TG). We demonstrated that the procoagulant activity of the cancer cells alone was not sufficient to induce hypercoagulability (TG higher than the upper normal limit).

Aims: We analyzed the specific procoagulant role of microparticles (MVs) originate from the cancer cells and we estimated their association with cancer cells for cancer induced hypercoagulability.

Methods: BXCP3 and MCF7 cells were cultured in 96-well plates. Primary human umbilical vein cells (HUVEC) were used as normal control experiment. The CAT® assay (Stago France) was used to study TG of normal platelet poor plasma added in wells carrying

(a) cancer cells,

(b) cancer cells in presence of their respectively isolated MVs, or

(c) MVs alone. TF activity (TFa) of cells and MVs was assessed with a specific clotting assay.

Results: The TFa were found in abundant amounts BXPC3 cells, and BXPC3 MVs compared to MCF7 cells and MCF7 MVs. The HUVEC

TABLE 1 Thrombin generation on cells in presence and absence of MVs in Normal Pool Plasma

	Pool	HUVEC	BXPC3	MCF7	HUVEC +MVs	BXPC3 +MVs	MCF7 +MVs	Pool +MVs(BXPC3)	Pool +MVs(MCF7)
Lag-time (min)	8.9±1.6	7.7±0.9	4.8±0.6	7.5±0.7	7.9±0.9	1.2±0.5	5.1±0.7	2.2±0.6	6.1±0.4
tt-Peak (min)	14.6±1.3	12.1±0.9	5.7±0.8	9.3±1.0	11.7±0.9	2.6±0.6	6.9±1.1	3.3±0.4	8.2±0.8
Peak(nM)	136±11	150±11	220±12	179±11	166±10	410±12	220±10	380±14	210±11
MRI (nM/min)	24±9	35±10	244±13	99±12	45±10	294±11	120±12	247±14	100±13

cells and HUVEC MVs showed TF activity comparable to a normal pool. Analytical data of TG are depicted in Table 1.

Conclusions: This experiment showed that hypercoagulability induced by cancer cells is the resultant of the combination of the procoagulant properties of cancer cells with procoagulant elements of the plasma microenvironment. To the best of our knowledge, the present study showed for the first time that the inherent procoagulant properties of cancer cells are not sufficient to induce hypercoagulability and documents that procoagulant elements of the microenvironment, namely MVs are necessary elements for cancer induced hypercoagulability.

PB 641 | Variability of Khorana Score and its Validity after First Chemotherapy in Patients with Gastric Cancer

H. Fuentes[1], L. Paz[1], X. Andrade[1], D. Oramas[2], A. Tafur[3]

[1]*John Stroger Hospital, Chicago, United States,* [2]*University of Illinois, Chicago, United States,* [3]*NorthShore University HealthSystem (University of Chicago Pritzker School of Medicine), Evanston, United States*

Background: Venous thromboembolism (VTE) is a leading cause of morbidity and mortality in patients with gastric cancer (GC). Risk stratification with the Khorana score (KRS) coupled with targeted prevention is one of the most validated approaches. However, the variability and validity of the KRS after chemotherapy (CT) is unknown.

Aims: To determine Variability of the KRS and its Validity after first CT in GC.

Methods: Single institution cohort of GC (2010-15). VTE events were objectively confirmed. GC was ascertained if biopsy proven and metastatic, or on active CT. We defined stage as limited (stage I to II) and advanced (stage III to IV). Along with cancer specific data, we abstracted the KRS before and after first CT. The KRS was dichotomized into intermediate and high based on the original description. The primary outcome was VTE prediction. Continuous and categorical variables are expressed by the median (interquartile range) and by percentages. We used SPSS version 23 specifically McNemar test, paired sample t-test, Wilcoxon and cox regression with forward modeling to analyze main objectives.

Results: We included 112 pts in the analysis who were men (66%), 58 (51-64) yo, with adenocarcinoma (84%) and advanced disease (59%). The median follow-up was 21.3 months (9.5-42.6). VTE occurred in 12% of patients. The median time from diagnosis to VTE occurrence was 59 days (3-258). Pre-CT KRS classified 53% of patients as high risk, but ~30% of them were reclassified as intermediate risk after CT. We found that only leucocytes counts changed after CT (P< 0.01). Performance Status (PS) and post-CT KRS were independent predictors of VTE after adjusting for stage in multivariate analysis. The strongest predictor was PS (HR: 7.6; 95%CI: 2.27-25.33; p< 0.01) followed by post-CT KRS (HR: 3.69; 95%CI: 1.17-11.65; p=0.03).

Conclusions: After further validation, post-CT KRS appears a valid tool identify patients with GC at high risk of VTE after first CT.

PB 642 | Venous Thromboembolism in Patients Undergoing Allogeneic Stem Cell Transplantation with Umbilical Cord Blood

G. Moyer, J. Gutman, J. Di Paola, T. Buckner

University of Colorado, Aurora, United States

Background: Venous thromboembolism (VTE) after hematopoietic stem cell transplantation (HSCT) has been shown to occur in approximately 4.6% of patients and is associated with graft versus host disease (GVHD) (Gerber D, et al. Blood 2008). We hypothesized that HSCT with use of umbilical cord blood, which is associated with less GVHD, would be associated with fewer post-transplant VTE events when compared to HSCT with matched related or unrelated donor stem cells.

Aims: Our primary aim was to compare the incidence of VTE following allogeneic HSCT between those who received umbilical cord blood stem cells and those who received matched related or unrelated donor stem cells.

Methods: A retrospective chart review was performed on all patients who underwent allogeneic HSCT for a hematologic malignancy between 1/2010 and 3/2016 at the University of Colorado Hospital. Data regarding baseline characteristics, VTE characteristics and diagnostic interventions were collected. A two-tailed Fisher's exact test was used to compare GVHD incidence and VTE characteristics between groups.

Results: Of 253 charts reviewed, 115 patients received cord blood and 138 patients received non-cord blood. Among those who received cord blood, fewer patients developed either acute or chronic GVHD compared to the non-cord cohort (37% vs 63%; p = 0.0001); however, VTE events and the number of patients with GVHD at time of VTE were similar between groups (Table 1). The number of positive and negative evaluations for VTE are described in Figure 1.

TABLE 1 VTE Characteristics

	Cord	Matched Related or Unrelated	P-Value
	115	138	
Total patients with VTE	37 (32%)	40 (29%)	0.5866
VTE with pulmonary embolism	7 (19%)	7 (17.5%)	1.0000
VTE with catheter-associated DVT	21 (57%)	22 (55%)	1.0000
Platelet count <50,000 at VTE diagnosis	15 (40.5%)	11 (27.5%)	0.2405
Total VTE recurrence or progression	10 (27%)	14 (35%)	0.4725
VTE recurrence with pulmonary embolism	4 (11%)	8 (20%)	0.3517
Bleeding event requiring anticoagulant discontinuation	4 (11%)	6 (15%)	0.7385
Active GVHD at time of VTE	6 (16%)	10 (15%)	0.4072

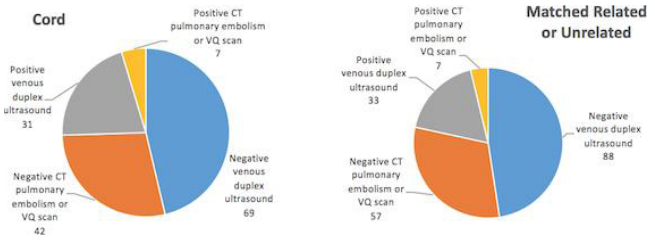

FIGURE 1 Fraction of positive and negative VTE investigations

Conclusions: Our analysis demonstrates that despite a lower overall rate of GVHD in those receiving cord blood, there was no difference in the incidence of VTE between groups, possibly due to a greater influence of GVHD on the development of VTE in those who received cord blood. Further investigation into this possibility and other contributing variables is required. A longer duration of follow-up and greater number of VTE investigations may account for the increased VTE incidence seen at our institution.

PB 643 | Joint Effects of FGG rs2066865 and Pre-cancer Fibrinogen Level on Cancer-related Venous Thromboembolism

B. Paulsen[1], O.V. Gran[1], H. Skille[1], S.K. Braekkan[1,2], E.N. Smith[3,4,5], T. Solomon[6], F.R. Rosendaal[1,7], K.A. Frazer[1,3], J.B. Hansen[1,2]

[1]UiT - The Arctic University of Norway, K.G. Jebsen Thrombosis Reaserch and Expertice Center (TREC), Tromsø, Norway, [2]University Hospital of North Norway, Division of Internal Medicine, Tromsø, Norway, [3]University of California San Diego, Rady Children's Hospital, Department of Pediatrics, La Jolla, United States, [4]University of California San Diego, Moores Cancer Center, La Jolla, United States, [5]University of California San Diego, Institute for Genomic Medicine, La Jolla, United States, [6]University of California San Diego, Biomedical Sciences Graduate Program, La Jolla, United States, [7]Leiden University Medical Center, Department of Clinical Epidemiology, Leiden, The Netherlands

Background: Studies on the association between plasma fibrinogen and risk of venous thromboembolism (VTE) are conflicting. Fibrinogen gamma (FGG) rs2066865 is a missense mutation that alters fibrinogen conformation and function, and is known to be associated with VTE. It is not known, however, to what extent the FGG rs2066865 affects the risk of VTE in cancer.

Aims: To study the joint effect of FGG rs2066865 and cancer on VTE risk in subjects with high and low pre-cancer fibrinogen levels.

Methods: Cases with a first VTE (n=648) and an age-weighted subcohort (n=1893) were recruited from 3 surveys of the Tromsø study (1994-95, 2001-02 and 2007-08) and followed until 31.12.2012. VTE-events were considered cancer-related if occuring from 6 months before until 2 years following a cancer diagnosis. Pre-cancer fibrinogen levels were dichotomized using the median value in the study population (3.5g/L). Age- and sex-adjusted Cox regression models were used to obtain hazard ratios (HRs) for VTE by cancer status, FGG and fibrinogen levels.

Results: There were 167 cancer-related VTE-events and 359 subcohort members diagnosed with cancer during the study period. In cancer patients, the risk of VTE increased per additional risk allele at FGG from 12-fold (HR 12.2, 95% CI 9.1-15.9) higher for 1 risk allele to 20-fold (HR 20.0, 95% CI 11.4-35.1) higher for 2 risk alleles, when compared to cancer-free subjects without risk alleles. However, in subjects with fibrinogen>3.5g/L, a joint effect of cancer and FGG was seen. The HRs were 13.2 (95% CI 7.9-22.2) and 32.3 (95% CI 11.5-90.8) for 1 and 2 risk alleles, respectively, when compared to cancer-free subjects with no risk alleles.

Conclusions: We showed an allele-dependent increased risk of VTE in cancer patients with FGG rs2066865 and a joint effect of FGG and cancer on the risk of VTE in subjects with high pre-cancer fibrinogen levels. Our findings imply an important role of fibrinogen in the pathogenesis of VTE in cancer.

PB 644 | Performance of Current Risk Assessment Models for Prediction of Venous Thromboembolism in Patients with Gastric Cancer

H. Fuentes[1], L. Paz[1], D. Oramas[2], Y. Wang[1], A. Tafur[3]

[1]John Stroger Hospital, Chicago, United States, [2]University of Illinois, Chicago, United States, [3]NorthShore University HealthSystem (University of Chicago Pritzker School of Medicine), Evanston, United States

Background: Cancer-associated thrombosis is a leading cause of morbidity and mortality. Gastric Cancer (GC) is among the most prothrombotic solid tumors. There is a paucity of data on the predictive value of current risk assessment tools (RATs) in GC.

Aims: To determine the predictive performance of current RATs in patients with GC.

Methods: Single institution cohort of GC treated patients (2010-15). VTE events were objectively confirmed. Active GC was defined as biopsy proven metastatic disease or on active chemotherapy. We defined stage as limited (stage I to II) and advanced (stage III to IV). Along with GC specific data, we abstracted the Khorana Score (KRS), platelet lymphocyte ratio (PLR) and neutrophil lymphocyte ratio (NLR). We divided the KRS into intermediate and high based on the original description; and used proposed values for NLR (>3) and PLR (>260) for dichotomization. The primary outcome was VTE prediction. Continuous and categorical data are expressed by the median (interquartile range) and percentages. We used SPSS version 23 to estimate prediction rates of VTE for each RAT in independent models using Cox proportional regression and receiver operating characteristic curves (ROC).

Results: We included 112 pts in the analysis who were predominantly men (66%), 58 (51-64) yo, with adenocarcinoma (84%) and advanced disease (59%). The median follow-up was 21.3 mo (9.5-42.6). VTE occurrence was 12%. The median time from diagnosis to VTE occurrence was 59 days (3-258). High KRS (53%) had a higher risk of developing VTE in univariate analysis but did not reach statistical difference (HR: 2.28; 95% CI: 0.7-7.4, ; p< 0.01). After adjusting for performance status (PS) and stage, only PS remained predictive of VTE (HR:6.2; 95%

CI: 1.9 - 20.2; p< 0.01). We did not find any VTE predictive value for NLR (AUC=0.466, p=0.07) and PLR (AUC=0.41, p=0.33) in our cohort.

Conclusions: Although potentially predictive in other cancer types, KRS NLR and PLR did not predict the occurrence of VTE in our GC database.

PB 645 | Clinical Course of Venous Thromboembolism in Patients with Pancreatic Cancer: Insights from the RIETE Registry

C. Frere[1], J. Trujillo-Santos[2], C. Fernández-Capitán[3], J. Del Toro[4], V. Rosa[5], L. Lopez-Jimenez[6], J.M. Pedrajas[7], C. Tolosa[8], D. Farge[9], M. Monreal[10]

[1]Assistance Publique-Hôpitaux de Marseille, Department of Haematology, Marseille, France, [2]Hospital General Universitario Santa Lucía, Murcia, Spain, [3]Hospital Universitario La Paz, Madrid, Spain, [4]Hospital General Universitario Gregorio Marañón, Madrid, Spain, [5]Hospital Universitario Virgen de Arrixaca, Murcia, Spain, [6]Hospital Universitario Reina Sofía, Cordoba, Spain, [7]Hospital Clínico San Carlos, Madrid, Spain, [8]Corporación Sanitaria Parc Taulí, Barcelona, Spain, [9]Assistance Publique Hôpitaux de Paris, Paris, France, [10]Hospital Universitari Germans Trias i Pujol de Badalona, Murcia, Spain

Background: Epidemiological studies have consistently highlighted an association between pancreatic cancer (PC), especially locally advanced or metastatic disease, and the highest risk of venous thromboembolism (VTE), including symptomatic deep-vein thrombosis and/or pulmonary embolism. However, few data are available regarding it's clinical course once the initial VTE event has occurred.

Aims: We aim to analyze the clinical VTE-related outcomes incidence and characteristics in PC patients throughout the whole duration of anticoagulation, as compared to other cancer patients.

Methods: We analyzed clinical data for cancer patients with VTE obtained from the RIETE registry.

Results: As of September 2016, 10951 cancer patients were recruited, of whom 497 had PC (103 non metastatic disease and 394 metastatic disease). Due to lower survival, the duration of anticoagulation was significantly shorter in metastatic as compared to non metastatic PC patients (median duration, 49 vs. 103 days; p < 0.001). In metastatic as well as in non metastatic PC patients, the rate of VTE recurrences nearly doubled the rate of major bleedings (31.65 [95%CI: 21.03-45.74] VTE recurrences per 100 patient-years vs. 15.82 [95%CI: 8.65-26.55] major bleedings per 100 patient-years, and 15.51 [95%CI: 6.22-31.97] vs. 8.87 [95%CI: 2.39-22.70] events per 100 patient-years, respectively). In PC patients, both VTE recurrences and major bleedings tend to be more frequent than in other cancer patients (14.70 [95%CI: 13.09-16.45] and 12.86 [95%CI: 11.36-14.50] events per 100 patient-years respectively in metastatic disease vs. 9.58 [95%CI: 8.42-10.85] and 6.83 [95%CI: 5.86-7.91] events per 100 patient-years respectively in non metastatic disease).

Conclusions: Our results highlight significant differences in the clinical profile of VTE-related outcomes in PC as compared to other cancers and suggest the need of developing specific anticoagulant strategies in PC patients.

PB 646 | Mean Platelet Volume (MPV) and MPV/Platelet (plt) Identify Essential Thrombocythemia (ET) Patients at High Thrombotic Risk

C. Verzeroli[1], M. Marchetti[1], C. Giaccherini[1], S. Gamba[1], A. Vignoli[1], L. Russo[1], G. Finazzi[2], A. Rambaldi[2], A. Falanga[1]

[1]ASST Papa Giovanni XXIII, Immunohematology and Transfusion Medicine, Bergamo, Italy, [2]ASST Papa Giovanni XXIII, Hematology, Bergamo, Italy

Background: ET, a BCR/ABL-negative myeloproliferative neoplasm, is hampered by a high risk of thrombotic complications. The persistent enhanced platelet activation contributes to the acquired thrombophilic condition typical of ET. Different studies have investigated MPV and MPV/plt ratio as emerging platelet activation biomarkers in other thrombophilic diseases.

Aims: To investigate whether in ET patients, MPV and MPV/plt correlate with other known thrombotic risk factors (i.e. glycoproteinV (GPV), mutational status, history of thrombosis) or with treatments.

Methods: Eighty-nine consecutive ET patients (56F/33M; median age 60 yrs) were enrolled and clinical data recorded. Fourty-six patients were JAK2V617F+, 23 CALR+, 3 MPL+, and 17 triple negative. Patients treatments included: hydroxyurea (HU) (n=6), aspirin (ASA) (n=25), HU+ASA (n=38), and none of them (n=20). MPV was measured by an automated hematology analyzer and plasma GPV antigen levels by commercial ELISA.

Results: MPV values were inversely related to platelet count (p< 0.05). Patients JAK2V617F+ showed higher MPV values than JAK2 wild type (p< 0.05) or other mutation carriers (p=ns). Higher MPV values and MPV/plt were also observed in patients with a history of thrombosis (n=15) *vs* those without
(p< 0.05). No differences in MPV values and MPV/plt were found in relation to therapies. GPV levels normalized for platelet count were greater in JAK2V617F+ patients, suggesting an increased shedding of this membrane receptor from platelets.

Conclusions: Data show that JAK2V617F mutation or a positive history of thrombosis are significantly associated with MPV values in ET patients: this may contribute to the prothrombotic status. In view of the increasing importance of MPV and MPV/plt as markers of platelet reactivity, prospective studies are warranted to evaluate the role of these hematological biomarkers in risk assessment models.

Project funded by „AIRC-IG2013“ grant Nr. 14505 from the “Italian Association for Cancer Research” (A.I.R.C.).

PB 647 | Interleukin Profile in Polycythemia Vera and its Correlation with the Risk of Thrombosis

P. Deo[1], P. Malhotra[1], S. Varma[1], N. Varma[2], M.U.S. Sachdeva[2], P. Jeeyaraman[1], G. Prakash[1], A. Khadwal[1], D. Lad[1]

[1]PGIMER, Internal Medicine, Chandigarh, India, [2]PGIMER, Hematology, Chandigarh, India

Background: Polycythemia Vera (PV) is a myeloproliferative neoplasm characterized by dysregulated hematopoiesis and a hypercoagulable state. PV patients are at risk of premature and accelerated thromboembolic events (arterial & venous), that can lead to significant morbidity & sudden deaths.

Aims: To evaluate the inflammatory cytokines in PV patients and correlate the cytokine profile with the clinical risk of thrombosis.

Methods: This was a prospective study carried out at a tertiary care hospital of North India from June 2015 to October 2016. PV patients were diagnosed by the WHO 2008 diagnostic criteria. A detailed history of PV patients was taken for past or current episodes of thrombosis. The thrombotic episodes were further divided into arterial, venous or both. Age and sex matched healthy controls were selected from the normal population. These patients underwent various cytokines (IL-1β, IL-2, IL-4, IL-6, IL-8, IL-10, IL-11, IL-12/23p40, TNF-α and IFN-γ) evaluation in blood by flow cytometry (Fig.1a) bead based assays (CBA kits, BD Biosciences™). Informed consents were obtained & this study was approved by the institute ethics committee. Statistical analysis were done using SPSS Statistics 22.0.

Results: A total of 52 PV patients and 20 healthy controls were included in the study. The median age of patients was 52 years with male:female ratio of 2:1. JAK2 mutations were positive in 49 patients. Thrombotic events were seen in 19(36.5%) patients(12 arterial & 7 venous). Levels of IL-6 (p< 0.001), 8(p=0.001), 12/23p40 (p=0.009) were higher in PV patients than controls (Fig.1b). IL-6 & IL-8 levels were significantly associated with the risk of thrombosis in PV (Table1). There was no association of thrombosis with leucocytosis or thrombocytosis.

Conclusions: An abnormal inflammatory cytokine milieu was seen in PV patients suggesting a possible role of IL-6, IL-8 & IL-12/23p40 in the pathogenesis of PV patients. In addition, IL-6 and IL-8 were significantly higher in PV patients with thrombosis.

Fig.1(a). flow cytometer images obtained after sample processing;
Fig.1(b). showing levels of IL-6, IL-8 & IL-12/23p40 in PV patients & controls

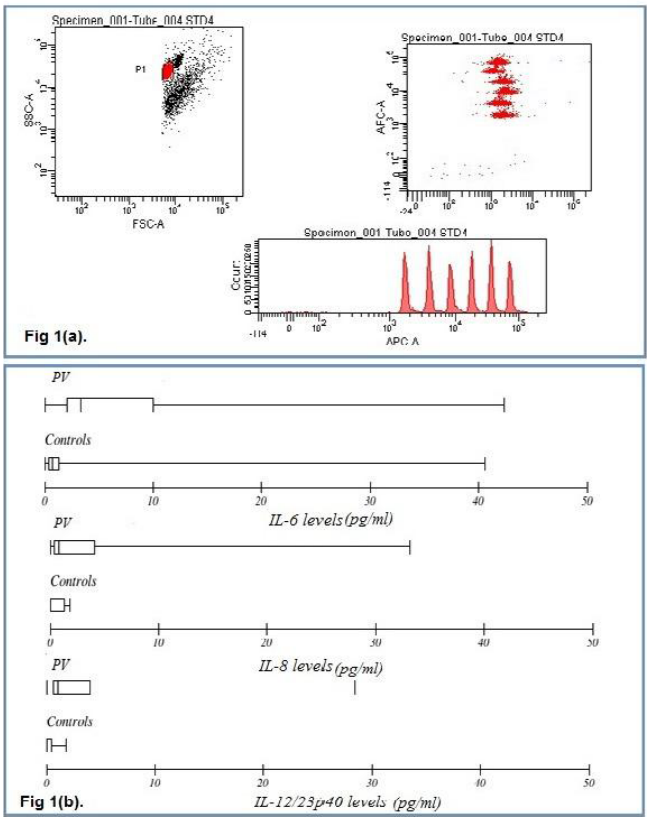

FIGURE 1 (a). flow cytometer images obtained after sample processing; Fig.1(b). showing levels of IL-6, IL-8 & IL-12/23p40 in PV patients & controls

TABLE 1 Association of IL-6 & 8 with thrombotic events (Mann U Whitney test)

Cytokines (mean±S.D)	Thrombotic events present(n=19)	Thrombotic events absent(n=33)	´p´ values
IL-6 (pg/ml)	13.88±12.60	2.55±2.13	<0.001
IL-8 (pg/ml)	3.66±7.17	1.06±1.33	0.021

PB 648 | Joint Modeling of Longitudinal Haemostatic and Inflammatory Biomarker Trajectories and Mortality in Patients with Cancer

F. Posch[1], E.-M. Reitter[1], J. Riedl[1], P. Quehenberger[2], C. Ay[1], I. Pabinger[1]

[1]*Medical University of Vienna, Clinical Division of Haematology & Haemostaseology, Department of Medicine I, Vienna, Austria,* [2]*Medical University of Vienna, Department of Laboratory Medicine, Vienna, Austria*

Background: Elevated biomarkers of hypercoagulability, such as D-Dimer, and inflammation, such as C-reactive protein (CRP), are associated with an increased risk of death in patients (pts) with cancer. However, the relationship between longitudinal changes of these biomarkers over time and mortality remains incompletely understood.

Aims: To explore the role of longitudinal changes in haemostatic and inflammatory biomarkers for dynamic overall mortality prediction in pts with cancer.

Methods: 105 pts with active malignancy were included in this prospective cohort study (**Table 1**). D-Dimer, Prothrombin fragment 1.2 (F1.2), CRP, and others (to be presented at the meeting) were measured at study inclusion, as well as during 6 follow-up visits, each 1 month apart. The prognostic impact of longitudinal biomarker trajectories on mortality was quantified with a so-called joint model.

Results: During the observation period of 250 days, we observed 17 deaths, for a 250-day mortality of 16.6% (95%CI: 10.6-25.3). Graphical inspection of biomarker trajectories suggested that levels of D-Dimer (**Figure 1A**), F1.2, and CRP (**Figure 1B**) increased before death. In joint modeling, a doubling of the D-Dimer trajectory was associated with a 2.3-fold increase in the risk of death (Hazard ratio (HR)=2.28, 95%CI: 1.54-3.37, p< 0.0001). A corresponding increase in F1.2 and CRP was associated with a 4.2-fold increase (HR=4.23, 1.43-12.53, p=0.009) and a 3.2-fold increase (HR=3.18, 1.75-5.81, p< 0.0001) in the risk of death, respectively. These associations

prevailed after adjusting for age and metastatic disease at baseline (Adjusted HR for D-Dimer=2.33, 1.54-3.53, p< 0.0001, others not shown).

Conclusions: Longitudinal trajectories of haemostatic and inflammatory biomarkers predict the occurrence of death in pts with cancer. The evolving biomarker profile of cancer pts over time is consistent with the co-occurrence of increased thrombin generation and systemic inflammation at the end of life.

TABLE 1 Characteristics of the study population (n=105)

Variable	Median [25th-75th percentile], or Absolute count (percent)
Age at entry (years)	62.7 [53.1-68.6]
Metastatic disease at entry	45 (43%)
D-Dimer at entry (µg/mL)	1.0 [0.5-2.1]
Prothrombin Fragment 1.2 at entry (pmol/L)	220 [153-277]
C-reactive protein at entry (mg/dL)	0.6 [0.1-1.8]
Number of follow-up visits per patient	6 [3-6]
Remission during antineoplastic treatment	36 (34%)

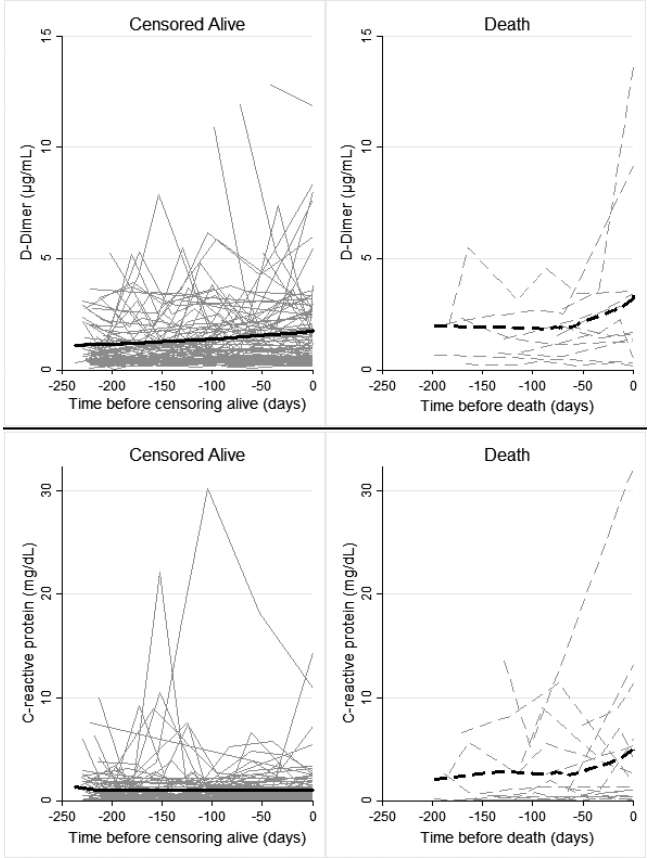

FIGURE 1 Trajectories of D-Dimer and CRP in patients with cancer who were censored alive or died during the study period

PB 649 | LMWH First Dose Program to treat Cancer-associated Thrombosis in a Pharmacy Setting

J. Easaw[1], S. McCall[2], A. Azzim[3]

[1]*Cross Cancer Insitute, Edmonton, Canada,* [2]*LEO Pharma Inc., Thornhill, Canada,* [3]*Shoppers Drug Mart North Hill Centre, Calgary, Canada*

Background: Currently, clinically stable patients diagnosed with a pulmonary embolism or deep vein thrombosis are referred to the emergency department (ED) for management. This practice strains an already overburdened ED and is associated with long wait times and poor injection education. Despite their elevated risk of venous thromboembolism (VTE), patients with cancer commonly receive little to no information to help them recognize the symptoms of thrombosis.

Aims: This pilot study sought to determine if clinically stable patients with a newly diagnosed blood clot could be effectively managed by a community pharmacist following a guidelines-based algorithm to prescribe and initiate low molecular weight heparin (LWMH) therapy.

Methods: Clinically stable cancer patients, with newly diagnosed VTE, were enrolled into this pilot study by their oncologist. A pharmacist trained in the algorithm prescribed a 14-day supply of LMWH, as well as provided injection teaching, VTE education and follow-up.

Results: Patients (N=48) were prescribed a LMWH (pre-filled dose-specific syringe) for a minimum of 10 days. Self-injection training was well received, < 5% of patients were unable to self-inject following training, with most confident in their ability to self-inject. No known occurrences of bleeding or other side-effects were observed in the patients enrolled in the study. Physician and patient satisfaction was high with the program.

Conclusions: This pilot study demonstrates that cancer patients with newly diagnosed VTE can be safely and effectively managed by pharmacists in the outpatient setting. This study also shows that pharmacists are capable of doing more than their traditional role of dispensing medications and are capable of delivering complex care services, particularly in the management of VTE. Stable patients with CAT can be managed in a local pharmacy with no need to visit the ED, overall affording the patient better care with a lower cost to the healthcare system.

PB 650 | Biomarkers for Venous Thromboembolism (VTE) in Newly Diagnosed Multiple Myeloma (NDMM): Early Results from the Thromboprophylaxis in Multiple Myeloma (TiMM) Trial at King's College Hospital

Z. Sayar, J. Czuprynska, R. Benjamin, J.P. Patel, L.N. Roberts, R.K. Patel, R. Arya

King's College Hospital NHS Foundation Trust, Haematology, London, United Kingdom

Background: There is a well-established link between myeloma and VTE risk, however there is limited information regarding the use of

TABLE 1 Mean Biomarker Results at each Visit

	Baseline	Visit 1 (Week 1)	Visit 2 (Week 3)	Visit 4 (Week 9)	Visit 7 (Week 18)
Mean (SD) F8	188 (87)	229 (39)	245 (58)	267 (98)	157 (57)
Mean (SD) VWF:Ag	188 (55)	224 (38)	244 (45)	260 (92)	168 (35)
Mean (SD) VWF:Act	128 (66)	172 (71)	193 (67)	250 (111)	124 (25)

biomarkers to identify alterations in risk. Currently myeloma patients receiving chemotherapy are the only group of ambulatory cancer patients who routinely receive thromboprophylaxis which takes the form of either aspirin or low molecular weight heparin, depending on risk stratification.

Aims: To describe Factor 8 (F8), von Willebrand Antigen (VWF:Ag) and Activity (VWF:Act) in NDMM patients as they progress through treatment as part of the TiMM trial.

Methods: The TiMM trial randomises patients to either standard thromboprophylaxis or apixaban 2.5mg BD. F8, VWF:Ag and VWF:Act were measured before starting treatment (baseline) and at weeks 1, 3, 9 and 18 into their myeloma treatment.

Results: To date 10 patients have been recruited to the TiMM trial. Two have been classified as high risk and randomised to apixaban as thromboprophylaxis. Eight patients have been classified as low risk, 4 randomised to receive aspirin and 4 apixaban. F8, VWF:Ag and VWF:Act concentrations increase during the first 2 months of treatment and normalise by week 18.

Conclusions: Our early findings indicate that the risk of VTE, as assessed by biomarkers, is elevated, and increases during the first 9 weeks of chemotherapy. This risk appears to reduce by week 18. This could be clinically useful to establish the period of highest risk and the optimal duration of thromboprophylaxis and also which patients may be at highest risk of VTE. Further results are required to assess the significance of this, along with additional biomarkers that are currently being assessed as part of the TiMM trial.

PB 651 | The CATs out of the Bag: Alternatives to Low Molecular Weight Heparin (LMWH) in Patients with Cancer Associated Thrombosis (CAT)

M.P. Crowley, D. McClinton, K.A. Breen, V. McDonald

Guys and St Thomas' Hospital, Thrombosis, London, United Kingdom

Background: CAT occurs in up to 19% of patients with malignancy and is a leading cause of death(1-4). The clot study (5) established the superiority of LMWH over coumarins for the treatment of CAT. Direct oral anticoagulants (DOAC) have become first line in the treatment of venous thromboembolism (VTE) but their role in patients with cancer associated thrombosis is unclear.

TABLES

Table 1 – Timing of DOAC

Timing of DOAC therapy	N
DOAC within the first 6 months of treatment	10
Rivaroxaban	9
Apixaban	1
DOAC after 6 months	24
Rivaroxaban	17
Apixaban	7

Table 2 – Complications of anticoagulation

	Treatment Phase	Secondary prophylaxis phase
Bleeding	2 - Haematuria on LMWH – 1 required red cell transfusion 1 - Rectal bleeding on LMWH (minor) 1 – Muscle bleed (post surgery) on LMWH	1 - Rivaroxaban associated menorrhagia 1 - Rivaroxaban associated upper GI bleed in the setting of peptic ulcers
Thrombosis	2 – New DVT after dose reduction in month 2 3 – Extension of DVT on LMWH	1 – New PE on prophylactic LMWH 1 – MI on prophylactic LMWH

Aims: To review anticoagulant choice and complications in patients with CAT.

Methods: A review of patient records of patients with a CAT at a tertiary hospital between July 2015 and June 2016 was undertaken.

Results: 145 patients (76M /69F) were identified for analysis. The median age was 66 (Range 22-90). 46% were PE and 32% DVT. A wide variety of cancer types were seen. 127 patients completed 6 months of anticoagulation, 16 died within 6 months of CAT, 1 patient was on anti-platelet therapy (MI) and 1 stopped anticoagulation against medical advice. 3 patients started a DOAC as part of a clinical trial and 2 were commenced on warfarin prior to the diagnosis of malignancy. 140 started LMWH and 115 patients completed 6 months of LMWH. Of these, 43 stopped anticoagulation after 6 months, 31 continued on prophylactic LMWH, 15 continued on therapeutic LMWH because of progressive thrombosis, 24 changed to a DOAC and 9 changed to warfarin. 34 patients (23%) received DOACs at some stage (Table 1). 24 were switched to a DOAC after completing 6 months of LMWH to continue secondary prevention. 13 patients reported complications while on anticoagulation (Table 2). Only one patient required a red cell transfusion.

Conclusions: LWMH remains the agent of choice in the treatment of CAT. In this cohort, DOACs appear to be as effective in secondary prevention as LWMH with no excess adverse events.

PB 652 | Additional Testing Following Screening Strategies for Occult Malignancy Diagnosis in Patients with Unprovoked Venous Thromboembolism

P. Robin[1], P.-Y. Le Roux[1], E. Le Moigne[2], B. Planquette[3], N. Prévot-Bitot[4], P.-M. Roy[5], J. Pastre[3], A. Merah[6], F. Couturaud[2], G. Le Gal[7], P.-Y. Salaun[1], MVTEP Study Group

[1]Centre Hospitalier Universitaire de Brest, Université de Bretagne Occidentale, Service de Médecine Nucléaire, EA 3878 (GETBO) IFR 148, Brest, France, [2]Centre Hospitalier Universitaire de Brest, Université de Bretagne Occidentale, Département de Médecine Interne et Pneumologie, EA 3878, CIC INSERM 1412, Brest, France, [3]Hôpital Européen Georges Pompidou, AP-HP, Université Paris Descartes, Sorbonne Paris Cité, Service de Pneumologie, INSERM UMR-S 1140, Paris, France, [4]Centre Hospitalier Universitaire de Saint-Etienne, Université Jean Monnet, Service de Médecine Nucléaire, Inserm U 1059, Saint-Etienne, France, [5]Centre Hospitalier Universitaire d'Angers, Département de Médecine d'Urgences, Angers, France, [6]Centre Hospitalier Universitaire de Saint-Etienne, Service de Médecine Vasculaire et Thérapeutique, Inserm CIC 1408, Saint-Etienne, France, [7]Ottawa Hospital Research Institute at the University of Ottawa, Department of Medicine, Ottawa, Canada

Background: ^{18}F-Fluorodesoxyglucose Positron-Emission-Tomography combined with Computed-Tomography (FDG PET/CT) might be an attractive tool for cancer screening in patients with venous thromboembolism (VTE), allowing non-invasive whole-body imaging. One of the frequent criticisms to the use of FDG PET/CT for screening is the potential for false positive results leading to unnecessary/invasive investigations.

Aims: To compare the frequency and invasiveness of additional testing following extensive and limited screening strategies for occult malignancy in patients with unprovoked VTE.

Methods: We analysed patients included in the MVTEP study, a randomized trial that compared a screening strategy based on FDG-PET/CT with a limited screening strategy for occult malignancy diagnosis in patients with unprovoked VTE. All additional diagnostic procedures following screening were recorded and classified as invasive or non invasive.

Results: A total of 394 patients were analysed. The mean number of additional tests per patient was 0.30 in the FDG PET/CT arm, vs. 0.27 in the control arm (p=0.65). Overall, 45 (22.8%) patients in the FDG PET/CT group underwent additional diagnostic tests, versus 32 (16.2%) in the limited screening group (absolute risk difference +6.6%, 95% CI -1.3 to +14.4%, p=0.13). Sixteen (8.1%) patients in the FDG PET/CT group underwent invasive procedures, versus 6 (3%) in the limited screening group (absolute risk difference +5.1%, 95% CI +0.5 to +10.0%, p=0.03).

Conclusions: We found no statistical difference in the number of additional procedures following each screening strategy. However, a higher number of invasive tests were performed in the FDG PET/CT group, but mostly leading to an underlying disease.

PB 653 | Assessing the Effects of Pre-analytical Variables on Thrombosis Biomarkers in Cancer Patients: Study Planning and Launch

R. Agarwal[1], E.J. Greenspan[2], J.H. Bavarva[1], C. Soria[1], L. Agrawal[3], T.H. Mondoro[4], A.L. Kindzelski[4], C. Andry[5,6], D. Remick[5,6], D. Stearns-Kurosawa[6], S. Kurosawa[6], E. Duffy[5,6], M. Sloan[5,6], J. Henderson[5,6], J. Kim[5], F. Sun[6], M. Thompson[5,6], C. Spencer[5], M.A. Berny-Lang[2]

[1]Leidos Biomedical Research, Inc., Rockville, United States, [2]Center for Strategic Scientific Initiatives, Office of the Director, National Cancer Institute (NCI), National Institutes of Health (NIH), Bethesda, United States, [3]Biorepositories and Biospecimen Research Branch, Cancer Diagnosis Program, Division of Cancer Treatment and Diagnosis, NCI, NIH, Bethesda, United States, [4]Division of Blood Diseases and Resources, National Heart, Lung, and Blood Institute (NHLBI), NIH, Bethesda, United States, [5]Boston Medical Center, Boston, United States, [6]Boston University School of Medicine, Boston, United States

Background: Thrombosis is a major cause of morbidity in cancer patients with an incidence that varies widely, impacted by factors related to the cancer, treatment, and patient characteristics. To accurately assess patient risk and build upon existing risk assessment tools, further biomarker development and standardization are needed.

Aims: To advance standardization and provide guidance for measurement of thrombosis biomarkers in cancer patients, a pilot study was designed to identify steps during biospecimen procurement, handling, and processing which are critical for optimal specimen preservation and accurate marker detection.

Methods: The study was designed with input from an NCI/NHLBI working group; a request for information to the research community; guidance from a Scientific Advisory Committee comprised of experts in clinical pathology, pre-analytical variables, biospecimen science, and thrombosis in cancer patients; and with an experimental design developed by investigators from Boston Medical Center.

Results: Blood will be collected from cancer patients and healthy donors using standard operating procedures. The impact of pre-analytical variables experienced in the clinical setting, including delay to blood processing, delay to assay, and freeze-thaw cycles, will be measured on markers of coagulation (factor VIII activity, prothrombin fragment 1+2), fibrinolysis (D-dimer, plasminogen activator inhibitor-1, plasmin-antiplasmin complex), cell injury (plasma DNA, nucleosomes), and inflammation (soluble P-selectin, myeloperoxidase). Participants will be followed for six months for cancer and thrombotic outcomes.

Conclusions: The study will provide best practices for biomarker assessment, a potential biospecimen source to enhance future NIH funding opportunities, and a foundation for future biomarker studies to assess thrombotic risk and predict efficacy of anti-thrombotics. The data generated will be widely shared with the research community through publications and deposition in a public data repository.

PB 654 | Predictors of Prolonged Hospitalization Deep Vein Thrombosis Patients

A. Kurniawan, N.P.H. Lugito, M.M. Tjiang, T.A. Yanto

School of Medicine, Pelita Harapan University, Internal Medicine, Tangerang, Indonesia

Background: Deep Vein thrombosis (DVT) patient usually need hospitalization after diagnosed approximately 5-7 days to get proper dose of anticoagulant and bridging into targeted dose vitamin K antagonist (VKA) at home. Several risk factors of prolonged hospitalization are well established, but prediction model of prolonged hospitalization DVT patients is still limited.

Aims: To Identify predictors of prolonged hospitalization DVT patients.

Methods: This was a cohort study conducted in our second referral general hospital, Karawaci, Tangerang, Banten, Indonesia from 2014-2015. We followed DVT patients after they were diagnosed using compression Doppler ultrasound. Prolonged hospitalization is defined as hospitalization more than 7 days after DVT was diagnosed. Eighteen potential predictors were evaluated using Binary Logistic statistical analysis.

Results: During 59 hospitalization DVT patients, 22 (37.3%) patients went home more than 7 days. Thirty-three (55.9%) patients were female with mean of age 47.1± 14.7 years old. Mostly the location of DVT was on popliteal vein 61.4%, followed by femoral (29.8%) vein and the rest was iliac vein. Most patients (81%) got weight based doses unfractionated heparin (UFH) followed by VKA. The rest were using Low Molecular Weight Heparin (LMWH) followed by VKA. Eight factors were included to be evaluated by binary logistic model. After adjusted for comorbidity conditions, cancer (OR 17.24; 95% CI: 2.11-142.28), hemoglobin level (OR 1.962; 95% CI: 1.242-3.100), high D-dimer (OR: 1.422; 95% CI: 0.94- 2.156), and high creatinine level (OR: 9.70; 95% CI: 1.03-90.90) were an independent predictors of prolonged hospitalization more than 7 days. The model was statistically significant p< 0.000. Those four variables could predict hospitalization for more than 7 days around 59,5%.

Conclusions: Predictors of prolonged hospitalization DVT patients were cancer, hemoglobin level, high D-dimer and creatinine level.

PB 655 | Incidence of Central Venous Catheter-related Venous Thrombosis in Japanese Inpatients with Hematological Malignancies: Single Center Experience

K. Miyazaki[1], T. Ishida[1,2], M. Danbara[2], M. Higashihara[2]

[1]Kitasato University School of Medicine, Department of Transfusion and Cell Transplantation, Sagamihara, Japan, [2]Kitasato University School of Medicine, Department of Hematology, Sagamihara, Japan

Background: Symptomatic catheter-related thrombosis (CRT) occurs in 3-5% of cancer patients with central venous catheter (CVC) and the incidence of CRT could reach 30% when including asymptomatic cases. However, little is known about the incidence of CRT in patients with hematological malignancies. Some of them might need CRT prophylaxis, but on the other hand have more bleeding risk. It is important to identify the risk factors for thrombosis in such patients with central venous catheters.

Aims: To determine the incidence of CRT, and review the characteristics of CRT patients and current practice of CRT management.

Methods: We conducted a retrospective chart review of adult patients with hematological malignancies at Kitasato University Hospital, Japan from December 2013 to November 2016.

Results: A total of 142 patients who received central venous catheter (CVC) insertion. Twenty-eight patients (19.7%) were diagnosed with deep vein thrombosis, of whom 8 (5.6%)were associated with CVC insertion, including 7 cases of non-Hodgkin lymphoma and one of acute myeloid leukemia. The platelet counts at CRT diagnosis were more than 100 x 10^9/L except one case of leukemia, whose platelet count was 14 x10^9/L. The ECOG performance status of 6 patients (75%) was 3-4. The median time from CVC insertion to CRT diagnosis was 22days (range 10-27days). The insertion site of CVCs was femoral vein in 6 and jugular vein in 2 patients. Three patients have local inflammation at the insertion site due to catheter infection. Seven patients (87.5%) were treated with therapeutic anticoagulation using unfractionated heparin, and one using edoxaban. A single bleeding event of melena during anticoagulation occurred in each treatment.

Conclusions: In this study, the incidence of CRT among hematological malignancies was relatively lower, compared with the previous investigations. Further large scale prospective studies will elucidate some risk factors for CRT and proper anticoagulation among patients with hematological malignancies.

PB 656 | Inaugural Thrombotic Events in Myeloproliferative Neoplasms

H. Baccouche, D. Bahri, A. Chakroun, Z. Manai, S. Mahjoub, N. Ben Romdhane

Rabta Hospital, El Manar University, Department of Hematology, Tunis, Tunisia

Background: BCR ABL negatives myeloproliferative neoplasms (MPN) including polycythemia vera (PV), essentiel thrombocythemia (ET) and primitive myelofibrosis (PMF) are clonal disorders characterized by hematopoietic progenitor cell proliferation. Thrombosis is a well known complication. It occurs particularly at diagnosis and involve both arterial and thrombotic vessels.

Aims: This study aimed to assess patients profile with inaugural thrombosis.

Methods: In a retrospective study, 67 patients with BCR ABL negatives MPN (WHO criteria 2016) were enrolled from January 2010 to December 2015. Clinical and biological data of patients with thrombosis were recorded.

Results: Among 67 patients (19 PV, 42 ET and 6 PMF), thrombotic events were reported in 20 (30%): 8 with PV, 9 with ET, and 3 with PMF. Mean age of patients with thrombosis was 59 years old [31-79], the sex ratio was 0.8. Cardiovascular risk factors were identified in

seven (35%) patients. Thrombotic localizations were venous thrombosis (n=7) and arterial thrombosis (n=13). Portal vein and peripheral arteries were the most frequent sites. The JAK2 mutation was found in 17 patients (85%). Two patients had recurrent thrombotic events during the follow up despite the cytoreductive therapy associated to antiplatelet drugs.

Conclusions: According to these results, in MPN, thrombotic events occur at diagnosis. Peripheral arteries and Intraabdominal vein are the most frequent localizations and usually reveal the diagnosis.

PB 657 | Biological Pro-coagulant and Pro-inflammatory Effect of Interferon Alpha in Myeloproliferative Neoplasms

N. Ajzenberg[1,2], D. Faille[1,2], L. Lamrani[2], S. Loyau[2], M.-G. Huisse[1,2], M. Jandrot-Perrus[2], S. Alkhaier[3], B. Cassinat[3,4], C. Chomienne[3,4], C. Dosquet[3,4]

[1]APHP, Hematology Bichat Hospital, Paris, France, [2]INSERM U 1148, Paris, France, [3]APHP, Service de Biologie Cellulaire, Hopital Saint Louis, Paris, France, [4]INSERM UMR 1131, Institut Universitaire d'Hématologie, Paris, France

Background: Myeloproliferative neoplasms (MPN) are associated with an increased risk of arterial and venous thrombosis. Pegylated-interferon alpha (IFN) has obviously a great therapeutic efficacy on hematopoietic cell proliferation but its effects on hemostasis and inflammation have not been studied.

Aims: To determine whether IFN impacts the biological profile of MPN patients comparing endothelial, platelet and coagulation parameters in IFN or hydroxyurea (HU) treated and non treated (NT) patients.

Methods: 88 patients were included: 28 treated by IFN : 20 polycythemia vera (PV) and 8 essential thrombocythemia (ET), 38 treated by HU (27 PV and 11 ET) and 22 NT (6 PV and 16 ET).

Results: We observed significant effects of HU on von Willebrand factor (vWF) levels and a more pronounced effect of IFN:vWF antigen increased from 111.7±9.5 % in NT to 162.9±10.3% in HU and 227±17.1% in IFN-patients (p< 0.01). VWF activity increased to a similar extend. We observed only in IFN patients significant decreased protein S activity compared to NT patients (62.2±2.5% vs 88.7±3.9%, p< 0.01) and also significant increased levels of factor VIII:C and fibrinogen.

We had the opportunity to test again 10 patients at least 6 months after IFN discontinuation. IFN was stopped for side effects in 6 patients, for complete molecular response in 2 and for normalization of hematological parameters in 2 others. VWF activity and antigen, protein S activity, FVIIIC and fibrinogen returned to levels similar to those of NT patients and were significantly different from levels observed in IFN-treated patients.

Conclusions: We observed an increase of procoagulant and inflammatory markers in IFN-treated MPN patients that could be considered as a part of IFN biological effects. Though minimal, these alterations could require more intensive preventive anticoagulation than aspirin in patients with associated minor thrombotic risk factors such as FV Leiden or FII G20210A.

PB 659 | Audit: Use of Khorana Score in Oncology Patients in Belfast Trust

C. Carson, G. Benson

Belfast Trust, Belfast, United Kingdom

Background: Venous Thromboembolism (VTE) is a well-documented cause of morbidity and mortality in cancer patients. The Khorana score has been validated as a means of risk assessing patients who would benefit from primary prophylaxis; advising low molecular weight heparin if the Khorana score is ≥3.

Aims: To audit if cancer patients in the Belfast trust were prescribed primary prophylaxis if they had a Khorana score of ≥3.

Methods: This audit retrospectively looked at all positive CT pulmonary angiography (CTPA) cases between January 2014 and December 2017. Cancer patients were identified and their Khorana score and evidence of VTE prophylaxis was gathered from their notes.

Results: 5321 CTPAs were performed in this period. 613 were identified with pulmonary embolisms (PE) of which 124 had a diagnosis of cancer and 54 of whom the Khorana score could apply. The mean age was 63, 56% were female, 44% were male. Of these 13% were local cancers, 24% with nodal spread, 44% were metastatic and extent of the disease was not clearly documented in 19%. 67% resulted in admission, with a mean hospital stay of 11 days. 15% had previously documented VTE and family history was poorly recorded in all cases.

7 patients were identified with a khorana score of 3 or more. Only 1 was on primary prophylaxis, 1 already on an anticoagulant.

Conclusions: This audit looked only at PE´s found by CTPA, it did not encompass incidental findings on staging CTs. The Khorana score was only applicable to small numbers of patients, however in these the standard of primary prophylaxis in high risk groups was not met. The Khorona score was not predictive in this group and of interest 2 patients who were prescribed primary prophylaxis still had a PE.

PB 660 | Treatment Tactics of Ulcerous Hemorrhage in Patients with Coronary Disease

R. Rakhimov

Republican Scientific Centre of the Emergency Medical Care, Tashkent, Uzbekistan

Background: Frequency of ulcerous gastroduodenal hemorrhage (UGDH) combining with coronary disease has no tendency for decreasing in spite of the successful drug treatment of ulcerous disease (CD).At occurrence of such combination there is a severe influence of one pathology to another one and this fact stipulates a high mortality from 37 to 55% at conservative and operative treatments of such patients.

Aims: Aim of this research is the analysis of treatment results ulcerous hemorrhage in patients with CD.

Methods: The treatment results of 72 patients with UGDH combining with CD for the period from 2010 till 2016 has been analyzed.

There were 51 men and 21 women. Average age was 53,2±4,2 years. Ulcerous hemorrhage activity has been determined by J. Forrest-Rosch (1974) classification and hemorrhagic shock level - by Algover index. In 34 patients the reason of hemorrhage was duodenum chronic ulcer (DCU) and in 38 patients - acute gastric and duodenum ulcers. As concomitant CD in 58 patients there was stable angina, in 14 cases - acute coronary syndrome (ACS) with rising (5) and without ST rising (9). In 2 patients ulcerous hemorrhage has been combined with acute cardiac infarction.

Results: As endoscopic ways of a hemostasis at 52 patients have been performed electric coagulation as endoscopic ways of hemostasis in 20 patients - introduction of 70° solution of ethanol around the ulcer. Reliable endoscopic hemostasis has been pointed in 61 patients. In 5,6% of patients it was impossible to get a primary hemostasis and in 9,6% of cases there was a recurrent hemorrhage. All those patients have been operated. Performed operations in 8 patients were palliative and in 3 of them - radical (resection of 2/3 of stomach by Bilrot 2). Mortality was 2,78 %.

Conclusions: The main treatment methods of such patients are conservative therapy and endoscopic ways of hemostasis. Surgical interventions should be performed at impossibility of achieving a primary hemostasis or at recurrent hemorrhage.

PB 661 | Venous Thrombosis and Thromboembolic Risk Factors in Outpatients with Lymphoma on Chemotherapy

M.E. Mingot-Castellano, I. Sánchez Bazán, J. Díaz Pastor, O.M. Benítez Hidalgo, M. Espeso de Haro

Hospital Regional Universitario de Málaga, Hematology, Málaga, Spain

Background: Prevalence of venous thrombotic events (VTE) in patients with lymphomas is approximately 4%. There are a number of thrombotic risk factors (TRF) identified in this group of patients in general, but not exactly in those with ambulatory chemotherapy.

Aims: To evaluate the prevalence, TRF and characteristics of VTE in patients with lymphomas under outhospital chemotherapy.

Methods: Retrospective unicenter study, single physician for the treatment and follow-up of patients. Data from all patients with lymphoma treated at our center between January 2014 and December 2015 were collected. We analized age at diagnosis, previous antithrombotic prophylaxis, histology, stage, chemotherapy scheme, use of epo, Hb< 10g/dl, platelets (Plat)>350x10^9/L, leucocite (LEU)>11x10^9/L, immobilization, Charlson, IMC >35, use of dexamethasone, radiotherapy or catheters, VTE.

Results: We analyzed 94 subjects, median age 52.5 years (IQR 36.7 to 72 years). The most prevalent histologies were diffuse large B-cell lymphoma (LDCGB) (34%) and Hodgkin (EH) (23.4%). Three patients were under secondary antiplatelet prophylaxis for prior arterial ischemia. 34% of patients had one or more TRF. 3 (3,2%) patients presented VTE:

· Female 19 years old, EH 2B, plat>350x10^9/L, Hb <10gr/L, leu 11x10^9/L, doxorubicin. Upper limb thrombosis 22 months after diagnosis. Treatment LMWH 3 months.

· Patient 2: Female 74 years old, LDCGB 2A, plat>350x10^9/L, Hb <10gr/L, charlson 4. Lower limb thrombosis 8 months arter diagnosis. Treatment antivitamin-K 6 months.

· Patient 3: Male 40 years old, LDCGB 1A, plat>350x10^9/L, doxorubicin. Upper limb thrombosis 8 months after lymphoma. Treatment LMWH 3 months. Digestive hemorrhage 20 days after iniciate anticoagulation.

Conclusions: Prevalence of VTE in patients with outpatient with lymphoma looks similar to the global lymphoma. Three VTE affected patients presented TRF. Upper limb thormbosis was the most frequent one, probably related with the local administration of chemotherapy.

PB 662 | Investigation of Plasma Microparticles in Patients with Type 1 Diabetes May Be Interfered by Elevated Endogenous Lactadherin Levels in this Patient Group

K. Bergen[1], F. Mobarrez[2], G. Jörneskog[1], H. Wallén[3], S. Tehrani[1]

[1]Karolinska Institutet, Department of Clinical Sciences, Danderyd Hospital, Division of Internal Medicine, Stockholm, Sweden, [2]Karolinska Institutet, Department of Medicine, Rheumatology Unit, Karolinska University Hospital Solna, Stockholm, Sweden, [3]Karolinska Institutet, Department of Clinical Sciences, Danderyd Hospital, Division of Cardiology, Stockholm, Sweden

Background: Type 1 diabetes is a prothrombotic state with elevated levels of procoagulant microparticles (MPs) in plasma. MPs may express phosphatidylserine (PS), a negatively charged phospholipid which can bind to coagulation factors and facilitate thrombin generation. Lactadherin is a membrane glycoprotein that binds to PS with high affinity and is used to detect PS expression on MPs.

Aims: To investigate levels of PS+ MPs in patients with type 1 diabetes and healthy controls and how this relates to endogenous lactadherin levels.

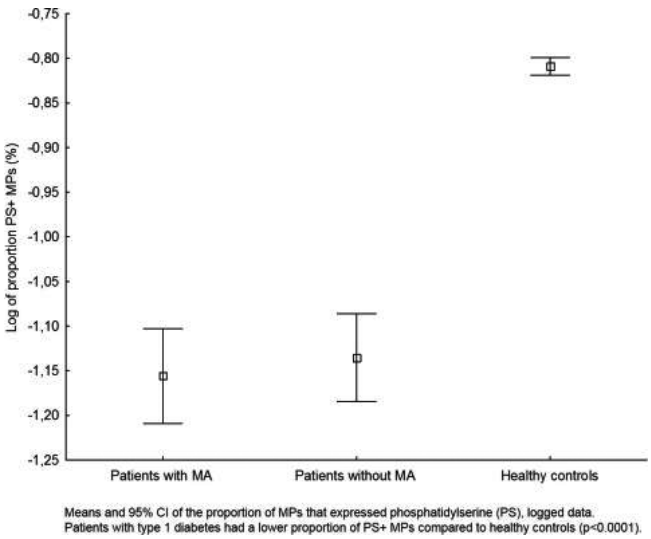

FIGURE 1 Proportion of total microparticles (MPs) expressing phosphatidylserine (PS+) among patients with type 1 diabetes and healthy controls.

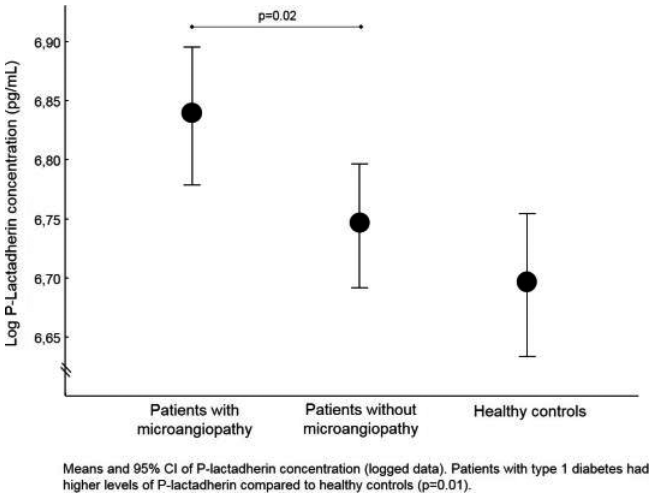

FIGURE 2 Endogenous plasma lactadherin levels in patients with type 1 diabetes and healthy controls.

Methods: We recruited 236 patients with type 1 diabetes aged 20 to 70 years with no history of cardiovascular disease, and 100 healthy individuals matched for age, BMI and sex. Plasma MP levels were assessed by flow cytometry, with lactadherin used as a marker of PS expression. Endogenous P-lactadherin levels were measured using ELISA (R&D systems, UK).

Results: Patients had higher levels of total circulating MPs compared to controls (41.5 (IQR 24.6 - 68.5) x 10^9/L vs. 23.2 (IQR 15.3 - 31.8) x 10^9/L, p< 0.0001), while the proportion of PS+ MPs was lower among patients compared to controls (p< 0.0001), see Figure 1.

Patients with type 1 diabetes had higher P-lactadherin levels compared to controls (median 874 pg/mL (IQR 747-1011) vs. 828 pg/mL (IQR 683-959), p=0.01). In addition, patients with microangiopathy (n=106) had higher P-lactadherin than patients without microangiopathy (p=0.02), see Figure 2. There was no significant correlation between P-lactadherin and number of PS+ MPs.

Conclusions: In our study, patients with type 1 diabetes had higher levels of circulating MPs compared to healthy controls, while a smaller proportion of MPs expressed procoagulant PS. However, the patients also had higher endogenous P-lactadherin levels, which could potentially bind to PS on MPs and interfere with analysis, giving false low PS positive MP levels. Future studies should take endogenous levels of P-lactadherin into account when analyzing PS expression on MPs using lactadherin as a marker.

PB 663 | Circulating Platelet Microparticles with Regards to Microvascular Complications and Sex Differences in Patients with Type 1 Diabetes

K. Bergen[1], F. Mobarrez[2], G. Jörneskog[1], H. Wallén[3], S. Tehrani[1]

[1]Karolinska Institutet, Department of Clinical Sciences, Danderyd Hospital, Division of Internal Medicine, Stockholm, Sweden, [2]Karolinska Institutet, Department of Medicine, Rheumatology Unit, Karolinska University Hospital Solna, Stockholm, Sweden, [3]Karolinska Institutet, Department of Clinical Sciences, Danderyd Hospital, Division of Cardiology, Stockholm, Sweden

Background: Patients with type 1 diabetes have high rates of vascular complications and women with diabetes lose their natural protection against cardiovascular disease. Platelet microparticles (PMPs) play an important role in inflammation and thrombosis, and high levels of circulating PMPs have been noted in patients with type 1 diabetes.

Aims: The aim of this study was to investigate the role of PMPs in the pathogenesis of diabetic microangiopathy.

Methods: We investigated PMP levels in plasma samples of 236 patients (107 women) with type 1 diabetes using flow cytometry and monoclonal antibodies against Glycoprotein IX (CD42a). The patients were aged between 20 to 70 years and had no history of cardiovascular disease. 106 patients had microvascular complications and 130 patients had no evidence of microvascular complications except for simplex retinopathy. PMP levels of 100 healthy individuals matched for sex, age and BMI were also analyzed. Data were log transformed and analyzed by independent t-test or ANOVA and contrasts.

Results: Patients with type 1 diabetes had higher levels of circulating PMPs compared to healthy controls 11.35 (IQR 7.29 - 19.49) x 109/L vs. 9.23 (IQR 5.68 - 12.10) x 109/L), p< 0.0001). PMP levels did not differ between patients with and without microvascular complications. However, healthy women had significantly lower PMP levels compared to healthy men (p=0.03), whereas PMP levels between men and women with type 1 diabetes were similar, see figure.

Conclusions: Our study confirms previous findings that patients with type 1 diabetes have higher PMP levels compared to healthy controls, but shows no clear relation between PMPs and microvascular complications. Interestingly, the favorable lower levels of PMPs among women compared to men among healthy controls are absent in women with type 1 diabetes. If this sex difference is of importance for the higher risk of cardiovascular disease in women with type 1 diabetes has to be investigated further.

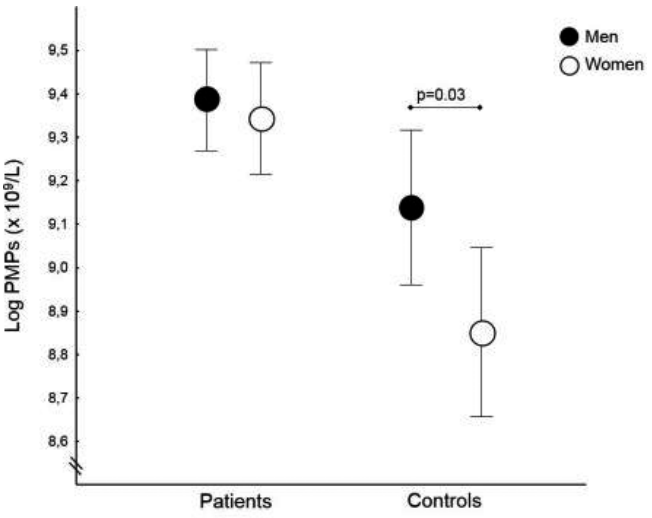

FIGURE 1 Platelet microparticles (PMPs) in men and women with type 1 diabetes and healthy controls

PB 664 | Effects of Low- and High-dose Doxorubicin and Paclitaxel on Tumorigenic, Thrombogenic and Angiogenic Properties of Extracellular Vesicles Derived from Breast Cancer Cell Lines

A. Aharon[1,2], A. Rebibo-Sabbah[3], L. Issman[4], Y. Abboud[2], Y. Talmon[4], B. Brenner[1,2]

[1]*Rambam Health Care Campus, Department of Hematology and Bone Marrow Transplantation, Haifa, Israel,* [2]*Bruce Rappaport Faculty of Medicine, Technion - Israel Institute of Technology, Haifa, Israel,* [3]*Rambam Health Care Campus, Department of Hematology, Haifa, Israel,* [4]*Technion - Israel Institute of Technology, Department of Chemical Engineering and The Russell Berrie Nanotechnology Institute (RBNI), Haifa, Israel*

Background: Extracellular vesicles (EVs) are shed from membranes of both normal and malignant cells. Various types of cell stimulation, including exposure to drugs, can affect the EV profile.

Aims: Eexplore the properties of EVs derived from breast cancer (BC) cells following exposure to high or low doses of chemotherapeutic drugs used for BC treatment and to evaluate ,thrombogenic and angiogenic effects of these EVs on endothelial cells (EC).

Methods: EVs were isolated from BC cell lines (MCF7 and MDA231), pre-exposed to increasing doses of doxorubicin or paclitaxel**.** Structure and size of cells and EVs were studied using electron microscopy and nano-tracking analysis. Antigen levels were measured by FACS. EV effects on EC thrombogenicity, proliferation, migration and tube formation were assessed by FACS, FXa chromogenic assay, XTT method and time-lapse microscopy.

Results: BC cell stimulation caused massive EV shedding. EV populations expressed reduced levels of the tumorigenic marker EpCAM compared to their parental cells. MDA231-EVs obtained after high-dose stimulation with both drugs demonstrated a 6-fold increase in procoagulant activity. High-dose doxorubicin induced a 2-fold increase in the expression of negatively charged phospholipids and eliminated TFPI from MDA231 EVs (P< 0.001). BC-EVs used nanotubes as a bridge for intra-cellular communication, and penetrated into ECs. EVs obtained from both BC cells increased EC thrombogenicity. EVs derived from doxorubicin-stimulated MDA231 cells induced EC proliferation and migration. EVs originating from both cell lines exposed to high-dose paclitaxel restricted EC proliferation and migration. EVs derived from high dose of paclitaxel-stimulated MDA231 cells induced massive tube formation similar to stimulation with VEGF.

Conclusions: These in vitro findings suggest that the tumorigenic, thrombogenic and angiogenic properties of cancer cell EVs are dependent on the type and dose of the applied agent, which could have relevance to tailoring chemotherapy

PB 665 | Functional Tissue Factor Activity on Endothelial Cells Conveyed by Bloodcell Microparticles

A. Brandtner, G.F. Lehner, A.-M. Mokina, B. Zassler, S. Klein, M. Joannidis

Medizinische Universität Innsbruck, Division of Intensive Care and Emergency Medicine, Innsbruck, Austria

Background: Microparticles (MP) can transfer their surface markers to other cells. Tissue factor (TF) can be detected on the surface of cells without mRNA upregulation, suggesting that TF is conveyed by MP. Systemic inflammation triggers higher levels of TF, resulting in a pro-coagulant state *in vivo*, contributing to dysregulated haemostasis in patients with inflammatory syndromes.

Aims: The aim of this project is to test MP derived from human primary blood cells and cell lines concerning their ability to induce functionally active TF on endothelial cells (EC) and identify the cellular source of the most potent MP.

Methods: MP were isolated from red blood cells, platelets, peripheral mononuclear cells and granulocytes of healthy donors. Endothelial MP were obtained from human umbilical vein EC (HUVEC). MP from untreated cells versus TNFalpha stimulated cells were compared to model inflammation. FIIa generation of the isolated MP was tested against a phospholipid standard for quantification. To test FX activation, HUVEC were cocultured with cellspecific MP for six. Total TF levels of MP, supernatants and cell lysates were tested.

Results: MP isolated from TNFalpha treated cells had higher procoagulant activity. Functional TF was detected both on MP and treated EC. FX activation on EC was elevated when incubated with MP from inflamed cells compared to MP from untreated cells. TF-specific FX activation was inhibited by antiCD142. Total TFlevels were higher in isolated MP derived from TNFalpha treated cells. Correspondingly total TF concentration was elevated in EC lysates and supernatants after stimulation with MP of stimulated cells. Leucocyte MP showed the highest procoagulant potential.

Conclusions: HUVEC exposed to MP of TNFalpha treated EC and leucocytes show the highest TF levels. The data suggest that TF is not only transferred from MP but might also stimulate expression of TF. This test system allows an *in vitro* evaluation of the interaction between MP and the endothelium of procoagulant mechanisms.

PB 666 | Impact of All Trans Retinoic Acid on the Plasmin Generation of Leukemic Cells and Microparticles in Acute Promyelocytic Leukemia

D. Frankel[1,2], C. Judicone[1,3], R. Lacroix[1,4], I. Weiss[5], A. Muller[1], C. Chareyre[4], S. Cointe[1,4], F. Dignat-George[1,4], H.C. Kwaan[5]

[1]*APHM, CHU La Conception, Haematology and Vascular Biology Department, Marseille, France,* [2]*Aix-Marseille Université, GMGF, UMR_S 910, INSERM, Marseille, France,* [3]*BioCytex, Research and Technology Department, Marseille, France,* [4]*Aix Marseille Université, VRCM, UMR-S1076 INSERM, Marseille, France,* [5]*Northwestern University, Division of Hematology/Oncology, Feinberg School of Medicine, and the Robert H. Lurie Cancer, Chicago, United States*

Background: Acute promyelocytic leukemia (APL) is associated with a high rate of coagulopathy leading to hemorrhagic events. We previously demonstrated that microparticle-derived from APL blast cells (APL-MPs) have the capacity to generate plasmin in an

urokinase-dependent manner. All Trans Retinoic Acid (ATRA) is the main treatment associated with chemotherapy in this disease.

Aims: The aim of this study was to investigate the influence of ATRA on the plasmin generation capacity of leukemic cells and microparticles in acute promyelocytic leukemia

Methods: To that aim, NB4 cells (APL cell line) were cultured with or without ATRA for 5 days. Plasmin generation capacity (PGC) from both cells and MPs were measured using a functional chromogenic assay. MP-PGC from 20 APL patients were compared before and after ATRA treatment.

Results: A 5 day-ATRA treatment significantly decreased the NB4 cell proliferation compared to control without ATRA ($3.2x10^5$*vs* $1.2x10^5$ cells, p=0.01) Interestingly, NB4 cells generated also significantly less plasmin in presence of ATRA compared to cells cultured without ATRA (20 *vs* 745 mOD/min, p=0.03) whereas no qualitative difference was observed on NB4-MPs. However, a significant increase of MP counts was observed in the supernatant of treated cells ($3.5x10^6$*vs* $0.9x10^6$ MPs/ml, p=0.04) resulting in a global increase in the NB4-MP PGC after release of the cellular plasmin activator on MPs. When, the MP-PGC of 20 APL patients was compared before (J0) and after ATRA treatment (J7-J14), the plasmin generation was significantly decreased (6.9 [4.8-9.0] mOD/min *vs* 5.1 [3.5-6.2] mOD/min, p=0.009) which may be explained both by the impact of ATRA on APL cells and the short half time of APL-MPs in the circulation.

Conclusions: Altogether these data show for the first time an impact of APL treatment by ATRA on microvesiculation which could contributes to reduce the risk of coagulopathy.

PB 667 | Circulating Microparticles Trend in Patients with HCV-related Liver Cirrhosis who Underwent Direct-acting Antiviral Therapy

E. Campello[1], A. Zanetto[2], C. Radu[1], L. Spiezia[1], C. Bulato[1], S. Shalaby[2], M. Senzolo[2], P. Burra[2], F.P. Russo[2], P. Simioni[1]

[1]University of Padua Medical School Department of Medicine, Padova, Italy, [2]University of Padova, Department of Surgery, Oncology and Gastroenterology, Padova, Italy

Background: Plasma microparticles (MP) have been reported in cirrhosis. Since they own the ability of induce the activation of coagulation cascade, high MPs levels have been associated with a higher risk of portal vein thrombosis (PVT).

Aims: To investigate the presence of MP in patients with HCV related-cirrhosis treated with direct-acting antiviral (DAA) therapy as well as to correlate the MP profile changes with the risk of PVT development.

Methods: Patients with HCV related-cirrhosis treated with DAA were prospectively enrolled. Plasma levels of Annexin V-MP, endothelial (E)-MP, platelet (P)-MP and tissue factor (TF) bearing MP were measured by cytofluorimetry at baseline, at the end of therapy and 12 weeks (12W) after the end of therapy. During follow-up, PVT onset was recorded. Fifty healthy subjects were enrolled as controls.

Results: Sixty patients were enrolled (Child A/B 50/10). All of them reached 12W after the end of therapy follow-up. Baseline median levels of Annexin V-MP (6640 MP/μL) and TF-bearing MP (32 MP/μL) were significantly higher than end of therapy levels (4280 MP/μL, p< 0.05; 24 MP/μL, p< 0.01, respectively) and 12W after end of therapy-levels (2747 MP/μL, p< 0.01; 21 MP/μL, p< 0.01, respectively). A statically significant increase in E-MP levels was observed after antiviral therapy (12W after end of therapy: 1269 MP/μL in comparison to baseline levels 395 MP/μL; p< 0.05). Baseline median levels of P-MP (164 MP/μL) were higher than 12W time point-levels (125 MP/μL), however the difference was not statistically significant (p=0.15). Median follow up was 9 months (4-14). One PVT episode was recorded (incidence 2%).

Conclusions: Eradication of HCV is associated with a significant change in Annexin V and endothelial MP profile, possibly related to both reduction of inflammatory systemic condition and to improvement of liver function. This amelioration may partially correct the disequilibrium of the hemostatic imbalance of liver cirrhosis, leading to a reduction in the risk of PVT development.

PB 668 | P2Y1 and P2Y12 Antagonists Mediate the Release and Composition of Platelet Extracellular Vesicles

A. Gasecka[1,2,3], E. van der Pol[2,3,4], A.N. Böing[2,3], N. Hajji[2,3], A. Sturk[2,3], P. Siljander[5,6], P. Harrison[7], K.J. Filipiak[1], G. Opolski[1], R. Nieuwland[2,3]

[1]Medical University of Warsaw, 1st Chair and Department of Cardiology, Warsaw, Poland, [2]Academic Medical Center, University of Amsterdam, Laboratory of Experimental Clinical Chemistry, Amsterdam, The Netherlands, [3]Academic Medical Center, University of Amsterdam, Vesicle Observation Centre, Amsterdam, The Netherlands, [4]Academic Medical Center, University of Amsterdam, Biomedical Engineering and Physics, Amsterdam, The Netherlands, [5]University of Helsinki, Division of Biochemistry and Biotechnology, Department of Biosciences, Helsinki, Finland, [6]University of Helsinki, Division of Pharmaceutical Biosciences, Faculty of Pharmacy, Helsinki, Finland, [7]University of Birmingham, Institute of Inflammation and Ageing, Birmingham, United Kingdom

Background: Activated platelets contribute to inflammation and thrombosis by release of platelet extracellular vesicles (PEV). Because the P2Y1 and P2Y12 receptors for adenosine diphosphate (ADP) regulate platelet activation, we hypothesize that inhibition of these receptors affects the concentration and composition of PEV.

Aims: To investigate the role of platelet ADP receptors in the release of PEV.

Methods: Platelet-rich plasma from 6 healthy volunteers was incubated with saline, P2Y1 antagonist MRS2179 (100 μM), and/or P2Y12 antagonist ticagrelor (1 μM). Platelets were activated by ADP (10 μM) under stirring conditions at 37 °C. The reactivity was assessed by impedance aggregometry. Concentrations of PEV exposing glycoprotein IIIa (CD61), P-selectin (CD62p) and phosphatidylserine (PS) were determined by a state-of-the-art flow cytometer (A60-Micro, Apogee). Size distributions of PEV were obtained by calibration with nanoparticles of known optical properties and light scattering theory. Data were analysed using Student´s t-test.

Results: ADP-induced aggregation was decreased 73% by P2Y1 antagonist, 86% by P2Y12 antagonist, and 95% by both antagonists (p<

0.001 for all).The release of PEV participating in haemostasis ($CD61^+$/$CD62p^-$/PS^-; 3.1±0.8x10^8 events/ml) was inhibited by 50% in presence of both antagonists (p=0.003). The release of proinflammatory and prothrombotic PEV ($CD61^+$/$CD62p^+$/PS^+; 2.4±1.6x10^7 events/ml) was unaffected by P2Y1 antagonist (p=0.59), but decreased 62% by P2Y12 antagonist (p=0.04) and 72% by both antagonists (p=0.03). The size distributions confirmed that flow cytometry measured PEV ranging from 150 nm to 1000 nm in diameter.

Conclusions: Inhibition of P2Y1 and P2Y12 receptors affects the release of distinct subpopulations of PEV upon activation by ADP. Our findings suggest that patients treated with P2Y12 antagonists have decreased concentrations of proinflammatory and prothrombotic PEV, and thereby attenuated inflammation and thrombosis.

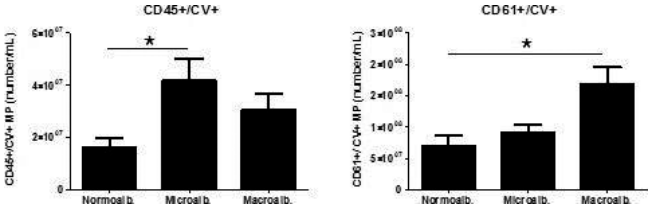

FIGURE 1 CD45+ and CD61+ mirovesicles in plasma. *p<0.05 with ANOVA

possibly reflects the pro-coagulant and pro-inflammatory state which accompanies DN. More research will be needed to further investigate the role of these MV in the progression of DN.

PB 669 | Characterization of Plasma Microvesicles in Patients with Diabetic Nephropathy

M. Uil[1], C.M. Hau[2], M. Ahdi[3], V. Gerdes[3], S. Florquin[1], R. Nieuwland[2], J.J.T.H. Roelofs[1]

[1]Academic Medical Center, University of Amsterdam, Pathology, Amsterdam, The Netherlands, [2]Academic Medical Center, Laboratory of Experimental Clinical Chemistry, Amsterdam, The Netherlands, [3]Slotervaart Hospital, Internal Medicine, Amsterdam, The Netherlands

Background: Diabetic nephropathy (DN) is a major complication of diabetes and is characterized by a hyper-coagulative and -inflammatory state. Microvesicles (MV) are small cell-derived vesicles that are secreted under physiological conditions, including inflammation and coagulation. MV numbers, size, cellular origin, composition and function can alter during disease. Evidence shows that MV can actively regulate cellular processes influencing disease progression.

Aims: To characterize plasma MV in type 2 diabetes mellitus (T2DM) patients with albuminuria (alb.).

Methods: Thirty T2DM patients were divided in three groups based on 24h urinary albumin levels; normoalb. (< 30mg/day), microalb. (30-300mg/day), and macroalb. (>300mg/day). MV from citrated plasma were stained with the live-cell labeling dye Calcein violet AM (CV), and simultaneously labelled for cell surface molecules CD14, CD235a, CD34, CD3, CD45, CD61, CD62p, CD62e, CD66b or IgG1 control antibody. The number of double positive MV were determined using flow cytometry (Apogee). This study was approved by a medical ethics committee and informed consent was obtained from all patients.

Results: The number of $CD61^+$ (platelet) MV were increased in patients with macroalb. compared with normoalb. patients (figure). Also the number of $CD45^+$ (leukocyte) MV were increased in patients with microalb. (figure), compared with normoalb. patients. In addition, both micro- and macroalb. patients showed mildly increased MV that are $CD14^+$ (monocyte) and $CD235a^+$ (erythrocyte), however, increased $CD62e^+$ (endothelium) MV were observed in microalb. patients only.

Conclusions: Our data show that MV from T2DM patients with micro- and macroalb. display different profiles of cellular origin. DN patients have increased numbers of leukocyte- and platelet derived MV, which

PB 670 | Coagulo-fibrinolytic Properties of Circulating Microparticles, and Subsequent Intravascular Coagulation, in Women with Ovarian Hyper Stimulation for *In vitro* Fertilization

S. Cointe[1,2], E. Dos Santos[3], R. Lacroix[1,2], F. Vialard[3,4], C. Judicone[2,5], P. Poncelet[5], V. Serazin[3], B. Wainer[3,6], A. Fauconnier[6,7], F. Dignat-George[2,8], F. Boitrelle[3,4], F. Sabatier[2,8], A. Torre[3,6]

[1]Aix-Marseille University, VRCM, UMR-S1076, Marseille, France, [2]APHM, CHU La Conception, Haematology and Vascular Biology Department, Marseille, France, [3]Université de Versailles Saint Quentin en Yvelines, EA7404, UFR des Sciences de la Santé Simone Veil, Saint Quentin en Yvelines, France, [4]Hôpital de Poissy, Service de Biologie de la Reproduction, Saint Germain en Laye, France, [5]BioCytex, Research and Technology Department, Marseille, France, [6]Hôpital de Poissy, Service de Gynécologie Obstétrique, Saint Germain en Laye, France, [7]Université de Versailles, EA7285, UFR des Sciences de la Santé Simone Veil, Saint Quentin en Yvelines, France, [8]Aix Marseille Université, VRCM, UMR-S1076 INSERM, Marseille, France

Background: Ovarian hyper stimulation for *in vitro* fertilization (IVF) is a risk factor for intravascular thrombosis during the first trimester of pregnancy. Several modifications of coagulation factors have been invoked to explain the procoagulant state following IVF; however, the involved mechanisms remain poorly understood. Recently, microparticles (MPs) have emerged as new cell-derived effectors with a key role in regulating haemostasis.

Aims: We aimed to determine if MP circulating subsets and activities are associated with the procoagulant state observed after ovarian hyper stimulation for IVF

Methods: Fifty one women were included in a prospective cohort study. Blood sampling was scheduled at 6 different times of the IVF cycle, including day 3 basal hormonal assessments, first day of FSH stimulation, ovarian triggering day, day 2 embryo transfer, mid-luteal phase, and pregnancy test. For each sample, MP circulating subsets, MP functional properties (Tissue Factor-Dependent Procoagulant Activity (MP-TF), Plasmin Generation Capacity (MP-PGC)), Fibrin monomer and D-dimer were measured.

Results: MP subsets showed no quantitative variation throughout IVF cycle. In contrast, MP-TF showed an early burst in activity, from 13.2 [5.9-20.3] fM to 32.5 [17.3-56.7] fM, limited to the time of embryo

transfer (p=0.01). A wave of MP-PGC subsequently occurred during the luteal phase, with maximum activity of 2.8 [1.6-4.6] mDO/min, compared to basal activity of 1.7 [1.2-2.7] mDO/min (p=0.028). This thrombolytic reaction was significantly associated with the peak of TF-MPs activity (r^2=0.63, p=0.001). Finally, a subclinical intravascular clot formation and degradation followed as showed by a significant increase in fibrin monomer (p=0.001) and D-dimer (p=0.001), at mid to late-luteal phase.

Conclusions: We highlighted for the first time a procoagulant process, occurring throughout IVF cycle, for which microparticles are mediators or early markers.

PB 671 | Immune Response Favors the Release of Leukocyte-derived Microparticles Mediating Endothelial Senescence, and Pro-coagulant and Pro-inflammatory Phenotype

A. El Habhab[1], M. Abbas[1], G. Kreutter[1], M. Kassem[1], S. Khemais[2], F. Zobairri[1], B. Yver[1], V. Schini-Kerth[2], L. Kessler[1], F. Toti[2]

[1]*University of Strasbourg/ EA7293 Vascular and Tissular Stress in Transplantation - Faculty of Pharmacy, Strasbourg, France,* [2]*University of Strasbourg/ UMR7213 CNRS - Faculty of Pharmacy, Strasbourg, France*

Background: Microparticles (MP) are surrogate markers of vascular endothelial cell injury and possible pro-inflammatory and pro-coagulant mediators in degenerative diseases with thrombotic disorders. MP expose phosphatidylserine that enhances the activity of tissue factor (TF) expressed by inflamed endothelium and activated leukocytes. Leukocyte-derived MP (LMP) are key in the coupling between thrombosis and inflammation.

Aims: To define the LMP-driven signalling pathways in endothelial cells (ECs) and to identify the LMP subsets involved in the crosstalk.

Methods: MP (1-30 nM) generated from isolated spleen rat leukocytes (LMP) by 24 h incubation with 5 mg/ml LPS or 25 ng/ml PMA + 1 μM A23187 ionophore, were applied to porcine coronary ECs. MP integration (PKH26), target cell apoptosis (a-5/IP), senescence (C12FDG SA-β-galactosidase probe), ROS formation (dihydroethidium probe) were assessed by flow cytometry, the expression of proteins by western blot.

Results: After 24h, a maximum of 82% ECs integrated $PKH26^+$-LMP. After 48 h, LMP induced a significant raise in SA-β-galactosidase activity in young ECs (18±5 *vs* 58±6 MFI) with p53, p21, p16 up-regulation, the two latter showing significant differences between LPS and PMA + A23187 stimuli. The 2-fold raise in NADPH oxidase expression and 3-fold down-expression of eNOS indicated MP-mediated oxidative stress. LMP prompted VCAM1, ICAM1, COX-2, TF, AT1, ACE up-regulation, indicating a pro-inflammatory and pro-coagulant phenotype, and a secondary generation of procoagulant ECs-derived MP. LMP induced MAPKs phosphorylation. The absent ECs apoptosis indicated a specific pro-senescent action.

Conclusions: LMP induce oxidative stress, premature senescence, pro-coagulant and pro-inflammatory responses in ECs. Because alteration of ECs function prematurely or with age could impair graft success, our data bring new information on circulating leukocyte MP as possible contributors to endothelial dysfunction in response to innate or adaptive immune system.

PB 672 | Increase in Microparticles TF/TFPI Procoagulant Ratio in Carriers of Inherited Bleeding Disorders

E. Campello, L. Spiezia, C. Radu, C. Bulato, G. Saggiorato, F. Sartorello, S. Maggiolo, P. Simioni

University of Padua Medical School Department of Medicine, Padova, Italy

Background: Although the presence of Microparticles (MPs) has been widely described in hypercoagulable states, their role in haemorrhagic disorders has been poorly evaluated.

Aims: To evaluate the presence and impact of prothrombotic MPs in congenital bleeding disorders.

Methods: Seventy-one consecutive carriers of inherited bleeding disorders [18 with haemophilia A, 3 with haemophilia B, 19 with factor (F)VII deficiency, 10 with FXII deficiency, 8 with FV deficiency, 8 with hypo/dysfibrinogenemia, and 5 with FXIII deficiency] were enrolled. Samples were performed prior to any administration of factor replacement therapy or plasma. Seventy healthy volunteers, age and gender-matched, unrelated to the cases acted as controls. MPs expressing phosphatidylserine (PS), tissue factor-bearing MPs (TF+MPs) and TF pathway inhibitor-bearing MPs (TFPI+MPs) were measured by flow-cytometry. The ratio of the TF/TFPI expression levels was calculated as the MPs procoagulant potential.

Results: Cases showed significantly higher median levels of PS-MPs (3608 [1666-5750] MPs/uL) than controls (2042 [985-3853] MPs/uL, p=0.04) The TF/TFPI MPs ratio was higher in cases (1.19 [0.9-1.4]) than in controls (0.94 [0.85-1.13], p=0.02). Compared to controls: FVII deficiency and hypo/dysfibrinogenemia showed reduced levels of TFPI+MPs (p=0.002) and an increased ratio (p=0.019); FXII deficiency showed higher levels of PS-MPs (p=0.035) and an increased ratio (p=0.015); FV deficiency (two homozygous) showed reduced MPs levels and ratio (p=0.04); FXIII deficiency carriers (one homozygous) presented higher PS-MPs (p=0.0139) levels and a reduced ratio (p=0.02); Haemophilia A and B showed significantly higher levels of PS-MPs (p=0.002) and no difference in other MPs.

Conclusions: Patients with congenital bleeding disorders had an increased TF/TFPI MPs ratio. MPs may constitute a procoagulant "rescue" mechanism that contribute to inhibit the TFPI pathway and protect carriers from bleeding diathesis.

PB 673 | Factor Xa Inhibitors Apixaban and Rivaroxaban Suppress the Release of TF-bearing Microvesicles from Cancer Cell Lines

S. Featherby[1], C. Ettelaie[1], A. Maraveyas[2]

[1]*Univeristy of Hull, School of Life Sciences, Hull, United Kingdom,* [2]*University of Hull, Hull York Medical School, Hull, United Kingdom*

Background: The release of procoagulant tumour-derived microvesicles into the bloodstream is associated with increased risk of thrombosis in cancer patients. One factor capable of promoting tissue factor (TF)-bearing microvesicle release is the activation of protease activated receptor 2 (PAR2) on the surface of cells. PAR2 is activated by factor Xa (fXa) and TF-factor VIIa (fVIIa) complex. Therefore the use of fXa inhibitors including Apixaban and Rivaroxaban may interfere with PAR2 activation and suppress the release of microvesicles.
Aims: To investigate the ability of Apixaban and Rivaroxaban to suppress the release of TF-bearing microvesicles from cancer cell lines.
Methods: MDA-MB-231 and AsPC-1 cell lines were activated with fXa (10 nM), PAR2-activating peptide (20 μM) or used without activation, in the presence and absence of therapeutic and sub-therapeutic concentrations of Apixaban (0-100 ng/ml) or Rivaroxaban (0-600 ng/ml). Microvesicles were collected from the conditioned media by ultracentrifugation and quantified. In addition, the released TF antigen, was measured by TF ELISA and microvesicle-associated TF activity was measured using a chromogenic thrombin generating assay, and by Calibrated Automated Thrombogram.
Results: Both test cells lines responded to activation by factor Xa or PAR2-AP releasing increased amounts of TF-bearing microvesicles. Pre-incubation of cells with therapeutic concentrations of either Apixaban or Rivaroxaban reduced the fXa-induced microvesicle release, and the associated TF antigen and activity, to levels comparable to those observed from non-activated cells. In contrast, PAR2-AP activation remained unaffected by DOACs. Basal release of TF-bearing microvesicles was attenuated to a lower extent.
Conclusions: Both Apixaban and Rivaroxaban can suppress the release of microvesicles from cancer cell lines following fXa activation.

PB 674 | Endothelial Nitric Oxide Synthase Gene Polymorphisms Influence on Endothelial Microparticles Levels in Renal Transplantation

S.R. Martins[1], L.S. Dusse[1], F.F. Campos[1], L.V. Alves[1], F.C.G. Evangelista[1], R.C.F. Duarte[1], A.C. Simões e Silva[2], P.N. Alpoim[1], A.P.I. Mota[1]

[1]*Federal University of Minas Gerais, Faculty of Pharmacy, Belo Horizonte, Brazil,* [2]*Federal University of Minas Gerais, Faculty of Medicine, Belo Horizonte, Brazil*

Background: Endothelial Microparticles (EMPs) are noninvasive cellular markers of endothelial function. Origin and size of MPs may predict the intensity of inflammation. Nitric oxide is an important vasodilator produced by endothelial cells. Decrease of NO levels may induce the occurrence of allograft injury in renal transplanted patients. eNOS gene polymorphisms can influence NO production and release
Aims: We investigated the relationship between eNOS gene polymorphisms and EMPs(number and size) in Renal Transplanted recipients (RTx).
Methods: Ninety-two renal transplant recipients were included. The polymorphisms in eNOS gene were determined by simple polymerase chain reaction (VNTR b/a) and polymerase chain reaction-restriction fragment-length polymorphism (G894T and T786C) analysis. EMPs were tested by flow cytometry (annexinV$^+$/CD51/61$^+$). Calibration beads were used to distribute the EMPs according to their size (≤or>0.7μm). Groups were distributed according to genotype and model allelic carriers model. Results are presented as median and interquartile range (Kruskall-Wallis followed by Dunn`s and Mann-Whitney U-test). p< 0.05 significative.

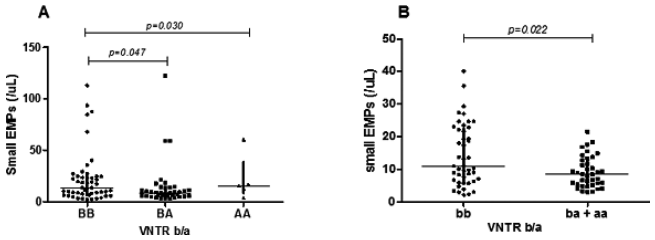

FIGURE 1 Levels of small EMPs according to polymorphisms of eNOS gene in Kidney Transplanted Recipients. (A: genotype. B: Allelic carrier model)

Results: The distribution of genotypes for the 3 polymorphisms studied showed no deviation from Hardy-Weinberg equilibrium (all P>0.05). EMPs numbers were not different according to G894T, VNTR b\a and T786C polymorphisms (p=0.749, 0.908 and 0.306). For EMPs size, we found more small EMPs (≤0.7μm) in bb (13.30;IQR=17,70) genotype (VNTR b\a) compared to ba (8.47; IQR=8.03)(Fig.1A). According to allelic carrier, presence of b (bb,13.30;IQR=17.76) showed higher number of small EMPs relation to allelic a (aa + ba, 8.96;IQR=15.6) (Fig 1B)
Conclusions: Since the genetic inheritance pattern of the eNOS polymorphisms is not known. Our data showed an association of VNTR b/a with small EMPs levels. The presence of allele b was related to higher levels of small EMPs and it reflects a pro inflammatory profile, characteristic of renal transplant patients. **Support**: Capes, CNPq, FAPEMIG

PB 675 | Effects of Chemotherapy on Extracellular Vesicles and Coagulation Activation in Colorectal Cancer Patients

L. Traby[1], H. Pur[1], M. Kollars[1], M. Kammer[2], G. Prager[3], W. Scheithauer[3], G. Kornek[3], P.A. Kyrle[1], S. Eichinger[1]

[1]*Medical University of Vienna, Department of Medicine I, Division of Hematology and Hemostasis, Vienna, Austria,* [2]*Medical University of Vienna, Center for Medical Statistics, Informatics and Intelligent Systems, Institute of Clinical Biometrics, Vienna, Austria,* [3]*Medical University of Vienna, Department of Medicine I, Division of Oncology, Vienna, Austria*

Background: Cancer patients are at risk of thrombosis and exhibit a hypercoagulable state. Extracellular vesicles (EV) which affect coagulation activation by exposing tissue factor (TF) and by providing a phospholipid rich surface are elevated in patients with colorectal cancer (CRC) (Hron, Thromb Haemost 2007).
Aims: We aimed to evaluate the long-term effect of chemotherapy (ChTx) on number and source of EV and D-Dimer as a parameter of coagulation activation.

TABLE 1 Number of extracellular vesicles (EV), levels of D-dimer and CEA in venous blood of colorectal cancer patients before and during chemotherapy

	Before 1st ChTx (baseline)	Before 2nd ChTx	p-value 1st vs 2nd	Before 3rd ChTx	p-value 1st vs 3rd
n	41	40		35	
EV (x 10^3 mL^{-1})	429 (288; 664)	376 (225; 584)	0.13	255 (181; 474)	0.007
PLT+EV (x 10^3 mL^{-1})	216 (129; 287)	171 (104;248)	0.056	119 (74; 210)	0.001
% of EV	50	45		47	
TF+EV (x 10^3 mL^{-1})	19 (10; 38)	20 (9; 32)	0.58	15 (9; 29)	0.101
% of EV	6	7		6	
D-Dimer (µg mL^{-1})	0.99 (0.48; 2.52)	0.69 (0.50; 3.06)	0.95	0.99 (0.52; 2.17)	0.95
CEA (µg L^{-1})	9.4 (1.9; 42.8)	9.7 (2.6; 70.6)	0.086	9.4 (3.0; 54.9)	0.39

Methods: Advanced CRC patients receiving 5-fluorouracil based ChTx were eligible. The number of EV was assessed by flow cytometry in fresh platelet poor plasma obtained from venous blood collected immediately before ChTx. EV were defined by size (forward scatter, < 1 µm) and annexin V binding and labeled using antibodies (anti-CD41a: platelet positive EV [PLT+EV]; anti-CD142: TF positive EV [TF+EV]). D-Dimer was assessed by ELISA. The paired *t*-test was used to compare baseline (BL) levels with levels obtained before ChTx. Data are given in absolute numbers (median [quartiles]) if not otherwise stated.
Results: 41 patients (mean age 64 years, 68% men) were included and 35 patients completed 3 cycles of ChTx. Table 1 shows the number of EV, the levels of D-dimer and CEA at BL and before 2nd and 3rd ChTx, respectively. EV significantly decreased from 429 (288; 664)x10^3 mL^{-1} at BL to 255 (181; 474)x10^3 mL^{-1} before the 3rd cycle. PLT+EV significantly decreased from 216 (129; 287)x10^3 mL^{-1} at BL to 119 (74; 210) x10^3 mL^{-1} before the 3rd cycle. The proportion of PLT+EV ranged from 45%-50% throughout ChTx. Number and proportion of TF+EV were small at all time points. D-dimer levels were 0.99 (0.48; 2.52) µg mL^{-1} at BL and did not decrease over the course of ChTx. D-dimer levels did not correlate with the number of EV.
Conclusions: In patients with advanced CRC, ChTx attenuates coagulation activation as indicated by a decline of the number of EV.

PB 676 | The Impact of the Eculizumab on the Thrombogenicity Induced by Extracellular Vesicles in Paroxysmal Nocturnal Hemoglobinuria Patients

A. Wannez[1,2], B. Devalet[2], C. Bouvy[1], B. Bihin[2], J. Douxfils[1], J.-M. Dogné[1], F. Mullier[2]

[1]*University of Namur, Pharmacy Department, Namur, Belgium,* [2]*Université Catholique de Louvain, CHU UCL Namur, Yvoir, Belgium*

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is characterized by a complement-mediated hemolysis. Complement attack induces extracellular vesicles (EV) production. These EV can be implied in thrombus formation, the leading cause of death in PNH patients. Eculizumab, an anti-C5 monoclonal antibody, decreases the thrombosis frequency in PNH.
Aims: We wanted to assess the impact of eculizumab on the EV quantification and on their procoagulant activity. The purpose is to check, if the antithrombotic activity of the eculizumab could be, in part, explained by its interaction with the EV.
Methods: We recruited 6 PNH patients. Informed consents were obtained for each patient. The study was led according to the declaration of Helsinki and approved by the local Ethic Committee. We collected platelet free plasma (PFP) for each patient before the start of eculizumab, after 4 weeks and after 11 weeks of treatment. We assessed the amount of platelets EV (flow cytometry), the procoagulant activity on PFP (Thrombin generation-TGA), provided by phospholipids (STA®-Procoag-PPL) and by isolated EV (TGA). We used mixed-effects linear regression (R 3.1.2 with nlme package) with logarithmic transformation for flow cytometry results.
Results: We compared the results obtained after 4 weeks or after 11 weeks of treatment compared to the value before the start of the treatment. The results on the patient's PFP show a decrease in the amount of platelet EV with the treatment. About the procoagulant activity of the EV, we observed a decrease in the procoagulant profile (PL and EV-induced) with the eculizumab.
Conclusions: Eculizumab can play its anti-thrombotic role by an action on the EV. With a bigger cohort, we could estimate a threshold value of the procoagulant activity induced by the EV. The purpose will be to measure the EV activity by STA®-Procoag PPL or TGA on isolated EV in order to assess the thrombotic risk of PNH patients treated with eculizumab.

PB 677 | Magnetic Capture of Extracellular Vesicles: A Quantitative Flow Cytometry Study

A. Brisson[1], R. Linares[1], Y. Boucaud[1], C. Gounou[1], S. Tan[1], L. Adumeau[2], S. Mornet[2]

[1]*University of Bordeaux, UMR-CBMN, Pessac, France,* [2]*UPR-ICMCB, CNRS, Pessac, France*

Background: Cells release small membrane vesicles, called microparticles, exosomes or extracellular vesicles (EV), which attract interest for their diverse properties and potential applications. However, EV found in body fluids are heterogeneous, and there is yet no reliable method allowing the isolation of selected EV populations.

Aims: We aim at developing a simple method of EV isolation, based on their specific capture with magnetic particles (MagP) conjugated with EV ligands. We focused first on EV exposing phosphatidylserine (PS), a major EV population in plasma[1] with procoagulant properties. EV derived from lyzed red blood cells (L-RBC) were used as a model of PS+ EV. The efficiency of EV isolation was evaluated qualitatively by electron microscopy (EM) and quantitatively by flow cytometry (FC).

Methods: Small (50 nm) MagP conjugated to annexin-5 (Anx5) were synthesized. FC and EM were performed on a Gallios (Beckman Coulter) and a CM120 (FEI), respectively.

Results: The specific binding of Anx5-MagP to L-RBC was demonstrated by EM. To quantify EV capture, we used two complementary approaches of FC, namely light-scatter triggering to detect large (~µm) EV and fluorescence triggering to detect small (~100 nm-1 µm) EV[2]. The influence of the following parameters on the efficiency of EV capture was investigated:

1) concentration of Anx5-MagP (from 10^{11} to 10^{15} MagP/L),

2) ratio between RBC and Anx5-MagP concentrations,

3) conditions of extraction.

The relationship between the amount of captured PS+ EV and the total concentration of Anx5-MagP was determined. At maximal Anx5-MagP concentration (10^{15}/L), nearly 100% PS+ EV -both large and small- were captured up to 10^5 L-RBC/µL.

The protocol of extraction optimized with L-RBC is currently applied to PS+ EV from plasma.

Conclusions: This method of isolation is simple, quantitative and of general application, opening the way toward EV omic analysis and biomarker discovery.

PB 678 | Procoagulant Extracellular Vesicles in Amniotic Fluid

J. Thaler[1], L. Hell[2], L. Wisgrill[3], C. Ay[2], A. Spittler[4], M. Schwameis[5], B. Jilma[5], P. Altevogt[6], I. Pabinger[2]

[1]Medical University of Vienna, Medicine I, Vienna, Austria, [2]Medical University of Vienna, Department of Haematology and Haemostaseology, Vienna, Austria, [3]Medical University of Vienna, Clinical Division of Neonatology, Paediatric Intensive Care & Neuropaediatrics, Vienna, Austria, [4]Medical University of Vienna, Department of Surgery, Vienna, Austria, [5]Medical University of Vienna, Department of Clinical Pharmacology, Vienna, Austria, [6]German Cancer Research Center, Heidelberg, Germany

Background: Embolization of amniotic fluid (AF) into the blood circulation leads to disseminated intravascular coagulation (DIC). Procoagulant phosphatidylserine (PS)- and tissue factor (TF) exposing extracellular vesicles (EVs) might play an important role in AF embolism induced DIC.

Aims: It was the aim of the present study to perform analyses of the procoagulant properties of AF with a panel of functional coagulation assays and flow cytometry.

Methods: We applied a prothrombinase assay (that quantifies PS exposure on EVs), an EV-associated TF activity assay, a fibrin generation assay, a thrombin generation assay, a whole blood clotting model and flow cytometry in AF and control plasma.

Results: We found that PS exposure on EVs was 21-fold increased in AF compared to plasma. Also EV-associated TF activity was highly increased in AF compared to plasma. AF derived EVs activated the blood coagulation cascade via PS and TF in the fibrin- and thrombin generation assay. In a whole blood clotting model AF derived EVs significantly shortened the clotting time from 734 ± 139 seconds in the presence- to 232 ± 139 seconds in the absence of an anti-TF antibody. The contact activation pathway via factor FXII was not affected. Applying flow cytometry, a sub-population of PS+ and TF+ EVs was identified in AF but not in control plasma.

Conclusions: We investigated the effect of AF on blood coagulation and found that PS+ and TF+ EVs determine its procoagulant potential. Taken together our data further delineate the pathomechanisms underlying AF induced coagulopathy.

PB 679 | Thrombin Generation Associated with Extracellular Vesicles is Increased Two Weeks Post-partum

C.E. Henriksson[1,2], M. Hellum[2,3], S. Sandberg[4,5], A.-H. Kristoffersen[4,5]

[1]Oslo University Hospital, Rikshospitalet, Department of Medical Biochemistry, Oslo, Norway, [2]University of Oslo, Institute of Clinical Medicine, Oslo, Norway, [3]Oslo University Hospital, Department of Medical Biochemistry, Oslo, Norway, [4]Haukeland University Hospital, Laboratory of Clinical Biochemistry, Bergen, Norway, [5]Haraldsplass Deaconess Hospital, Norwegian Quality Improvement of Laboratory Examinations (NOKLUS), Bergen, Norway

Background: In pregnancy, the incidence of venous thromboembolism (VTE) is highest 2-3 weeks post-partum. Contradictory to this, most of the procoagulant markers in plasma increase with time of pregnancy, peak right after delivery and then decrease. Extracellular vesicles (EVs) are suggested to be important contributors to thrombosis due to the presence of surface-bound tissue factor (TF) and phosphatidylserine (PS). The role of EVs in healthy pregnancy is unclear.

Aims: To measure thrombin generation (TG) associated with EVs, and in plasma, in 20 healthy pregnant women and in healthy controls.

Methods: Citrated whole blood was drawn from healthy pregnant women at 6 time-points (3 before delivery and 3 after delivery). Citrated plasma was prepared by centrifugation at 2500 g, 15 min and then frozen. TG was measured directly in thawed plasma (with PPP-reagent). Furthermore, EVs were isolated from citrated plasma by sequential centrifugation (17000 g, 30 min), added to pooled normal plasma (PNP), and EV-associated TG was measured. EV-bound PS activity was measured with the Zymuphen PS activity kit.

Results: In plasma, the TG parameters peak and ETP increased with time of pregnancy, peaked right after delivery and then decreased. On the other hand, EV-associated thrombin generation and EV-bound PS activity peaked 2 weeks after delivery.

Conclusions: In healthy pregnancy and puerperium, EV-associated TG, but not plasma-based TG, is increased two weeks post-partum, where also the incidence of VTE is the highest. Future studies will show if measurements of EV-associated thrombin generation may be useful to assess the thrombotic risk in healthy- and "at-risk" pregnancies.

PB 680 | Enumeration of Circulating Microparticles in Healthy Medical Workers Occupationally Exposed to Low Doses of Ionizing Radiation

G. Al Massarani, F. Najjar

Atomic Energy Commission of Syria, Radiation Medicine, Biomarkers Laboratory, Damascus, Syrian Arab Republic

Background: Strong evidence suggests microparticles (MP) as a biomarker of vascular injury. It may also contribute to the initiation and the development of atherosclerosis. In fact, several biological mechanisms might be responsible of atherosclerosis caused by radiation exposure even at a low dose. Therefore, the measurement of MP might be of a great potential for providing new insight into low-dose radiation cardiovascular risk.

Aims: We investigated the effect of long-term medical occupational exposure to low doses of ionizing radiation (LDIR) on MP populations levels.

Methods: The current study was conducted in accordance with the Helsinki Declaration on 38 healthy medical workers occupationally exposed to LDIR and 29 matched controls by gender, age, and smoking habits. The measured MP by flow cytometry were classified as positive or negative phosphatidylserine (PS^+ or PS^-), and phenotyped according to their cellular origin.

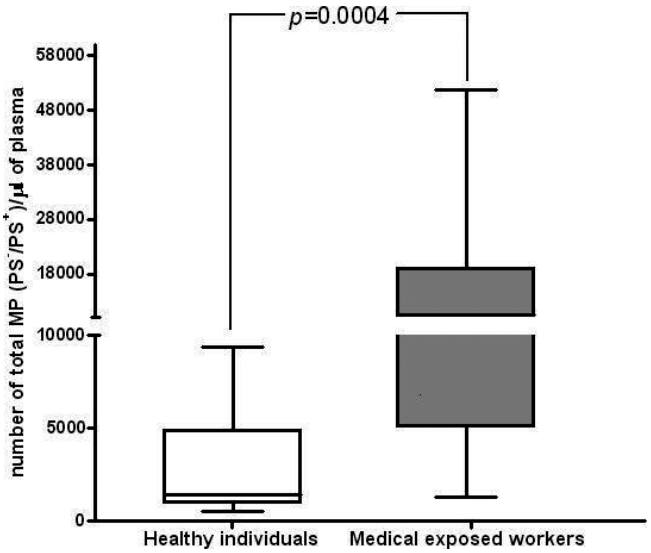

FIGURE 1 Levels of circulating total microparticles (PS−/PS+) in medical workers exposed to low doses of ionizing radiation and in healthy individuals

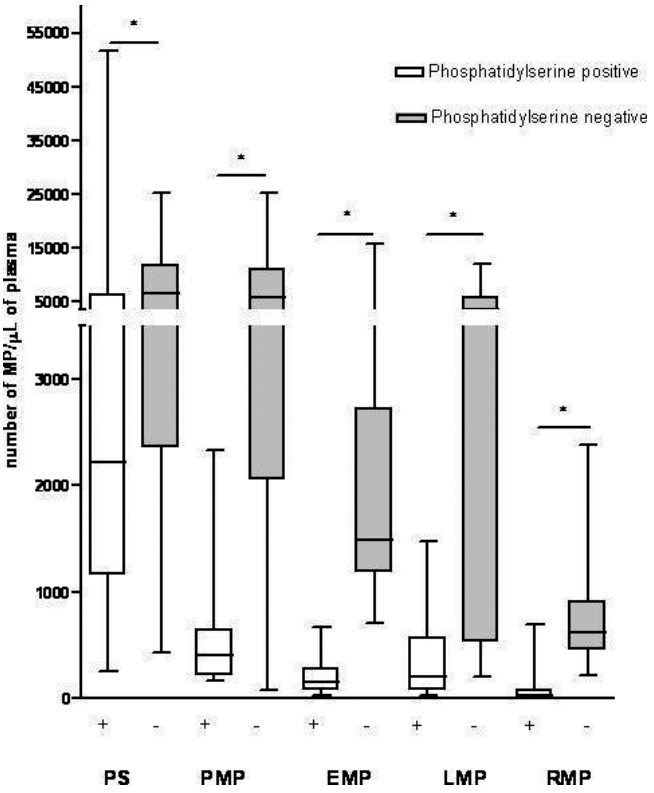

FIGURE 2 Distribution of phosphatidylserine negative and phosphatidylserine positive MP in medical workers exposed to LDIR

Results: Total MP (PS^-/PS^+), regardless of phenotype, were significantly higher in workers occupationally exposed to LDIR than controls (p=0.0004).

In medical exposed workers, PS^- MP predominated (68%) and were approximately three times more common than PS^+ MP.

Concerning the measurement of MP according to their cellular origin, we found that MP derived from platelets ($CD41a^+$ PMP), endothelial ($CD146^+$ EMP), leucocytes ($CD45^+$ LMP) and erythrocytes ($CD235a^+$ RMP) are more abundant in exposed workers than those in controls (p< 0.0001). However, no significant difference was found in the proportion of the other blood elements in the peripheral circulation between the two groups. In addition, no association was observed between MP levels and the studied confounding factors.

Conclusions: Our results suggest that elevated circulating MP populations levels represent an indicator of cellular damage caused by medical exposure to LDIR. By consequence, the quantification of MP seems to a useful biomarker for assessing the negative effects of occupational exposure to ionizing radiation.

PB 681 | A High Throughput Flow Cytometry Assay for the Detection of Platelet Microparticles

C.J. Reddel[1,2], G.J. Pennings[1,2], V.M.Y. Chen[1,3], L. Kritharides[1,4]

[1]ANZAC Research Institute, Concord, Australia, [2]University of Sydney, Camperdown, Australia, [3]Concord Repatriation General Hospital, Department of Haematology, Concord, Australia, [4]Concord Repatriation General Hospital, Department of Cardiology, Concord, Australia

Background: Platelet-derived microparticles (PMP) are crucial in disease states such as cancer, signalling through surface markers and promoting coagulation. There is a need for detection methods for PMP which are sensitive, specific and attainable by clinical and research laboratories.

Aims: To develop a high throughput and simple detection method for PMP.

Methods: A novel flow cytometry assay was adapted from previous methods (Nielsen et al., *J Extracell Vesicles*, 2014; 3, Pasalic et al., *Nanomedicine*, 2016; 12:977-86) on the BD LSRFortessa X-20 equipped with a volumetric 96-well plate sampler and 200mW 488nm laser. Platelet-free plasma (PFP, citrated blood, 2x15 min 2500g, stored -80°C) was stained with lactadherin (L)-FITC + antibodies for 20 min, diluted 1/10 in DPBS, and 15 µL sampled (0.5 µL/s). All buffers were 0.1 µm filtered. MP event collection was triggered on FITC fluorescence threshold to reduce noise. Negative control: ultracentrifuged plasma supernatant (22 min 19,610g then supernatant 47 min 158,397g). Positive control: platelet-rich plasma (PRP, citrated blood, 10 min 200g) stimulated with 20 µM ADP or 10 µM epinephrine for 2.5h at 37°C (n=4), then PFP prepared as above. Results are mean±SD, significance by paired t-test.

Results: Volumetric sampling accuracy was confirmed both by sampling a consistent volume of varying bead concentration and by sampling varying volumes of known bead counts (linear regression r^2>0.99 for each); run-to-run count beads were used per plate. Plasma PMP events were predominantly removed by prior ultracentrifugation (e.g. plasma L+/CD41+ count 1102 ± 270 before vs 104.3 ± 6 after spinning, p=0.02, n=3), indicating specific binding of fluorescent labels (Fig 1A-B). ADP or epinephrine with PRP (Fig 1C-D) increased CD41a+, CD61+, CD42b+, CD31+ and CD62P+ PMP plasma counts (e.g. ADP increased L+/CD41+ MP from 370±90 to 1012±211, p < 0.01).

Conclusions: This simple flow cytometry assay produces absolute counts of PMP in plasma, and shows sensitivity to changes in MP levels.

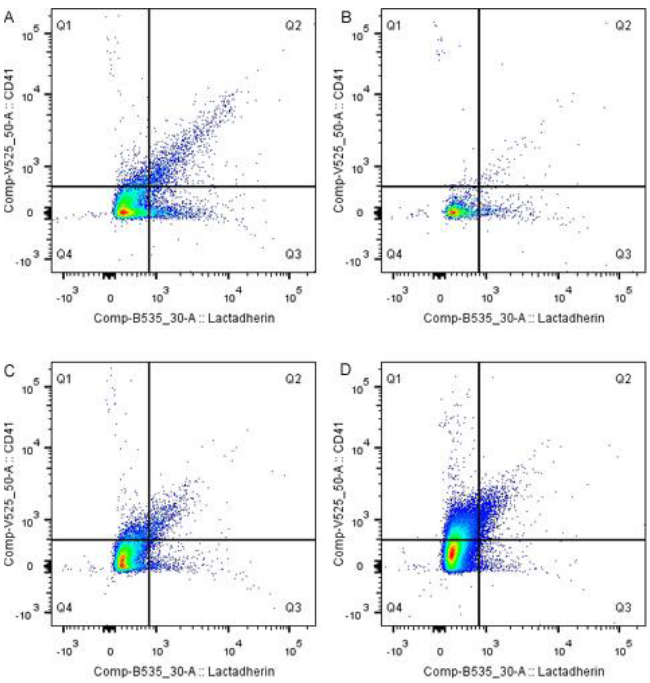

FIGURE 1 Plasma PMP events (A), showing 90% removed by prior ultracentrifugation (B). Plasma PMP from PRP (C) increased 270% by ADP stimulation (D).

PB 682 | Visualization of Tissue Factor-positive Microvesicles from Patients with Pancreatic Cancer Using Laser Scanning Confocal Microscopy

Y. Hisada[1,2], A. Auriemma[1], W. Alexander[1], C. Ay[3], N. Mackman[1,2]

[1]*University of North Carolina at Chapel Hill, Department of Medicine, Chapel Hill, United States,* [2]*University of Tromso, K.G. Jebsen Thrombosis Research and Expertise Center, Tromso, Norway,* [3]*Medical University of Vienna, Department of Medicine I, Vienna, Austria*

Background: Elevated levels of microvesicle-tissue factor (MV-TF) activity is associated with venous thrombosis in patients with pancreatic cancer (PC) patients. There were not any methods to detect antigens on MVs. In a recent study, tissue type plasminogen-positive MVs were visualized using laser scanning confocal microscopy (LSCM).

Aims: To visualize and quantitate TF-positive MVs (TF+MVs) from the culture supernatant of PC cell lines and plasma of PC patients using LSCM.

Methods: MVs were collected from the supernatant of the high and low TF-expressing human PC cell lines (BxPc-3 and Panc-1, respectively), from untreated or lipopolysaccharide (LPS) treated whole blood, and from plasma of PC patients. MV-TF activity was measured using an in-house assay. MVs were labeled with 5(6)-carboxyfluorescein diacetate N-succinimidyl ester, which is changed to the green fluorescent molecule carboxyfluorescein inside the MVs. MVs were either captured using annexin V and detected using a fluorescent-labeled anti-TF antibody, or captured using an anti-TF antibody and detected using fluorescent-labeled annexin V. Tyramide signal amplification (TSA) was used for some studies.

Results: TF+MVs were detected from BxPc-3 cells using annexin V capture, whereas TSA was required to detect TF+MVs from Panc-1 cells. Visualization of TF+MVs in plasma from LPS treated whole blood and in plasma from PC patients required either capture with annexin V and detection with a fluorescent-labeled anti-TF antibody with TSA, or capture with an anti-TF antibody and detection with a fluorescent-labeled annexin V. The coefficient of determination of fluorescent signal and concentration of EVs or fluorescent signal of TF were R^2 = 0.642 and R^2 = 0.679, respectively.

Conclusions: We successfully visualized TF+MVs from the supernatant of PC cell lines and plasma of PC patients. LSCM may be a useful tool to characterize various antigens expressing on MVs from cell lines and clinical samples.

PB 683 | New Specific and Highly Sensitive Procoagulant Test to Measure Tissue Factor Activity on Microparticles

L. Vallier[1], T. Bouriche[2], A. Bonifay[1], J. Bez[2], R. Lacroix[1,3], P. Poncelet[2], F. Dignat-george[1,3]

[1]Aix-Marseille Université, VRCM, UMR-S1076, INSERM, UFR de Pharmacie, Marseille, France, Marseille, France, [2]Research and Technology Department, BioCytex, Marseille, France, Marseille, France, [3]Department of Hematology and Vascular Biology, CHU La Conception, APHM, Marseille, France, Marseille, France

Background: Tissue factor-dependent procoagulant activity of microparticles (MP-TF) is associated with an increase risk of thrombosis in different clinical settings. However, MP-TF remains difficult to measure due to a lack sensitivity of the current functional assays.

Aims: Therefore, the aim of this work was to develop a new test to measure MP-TF dependent procoagulant activity, optimizing sensitivity while maintening a good specificity.

Methods: The assay works on total MPs washed from platelet-free plasma (PFP) samples by high-speed centrifugation. FXa is generated by incubating MPs with FVII, FX and $Ca^{2}+$. FXa is measured by monitoring the degradation of a fluorogenic substrate. TF specificity is ensured by running the same MPs pre-incubated with control IgG or a high affinity blocking anti-TF antibody (SBTF1, BioCytex).

Results: A high sensitivity (< 3 fM) was obtained by using i) FVII instead of FVIIa (+47±3% at 10nM), ii) a supra-physiological dose (760nM) of factor X, iii) high initial volume of PFP: 500 µL, iv) low plasma viscosity before centrifugation by an optimal 1:2 dilution and v) a centrifugation of 24000g, 1h. A good specificity was maintained using SBTF1 which shows a more potent inhibition than HTF1 (94±1,7% versus 70±6,2% at 2,5µg/mL). Specificity of this antibody was confirmed by the absence of activity on MPs derived from knock out-TF cell line. Taken together, these optimizations allow us to detect a measurable level of MP-TF activity in normal PFP samples (~10 fM) and a significant increase of MP-TF activity after LPS activation of whole blood samples (1.2 to 58 fold, n=27, p=0,0077). The assay shows a good linearity (r^2 = 0,99) and a repeatability at 17±11%.

Conclusions: This optimized test specifically measures MP-TF due to specific inhibition by SBTF1. The high sensitivity given by optimal conditions allow to measure TF activity in normal samples and to demonstrate increased MP-TF activity after LPS activation of whole blood samples.

PB 684 | Circulating Microparticles in Women with Polycystic Ovary Syndrome: Preliminary Results

E. Campello, R. Mioni, A. Dalla Cà, S. Maggiolo, C. Radu, C. Bulato, P. Simioni

University of Padua Medical School Department of Medicine, Padova, Italy

Background: The impact of hormonal imbalance in the production of circulating Microparticles (MPs) is still a matter of debate.

Aims: The aim of our study was to evaluate the presence and cellular origin of circulating MPs in a consecutive cohort of women with and without polycystic ovary syndrome (PCOS).

Methods: Fifteen consecutive hyperandrogenic women and 23 healthy women age and BMI-matched were enrolled. Blood samples were collected during the luteal phase both in cases and in controls. Moreover, in cases we also collected sample in the follicular phase before (T0) and 24 h after (T24) stimulation test with GnRH analogue (Triptarelin 0.1 mg s.c.). MPs expressing phosphatidylserine (AnnexinV-MP), MPs derived from endothelial cells (CD62E+), platelet (CD61+), and tissue factor-bearing MPs (TF+) were measured by flow-cytometry.

Results: Hyperandrogenic women showed significantly higher median levels of Annexin V (p 0.001), endothelial-(p< 0.001), platelet-(p< 0.001) and TF+MPs (p 0.003) than healthy controls during the luteal phase. When we considered women with hyperandrogenism, we found that median levels of Annexin V MPs and platelet-MPs significantly increased at T0 compared to T24 (p=0.014 and 0.03, respectively). Moreover, levels of Annexin V and platelet-MPs were significantly higher at T24 versus basal levels (p=0.02 for both comparisons). Finally, we did not detect any difference in women who had confirmed PCOS after stimulation test (n.8) compared to women without PCOS diagnosis (n.7). In PCOS levels of MPs did not correlate with insulin levels, but Annexin V MPs positively correlated with androgen hormone levels (testosterone and dehydroepiandrosterone).

Conclusions: Our preliminary results suggest that hormonal disorders impair MPs levels in women. Moreover, hormonal stimulation seemed to affect mainly Annexin V and platelet-MPs.

PB 685 | Plasma Platelets Microparticles Evaluation in Thrombotic Thrombocytopenic Purpura

L. Tahmasbi[1], M. Karimi[2], S. Amini Kafiabadi[1], M. Nikougoftar[1], S. Haghpanah[2]

[1]High Institute for Research and Education in Transfusion Medicine, Blood Transfusion Research Center, Tehran, Iran, Islamic Republic of, [2]Shiraz University of Medical Sciences, Hematology Research Center, Shiraz, Iran, Islamic Republic of

Background: ´Platelet microparticles (PMPs)′ have a procoagulant activity about 100-50 times more than active platelets because of high expression of negative charge phospholipids on their surfaces. PMPs assay in TTP patients could be apply as a diagnostic biomarker of patients clinical status.

Aims: This study investigate the role of microparticles in thrombotic thrombocytopenic purpura by immunophenotyping and plasma PMPs count in Iranian patients.

Methods: We had 2 study groups, 15 TTP patients and 15 healthy control group, Microparticles prepared in two step by low (2000g) and high (18000g) centrifugation and then size confirmation, was done by ´Dynamic Light Scattering (DLS)´ Zetasizer, PMPs immunophenotyping was done by FITC Anti-Human CD41a, FITC Anti-Human CD42b, FITC Anti-Human CD61, FITC Mouse Anti-Human CD31

and PE Anti-Human CD62P, with FACS Calibur flow cytometer (BD, USA) and also PMPs count was determined by PE Anti-Human CD61, and Polysciences Microbeads (1 micron in diameter) with Partec-cyflow and results analyzed by FlowJo 7.6 (Treestar, USA) and Partec FlowMax software.

Results: Our results showed that the majority of microparticles in TTP patients and normal individuals were platelet-derived microparticles (PMPs) but indicated that PMPs in TTP patients originated from activated platelets because a high percentage of them were positive for CD62p (p-selectin). While in normal healthy controls PMPs had low expression of this activity marker. PMPs plasma level results also demonstrated that plasma PMPs level in TTP patients was higher than normal control group
(P-value< 0.001).

Conclusions: Our results from the count of microparticles showed that PMP's plasma level in TTP patients was significantly higher than normal healthy individuals, also we suggest that elevated PMPs level in plasma with considering the patients history, may be related to thrombotic events in TTP patients, but for confirmation of this hypothesis requires more evaluations and investigations with the larger size of study groups.

PB 686 | Endothelial and Platelet Microparticles in Kidney Transplanted Recipients: Influence of Time Post Transplantation and Donor Type

S.R. Martins[1], P.N. Alpoim[1], F.F. Campos[1], L.V. Alves[1], F.C.G. Evangelista[1], R.C.F. Duarte[1], A.C. Simões e Silva[2], M.G. Carvalho[1], L.S. Dusse[1], A.P.L. Mota[1]

[1]*Federal University of Minas Gerais, Faculty of Pharmacy, Belo Horizonte, Brazil,* [2]*Federal University of Minas Gerais, Faculty of Medicine, Belo Horizonte, Brazil*

Background: Microparticles (MPs) are membrane fragments shed from damaged or activated cells. Origin and size of MPs may predict the intensity of inflammation and the cell type involved in several conditions. Vascular endothelial cells of renal allograft are mainly recognized by receptor's immune system after transplantation and allograft rejection is the main cause of post-transplantation complication.

Aims: To investigate whether time post transplantation and donor type may influence on number and size of Endothelial (EMPs) and Platelet (PMPs) microparticles in kidney transplanted patients (KTx).

Methods: The study was conducted in accordance with the declaration of Helsinki and local committee of ethics. EMPs and PMPs were isolated from whole blood samples of 97 KTx and analyzed by flow cytometry. Patients were distributed in groups according to time post transplant (≤ or > 60 months) and donor type (Deceased or Living). All data are presented as median and interquartile range (Mann-Whitney U-test). $p < 0.05$ was considered significant.

Results: The number of EMPs was higher in recipients with ≤ 60 months postgraft (p=0.049) and no difference was found for PMPs (p=0.109). Concerning to the type of allograft donor, patients that received kidney from deceased donor had higher number of EMPs comparing to living donor (p=0.050) and no difference was found for PMPs (p=0.170). No difference was found between groups for size of MPs. Table 1.

Conclusions: It has been admitted that the endothelial injury provided by the surgical act can contribute to allograft rejection risk. Our data corroborate with this hypothesis, since patients before 60 months post transplant showed higher number of EMPs. Our data also support that allograft derived from living donor is associated with better vascular conditions, as showed by lower number of EMPs. **Funding agency:** CAPES; CNPq; FAPEMIG.

PB 687 | The Relation between Circulating Endothelial Microparticles and Asymetric Dimethylarginine in Vitamin B12 Deficient

M.A. Dundar[1], Y. Altuner Torun[2], F. Cetin[3], S. Celik[4], C. Karakukcu[5]

[1]*Medical Health University, Department of Pediatrics, Kayseri, Turkey,* [2]*Medical Health University, Pediatric Hematology, Kayseri, Turkey,* [3]*Medical Health University, Cilinical Microbiology, Kayseri, Turkey,* [4]*Medical Health University, Kayseri, Turkey,* [5]*Medical Health University, Department of Biochemistry, Kayseri, Turkey*

Background: Hyperhomocysteinemia, increased RDW, MCV and the proliferation of smooth muscle cells induced by hypomethylation are cardiovascular disease risk factors in vitamin B12 deficienct adolescents.

Aims: The aim of our study is to investigate the levels of cIMT (carotid intima media thickness), EMP (endothelial microparticle) and ADMA (asymmetric dimethylarginine) which are indicative of susceptibility to atherosclerosis and endothelial dysfunction in adolescents with deficiency of vitamin B12.

Methods: Adolescent with age ranging between 11-17 years age eighty-eight patients detected; 50 patients of vitamine B12 deficiency (B12< 130 pg/ml) and 38 healthy controls (B12>200 pg/ml) were included in the study. In all cases number of EMPs (CD144+EMP,

TABLE 1 Time post transplantation and donor type in studied patients.

Parameters	Groups	EMPs (/μL)	P	PMPs (/μL)	P	MPs (/μL)	P
Time post-transplant (months)	T1≤60(N=41) T2>60(N=54)	36.5 (19.5) 30.4 (19.3)	0.049	158.8(124.8) 191.8(175.8)	0.109	232.6(149.8) 275.0(274.4)	0.691
Donor	Deceased(N=52) Living(N=45)	33.6 (19.7) 29.1 (12.5)	0.050	188.3(308.22) 155.8 (119.6)	0.170	270.5(302.6) 238.5(229.1)	0.638

CD146+EMP, CD105+EMP) were measured in the flow cytometry and ADMA levels were measured with High Performance Liquid Chromatography method. The cIMT and LVMİ were assessed using high-resolution echocardiography.

Results: The levels of ADMA, cIMT, CD144+EMP and CD146+EMP in vitamine B12 deficiency group were significantly higher than control group ($p < 0.05$). In patients, the vitamine B12 has negatively relationship with homocysteine, ADMA, CD144+EMP, CD146+EMP and cIMT ($p < 0.05$). Homocysteine and ADMA were identified as the parameters affecting vitamin B12 deficiency ($p < 0.001$). Also cIMT, triglycerides, HDL and CD144+/CD146+EMP are other risk factors for vitamine B12 deficiency.

Conclusions: The demonstration of increased EMP and ADMA in adolescents with vitamin B12 deficiency indicates that these markers may be used as markers for predicting atherosclerosis and endothelial dysfunction in adolescents with vitamin B12 deficiency. One of the important variable affecting atherosclerosis and endothelial dysfunction is vitamin B12, which is important to emphasize the need for close vitamin B12 control in the prevention of cardiovascular disease-related problems in adolescents with vitamin B12 deficiency.

PB 688 | Circulating Microparticles as Predictive Biomarkers for Tumor Progression in Advanced Non-small Cell Lung Cancer

F. Najjar[1], M. Alammar[2], G. Al Massarani[1]

[1]*Atomic Energy Commission of Syria, Radiation Medicine Department, Biomarkers Laboratory, Damascus, Syrian Arab Republic,* [2]*Al-Bairouni University Hospital, Thoracic Oncology, Damascus, Syrian Arab Republic*

Background: Microparticles (MPs) are proposed as useful biosensors for membrane damage in cancer patients.

Aims: We investigated the clinical significance circulating MPs for the prediction of progression disease (PD) and prognostic outcome in patients with advanced non-small cell lung cancer (NSCLC) treated with cytotoxic chemotherapy.

Methods: This study was performed according to the guidelines of Helsinki Declaration. All parents signed a written informed consent. Peripheral blood samples were obtained from 60 patients with advanced NSCLC before and after first-line platinum-based chemotherapy. Flow cytometry measurement (FCM) was used to quantify circulating MPs. Receiver operating characteristic (ROC) analysis was performed to determine the optimal cutoff values for plasma levels of MPs to discriminate between patients with clinical benefit and non-responders after treatment. The relationship between baseline MPs levels and tumor response was investigated in advanced NSCLC patients.

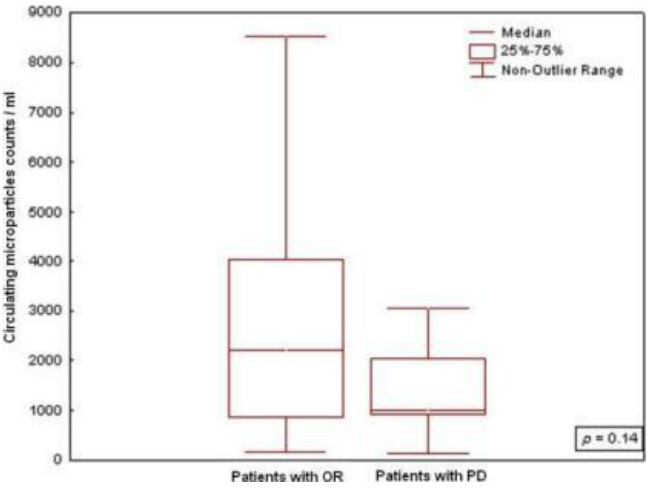

FIGURE 1 Baseline circulating MPs values in advanced NSCLC patients with OR and those with PD after chemotherapy

Results: The median pretreatment MPs number was notably higher but without significant difference in patients with objective response (OR) than that in patients with PD after chemotherapy (2983 ± 384 vs. 1839 ± 478, $p = 0.14$).

Using multivariate analysis, it was found that treatment response was independent of clinical features (age, gender, smoking status, histological sub-types, clinical stage) ($P > 0.05$)

TABLE 1 Correlation of treatment response with clinical features in advanced NSCLC patients. SCC: sqamous cell carcinoma, ADK: adenocarcinoma

Variables	OR	PD	X^2	P value
Gender (Female/Male)	40/7	10/3	0.491	0.48
Age (<60 /≥60) years	26/21	8/5	0.16	0.68
Smoking (yes/no)	43/4	10/3	2.88	0.11
Histopathology (SCC/ADK)	25/22	4/9	2.15	0.34
Staging (III/IV)	19/28	3/10	1.46	0.48

By contrast, increased levels of MPs in patients with clinical benefit during or after chemotherapy correctly predicted PD radiologically confirmed in 61% of evaluable cases. However, there was no significant difference in the median duration of time to progression (TTP) between patients with high percentage change and those with low percentage change in MPs counts after chemotherapy ($p = 0.39$).

Conclusions: The increase in MPs numbers during or after chemotherapy might be a predictive factor of PD in advanced NSCLC patients. Furthermore, baseline MPs levels could be considered for tumor response in advanced NSCLC patients.

PB 689 | Microparticles with Platelet Pro-aggregation Potential Are Present in Patients with Acute Coronary Syndrome and No Perfusion (TIMI-0)

A. de la Peña Díaz[1,2], M. Flores Garcia[2], A. Candia Ramirez[3], O. Zepeda García[4], R. Botello Maraver[5], C. García Meré[1], E.J. Guerrero Casillas[1], M.A. Peña Duque[6], M.A. Martínez Ríos[6], A.M. Mejia Dominguez[7], E. Anglés-Cano[8], Genetica Intervencionista

[1]Universidad Nacional Autonoma de Mexico, Facultad de Medicina. Departamento Farmacologia, Mexico City, Mexico, [2]Instituto Nacional de Cardiología Ignacio Chávez, Biologia Molecular, Mexico City, Mexico, [3]Universidad Nacional Autonoma de Mexico, Pharmacology, Mexico City, Mexico, [4]Universidad Autónoma Metropolitana Xochimilco, Mexico City, Mexico, [5]Instituto Politecnico Nacional, Escuela Superior de Medicina, Mexico City, Mexico, [6]Instituto Nacional de Cardiología Ignacio Chávez, Hemodinamia, Mexico City, Mexico, [7]Instituto Nacional de Cardiología Ignacio Chávez, Banco de Sangre, Mexico City, Mexico, [8]INSERM, UMR_S 1140, Paris, France

Background: Hyperactivity of platelets play an important role in acute coronary syndromes and therapy is oriented to decrease it. The presence of microparticles (MPs) signs a pro-coagulant prone condition.
Aims: To study MPs with platelet pro-aggregation potential in patients with acute coronary syndrome and flow grade TIMI-0 or TIMI-3.
Methods: Fifty six male patients were recluted at the Hemodynamic Department of Instituto Nacional de Cardiologia; only was considered patients who had a percutaneous transluminal coronary angioplasty (PTCA) at the anterior descending coronary artery. Patients were under antiplatelet (clopidogrel, aspirin) medication. Blood was obtained in sodium citrate as anticoagulant and MPs were separated by high speed centrifugation of platelet-free plasma. The amount of MPs was expressed as mg/mL of protein.
A volume of 40 uL of platelet rich plasma (PRP) obtained from blood bank healthy donors was supplemented with 30 ug/mL of MPs from each patient and incubated during 5 min at 37°C. We used a 96-wells plate, placed on a EON™ Microplate Spectrophotometer (BioTek) and absorbance at 595 nm was recorded. Platelet aggregation was induced with 10 uM ADP. Results were calculated considering the absorbance obtained with platelet poor plasma as 100% of aggregation.
Results: Table 1 shows the median value of the platelet aggregation test in TIMI 0 and TIMI 3 groups.

TABLE 1 Shows the median value of the platelet aggregation percentage in each group.

TIMI	Median	Range	p*
0	61.2	41-73	0.03
3	53.3	40-77	

Conclusions: This approach allow us to observe that TIMI 0 patients have more platelet pro-aggregation MPs as compared to patients in the TIMI 3 group.
Project supported by DGAPA UNAM IN219117

PB 1442 | Anti-β2-Glycoprotein I Antibodies Cause Lupus Anticoagulant and Activated Protein C Resistance via Coagulation Factor V

J.E. Molhoek[1], J.C.M. Meijers[2,3], S. Verhoef[1], P.G. de Groot[1], R.T. Urbanus[1]

[1]University Medical Center Utrecht, Clinical Chemistry and Haematology, Utrecht, The Netherlands, [2]Sanquin Research, Plasma Proteins, Amsterdam, The Netherlands, [3]Academic Medical Center, Experimental Vascular Medicine, Amsterdam, The Netherlands

Background: The presence of lupus anticoagulant (LA), measured as a prolonged clotting time, correlates best with thrombotic events in the antiphospholipid syndrome. The mechanism behind the paradoxical association between thrombosis and LA is not understood. It is assumed that antibodies against β2-glycoprotein I (β2GPI) prolong clotting time by competing with coagulation factors for anionic phospholipids, but this does not explain the prothrombotic phenotype in patients with LA.
Aims: To understand the mechanism behind the thrombotic tendency associated with lupus anticoagulant.
Methods: We assessed the effects of monoclonal anti-β2GPI IgG on coagulation in plasma and with purified coagulation factors.
Results: Addition of anti-β2GPI IgG to plasma caused a dose-dependent prolongation of clotting time, which was corrected in the presence of excess phospholipids, confirming LA activity of the antibodies. Experiments with factor (F)V-depleted plasma indicated that the LA effect depends on the presence of FV. Binding studies showed that β2GPI binds to both FV and FVa. Further exploration of the effects of anti-β2GPI IgG on the prothrombinase complex showed that IgG-β2GPI complexes inhibit the activation of FV by FXa in a phospholipid-dependent manner, thereby interfering with the initiation of coagulation. Thrombin generation experiments showed that anti-β2GPI IgG only prolongs the lag time, confirming these observations. In addition, the interaction between β2GPI and FV caused activated protein C (APC) resistance. Although the antibodies did not impair degradation of FVa by APC, they interfered with the cofactor role of FV in the APC-mediated degradation of FVIIIa.
Conclusions: Here, we provide an explanation for the LA paradox. The interaction between antibody-β2GPI complexes and FV causes a prolonged clotting time in sensitive assays in vitro. This interaction also results in APC resistance, a well-known risk factor for thrombosis.

PB 1443 | Plasma Clot Properties, Disease Phenotype, and Thrombotic Risk in Patients with a Lupus Anticoagulant: Results from the Vienna Lupus Anticoagulant and Thrombosis Study (LATS)

F. Posch[1], J. Gebhart[1], S. Koder[1], J. Thaler[1], L. Hell[1], L.-M. Mauracher[1], S. Hofer[1], O. Köngigsbrügge[1], P. Quehenberger[2], B. Jilma[3], C. Ay[1], I. Pabinger[1]

[1]*Medical University of Vienna, Clinical Division of Haematology & Haemostaseology, Department of Medicine I, Vienna, Austria,* [2]*Medical University of Vienna, Department of Laboratory Medicine, Vienna, Austria,* [3]*Medical University of Vienna, Section of Hematology & Immunology, Department of Clinical Pharmacology, Vienna, Austria*

Background: Patients (pts) with a lupus anticoagulant (LA) have a high risk of thrombosis. Altered properties of *ex vivo* plasma clot formation and lysis have been associated with thrombotic risk in several human studies.

Aims: To explore the relationship between plasma clot properties, LA phenotype and thrombosis in pts with a persistent LA.

Methods: In our prospective LA and thrombosis study we measured plasma clot properties using a tissue-factor-based turbidimetric assay with concurrent addition of rt-PA in 97 healthy controls and 171 pts with the LA.

Results: As compared to healthy controls, pts with the LA had significantly longer lagphases, lower clot formation rates (CFR), and longer clot lysis times (CLT, all p< 0.0001, **Table 1**). This finding was even more pronounced in LA pts with a prior history of thrombosis, and prevailed after adjusting for vitamin K antagonist (VKA) exposure. In LA pts, a prolonged lupus-sensitive aPTT (aPTT-LA) was strongly correlated with a longer lagphase (rho=0.54, p< 0.0001) and a lower CFR (rho=-0.46, p< 0.0001). 13 pts were started on VKA during follow-up, and this exposure significantly increased lagphase (mean: 20.5 vs. 14.2 minutes, p=0.02) while decreasing CFR (mean: 0.09 vs. 0.14 OD/min, p=0.01). 148 LA pts were followed-up for a median of 9.0 years, during which we observed 34 thrombotic events. In univariable time-to-thrombosis regression, a higher CFR was associated with a lower risk of thrombosis (Hazard ratio per 0.1 OD/min increase=0.55, 95%CI: 0.30-0.98, p=0.04). This association did not prevail after adjusting for the aPTT-LA and VKA.

Conclusions: The plasma clot property-assay is highly lupus-sensitive. Interestingly, *ex vivo* analysis of plasma clot formation could distinguish between healthy controls and LA pts with and without prior thrombosis and indicated an increased risk for future thrombosis. Obviously, the observed associations with higher thrombosis risk are not causal, but seem to reflect the confounding influence of a more aggressive LA phenotype.

PB 1444 | Biophysical Characterization of Clot Retraction in Platelet Rich Plasma of Patients with Primary Anti-phospholipid Syndrome
