[1]*Semmelweis University, Biophysical and Radiation Biology, Budapest, Hungary,* [2]*Semmelweis University, Department of Laboratory Medicine, Budapest, Hungary,* [3]*Semmelweis University, 1st Department of Medicine, Budapest, Hungary*

Background: Anti-phospholipid syndrome (APS) is an autoimmune process, leads to thrombotic disorders. The most significant autoantibody is the one against beta-2-glycoprotein I (β2GPI). The complex of the β2GPI and its antibody is targeted at the platelet thrombus.

Aims: Our aim is to use a nano-thrombelastographic (nTEG) method based on atomic force microscopy that gives information about the viscoelasticity and contractility of platelet rich fibrin network during clot formation and degradation in platelet rich plasma (PRP) of primary APS patients.

Methods: Patients with primary APS or VTE as controls were selected in the study. Both groups (age and therapy matched; n=60) were under vitamin K antagonists (VKA) or direct oral anticoagulants (DOAC; II- or Xa-Inhibitors) therapy. None of them had inter-current disease in the previous one year. Citrated blood was centrifuged for PRP at room temperature, 150g, 10 minutes.

An AFM cantilever was submerged in a 300µL sample and cyclically moved up and down with 1 µm amplitude and 1 µm/s speed. The sample contained PRP and Ca^{2+} 10 mM, clotting was initiated with thrombin, 1 IU/ml final activity. As the sample clotted the cantilever increasingly deflected during its vertical travel.

Results: Preliminary results of APS vs. controls are given in median. The force difference of each cycle -calculated from the maximum

TABLE 1 Selected plasma clot properties of the study population (n=268). Data represent medians [25th-75th percentile].

Variable	Healthy controls (n=97)	LA patients without prior history of thrombosis (n=57)	LA patients with prior history of thrombosis (n=114)
Baseline absorbance (OD)	0.21 [0.19-0.26]	0.22 [0.18-0.28]	0.23 [0.19-0.30]
Lagphase (minutes)	3.6 [3.0-4.1]	9.3 [6.8-15.4]	12.6 [9.3-18.6]
Maximum clot formation rate (OD/minute)	0.20 [0.18-0.25]	0.14 [0.08-0.20]	0.11 [0.06-0.16]
Peak Optical Density (OD)	0.80 [0.70-0.90]	0.74 [0.61-0.87]	0.78 [0.55-0.89]
Time to Peak Optical Density (minutes)	8.4 [7.7-9.0]	15.6 [12.1-23.7]	21.6 [15.4-29.6]
Clot lysis time (minutes)	11.1 [10.0-12.3]	12.4 [10.7-15.2]	14.9 [12.5-18.5]
Maximum clot lysis rate (OD/min)	0.05 [0.04-0.05]	0.04 [0.03-0.05]	0.04 [0.03-0.05]

deflection signal- for the APS group (n=9) was 56 vs. 221nN of the controls (n=8); delay until the first force signals was 248 vs. 140sec; slope of the force generation was 0.15 vs. 0.41nN/sec. Platelet count and fibrinogen content was equal.

Conclusions: APS clots were much later formed and less retracted than VTE clots. These data are the first to evidence the nanoscale changes in the viscoelastic properties of platelet rich clot affected by β2GPI and its antibody complex.

PB 1445 | Patient-derived Anti-β2GP1 Antibodies Recognize a Peptide Motif Pattern and Not a Specific Sequence of Residues

P. de Moerloose[1], C. Fickentscher[1], F. Boehlen[2], J.-M. Tiercy[2], E.K.O. Kruithof[1], K.J. Brandt[3]

[1]*University of Geneva, Geneva, Switzerland,* [2]*University Hospital of Geneva, Geneva, Switzerland,* [3]*University of Geneva, Division of Cardiology, Geneva, Switzerland*

Background: Antiphospholipid antibody syndrome (APS) is an autoimmune disease characterized by the presence of so-called antiphospholipid antibodies (aPLA) and clinical manifestations such as recurrent thromboembolic or pregnancy complications. Although the main antigenic determinant for aPLA has been identified as the beta-2-glycoprotein 1 (β2GP1), the precise epitope recognized by aPLA still remains largely unknown.

Aims: Characterization of the epitope of antiphospholipid antibodies

Methods: Proliferation assay was performed on APS patient-derived $CD4^+$ T cell in presence of different domains and peptides. We generated an alanine-scanning library to perform and ELISA epitope-mapping assay to identify the aPLA epitope.

Results: In the present study we identify a sequence of β2GP1 able to induce the proliferation of $CD4^+$ T cells isolated from APS patients but not from healthy donors. A comparison of this sequence with previously reported epitopes recognized by aPLA antibodies reveals the presence of a motif in β2GP1 in which the polarity but not the sequence of amino acids determines the characteristics and specificity of aPLA-interacting motifs. We further determined the sequence of polar and nonpolar residues in the main aPLA-interacting motif using point mutations. We have further demonstrated in vitro that peptides and domains of β2GP1 containing these motifs were able to interact with aPLA and to inhibit their monocyte activating activity.

Conclusions: We have characterized the main aPLA-interacting motif, which is present, at least once, in all aPLA-related receptors described so far. These data could also contribute to the future development of more sensitive and specific diagnostic tools for APS determination and potential peptide- or β2GP1 domain-based clinical therapies.

PB 1446 | Longitudinal Anti-phospholipid-Antibody Trajectories for Dynamic Thrombotic Risk Prediction in Patients with the Lupus Anticoagulant: A Joint Model

F. Posch[1], J. Gebhart[1], S. Koder[1], P. Quehenberger[2], C. Ay[1], I. Pabinger[1]

[1]*Medical University of Vienna, Clinical Division of Haematology & Haemostaseology, Department of Medicine I, Vienna, Austria,* [2]*Medical University of Vienna, Department of Laboratory Medicine, Vienna, Austria*

Background: Thrombosis is a frequent complication in patients (pts) with the antiphospholipid syndrome (APS). Longitudinal trajectories of antiphospholipid-antibodies (aPLAs) may harbor important prognostic information on this risk over time.

Aims: To define the role of repeated aPLAs measurement for dynamic thrombosis risk prediction in pts with a lupus anticoagulant (LA).

Methods: In this prospective cohort study, we measured 5 aPLAs (Lupus-sensitive aPTT (APTT-LA, Diagnostica Stago), IgM & IgG anti-Cardiolipin (aCL) and anti-β2-glycoprotein-I (aβ2-GPI)) in 165 pts with persistently positive LA at study inclusion (**Table 1**), and during 1,047 follow-up visits. The prognostic impact of the longitudinal aPLAs trajectory on thrombosis was analyzed with a so-called joint model.

Results: During a median follow-up of 9.2 years, we observed 41 thrombotic events (arterial n=20, venous n=21). The aPTT-LA (mean±SD at baseline: 95 seconds (sec) ± 34) declined by 1.1 sec/year in pts who did not develop thrombosis, and increased by 1.6 sec/year in pts who developed thrombosis (difference/year=2.6 sec, 95%CI:1.6-5.8, p=0.001, **Figure 1A**). In joint modeling, a 5 sec prolongation of the aPTT-LA over time was associated with a 9% increase in the risk of thrombosis (Hazard ratio (HR)=1.09, 95%CI:1.04-1.15, p=0.001). This association prevailed after adjusting for the time-dependent exposure to vitamin-K-antagonists (Adjusted HR=1.14, 1.03-1.14, p=0.001),

TABLE 1 Baseline characteristics of the study population (n=165)

Variable	Median [25th-75th percentile], or Absolute count (percent)
Age at entry (years)	41 [30-60]
Female Gender	136 (82%)
Prior history of thrombosis	105 (64%)
Prior history of pregnancy complications	54 (33%)
aPTT-LA (seconds)	87 [70-117]
β2GPI IgM (MPL)	5.6 [2.5-15.2]
β2GPI IgG (GPL)	9.4 [2.1-48.6]
aCL IgM (MPL)	9.1 [3.5-23.0]
aCL IgG (GPL)	18.6 [6.3-71.7]

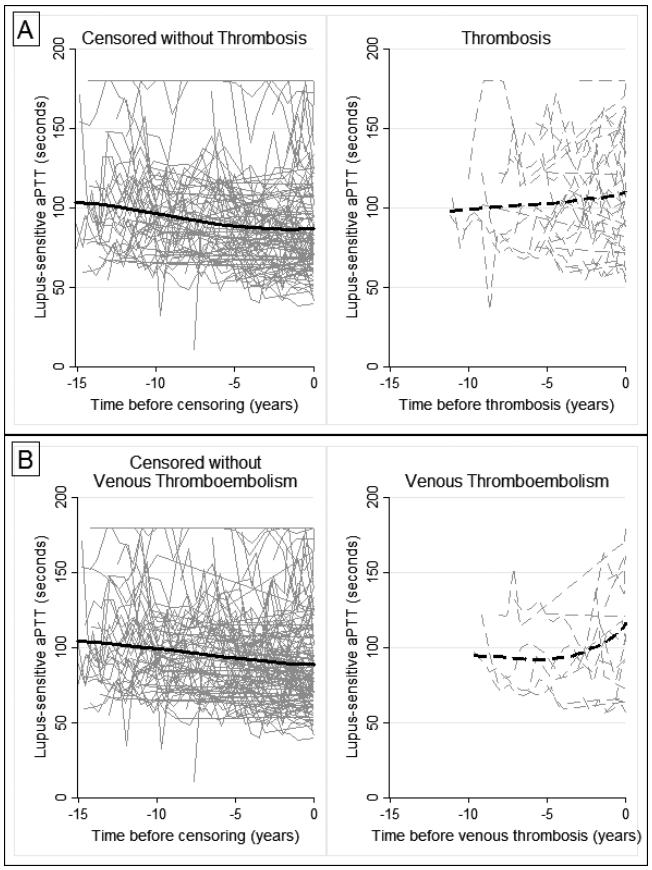

FIGURE 1 Trajectories of the aPTT-LA in LA-positive patients without and with thrombosis (Fig 1A - All events. Fig 1B - Venous Thromboembolism only)

and was even more pronounced for venous events (**Figure 1B**). No prognostic information on thrombotic risk could be extracted from the APLAs trajectory of IgM/IgG aCL or aβ2-GPI.

Conclusions: An increasing aPTT-LA over time predicts the occurrence of thrombosis in pts with the LA. This defines a critical link between a more aggressive APS phenotype *in vivo* and the most important disease-defining laboratory test, the LA. Clinically, routine monitoring of the aPTT-LA may help in dynamically stratifiying LA pts according to their thrombotic risk.

PB 1447 | Impact of Adding Antiphosphatidylserine/Prothrombin Antibodies in the Thrombotic Risk of Patients with APS Laboratory Criteria: A Prospective Study

R. Forastiero[1], M. Martinuzzo[2], A. Rossi[3], D. Puente[3], C. Colorio[3]

[1]Favaloro University, Buenos Aires, Argentina, [2]Italian Hospital, Buenos Aires, Argentina, [3]Favaloro Foundation, Buenos Aires, Argentina

Background: APS is an autoimmune disorder characterized by thrombosis/pregnancy morbidity associated with lupus anticoagulant (LA) and/or anticardiolipin (aCL) and/or anti-b2-glycoprotein I (ab2GPI) antibodies. At least two other novel antibodies seem to be important markers of the thrombotic risk in patients with aPL: antibodies against phosphatidylserine/prothrombin complex (aPS/PT) and ab2GPI directed to domain I.

Aims: There is evidence that patients having triple positivity of conventional aPL have a greater risk of thrombosis than those having two or one positive aPL tests. We assessed the contribution of aPS/PT to the thrombotic risk in a prospective study.

Methods: This cohort enrolled 180 consecutive patients (59 men, 121 women; 40 with SLE; median age 40 years) with persistent aPL. Median follow-up was 31 months (range 3-60). The APS group includes 99 patients while there were 81 aPL subjects belonging to the non-APS group. LA, IgG and IgM aCL and ab2GPI were measured following ISTH guidelines. IgG and IgM aPS/PT were evaluated using the ELISA QUANTA Lite from INOVA Diagnostics, USA (positive results >30 Units for both isotypes).

Results: 29 patients (16.1%) had at least one thrombotic episode during follow-up, 10 without previous thrombosis and 19 had recurrences of thrombosis (16 venous and 13 arterial) and the overall incidence of thrombosis was 4.7% per patient-year. First event was arterial in 5 and venous in 5 non-APS subjects. Positive aPS/PT was found in 48% of APS patients and in 12% of non-APS patients. High levels of IgG aPS/PT were predictive of thrombotic events (HR 2.6, CI95% 1.2-3.9). The highest incidence of thrombosis was found in patients with triple positivity (LA/aCL/ab2GPI) also having positive results in the aPS/PT assay (HR 2.9, CI95% 1.5-4.9) as compared with aPL patients with triple or double positivity.

Conclusions: Adding the aPS/PT assay to the panel of conventional aPL is an important tool to achieve a better stratification of patients with high risk prediction of thrombosis.

PB 1448 | Triple Positive Antiphospholipid Antibodies: Away with Titres and Ratios?

P.R.J. Ames[1], V. Marottoli[2], L. Iannaccone[2], A. Ciampa[3]

[1]Nova University Lisbon, Immune Response and Vascular Disease, Lisbon, Portugal, [2]Multimedica, Naples, Italy, [3]S Giovanni Moscati Hospital, Haemostasis Unit, Avellino, Italy

Background: Triple antiphospholipid antibody (aPL) positivity (TP) is associated with worse clinical outcomes than non TP subjects.

Aims: TP aPL positivity (TP) [lupus anticoagulant (LA) plus anticardiolipin (aCL) plus anti-beta-2-glycoprotein antibodies ($a\beta_2$GPI) of either isotype] was evaluated in persistent aPL carriers who never suffered thrombosis (NTHR), in thrombotic (THR) primary antiphospholipid syndrome (PAPS) and deceased (D) PAPS patients.

Methods: Activated partial thromboplastin time (aPTT), dilute Russell's viper venom time (DRVVT) (coagulation assays) IgM/IgG aCL and $a\beta_2$GPI (immune assays) were measured in 33 NTHR (M/F 5/26, age 48.5±15), in 64 THR APS (M/F 22/42, age 46.2±13) and 11 D PAPS (M/F 5/6, age 55.5±8) before initiating of warfarin anticoagulation.

TABLE 1 triple and non triple positive aPL in non thrombotic, thrombotic and deceased PAPS

	NTHR			THR			D		
	TP	NTP	p	TP	NTP	p	TP	NTP	p
DRVVTr $\bar{x}$±SD)	1.63±0.3	1.22±0.2	0.001	1.84±0.4	1.49±0.3	0.0006	2.47±0.8	2.40±0.6	0.8
IgGaCL($\bar{x}$±SD)	165±77	20±13	<0.0001	153±125	36±51	<0.0001	445±440	113±139	0.07
IgGaβ2GPI $\bar{x}$SD)	70±27	4±3	<0.0001	90±76	16±30	<0.0001	153±103	10±8.500000	0.006
aPTTr ($\bar{x}$±SD)	2.59±1.0	1.57±0.7	0.02	2.31±0.71	1.7±0.53	0.0005	2.31±0.49	1.93±0.32	0.2
IgGaCL ($\bar{x}$±SD)	169±83	24±27	<0.0001	162±131	45±56	<0.0001	445±440	113±139	0.07
IgGaβ2GPI ($\bar{x}$±SD)	63±23	6±9	<0.0001	86±67	22±33	<0.0001	153±103	10±8.5	0.006

Results:
The frequency of TP expressed as any LA and/or aPL increased was 25% in NTHR, 55% in THR and 100% in D PAPS (p< 0.0001); that of aPTTr with any IgG aPL was 15.6%, 45.3% and 63.5% in the same groups (p=0.003); that of DRVVTr with any IgG aPL was 22%, 53% and 63.6% in the same groups (p=0.006). The combination of either DRVVTr or aPTTr with IgM aPL was not significant.Within each group (NTHR, THR and D PAPS) mean DRVVTr, aPTTr, IgG aCL and IgG aβ_2GPI titres were always greater in TP patients than in NTP patients (Table 1). The TP tests were split according to DRVVTr and aPTTr and according to their triple positive partners, IgG aCL and IgG β_2GPI; the DRVVTr was progressively higher across the three groups (p< 0.01) compared to the aPTTr; the average IgG aβ_2GPI progressively increased across the three groups (p=0.006) regardless of its partnership with DRVVTr or aPTTr; the IgG aCL was significantly higher in the D than in other groups.
Conclusions: Although TP frequency was progressively higher across NTHR, THR and D groups, the intensity of the TP tests was much greater in the D than in other groups: the concept of TP must not part with that of intensity, as they may both retain prognostic relevance.

PB 1449 | oThe Effect of Treatment with Hydroxychloroquine on Soluble Tissue Factor Levels in Patients with Antiphospholipid Antibodies and Antiphospholipid Syndrome

K. Breen[1], K. Schreiber[1,2], K. Parmar[1], B.J. Hunt[1]

[1]Guy's and St Thomas' NHS Foundation Trust, Centre for Thrombosis and Haemostasis, London, United Kingdom, [2]Copenhagen University Hospital, Rigshospitalet, Department of Rheumatology, Copenhagen, Denmark

Background: Antiphospholipid syndrome (APS) is characterised by venous, microvascular and/or arterial and/or obstetric morbidity in patients who are persistently positive for antiphospholipid antibodies (aPL) (Miyakis 2006) . The mainstay of treatment is based on anticoagulation therapy; however, increasing interest is currently received by the antimalarial hydroxychloroquine (HCQ). The use of HCQ has been associated with a reduced risk of thrombosis but HCQ's antithrombotic mechanism of action is unclear particularly in patients with aPL and APS.

Aims: The aim of our study was to assess soluble tissue factor (TF) levels in HCQ naïve-patients with persistent aPL or APS at baseline and 12 weeks after commencing HCQ. We hypothesise that HCQ lowers levels of soluble TF.
Methods: Twenty- two individuals with APS with or without other associated autoimmune disease had blood samples taken before and 12 weeks after starting HCQ 200mg (see table 1). Plasma was stored at -80°C and thawed to measure TF using Imubind TF kit (Invitech Ltd, Cambridgeshire, UK) according to the manufacturer's instructions. A two-tailed student's paired t-test was performed and p=0.05 was

TABLE 1 Patient Characteristics

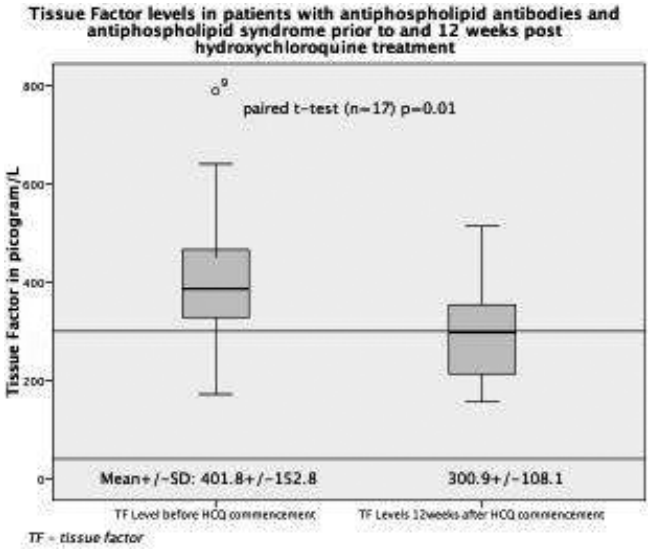

FIGURE 1 Soluble tissue factor prior to and post hydroxychloroquine commencement

considered as significant. There are no previous data in this area, and our study is therefore a pilot study.

Results: Soluble TF levels were above our normal range (40-300 pg/ml) prior to the commencement of HCQ and were significantly reduced (pre level mean (SD) 401.8 (152.8) pg/ml versus post 300.9 (108) pg/ml (p = 0.010) (see graph).

Conclusions: There was a significant reduction in soluble TF levels in this patient cohort of patients with apL and APS after commencing HCQ. Our previous work has shown that HCQ has not affected complement turnover, VEGF levels, thromboelastometry findings or CRP levels. Our findings of a reduction of soluble TF levels in aPL positive patients after the commencement of HCQ maybe a key mechanisim by which HCQ reduces thrombotic risk. Further studies of a larger patient cohort are required to confirm our observation.

PB 1450 | Increased Plasma Cell-free DNA (cfDNA) and Myeloperoxidase (MPO) and Impaired Fibrinolysis in High-risk Patients with Antiphospholipid Antibodies (aPL)

F. Semeraro[1], C.T. Ammollo[1], E. Bison[2], A. Banzato[2], V. Pengo[2], M. Colucci[1]

[1]*Aldo Moro University of Bari, Dept. Biomedical Sciences and Human Oncology, Bari, Italy,* [2]*University of Padua, Clinical Cardiology, Thrombosis Centre, Padua, Italy*

Background: NETosis and impaired fibrinolysis have been implicated in the pathogenesis of thrombosis associated with aPL.

Aims: To evaluate plasma cfDNA and MPO, and their possible influence on fibrinolytic resistance in individuals positive for aPL at different risk of thromboembolic events.

Methods: Forty-nine patients with different aPL profiles (11 single, 13 double, 25 triple positive) and 20 controls were studied. Plasma cfDNA and MPO were evaluated by fluorometric and chromogenic assays, respectively. Clot formation and clot lysis were evaluated by turbidimetric assay in tissue factor (5 pM)-activated plasma challenged with t-PA (30 ng/ml).

Results: Positive aPL individuals had higher levels of cfDNA and MPO than controls (Table 1). Clot time was longer in patients (many were on warfarin) whereas clot lysis time did not differ from controls. Upon addition of activated protein C (APC, 0.3 µg/ml), clot time prolongation (APC clot ratio) was similar in patients and controls whereas lysis time shortening (APC lysis ratio) was much weaker in aPL, indicating a resistance to the profibrinolytic activity of APC. Levels of cfDNA and MPO, and resistance to APC profibrinolytic activity were markedly higher in triple positive than single or double positive aPL (table 1). There was an inverse correlation between APC lysis ratio and either cfDNA or MPO (rho -0.38 and -0.41, respectively, p< 0.002). Moreover, ROC curve analysis (aPL only) revealed a good accuracy of MPO and resistance to APC profibrinolytic activity to identify patients with triple positivity (AUC >0.7, P≤ 0.01).

TABLE 1 Markers of NETosis and responses to APC in patients with different aPL profiles

Assay	Controls (n=20)	aPL profiles			P (aPL vs Controls)	P (Single+double vs triple)
		Single positivity (n=11)	Double positivity (n=13)	Triple positivity (n=25)		
cfDNA, ng/ml	210 (181-234)	243 (189-303)	242 (208-401)	284 (236-363)	0.002	ns
MPO, mOD	68 (38-81)	73 (46-136)	96 (55-122)	161 (74-459)	0.005	0.01
Clot time, min	3.5 (3.0-3.8)	3.5 (2.6-4.3)	3.5 (3.0-4.8)	11 (9.3-13)	0.0004	< 0.0001
APC clot ratio	1.39 (1.33-1.46)	1.38 (1.27-1.50)	1.26 (1.16-1.55)	1.33 (1.12-1.49)	ns	ns
Lysis time, min	76 (69-83)	76 (63-81)	71 (63-74)	71 (64-78)	ns	ns
APC lysis ratio	1.57 (1.47-1.88)	1.32 (1.12-1.46)	1.22 (1.09-1.32)	1.08 (1.06-1.16)	< 0.0001	0.015
Warfarin treatment, n (%)	__	0 (0)	3 (23.1)	21 (84)		< 0.0001

Conclusions: aPL positive individuals at the highest risk of thrombosis (triple positive) display markedly increased cell activation/damage and NETosis and enhanced resistance to the profibrinolytic activity of APC, despite warfarin treatment (which enhances the response to APC). These phenomena may represent new pathogenetic mechanisms leading to increased thrombotic risk in aPL positive individuals.

PB 1451 | Alteration of Beta 2 Glycoprotein I Conformation upon Domain V Disulfide Bond Reduction

I. Buchholz[1,2], P. Nestler[1,2], T. McDonnell[3], A. Radziszewska[3], A. Rahman[3], M. Delcea[1,2]

[1]*University of Greifswald, Biochemistry Institute, Greifswald, Germany,* [2]*ZIK HIKE, Greifswald, Germany,* [3]*University College London, Rayne Institute, London, United Kingdom*

Background: Antiphospholipid syndrome (APS) is an autoimmune disease characterized by the presence of anti-beta 2 glycoprotein I (anti-beta2GPI) antibodies in serum. It was previously found, that APS patients have a higher proportion of beta2GPI in oxidized state than healthy people. Beta2GPI exists in two main structural conformations: the closed (circular) form where the first domain (DI) interacts with domain V (DV), and the open (linear) form which exposes a cryptic epitope within DI. The open and potentially antigenic conformation may lead to formation of antibody-protein complexes, resulting in disease progression.

Aims: It is not known whether reduction/oxidation of beta2GPI is related to changes in its structure. In this study we investigate the influence of redox changes at a disulfide bond in DV (which is considered to be located at the DI/DV interaction surface) on the conformation of beta2GPI.

Methods: We prepared enzymatically reduced and labelled beta2GPI and compared its structure and properties to those of beta2GPI treated by pH shift to induce an open or closed conformation. Comparisons were made using tryptophan fluorescence quenching experiments, western blot and atomic force microscopy (AFM). ELISA was used to test the binding of anti-DI antibodies from APS patients to each of the beta2GPI species.

Results: For the first time, AFM confirmed the conformation of beta2GPI in open or closed state. These results were further correlated to fluorescence quenching experiments and ELISA. After reduction of the DV disulfide bond, a mixture of beta2GPI conformational populations was found. This finding is supported by western blot analyses showing multiple bands.

Conclusions: Beta2GPI conformation may be altered by reduction of the disulfide bond in DV. Therefore, oxidation of the free thiol groups in this position could trigger APS antibody binding by causing beta2GPI to adopt an open conformation. This paradigm can be further translated to proteins involved in other autoimmune diseases.

PB 1452 | High Prevalence of Activated Protein C Resistance Associated with High Avidity Anti-protein C Antibodies in Various Antiphospholipid Syndrome Clinical Phenotypes

M. Efthymiou[1], I. Mackie[1], P. Lane[1], D. Erkan[2], H. Cohen[1,3]

[1]*University College London, Haemostasis Research Unit, Department of Haematology, London, United Kingdom,* [2]*Hospital for Special Surgery, Weill Cornel Medicine, Barbara Volcker Center for Women and Rheumatic Diseases, New York, United States,* [3]*University College London Hospitals NHS Foundation Trust, Department of Haematology, London, United Kingdom*

Background: Acquired activated protein C resistance (APCr) in association with anti-protein C antibodies (anti-PC) may provide a marker for a more severe thrombotic phenotype in antiphospholipid syndrome (APS) patients with venous thromboembolism (VTE). The role of APCr and anti-PC in other APS subgroups is unknown.

Aims: To determine the prevalence of anti-PC and association with APCr in APS clinical phenotypes: VTE or arterial thrombosis (AT) ± pregnancy morbidity (PM), PM only; and asymptomatic antiphospholipid antibodies (aPL).

Methods: Patient samples were collected locally and from the international APS ACTION cohort. Anti-PC and avidity were determined by in-house ELISA. APCr was measured as % inhibition of ETP by thrombin generation (5 pM TF and 4 μM phospholipids +/- exogenous APC (rh-APC; NR 56-132%) or endogenous PC (using Protac; NR 63-141%).

Results: In this ongoing study, 380 patients have been tested (325 for anti-PC; 289 for APCr): 158 VTE, 116 AT (27 AT + VTE), 36 PM, 70 aPL. 39% (126/325) had anti-PC, with a higher prevalence in PM (53%) compared to the other groups (34-38%) (p=0.003, one way ANOVA). High avidity anti-PC were detected in 19% of 325 patients (63/126 [50%] of patients with anti-PC); these high avidity antibodies were observed in 20%, 19%, 33% and 11%, of VTE, AT, PM and aPL patients, respectively. In APCr tests, a higher proportion of patients showed resistance to activation of endogenous PC (62%) vs exogenous APC (39%; p< 0.0001). Overall, 39% of 289 patients were resistant to both, with APCr associated with high avidity anti-PC in 70% VTE, 78% AT, 92% PM and 44% aPL patients (Fisher´s exact test p < 0.0001).

Conclusions: APS (VTE, AT and PM) and aPL patients showed a high prevalence of APCr (using activation of endogenous PC or exogenous APC), and this in association with high avidity anti-PC may provide a pathogenic marker. Associations with severity and course of disease in various APS clinical phenotypes remain to be established.

PB 1453 | Clinical Impact of Triple Positivity of Antiphospholipid Antibodies in Primary Thrombotic Antiphospholipid Syndrome

S. Saraiva[1], B. Mazetto[1], F. Talge[2], I.R. Brito[1], L. Quinteiro[2], M. Colella[1], E.V. de Paula[1,2], J. Annichino Bizzacchi[1], F. Orsi[1,2]

[1]*University of Campinas-Unicamp/Hematology and Hemotherapy Center, Campinas, Brazil,* [2]*University of Campinas/Faculty of Medical Sciences, Campinas, Brazil*

Background: Lupus anticoagulant (LAC), anticardiolipin (aCL) or anti-b2-glycoprotein I (aB2GP1) are the antiphospholipid antibodies (aPL) required for the diagnosis of antiphospholipid syndrome (APS). Triple positivity (TP) for aPL is a suggested marker of disease severity. However, the clinical impact of TP in primary thrombotic APS (PAPS) is controversial and further clinical evidences are needed.

Aims: The aim of this study was to evaluate the impact of TP on the clinical presentation of PAPS, comparing TP with other aPL profiles.

Methods: Our cohort included 96 PAPS patients followed in the Hematology Center at Unicamp, Brazil.

Results: Twenty patients (21%) presented TP, 10.4% had double positivity, 49% were only LAC positive and 19.6% were aB2GP1 or aCL. Patients with double and single positivity were grouped as non-TP. The distribution of gender, age, site of the first thrombosis (arterial x venous) and incidence of thrombosis recurrence were not different between TP and non-TP groups. Clinically, the TP group presented a higher incidence of pregnancy morbidity (total=85% vs 50%, P=0.04). Compared to non-TP patients, the aCL-IgG title was higher in TP patients (50 vs. 35U, P< 0.0001), as well as the DRVVT-R for those with positive LAC (2.44 vs. 1.57, P< 0.0001). Patients with TP had higher frequency of positive ANA test (50% vs 18%, P=0.007), and lower complement C3 levels (median=1.04 vs. 1.29, P=0.001) when compared with non-TP. The levels of C4 were similar between the groups (median= 0.23 vs. 0.24, P=0.21). In multivariate analysis, positive ANA and C3 levels were independently associated with TP, odds ratio of 4.7 (95%CI=1.2-18.9) and 0.15 (95%CI= 0.0-0.63, P=0.02).

Conclusions: In conclusion, in thrombotic PAPS the clinical presentation in TP was similar to non-TP. However, we observed that the presence of TP in patients with PAPS was associated with a more complex immune profile. That may suggest the need for specialized follow-up, attending to the development of systemic autoimmune manifestations.

TABLE 1 Demographic and clinical features of thrombotic PAPS according to the antibody profile

	Triple positive n= 20	Non-triple positive n= 76	P
GENDER F/M	15/ 5	49/27	0.43
AGE AT DIAGNOSIS, years	28.9 (24-33.2)	32.7 (22.2-47.5)	0.29
PERIOD OF TIME SINCE DIAGNOSIS in years	8.0 (3.5-13.0)	5.2 (2.2-9.4)	0.29

PB 1454 | β2GpI Binds to Fibrinogen and Alters Fibrin Generation and Degradation

L. Acquasaliente[1], D. Peterle[1], G. Pontarollo[1], R. De Crisofaro[2], V. Pengo[3], N. Pozzi[4], V. De Filippis[1]

[1]*University of Padua, Department of Pharmaceutical and Pharmacological Sciences, Padua, Italy,* [2]*Catholic University, Institute of Internal Medicine, Hemostasis Research Center, Rome, Italy,* [3]*University of Padua, Department of Cardiac, Thoracic and Vascular Sciences, Padua, Italy,* [4]*Saint Louis University, Doisy Research Centre, Saint Louis, United States*

Background: β-2Glycoprotein I (β2GpI) is an abundant plasma protein identified as the major autoantigen in the antiphospholipid syndrome (APS), an autoimmune disease characterized by venous and arterial thrombosis. Nonetheless, the physiological functions of this protein are still unclear. We have recently discovered that β2GpI binds to thrombin (αT) with high affinity (K_d = 60 nM), while altering fibrin generation and inhibiting platelet aggregation [Pozzi et al., 2013; Acquasaliente et al., 2016]. Although it seems clear that β2GpI alters the αT-fibrinogen axis by interacting with the protease, no information is available for the possible binding of β2GpI to fibrinogen.

Aims: Probe the interaction of β2GpI to fibrinogen and investigate the effect of β2GpI binding on fibrin generation by αT and its degradation by the fibrinolytic system.

Methods: Binding measurement were performed by fluorescence, Surface Plasmon Resonance (SPR) and Dynamic Light Scattering (DLS). Fibrin generation and degradation was monitored by turbidimetry in the presence of αT alone or with tissue-plasminogen activator (TPA) and plasminogen. Fibrin structure was studied by DLS and scanning electron microscopy (SEM).

Results: Fluorescence and SPR data concurrently indicate that β2GpI binds to fibrinogen with high affinity, with K_d values of 48±4 nM or 179±20 nM. Turbidimetric, DLS and SEM analyses indicate that β2GpI induces the formation of thinner and shorter fibrin fibers from fibrinogen and αT. Intriguingly, when fibrin clot formation was carried out also in the presence of TPA and plasminogen, β2GpI strongly accelerated fibrinolysis.

Conclusions: β2GpI has strong affinity for fibrinogen and it is likely that at physiological concentrations of the two proteins (4 and 7 μM) it circulates in the bloodstream bound to fibrinogen, altering the structure of the ensuing fibrin clot and its degradation by the fibrinolytic system. These results are consistent with the prothrombotic effect of anti-β2GpI autoantibodies found in APS patients.

PB 1455 | Circulating Microparticles in Pregnant Patients with Primary Antiphospholipid Antibody Syndrome: An Explorative Study

E. Campello, C. Radu, M. Tonello, C. Bulato, A. Kuzenko, E. Mattia, L. Spiezia, A. Ruffatti, P. Simioni

University of Padua Medical School Department of Medicine, Padova, Italy

Background: Identifying biomarkers associated with a high risk of maternal/fetal complications in patients with antiphospholipid antibody (aPL) syndrome (APS) can help to better define clinical management.

Aims: Our aim was to evaluate the presence, cellular origin and trend during pregnancy of circulating microparticles (MPs) in a consecutive cohort of APS women.

Methods: Eleven pregnant women affected by primary APS and 15 healthy women age and BMI-matched were enrolled and blood samples were longitudinally collected at three time points (I, II and III trimester). MPs expressing phosphatidylserine (AnnexinV-MP), MPs derived from endothelial (CD62E+), platelet (CD61+), trophoblast (CD105+) and tissue factor-bearing MPs (TF+) were measured by flow-cytometry.

Results: APS pregnant patients showed increased levels of endothelium, platelet, TF+ and trophoblast-MPs during pregnancy compared to healthy pregnant controls

. High risk APS patients (triple aPL positivity and a history of vascular thrombosis and/or severe pregnancy complications) showed significantly higher levels of Annexin V-MPs ($p < 0.001$), platelet-derived ($p < 0.001$) and trophoblast-derived MPs ($p < 0.0001$) compared to healthy controls in all trimesters probably due to a global activation of coagulation (platelets and TF-driven) as well as a damage to the trophoblast. Low risk APS patients (only history of pregnancy morbidity or vascular thrombosis) showed significantly higher trophoblast-derived MP levels in II ($p=0.018$) and III trimesters ($p < 0.01$) confirming the pathological effect of aPL on the trophoblast. The ratios of trophoblast and platelet-derived MPs were significantly higher in high versus low risk APS patients since the I trimester ($p=0.02$).

Fig. 1 Circulating MPs levels in the study population. Data are expressed as median levels of MPs. p are calculated between APS and healthy pregnant women * <0.05; ** < 0.01; *** < 0.001. Trim: trimester; APS: antiphospholipid antibody syndrome

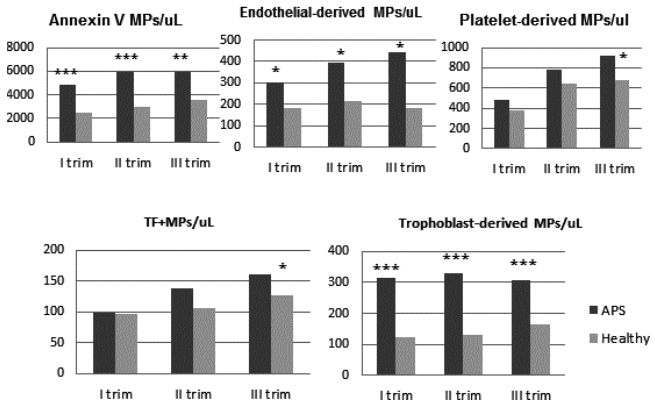

FIGURE 1 Circulating MPs levels in the study population.

Conclusions: This explorative study showed high levels of MPs in pregnant women with primary APS. Platelet and trophoblast-derived MPs detected in the I trimester might constitute a novel laboratory marker to assess the risk for pregnancy complications.

PB 1456 | Outcomes of Anticoagulant Therapy in Patients with Antiphospholipid Syndrome Managed in an Anticoagulation Clinic

A. Mavri[1], M. Stalc[2]

[1]*University Medical Centre, Department of Vascular Diseases, Ljubljana, Slovenia,*
[2]*University Medical Centre, Department for Nuclear Medicine, Ljubljana, Slovenia*

Background: Prolonged oral anticoagulation with vitamin K antagonists (VKA) is the treatment of choice for secondary prevention of thrombosis in patients with antiphospholipid syndrome (APS). However, data on long-term safety and efficacy of anticoagulant therapy in APS patients is scarce.

Aims: To analyse the risks and benefits of extended oral anticoagulation in patients with thrombotic APS.

Methods: Anticoagulant treatment was assessed in 237 consecutive patients with definite APS (revised Sapporo criteria) and previous thrombosis treated in our anticoagulation clinic from 2000 to 2017. Bleeding events (major and minor) and recurrent thrombotic events were identified by reviewing the data from the anticoagulant therapy management computer program Trombo.

Results: The clinical profile of our cohort is summarized in table 1. 230 (97%) of patients were treated with VKA (77% with a target international normalized ratio (INR) of 2.0-3.0 and 23% with a target INR of 2.5-3.5). The time in therapeutic range was 60 ± 18%. Only four patients were treated with low molecular weight heparin and three with rivaroxaban. During a total follow-up of 1564 patient-years the rate of minor bleeding was 19.6 cases per 100 patient-years and the rate of major bleeding was 1.2 cases per 100 patient-years. None of the bleeding episodes were fatal. The rate of thrombotic recurrence was 1.8 cases per 100 patient-years. Two patients died of thrombosis. Details on major bleeding and thrombotic complications are given in table 2.

TABLE 1 Clinical features of patients (VT - vein thrombosis, PE - pulmonary embolism, TIA - transient ischaemic attack, TE - thromboembolism).

Age (mean ± S.D.) (years)	**47 ± 16**
Sex (female) N (%)	128 (54)
Type of APS (primary/secondary) N (%)	212/25 (78/22)
Types of thrombotic events N Arterial system (Stroke/ TIA/Peripheral TE) Venous system (VT/PE/both) Arterial and venous thrombosis Microthrombosis	 62 (47/4/11) 148 (77/28/43) 2 25
Additional risk factors for thrombosis N (%)	53 (22)

TABLE 2 Major bleeding and thrombotic complications

Event	Site/Type of event	N
Bleeding	Central nervous system	2
	Gastrointestinal tract	3
	Locomotor system	6
	Parenchymal organs	4
	Gynaecological tract	3
Thrombosis	Venous thromboembolism	18
	Stroke	10

Conclusions: In patients with APS the extended anticoagulant therapy with VKA is safe and efficient in a dedicated anticoagulation clinic setting. In this high-risk group of patients the rate of adverse events of anticoagulant therapy is comparable to general VKA-treated population.

PB 1457 | Elevated Oxidized Low Density Lipoprotein Levels in Antiphospholipid Syndrome is Related to the Autoantibodies against High Density Lipoprotein and its Associated Proteins

K. Oku[1], J. Batuca[2], O. Amengual[1], N. Ohnishi[1], Y. Ogata[1], K. Ohmura[1], Y. Fujieda[1], M. Kato[1], T. Bohgaki[1], S. Yasuda[1], D. Alves[2,3], T. Atsumi[1]

[1]Hokkaido University Graduate School of Medicine, Department of Rheumatology, Endocrinology and Nephrology, Sapporo, Japan, [2]CEDOC/NOVA Medical School, Lisbon, Portugal, [3]Fernando Fonseca Hospital, Systemic Autoimmune Diseases Unit, Amadora, Portugal

Background: In antiphospholipid syndrome(APS), oxidized low-density lipoprotein (oxLDL), a key molecule in atherogenesis, serves as the source of anionic particles that bind to beta2glycoprotein I and reinforces procoagulant activity or concomitant atherosclerosis. High density lipoprotein (HDL) is the major molecule that not only blocks function of oxLDL but helps prevent its production with the assistance of HDL-associated proteins such as paraoxonase type 1 (PON-1) and apolipoprotein A-1 (ApoA-1). In systemic lupus erythematosus (SLE), autoantibodies against HDL are prevalent.

Aims: To clarify the contributions of autoantibodies against HDL or its associated proteins on oxLDL production in APS.

Methods: Total of consecutive patients with primary APS (PAPS) (n=26), SLE (n= 48: SLE with APS 24) and non-lupus connective tissue diseases (others)(n=19) who visited Hokkaido University Hospital during 2009 and 2012 were comprised. ELISA were performed to detect aHDL, aApo-A1,aPON-1 and oxLDL levels.

Results: Serum levels of oxLDL were significantly elevated in PAPS (PAPS vs. SLE without APS vs. SLE with APS vs. others: 3.27+/-6.89 vs. 1.06+/- 2.32 vs. 2.51 +/- 4.12 vs. 0.8 +/- 3.72 mg/ml, p< 0.05). Titers of aHDL were similar among patient groups, while titers of aApo-A1 and aPON-1 were significantly elevated in PAPS. Multiple autoantibodies positivity were highly observed in PAPS(17/26) and SLE with APS(20/24) while low in others (SLE without APS 10/24, control 8/19). None of the autoantibodies independently correlated with the serum level of ox-LDL, however, patients with multiple antibodies showed higher titers of serum oxLDL(multi-positive vs less than one antibody positive: 2.54 +/-1.82 vs. 1.87+/- 2.21 p< 0.0001). None of the aPL or aPL scores correlated with serum oxLDL levels.

Conclusions: Elevated oxLDL in APS may be one of the causal mechanisms of the disease and might be consequence of the impairment of the antioxidant function of HDL induced by the presence of antibodies against HDL and its associated proteins.

PB 1458 | Platelet Activation by Antiphospholipid Antibodies through the IgG Receptor FcγRIIa: Possible Role in Thrombosis Associated with Antiphospholipid Syndrome?

E. Coll[1], M. Brodie[1], L. Robles-Carrillo[1], E. Lindhoff-Last[2], J.L. Francis[1], A. Amirkhosravi[1]

[1]Florida Hospital, Center for Thrombosis Research, Winterpark, United States, [2]Cardiology Angiology Center Bethanien, Coagulation Research Center, Frankfurt, Germany

Background: Antiphospholipid antibodies (aPLAbs) targeting beta-2 glycoprotein I (B2GPI) are of primary importance in thrombosis associated with antiphospholipid syndrome (APS). The predominance of the IgG isotype in APS is conspicuously linked with increased risk of thrombosis, raising the question whether the platelet IgG receptor, FcγRIIa, may play a role in thrombosis caused by aPLAbs, as is the case in heparin-induced thrombocytopenia in which heparin Abs directly activate platelets through FcγRIIa. We have previously shown that:

(1) goat anti-human B2GPI-Abs ± human B2GPI strongly activate human platelets in vitro, and that this activity is abolished by the anti-FcγRIIa antibody IV.3;

(2) anti-B2GPI immune complexes are thrombotic in mice transgenic for human FcγRIIa but not in wild type mice.

Aims: We sought to investigate if IgG from patients with aPLAbs can activate platelets in a manner dependent on FcγRIIa.

Methods: IgG was purified from plasma of 46 patients with aPLAbs and/or lupus anticoagulant. The capacity of the IgG to activate platelets (±B2GPI) was evaluated by serotonin release assay (SRA) and washed platelet aggregation (WPA). With WPA, platelets ± IV.3 were either: (a) primed with ADP followed by IgG introduction or (b) incubated with IgG (30 min) followed by introduction of low thrombin concentrations.

Results: With or without B2GPI, IgG from 10 of 46 (22%) patients caused platelet dense granule release. In all cases this was abolished by IV.3, indicating the dependence of FcγRIIa. Aggregation of ADP-primed platelets was observed with 1 of 2 of the above 10 IgGs. Preincubation of platelets with aPL IgG from 2 patients, sensitized platelets to aggregate in response to otherwise

subaggregetory thrombin stimuli. This effect was also abolished by IV.3.

Conclusions: These findings suggest that aPLAbs from patients can directly activate and/or sensitize platelets in a FcγRIIa-dependent manner. This mechanism may contribute to thrombosis in patients with aPLAbs.

PB 1459 | Prognostic Impact of Antiphospholipid Antibodies on the Clinical Course of Primary Immune Thrombocytopenia or Autoimmune Hemolytic Anemia

A.C. Ladeira Cruz[1], M. Pereira Colella[2], G. Yamaguti Hayakawa[2], E.V. de Paula[2,3], J. Annichino-Bizzacchi[2,3], F. Andrade Orsi[2,4]

[1]School of Medical Sciences of the University of Campinas, Campinas, Brazil, [2]Hematology and Hemotherapy Center of Campinas, University of Campinas, Campinas, Brazil, [3]School of Medical Sciences of the University of Campinas, Department of Clinical Medicine, Campinas, Brazil, [4]School of Medical Sciences of the University of Campinas, Department of Clinical Pathology, Campinas, Brazil

Background: It is controversial if antiphospholipid (aPL)-related primary immune thrombocytopenic purpura (ITP) or autoimmune hemolytic anemia (AHA) should be defined as antiphospholipid syndrome (APS).

Aims: To evaluate if aPLs influence the clinical course of primary ITP or AHA.

Methods: This is a prospective cohort study, participants had newly diagnosed primary ITP or AHA, they were enrolled between January 2013 and January 2016 and followed up until December 2016. Lupus anticoagulant (LAC), IgG/IgM anticardiolipin and anti-beta2-glycoprotein1 (aB2GP-1) assays were performed at diagnosis. The primary endpoint was the response to first-line treatment and the secondary endpoints were multiple treatment lines, splenectomy, thrombosis and bleeding events.

Results: Eighty-four patients (72 ITP, 11 AHA, 1 Evans syndrome) were included and followed for 17 months (3.5 - 38 months). Twenty-two patients (26.2%) were positive for aPL (10 LAC, 7aB2GP-1 and 5 double-positive). aPL-positive patients were predominantly female (77.3% vs. 53.2%,P=0.04) and 90.9% met the criteria for initial treatment (versus 85.5% of aPL-negative patients, P=0.5). The response to first line-treatment was similar between groups (75% in aPL-positive vs. 70.5% in aPL-negative;P=0.5). Cox regression analysis revealed that aPL positivity was not a risk factor for first-line treatment failure (HR= 1.38 95%CI=0.69-2.75, P=0.3), multiple treatment lines (HR= 1.30 95%CI=0.66-2.59, P=0.4) and splenectomy (HR=0.88 95%CI=0.26-3.08, P=0.8). Four patients had thrombosis and aPL positivity was not a risk factor for thrombosis (HR=0.65 95%CI=0.09-4.69, P=0.6). The risk for bleeding events was also similar between positive and negative aPL patients (HR=1.55 95%CI=0.82-2.93, P=0.2).

TABLE 1 Demographic and clinical features of the cohort patients

	aPL positive n=22	aPL negative n=62	P value
ITP	18 (81,8%)	54 (87,1%)	
AHA	4 (18,2%)	7 (11,3%)	
Follow-up duration in months, media (IQ)	22.3 (15.2-31.5)	16.2 (8.5-25.2)	0.76
Male:Female	1:1.14	1:3.4	0.04
Age in years media (IQ)	33.9 (21.6-58.1)	39.5 (28.4 - 61.4)	0.20
P value was calculated using Fisher test for categorical data and Mann Whitney test for continuous data			

TABLE 2 Patients clinical course

	aPL positive n=22	aPL negative n=62	P
Patients requiring treatment, number (%)	20 (90.9%)	53 (85.5%)	0.72
First-line therapy wt corticosteroids	72.7%	77.4%	0.9
Patients with sustained remission after first-line therapy, number (%)	15 (75%)	32 (71%)	0.2
Patients requiring two or more treatment lines, number (%)	13 (59%)	27 (44%)	0.31
Splenectomy, number (%)	5 (22.7%)	7 (11.3%)	0.28
Anual incidence of thrombosis during the follow-up	4.5%	2.1%	0.28
Anual incidence of bleeding events during the follow-up	31.8%	40.8%	0.84
P values were calculated using Fisher test for categorical data and Mann Whitney test for continuous data			

Conclusions: The results demonstrated that aPLs do not influence the clinical course of primary ITP or AHA. The study suggests that aPL-positive ITP or AHA are not distinct entities, not supporting the inclusion of these aPL-related manifestations as clinical criteria for APS diagnosis.

PB 1460 | Identifying "Second Hit" Risk Factors Associated with Thrombosis and Pregnancy Morbidity in aPLs Positive Patients

Y. Zuo, J. Fan, R. Sarode, D. Karp, Y.-M. Shen

University of Texas Southwestern Medical Center, Dallas, United States

Background: The evaluation of thrombotic and pregnancy risks associated with antiphospholipid antibodies (aPL) in individual patients without APS clinical manifestation is challenging.

Aims: To identify potential predictors of thrombosis and pregnancy morbidities among aPL positive patients.

Methods: This study included 112 consecutive persistent aPL positive patients who attended clinic at University of Texas Southwestern Medical Center. All patients had persistent positive moderate to high titer aPL. The aPL profiles were assessed with commercial assay. Hypertension (HTN) was classified based on 8th Joint National Committee guidelines. Hyperlipidemia (HLD) was defined as fasting total cholesterol >200 mg/dl. When assessing risk factors associated with pregnancy morbidities, only reproductive age (age< 45) female controls were used. Pearson Chi-squared analysis and multivariable logistic regression were used to evaluate correlation between different risk factors and clinical manifestations.

Results: Of the 112 aPL positive patients, 69 (61.6%) patients had criteria APS clinical manifestations and 43 patients did not. Among APS patients, 57 (82.6%) patients had primary APS. When comparing APS patients to asymptomatic aPL positive patients, HTN (OR=5.357, 95%CI 1.343 - 19.06, P=0.0116) was significantly associated with arterial thrombosis (Fig 1) and the presence of lupus anticoagulant (OR=3.075, 95%CI 1.289- 7.346, P=0.0114) was significantly associated with venous thrombosis (Fig 2). Age, HLD, smoking, raynaud, livedoid reticularis, presence of IgA aPL or triple positive aPL did not demonstrate significant correlation with either arterial or venous thrombosis. None of the analyzed clinical characteristics or aPL profiles showed significant correlation with obstetric manifestations.

Conclusions: HTN is a potential predictor of arterial thrombosis and the presence of LA is a potential predictor of venous thrombosis in aPL positive patients.

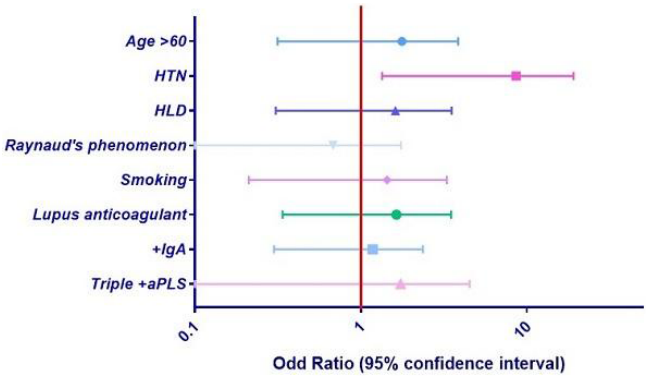

FIGURE 1 Arterial thrombosis risk factors

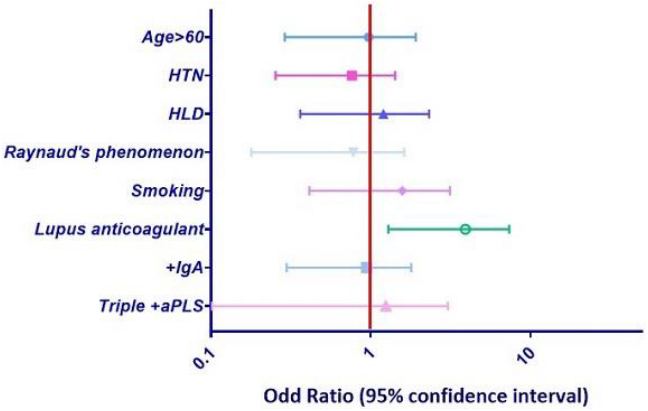

FIGURE 2 Venous thrombosis risk factors

PB 1462 | Are Antiβ2-glycoprotein I IgG Domain I a Useful Tool to Predict Thrombosis?

A. Marco[1], A. Palazon-Bru[2], P. Marco[1]

[1]General University Hospital, Haematology Service, Alicante, Spain, [2]Miguel Hernandez University, Clinical Medicine Department, Alicante, Spain

Background: Antiphospholipid syndrome (APS) is a high-risk acquired thrombophilia characterized by thrombosis and the presence of antiphopholipid antibodies (APL). Thrombotic risk assessment is still a challenge and, for this purpose, the sensitivity and specificity of some antibodies have been tested (lupus anticoagulant (LAC), anticardiolipin and anti ß2-glycoprotein I (Aß2GPI)). Aß2GPI are an independent risk factor for thrombosis in APS. Recently, Aß2GPI binding a limited epitope of domain I (Gly40-Arg43) have been particularly associated with thrombosis.

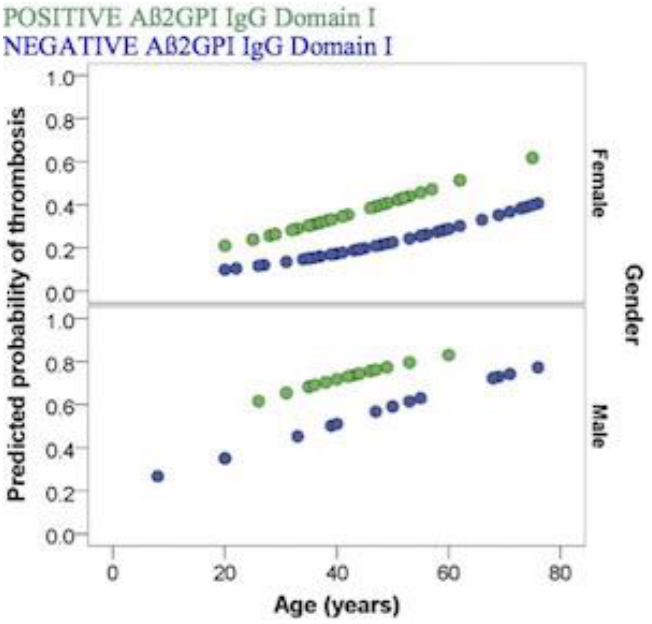

FIGURE 1 Aß2GPI IgG Domain I and probability of thrombosis in LAC negative patients

Aims: The aims of this study was to evaluate the clinical association of Aß2GPI-domain I and thrombosis in Aß2GPI IgG positive patients.

Methods: We have performed a cross-sectional observational study including 114 Aß2GPI IgG positive patients (44 thrombotic APS). We have studied LAC and the APL recommended in the Sydney criteria as well. All APL including Aß2GPI-domain I IgG have been performed by chemoluminiscent immunoassay and LAC has been confirmed by dilute Russell viper venom time coagulation test. We have also considered the variables age and gender. The statistical analysis (logistic regression- multivariate analysis) was carried out using the IBM SPSS ($p< 0.05$).

Results: In thrombotic APS, 68% of patients were LAC and Aß2GPI IgG positive, not showing Aß2GPI IgG Domain I a statistical association (p:0.09). In contrast, 32% were LAC negative and Aß2GPI IgG positive. In this cohort, we have observed a statistical association between Aß2GPI IgG Domain I and thrombosis (p: 0.042), with an odds ratio of 2.429 (1.311-5.733), enhanced by age and male gender (see figure 1).

Conclusions: According to our results, older patients and male gender with Aß2GPI IgG Domain I positivity but LAC negativity have a high risk of developing thrombosis.

PB 1463 | Oral Anticoagulation Cost in Primary Antiphospholipid Syndrome: Comparison between Warfarin and Hypothetical Rivaroxaban

A. Ciampa[1], S. Vivolo[1], C. Salapete[1], P. Ames[2]

[1]San Giuseppe Moscati Hospital, Avellino, Italy, [2]Nova University Lisbon, Immune Disorders and Vascular Diseases, Lisbon, Portugal

Background: The novel direct oral anticoagulants are challenging warfarin in several clinical settings including antiphospholipid syndrome with the incentive of lower cost than warfarin.

Aims: To perform a cost comparison of one year of oral anticoagulation management with warfarin versus hypothetical rivaroxaban in twenty patients whose average international normalised ratio (INR) time in therapeutic range was 69±11%.

Methods: For twenty consecutive patients with thrombotic primary APS attending a dedicated anticoagulant clinic we assessed average individual weekly dose of warfarin, average INR, average time in therapeutic range, average yearly attendance to calculate the average yearly cost of warfarin management and compared with hypothetical daily fixed dose rivaroxaban at 20 mgs. The averages of individual patients were summed and divided by 20 to gain a total avarage. Paired T-test was used for cost comparison

Results: Each attendance costs the Italian Health Service 17.85 euros that includes clinic attendance, venepuncture and INR cost; the average patient attendance was 18.3 times a year and average yearly warfarin consumption was 10 boxes (300 tablets of 5 mgs). Average yearly individual warfarin cost was 22±6 euros and total yearly warfarin cost for 20 patients was 446.36 euros; average yearly individual attendance and laboratory cost was 334±56 euros and total cost for 20 patients was 6,693.75 euros. This the total cost of managing 20 patients was 7,140.11 euros. The same costs for managing patients with rivaroxaban 20 mg daily would be 663.66 euros per patient per year that for 20 patients would be **13,273.20** euros per year compared to 7,140.11 ($p< 0.0001$).

Conclusions: The management of 20 thrombotic APS patients with rivaroxaban 20 mg day for one year is 46% more expensive than warfarin; with a time in therapeutic range of almost 70% we cannot justify the use of rivaroxaban on the basis of cost alone that would be a major economic burden to the Italian Health Service.

PB 1464 | Comprehensive Characterization of Platelet Parameters for Thrombosis Risk Prediction in Patients with the Lupus Anticoagulant

J. Gebhart[1], F. Posch[1], S. Koder[1], P. Quehenberger[2], C. Ay[1], I. Pabinger[1]

[1]Medical University of Vienna, Department of Medicine I, Clinical Division of Hematology and Hemostaseology, Vienna, Austria, [2]Medical University of Vienna, Department of Laboratory Medicine, Vienna, Austria

Background: Lupus anticoagulant (LA) positive patients are at high risk for arterial and/or venous thromboembolic events.

Aims: To investigate the association of platelet parameters, namely platelet count (PLT), mean platelet volume (MPV), and the MPV/PLT ratio with thrombosis risk in patients with the LA.

Methods: In this prospective cohort study, we followed 165 persistently LA positive patients (female=136, 82%) over a median follow-up (FU) of 9.2 years.

TABLE 1 Baseline characteristics of the study population (n=165)

Variable	Median [25th-75th percentile], or absolute count (percent)
Age at entry (years)	41 [30-60]
Platelet count (G/L)	222 [175-258]
MPV (fL)	10.5 [9.9-11.2]
MPV/Platelet ratio	0.5 [0.4-0.6]
aPTT-LA (seconds)	87.3 [69.9-116.5]
aβ2GPI IgM (MPL)	5.6 [2.5-15.2]
aβ2GPI IgG (GPL)	9.4 [2.1-48.6]
aCL IgM (MPL)	9.1 [3.5-23.0]
aCL IgG (GPL)	18.6 [6.3-71.7]

Platelet parameters were investigated at baseline, and at each of the 1,047 FU visits. During FU, 41 thrombotic events (arterial n=21, venous n=20) occurred.

Results: At baseline, the median PLT and MPV levels were 222G/L [25^{th}-75^{th} percentile: 175-258] and 10.5fL [9.9-11.2], respectively.

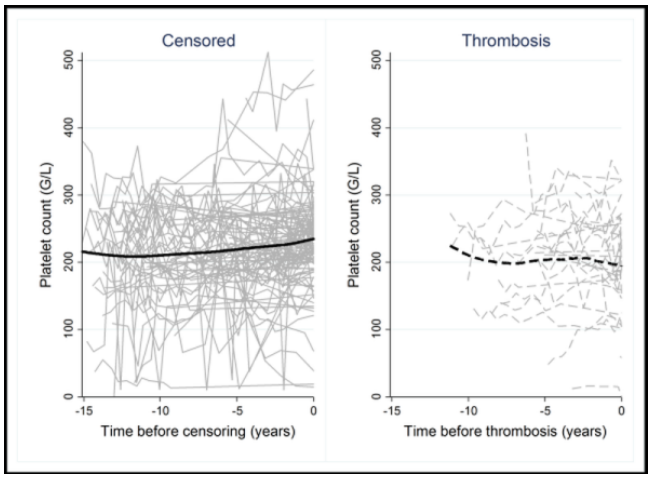

FIGURE 1 Platelet count trajectory in LA-positive patients with and without thrombotic complications during follow-up

In univariable time-to-thrombosis competing risk regression, a higher MPV (SHR per 1fL increase=1.13, 1.05-1.21, p=0.001), and higher MPV/PLT ratio (SHR per 1 unit increase=2.45, 1.75-3.42, p< 0.0001) predicted for a higher risk of thrombosis. However, these associations did not prevail after multivariable adjustment for diabetes, active smoking, and the lupus-sensitive aPTT (Adjusted SHR=1.04, 0.96-1.13, p=0.33 and 1.43, 0.84-1.42, p=0.19). In longitudinal analysis of 1,047 follow-up visits, PLT count slightly increased over time (change/year=+1.4G/L, 0.0-2.94, p=0.06), whereas the other two parameters remained constant throughout FU (not shown). In joint modeling of longitudinal platelet characteristics and time-to-thrombosis, longitudinal changes of platelet characteristics were not associated with thrombosis risk (Hazard ratio for a 5G/L increase in PLT=0.98, 0.96-1.00, p=0.12, Figure 1, others not shown).

Conclusions: In the current analysis, the three investigated platelet parameters were not prognostic for thrombosis risk in patients with the LA. However, high MPV might generally express a cardiovascular phenotype at high thrombotic risk.

PB 1465 | Severe Vitamin D Deficiency a Potentially Risk Factor for Recurrent Miscarriages in Women with Positive Antiphospholipid Antibodies

E. Lefkou[1], S. Petousis[1], V. Gogou[1], P. Anagnostis[1], A. Mamopoulos[1], T. Dagklis[1], A. Nikolopoulou[1], G. Gerotziafas[2,3], A. Athanasiadis[1]

[1]Aristotelion University of Thessaloniki, 3rd Department of Obstetrics and Gynaecology, Thessaloniki, Greece, [2]Hôpital Tenon, Hôpitaux Universitaires Est Parisien, Assistance Publique Hôpitaux de Paris, Service d'Hématologie Biologique, Paris, France, [3]Centre de Recherche Saint-Antoine, Institut National de la Santé et de la Recherche Médicale (INSERM) U 938 and Université Pierre et Marie Curie (UPMC), Sorbonne Universities, Cancer Biology and Therapeutics, Paris, France

Background: Vitamin D levels are low in patients with antiphospholipid syndrome (APS), especially on thrombotic APS, and also related to the recurrence of thrombosis. In vitro studies showed that vitamin D exerts an antithrombotic and immunomodulator function by inhibiting anti-β2GPI antibody-mediated tissue factor expression. There are no enough data between the relation of vitamin D levels and miscarriages/ infertility in women with positive antiphospholipid antibodies (APL).

Aims: We aimed to investigate if Vitamin D deficiency in women with APL is related with a risk of recurrent miscarriage or repeated (>three) in vitro fertilization (IVF) failures.

Methods: A prospective observational study was conducted in women positive antiphospholipid antibodies (at least one antiphospholipid antibody, twice positive with an interval >12 weeks), between -2013 2016. Primary outcome of the study was to correlate the presence of APL antibodies with blood levels of vitamin D. Linear regression model was used and level of statistical significance was defined at P< 0.05.

Results: There were 268 women enrolled in the study. Mean levels of vitamin D were 9.2 ± 18.6ng/ml (normal >30ng/ml).122 women had APL antibodies but incomplete APS diagnosis (only one miscarriage and/or repeated IVF failures) and 146 classical obstetric APS. Rate of vitamin D deficiency was %88.8, of which %28.7 mild (30-20ng/ml), %41.4 moderate (20-10ng/ml) and %18.7 severe deficiency < 10ng.ml. No significant correlation was detected regarding infertility (P=.47) and miscarriage (P=.58). Vitamin D levels were 9.8 ± 17.9 in patients with recurrent miscarriage vs. 8.9 ± 18.8 in women with infertility. Rate of recurrent miscarriages was significantly higher in the category of women with severe deficiency of vitamin D (%42.0 vs. %28 in the rest of women, P< 0.05).

Conclusions: Women with APS, or APL antibodies have low levels of vitamin D. Severe deficiency of vitamin D is associated with recurrent miscarriages in women with antiphospholipid antibodies.

PB 1466 | Antibodies against Domain I of Beta2-glycoprotein I Have No Added Value for Prediction of Antiphospholipid Syndrome Compared to Classical Antiphospholipid Antibodies

N. Pequeriaux[1], D. Hammann-Wenzlau[2], E. Gemen[1], I.-A. Haagen[3], M.J. Hollestelle[2]

[1]Jeroen Bosch Hospital, Laboratory of Clinical Chemistry and Haematology, ,s-Hertogenbosch, The Netherlands, [2]Sanquin Diagnostic Services, Dept. Immunopathology and Blood Coagulation, Amsterdam, The Netherlands, [3]OLVG-OOST Hospital, Laboratory of Clinical Chemistry and Haematology, Amsterdam, The Netherlands

Background: The diagnosis of antiphospholipid syndrome (APS) is made by the combination of vascular thrombosis and/or obstetric complications together with antiphospholipid antibodies (aPLs). Beta 2-glycoprotein I (ß2GPI) is the major antigen for aPLs. Recently, antibodies directed to the first domain of ß2GPI have been suggested to have added value above total ß2GPI for diagnosis of APS.

Aims: To evaluate whether ß2GPI-domain I antibodies (anti-ß2GPI DI) are a better predictor of APS.

Methods: In two hospitals blood samples from patients referred for suspicion of APS and with one positive classical antibody test, were collected. Lupus anticoagulant (LAC), anticardiolipin antibodies (aCL), anti-ß2GPI antibodies (anti-ß2GPI) and anti-ß2GPI-DI were measured. Anti-ß2GPI DI, anti-ß2GPI and aCL were determined using EIA (chemiluminescent or fluoro-enzyme immunoassay). Final diagnosis of APS was made by the combination of clinical features and the positivity of one of the three accepted aPLs. Results were correlated with diagnosis of APS.

Results: 62 patients were included. Finally, 25 patients were classified having an APS while 37 patients did not fulfill the criteria. Odds ratio for APS were as follow: LAC 2.2 (95% CI 0.7-7.0), aCL 2.6 (95% CI 0.9-7.7), anti-ß2GPI 3.8 (95% CI 1.3-11.5) and anti-ß2GPI DI 2.4 (95% CI 0.8-7.0). Anti-ß2GPI and anti-ß2GPI DI as aCL and anti-ß2GPI DI correlated well (Spearman's correlation coefficient respectively ρ:0.3 , $p< 0.05$; ρ:0.6 , $p< 0.01$).

Conclusions: In this patient population, anti-ß2GPI DI have no added value in predicting APS compared to anti-ß2GPI, aCL or LAC.

PB 1467 | Antiphospholipid Syndrome Alliance for Clinical Trials and International Networking (APS ACTION): Comparison of Real World and Core Laboratory Lupus Anticoagulant Results

M. Efthymiou[1], I. Mackie[1], P. Lane[1], V. Pengo[2], D. Andrade[3], R. Willis[4], S. Krilis[5], D. Erkan[6], H. Cohen[1,7]

[1]*University College London, Haemostasis Research Unit, Department of Haematology, London, United Kingdom,* [2]*University of Padova, Cardiology Clinic, Department of Cardiac, Thoracic and Vascular Sciences, Padua, Italy,* [3]*University of São Paulo, Rheumatology Department, São Paulo, Brazil,* [4]*University of Texas Medical Branch, Antiphospholipid Standardization Laboratory, Department of Internal Medicine, Rheumatology Division, Galveston, Texas, United States,* [5]*St George Hospital, Department of Infectious Diseases, Immunology and Sexual Health, Sydney, Australia,* [6]*Hospital for Special Surgery, Weill Cornel Medicine, Barbara Volcker Center for Women and Rheumatic Diseases, New York, United States,* [7]*University College London Hospitals NHS Foundation Trust, Department of Haematology, London, United Kingdom*

Background: APS ACTION is conducting a 10-year international study of disease course in antiphospholipid (aPL) positive patients. The five Core Laboratories (CL) perform lupus anticoagulant (LA) and other aPL assays to confirm aPL positivity. A previous exercise showed good agreement between the CL by using the same methodology, analyser type, and reagents.

Aims: To examine agreement in LA status between Core and hospital laboratories of centres entering patients. APS patients were included if they were tested for LA within one year prior to enrolment and fulfilled International consensus criteria.

Methods: LA in non-anticoagulated (AC) samples by DRVVT (Screen/Confirm) and silica clotting time using an ACL TOP500 analyser (IL) was assessed by all CL. LA status of patients on vitamin K antagonists (VKA) was assessed at a single CL (UK) by DRVVT (using equal volume of patient/normal plasma mixtures) and Taipan/Ecarin time ratio.

Results: In this ongoing study, 355 samples were analysed. Results are shown for 239 samples (105 non-AC and 134 VKA). 116 samples were excluded due to incomplete clinical information, insufficient plasma, or on other anticoagulants. Of the included samples, hospitals submitted LA results on >3 occasions in 154 patients, 2 occasions in 61 patients, and 1 occasion in 24 patients. Results judged as equivocal at the CL (abnormal results and lack of evidence for an inhibitor) were considered as "LA not detected". Agreement for LA results between the original hospital and CL was 88.8% and 78.1% for non-AC and VKA patients, respectively. Inclusion of LA equivocal samples as LA positive would have decreased the agreement to 75.4% for the non-AC samples but increased it to 84.8% for the VKA samples.

Conclusions: There was very good agreement on LA status between the original hospital and CL, particularly for the non-AC samples. This is encouraging both for international consensus on LA testing and the validity of aPL data accumulating in the APS ACTION database.

PB 1469 | Thrombocytopenia is Uncommon in High-risk Patients with Antiphospholipid Syndrome (APS)

E. Pontara[1], A. Banzato[1], M.G. Cattini[1], E. Bison[1], G. Baroni[1], A. Hoxha[2], A. Ruffatti[2], V. Pengo[1]

[1]*University of Padova, Department of Cardiac, Thoracic and Vascular Sciences, Padova, Italy,* [2]*University of Padova, Department of Medicine, Padova, Italy*

Background: Thrombocytopenia is the most common non-criteria hematologic manifestation in patients with the antiphospholipid syndrome (APS). It has been often reported with a prevalence beetween20 to 53%. In the Euro-Phospholipid project,29,6% of patients had thrombocytopenia (< $100x10^9$/L). The rate in patients with primary APS (PAPS) was 21% and 41,9% in those with secondary APS (SAPS).Prevalence reported in the literature depends on the different cut-off (< $100x10^9$/L or < $150x10^9$/L) used.

Aims: To assess the prevalence of thrombocytopenia in a cohort of high-risk APS patients.

Methods: We analyzed 116 high-risk triple positive APS patients (41 males and75 females, aged from 22 to 80 years, median 48,6 years). Among these patients, 82 were PAPS and 34 SAPS (21 LES, 13 lupus-like disease).

Results: Using a cut-off of $150x10^9$/L, the rate of thrombocytopenia is 15% (mean $208,6x10^9$/L± 72, minimum $6x10^9$/L - maximum $541x10^9$/L). The prevalence is 16% in PAPS and 12% in SAPS. Considering a cut-off of $100x10^9$/L, the rate of thrombocytopenia decreases to 6% (7% in PAPS and 3% in SAPS). Two patients with very low platelet count had associated immune thrombocytopenia and underwent splenectomy.

Five of these patients, with normal platelet count, underwent a catastrophic phase of the disease. During this period, the rate of thrombocytopenia was 100%.

Conclusions: This study shows that in high-risk APS patients the rate of thrombocytopenia is lower than that reported in the literature. A

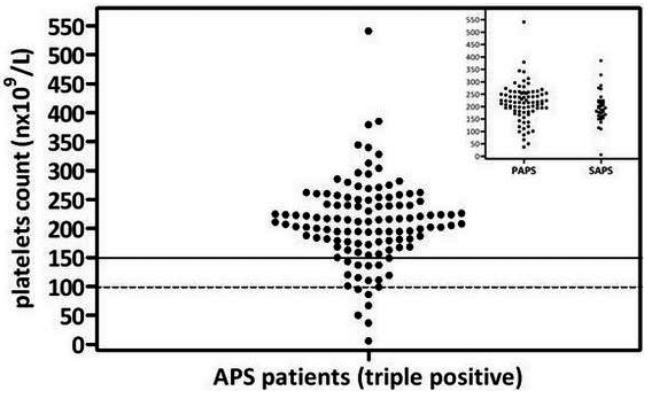

FIGURE 1 Platelets count in all triple APS patients, and in subgroups PAPS (Primary APS) and SAPS (Secondary APS).

drop in platelet count was observed in all patients who deteriorate into the catastrophic form of the disease.

No significative difference between PAPS and SAPS platelet counts has been found.

PB 1470 | Circulating Neutrophil-Extracellular Traps (NETs) in Patients with the Antiphospholipid Syndrome

J.C. Reverter[1], J. Bravo[1], G. Espinosa[2], R. Cervera[2], D. Tàssies[1]

[1]*Hospital Clinic, IDIBAPS, University of Barcelona, Hemotherapy and Hemostasis (ICMHO), Barcelona, Spain,* [2]*Hospital Clinic, IDIBAPS, University of Barcelona, Systemic Autoimmune Diseases (ICMID), Barcelona, Spain*

Background: Antiphospholipid syndrome (APS) is an autoimmune disease characterized by the presence of antiphospholipid antibodies (APLs), arterial and venous thrombosis, and fetal losses. Neutrophil-extracellular traps (NETs) are related with inflammatory and autoimmune diseases and it has been suggested that autoantibodies can induce NETs and enhance thrombotic risk.

Aims: To evaluate plasma circulating NETs levels in a cohort of patients with APS as a model of autoimmune disease associated with hypercoagulability.

Methods: In this cross-sectional study plasma circulating NETs levels were measured in 60 patients with APS [48 primary APS (PAPS), and 12 APS associated with systemic lupus erythematous (SLE) (SAPS)], in 32 patients with SLE [10 with APLs, and 22 without APLs], and in 50 healthy individuals (control group). No statistically significant differences in age and sex were found among groups. A total of 33 APS patients had history of arterial thrombosis (26 in PAPS and 7 in SAPS groups) and 17 history of venous thrombosis (12 in PAPS and 5 in SAPS groups). Samples were obtained outside of acute active phase of the disease. Plasma circulating NETs levels were measured as histone-DNA complexes by a quantitative sandwich-enzyme-linked immunosorbent assay (ELISA). Results were expressed as a ratio between mU of patient/ mU of standard sample. Results are reported as mean± SD. Statistical significance was defined as a p-value < 0.05.

Results: Plasma circulating NETs levels were 0.86± 0.33 in PAPS patients, 0.81± 0.37 in SAPS patients, 0.86± 0.26 in SLE patients with APLs, and 0.71± 0.10 in SLE patients without APLs, and 1.06± 0.28 in controls. There were no significant differences in the levels of NETs among the groups. In addition, in the patients with APS no statistically significant differences were found between patients with or without history of venous or arterial thrombosis.

Conclusions: Patients with APS in a non-active phase of the disease have not significantly elevated plasma circulating NETs levels.

PB 1471 | Catastrophic Antiphospholipid Syndrome: Onset and Outcome

T. Reshetnyak[1], I. Shtivelband[2], S. Radenska-Lopovok[2], M. Satibaldieva[2], N. Seredavkina[2], E. Nasonov[2]

[1]*V.A. Nasonova Research Institute of Rheumatology, Russian Medical Academy of Postgraduate Education, Systemic Rheumatic Disease, Moscow, Russian Federation,* [2]*V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

Background: Multiple vascular occlusions in three or more organs associated with high titer antiphospholipid antibodies (aPL) is known as catastrophic antiphospholipid syndrome (CAPS)

Aims: To assess retrospectively the prevalence of CAPS in pts with APS and to determine the long-term outcome of CAPS pts who survived after CAPS.

Methods: Data of 162 pts. with systemic lupus erythematosus (SLE) and with aPL and 94 pts. with primary APS (PAPS) were analyzed. Mean (±SD) follow-up was 10.7 (4.6) years and mean age at time of including in the study was 33.0 (11.0) and 35.4 (10.1) years respectively. IgG/M anticardiolipin antibodies (aCL), lupus anticoagulant were measured in all pts.

Results: The development of CAPS was found in 43 pts: 33/162 (20.4%) pts with SLE and aPL (23F; 10M) and 10/94 (10.6%) with PAPS (8F; 2M) respectively. Thirty two (25/33 (75.5%) and 7/10 (70.0%) patients were died. Two of 11 survived CAPS pts. developed thrombosis in a year with death event. The analyses of the concomitant factors which may initiate CAPS were assessed. There were SLE flare (n=12), initial menopause (n=2), infections (n=12) including pneumonia (n=7), acute respiratory disease (n=3), food poisoning (n=1), abscess (n=1) as provoking factors in SLE+APS pts. Cancer was revealed in 1 SLE pts and trauma after road accident in 1 SLE pts. Thrombotic microangiopathy as cause of CAPS was found in 3 pts (1 with SLE, 2 with PAPS). Fulminant purpura was at onset of CAPS in all 3 cases. Two of them had recurrent severe skin necrosis with multiple organ failure and died due to severe sepsis in 1 and 2 years. Triggering factor in PAPS pts. was pneumonia (n=2) and abscess (n=1), in 7 pts these factors were not detected. Treatment comprised high dose of steroids, full anticoagulation and immunosuppressant in most of the cases, antibiotics administered when infection was evident.

Conclusions: Triggering factors of CAPS were flare of SLE and infection. Significant functional impairment due to initial CAPS had all 9 survived CAPS patients.

PB 1472 | Effect of Hydroxychloroquine on Circulating Levels of Inflammatory Cytokines in Patients with Primary Antiphospholipid Syndrome

B. Mazetto[1], S. Saraiva[1], S. Huber[1], F. Talge[2], L. Quinteiro[2], I.R. Brito[2], K. Zapponi[1], F. Bassora[1], J. Annichino Bizzacchi[1,2], F. Orsi[1,2]

[1]*University of Campinas-Unicamp/Hematology and Hemotherapy Center, Campinas, Brazil,* [2]*University of Campinas/Faculty of Medical Sciences, Campinas, Brazil*

Background: Hydroxychloroquine (HCQ) has immunologic and antithrombotic effects in systemic lupus erythematous (SLE). However, the effect of HCQ in primary antiphospholipid syndrome (PAPS) with thrombosis is not determined.

Aims: The aim of this study was to evaluate the impact of HCQ on the immunologic profile of PAPS patients.

Methods: This is a prospective study that included 23 patients with PAPS and thrombosis, we quantified the circulation levels of cytokines before treatment (BT) and after 6 months of HCQ 400mg/day. We also included 28 healthy controls, matched by age and gender, for reference values. Serum levels of tumor necrosis factor-alpha (TNF-a), interleukin (IL) -2, -4, -8, -10, -17, CD40L and interferon-gama (INF-g) were performed by multiplex assays (Milliplex,Millipore).

Results: Patients median age was 44 years-old and 87% were female. The antibody profiles were: 6 triple positive, 6 double positive (lupus anticoagulant -LAC plus anti-beta2glycoprotein1) and 11 isolated LAC. Before treatment, circulating levels of TNF-a were similar to controls (median 3.5 vs. 0.2pg/mL; P=0.4), but decreased after-HCQ (median 0.01pg/mL; P=0.05). Levels of IL-8 were higher BT compared to controls (median 6.4 vs. 4.7 pg/mL; P=0.04) and did not change after-HCQ (median=7.5pg/mL; P=0.1). Conversely, levels of CD40L were lower BT than in controls (median 2598 vs. 3562 pg/mL; P=0.01) and remained low after-HCQ (median=2297 pg/mL; P=0.6). Before treatment, levels of IL-2 were similar to controls, but had a trend to decrease after-HCQ (median 0.46 pre-HCQ and 0.01 pg/mL after-HCQ, P=0.09). Levels of INF-g and IL-10 were similar between controls and patients and did not alter after-HCQ, however the amount of cytokines detected was variable. IL-4 and IL-17 were not detected.

Conclusions: In conclusion, HCQ may inhibit TNF-a, an inflammatory cytokine released mainly by monocytes, which is the main inflammatory cell involved in APS pathogenesis. However, the drug has minimal effect on the levels of other interleukins.

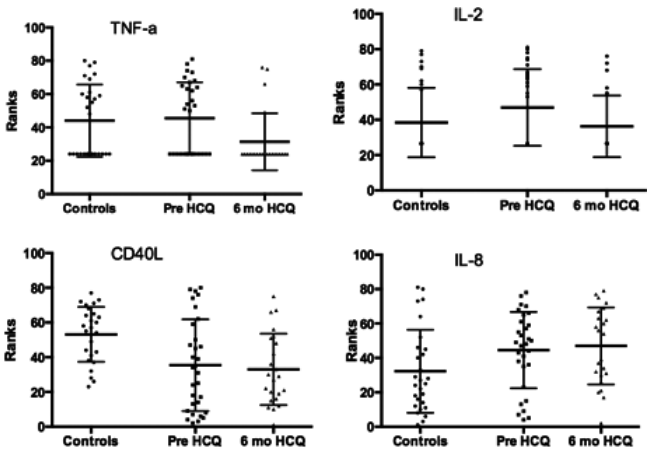

Figure 1. Distribution of the levels of TNFa, IL-2, CD40L and IL-8 in controls and in patients, before and during the treatment with HCQ.

FIGURE 1

PB 1473 | A High Molecular Weigh Protein Is Responsible of Anticoagulant Activity in Isolated Lupus Anticoagulant

A. Banzato[1], M.G. Cattini[1], T. Del Ross[2], S. Testa[3], C. Legnani[4], D. Petterle[5], E. Pontara[1], E. Bison[1], A. Ruffatti[2], V. De Filippis[5], V. Pengo[1]

[1]*University of Padova, Department of Cardiac, Thoracic and Vascular Sciences, Padova, Italy,* [2]*University of Padova, Department of Medicine, Padova, Italy,* [3]*AO Istituti Ospitalieri, Department of Laboratory Medicine, Hemostasis and Thrombosis Center, Cremona, Italy,* [4]*University Hospital of Bologna, Angiology and Blood Coagulation, Bologna, Italy,* [5]*University of Padova, Department of Pharmaceutical and Pharmacological Sciences, Padova, Italy*

Background: The term „lupus anticoagulant“ (LAC) refers to an acquired *in vitro* inhibitor blood coagulation. This activity is usually associated to the presence heterogeneous group of immunoglobulins directed towards βeta2 glycoprotein I (β2GPI). However, in the case of isolated LAC (negative anticardiolipin and anti-β2GPI antibodies), the substance conferring anticoagulant activity to the plasma is unknown.

Aims: To analyze the plasma of patients with isolated LAC to identify the substance responsible for this activity.

Methods: We analyzed the plasma of 14 patients with isolated LAC by affinity purifying IgG using a Protein G column. We then tested the anticoagulant activity of eluted IgG and that of flow through (FT) both with dRVVT and aPTT. Plasma of strongest isolated LAC was poured into a Sephacryl High Resolution S-300 column from which 43 1mL fractions were collected and tested for LAC activity and the presence of IgM, IgG and β2GPI in specific ELISA assays. Finally, we precipitated the euglobulin fraction from plasma of positive LAC patients with PEG 8.000 at 5% to isolate the globulin plasma fraction.

Results: IgG isolated from 14 patients with only LAC positivity didn't prolong dRVVT test (37"±0.33 control time vs a mean of 37.46"±0.55 for IgG fractions). Anticoagulant activity was in the FT (dRVVT= 56.58"±12.46 SD). Using the plasma of the strongest LAC patient, LAC activity was in the first peak coming from the S-300 column . The dRVVT in these fractions was 45.9"±1.9 (control 37"±0.2). In this peak we found a high concentration of IgM, and very low concentration of IgG and β2GPI. LAC activity was also present in globulin fraction isolated with PEG 8.000 precipitation at first and then with S-300 column (dRVVT=52.1"±2.33, control 35.85"±0.85). This peak analyzed by SDS-page showed the several proteins with high molecular weigh.

Conclusions: We can hypothesize that the responsible of LAC activity in isolated LAC is a high molecular weight protein that needs more studies for its identification.

PB 1474 | DNA Methylation Pattern Analyses in Patients with Antiphospholipid Syndrome: Screening Study

J.Y. Kim[1,2], H.-J. Kim[3], J.W. Han[4], H.-J. Yoon[5], K.S. Lee[2]

[1]Kyungpook National University Children's Hospital, Pediatrics, Daegu, Korea, Republic of, [2]Kyungpook National University Hospital, Pediatrics, Daegu, Korea, Republic of, [3]Kyungpook National University School of Medicine, Physiology, Daegu, Korea, Republic of, [4]Yonsei University College of Medicine, Department of Pediatrics, Seoul, Korea, Republic of, [5]Kyung Hee University Hospital, Internal Medicine, Seoul, Korea, Republic of

Background: Epigenetic modification has been studied in many immune disorders to elucidate its pathophysiologic correlation, along with genomic, epigenomic profiling. Aberrant DNA methylation and its impact on gene expression have been implicated.

Aims: This study is to investigate a global DNA methylation status of antiphospholipid syndrome (APS) patients with CpG microarray, and compared it with healthy controls.

Methods: Human peripheral whole blood were obtained from 6 APS (2 primary and 4 secondary APS) and from 6 age, sex-matched healthy controls. Total genomic DNA extracted using the QIAamp DNA mini and blood kit protocol. To discover aberrantly methylated genes in APS by genome-wide search, we introduce Illumina Infinium Human Methylation 450K BeadChip for directly identifying differentially methylated regions of the genomes in each pooled whole blood between APS patients and healthy controls. Immunologic profiles of the patient group including aPL, aCL, LA, anti-b2GP1 were obtained.

Results: The fluorescent signal intensities were extracted using GenomeStudio Methylation module software. One-hundred and thirty two CpG sites were filtered by criteria of delta mean >0.2, and p value < 0.05 after the quantile normalization to reliably compare data from multiple samples by minimize non-biologic differences. Seventy nine CpG sites (KNDC1, ABHD8, CDK2AP1, MX1, IL16, ROCK2, SNTG2, etc) were hypermethylated and 53 sites (CYP2E1, BTNL2, DTX2, GCC2, SLC9A3, etc) were hypomethylated. All differentially methylated CpG sites were located in 5'UTR, TSS1500, TSS200, Exon, intergenic body, 3'UTR. Hierachical clustering (figure1) and the functional classification analysis using DAVID was done.

Conclusions: Hundreds of candidate genes were screened by BeadChip microarray of peripheral blood in APS patients. High-throughput, next generation sequencing of the individual patients for validation will be underwent and the correlation with immunologic profile and thrombotic features will be investigated.

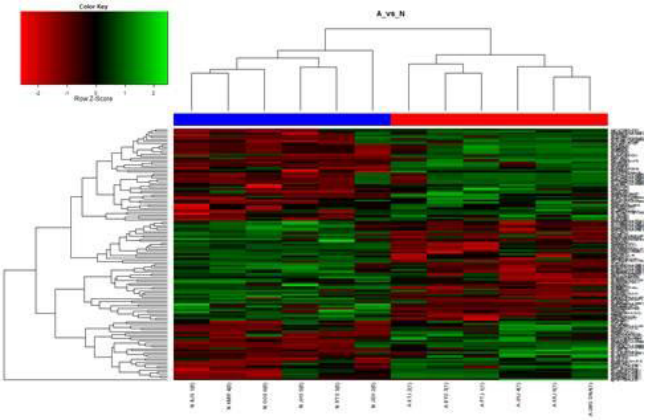

FIGURE 1 Hierachical clustering of the most significantly different CpG sites.

PB 1475 | What Is the Risk of First Thrombosis in Asymptomatic Antiphospholipid Antibodies Carriers?

L. Costa, R. Matos, L. Moreira, E. Cruz, S. Morais

Centro Hospitalar do Porto, Thrombosis & Hemostasis Unit - Clinical Hematology, Porto, Portugal

Background: Antiphospholipid Syndrome (APS) is defined by the presence of antiphospholipid antibodies (aPL) plus thrombotic events (TE) or obstetric morbidity (OM). Persistent aPL are occasionally found in individuals without previous TE. However, the risk of first TE in asymptomatic aPL carriers is unknown. Recently, triple positivity (Lupus Anticoagulant (LA), Anticardiolipin Antibodies (ACA) and anti-ß2-glicoprotein I (aß2GPI) positivity is claimed to increase the risk of APS.

Aims: Evaluate the incidence of TE in a group of asymptomatic aPL carriers.

Methods: We evaluated retrospectively and prospectively 49 individuals (38 women, 11 men), with a median age at diagnosis of 45 years-old (yo) (7-80 yo) and a laboratorial diagnosis of aPL positivity. Individuals were excluded if it was not possible to confirm aPL in a second sample or if follow-up was less than 2 years.

Results: The studied population's characteristics are depicted on Table 1. Different aPL profiles are described in Table 2. Our follow-up was of 416 individuals/year with an average duration of 8.5 years (2-27 years). During this period, it was reported only one TE in a 75 yo woman with isolated LA+ and essential hypertension who had stroke symptoms, but without imaging confirmation.

TABLE 1 Characterization of the studied population

Sex (Female/ Male)	38 / 11
Median age at diagnosis (years)	45 (7-80)
Autoimmune diseases (n=12)	
SLE / others	10 / 2
aPL profile	
Isolated LA positivity	27
Triple positivity	16
ACA and/ or aß2GP positivity*	6
Mean follow-up (years)	8.5 (2-27)

*ACA IgG / ACA IgM / aβ2GPI IgM / ACA IgM and β2GPI IgM (3/1/1/1); SLE: Systemic Lupus Erythematosus

TABLE 2 Characterization of the different aPL profiles

	Isolated LA positivity (n=27)	Triple positivity (n=16)	ACA and/ or aß2GP positivity (n=6)
Sex (Female/ Male)	19/ 8	13/ 3	6/ 0
Median age (years)	56 (8-80)	28.5 (7-75)	38 (30-61)
Context of aPL detection	19 aPTT E / 4 AI / 2 OM	3 aPTT E / 7 AI / 3 OM	1 AI / 4 OM
AAS prophylaxis (Yes/ No)	9/ 13	6/ 9	6/ 0
AI diagnosed	5	6	1
LA intensity	1.68	2.1	-
Mean follow-up (years)	8.3	8.4	8.0

AAS: Acetylsalicylic Acid; AI: Autoimmune disease; E: Extended; SLE: Systemic Lupus Erythematous

Conclusions: Among aPL, LA is considered the most import risk predictor for TE. However, when it is present alone, it seems not to relate with an increased thrombotic risk. In our population, considering that episode as a TE (even without confirmation), the incidence of TE was of 0.45%/year, not different of the same age Caucasian population (approximately 0.4%/year). On the other side, triple positivity has been related with an increased risk of TE, with an incidence of 5.3%/year[1]. However, in our population, we didn´t find such association. Our data differs from previous studies that suggest triple positivity as an important risk factor for thrombosis.

[1]Pengo V et al., Blood 2015

PB 1476 | Clinical Relevance of Anti Phospholipid Antibodies in Deep Venous Thrombosis

D. Eissa, H. Affify, M. Ismail, A. Saad, N. Abo Shanab

Ain Shams University, Clinical Pathology, Cairo, Egypt

Background: Diagnosis of antiphospholipid syndrome (APS) is quite difficult and challenging. Our study deduced the sensitivity & specificity for each test to antiphospholipid antibodies (APA) in patients with deep venous thrombosis (DVT) and the relation of increasing antibody titer to recurrent thrombosis.

Aims: We aimed to determine the frequency of positive APS detected by laboratory investigations in patients with unexplained DVT.

Methods: Eighty patients with DVT diagnosed by Doppler ultrasonograpy were screened for lupus anticoagulant by (APTT-LA) and dilute russel viper venom time (dRVVT) screen ratio then positive patients were confirmed by mixing study and (dRVVT) confirm test respectively. Anticardiolipin (ACL) IgG and beta2 glycoprotein I (β2GPI) IgG were done for all patients using enzyme linked immune sorbent assay.

Results: APS showed positivity in (68/80) 85% of our patients using APTT-LA and dRVVT screen ratio that was confirmed by mixing studies, Rosner index and dRVVT correction ratio. Twelve patients out of all patients (12/80) were positive by either ACL or β2GPI . Both ACL and β2GPI showed perfect agreement with Rosner index and dRVVT correction ratio (Kappa index=1.000).Our results showed a significant correlation between increasing age and number of DVT attacks. Rosner index and ACL IgG were significantly correlated with age and increased number of attacks. Accordingly patients with recurrent attacks of DVT showed significantly higher median age and higher median ACL IgG titer in our study. The most striking result was the high sensitivity & specificity of APTT-LA and dRVVT screen ratio (100%) for each of them in comparison to other tests.

Conclusions: Positivity in this study highlighted the importance of using both APTT-LA and dRVVT tests together in the detection of LA. However, further studies on larger number of patients using the four tests (APTT-LA, dRVVT, ACL and β2GPI) are recommended to be performed to explore the best diagnostic assays for APS.

PB 1477 | Results of Lupus Anticoagulant Investigation in Unselective Population of Patients Referred for Testing

S. Margetic[1], B. Getaldic[1], D. Ferenec Ruzic[1], I. Vuga[1], N. Vrkic[2]

[1]Medical School University Hospital ´Sestre Milosrdnice´, Laboratory Haematology and Coagulation, Zagreb, Croatia, [2]Medical School University Hospital ´Sestre Milosrdnice´, Clinical Institute of Chemistry, Zagreb, Croatia

Background: Laboratory evaluation of lupus anticoagulant (LA) antiphospholipid antibodies is an integral part of the diagnostic criteria for antiphospholipid syndrome (APS).

Aims: The aim of this study was to analyze the results of laboratory evaluation of LA antibodies in unselected patients referred for testing during a period of two consecutive years (from January 2015 to December 2016).

Methods: LA antibodies were evaluated by a panel of commercial coagulation assays (Siemens, Germany) including three screening tests: activated partial thromboplastin time (APTT), APTT mixing test, dilute Russell´s viper venom time (dRVVT) screen test (LA1) and confirmation test (LA2).

Results: The prevalences of positive LA results in unselected consecutive patients referred for testing were: 26/810 (3.2%) in 2015 and 24/878 (2.7%) in 2016 with the overall prevalence of 50/1688 (3.0%) for the period of two years. There were 26 female and 24 male patients with positive LA results, with a median age of 40 years (95%CI for median 37-48 yrs; interquartile range 29-59 yrs). Among all LA positives, venous thromboembolism (VTE) accounted for more than a half of all cases (28/50), including positive LA result in 25 cases of deep venous thrombosis (DVT) and in 3 cases of pulmonary embolism (PE). The prevalences of other clinical diagnoses among all LA positive results were as followed: cerebrovascular insult (3), varicose veins (2), cardiovascular disease (2), transient ichemic attack (2), miscarriage (2), infertility (1), autoimune haemolytic anemia (2), systemic lupus

erythematodes (2), rheumatoid arthritis (2), epilepsy (1), vasculitis (1), hemiplegia (1) and urticaria (1).

Conclusions: Laboratory investigation of LA antibodies among unselected consecutive patients referred for testing has shown an overall prevalence of 3.0%. As expected, VTE accounted for most of the positive LA results. However, beside of VTE patients, there were a number of other clinical diagnoses with positive LA results.

PB 1479 | Detection of Thrombogenicity Positive Antiphospholipid Antibodies in Antiphospholipid Syndrome Diagnosis

J. Ulehlova, L. Slavik, J. Prochazkova, A. Hlusi, V. Krcova

Faculty of Medicine and Dentistry, Palacký University Olomouc; University Hospital Olomouc, Department of Hematology-Oncology, Olomouc, Czech Republic

Background: Anti-cardiolipin antibodies (aCL) and anti-β-2-glycoprotein I antibodies (ab2GPI) represent two out of three laboratory criteria for detection of antiphospholipid syndrome (APS). The domain I in anti-β-2-glycoprotein I is a new target for better identification of antibodies and are associated to thrombotic risk in antiphospholipid syndrome.

Aims: The aids of our study was to determine the significance of Domain I in anti-β-2-glycoprotein I as new biomarker for determining thrombotic risk in antiphospholipid syndrome and detection their thrombogenicity

Methods: We detect Domain I ab2GPI and diluted prothrombin time on a group of 74 patients with antiphospholipid syndrome diagnosis. All patients has positive antibodies in at least one class aCL and ab-2GPI antibodies. The determination of ACL and β-2-GPI IgG and IgM antibodies was performed by the chemiluminescent assay (HemosIL AcuStar®) in singlet.

Results: We detect Domain I ab2GPI positivity at 21 samples in our group. The thrombotic complications was been observed at 21 from 74 patients. The incidence of thrombotic complications in the total group was established as 28,4 %, in comparison to group positive for DI anti-β2GPI with the incidence of thrombotic complications 57 %. Performing of assay improved positive predictive value from 25% pretest to 68% for patients with positive test.

Conclusions: The new chemiluminescent method for detection of Domain I ab2GPI with detection of thrombogenicity of antibodies shows better compliance with clinical outcome than the actual examination.

PB 1480 | Tissue Factor-bearing Microvesicles and Acquired Protein S Deficiency Contribute to DIC in a Patient with Elevated Antiphospholipid Antibodies

C. Dicke[1], K. Holstein[1], M. Voigtländer[1], F. Stahl[2], U. Schnoor[3], C. Bokemeyer[1], F. Langer[1]

[1]Universitätsklinikum Hamburg-Eppendorf, II. Medizinische Klinik und Poliklinik, Hamburg, Germany, [2]Universitätsklinikum Hamburg-Eppendorf, Institut für Klinische Chemie und Laborationsmedizin, Hamburg, Germany, [3]Universitätsklinikum Hamburg-Eppendorf, III. Medizinische Klinik und Poliklinik, Hamburg, Germany

Background: Acquired (i.e. autoimmune) protein S (PS) deficiency is a rare and potentially life-threatening disorder.

Aims: We report the case of a 76-year-old woman with a thrombohemorrhagic syndrome due to DIC in the context of elevated antiphospholipid antibodies and acquired PS deficiency.

Methods: We used standard laboratory tests to measure PC, PS, activated PC resistance (APC-R), factor V gene mutation Leiden, lupus anticoagulant (LA), and antibodies to cardiolipin (aCL) and beta2-glycoprotein I (anti-β2-GPI). Mixing studies with normal human plasma (NHP) were used to screen for a functional PS inhibitor. Tissue factor (TF)-specific procoagulant activity (PCA) of plasma microvesicles (MVs) was assessed by single-stage clotting assay.

Results: The patient presented with a painful reticular erythema indicating microvascular thrombosis and a consumptive coagulopathy: prothrombin time 45.5% (normal: 80-130%), fibrinogen 0.5 g/L (1.8-4.0 g/L), D-dimer 34 mg/L (< 0.5 mg/L). Surgical and antibiotic treatment of concurrent sigmoid diverticulitis did not resolve DIC. Overt malignancy was excluded. The coagulopathy was only controlled by continuous systemic anticoagulation. Titers of IgM-aCL were elevated to 90 U/mL
(< 10 U/mL). Antinuclear antibodies and tests for LA and anti-β2GPI were negative. There was APC-R with a ratio of 1.7 (> 2.0) in the absence of factor V gene mutation Leiden. Free and total PS antigen was normal, but PS activity was severely reduced to 14% (55-125%) with no correction upon mixing with NHP. Significant MV-associated TF PCA was detected. A short-term course of oral glucocorticoids was ineffective.

Conclusions: In this case, generation of MV-associated TF PCA, possibly due to monocyte activation by antiphospholipid antibodies, in combination with acquired APC-R and depletion of protein S activity caused a systemic coagulopathy characterized by microvascular thrombosis, which could only be controlled by uninterrupted systemic anticoagulation.

PB 1481 | Use of Direct Oral Anticoagulant in Antiphospholipid Syndrome: Systematic Review of Literature

V. Dufrost, J. Risse, S. Zuily, D. Wahl

CHRU Nancy, Vascular Medicine Division, Vandoeuvre Les Nancy, France

Background: Direct oral anticoagulants (DOACs) are approved for prevent thrombotic recurrence in venous thromboembolism disease but their clinical efficacy and safety are not studied in APS patients. The RAPS trial demonstrated an increased thrombin potential in APS patients with rivaroxaban versus warfarin, suggesting a higher thrombotic risk. Authors concluded that rivaroxaban is safe in APS patients

because there was not thrombotic recurrence during the follow up of 7 months. Several reports of APS patients treated with DOACs have raised safety issues with thrombotic recurrence during treatment.

Aims: We want clarify the safety of DOACs in APS patient and if there are factors associated with thrombosis recurrence.

Methods: We summarized available literature on DOACs use in APS patients through a systematic review and we used Wilcoxon and Fisher's exact test. Missing data were excluded from analyses.

Results: Our systematic review identified 299 published APS patients treated with DOACs; among them, 31 experienced a recurrent thrombosis while on treatment. The three DOACs used was rivaroxaban (N=206), dabigatran etexilate (N=89) and apixaban (N=4) ; there was no difference between them. Triple positivity (positivity of all three laboratory criteria for APS) was associated with a 3-fold increased risk for recurrent thrombosis (19% versus 58%; p< 0,05). There was no difference between previous APS manifestation. Comparisons of a part of the patients' characteristics according to the presence of a thrombotic recurrence while on DOACs are available in Table 1.

TABLE 1 Comparisons of a part of the patients' characteristics according to the presence of a thrombotic recurrence while on DOACs

	APS without recurrence thrombosis (n= 268)	APS with recurrence thrombosis (n= 31)	p value
aPL profile :			
Lupus anticoagulant	112 (75)	19 (79)	
Anticardiolipin	76 (51)	21 (88)	< 0.05
Antibeta2glycoprotein 1	58 (39)	18 (75)	< 0.05
Triple positivity	31 (19)	14 (58)	< 0.05
Oral anticoagulant :			
Rivaroxaban	180 (67)	26 (84)	
Dabigatran	84 (31)	5 (16)	
Apixaban	4 (2)	0 (0)	

Conclusions: In conclusion, DOACs should be used with caution in APS patients and randomized control trials with clinical primary endpoints assessing clinical efficacy and safety are awaited to establish whether the prescription of DOACs could be a safe alternative to warfarin.

PB 1482 | Plasma Thrombogenic Potential in Patients with Granulomatosis with Polyangiitis in Comparison to Antiphospholipid Syndrome

M. Celińska-Lowenhoff, T. Iwaniec, J. Kosałka, J. Musiał

Jagiellonian University Medical College, Department of Medicine, Kraków, Poland

Background: Granulomatosis with polyngiitis (GPA) is a multisystem inflammatory disease characterized by the antineutrophil cytoplasmic antibody (ANCA)-associated necrotizing vasculitis of small vessels. To the varying degree GPA may be associated with thrombotic complications. Antiphospholipid syndrome (APS) is an autoimmune disorder where venous and arterial thrombosis dominate.

Aims: We assessed *in vitro* endogenous thrombin generation potential in GPA patients in comparison to APS in order to elucidate possible mechanisms responsible for thrombotic manifestations in this disease.

Methods: *In vitro* endogenous thrombin generation potential was assessed using a calibrated automated thrombogram (CAT, Thrombinoscope BV, Maastricht, the Netherlands) and thrombin-antithrombin complexes were determined using ELISA (TAT, Siemens, Germany). All test were performed in 8 patients with GPA, 7 patients with APS and 13 healthy controls. All APS patients received enoxaparine at the time of blood drawing.

Results: Peak thrombin generation was highest in GPA patients compared to APS and control subjects: 498.5 vs 183.2 and 298.1 nM (p=0.0006 and p< 0.0001, respectively). Similar observation was made for endogenous thrombin potential (ETP): 2322.6 vs 1511.3 and 1281.4 nM/min (p=0.009 and p=0.0002, respectively) and TAT concentrations: 11.15 vs 3.6 and 2.99 µg/L (p=0.06 and p=0.0045, respectively). The longest lag time and time to peak thrombin generation were observed in APS compared to GPA and controls: 10.6 vs 3.3 and 2.3 min (p=0.0005 and p< 0.0001, respectively) and 14.9 vs 5.3 and 4.8 min (p=0.0003 and p< 0.0001, respectively).

Conclusions: To our knowledge, this is the first study showing an increased thrombin generation potential in patients with GPA, which can at least in part explain the mechanism responsible for a higher tendency to thrombotic incidents in this disease. It may also indicate an unmet need in terms of GPA therapy strategy.

This study was supported by the Polish National Science Centre UMO-2015/17/B/NZ6/03459.

PB 1483 | Evaluation of Antiphospholipid Antibodies Level in Patients with Type 2 Diabetes mellitus in Enugu South East Nigeria

T. Nwagha, O. Agwu, O. Ibegbulam

University of Nigeria Nsukka/University of Nigeria Teaching Hospital Ituku Ozalla, Haematology, Ituku Ozalla, Nigeria

Background: Antiphospholipid antibodies (APLs) are implicated in ischaemic thrombotic phenomena. DM, in particular type 2 is often complicated with ischaemic thrombotic events. This study therefore seeks to investigate the role of APLs in the pathogenesis of thrombotic events in type 2 DM. The detection of APLs may predict the risk of developing ischaemic thrombotic events.

Aims: To detect and assess the prevalence of antiphospholipid antibodies (APLS) in subjects with type 2 diabetes mellitus (T2DM).

Methods: This is a consecutive cross sectional study of subjects with T2DM attending diabetic clinic of UNTH. A total of 210 subjects, age and sex matched, were randomly recruited; 70 with complicated T2DM,70 with uncomplicated T2DM and 70 healthy controls. Ethical

clearance was obtained from UNTH ethical committee. The lupus anticoagulant(LA) was assayed using commercial dilute Russells viper venom time (DRVVT) by Technoclone GMbH Austria,Vienna. IgG-B_2 GPI-dependent ACA was assayed using ELISA test kit (anticardiolipin IgG ELISA kit GWB-521211 by Genway Biotech San Diego USA), platelet count was done using haematology analyser-mythic 22.

Results: The prevalence of lupus anticoagulant (LA) showed a prevalence of 7.1%in complicated T2DM, 4.3%in uncomplicated T2DM and healthy control subjects respectively, while the prevalence of IgG-B_2 GPI-dependent ACA was 4.3% in all the groups. Analysis of variance (ANOVA) showed significant statistical difference in mean platelet count for complicted T2DM 208.5(52.30) and healthy control277.5(23.90), (F=77.993,P< 0.001). Pearsons statistical analysis showed significant correlation for APLS and platelet count in complicated T2DM subjects (r=0.316, p=0.008).

Conclusions: The study didnot find any causal or other casual association between T2DM and the occurrence of APLS positivity however APLS may be simply an aggravating factor for thrombosis in T2DM where the two consitions co exist in the same patient.

PB 1484 | Antiphospholipid Antibodies Related with Thrombosis

I. Nikoloska[1], R. Apostolovska[1], V. Neceva[1], S. Krstevska Balkanov[2], E. Velkova[3]

[1]*Institute of Transfusion Medicine, Skopje, Macedonia, the Former Yugoslav Republic of,* [2]*Department of Hematology Skopje, Skopje, Macedonia, the Former Yugoslav Republic of,* [3]*Institut of Transfusion Medicine, Skopje, Macedonia, the Former Yugoslav Republic of*

Background: Antiphospholipid antibodies (APA) are a family of antibodies directed against proteins bound to negatively charged phospholipids. The presence of APA is a biological marker for antiphospholipid syndrome (APS).

Aims: To evaluate the correlation between APA and thrombosis in patients with CVI (cerebrovascular infarct), AMI (acute myocardial infarct), and DVT (deep venous thrombosis) and pregnancy.

Methods: It is a retrospective study on patients from the Outpatient Department. We used micro ELISA kit to compare with commercial micro ELISA kits (QUANTA Lite TM b_2GP I).

Results: We made a clinical investigation for three classes of immunoglobulin - b_2GP I antibodies of 833 patients in four groups with different diagnoses. 218 were diagnosed with CVI, 232 with AMI, 123 with DVT and 260 were pregnant women. All patients have augmented concentration of all three classes of immunoglobulin and there is high correlation of APA and clinical manifestation of the different diseases. At highest risk were patients with DVT, because 30% had augmented IgG (59, 2 IU) and IgA (5, 63 IU) antibodies. The largest portion of them (32%) had augmented IgM (4, 47 IU).

From 218 patients with CVI - 19% had augmented concentration of IgG (40,91IU), but mostly augmented concentration were antibody from IgG classes.

From 232 patients with AIM -17% were with high concentration of IgM (3,56 IU) immunoglobulin classes the value of other classes of immunoglobulin were less.

From 260 pregnant women with pathological pregnancy, (29%) have augmented concentration of IgG (35, 76 IU). Concentration of IgG is the biggest.

Conclusions: CVI and pathological pregnant women were augmented concentration of IgG class,in patients with AMI and DVT were augmented concentration of IgM class Augmented concentration of all APA classes is in correlation with thrombosis, or a very elevated risk for thrombosis. It is very important to devise a protocol or algorithm to follow up and treat .

PB 1485 | Outcomes in Patients with Antiphospholipid Antibodies at a Tertiary Care Center

G. Abu Zeinah[1], C. Omendia[2], M.T. DeSancho[2]

[1]*New York Presbyterian Hospital/ Weill Cornell Medicine, New York, United States,* [2]*Weill Cornell Medicine, New York, United States*

Background: The diagnosis of "definite antiphospholipid syndrome" (APS) requires one clinical manifestation and confirmed laboratory criterion. Patients (pts) may be suspected to have APS without meeting strict criteria and others are referred for an incidental prolonged aPTT, or a falsely positive VDRL. Management of these patients remains a challenge.

Aims: To identify scenarios that prompt APS work-up and to evaluate the course of pts with aPLAs without strict clinical criteria for APS.

Methods: Retrospective review of records of pts referred to the Hematology clinic for APS evaluation from January 2006 to December 2016. We collected demographics, reason for referral, type of aPLs, clinical manifestations, treatment and outcomes. The institutional review board approved the study.

Results: Eighty-four pts were identified. The median age was 36 (range 19-85), and 63 (75%) were female. Reason for referral was identified for all pts (table 1).

TABLE 1 Reasons for referral for APS work-up

		Count
Sex	Female	63 (75%)
	Male	21 (25%)
Reason to work-up	Prolonged aptt	21 (25%)
	First or single event	37 (44%)
	Recurrent events	16 (20%)
	Other (SLE, positive VDRL, Family history, Mitral valve vegetation and neurologic manifestations)	10 (12%)

APS work-up was initiated in 20 (24%) pts for incidental prolonged aPTT, in 38 (45%) after a single APS-defining event, in 16 (19%) due to

>1 prior event, and in 12% for other reasons. The diagnoses of primary, secondary APS or CAPS were made in 51% of patients. Asymptomatic positivity for aPLs was found in 49%. Amongst the asymptomatic pts only 5/30 (17%) later diagnosed with APS, while the majority 23 (77%) remained asymptomatic during a median follow-up of 64 months. Amongst these 30 pts, 15 (50%) received no prophylaxis while other 15 were on long-term ASA, or ASA +/- LMWH during pregnancy. The 5 pts in this subgroup who were diagnosed with APS were all on thromboprophylaxis when the event occurred.

Conclusions: Incidental finding of aPLS, specifically aPTT prolongation in asymptomatic individuals appears to be associated with benign outcomes. Clinical prediction tools may be useful in selecting pts from this subgroup who may benefit from thromboprophylaxis.

PB 1486 | Recurrent Arteriovenous Fistula Thrombosis in Female Patient with Antiphospholipid Syndrome (APS), Factor V Leiden Mutation and MTHFR C677 T Mutation

B. Ceglarek[1], A.J. Sikorska[1], K. Bykowska[2], J.M. Teliga Czajkowska[3], J. Windyga[1,4]

[1]Institute of Hematology and Transfusion Medicine, Department of Disorders of Hemostasis and Internal Medicine, Warsaw, Poland, [2]Institute of Hematology and Transfusion Medicine, Department of Hemostasis and Metabolic Disorders, Warsaw, Poland, [3]Medical University of Warsaw, Department for Didactics in Obstetrics and Gynecology, Warsaw, Poland, [4]Institute of Hematology and Transfusion Medicine, Department of Hemostasis and Metabolic Disorders Department of Hemostasis and Metabolic Disorders, Warsaw, Poland

Background: Vascular access-related complications are an important cause of morbidity which accounts for 14-17% of hospitalizations for regular dialyses. Some studies imply anastomatic stenosis as the major predisposing factor for thrombotic complications. Some recent reports suggest antiphospholipid antibodies as the likely cause of such complications.

Aims: We describe the case of a 43 year old female with LA, factor V Leiden and MTHFR C 677T gene mutations who experienced 3 episodes of recurrent arteriovenous fistula thrombosis.

Methods: Her recurrent thrombotic complications were related to PTFE grafts. In the perioperative period she was monitored for anastomotic stenosis and evaluation of hypercoagulable states.

Results: The patient was hospitalized for 3 severe recurrent arteriovenous fistula thrombosis episodes following 22 years of hemodialysis and was treated with enoxoparin. No lymphadenopathy or hepatosplenomegaly were determined. Laboratory findings included: factor V Leiden and MTHFR C 677T gene mutations-heterozygotes, elevated level of plasma : homocysteine (43,9 umol/l ref. range 5-14umol/l), LDL and HDL cholesterol (298,6mg/dl) and triglicerydes (278,9ng/dl) and factor VIII activity-268.22%. Weak lupus anticoagulant was found, Therapy with enoxoparin at 1.0 mg/kg dose for 4/7 no hemodialysis days and 0.7mg/kg dose for 3/7 hemodialysis days s.c. daily dose resulted in clinical improvement: elimination of severe recurrent arteriovenous fistula thrombosis.

Conclusions: In the female patient with factor V Leiden and MTHFR C 677T gene mutations recurrent episodes of arteriovenous fistula thrombosis occurred only when lupus anticoagulant was recognized. Long-term enoxoparin therapy was effective in prevention subsequent thrombotic events.

PB 1487 | Comparison of Genetic Risk Score Models to Predict First Venous Thromboembolism in a Population-based Case-cohort. The Tromsø Study

S.K. Braekkan[1,2], I. Ortega[3], E. Smith[1,4], K.A. Frazer[1,4], S. Pich[3], J.-M. Soria[5], E. Salas[3], J.-B. Hansen[1,2]

[1]K.G. Jebsen Thrombosis Research and Expertise Center, University of Tromso, Tromso, Norway, [2]Division of Internal Medicine, University Hospital of North Norway, Tromso, Norway, [3]GenDiag.exe, Barcelona, Spain, [4]University of California San Diego, Department of Pediatrics and Rady's Children's Hospital, La Jolla, United States, [5]Unitat de Genómica de Malalties Complexes (UGMC), Institut de Recerca de l'Hospital de la Santa Creu i Sant Pau, IIB-Sant Pau, Barecelona, Spain

Background: The predictive capability of genetic risk score models for first venous thromboembolism (VTE) has not been extensively studied in prospective population-based studies.

Aims: To evaluate and compare the capability of three different genetic risk score models to predict first VTE in a case-cohort recruited from the general population.

Methods: Cases with a first VTE (n=660) and an age-weighted subcohort (n=1803) were sampled from three surveys of the Tromsø study (inclusions in 1994-95, 2001-02 and 2007-08, and follow-up until 31.12.2012). Single nucleotide polymorphisms (SNPs) previously implicated in VTE were genotyped in DNA isolated from whole blood (ABO: rs8176719, rs7853989, rs8176743 and rs8176750; F2: rs1799963; F5:rs6025, rs11823905 and rs118203906; F11: rs2036914; F12: rs1801020; F13: rs5985; FGG: rs2066865; SERPINC1: rs121909548; SERPINA10: rs2232698). Individual genetic risk scores were calculated using three genetic risk score models: *Factor V Leiden + Prothrombin (FVL+PT)*; *De Haan 5-SNP score(de Haan)* and *Thrombo inCode(TiC)*. The models were evaluated in terms of discrimination (C-statistics) and reclassification (continuous net reclassification improvement, NRI).

Results: The C-statistic was 0.551 (95% 0.539-0.573) for FVL+PT, 0.611 (95% 0.590-0.643) for TiC (p=0.0002 versus FVL+PT), and 0.594 (95% 0.573-0.634) for de Haan (p=0.017 versus FVL+PT). The NRIs considering FVL+PT as standard procedure were 0.67% (95% CI -1.78-2.42) for de Haan and 17.2% (95% CI 6.3-25.0) for TiC (p=0.0007).

Conclusions: Both the TiC and de Haan genetic risk score models performed better than FVL+PT, and overall, TiC appeared to be better than the de Haan score in predicting first VTE in a general population. Future research should focus on the predictive ability of these risk score models in high-risk situations of VTE and combine genetic risk scores with clinical information.

PB 1488 | Next-Generation DNA Sequencing Approach to Study Burden of Rare Variants in Loci Susceptible to Cerebral Vein Thrombosis

M.M. Gorski[1], H.G. de Haan[2], L.A. Lotta[1], I. Mancini[3], P. Bucciarelli[4], S.M. Passamonti[4], A. Cairo[1], E. Pappalardo[3], A. van Hylckama Vlieg[2], I. Martinelli[4], F.R. Rosendaal[2], F. Peyvandi[3,4]

[1]Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico and Fondazione Luigi Villa, Milan, Italy, [2]Leiden University Medical Center, Department of Clinical Epidemiology, Leiden, The Netherlands, [3]Università degli Studi di Milano, Department of Pathophysiology and Transplantation, Milan, Italy, [4]Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy

Background: Cerebral vein thrombosis (CVT) is a rare life-threatening disease annually affecting 4 adults/million. Genetic risk factors are deficiencies of the natural anticoagulant proteins antithrombin, protein C, protein S, factor V Leiden and prothrombin 20210A mutation. In 20% of patients, the cause of CVT remains unknown.

Aims: To identify genetic loci with an increased burden of rare variants as putative risk factors for CVT.

Methods: We investigated 171 Italian CVT patients and 298 healthy controls. Patients were selected using the following criteria: objective diagnosis of CVT, Caucasian decent, no active cancer. Targeted sequencing of the protein-coding regions of 737 candidate genes related to hemostasis and inflammation, 150 ancestry informative markers and 28 thrombosis-associated variants with a final target size of approximately 4 Mb was performed on Illumina HiSeq2000.

Results: Sequencing and data analysis revealed 13,161 rare variants (MAF< 1%) in 733 genes, of which 13,107 single nucleotide variants and 54 insertions/deletions. Gene-based association analysis of these rare variants using Burden test revealed 33 loci with $P< 0.05$, of which the top associations were found in the *ANO6* ($P=0.002$), *HABP2* ($P=0.004$) and *NQO1* ($P=0.004$). In the Sequence Kernel Association Test (SKAT), we identified 17 loci with $P< 0.05$. The top association was found in the *USF1* locus ($P=0.003$). However, none of these loci passed the 20% Bonferroni-Hochberg threshold for multiple testing. In addition, we performed separate analysis for *F5*, *F8* and *VWF* loci, for which the entire genomic region was sequenced. We found non-significant association of variants located in intron 2 ($P=0.02$) and introns 15-20 ($P=0.01$) of the *F8* locus with CVT.

Conclusions: Gene-based tests of association using Burden and SKAT did not yield definitive evidence for rare variants in loci related to hemostasis and inflammation associated with CVT.

PB 1489 | Impact of Age and Prothrombotic Genotypes on the Risk of Incident Venous Thromboembolism

B. Småbrekke[1], L. Balteskard Rinde[2], E.N. Smith[2,3], F.R. Rosendaal[2,4], S. Brækkan[2,5], K.A. Frazer[2,3], J.-B. Hansen[2,5]

[1]K.G. Jebsen TREC - Thrombosis Research and Expertise Center, Department of Clinical Medicine, UiT - The Arctic University of Norway, Tromsø, Norway, [2]K. G. Jebsen TREC - Thrombosis Research and Expertise Center, Department of Clinical Medicine, UiT - The Arctic University of Norway, Tromsø, Norway, [3]University of California, San Diego, La Jolla, California, United States, [4]Leiden University Medical Center, Department of Clinical Epidemiology, Leiden, The Netherlands, [5]Division of Internal Medicine, University Hospital of North Norway, Tromsø, Norway

Background: Venous thromboembolism (VTE) is a mulitcausal disease with genetic and acquired risk factors. The incidence increases exponentially with increasing age. It is, however, uncertain how prothrombotic genotypes affects the risk of VTE in different age-groups.

Aims: To investigate the age-specific effect of prothrombotic genotypes on the hazard ratio (HR), incidence rate difference (IRD) and population attributable risk (%PAR) of incident VTE in subjects below and above 60 years in a general population with a wide age range.

Methods: Cases with a first VTE (n=692) and an age-weighted randomly selected sub-cohort (n=2016) sampled from the Tromsø 4-6 surveys (1994-2012) were included. DNA isolated from blood was genotyped for ABO (rs8176719), FV-Leiden (rs6025), prothrombin 20210A (rs1799963) and KNG1 (rs710446). Cox regression models adjusted for age, sex and BMI were used to calculate age-stratified HR across gene variants. IRDs and %PAR were calculated.

Results: In subjects < 60 years of age, prothrombotic genotypes were generally associated with equal or higher HRs, equal or lower IRDs, and higher %PARs for VTE than in subjects ≥60 years of age. For ABO, HRs were 1.47 (95% CI 1.17-1.86) and 1.22 (95% CI 0.97-1.53), IRDs 0.57 (95% CI 0.29-0.85) and 0.43 (95% CI 0.04-0.82), and %PARs 26% and 11% in subjects below and above 60 years, respectively. For FV-Leiden, HRs were 2.20 (95% CI 1.66-2.92) and 2.21 (95% CI 1.60-3.07), IRDs 2.02 (95% CI 1.18-2.88) and 2.41 (95% CI 1.19-3.64), and %PARs 10% and 7% in subjects below and above 60 years, respectively.

Conclusions: Our findings show that, even though the relative risk of VTE according to prothrombotic genotypes is highest in the young, the absolute risk difference is similar in young and elderly due to a higher incidence of VTE in the elderly. The proportion of VTEs that can be attributed to the individual prothrombotic genotypes was, however, substantially higher in the young population.

PB 1490 | Joint Effects of Ischemic Stroke and Prothrombotic Genotypes on the Risk of Venous Thromboembolism. The Tromsø Study

L.B. Rinde[1], B. Småbrekke[1], E. Mathiesen[1,2], M.-L. Løchen[1,3], I. Njølstad[1,3], E.M. Hald[1,4], T. Wilsgaard[1,3], E. Smith[1,5], T. Solomon[5], K.A. Frazer[1,5], S. Brækkan[1,4], J.-B. Hansen[1,4]

[1]UiT The Arctic University of Norway, K. G. Jebsen -Thrombosis Research and Expertise Center (TREC), Department of Clinical Medicine, Tromsø, Norway, [2]UiT The Arctic University of Norway, Brain and Circulation Research Group, Department of Clinical Medicine, Tromsø, Norway, [3]UiT The Arctic University of Norway, Epidemiology of Chronic Diseases Research Group, Department of Community Medicine, Tromsø, Norway, [4]University Hospital of North Norway, Division of Internal Medicine, Tromsø, Norway, [5]University of California San Diego, Department of Pediatrics and Rady's Children's Hospital, San Diego, United States

Background: Previous studies have reported that patients with ischemic stroke are at transient increased risk of venous thromboembolism (VTE), particularly provoked VTE during the first 3 months following the stroke. Prothrombotic genotypes may augment the risk of VTE under conditions of high thrombosis risk related to the stroke (e.g. hospitalization, immobilization).

Aims: To investigate the joint effect of prothrombotic genotypes and ischemic stroke on risk of VTE in a case-cohort recruited from a general population.

Methods: Cases with incident VTE (n=660) and a randomly selected age-weighted sub-cohort (n=1803) were sampled from 3 surveys of the Tromsø study. DNA isolated from blood was genotyped for rs6025 (factor V Leiden [FVL]), rs1799963 (F2), rs8176719 (ABO), rs2066865 (FGG) and rs2036914 (F11). Cox regression models were used to calculate hazard ratio (HR) for incident VTE by individual- and categories of risk alleles (de Haan 5-SNP score; 0-1, 2, 3-4 and ≥5) and ischemic stroke.

Results: There were 264 incident ischemic strokes of which 60 had an incident VTE. The risk of VTE increased linearly across categories of total number of risk alleles in subjects without and with stroke (p-values < 0.001). A joint effect was observed for the total number of risk alleles and stroke on VTE risk. Subjects with ≥5 risk alleles without stroke had a 2.6-fold (HR 2.58, 95% CI 1.52-4.41) higher VTE risk, whereas subjects with ≥5 risk alleles and stroke had a 6.3-fold (HR 6.31, 95% CI 2.57-15.48) higher VTE risk compared to stroke-free subjects with 0-1 risk alleles. Similar effects were displayed for stroke combined with individual risk alleles of ABO, FVL and FGG on the risk of VTE.

Conclusions: We showed an allele-dependent risk of VTE in ischemic stroke and a joint effect of increasing number of risk alleles and stroke on VTE risk. Our findings may suggest that the number of risk alleles in the de Haan score should be considered when assessing thrombosis risk in patients with ischemic stroke.

PB 1491 | Joint Effects of Myocardial Infarction and Prothrombotic Genotypes on the Risk of Venous Thromboembolism. The Tromsø Study

L.B. Rinde[1], B. Småbrekke[1], E. Mathiesen[1,2], M.-L. Løchen[1,3], I. Njølstad[1,3], E.M. Hald[1,4], T. Wilsgaard[3], E. Smith[1,5], K.A. Frazer[1,5], S. Brækkan[1,4], J.-B. Hansen[1,4]

[1]UiT The Arctic University of Norway, K. G. Jebsen -Thrombosis Research and Expertise Center (TREC), Department of Clinical Medicine, Tromsø, Norway, [2]UiT The Arctic University of Norway, Brain and Circulation Research Group, Department of Clinical Medicine, Tromsø, Norway, [3]UiT The Arctic University of Norway, Epidemiology of Chronic Diseases Research Group, Department of Community Medicine, Tromsø, Norway, [4]University Hospital of North Norway, Division of Internal Medicine, Tromsø, Norway, [5]University of California San Diego, San Diego, United States

Background: Previous studies have shown that myocardial infarction (MI) is associated with a transient increased risk of venous thromboembolism (VTE). Some prothrombotic genotypes, associated with VTE risk, are also shown to increase the risk of arterial thrombosis. However, it is not known whether prothrombotic genotypes in subject with acute MI increases the future risk of VTE.

Aims: To investigate the joint effect of prothrombotic genotypes and MI on risk of VTE in a case-cohort recruited from a general population.

Methods: Cases with a first venous thromboembolism (n=643) and a randomly selected age-weighted cohort (n=1768) were sampled from 3 surveys of the Tromsø study (1994-95, 2001-02 and 2007-08). DNA isolated from blood was genotyped for rs6025 (F5, factor V Leiden [FVL]), rs1799963 (Prothrombin 20210A), rs8176719 (ABO), rs2066865 (FGG) and rs2036914 (F11). Cox regression models were used to calculate hazard ratios (HR) with 95% confidence interval (CI) for incident VTE by single and categories of risk alleles (de Haan 5-SNP score; 0-1, 2, 3 and ≥4 risk alleles) and MI.

Results: There were 272 incident MIs and of which 47 had an incident VTE. In subjects without MI, the risk of VTE increased linearly (p< 0.001) across increasing categories of risk alleles with HR 1.64 (95% CI 1.24-2.18) for subjects with ≥4 compared to those with 0-1 risk alleles. In contrast, there was no linear increase in VTE risk across categories of risk alleles in MI patients, and no joint effect of MI and increasing risk alleles on VTE risk. Among the individual SNPs, a joint effect on VTE risk was found for two risk alleles at FGG and MI (HR 4.87, 95% CI 2.30-10.32) compared to those with no risk alleles and no MI (HR 1.35, 95% CI 1.01-1.80).

Conclusions: Our findings showed that, except for FGG, no combined effects were observed for prothrombotic genotypes and MI on risk of VTE. This suggests that the number of risk alleles in the de Haan score should not be considered when assessing thrombosis risk in patients with MI.

PB 1492 | Population-based Incidence of Venous Thromboembolism in Oklahoma County, OK April 1, 2012-March 31, 2014

A. Wendelboe[1], J. Dvorak[1], M. McCumber[1], N. Feland[2], J. Campbell[1], K. Ding[1], D. Bratzler[3], N. Reyes[4], M. Beckman[4], G. Raskob[2]

[1]University of Oklahoma Health Sciences Center, Biostatistics and Epidemiology, Oklahoma City, United States, [2]University of Oklahoma Health Sciences Center, Oklahoma City, United States, [3]University of Oklahoma Health Sciences Center, Health Administration and Policy, Oklahoma City, United States, [4]Centers for Disease Control and Prevention, Division of Blood Disorders, Atlanta, United States

Background: Although published venous thromboembolism (VTE) incidences range from 1-2 per 1,000 population in the US, there is uncertainty in differentiating event-based from patient-based estimates, especially by race/ethnicity.

Aims: We aimed to estimate the incidence of patient-based and event-based VTE events in Oklahoma County by race/ethnicity.

Methods: In collaboration with the Centers for Disease Control and Prevention, we established a population-based surveillance system in Oklahoma County, OK for April 1, 2012-March 31, 2014 to estimate the incidence of VTE events. The Health Commissioner

TABLE 1 Age-adjusted overall and race/ethnicity-stratified patient-based VTE incidence rates (IR) per 1,000 by disease presentation

Demographic characteristic	VTE		DVT Only		PE±DVT	
	IR	95% CI	IR	95% CI	IR	95% CI
Age-Adjusted Overall	2.35	2.27, 2.43	1.47	1.41, 1.54	0.87	0.82, 0.92
Age-Adjusted Race/Ethnicity						
American Indian/Alaska Native	1.09	0.81, 1.37	0.69	0.47, 0.91	0.40	0.23, 0.57
Asian/Pacific Islander	0.63	0.40, 0.86	0.41	0.23, 0.60	0.22	0.08, 0.35
Black	3.14	2.90, 3.37	1.97	1.79, 2.16	1.16	1.02, 1.30
Hispanic	0.63	0.50, 0.77	0.39	0.29, 0.50	0.24	0.16, .032
White	2.57	2.46, 2.67	1.59	1.50, 1.67	0.98	0.92, 1.05

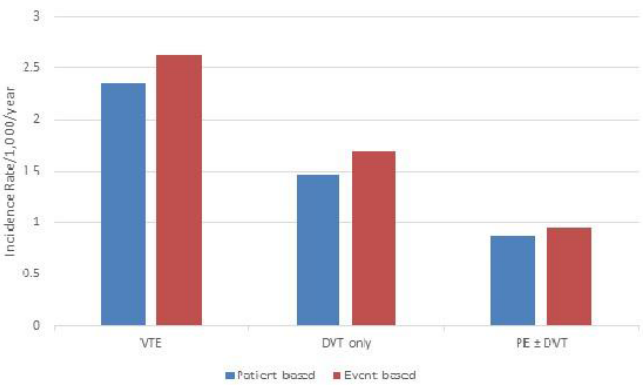

FIGURE 1 Age-adjusted IRs for VTE, DVT, and PE with or without DVT for patient-based and event-based events

made VTE reportable and delegated surveillance responsibilities to the University of Oklahoma, College of Public Health, making IRB unnecessary under Federal statute. Active surveillance involved reviewing imaging studies (e.g., chest computed tomography and compression ultrasound) from all inpatient and eligible outpatient facilities. Passive surveillance included obtaining hospital discharge data for VTE-related conditions. We merged datasets from active and passive methods and reviewed discordant patients. We used Census Bureau estimates to define the Oklahoma County population at risk. All crude and age-adjusted incidence rates (IR) are reported per 1,000 population per year with 95% confidence intervals (CI).

Results: We identified 3255 unique patients and 3650 VTE events. The crude and age-adjusted patient-based VTE IRs were 2.16 (2.08, 2.23) and 2.35 (2.27, 2.43), respectively. Overall age-adjusted event-based IR was 2.63 (2.54, 2.71). Overall and race-stratified patient-based IRs are reported in Table. The figure compares age-adjusted patient- and event-based IRs.

Conclusions: Patient-based VTE IR indicates a significant burden of VTE. Event-based IR estimates are 12% higher than patient-based. VTE IRs differ significantly by race/ethnicity.

PB 1493 | Differential Impact of Surgery as a Trigger Factor for Venous Thromboembolism in Patients with and without Prothrombotic Genotypes

E. Bjøri[1], H.S. Johnsen[1], J.-B. Hansen[1,2], S.K. Brækkan[1]

[1]*K.G.Jebsen Thrombosis Research and Expertise Center (TREC), Department of Clinical Medicine, UiT - The Arctic University of Norway, Tromsø, Norway,* [2]*Division of Internal Medicine, University Hospital of North Norway, Tromsø, Norway*

Background: Surgery is widely known to increase the risk of venous thromboembolism (VTE), but limited knowledge exists on the differential impact of surgery as a trigger for VTE in patients with and without prothrombotic genotypes.

Aims: To explore the influence of surgery as a trigger for VTE in patients with and without common prothrombotic genotypes, using a case-crossover design.

Methods: The study included 531 cancer-free patients with an objectively confirmed first-lifetime VTE. DNA isolated from whole blood was genotyped for rs6025 (FV Leiden) and rs8176719 (ABO). All surgical procedures were registered within each subject during the last 90-day period before the VTE diagnosis (risk period), and in four preceding 90-day comparison periods. To avoid potential carry-over effects, a 90-day washout period was implemented between the risk and control periods. Statistical analysis was performed using conditional logistic regression models.

Results: Overall, 85 (16%) patients underwent surgery in the risk period, and the OR of surgery was 11.4 (95% CI: 7.4-17.5). When we stratified the analysis according to blood type, the risk of VTE by surgery was 13-fold (OR: 13.1, 95% CI: 7.4-23.4) and 7.5-fold (OR: 7.5, 95% CI: 3.9-14.7) among patients with non-O and O, respectively. The OR of surgery in patients with and without FV Leiden, was 12.9 (95% CI: 2.7-62.5) and 10.9 (95% CI: 7.0-17.1), respectively.

Conclusions: Surgery is a major trigger factor for VTE independent of the presence of prothrombotic genotypes. However, surgery may have greater impact as a trigger for VTE in patients with non-O blood type, than those with blood type O.

PB 1494 | Hospitalization as a Trigger for Venous Thromboembolism - Results from a Large Population-based Case-crossover Study

E. Bjøri[1], H.S. Johnsen[1], J.-B. Hansen[1,2], S.K. Brækkan[1]

[1]K.G. Jebsen Thrombosis Research and Expertise Center (TREC), Department of Clinical Medicine, UiT - The Arctic University of Norway, Tromsø, Norway, [2]Division of Internal Medicine, University Hospital of North Norway, Tromsø, Norway

Background: Previous studies have reported that up to 50% of patients with venous thromboembolism (VTE) has undergone recent hospitalization. However, studies on the impact of hospitalization as a trigger factor for VTE are limited.

Aims: To investigate the impact of hospitalization as a trigger factor for VTE.

Methods: We conducted a population-based case-crossover study of 531 cancer-free subjects with an objectively confirmed first-lifetime VTE. All hospitalizations were registered within each subject during the last 90-day period before the VTE diagnosis (risk period), and in four preceding 90-day comparison periods. A 90-day washout period between the control- and risk periods was implemented to avoid potential carry-over effects. Conditional logistic regression was used to calculate odds ratios (OR) of VTE according to hospitalization.

Results: In total, 249 (47%) of the VTE-patients had been hospitalized in the risk period. The OR of hospitalization was 21.3 (95% CI: 15.1-30.0). Moreover, the OR increased according to the number of hospitalizations within each period from 18.7 (95% CI: 13.1-26.6) in those with one hospitalization to 45.7 (95% CI 23.7-87.9) in those with ≥2 hospitalizations. The OR of hospitalization for reasons other than surgery, was 19.7 (95% CI: 13.2-29.3), and increased from 18.1 (95% CI: 12.1-27.2) in those with one hospitalization to 37.2 (95% CI: 16.0-86.5) in those with ≥2 hospitalizations. Overall, the risk increased slightly with increasing number of total days spent in hospital (OR per one day increase: 1.08, 95% CI: 1.04-1.13), and the OR for hospitalization ≥5 days was 5.7 (95% CI: 2.4-13.7).

Conclusions: Hospitalization is a major trigger factor for VTE, regardless of the reason for hospitalization. The risk increases with increasing number of hospitalizations and length of hospital stay.

PB 1495 | The Rare Allele of the K858R Variant of Factor V Protects from the Risk of Venous Thrombosis but Only in Non Carriers of the FV Leiden Mutation

P.E. Morange[1], P. Suchon[1], A. Delluc[2], D. Smadja[3], R. Olaso[4], M. Germain[5], N. Saut[6], J.-F. Deleuze[4], D.A. Tregouët[5]

[1]Aix-Marseille Université, Marseille, France, [2]Université de Brest, Brest, France, [3]AP-HP, Paris, France, [4]Centre National de Génotypage, Institut de Génomique, Evry, France, [5]ICAN Institute for Cardiometabolism and Nutrition, Paris, France, [6]Hôpital de la Timone, Marseille, France

Background: Activated factor V (FV) is an important cofactor of the coagulation cascade, which acts mainly by facilitating the conversion of prothrombin to thrombin by activated factor X. Two genetic variations within the F5 gene are now known to influence the risk of venous thrombosis (VT): the FV Leiden (rs6025, R534Q), associated with a resistance to activated protein C (PCa), and the more recently identified polymorphism rs4524 (K858R). While the rare allele Q534 is associated with an increased risk of VT, the rare R858 allele is associated with a decreased risk.

Aims: However, no study has examined the cumulative impact of these two variations on VT risk.

Methods: In this work, we studied the association between these 2 genetic variations and the risk of VT in 4 French case-control samples gathering 4173 patients and 5970 controls.

Results: We first confirmed that the Q534 allele (frequency ~ 2%) is associated with an increased risk of VT (OR = 3.41, p = 6.97 10^{-41}) while the R858 (frequency ~ 26%) is associated with a decrease in risk (OR = 0.83, p = 6.11 10^{-6}). Since the linkage disequilibrium between these two variations was complete and negative (D ´= -1), only 3 haplotypes were observed (R534K858, R534R858 and Q534K858), the Q534R858 haplotype not being present in the French population. In addition, an haplotype analysis demonstrated that the mutation of FV Leiden has a dominant effect on that of R858 since individuals mutated for FV Leiden are at the same risk of disease whenever they are composite heterozygotes or not for the rare allele R858 (ie diplotype R534K858 / Q534K858 vs R534R858 / Q534K858) OR :3.37 vs 2.52 (p=0.15).

Conclusions: In conclusion, our study demonstrated that the allele R858 of F5 rs4524 variant protects from the risk of VT but that its presence does not reduce the risk of VT in individuals mutated for FV Leiden. The mechanisms involved in protection on VT deserve to be studied more precisely since this polymorphism is located at distance from the sites of cleavage of the PCa.

PB 1496 | Joint Effects of Prothrombotic Genotypes and Body Height on Risk of Venous Thromboembolism: The Tromsø Study

L.D. Horvei[1,2], S. Erin N.[3,4,5], K. Hindberg[1], K.A. Frazer[1,3], S.K. Brækkan[1,2], J.-B. Hansen[1,2]

[1]UiT - The Arctic University of Norway, KG Jebsen TREC, Department of Clinical Medicine, Tromsø, Norway, [2]University Hospital of North Norway, Division of Internal Medicine, Tromsø, Norway, [3]University of California San Diego, Department of Pediatrics and Rady`s Children`s Hospital, San Diego, United States, [4]University of California San Diego, Moores Cancer Center, San Diego, United States, [5]University of California San Diego, Institute for Genomic Medicine, San Diego, United States

Background: Previous studies have reported synergistic effects of several thrombosis-associated single nucleotide polymorphisms (SNPs) and obesity on the risk of venous thromboembolism (VTE). Tall stature is associated with increased VTE risk, but the joint effect of prothrombotic genotypes and tall stature on VTE risk is unknown.

Aims: To investigate the joint effects of prothrombotic genotypes and tall stature on the risk of VTE.

Methods: Cases with incident VTE (n=675) and a randomly selected age-weighted sub-cohort (n=1845) were sampled from 3 surveys of the Tromsø study. DNA isolated from blood was genotyped for rs6025 (factor V Leiden [FVL]), rs1799963 (F2), rs8176719 (ABO), rs2066865 (FGG) and rs2036914 (F11). Cox regression models were used to calculate age- and sex-adjusted hazard ratios (HR) for incident VTE by categories of risk alleles (de Haan 5-SNP score; 0-1, 2, 3-4 and ≥5) and body height, and for the combined exposures (tall stature and ≥5 risk alleles).
Results: There was a linear increase in VTE risk by increasing categories of body height where subjects in the upper quintile (≥ 178 cm) had 1.6-fold higher VTE risk (HR 1.60; 95% CI 1.19-2.16) than those in the two lowest quintiles (40 percentile,< 166 cm). The risk of VTE increased across categories of risk alleles (p< 0.001) to HR 2.14; 95% CI 1.45-3.16 in those with ≥ 5 compared to those with 0-1 risk alleles. Subjects with ≥5 risk alleles and tall stature (≥ 178 cm) had a 2.6 -fold (HR 2.57, 95% CI 1.15-5.76) higher VTE risk than subjects < 166 cm with 0-1 risk alleles. The relative excess risk caused by interaction (RERI) was -0.54, suggesting that the combined effect of the exposures was less than each factor alone.
Conclusions: We found that the combined effect of risk alleles and body height was essential similar to each factor alone. In contrast to obesity, tall stature and the number of risk alleles did not show a synergistic effect on the risk of VTE.

PB 1497 | Factor XIII Val34Leu Polymorphism Reduces Whole Blood Clot Weight in a Fibrinogen-dependent Manner

S. Kattula[1], Z. Bagoly[2], N.K. Tóth[2], L. Muszbek[2], A.S. Wolberg[1]

[1]University of North Carolina at Chapel Hill, Department of Pathology and Laboratory Medicine, Chapel Hill, United States, [2]University of Debrecen, Faculty of Medicine, Division of Clinical Laboratory Sciences, Debrecen, Hungary

Background: The common FXIII-A polymorphism, Val34Leu (V34L) results in 2.5-fold faster FXIII activation, but paradoxically, protection against venous thrombosis (VT). This effect is hypothesized to result from fibrinogen concentration-dependent changes in fibrin clot structure; at high (prothrombotic) fibrinogen levels, presence of the Leu allele decreases fibrin network density. Notably, during VT, both FXIII activity and fibrin network density are positively associated with red blood cell (RBC) retention in contracted clots and consequently, clot weight. The effect of the V34L polymorphism during whole blood clot formation has not been investigated.
Aims: Determine the effect of the FXIII-A V34L polymorphism on whole blood clot composition and weight.
Methods: Platelet-poor plasmas from 86 healthy human donors (40 FXIII-$A^{Val/Val}$, 28 FXIII-$A^{Val/Leu}$, and 18 FXIII-$A^{Leu/Leu}$) were reconstituted with freshly-isolated platelets and O-negative RBCs. Clotting was triggered with tissue factor and re-calcification, and contracted clots were weighed. Clot weights were correlated with donor sex, age, FXIII activity, presence of major FXIII polymorphisms, factor V Leiden mutation, and fibrinogen level.
Results: Univariate analysis showed mean clot weight did not differ between reconstituted whole blood clots generated from $FXIII^{Val/Val}$, $FXIII^{Val/Leu}$, or $FXIII^{Leu/Leu}$ plasmas. Neither sex or FXIII activity, nor presence of the FXIII-B intron K polymorphism or factor V Leiden mutation, correlated with whole blood clot weight for any genotype. In a multiple linear regression analysis adjusting for fibrinogen level and age, compared to $FXIII^{Val/Val}$ and $FXIII^{Val/Leu}$, $FXIII^{Leu/Leu}$ was significantly associated with reduced clot weight.
Conclusions: In plasmas with high fibrinogen levels, homozygous presence of the Leu34 allele results in the production of smaller whole blood clots. The V34L polymorphism may protect against VT by decreasing fibrin network density and RBC retention in clots and consequently, reducing thrombus size.

PB 1498 | Impact of Prothrombotic Genotypes on the Association Between Red Cell Distribution Width and Risk of Venous Thromboembolism. The Tromsø Study

J. Lappegård[1], T.S. Ellingsen[1], E. Smith[2], S.K. Brækkan[1,3], K.A. Frazer[2], J.-B. Hansen[1,3]

[1]K.G. Jebsen Thrombosis Research and Expertise Center (TREC), Department of Clinical Medicine, UiT The Arctic University of Norway, Tromsø, Norway, [2]University of California San Diego, Frazer Lab, San Diego, United States, [3]University Hospital of North Norway, Division of Internal Medicine, Tromsø, Norway

Background: Red cell distribution width (RDW), a measure of the variability in size of circulating erythrocytes, is associated with incident venous thromboembolism (VTE). The mechanism underlying the association remains unclear.
Aims: To investigate the joint effects of prothrombotic genotypes and RDW on the risk of VTE in a case-cohort recruited from the general population.
Methods: The study included 666 cases with a first-ever VTE and a randomly selected age-weighted sub-cohort (n=1937) sampled from the fourth survey of the Tromsø Study. Baseline characteristics, including RDW, were obtained in 1994/95, and subjects were followed until December 31st 2012. DNA isolated from blood was genotyped for rs6025 (factor V Leiden (FVL)), rs179963 (F2), rs8176719 (ABO), rs2066865 (FGG) and rs2036914 (F11). Cox regression models were used to calculate hazard ratios (HR) with 95% confidence intervals (CI) for incident VTE by categories of RDW and risk alleles (de Haan 5-SNP score; 0-1, 2, 3-4, and ≥5), and for the combined exposures (high RDW and ≥5 risk alleles).
Results: Subjects with RDW values above the 80th percentile had a 26% increased risk of VTE compared to those with RDW values below the 40th percentile (HR 1.26, 95% CI: 1.01-1.56). The risk of VTE increased across categories of risk alleles (p< 0.001) to HR 2.20 (95% CI 1.50-3.23) in those with ≥5 compared to those with 0-1 risk alleles. Subjects within the highest RDW quintile and with ≥5 risk alleles had a 3.9-fold (HR 3.95, 95% CI: 2.15-7.26) higher risk of VTE than those in the lowest RDW category and with ≤1 risk allele. The relative

excess risk caused by interaction (RERI) was 1.62, suggesting that the combined effect of the exposures was higher than the sum of the individual exposures.

Conclusions: We found that a high number of risk alleles in combination with a high RDW yielded a modest synergistic effect on the risk of VTE.

PB 1499 | Homozygous and Heterozygous Factor V Leiden Mutation (FVL) Is Associated with an Increased Risk for Recurrent Venous Thromboembolism (VTE) after First VTE

R.B. Zotz[1,2], R.E. Scharf[2], A. Gerhardt[2,3]

[1]*Institute for Laboratory Medicine, Blood Coagulation and Transfusion Medicine (LBT), Duesseldorf, Germany,* [2]*Heinrich Heine University Medical Center, Department of Hemostasis, Hemotherapy and Transfusion Medicine, Duesseldorf, Germany,* [3]*Blutgerinnung Ulm, Department of Hemostasis and Transfusion Medicine, Ulm, Germany*

Background: A better risk stratification for recurrent VTE in patients with a first episode of VTE is urgently needed.

Aims: To evaluate the relative risk (hazard ratio, HR) of spontaneous recurrent VTE associated with FVL and prothrombin G20210A mutation (PTM).

Methods: This is a retrospective study covering more than 20 years after a first VTE event in a group of 1,440 patients with first VTE. For statistical analysis, we used a multivariate proportional hazard model adjusted for age, sex, and type of first VTE (spontaneous vs. non-spontaneous).

Results: The adjusted hazard ratios for recurrent spontaneous VTE were as follows: PTM heterozygous 1.30 (95% CI 0.81-2.1), FVL heterozygous 1.33 (95% CI 1.03-1.74), FVL homozygous 2.27 (95% CI 1.19-4.36), combined heterozygous FVL and PTM 1.40 (95% CI 0.64-3.06). Detailed results on absolute risks per year stratified according to spontaneous and non-spontaneous first VTE will be presented.

Conclusions: In contrast to previous smaller studies we now could demonstrate a significantly increased risk of VTE recurrence associated with heterozygous and homozygous FVL. This is in opposition to previous guideline statements. Our results may influence future treatment recommendations.

PB 1500 | Genotype-phenotype Correlations in a Large Cohort of Subjects with Suspicion of Inherited Protein C or Protein S Deficiency

C. Geisen[1], L. Boeff[1], S. Koerber[1], F. Bergmann[2], A. Czwalinna[2], C. Heller[3], M. Krause[4], W. Miesbach[5], E. Seifried[1]

[1]*Institute of Transfusion Medicine and Immunohematology, German Red Cross Blood Center, University Hospital Frankfurt, Molecular Hemostasis, Frankfurt / Main, Germany,* [2]*MVZ wagnerstibbe, Hannover, Germany,* [3]*University Hospital Frankfurt, Department of Pediatric Medicine, Frankfurt / Main, Germany,* [4]*Deutsche Klinik für Diagnostik, Helios Klinik, Division of Hemostaseology, Wiesbaden, Germany,* [5]*University Hospital Frankfurt, Medical Clinic II, Frankfurt / Main, Germany*

Background: Hereditary deficiencies of natural anticoagulant proteins including protein C (PC) and protein S (PS) are known causes of inherited thrombophilia.

Aims: We aimed to assess the performance of genetic analysis of *PROC* and *PROS1* with relation to PC and PS assay data.

Methods: In a retrospective cohort study we genotyped 314 subjects with PC and 460 subjects with PS deficiency. Mutations were detected by direct sequencing of the coding regions including splice sites of *PROC* and *PROS1*. We performed MLPA in order to reveal large copy number variations. The characterisation of the variants was performed by in silico evaluation tools, including Polyhen-2, SIFT, multiple sequence alignment, splicing prediction and molecular graphic imaging. PC and PS assay data were provided by external centres. Statistic methods of logistic regression and ROC curve analysis were applied to evaluate the correlation between laboratory status and inherited deficiencies and to propose cut-off values for the indication of genetic testing.

Results: 101 (36 previously unknown) different mutations were identified in 226 subjects of the PC and 81 (36 previously unknown) in 197 subjects of the PS deficiency cohort, correlating with an overall mutation detection rate (MDR) for *PROC* of 72% and *PROS1* of 43%, respectively. MDR correlated negatively with PC and PS levels. In addition, we observed a clear correlation between laboratory data and the type of mutation. For PC activity we determined a cut-off value of 61% with a sensitivity of 81% and a specificity of 64% for revealing a causal gene mutation. Within the PS cohort factor V Leiden (FVL) showed a significant influence on MDR. For individuals without FVL the proposed cut-off value for PS activity is 45% associated with a sensitivity of 70% and a specificity of 65%.

Conclusions: Our findings suggest that in patients with PC activity below 61% and PS levels (activity or free antigen) below 45% genetic analysis represents a useful diagnostic tool to confirm inherited PC and PS deficiency.

PB 1501 | Identification and Characterization of a Novel Mutation at the C-terminal Region of Antithrombin Leading to *in vivo* Polymerization and Venous Thrombosis

T. Bhakuni[1], A. Sharma[2], M. Mahapatra[2], R. Saxena[2], M.A. Jairajpuri[1]

[1]*Jamia Millia Islamia, Department of Biosciences, New Delhi, India,* [2]*All India Institute of Medical Sciences, Department of Haematology, New Delhi, India*

Background: Antithrombin (AT) belongs to serpin superfamily and identification of natural variants in AT improves our understanding of the molecular mechanisms involved in its interaction with target proteases and heparin.

Aims: Identification and characterization of genetic basis of low AT levels.

Methods: DNA sequencing was used for identification of genetic variations in AT deficient Indian DVT patients followed by purification

of wild type and variant AT using hi-trap heparin affinity chromatography. Variant AT was characterized using *in silico* studies and techniques like electrophoretic mobility, fluorescence, circular-dichroism (CD) and transmission electron microscopy (TEM). Informed consent was obtained from the patients.

Results: In an Indian patient with type II AT deficiency (activity: 55%, antigen: 82%), a novel point mutation, g.13397A>G (Ala427Thr) was identified. Previously reported polymorphisms in Indian DVT patients like rs2227589, *Dde*I and C-4X were found to be absent. High molecular weight bands on SDS-PAGE elution profile and reduced fluorescence emission intensities of both tryptophan and bis-ANS were observed for Ala427Thr. Far-UV CD and thermal denaturation studies showed increased α-helical content, decreased β-strands and a high melting temperature (T_m= 77.06 ± 0.15°C) indicating variation in secondary structure and a change in conformation. Visualization of wild type and Ala427Thr AT through TEM incubated at 60°C for 0, 30 and 90 minutes showed the presence of polymeric variant AT even at 0 minute which were otherwise absent from the wild type AT. ASA analysis of variant AT revealed decreased stability and post mutation, Ala427Thr formed additional hydrogen bonds with Asp72 and Asp74 in addition to Asn75.

Conclusions: Substitutions at tail of AT have global effects, altering the conformation and affecting functions elsewhere. Study of AT mutations in Indian patients will help not only in mechanistic understanding of AT but also in diagnosis and treatment of thrombotic patients in India.

PB 1502 | Genetic Characterization of Antithrombin, Protein C and Protein S Deficiencies in Slavic Thromboembolic Patients

E. Wypasek[1,2], J. Corral[3], M. Alhenc-Gelas[4], D.P. Potaczek[1,5], T. Iwaniec[6], W. Sydor[6], M. Celińska-Lowenhoff[6], J. Musiał[6], A. Undas[1,2]

[1]John Paul II Hospital, Cracow, Poland, [2]Jagiellonian University School of Medicine, Cracow, Poland, [3]Universidad de Murcia, Murcia, Spain, [4]AP-HP Hôpital Européen G. Pompidou, Paris, France, [5]Philipps-Universität, Marburg, Institute of Laboratory Medicine and Pathobiochemistry, Molecular Diagnostics, Marburg, Germany, [6]Jagiellonian University Medical College, Department of Internal Medicine, Cracow, Poland

Background: Inherited deficiencies of natural anticoagulants such as antithrombin (AT), protein C (PC) and protein S (PS), with the prevalence of 0.02-0.17%, 0.2-0.3% and 0.5%, respectively, in the general population of Europe, are associated with an increased risk of thromboembolic events.

Aims: We sought to assess the prevalence of *SERPINC1*, *PROC* and *PROS1* gene mutations and their impact on the thromboembolic manifestations in Central-Eastern European patients with natural anticoagulants deficiencies.

Methods: A total of 91 unrelated patients aged 40.1±13.6 years with AT (n=39), PC (n=26) and PS (n=26) deficiencies were screened for mutations by Sanger sequencing and multiplex ligation-dependent probe amplification.

Results: The overall mutation detection rate for *SERPINC1* and *PROC* genes was 97 and 92%, respectively. For AT and PC activities close to the normal range (83 and 70%, respectively), the mutation detection rate remained high (66 and 90%, respectively). For *PROS1* gene, mutation detection rate reached 90% only when the PS activities were below 55%. Above this value the mutation detection rate decreased to 40%.Missense mutations accounted for 83% of all mutations in *PROS1* gene and up to 56% in the *SERPINC1* and *PROC* genes. The profile of nonsense and splice-site mutations was 8-23% and 8-15%, respectively, for all three genes. Small deletions were present in *SERPINC1* and *PROC* genes (7% for both) but gross deletions only in *SERPINC1* gene (11%). Approximately one-third of mutations reported here are novel. Missense mutations occurred more frequently in patients with venous thrombosis compared to those with arterial thrombosis (30 vs. 10%, p=0.04).

Conclusions: To our knowledge, this is the largest cohort of Slavic patients deficient in natural anticoagulants evaluated for genetic background. Selection of patients for genetic screening of inherited thrombophilia, including mainly PS deficiency, should be based on activity of this protein.

PB 1503 | The Association between Genetic Variants in *Cholesteryl* Ester Transfer Protein (CETP) Gene and Hemostatic Factor Levels in Healthy Controls and the Associated Risk of a First Venous Thrombosis

R. Li-Gao, S.C. Cannegieter, F.R. Rosendaal, A. van Hylckama Vlieg

Leiden University Medical Center, Clinical Epidemiology, Leiden, The Netherlands

Background: Cholesteryl ester transfer protein (CETP) plays an important role in lipoprotein metabolism. Previous studies have suggested that the *CETPTaqI* B1/B2 allele is associated with the risk of venous thrombosis (VT), and the potential mechanism of CETP procoagulant activity was related to the direct binding of CETP to FXa.

Aims: To investigate the association between genetic variants located in *CETP* gene and haemostatic factors in healthy individuals and to assess the associated risk of a first event of VT with these *CETP* genetic variants.

Methods: Analyses were performed in the Multiple Environmental and Genetic Assessment of Risk Factors for Venous Thrombosis (MEGA) case-control study, with ethical approval obtained. Three independent SNPs identified from a large genome-wide association study (GWAS) in the Netherlands Epidemiology of Obesity (NEO) study (unpublished data) explain >16% of the variance of serum CETP concentrations. CETP unweighted/weighted genetic risk scores (GRS) were derived from these three SNPs to reflect genetically determined CETP concentrations. The association between CETP and 22 haemostatic factors (pro-/anti-coagulant and fibrinolytic factors) was assessed by linear regression from an additive model in controls

only (n=2,853), adjusted for age and sex. 3,960 VT cases and 4,787 controls were included to investigate the association between genetically determined CETP concentrations and VT risk by logistic regression analysis.

Results: In the controls (median age, 50 years; 52.8% women), both unweighted and weighted GRSs indicated that only factor VII activity was (negatively) associated with genetically determined CETP concentrations (weighted GRS β -2.81%, 95% CI: -5.44 to -0.17). However, no association was observed with the risk of a first VT.

Conclusions: Genetically determined CETP concentrations showed a weak (negative) association to factor VII activity. However, this did not affect the associated risk of a first VT.

PB 1504 | Molecular Genetic Diagnostics of Protein S and Protein C Deficiency

O.H. Larsen[1,2], A.D. Kjærgaard[2], A.-M. Hvas[2], P.H. Nissen[2]

[1]Aalborg University Hospital, Department of Clinical Biochemistry, Aalborg, Denmark, [2]Aarhus University Hospital, Centre for Haemophilia and Thrombosis, Department of Clinical Biochemistry, Aarhus, Denmark

Background: Deficiency of the natural anticoagulants protein S or protein C are important risk factors for venous thromboembolism. Genetic testing for protein S and C variants may improve diagnostics of protein S and C deficiency.

Aims: To investigate for disease-causing variants in the *PROS1* or *PROC* genes in patients with suspected inherited protein S or protein C deficiency and their first-degree relatives.

Methods: The study was approved by a recognized medical ethics committee. Following informed consent, patients with suspected protein S or C deficiency based on specialised coagulation tests and their first-degree relatives were investigated. In total, 83 individuals from 40 families with protein S deficiency and 46 individuals from 17 families with protein C deficiency were genotyped using direct sequencing of exons and flanking intronic regions of the *PROS1* or *PROC* genes. Patient samples with no causative point mutation were further investigated using Multiplex ligation-dependent probe amplification (MLPA) in order to identify large structural rearrangements. History of thrombosis and use of anticoagulation was recorded.

Results: Variants likely to be disease-causing were identified in 62% of the protein S deficiency families whereas variants were discovered in more than 64% of the families with protein C deficiency. The findings included several not previously reported variants such as the nonsense variants in *PROS1*: c.1467_1468delA; p.(Ile490Leufs*6) and c.1351C>T; p.Arg451* and the missense variant *PROC*: c.503T>C; p.Leu168Pro.

Conclusions: Genetic testing provides a useful tool to validate inherited protein S or protein C deficiencies and facilitate diagnostics in affected families. Although no causative variants could be identified in a significant number of families, we propose genetic testing in all patients when specialised coagulation tests indicate protein S or C deficiency.

PB 1505 | GPX1 Pro198LEU Polymorphism as a Risk Factor for Venous Thromboembolism in Young Men from North-Western Russia

Z. Sidorova[1], S. Svitina[1], L. Aleksanyan[1], V. Shmeleva[2], V. Kargin[3], V. Soldatenkov[3], S. Kapustin[1], A. Chechetkin[4]

[1]Russian Research Institute of Hematology and Transfusiology of FMBA, Laboratory of Biochemestry, St. Petersburg, Russian Federation, [2]Russian Research Institute of Hematology and Transfusiology of FMBA, Coagulation Laboratory, St. Petersburg, Russian Federation, [3]Russian Research Institute of Hematology and Transfusiology of FMBA, Department of Surgery, St. Petersburg, Russian Federation, [4]Russian Research Institute of Hematology and Transfusiology of FMBA, St. Petersburg, Russian Federation

Background: Oxidative stress is often involved in pathogenesis of endothelial dysfunction which, in turn, could be frequently seen in patients with thrombotic complications, in particular, venous thromboembolism (VT). Glutathione peroxidase encoded by GPX1 gene has an important role in prevention of oxidative damage since it catalyzes the reduction of organic hydroperoxides and hydrogen peroxide by glutathione. GPX1 Pro198Leu polymorphism may affect enzymatic activity and, thus, the risk of VT development.

Aims: To evaluate the role of GPX1 Pro198Leu polymorphism in pathogenesis of VT in young men from North-Western Russia (NWR).

Methods: Retrospective study involved 172 men suffered from episode(s) of VT before 45 years old (mean age 33.7±8.4 years) and 129 age-matched healthy men (HM). All individuals originated from NWR. GPX1 Pro198Leu polymorphism was discriminated by PCR-RFLP technique. The differences in genotype distributions between the groups were estimated by Fisher`s exact test. Odds ratios (OR), their 95% confidence intervals (CI) and p-values were calculated by using GraphPad Prism software.

Results: Homozygosity for the GPX1 Leu198 variant was more frequently seen in VT patients compared to HM (15.7% vs. 4.7%; OR=3.8; 95%CI: 1.5-9.5; p=0.003). In young men with isolated deep-vein thrombosis (DVT), DVT complicated by pulmonary embolism (PE) or isolated PE GPX1 198 Leu/Leu genotype was seen in 16.0%, 15.4% and 16.0% of cases, respectively. In the group of 126 VT patients having neither FV Leiden nor FII G20210A mutation, the GPX1 198 Leu/Leu genotype was present in 21 (16.7%) cases (OR=4.1; 95%CI: 1.6-10.5; p=0.002, compared to HM). Moreover, the frequency of homozygous 198 Leu/Leu variant was almost 2-fold higher in men with recurrent VT (20.9% vs. 11.6% in patients with non-recurrent VTE; OR=2.0; 95%CI: 0.9-4.8; p=0.12).

Conclusions: We suggest that GPX1 Pro198Leu polymorphism is an independent risk factor for VT in young men from North-Western Russia and could have an impact on recurrence of disease.

PB 1506 | Genetic Association Study between Candidate SNPs and Brazilian Patients with Venous Thromboembolism (VTE)

A.V.C. Romano[1], J.L. Cunha[1], A. Barnabé[1], L.F.B. Sckayer[1], R. Secolin[2], Í. Lopes-Cendes[2], N. Wolosker[3], J.C.C. Guerra[3], T.B. Gadelha[4], E.V. de Paula[1], F.A. Orsi[1], J.M. Annichino-Bizzacchi[1]

[1]*University of Campinas-Unicamp, Hematology and Hemotherapy Center, Campinas, Brazil,* [2]*University of Campinas-Unicamp, Faculty of Medical Sciences, Campinas, Brazil,* [3]*Israelite Hospital Albert Einstein, Clinical Pathology, São Paulo, Brazil,* [4]*Federal University of Rio de Janeiro, Hematology, Rio de Janeiro, Brazil*

Background: VTE is a multifactorial disease, caused by the interaction of genetic and environmental factors. Genome-wide association studies (GWAS) have been performed in the last years, and genetic variants associated to VTE susceptibility were identified mainly in Caucasian populations.

Aims: The aim of this study was to validate 29 SNPs associated to VTE in a Brazilian population.

Methods: The VTE group included 436 patients with a history of unprovoked VTE without acquired or inherited thrombophilia. The control group included 430 healthy individuals. This sample presented 94.76% of statistical power to detect genetic association, estimated by GPOWER v.3.1 software. Among both groups, we genotyped 29 SNPs within 22 genes related to VTE and additional 90 SNPs to evaluate population structure between cases and controls. We estimated allele frequency and Hardy-Weinberg disequilibrium of the SNPs by PLINK v.1.07 software. Association analysis and odds ratio estimation were performed by logistic regression in PLINK software either. The statistical results were adjusted by Bonferroni correction to avoid bias due to multiple comparisons. In order to evaluate whether VTE and control sample present similar genetic structure, we performed the Analysis of Molecular Variance (AMOVA) by ARLEQUIN v3.5.1.2 software

Results: AMOVA results showed a Fst < 0.05 over all loci, and a between-groups variance component of 0.0%, indicating that the two groups did not present differences in genetic structure between each other. Among the 29 SNPs genotyped in association study, after Bonferroni correction of logistic regression none was found associated with VTE ($p>0.05$ in all SNPs).

Conclusions: We compared VTE and control populations, who presented genetically similar, and found different results in SNPs association study with VTE when compared to literature. Brazilian´s population genetic heterogeneity probably explains this result, highlighting the influence of population´s genetic structure in association studies.

PB 1507 | Absolute Quantification of Jak2 V617F in Patients with Splanchnic Venous Thrombosis by Droplet Digital PCR

D. Colaizzo[1], M.A. Guardascione[2], G. Favuzzi[1], F. Cappucci[1], L. Fischetti[1], G. Vecchione[1], M. Margaglione[3], E. Grandone[1]

[1]*IRCCS Casa Sollievo della Sofferenza, Thrombosis and Haemostasis Unit, San Giovanni Rotondo, Italy,* [2]*Hospital ‚A. Cardarelli', Gastroenteroly Unit, Naple, Italy,* [3]*Univeristy of Foggia, Medical Genetics, Foggia, Italy*

Background: Myeloproliferative disorders (MPDs) represent a risk factor for thrombosis in the portal, mesenteric, and hepatic districts (SVT). The acquired somatic V617F mutation on Janus kinase 2 (JAK2), containing the G-to-T transvertion in exon 14, can occur in MPD patients, and is a risk factor for SVT independently of the presence of overt MPDs.

Aims: This study was aimed to test the utility and efficiency of JAK2 V617F quantification in SVT patients tested by Droplet Digital PCR (ddPCR).

Methods: A cohort of 132 patients with documented SVT, prospectively enrolled at our center between 1997 and 2015, were re-evaluated for JAK2 V617F mutation by using ddPCR to absolutely quantify the mutate allele in each patient.

Results: The JAK2 V617F mutation was detected in 42 out of 132 patients (31.8%). In all patients the mutation was in heterozygous state. The ddPCR allowed us to quantify the mutate allele in all the 42 positive patients at the diagnosis and during the clinical follow-up. It was possible to evaluate JAK2 V617F mutation changes over time in each positive patient and to uncover the mutation at low percentage in patients negative at the diagnosis.

Conclusions: The ddPCR is a suitable, precise, and sensitive method for absolute quantification of the JAK 2 V617F mutation in patients with SVT, and may be useful for early disease detection and clinical management of patients without the need for a standard curve or comparison to a reference gene
(limit of detention was 0.01% for both qPCR and ddPCR).

PB 1508 | Screening of Deletions in Protein S Deficient Families

T. Fenclova[1], D. Provaznikova[1], M. Matyskova[2], F. Marecek[1], I. Hrachovinova[1]

[1]*Institute of Hematology and Blood Transfusion, National Reference Laboratory for Hemostasis, Prague, Czech Republic,* [2]*University Hospital Brno, Clinical Hematology, Brno, Czech Republic*

Background: Inherited protein S (PS) deficiency is known to be associated with increased thrombotic risk in deficient families. This autosomally dominant disorder is usually caused by mutations in the *PROS1* gene, but there is an increasing evidence of large deletions/duplications, which are relatively common in point mutation negative PS deficient families.

Aims: The aim of our study was to examine variations in the *PROS1* gene in 13 unrelated Czech families with manifested PS deficiency and a history of thrombosis.

Methods: We used the direct sequencing of all exons with intron flanking regions of *PROS1* (Castoldi E., 2010) to search for point mutations and other variations. We also used multiplex ligation-dependent probe amplification (MLPA) (MRC HOLLAND, NL) to check for deletions/duplications. All index patients from 13 families were screened for protein S gene mutation both by direct sequencing and by MLPA.
Results: We identified one large deletion spanning the whole gene and we also found 12 different point mutations (9 missense, 2 single nucleotide insertions and 1 splice site mutation). Two of the unrelated families had the same mutation. We identified six novel mutations. We also found possible deletion in exon 2 by MLPA in one patient. However, this was later explained by a point mutation present at the ligation site of the MLPA probe for exon 2, resulting in false positive deletion signal. All patients except two were heterozygous for one mutation. Second mutation in these two families is under causality screening.
Conclusions: We found mutations in all protein S deficient families, six of them were novel. One large deletion (1 of 13) was proven by MLPA. Although MLPA is a useful tool for the detection of large deletions or duplications, it is susceptible to error. Patients who have positive deletion output should be checked by sequencing. Moreover, the possibility of two or more mutations in a single patient should be considered in the mutation screening schedule.

PB 1509 | microRNA gene (miR -146aC>G, miR -149T>C, miR -196a2T>C and miR -499A>G) Polymorphisms in Korean Patients with Venous Thromboembolism

H.W. Kim[1,2], J.O. Kim[1,2], H.J. An[1,2], K.A. Kim[1,2], E.S. Kim[1,2], J.H. Sakong[1,2], H.A. Lee[1,2], C.S. Ryu[1,2], O.J. Kim[3], H.-J. Yoon[4], N.K. Kim[1,2]

[1]CHA University, Department of Biomedical Science, College of Life Science, Seongnam, Korea, Republic of, [2]CHA University, Institute for Clinical Research, CHA Bundang Medical Center, Seongnam, Korea, Republic of, [3]CHA University, Department of Internal Medicine, School of Medicine, Seongnam, Korea, Republic of, [4]Kyunghee University, Department of Internal Medicine, College of Medicine, Seoul, Korea, Republic of

Background: MicroRNAs are well known to short non-coding RNAs that play a role in post-transcriptional regulation of gene expression. Recent studies were reported microRNAs are potential biomarkers in different cardiovascular diseases. So, we focused that Venous thromboembolism (VTE), one of the cardiovascular diseases, may be associated with microRNA gene.
Aims: Aim of this study was four microRNA polymorphisms that miR -146aC>G, -149T>C, -196a2T>C and -499A>G association with venous thromboembolism susceptibility.
Methods: We investigated the associations with microRNA polymorphisms in 203 venous thromboembolism patients and 300 controls. The patients were enrolled between March 1999 and February 2010 at the Department of CHA Bundang Medical Center (Seongnam, South Korea). DNA was extracted from leukocytes using a G-DEX™ II Genomic DNA Extraction kit (Intron Biotechnology, Seongnam, Korea) according to the manufacturer´s instructions.
Results: Genotyping was performed with polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) analysis. The haplotype combination analysis of microRNA was shown that microRNA (miR -146a, miR -149, miR -196a2, miR -499) in G-T-C-G haplotypes (OR, 51.68; 95% CI, 3.028-881.9, P=0.0001) and microRNA (miR -146a, miR -196a2, miR -499) in G-T-A haplotypes (OR, 1.750; 95% CI, 1.194-2.566, P=0.005) were increased risk of venous thromboembolism. Whereas microRNA (miR -146a, miR -196a2, miR -499) in C-C-G haplotypes (OR, 0.318; 95% CI, 0.129-0.784, P=0.011) were decreased risk of venous thromboembolism. Especially, miR -196a2T>C in male (TC: AOR, 0.498; 95% CI, 0.260-0.956, P=0.036; TC+CC: AOR, 0.528; 95% CI, 0.290-0.961, P=0.037) was significantly associated with primary venous thromboembolism.
Conclusions: Our finding suggests that miR -196a2T>C polymorphism associated with venous thromboembolism susceptibility.

PB 1510 | The Association of Arg485Lys Polymorphism with FV Levels, APC Ratio and its Role in DVT: A Study from India

A. Sharma[1], T. Bhakuni[2], A. Biswas[3], R. Ranjan[1], K. Kishor[1], J. Oldenburg[4], R. Saxena[1]

[1]All India Institute of Medical Sciences, Hematology, New Delhi, India, [2]Jamia Millia Islamia, Department of Biosciences, New Delhi, India, [3]Institute of Experimental Haematology and Transfusion Medicine, University Clinic Bonn, Bonn, Germany, [4]Institute of Experimental Hematology and Transfusion Medicine, Bonn, Germany

Background: Arg485Lys polymorphism, located in A2 domain of FV, has been associated with increased risk of thrombosis. However, association of this polymorphism with FV levels and APC ratio is controversial and its role in DVT is not fully elucidated in India.
Aims: To study the effect of Arg485Lys polymorphism on FV levels, APC ratio and its association with DVT in India.
Methods: 75 Doppler proven DVT patients and 75 age and sex matched healthy controls were studied. FV Leiden and Arg485Lys were detected by PCR-RFLP and allele specific PCR respectively. Patients with acquired factors like malignancy, pregnancy and acute thrombotic phase were excluded. FV activity levels were determined using FV deficient plasma kits. APC ratio was calculated by dividing of clotting time in the presence and absence of APC.
Results: FV Leiden was seen in 13.3% (10/75) of patients and absent in controls. 20 (26.6%) patients and 8 (10.6%) controls carried Arg485Lys polymorphism and difference was statistically significant (p=0.024, χ^2=6.35). FV levels in patients and controls were significantly reduced in carriers of 485Lys than noncarriers (Patients: carriers 97.7±11.0%, noncarriers 107.4±13.4%, p=0.008, Controls: carriers 95.2±8.0%, noncarriers 103.1±10.9%, p=0.043). As compared to APC ratio in noncarriers of 485Lys (2.94±0.468), values were lower in carriers of 485Lys in patients (2.68±0.460, p=0.042) and controls (2.71±0.290, p=0.192). 5 patients carried both FV Leiden and Arg485Lys polymorphism. APC ratio was further reduced in carriers

of both FV Leiden and Arg485Lys (1.52±0.178) than FV Leiden alone (1.82 ±0.198, p=0.014).

Conclusions: Carriership of the 485Lys allele reduces FV levels and APC ratio. In combination with FV Leiden, it significantly decreases APC ratio as compared to FV Leiden alone. Significantly higher prevalence of this polymorphism in patients is suggestive of its association with DVT, however study on larger sample size is required to confirm these findings.

PB 1511 | A Novel Splice Site Mutation Leading to AT Deficiency

D. Provaznikova[1], A. Radovska[1], M. Simonikova[1], N. Rytikova[2], Z. Novak[3], I. Hrachovinova[1]

[1]*Institute of Hematology and Blood Transfusion, NRL for Disorders in Hemostasis, Prague, Czech Republic,* [2]*Hospital Krnov, Hematologic Ambulance, Krnov, Czech Republic,* [3]*FN Olomouc, Pediatric Clinic, Olomouc, Czech Republic*

Background: Antithrombin (AT) is an important inhibitor of blood coagulation, which regulates the amount of thrombin in the bloodstream. AT deficiency is associated with a high risk of venous thromboembolism and correlates with a genetic defect of AT encoding the gene *SERPINC1*. However, in 18% no mutation is being found.

Aims: To identify a mutation in the patient from the AT deficiency family where no mutation was detected in *SERPINC1* in previous screening.

Methods: We investigated an 18-years old boy with a severe AT deficiency and a severe thromboembolic event. His father and brother had low levels of AT as well. We evaluated AT:AT(Xa) activity (Biophen AT anti(h)Xa LRT, Hyphen Biomed), AT(FIIa) activity (Biophen AT ANTI-IIa, Hyphen Biomed), AT:Ag (LIAtest ATIII, Stago). Human genomic DNA was isolated from the whole blood. All 7 exons of *SERPINC1* including the intron-exon boundaries were PCR-amplified and analysed using corresponding intronic primers, AmpliTaq Gold DNA Polymerase, BigDye Terminator v3.1 Cycle Sequencing kit and 3500 Series Genetic Analyzer (all ThermoFisher Scientific).

Results: We confirmed a severe form of AT deficiency: AT(FXa)- 47%, AT(FIIa)- 53%, AT:Ag- 65%. We found no mutation repeatedly from 2 different DNA in *SERPINC1*. So, we analysed DNA of proband`s brother and father. We detected no mutation in brother`s, but we found a mutation in father`s DNA in the front of exon 6 c.1154-1G>C. Boys also had a known polymorphism rs2759328 in intron 5 inherited from their mother. It was located in the forward primer of exon 6, which then worked as an allele specific primer and amplified the healthy allele inherited from the mother predominantly. When, we designed a new primer located out of the area of the polymorphism, we found the mutation in both boys.

Conclusions: We realized that location of primers could sometimes be a cause of not detecting a mutation. Finally, we identified a novel familial splice site mutation c.1154-1G>C of *SERPINC1* that causes AT deficiency.

PB 1512 | Gender Differences in the Incidence of Venous Thromboembolism among Chronic Lung Diseases and Rheumatoid Arthritis in Korea

W.-I. Choi

Keimyung University School of Medicine and Dongsan Medical Center, Daegu, Korea, Republic of

Background: The effect of gender on the incidence of venous thromboembolism (VTE) has not been well studied among chronic lung diseases and rheumatoid arthritis in Korea.

Aims: We evaluated the venous thromboembolism incidence associated with chronic obstructive pulmonary disease (COPD), interstitial lung disease (ILD), rheumatoid arthritis (RA), and general population.

Methods: We used Korean Health Insurance Review and Assessment Service (HIRA) data from January 2013 to December 2013 among 51,448,491 Korean residents. Patients with COPD (n = 222,130), ILD (n = 20,946), or RA (89,562) were identified using the International Classification of Disease-10 diagnostic codes.

Results: The women with VTE incidence rates per 100,000 persons for the study population with COPD, ILD, RA, and the general population were 1642, 1551, 299, and 48 respectively, while men with the VTE incidence for each group was 1033, 1280, 396, and 38, respectively.

Conclusions: VTE incidence was significantly higher in women with COPD, ILD, general population than that of men, while the women with an incidence of VTE was lower than that for men in patients with RA in Korea.

PB 1513 | Application of Massive Parallel Sequencing Searching for Rare Genetic Variants of Protein C and S Associated with Thrombophilia - Implementation to Clinical Practice

P. Vrtel[1], R. Vodicka[1], J. Ulehlova[2], L. Slavík[2], J. Prochazkova[2], R. Vrtel[1], M. Prochazka[1]

[1]*Faculty of Medicine and Dentistry, Palacký University Olomouc, University Hospital Olomouc, Department of Genetics, Olomouc, Czech Republic,* [2]*Faculty of Medicine and Dentistry, Palacký University Olomouc, University Hospital Olomouc, Department of Hematology-Oncology, Olomouc, Czech Republic*

Background: Thromboembolism have multifactorial etiology but one of the main causes is thrombophilia. Really common and severe cause of thrombophilia is deficiency of protein C, S or antithrombin III (PC, PS, AT III). The genetic cause are mutations without mutational hotspots areas in the studied genes. Therefore it is appropriate to use methodology of massive parallel sequencing (MPS) and expanded molecular genetic analysis for detection of genetic cause of deficiency of those proteins. Selected proteins are encoded by genes: PROS, PROC, SERPINC1. In these genes have been described more than 800 mutations whose clinical manifestation may be a lack or loss of function of the gene product, which are involved in the inhibition of coagulation factors. Pathogenic mutations in these genes exhibit similar

risk of thrombosis as routinely tested mutations of FV Leiden and FII Prothrombin (G20210A).

Aims: Apply the massive parallel sequencing (MPS) and expanded molecular genetic analysis for detection of genetic cause of deficiency of protein C and S.

Methods: MPS was carried out by Ion Torrent PGM platform. We used Ampliseq Designer for design of multiplex with 100% coverage of coding sequences and exon / intron border areas. The data were processed by Torrent Suite programs - Ion Reporter and Next Gene - available database of clinical variants (ClinVar, HGMD).

Results: In the first run there were examined 10 patients. They were selected for repeatedly detected reduced levels of protein C or S, at the same time they were excluded for secondary etiology of that condition. We have revealed six missense mutations in PROS1(2) and PROC (4) so far.

Conclusions: MPS offers complex tool for identification genetic causes of severe thrombophilia states applicable to laboratory and clinical praxis. Further it will be useful to add MLPA analysis for patients where MPS doesn´t reveal any genetic cause. MLPA should improve testing for better detection of large rearrangements in examined genes.

PB 1514 | Combined Protein C / Protein S Deficiency: Genotype-Phenotype Relationship in an Italian Family Carrying Two Novel Mutations

G. Favuzzi[1], G. D'Andrea[2], G.L. Tiscia[1], F. Cappucci[1], L. Fischetti[1], E. Chinni[1], P. Vergura[1], E. Grandone[1], M. Margaglione[2]

[1]IRCCS Casa Sollievo della Sofferenza, Thrombosis and Haemostasis Unit, San Giovanni Rotondo, Italy, [2]University of Foggia, Medical Genetics, Foggia, Italy

Background: Protein C (PC) and Protein S (PS) defects may lead to an increased risk of venous thromboembolism and arterial disease. Individuals with inherited PC/PS deficiency have about a 2-to 11-fold increased risk for venous thromboembolism.

Aims: We describe a case of PC/PS deficiency. Two novel mutations in PC and PS genes were identified.

Methods: We observed a 50-years-old man who had suffered from idiopathic superficial vein thrombosis at right leg at 49-year-old and a myocardial infarction at 45-year-old in presence of modifiable risk factors (BMI 33, smoking, diabetes mellitus). Laboratory investigations evidenced low plasma levels of functionally active PC (56.7%; n.v.:70-140%) and free PS (25%; n.v.: 60-150%). Family history documented that: his father died at 54-year-old because of a myocardial infarction and his daughter (25-year-old, BMI 21.4, smoking) had low plasma levels of functionally active PC (57%) and of free PS (22%), and no noteworthy clinical event. Functionally active PC was determined by a chromogenic method. Quantitative free PS was determined by an ELISA method. Direct sequencing analysis of the PC and PS genes was performed to identify the causative mutations. Multiple alignments of PC and PS proteins was created by the HomoloGene system.

Results: Both the patient and his daughter were found double heterozygotes for two novel mutations, p. Met255Lys in the PC gene and p.Ala525Asp in the PS gene. HomoloGene indicated that the Met255 in PC gene represents a poor conserved residue across species while the Ala525 in PS gene seems to be a more conserved residue. However, findings from SIFT predictions suggested a possible damaging effect of both mutations on PC and PS structures. At variance with the SIFT, Polyphen-2 predictions revealed the only PC mutation could have a damaging effect on protein structure.

Conclusions: The PC/PS deficiency of our case is likely due to the p.Met255Lys and p.Ala525Asp variants identified in PC and PS genes, respectively.

PB 1515 | Impact of Factor V-Leiden, Prothrombin G20210A and MTHFR C677T Mutations on Egyptian Patients with Sickle Cell Disease

A. Saad[1], H. Sedky[1], A. Osman[1], A. Abu-skeen[1], A. Abd El Maksoud[2], D. Gamal Eldin[1]

[1]Ain Shams University, Clinical Pathology, Cairo, Egypt, [2]Ain Shams University, Pediatric, Cairo, Egypt

Background: Sickle cell disease (SCD) shows activation of the blood coagulation, fibrinolytic system, increased platelet activity and consumption of coagulation inhibitors. Many thrombophilic genes polymorphisms are suggested as potential modifiers of vascular complications pathophysiology.

Aims: is to study the impact of factor V Leiden (FVL), prothrombin (PTH) gene mutation, and methylenetetrahydrofolate reductase (MTHFR) polymorphism as risk factors for vascular complications in patients with SCD.

Methods: This case-control study was carried on 40 SCD patients, and 40 healthy control subjects of matched age and sex attending Ain Shams University Hospitals after obtaining an informed consent. All the studied individuals were subjected to: complete blood picture, blood film examination, reticulocyte count, hemoglobin electrophoresis, prothrombin time, activated partial thromboplastin time, polymerase chain reaction detection of FVL (G1691A), PTH (G20210A) and MTHFR (C677T) genes mutations. Data were analyzed statistically using SPSS version 24.

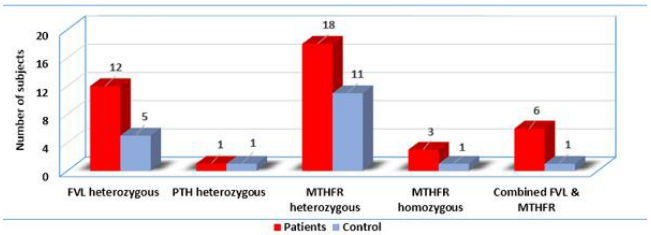

FIGURE 1 Prevalence of genetic mutations in patient and control groups

TABLE 1 Association between FVL; MTHFR genotypes and demographic, clinical & laboratory data

Parameter	Wild FVL No=28	Hetero FVL No=12	Test of Significance	P value	Hetero MTHFR No=19	Wild MTHFR No=18	Homo MTHFR No=3	Test of Significance	P value
Disease onset: Median, months	21	15	Z=1.434	0.1	24	18	6	Z=0.787	0.4
Sex:			Fisher´s Exact Test	0.03				X2=1.367	0.5
girls (16)	8	8			6	9	1		
boys (24)	20	4			13	9	2		
BMI: mean± SD	19.5±5.1	18.1±4.5	t=0.82	0.4	21.1±5.8	16.9±2.7	19.3±4.5	t=4.019	0.02
SCD type:			Fisher´s Exact Test	1.0				X2=2.426	0.2
SCA (13)	9	4			8	5	0		
S. Thalassemia (27)	19	8			11	13	3		
Dactylitis:			X2=5.199	0.02				X2=0.932	0.6
Present (21)	18	3			11	8	2		
Absent (19)	10	9			8	10	1		
VOC:			Fisher´s Exact Test	1.0				X2=1.787	0.4
Present (13)	9	4			6	5	2		
Absent (27)	19	8			13	13	1		
Stroke:			Fisher´s Exact Test	0.006				X2=6.793	0.03
Present (6)	1	5			2	2	2		
Absent (34)	27	7			17	16	1		
HBF%: Median	9.2	8.5	Z=1.348	0.1	9.1	9	15.1	Z=3.221	0.052
HBS%: Median	56.5	50.4	Z=0.215	0.8	60	39.5	53.6	Z=0.677	0.5

Results: Significant difference was found between patients and control subjects as regards the thrombophilic genes mutation rate (70% and 42.5% respectively; P=0.01), however insignificant difference was found when each genotype prevalence of FVL, PTH and MTHFR were compared separately(P=0.056, 1.0, 0.1 respectively) (figure1).

FVL and MTHFR mutations were significantly associated with stroke (table1).

Logistic regression analysis (including age, disease duration, hemoglobin (Hb) level, HbF%, HbS%, FVL, MTHFR) showed significant association between decreased HbF and occurrence of vascular complications (P=0.03).

Conclusions: Despite of low impact of these genes mutation in the occurrence of vaso-occlusive crises in SCD patients, FVL and MTHFR mutations are found to be associated with occurrence of stroke. The early detection of these mutations may be useful for better management. Moreover, patients with low HbF or high HbS should be candidates for extensive therapy.

PB 1516 | Heightened Hypercoagulability in Sickle Cell Anemia Patients with Chronic Leg Ulcers

E. Olayemi[1,2], D. Sackey[3], Y. Dei-Adomakoh[1]

[1]*University of Ghana, Department of Hematology, Accra, Ghana,* [2]*Ghana Institute of Clinical Genetics, Accra, Ghana,* [3]*Komfo Anokye Teaching Hospital, Department of Hematology, Kumasi, Ghana*

Background: Sickle Cell Anemia (SCA) is associated with an increase in pro-thrombotic factors and a decrease in physiologic anticoagulants, resulting in predisposition to venous thrombo-embolism. SCA patients suffer from chronic, recurrent, painful, slow-to-heal chronic leg ulcers (CLU); which are associated with aesthetic deformities and reduced quality of life.

Aims: This study was designed to compare the coagulation profile of Ghanaian SCA patients with CLU to controls.

Methods: The coagulation profile consisting of prothrombin time (PT), activated partial thromboplastin time (APTT), and fibrinogen concentration along with complete blood count (CBC) was determined in 50 SCA patients with CLU, compared with 50 SCA patients without CLU and 45 HbAA participants. SCA patients were recruited from Ghana Institute of Clinical Genetics, Accra, while the HbAA participants were voluntary blood donors. All participants gave written informed consent and the study was approved by our ethical and protocol review committee. ANOVA was used to analyse mean difference across the 3 groups.

Results: SCA patients with CLU had the lowest mean Hb concentration of 7.30±1.42g/dl, followed by SCA without CLU (7.99±1.39g/dl), with controls having the highest (14.01±1.29 g/dl) P=0.000. As shown in table 1.SCA patients with and without CLU had increased mean platelet counts (p=0.000); shorter mean APTT (p=0.007) and marginally prolonged mean PT (p=0.008) compared to HbAA controls. Mean fibrinogen concentration was higher in SCA patients with CLU and without CLU compared to HbAA controls, however this was not statistically significant (P = 0.127).

TABLE 1 Markers of Coagulation in Study Subjects (mean ± standard deviation)

Parameter	SCA With CLU (n = 50)	SCA Without LU (n = 50)	Control (n = 45)	P-value	Reference Range
Platelet Count(×10^9/L)	478.1±177.3	424.2±169.0	226.3±53.2	0.000	150 - 400
PT (Seconds)	16.0±2.6	16.0±1.7	14.9±1.2	0.008	12 - 16
APTT (Seconds)	31.3±6.2	34.5±6.8	35.2±6.1	0.007	26 - 36
Fibrinogen (mg/dl)	314.3±109.8	284.9±83.5	276.9±88.0	0.127	150 - 350

Conclusions: Our findings suggest heightened hypercoagulability in SCD patients with CLU. It is however uncertain if this increase plays a role in the pathogenesis of chronic leg ulcers in SCA.

PB 1517 | Chronic Thromboembolic Pulmonary Hypertension (CTEPH) and Trombophilia: What Should We Know?

V. Shemenkova, A. Klimenko, N. Shostak

Pirogov's Russian National Research Medical University, Faculty Therapy named after A.I. Nesterov, Moscow, Russian Federation

Background: Venous thromboembolism (VTE) is a chronic disease. Recurrence can be prevented by anticoagulants. Numerous laboratory risk factors of VTE have been identified, which has lead to a practice called laboratory thrombophilia screening. The knowledge of these factors should improve counseling patients regarding their duration of anticoagulation.

Aims: To study the frequency of thrombophilia in patients with CTEPH.

Methods: We examined 36 patients with different degree of pulmonary hypertension (PH) by echo-cardiography: 20 people (55,6%) with the first degree (SPAP 30 - 50 mmHg), 9 people (25%) with the second degree (SPAP 51 - 80 mmHg), 7 people (19.4%) with the third degree (SPAP over 80 mmHg). Blood was testing for the presence of a lupus anticoagulant (LA), antibodies (Ab) to cardiolipin classes IgM and IgG, Ab to β2 glycoprotein 1 (Ab to β2GP1).

Results: In 16 of the 36 patients revealed a high titer of anticardiolipin Ab/LA/Ab to β2GP1. In 7 patients of the main group (4 men and 3 women) was diagnosed antiphospholipid syndrome (APS). The feature of APS in patients with CTEPH was the primary character APS (71,4%), whereas secondary APS detected only in 28,6%. Patients with identified high titer of Ab to phospholipids in most cases, there had been multiple lesions in both lungs, recurrent pulmonary embolism (PE). Increase in titer anticardiolipin Ab/LA/Ab to β2GP1 detected in 44,4% of patients and the comparison of clinical markers APS and increase resistance of specified Ab allowed to diagnose APS in 19,4% of cases.

Conclusions: In 33,3% of cases there were associated forms of thrombophilia in patients with CTEPH, which helped to explain the recurrent nature of venous thrombosis/thromboembolism in this subgroup of patients. These results can be the basis of the strategy of patients with CTEPH, forming groups of risk of recurrent venous thrombosis and CTEPH, which help us to preventive incidents of PE.

PB 1518 | Apolipoprotein E Gene Polymorphisms: An Indian Study Showing Lateral Association with Thrombophilic Risk Factors in Patients with Deep Vein Thrombosis

P. Rastogi, N. Kumar, J. Ahluwalia, R. Das, N. Varma, V. Suri, H. Senee

Postgraduate Institute of Medical Education and Research, Hematology, Chandigarh, India

Background: Deep vein thrombosis (DVT) is a multifactorial disease; many acquired and genetic factors being implicated in its etiology. The degree of association for these factors may vary from strong to only modest for some. Polymorphisms in the *APOE* gene encoding for three common isoforms (*ε2*, *ε3*, *ε4*) is an upcoming potential pathogenic factor whose role is unclear in DVT.

Aims: To investigate the association of *APOE* gene polymorphisms in Indian DVT cases and to understand its interplay with the known risk factors.

Methods: Equal number of DVT cases and healthy controls (N=100, each) were studied for known acquired and hereditable thrombophilic risk factors. *APOE* gene polymorphisms were studied using polymerase chain reaction (Figure 1A). Odds ratio and χ^2-test were applied to study the association of the *APOE* genotypes/alleles with DVT and its risk factors.

Results: The known factors showing significant difference for cases *versus* controls are summarized in Table 1.

TABLE 1 Risk factors showing significant association with DVT cases

Risk factor	Cases (N)	Controls (N)	Odds ratio (95% confidence interval)	p-value
Median weight, kg	70 (100)	67 (100)	-	0.008
History of fracture	12 (100)	2 (100)	6.7 (1.4-30.7)	0.006
Smoking	20 (100)	8 (100)	2.9 (1.2-6.9)	0.014
Pregnancy	11 (29)	0 (34)	42.9 (2.4-769.6)	0.011
Recurrent pregnancy loss	10 (29)	1 (34)	17.4 (2.1-146.4)	<0.001
Lupus anticoagulant positivity	5 (62)	1 (100)	8.7 (1-76.2)	0.021
β2-glycoprotein1 antibody, IgG isotype positivity	9 (100)	0 (100)	9.8 (1.2-78.8)	0.009
Factor V Leiden mutation	16 (100)	2 (100)	9.3 (2.1-41.8)	0.004

The *ε2/ε3* and *ε3/ε4APOE* genotypes were commoner in DVT cases than controls (for *ε2/ε3*⇒10% *vs.* 9%, OR=1.123, CI=0.436-2.895; for *ε3/ε4* ⇒18% *vs.* 11%, OR=1.776, CI=0.792-3.984) but not statistically significant (Figure 1B).

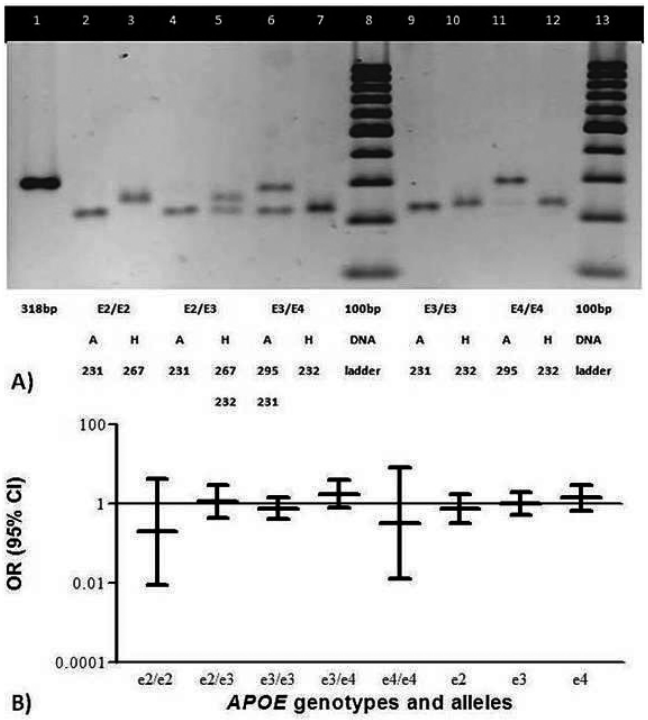

FIGURE 1 A) APOE digestion products with RE AflII (A) and HaeII (H). B) Odds ratio and 95% confidence interval for various APOE genotypes and alleles

[A) APOE digestion products with RE AflII (A) and HaeII (H). B) Odds ratio and 95% confidence interval for various APOE genotypes and alleles.]

The chance of developing DVT during/after pregnancy was more in a female with $\varepsilon 2/\varepsilon 3$ genotype (N=29; p= 0.019). The $\varepsilon 3/\varepsilon 3$ genotype offered a protective effect from DVT in a female with recurrent pregnancy loss (N=29; p= 0.016). Normal antithrombin levels in DVT cases were seen significantly frequent with a $\varepsilon 3/\varepsilon 3$ genotype (N=62; p=0.03) than those with low levels. Non-O blood group DVT individuals showed a significantly frequent $\varepsilon 3/\varepsilon 4$ genotype (N=100; p=0.023) compared to O blood group.

Conclusions: The study showed that the distribution of *APOE* genotypes was not statistically significant in DVT and has only modest association. A lateral association of these genotypes with thrombophilic risk factors was observed which may have prophylactic and therapeutic implications in the future by targeting the pathways of ApoE action.

PB 1520 | The Factor V Leiden Mutation Is Associated with Increased Sperm Count

T.E. van Mens[1,2], U.N. Joensen[3,4], Z. Bochdanovits[5], A. Takizawa[6], J. Peter[7], N. Jørgensen[3], P. Szecsi[8], J.C.M. Meijers[7,9], H. Weiler[2], E. Rajpert-De Meyts[3], S. Repping[10], S. Middeldorp[1]

[1]Academic Medical Center, Vascular Medicine, Amsterdam, The Netherlands, [2]Blood Research Institute, Blood Center of Wisconsin, Milwaukee, United States, [3]Rigshospitalet/Copenhagen University Hospital, Department of Growth and Reproduction, Copenhagen, Denmark, [4]Rigshospitalet/Copenhagen University Hospital, International Center for Research and Research Training in Endocrine Disruption of Male Reproduction and Child Health (EDMaRC), Copenhagen, Denmark, [5]VU University Medical Center, Department of Clinical Genetics, Amsterdam, The Netherlands, [6]Medical College of Wisconsin, Department of Physiology, Milwaukee, United States, [7]Academic Medical Center, Department of Experimental Vascular Medicine, Amsterdam, The Netherlands, [8]Herlev and Gentofte Hospital, University of Copenhagen, Department of Clinical Biochemistry, Hellerup, Denmark, [9]Sanquin, Department of Plasma Proteins, Amsterdam, The Netherlands, [10]Academic Medical Center, Center for Reproductive Medicine, Amsterdam, The Netherlands

Background: The coagulation factor V Leiden mutation G1691A (FVL) has a high prevalence in Caucasians despite its association with venous thromboembolism. Male carriers have higher fecundity, which might partly explain this apparent evolutionary paradox. We previously observed a statistically non-significant increase in sperm count in FVL carriers.

Aims: To test whether FVL was associated with increased total sperm count and to find an underlying biological mechanism. We also tested the association with the prothrombin G20210A mutation (PGM).

Methods: We determined the FVL and PGM genotype in two cohorts and aggregated the results with a previously published cohort. We accounted for baseline differences and study level clustering using a mixed effects model. We explored possible biological underpinnings by investigations of genetic linkage and a FVL mouse model (R504Q mutation). In public haplotype data from subjects of European descent, we tested linkage disequilibrium of FVL with all SNPs in a 1.5 MB region around the *F5* gene. We sequenced exons of four genes hypothesized to be linked to FVL in carriers with extreme sperm counts.

Results: The cohorts are summarized in Table 1. Carriers of FVL, but not of PGM, had a higher total sperm count than non-carriers (Figure 1), with an adjusted mean difference of 31x 10^6 (p = 0.048). There were no differences in normalized internal genitalia weights, epididymis sperm content and sperm motility between FVL (n=14) and wild type mice (n=7). No polymorphisms were found to be in linkage disequilibrium, neither in the public databases nor in a subgroup of FVL carriers with extreme sperm counts.

Conclusions: FVL is associated with higher sperm count. Although the effect seemed present in all three cohorts, it had a borderline statistical significance and would thus benefit from further confirmation. Absence of the effect in PGM carriers and in mice might suggest the cause is indirect, but we found no evidence of genetic linkage.

TABLE 1 Baseline characteristics and total sperm count.

	Amsterdam 1* Jan 2000 - Jul 2007	Amsterdam 2 Jul 2007 - Dec 2014	Copenhagen Jan 2007 - Dec 2009

PB 1521 | Risk Factors of Cerebral Venous Sinus Thrombosis - Single Center Experience

A. Gwozdowska[1], E. Odnoczko[2], B. Baran[2], K. Bykowska[2], J. Windyga[1]

[1]Institute of Hematology and Transfusion Medicine (IHTM), Department of Disorder of Haemostasis and Internal Medicine, Warsaw, Poland, [2]Institute of Hematology and Transfusion Medicine (IHTM), Department of Haemostasis and Metabolic Disorders, Warsaw, Poland

Background: Cerebral venous sinus thrombosis (CVST) is a rare manifestation of venous thromboembolism (VTE). The estimated CVST incidence for adults is 3-4 per million cases. The potential risk factors for CVST are congenital and acquired thrombophilia.

Aims: Evaluation of the prevalence of congenital thrombophilia, antiphospholipid syndrome (APS) and other acquired risk factors for VTE in patients with a history of CVST.

Methods: patients with recognized CVST are referred to IHTM for identification of hematological and other risk factors for this disease. Our study comprised 204 fully diagnosed CVST patients from the register data-base: 154 women and 50 men, mean age - 39 years (range 14-78). Medical interview included age at the time of the CVST diagnosis and coexistence of VTE acquired risk factors (pregnancy, delivery, oral contraceptives (OCPs), infection, cancer). Each patient was examined for congenital thrombophilia (antithrombin, protein C and S deficiency, factor V Leiden and prothrombin gene mutation G20210A). Antiphospholipid antibodies were also determined.

Results: Thirty-five (17,2%) patients had congenital thrombophilia, eleven (5,4%) were diagnosed with APS. In 9/12 cases (4,4% of all patients) JAK-2 positive myeloproliferative neoplasm was confirmed. At the time of CVST diagnosis sixty-eight/154 (44,2%) women ingested OCPs, while in twenty-five (16,2%) CVST occurred during pregnancy or at delivery.

Conclusions: In our population of patients the ingestion of oral contraceptives, pregnancy and delivery were the main risk factors for CVST.

PB 1523 | Platelet to Lymphocyte Ratio and Neutrophil to Lymphocyte Ratio as Risk Factors for Venous Thromboembolism

A. Artoni, M. Abbattista, P. Bucciarelli, F. Gianniello, I. Martinelli

Fondazione IRCCS Ca' Granda - Ospedale Maggiore Policlinico, A. Bianchi Bonomi Hemophilia and Thrombosis Center, Milan, Italy

Background: High Platelet to Lymphocyte Ratio (PLR) and Neutrophils to Lymphocyte Ratio (NLR) are markers of subclinical inflammation associated with arterial thrombosis. The association between high PLR and NLR and the risk of venous thromboembolism has not been investigated yet.

Aims: To investigate whether high PLR or NLR are associated with an increased risk of venous thromboembolism (VTE) or cerebral venous thrombosis (CVT).

Methods: Case-control study of patients with VTE or CVT referred to Milan Thrombosis Center for thrombophilia screening from Jan 2007 and Dec 2013. Patients had already discontinued anticoagulant therapies and healthy individuals referred in the same time period were used as control. Patients were investigated at least after three months from the acute event. Multivariable logistic regression was used to calculate odds ratios (OR) for PLR and NLR values >95th percentile. The interaction of high values of PLR and NLR with thrombophilia in determining the risk of VTE or CVT was also investigated. 486 VTE patients, 100 CVT patients and 299 controls were included in the study.

Results: Patients with high PLR or NLR were not at increased risk of VTE or CVT. Subgroups analysis showed that high PLR increased the risk of CVT associated with transient risk factors (OR 2.65, 95%CI 1.02-6.92). A synergistic effect on the risk of CVT for the combination of high values of PLR and thrombophilia abnormalities was observed (OR 7.67, 95%CI 1.67-35.27).

Conclusions: PLR and NLR are not associated with VTE or CVT. Perhaps, high PLR increases the risk of CVT associated with transient risk factors.

PB 1524 | Quantification of the Effect of NET-derived Cell-free DNA on Thrombosis and Haemostasis Phenotypes

S. Lopez[1], A. Martinez-Perez[1], N. Vilalta[2], A. Rodriguez-Rius[1], C. Muñoz[1], J.C. Souto[2], J.M. Soria[1]

[1]IIB Sant Pau, Research Institute of Hospital de la Santa Creu i Sant Pau, Unit of Genomics of Complex Diseases, Barcelona, Spain, [2]Hospital de la Santa Creu i Sant Pau, Haemostasis and Thrombosis Unit, Department of Hematology, Barcelona, Spain

Background: Cell-free DNA (cfDNA) is a surrogate marker of neutrophil extracellular traps (NETs). It has been shown that cfDNA provide scaffolding for platelet adhesion and promote fibrin deposition in the vasculature by enhancing the activity of coagulation factors, thus contributing to thrombosis.

Aims: Evaluate the effect of cfDNA on quantitative intermediate phenotypes related to thrombosis, haemostasis and inflammation in Spanish families from the Genetic Analysis of Idiopathic Thrombophilia (GAIT2) Project.

Methods: cfDNA was quantified in platelet poor plasma of 935 subjects belonging to 35 families with thrombosis of GAIT2. Sytox Green was used to label DNA. Fluorescence was measured at 485 excitation and 538 emission wavelengths. cfDNA concentrations were calculated through a standard curve. Associations between cfDNA and phenotypes were quantified using mixed effects models, and the significance using likelihood ratio test. All the models used take into account the family structure and have the proband correction. This ascertainment scheme was used to minimize bias and allow the best estimation for general population parameters.

Results: Significant positive correlations with cfDNA were observed for some blood coagulation factors. The most significant one was for functional fibrinogen (FIBc b=0.151; p-val=6.44e-07), indicating that extracellular DNA from NETs could mainly enhance fibrinogen deposition and fibrin formation. Functional clotting FVIII (FVIIIc b=0.083; p-val=3.91e-03), FIXc (b=0.059; p-val=3.31e-02) and FXIIc (b=0.056; p-val=3.30e-02) also exhibited positive correlations with cfDNA.

Conclusions: Haemostasis-related phenotypes such as FIBc, FVIIIc, FIXc and FXIIc might be involved in the interaction between NET-derived cfDNA and thrombosis. In addition, the quantification of the effect of cfDNA on these coagulation factors showed that extracellular DNA could promote their activation and contribute to a prothrombotic phenotype.

PB 1525 | Iron Deficiency Alters Red Blood Cell and Neutrophil Adhesion and Arterial Thrombosis

S. Lapping[1], E. Kucukal[2], U. Gurkan[2], M.K. Jain[1], L. Nayak[3]

[1]Case Western Reserve University, Cardiovascular Research Institute, Cleveland, United States, [2]Case Western Reserve University, Department of Mechanical and Aerospace Engineering, Cleveland, United States, [3]Case Western Reserve University, Department of Internal Medicine, University Hospitals, Cleveland, United States

Background: Clinical studies describe a link between iron deficiency and thrombosis. The pathophysiological basis is poorly understood.

Aims: We generated a mouse model of iron deficiency to examine the cellular and molecular determinants of thrombosis in this setting.

Methods: C57BL6J mice were initiated on an iron poor or iron sufficient diet (Takeda) starting at 3 weeks of age for a total of 5 weeks. To examine thrombosis, we used the carotid artery thrombosis photochemical injury model. Microfluidic channels coated with endothelial proteins laminin, fibronectin or VCAM-1 were flowed with citrated whole mouse blood and examined for RBC adhesion. E-selectin immobilized microfluidic channels were perfused with neutrophils.

Results: Mice on the iron deficient diet developed significant microcytic anemia and mild thrombocytosis and lower plasma ferritin levels as compared to controls. No difference was noted in total white cell or differential count. Iron deficient mice had significantly shorter times to occlusive carotid artery thrombosis. Coagulation assays (PT and aPTT) were not different between the two groups. Significantly larger number of iron deficient RBCs adhered to all three endothelial proteins (laminin, fibronectin, and VACM-1) and neutrophils to E-selectin as compared to controls on microfluidic studies.

Conclusions: These studies demonstrate that iron deficiency affects arterial thrombosis. Our studies are the first to identify cellular elements that may be involved in the generation of the increased risk to thrombosis in iron deficiency, i.e. red blood cells and neutrophils as demonstrated by our microfluidic assays. Presently, studies are examining endothelial and platelet activation, venous thrombosis, and molecular mechanisms. Iron deficiency has a high prevalence worldwide. Understanding the molecular underpinnings offers insight into thrombotic mechanisms affecting a large group of people, especially in women of the reproductive age.

PB 1526 | Complete Protein S Deficiency and Pregnancy Outcome in Murine Model

R. Prince[1], N. Dewarrat[1,2], M.D. Reina Caro[1,2], J. Brodard[1,2], C. Quarroz[1,2], F. Saller[3], S. Calzavarini[1,2], A. Angelillo-Scherrer[1,2]

[1]University of Bern, Department of Clinical Research, Bern, Switzerland, [2]Inselspital, Bern University Hospital, University of Bern, Department of Hematology and Central Hematology Laboratory, Bern, Switzerland, [3]INSERM U1176 & UMR 1176, University of Paris Sud, Hemostasis, Inflammation, Thrombosis (HITh), Paris, France

Background: Complete protein S (PS) deficiency is a rare fatal thrombophilia associating purpura fulminans (PF) and disseminated intravascular coagulation (DIC). We obtained a full rescue of *Pros1*$^{-/-}$ lethality by targeting *F8*. *F8*$^{-/-}$*Pros1*$^{-/-}$ mice did not show PF or DIC.

Aims: Because thrombophilias are associated with pregnancy loss, we investigated complete PS deficiency on pregnancy outcome.

Methods: Pregnancy monitoring, blood cells count, coagulation tests and histology in *F8*$^{-/-}$*Pros1*$^{-/-}$, *F8*$^{-/-}$*Pros1*$^{+/+}$ and *F8*$^{+/+}$*Pros1*$^{+/+}$ pregnant mice and embryos.

Results: Vaginal plugs were observed in all 19 *F8*$^{-/-}$*Pros1*$^{-/-}$ females but, independently of the male breeder genotype, no litters were produced. Relevant embryonic mortality was found at E11.5-12.5 (58%): embryos were mostly macerated but some of them showed hemorrhages and thrombosis with no PF. *F8*$^{-/-}$*Pros1*$^{-/-}$ genotype was underrepresented among embryos (33*vs*50%) at E9.5-10.5 and suppressed after E12.5. Differently all embryos collected from *F8*$^{-/-}$*Pros1*$^{+/+}$ and *F8*$^{+/+}$*Pros1*$^{+/+}$ pregnant mice were alive. Recurrent pregnancy loss never affected *F8*$^{-/-}$*Pros1*$^{-/-}$ mice survival. In comparison to E12-16 *F8*$^{-/-}$*Pros1*$^{+/+}$ gravid mice, *F8*$^{-/-}$*Pros1*$^{-/-}$ pregnant mice had reduced platelet count (829±92*vs*559±79G/L), fibrinogen (2.4±0.3*vs*1.0±0.1g/L), increased TAT (12.6±4.3*vs*25.4±2.8ng/L) whereas PT was normal. In addition, placenta but not lung and liver sections showed fibrin clots only in *F8*$^{-/-}$*Pros1*$^{-/-}$. Treatment of *F8*$^{-/-}$*Pros1*$^{-/-}$ pregnant mice with enoxaparin or low-dose aspirin prevented pregnancy loss. However, litter size was slightly reduced in the aspirin compared to the enoxaparin group (2-4 *vs* 5-6).

Conclusions: Targeting F8 did not prevent pregnancy loss due to placental thrombosis in gravid *Pros1*$^{-/-}$ mice. *F8*$^{-/-}$*Pros1*$^{-/-}$ pregnant mice displayed coagulation activation with no overt DIC. Aspirin or better enoxaparin treatment prevented pregnancy loss, indicating that thromboprophylaxis might apply to pregnancy in severe inherited thrombophilias.

PB 1527 | Thrombophilic Phenotype in a Neonate and Five Young Siblings of a Family with Homozygous Antithrombin Type 2 (Budapest III) Deficiency

H.-J. Hertfelder[1], M. Scheler[2], A. Pavlova[1], B. Pezeshkpoor[1], V. Jennissen[3], M. Hoemberg[2], T. Streichert[3], J. Mueller[1], J. Oldenburg[1], C. Huenseler[4]

[1]University Hospital Bonn, Institute of Exp. Haematology & Transfusion Medicine, Bonn, Germany, [2]University of Cologne, Department of Pediatric Oncology and Hematology, Cologne, Germany, [3]University Hospital Cologne, Institute of Clinical Chemistry, Cologne, Germany, [4]University of Cologne, Department of Neonatology, Children's Hospital, Cologne, Germany

Background: Identification of a neonate with inferior vena cava (IVC) and right renal vein thrombosis, related with discrepant antithrombin (AT) laboratory findings and low efficacy of enoxaparin (ENOX) treatment.

Aims: To identify the nature of the AT deficiency and subsequently modification of treatment. Furthermore examination of family members was performed to clarify the mode of inheritance and establish a phenotype genotype correlation.

Methods: IVC and renal vein thromboses of the neonate were diagnosed on the 12th day of life. AT activity was first determined by chromogenic factor Xa-based assay (AT-Xa). For control AT was examined by chromogenic thrombin-based assay (AT-T) and AT antigen concentration by AT LIA assay (AT ag). ENOX was monitored by anti factor Xa activity (AXa) assay. Molecular genetic analysis was performed by direct sequencing. For treatment ENOX 3 mg/kg per day i.v., AT was supplied i.v. for 30 days. For long-term treatment the child was switched to warfarin.

Results: The initial AT-Xa level was 18%, age-related other clotting parameters were normal. AT-T of 60% and AT-Ag of 59% indicated an AT deficiency type 2. Low AXa levels under ENOX indicated an impaired interaction of AT, heparin and FXa. Moreover, AT supplementation improved ENOX AXa effect from 0 to 1.8 AXa-IU/ml, and the IVC thrombus was dissolved. Molecular genetic analysis revealed a homozygous (+/+) mutation in exon 2 of *SERPINC1*-gene (c.391C>T p.Leu131Phe) identified also in his parents and siblings (Table 1). All family members except the father (+/-) were found to be homozygous for the AT mutation. Interestingly, even under warfarin treatment the propositus showed elevated d-dimer.

TABLE 1 Patient and family data of the antithrombin phenotype, genotype and d-dimer as a molecular activation marker (adult reference ranges)

Table 1	Patient	Mother	Father	Brother	Sister 1	Sister 2	Sister 3	Sister 4
Age (Y, days)	12 d	34.9	37.2	13.8	12.4	10.4	4.2	2.8
AT-Xa (%) (ref. 83-118)	18	55	56	14	13	14	22	16
AT-T (%) (ref. 85-120)	59	98	93	60	71	65	73	74
AT ag (%) (ref. 80-120)	51	87	85	62	69	64	65	67
d-dimer (mg/l) (ref. <0.5)	0.79	0.18	0.42	0.65	0.81	0.55	1.08	1.04
p.Leu131Phe	+/+	+/+	+/-	+/+	+/+	+/+	+/+	+/+

Conclusions: The p.L131F mutation (Budapest III) is well-known to be associated with a defective heparin binding. However, our data indicate that predominantly the interaction with FXa is impaired while the interaction with thrombin is obviously not affected. Increased d-dimer levels indicated a prethrombotic state in all children of the family.

PB 1528 | Venous Thromboembolism in Women Using Hormonal Contraception and the Risk of Recurrence. Findings from a Single Center

A. Latorre[1], A.S. Vilches[2], J. Cacha[1], M.J. Gomez[1]

[1]*Hospital Universitario Mostoles, Hematologia, Mostoles, Spain,* [2]*Hospital Mostoles, Hematologia, Mostoles, Spain*

Background: Venous thrombosis including deep-vein thrombosis (DVT) and pulmonary embolism (PE) is considered a multifactorial disease associated with genetic and acquired risk factors. In women of reproductive age, the main cause of venous thromboembolic disease (VTD) is hormonal contraception. However, other risk factors interact to produce VTD. Identifying these factors may allow intervene in risk situations and limit the occurrence of VTD with its potential morbidity and mortality.

Aims: Identified risk factors in VTD.

Methods: We reviewed the characteristics of our series of 120 women with objectively confirmed VTD associated with hormonal contraception. We analyzed its clinical data and thrombophilia studies which were performed in more than 80% of them. Recurrent VTE was recorded in 12 of the 120 female patients (10%) and we analyzed the principal risks factors. All statistical analysis was performed using R statistical software version 3.1.1 (2014-07-10).

Results:

TABLE 1 Results

Patients (N)	Total (120)	Recurrence (12)	P-Value
Clinical Features			
Mean age (years +- SD)	29 (+/- 7.5)	33 (±8.9)	0.1
Body mass Index (Kg/m2 +-SD)	26 (+/-6)	26 (±3.2)	0.69
Risk factors for VTD			
Immobility	32 (26.67%)	5 (41.67%)	0.12
Family history	29 (24.19%)	3 (25.00%)	0.42
Venous thromboembolism characteristics			
Pulmonary embolism	53 (44.17%)	3 (25.00%)	0.08
Proximal deep vein thrombosis	63 (52.50%)	9 (75.00%)	0.72

TABLE 2 Results

Patients	Total (120)	Recurrence (12)	P-Value
Type of combined oral contraceptive			
Antiandrogen	31 (25.83%)		NA
Third generation progestogen	26 (21.67%)		NA
Thrombophilia tests			
Factor V Leiden	11 (9.17%)	1 (8.33%)	1.00
Prothrombin mutation	19 (15.83%)	3 (25.00%)	0.44
Increased factor VIII (>195%)	20 (16.67%)	8 (66.67%)	0.06
Combined trombophilia	4 (3.33%)	2 (16.67%)	NA
Time to recurrence >= 10 years		7 (58.00%)	

Conclusions: Contraceptive use remains the most important risk factor for VTD in women of reproductive age. Additional risk factors such as obesity, immobilization, family history of VTD and certain thrombophilic defects, as well as elevated factor VIII, are frequent and should be part of thrombophilia study. Defining high risk patients, may improve interventions in risk situations (e.g. administering antithrombotic prophylaxis or discontinuing contraceptive use after lower limb trauma) in order to prevent VTD.

Recurrence is low in this population, once contraceptive use is discontinued and thrombophylaxis is offered in subsequent pregnancies. In our subgroup, high levels of factor VIII was a prominent thrombophilic feature and though it has been implicated in recurrence in idiopathic VTD, is less recognized in this situation. However larger studies are needed to confirm this.

PB 1529 | Thrombophilia Screening Practices in a Tertiary Care Hospital: An Assessment of Appropriateness and Financial Impact

N. Ganta[1], D. Suryanarayan[1], X.Y. Jiang[2]

[1]*University of Calgary, Hematology, Calgary, Canada,* [2]*University of Calgary, Hematopathology/Calgary Laboratory Services, Calgary, Canada*

Background: Despite the limited value of routine thrombophilia testing in determining etiology of venous thromboembolic events (VTE), thrombophilia screening is increasing, often for inappropriate clinical indications.

Aims: To assess appropriateness of current thrombophilia testing practices in a tertiary care hospital in Calgary, Alberta, financial impact and patient morbidity.

Methods: We retrospectively obtained a random sample of 500 patients from the list of patients aged >18 years who underwent thrombophilia testing (n=3578) in 2015. Demographics, test

indication, requesting specialty, results and cost incurred were collected. Appropriateness of testing was determined using major published guidelines with input from clinical experts. Statistical analysis was performed using descriptive summary measures.

Results: Out of 500 patients who underwent testing, 469 were included in the study. 74% of patients were women (mean age 41 years, range 18-87 years) and 26% were men (mean age 52 years, age range 18- 83 years). Among 2691 tests performed, 78% were deemed inappropriate, 15% appropriate and 7% lacked sufficient clinical information. Inappropriate testing was mainly ordered by Family Medicine (47%) and Rheumatology (21%). Autoimmune disease (excluding workup for lupus) (51%) provoked VTE (14%), early pregnancy loss (not meeting clinical criteria for testing) (13%) were main indications for inappropriate testing. The cost of inappropriate testing was $42,699 (80% total testing cost). This translates to a total cost of $358,797 for inappropriate testing annually.

Conclusions: Our study indicates a higher incidence of indiscriminate and inappropriate testing resulting in a significant financial impact on the health care system. There is potential for substantial health care cost savings with implementation of stringent criteria for ordering thrombophilia screens. Service specific educational intervention remains key to reducing inappropriate testing.

PB 1530 | Retrospective Analysis of the Size of Recurrent Pulmonary Embolus: Single Centre Study

W. Thomas, O. Firth, M. Beveridge, M. Besser, T. Baglin

Addenbrooke's Hospital, Dept. of Haematology, Cambridge, United Kingdom

Background: There are currently three different models that predict risk of recurrence for patients with unprovoked venous thromboembolism; HERDOO2 score, Vienna prediction model and DASH score. As far as we know, no study has addressed whether the size of a first pulmonary embolism (PE) correlates with size of PE at recurrence. If a correlation were to be found, then this could be used, along with the current risk prediction models, to assess the balance of risks of long-term anti-coagulation.

Aims: Our aim was to determine, through a retrospective cohort of patients with PE, whether radiological size of a first PE predicted radiological size at recurrence.

Methods: Retrospective analysis of all patients with recurrent PE over 25 months (1st November 2014-30th November 2016) at our teaching hospital. PE was defined as radiologically massive (RMPE) if it was bilateral main pulmonary artery, saddle PE or there was evidence of right heart strain. All other PE´s were radiologically non-massive (RNMPE). Patient exclusions: on anti-coagulation at recurrence, if CT pulmonary angiogram not used to diagnose first and recurrent PE or if historical information unavailable.

Results: 837 patients had PE in the study period at our hospital. 100 patients had recurrent PE and 37 were excluded (n=63). Patients whose first PE was RNMPE (46/63, 73% of patients) had a 15.2% chance of RMPE at recurrence where as those who presented first with a RMPE (17/63, 27% of patients), had a 17.6% chance of RMPE at recurrence (odds ratio 1.19, 95% confidence interval 0.27-5.27, p=0.81).

Conclusions: The chances of having a radiologically massive PE at recurrence are similarly low irrespective of the size of the first PE (15.2% v 17.6% for first RNMPE or RMPE respectively). Currently, the size of a first PE should not be considered as a major factor in whether long term anti-coagulation is continued after an initial treatment period. Further prospective multi-centre studies with clinical endpoints are needed to further expand on this study.

PB 1531 | Hyperaggregability of Platelets with Low Dose of ADP and Epinephrin in Patients with Venous Thrombosis: Preliminary Results from the RETROVE Project (Risk of Enfermedad TROmboembólica VEnosa)

D. Llobet, C. Vallvé, I. Tirado, J. Murillo, N. Vilalta, M. Carrasco, J. Mateo, J. Fontcuberta, J.C. Souto

Hospital de la Santa Creu i Sant Pau, Haemostasis and Thrombosis Unit, Barcelona, Spain

Background: Aggregability of platelets (PLT) with low doses of epinephrine (EPI) and/or ADP in normal people is manifested in two states. One is where PLT aggregation is greater than 60 % (PLT hyperreactivity) and the other is where aggregation is less than 40% (PLT hyporreactivity). This PTL hyperreactivity has been associated with thrombosis.

Aims: To determine if this aggregability is associated with venous thrombosis in the Spanish population.

Methods: A total of 397 controls with a mean age of 49±18 years (190 men and 207 women) and 397 patients with thrombosis with a mean age of 64±18 years (193 men and 204 women) were included in our study. None of the individuals had taken aspirin in the 10 days before blood extraction.

Platelet Aggregation in PRP: we use ADP and EPI at 0.5µM to separate hyper and hyporreactivity populations. We used Aggregation analyzer to generate the curves of aggregation. It measured % of maximum aggregation and % of area under curve (AUC). *Statistics Analyses:* Frequencies were compared using the Chi squared test. p values < 0.05 were considered statistically significant. 50th percentile of % AUC were calculated and analyzed.

Results:

Aggregability of 0.5µM of EPI (AUC) showed statistically significant differences with 50th percentile (>22.83 %): which was a higher percentage in patients than in controls (57.9% vs 50.0%; difference of 7.9%; CI95%:1.03-1.83) (p=0.03). Individuals in the upper 22.83% AUC corresponded to individuals with PLT hyperreactivity.

Aggregability of 0.5µM of ADP(AUC) showed also statistically significant differences with 50th percentile (>13.13 %): a higher percentage in patients than in controls was observed (62.9% vs 50.0%; difference of 12.9%; CI95%:1.27-2.27) (p=0.0001).

Conclusions: Our results suggest that hyper- and hypoaggregability is significantly different in the control population than in the patients. It is notable that PLT hyperreactivity is associated with an increased risk of venous thrombosis.

RIC RD12/0042/0032, FIS PI12/00612 and FIS PI 15/0269.

PB 1532 | The Association of D-dimer Level with Common Inherited and Acquired Risk Factors of Thrombosis

A. Dobrovolsky[1], E. Panchenko[1], Z. Khasanova[1], E. Titaeva[1], E. Yarovaya[2], I. Trubacheva[3], V. Serebryakova[3], V. Kaveshnikov[3], R. Karpov[3]

[1]Russian Cardiology Research and Production Complex, Moscow, Russian Federation, [2]Lomonosov Moscow State University, Faculty of Mechanics and Mathematics, Moscow, Russian Federation, [3]Federal State Budgetary Scientific Institution ‚Research Institute for Cardiology', Tomsk, Russian Federation

Background: D-dimer is a sensitive laboratory marker of intravascular fibrin formation and data of prospective studies showed that elevated D-d levels might be associated with poor outcomes in patients with different diseases.

Aims: The objective of this study was to identify hemostatic, biochemical and clinical determinants of D-d level in a population-based cohort of 1104 dwellers of Tomsk aged 25-64 years, which were evaluated withing the frame of the multicenter epidemiological survey of cardiovascular diseases in different regions of the Russian Federation (ESSE-RF study).

Methods: In addition to routine tests, we measured D-dimer by an ELISA (Asserachrom, Stago) and screened for prothrombotic mutation (FV G1691A, FII G20210A, FG-β -G455A) by RT PCR (Applied Biosystems). The functionality of the protein C pathway was assessed with a chromogenic assay (ThromboPath, Instrumentation Laboratory) and presented as Protac-induced Coagulation inhibition Percent (PiCi%). Categorical variables are presented as number and percent, continuous - as median and interquartile ranges (IQR).

Results: D-dimer was higher in women (n=727) than in men (n=327): [330 (223-519) vs. 255 (167-431) ng/ml] and in carriers of FV G1691A (n=34, 3.1%) compared to non-carriers (n=1068): [553 (336-1015) vs. 304 (206-493) ng/ml]. All values of PiCi% in carriers of FV G1691A were within Q1 of distribution and were significantly lower than in non-carriers [71.9 (35.4-76.4) vs. 88.6 (84.9-90.9)] (Mann-Whitney U test p< 0.0001 for all). In contrast, there was no difference between carriers (n=23, 2.1%) of FII G20210A and non-carriers in D-d (307 vs 321 ng/ml) or PiCi% (89.4 vs. 88.5%). In the total cohort D-d correlated (Spearman) with age (r=0.408), hs-CRP (r=0.320), body mass index (r=0,179), fibrinogen (r=0,170), systolic BP (r=0.136) and inversely with PiCi% (r=-0,151), all p< 0.0001.

Conclusions: In a population-based cohort the strongest determinant of D-d levels were age, hs-CRP and FV G1691A.

PB 1533 | Antithrombin p.Thr147Ala: Not Just Another SNP?

C. Orlando[1], I. Pareyn[2], A.-S. Schelpe[2], K. Vanhoorelbeke[2], K. Jochmans[1]

[1]Universitair Ziekenhuis Brussel, Vrije Universiteit Brussel (VUB), Department of Haematology, Brussels, Belgium, [2]KU Leuven Campus Kulak Kortrijk, Laboratory for Thrombosis Research, Kortrijk, Belgium

Background: Hereditary antithrombin (AT) deficiency is a rare autosomal dominant disorder characterised by decreased AT activity in plasma and predisposition to recurrent venous thromboembolism (VTE). Hereditary AT deficiency is caused by mutations in the *SERPINC1* gene.

Aims: We investigated a variant in the *SERPINC1* gene, p.Thr147Ala, in six women of African origin. This variant is known as single nucleotide polymorphism (SNP) rs2227606 with minor allele frequency of 0.67% in Africans and absent in all other studied populations. *In silico* prediction tools for pathogenicity render conflicting results.

Methods: We collected plasma and DNA samples from six affected women. Mutations were identified by sequencing of all exons and intron-exon junctions of *SERPINC1*. Plasma AT activity was measured by chromogenic anti-Xa and anti-IIa methods and antigen by rocket immunoelectrophoresis. Heparin affinity was assessed with crossed immunoelectrophoresis. Recombinant AT molecules were constructed by site-directed mutagenesis and expressed in HEK-293T cells. Secreted AT was purified and studied with functional assays.

Results: Six unrelated women of Black African origin were found to carry the p.Thr147Ala variant. All but one experienced VTE, stroke or obstetric complications. AT anti-Xa activity was reduced in all patients: range 54-76% (reference value >80%) while anti-IIa activity and antigen levels were normal. On crossed immunoelectrophoresis, no AT fraction with aberrant heparin affinity was detected. The purified recombinant p.Thr147Ala protein displayed anti-Xa activity of 61.6±1.58% of the wild type recombinant AT (p< 0.05).

Conclusions: Antithrombin p.Thr147Ala, a variant reported as SNP in Black Africans, is responsible for type II AT deficiency. Type II AT mutations are known to cluster in specific regions, like p.Phe131Leu (Budapest III) in the Balkan and p.Ala416Ser (Cambridge II) in Spain and Scotland. Our data suggest a pathogenic phenotype. Further studies to unravel the exact molecular mechanism are ongoing.

PB 1534 | EPCR 6936A/G Gene Polymorphism and Plasma Levels of Endothelial Protein C Receptor as Risk Factors for Early-onset Venous Thromboembolism in North-Western Russia

V. Shmeleva[1], S. Kapustin[2], S. Karpich[1], O. Smirnova[1], J. Sidorova[2], L. Papayan[1]

[1]Russian Research Institute of Haematology and Transfusiology, Laboratory of Blood Coagulation, Saint Petersburg, Russian Federation, [2]Russian Research Institute of Haematology and Transfusiology, Biochemistry Laboratory, Saint Petersburg, Russian Federation

Background: Polymorphism 6936A/G in the endothelial protein C (PC) receptor gene is supposed to be a risk factor for venous thromboembolism (VTE) due to elevated plasma levels of the soluble form of endothelial protein C receptor (sEPCR). The mechanisms linking sEPCR levels to VTE remain to be determined. Thrombin generation test (TGT) in the presence of thrombomodulin (TM) is sensitive to defects of the PC system.

Aims: Aim of our study was to assess possible implication of 6936A/G polymorphism and sEPCR levels for TGT parameters in patients with early manifestation of VTE.

Methods: PCR-RFLP was used for detection of EPCR 6936 A/G polymorphism in 207 patients with VTE before 45 years old and 200 controls. TGT according to Hemker et al. and sEPCR level by ELISA were measured in subgroup of 36 patients and 28 controls. STATISTICA 6.1 was used.

Results: G allele was more prevalent in patients without than with FV Leiden mutation (28,5% vs 18,7%; OR=1,4; 95%CI: 0,8-2,4; p=0,05). Mean sEPCR level in patients was lower than in controls (72,6±30,9 $ngmL^{-1}$ vs.102,0±26,7$ngmL^{-1}$, p=0,08). We didn't find significant difference between subjects with AA or AG genotypes in the levels of sEPCR, probably due to low frequency of heterozygotes in our sample. In patients with FV Leiden mutation sEPCR levels were higher than in those without this mutation (86,4±48,5 vs. 67,9±21,8 p=0,07). Moreover, sEPCR level showed correlation with endogenous thrombin potential (ETP) and peak thrombin (PT) in the presence of TM (R=0,41 and R=0,46 respectively, p<0,05). When PC pathway was challenged by adding TM to plasma, both ETP and PT were markedly reduced. Significant correlation with sEPCR was found for reduction of PT (R=0,49, p<0,05).

Conclusions: Polymorphism 6936 A/G demonstrated no significant correlation with TGT parametres, though sEPCR levels were associated with PC system activity and prothrombotic potential. Prevalence of polymorphism 6936G and sEPCR levels in patients with FV Leiden mutation need further investigation.

PB 1535 | Risk Factor Stratification for Venous Thromboembolim in Patients with Below Knee Injuries Treated with Immobilisation and the Future Role of Thromboprophylaxis

D. Mulligan[1], A. Farrell[2], B. Lenihan[2], M. Watts[1], D. O'Keeffe[3]

[1]*University Hospital Limerick, Department of Medicine, Limerick, Ireland,* [2]*University Hospital Limerick, Department of Orthopaedics, Limerick, Ireland,* [3]*University Hospital Limerick, Department of Haematology, Limerick, Ireland*

Background: Below knee injuries are a common presentation in orthopaedic departments, but the incidence of venous thromboembolism (VTE) and need for thromboprophylaxis in these patients is controversial, with the incidence of VTE ranging from 4.3% to 40%. However, it remains unclear if risk assessment can identify a group which could benefit from thromboprophylaxis.

Aims: The primary aims of this study were to determine the incidence and types of risk factors associated with VTE in the selected patient cohort.

Methods: This study was designed as a prospective single cohort study. Patients with below knee injuries, including both fractures and soft tissue injuries, treated with any form of lower limb immobilisation were included in the study. Patients who were receiving oral anticoagulation were excluded from the study. Patients who satisfied the inclusion and exclusion criteria were administered a VTE risk factor questionnaire. The questionnaire assessed age, sex, BMI, performance status, presence of co-morbidities, history of VTE, oestrogen exposure, pregnancy, active cancer, thrombophilia, injury type, smoking, type of immobilisation, and family history. Patients were contacted and radiological imaging reviewed twelve weeks from the date of their initial injury to determine if VTE occurred.

Results: A total of 120 patients were surveyed, 70 males and 40 females. 5 patients developed clinically significant VTE, 3 developed isolated DVT and 2 developing DVT and PE. All but 1 of these patients had 3 or more risk factors. The overall incidence of VTE among this patient cohort was 4.1%, with 4 out of 5 (80%) of episodes of VTE occurring in patients with at least 3 risk factors.

Conclusions: The overall incidence of VTE in this population is 4.1%. This study confirms the propensity of patients with multiple risk factors, with below knee injury to develop VTE. This study suggests that it may be possible to identify a high risk group of patients at the time of injury who may benefit from chemical thromboprophylaxis.

PB 1536 | Paroxysmal Nocturnal Hemoglobinuria (PNH) in Patients Presenting with Cerebral Vein and Sinus Thrombosis (CVST) - Results of Flow Cytometry Based Screening in Indian Patients

J. Ahluwalia[1], M.U.S. Sachdeva[1], M. Modi[2], N. Kumar[1], P. Bose[1], S.K. Bose[1], V. Uppal[1], N. Varma[1]

[1]*Postgraduate Institute of Medical Education and Research, Hematology, Chandigarh, India,* [2]*Postgraduate Institute of Medical Education and Research, Neurology, Chandigarh, India*

Background: PNH is known to present with thrombosis at unusual sites especially the intracranial sinovenous vasculature and may be missed unless looked for. Thrombotic PNH is associated with large clone sizes that can be detected by flowcytometry. Guidelines suggest routine screening for PNH in these patients, however there is a paucity of data on the prevalence of PNH in patients presenting with CVST.

Aims: To determine the prevalence of PNH in Indian patients presenting with CVST.

Methods: Adults presenting with CVST, confirmed by imaging studies, referred to our laboratory for workup for thrombophilic risk factors were screened for Protein C, S and antithrombin deficiency, positivity for the antiphospholipid antibodies and the Factor V Leiden (FVL) mutation. Flow cytometry was performed on the leucocytes with the "lyse stain wash" technique. PNH was diagnosed by the presence of deficiency of FLAER and CD24 in the neutrophils; and FLAER and CD14 and monocytes respectively. Control samples were included in each run.

Results: Over a period of 5 years, 180 adults, aged 18 to 65 (mean - 31.8) years with CVST and 180 healthy volunteers were screened for PNH. Pregnancy was a risk factor in 18% of the females in the reproductive age group. None of the cases or controls showed presence of PNH clones, with median deficient clone sizes being nil for FLAER in (both neutrophils and monocytes) and CD24 in the neutrophils. CD14 deficiency was not statistically significantly different in cases and controls (0.3 vs 0.2%, *p*=0.08).Protein C, S and antithrombin deficiency were seen in 2.1, 2.8 and 1.4%; positivity for the antiphospholipid antibodies in 12.6% and heterozygosity for FVL in 3% of the cases tested.
Conclusions: Young age, pregnancy and antiphospholipid antibodies are common risk factors for CVST, however PNH clones were not seen in the granulocytes or monocytes. PNH does not appear to be a common risk factor in Indian patients presenting with CVST.

PB 1537 | High Levels of VAMP 8 and Serotonin Transporter Suggest a Tendency of Thrombosis in Spanish Population. Preliminary Results from the RETROVE Project (Risk of Enfermedad TROmboembólica VEnosa)

D. Llobet, C. Vallvé, I. Tirado, N. Vilalta, J. Murillo, J. Millón, J. Mateo, J. Fontcuberta, J.C. Souto

Hospital de la Santa Creu i Sant Pau, Haemostasis and Thrombosis Unit, Barcelona, Spain

Background: Platelet (PTL) hyperreactivity has been associated with thrombosis and with high levels of human vesicle-associated membrane protein 8 (VAMP-8) and serotonin transporter (SERT).
Aims: To determine if Serotonin, SERT and/or VAMP8 are associated with a risk of venous thrombosis.
Methods: A total of 195 healthy controls (87 men and 108 women) and 162 patients with venous thrombosis (80 men and 82 women) were included in our study.
VAMP 8: An ELISA kit was used to determine the levels of VAMP8. PLTs were isolated previously: Plasma Rich Protein was washed with the equal volume using physiological saline (0.9%) and centrifugation at 4500 x g for 10 minutes. PLT pellet was frozen at -40°C. Before determination, PLT pellet was resuspended with Triton X-100 and cooled with ice for 1 hour.
SERT: An ELISA kit was used to determine the levels of SERT. PLTs were isolated as previously described.
Serotonin: An ELISA kit was used to determine the levels of Serotonin. PLTs were isolated as previously described, but the PLT pellet was resuspended with 200µL of distilled water.
Statistics Analyses: the controls and patients were compared by the Mann-Whitney test. p values < 0.05 were considered statistically significant. Interquartiles (25th and 75th percentiles) were calculated for the three parameters; median was calculated also.
Results: VAMP8 and SERT showed statistically significant higher levels in patients than in the controls. In contrast, Serotonin showed lower levels in patients than in controls:
Conclusions: High levels of VAMP 8 and SERT were associated with thrombosis in Spanish population.
SERT is a PLT membrane protein that regulates serotonin levels allowing its recycling. High levels of SERT might explain the decrease in the levels of Serotonin observed in our study.
Further studies are necessary to confirm our results.
RIC RD12/0042/0032, FIS PI12/00612 and FIS PI 15/0269

PB 1538 | Genetic Heterogeneity of Protein C Deficiency in Hungary; Genotype-phenotype Correlations

M. Speker[1], G. Balogh[1], G. Pfliegler[2], Z. Oláh[3], P. Ilonczai[3], K.B. Kovács[1], A. Kerényi[4], Á. Schlammadinger[3], K. Rázsó[3], Z. Boda[3], I. Komáromi[1], Z. Bereczky[1]

[1]University of Debrecen, Faculty of Medicine, Division of Clinical Laboratory Science, Department of Laboratory Medicine, Debrecen, Hungary, [2]University of Debrecen, Faculty of Medicine, Division of Rare Diseases, Department of Internal Medicine, Debrecen, Hungary, [3]University of Debrecen, Faculty of Medicine, Department of Internal Medicine, Debrecen, Hungary, [4]University of Debrecen, Faculty of Medicine, Department of Laboratory Medicine, Debrecen, Hungary

Background: In the background of hereditary Protein C (PC) deficiency more than 300 different mutations have been identified, so far. Type I (quantitative) and type II (qualitative) PC deficiencies can be distinguished, the latter can be subdivided according to the result of the chromogenic functional assay (CHR), that gives a normal PC activity in the case of the rare type IIb variants.
Aims: Our aims were to map the mutation spectrum of PC deficiency in the Hungarian population and to predict the potential effect of novel mutations detected in this cohort and to investigate the effect of the different mutations on laboratory results.
Methods: Non-related individuals having 70% or lower PC activity were selected (n=134). PC activity was determined by clotting and CHR tests and PC antigen was measured by ELISA. Direct sequencing of PROC gene and MLPA analysis were performed to detect potentially causative mutations. The prediction of pathogenicity of the

TABLE 1 Results

	Median	Median	25th Percentile	25th Percentile	75th Percentile	75 th Percentile	
	Patient	Control	Patient	Control	Patient	Control	p
VAMP8 (pg/10E9PLT)	1502	1138	923	536	2373	1930	0.001
SERT (pg/10E9PLT)	650	541	459	364	989	776	0.001
SEROTONIN (ng/10E9PLT)	144	171	69	110	211	257	0.002

novel missense mutations was evaluated by MutPred, PhD-SNP and Poly-Phen-2 in silico tools.

Results: A total of 44 different mutations were identified in 82 index patients. Among them 18 (41%) novel and 26 (59%) known mutations were found. Of the novel alterations 12 missense, 1 splice site, 4 nonsense and 1 large gene deletion were detected. Most of the mutations (n=28, 64%) resulted in type I, six (14%) caused type II deficiency from which 4 were type IIb and 10 mutations resulted in uncertain laboratory phenotype. Among type IIb, p.Arg57Gln, p.Gly392Arg were suggested as pathogenic by all in silico tools. The consequence of p.Ala333Asp was uncertain and p.Ala408Thr was predicted as rather non-pathogenic variant.

Conclusions: No founder mutation was identified in the Hungarian PC deficient population and a high number of novel variants were described. Since the in silico tools did not clarify the consequences of type IIb mutations biochemical studies are needed to establish their clinical relevance.

PB 1539 | Elevated Plasma Factor IXa Activity in Women Using Hormonal Contraception

P. Tanratana[1,2], P. Ellery[3,4], P. Westmark[5], A. Mast[3], J. Sheehan[5]

[1]University of Wisconsin School of Medicine and Public Health, Pathology and Laboratory Medicine, Madison, United States, [2]Mahidol University, Pharmacology, Faculty of Science, Bangkok, Thailand, [3]Blood Research Institute, Blood Center of Wisconsin, Milwaukee, United States, [4]Curtin University, Perth, Australia, [5]University of Wisconsin School of Medicine and Public Health, Medicine/Hematology-Oncology, Madison, United States

Background: Oral contraceptives (OCP) are associated with a 2-6 fold increase in venous thromboembolism, but the mechanism(s) remain unclear.

Aims: To determine the relationship between plasma FIXa activity and OCP use.

Methods: Plasma from 36 premenopausal female blood donors on hormonal contraception (PreHC), 36 premenopausal females not on hormonal contraception (PreNO), 36 post-menopausal females (POST) and 10 males (MEN) were analyzed for FIXa activity with the enhanced thrombin generation assay. Total protein S (PS), total tissue factor pathway inhibitor (TFPI) and TFPI-α were determined by ELISA. Tissue factor (TF) triggered FIX activation was examined in vitro using FV-deficient plasma to avoid quantitative thrombin generation.

Results: The PreHC group demonstrated significantly higher FIXa activity and a non-normal distribution (Fig 1). Median FIXa activity, TFPI-α and total PS antigen levels with interquartile distribution (IQR) were compared in female subgroups (Table 1). Similar to FIXa activity, TFPI-α was significantly lower in the PreHC group. In contrast, total PS and TFPI (not shown) had significantly lower values in the premenopausal (PreHC and PreNO) compared to post-menopausal (POST) females without a discernible effect of hormonal contraception. MEN were similar to the POST group for all parameters (not shown). Using the aggregate data (n=116), FIXa activity demonstrated modest but statistically significant negative correlations with both TFPI-α ($r=-0.36$, $p < 0.0001$) and total PS antigen ($r=-0.32$, $p < 0.0004$). Total protein S had a moderate strength positive correlation with TFPI-α antigen ($r=0.52$, $p < 0.0001$). Evaluation of TF-triggered FIX activation in FV-deficient plasma demonstrated that Inhibitory antibodies vs. the TFPI K1 and/or K2 domains enhanced TF-dependent FIXa generation by 2-3 fold, while addition of 2.4 nM TFPI or 75 nM PS reduced FIXa levels by ~2-fold.

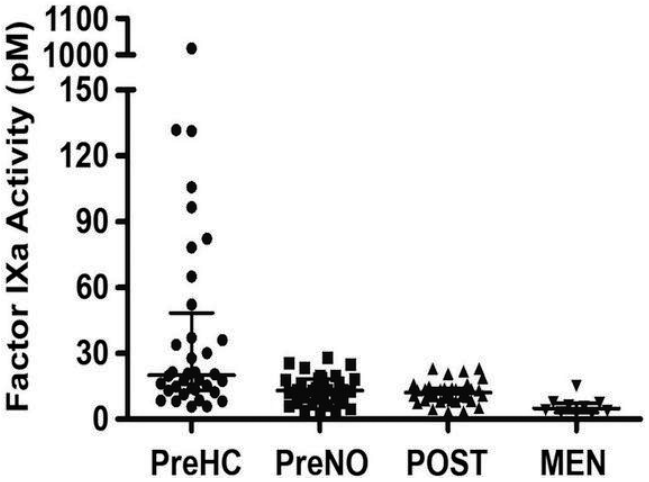

FIGURE 1 Plasma FIXa Activity in Blood Donor Subgroups

TABLE 1 FIXa Actvity, TFPI and Total PS antigen levels in Blood Donor Subgroups (Mann-Whitney)

	Blood Donor Subgroup	Median	IQR	p-value
FIXa Activity (pM)	PreHC	20.1	13.2-48.4	
	PreNO	13.0	7.9-18.2	0.0006
	POST	12.1	8.6-14.0	<0.0001
TFPI-α (ng/ml)	PreHC	12.9	9.2-18.7	
	PreNO	20.1	15.9-24.8	0.0001
	POST	27.9	23.0-35.0	<0.0001
Total PS (μg/ml)	PreHC	20.1	16.0-26.8	
	PreNO	22.9	17.8-27.7	0.74
	POST	31.6	22.6-36.4	0.0037

Conclusions: Plasma FIXa activity is a potential biomarker for hypercoagulability in premenopausal females taking OCPs.

PB 1540 | Analysis of Factor V Leiden Paradox from a Large Monocentric Cohort Study: A Role for Distal Thrombosis?

E. Campello, L. Spiezia, F. Dalla Valle, P. Simioni

University of Padua Medical School, Department of Medicine, Padova, Italy

Background: Factor V Leiden (FVL) is a stronger risk factor for deep vein thrombosis (DVT) than for pulmonary embolism (PE), hence the so-called FVL paradox.

Aims: To overview the venous thromboembolism (VTE) clinical presentation in our cohort of FVL and prothrombin mutation (PTM) carriers.

Methods: Consecutive patients with a first VTE homozygous or heterozygous FVL and/or PTM were considered. VTE patients in the same study period without thrombophilia acted as controls.

Results: Among 1970 VTE patients, 659 were carriers of FVL and/or PTM. 336 heterozygous FVL, 32 homozygous FVL, 10 homozygous PTM, 238 heterozygous PTM, 35 double heterozygous (FVL and PTM), and 8 FVL pseudohomozygous. A higher percentage of heterozygous FVL (61%) presented with isolated DVT than controls (43%, p< 0.0001). A similar figure was observed in homozygous FVL. There was no difference in heterozygous PTM and in double heterozygous compared to controls. 6 of pseudohomozygous (75%) had isolated DVT. A higher proportion of isolated distal DVT was observed in heterozygous FVL (30.2%) compared both to controls (18.6%, p< 0.001) and heterozygous PTM (18%, p=0.003). Multivariate risk of isolated DVT: 2.15 (95% CI 1.6-2.7) in heterozygous and 2.21 (95% CI 1.07-4.5) in homozygous FVL compared to controls. Heterozygous PTM and double heterozygous had a non-significantly higher risk of isolated DVT.

TABLE 1 Odds ratios (OR) for isolated DVT associated with different thrombophilic defects

	Univariate OR (95%CI)	Multivariate OR (95%CI)
No thrombophilia	1 (ref)	1 (ref)
Hetero FVL	2.22 (1.54-2.3)	2.15 (1.6-2.7)
Homo FVL	2.31 (1.18-3.7)	2.21 (1.07-4.5)
Hetero PTM	1.14 (0.7-1.6)	1.17 (0.8-1.56)
Homo PTM	2.24 (0.88-5.0)	1.98 (0.55-7.09)
Double heterozygosity	1.8 (0.91-2.6)	1.40 (0.71-2.75)
Pseudohomozygosity	3.31 (0.8-19.8)	3.19 (0.87-19.9)

Heterozygous FVL showed a similar risk of isolated DVT as homozygous FVL (0.98, 95%CI 0.93-1.04), a higher risk of isolated DVT (1.83, 95%CI 1.31-2.56) and of distal DVT (3.31 95%CI 1.73-6.33) than heterozygous PTM. There was no difference in the activated protein C resistance ratio in FVL with isolated DVT (1.66 ± 0.20) and FVL with isolated PE and combined DVT/PE (1.59 ± 0.19).

Conclusions: The paradox was limited to heterozygous and homozygous FVL, with a trend in pseudohomozygous. Double heterozygosity presented an intermediate clinical pattern. The higher prevalence of isolated distal DVT might in part explain the presence of paradox only in FVL.

PB 1541 | Paroxysmal Nocturnal Hemoglobinuria (PNH) and Thrombosis: Experience from an Asian Tertiary Centre

R.J. Lim[1], H.T. Mya[2], H.J. Ng[2], L.H. Lee[2]

[1]*Yong Loo Lin School of Medicine (NUS), Singapore, Singapore,* [2]*Singapore General Hospital, Singapore, Singapore*

Background: PNH was touted to be the most vicious acquired thrombophilia. We retrospectively reviewed the thrombotic events in our patient cohort that was followed up since January 2005 to date.

Aims: To review the characteristics of thrombotic events, treatment and the outcomes in the patients with PNH.

Methods: Our data was collected from the patients' laboratory and clinical records. Diagnosis of PNH was confirmed on flow cytometry assay (ISCH guidelines).

Results: There were 24 patients with PNH who were followed up since 1/1/2005 to date in our institution. 10 had classic PNH with significant hemolysis, 12 had associated bone marrow failure without significant hemolysis and 2 had asymptomatic PNH clone. Gender ratio was equal and racial distribution was as follows: Chinese 67%, Malay 12.5%, Indian 4% and other races 16.5%. Median age at diagnosis was 38.5 (17-81) and median follow up was 5.75 years with a total person-years of follow up 143.08 years. Venous thromboembolism (VTE) occurred in 4 patients (17% of total and 40% of classic PNH) and arterial thrombosis, coronary artery disease (CAD) in 2(8% of total). The incidence rates were 2.8% for VTE and 1.4% for arterial thrombosis per 100 patient-years. All VTEs responded well to the treatment with no recurrence during the follow up period. Table 1 summarized the characteristics of thrombotic events and their outcomes.

Conclusions: Our patients with PNH did not demonstrate the high risks of vicious thrombotic complications as described in literature. The patients with CAD had multiple cardiovascular risk factors. VTEs responded well to standard anticoagulation therapy with no recurrences while on long term anticoagulation. All patients with unprovoked and visceral VTE are of non-Chinese descent. Considering majority of Singapore population is ethnic Chinese, it seems probable that Chinese patients with classic PNH are at lower risk of developing VTE. Though overall mortality rate was higher in the patients with thrombosis, the mortality was not attributed to VTE.

TABLE 1 Characteristics of thrombotic events, treatment and outcomes in the study cohort

Patients with thrombotic events	Race	Types of PNH	Types of thrombosis	Sites of thrombosis	Risk factors other than PNH	Treatment of thrombosis	Outcome
1	Myanmar	Classic	Venous	Intra-abdominal	None	Warfarin	Alive
2	Indian	Classic	Venous	Intra-abdominal and right lower limb (proximal)	None	Warfarin	Alive
3	Malay	Classic	Venous	Right lower limb (proximal)	None	Warfarin	Death (Cause : sepsis)
4	Chinese	Classic	Venous	Right lower limb (distal)	Severe Sepsis Immobility	Enoxaparin	Death (Cause : sepsis)
5	Chinese	PNH with aplastic anemia	Arterial	Coronary artery	Pneumonia Renal failure Hypertension Hyperlipidemia Diabetes mellitus	Aspirin and clopidogrel	Death (acute myocardial infarction)
6	Malay	PNH with aplastic anemia	Arterial	Coronary artery	Hypertension Hyperlipidemia Diabetes mellitus	Bypass surgery, Aspirin Warfarin (short term)	Alive

PB 1542 | Results of Thrombophilia Testing in Infertile Women and Women Experienced a Miscarriage

S. Margetic[1], B. Getaldic[1], D. Ruzic Ferenec[1], I. Vuga[1], N. Vrkic[2]

[1]Medical School University Hospital ´Sestre Milosrdnice´, Laboratory Haematology and Coagulation, Zagreb, Croatia, [2]Medical School University Hospital ´Sestre Milosrdnice´, Clinical Institute of Chemistry, Zagreb, Croatia

Background: Although some studies suggested an association between thrombophilic risk factors and infertility and miscarriage, others did not confirmed these findings and disagreement regarding this association still exists.

Aims: The aim was to analyze results of thrombophilia testing in infertile women and women experienced miscarriage referred for testing at our laboratory during the two consecutive years (2015 and 2016).

Methods: The study included lupus anticoagulant (LA) investigation, functional assays for antithrombin (AT), protein C (PC), protein (PS), resistance to activated protein C (APCR) and coagulation FVIIII (FVIII) activitiy using commercially available coagulation methods (Siemens, Germany).

Results: Among all patients referred for testing, infertile women accounted for 150/1688; 8.9% (LA), 112/783; 14.3% (PS), 85/911; 9.4% (PC), 90/1054; 8.5% (AT), 25/356; 7.0% (APCR) and 9/451; 2.0% (FVIII). Positive results among all infertile women were: 1/150; 0.7% (LA), 2/112; 1.8% (PS) and 1/25 (APCR). There were no positive results for PC (0/85), AT (0/90) and FVIII (0/9) among infertile women. Women with miscarriage were represented as follows: 132/1688; 7.8% (LA), 93/783; 11.9% (PS), 50/911; 5.5% (PC), 52/1054; 4.9% (AT), 16/356; 3.5% (APCR) and 8/451; 1.8% (FVIII). Positive results among women with miscarriages were: 2/132; 1.5% (LA), 2/93; 2.2% (PS) and 1/16 (APCR) while there were no positive results for PC (0/50), AT (0/52) and FVIII (0/8).

Conclusions: Our results do not support nondiscriminate testing for all thrombophilic risk factors in all infertile women and all women experienced a miscarriage. The clear association between individual risk factors and infertility or miscarriage still remains controversial and inconclusive. A further large prospecitve and retrospective studies are necessary for clarifying and understanding this association. In order to contribute to these findings, we intend to follow and analyze our results during the next 5 years.

PB 1543 | Importance of Thrombophilia Screening in Patients with Ocular Thrombosis

M. Alrifai, R. Fischer, K. Heidinger, B. Kemkes-Matthes

University Hospital Giessen and Marburg, Giessen, Germany

Background: Ocular thrombosis (OT) is the second most common retinal vascular disease following diabetic retinopathy. It is still questionable if screening of thrombophilia in these cases has an important diagnostic and therapeutic impact as in other non-ocular thrombosis. We here report upon thrombophilia screening in 140 patients with OT.

Aims: We aimed to assess the role of thrombophilia as an etiology of ocular thrombosis, as seen in extremities thrombosis or pulmonary embolism.

Methods: 116 patients with ocular venous thrombosis and 21 with ocular arterial thrombosis and 3 patients with both arterial and venous thrombosis were examined. The patients presented in our department few weeks after incidence of OT. We carried out usual screening for most common inherited and acquired thrombophilia in all patients.

Results: Thromboembolic history was positive in 49 patients (35 %), 40 % of them were younger than 50 years old. Thrombophilia

screening showed: detected antiphospholipid antibodies in 28, lipoprotein (a) elevation in 23, factor VIII:c elevation in 23, antithrombin deficiency in 4, prothrombin (G20210A) polymorphism in 7, factor V Leiden mutation in 14 patients.

Conclusions: These results showed statistically no correlation between common risk factors of venous thromboembolism like factor V Leiden mutation, prothrombin polymorphism, antithrombin deficiency and factor VIII:c elevation and incidence of OT, while antiphospholipid antibodies and lipoprotein (a) elevation seem to play a major role. Positive history of deep venous thrombosis and pulmonary embolism in 35 % of these patients has an important impact on the prognosis and on the choice of therapeutic approach.

PB 1544 | Screening of Thrombophilia in Latin America

C. Guillermo[1,2], A. Blanco[3,4], M. Echenagucia[5,6], D.N. García[7,8], B. Steffano[2,9], V. Mérola[1], S. Grille[1], P. Turcatti[1], M. Stevenazzi[1], L. Diaz[1], R. Martínez[1]

[1]Hospital de Clinicas, Facultad de Medicina, Unidad de Hemostasis y Trombosis, Montevideo, Uruguay, [2]Grupo CLAHT, Comité de Normatización, Montevideo, Uruguay, [3]Academia Nacional de Medicina, Instituto de Investigaciones Hematológicas Mariano R Castex, Buenos Aires, Argentina, [4]Grupo CLAHT, Buenos Aires, Argentina, [5]Universidad Central de Venezuela, Escuela de Bioanálisis, Caracas, Venezuela, [6]Grupo CLAHT, Secretaria, Caracas, Venezuela, [7]Laboratorio de Hemostasis y Trombosis de la Clinica 25 de Mayo y CEDEAC, Mar del Plata, Argentina, [8]Grupo CLAHT, Comité de Normatización, Mar del Plata, Argentina, [9]Laboratorio de Hemostasis y Trombosis HYGEA, Montevideo, Uruguay

Background: Latin America is an heterogeneous region. A population in excess of 6 hundred million people belong to different ethnicities and cover different socio economic conditions.

Aims: In order to know how thrombophilia defects are investigated in the area the Latin American Group on Thrombosis and Haemostasis (Grupo Cooperativo Latinoamericano de Hemostasis y Trombosis-CLAHT) conducted a survey (March to April 2016).

Methods: The questionnaire was sent to members of different societies dedicated to haematology, thrombosis and haemostasis or internal medicine in various countries. It enquired about tests requested in case of patients with a first thromboembolic event and neither personal nor family history of thrombosis in four different situations: unprovoked event under either < 50 year old (A) or >50 year old (B); provoked event either < 50 year old (C) or >50 year old (D).

Results: Answers: 169 were obtained, mostly from haematologist (71.9%). The overall responses were made up as follows: Uruguay (43.2%), Argentina (17.4%), Brazil (8.3%), Perú (6.8%), Venezuela (6.8%) and other countries (17.5%). A: 74-81% requested tests of inherited thrombophilias (IT) (AT, PC, PS, FVL, P20210A) and antiphospholipid antibodies (APA); there is a surprisingly high number of requests for thermolabile MTHFR and PAI 4G5G (29%-15%) polymorphisms. B: 78% requested cancer screening and 64% APA; again, there is a high number of requests for homocysteinemia (44%) and IT (28-36%). C: 45% requested APA and 41% required no test; however, 27-36% also request some IT. D: 77.5% requested cancer screening despite being a provoked event.

Conclusions: The survey shows the need for more educational actions in order to abolish incorrect requests (MTHFR and PAI in A; APA in C and D; IT in B) by applying International Guidelines in the region, which will result in considerable economic and social benefits.

PB 1545 | First Do Not Harm: Questioning Ethics Aspects of Thrombophilia Law in Argentina

B. Grand, A. Rossi

On behalf of the Women Health Issues in Thrombosis and Hemostasis Group (WHITH-CAHT) and the Argentine Thrombosis and Hemostasis Cooperative Group (CAHT), Buenos Aires, Argentina

Background: Universal study of hereditable thrombophilia (HT)in pregnancy complications(pgC)is not indicated. Risks of treatment with low molecular weight heparin(LMWH)are low. Decision making upon starting treatment in pgC should come from well designed randomized controlled trials(RCT), there is no benefit in preventing early recurrent pregnancy lost(RPL)in women without thrombophilia(TP). RCT in RPL and HT are ongoing. The strongest evidence for the use of heparin and aspirin is in the antiphospholipid syndrome. In spite of this information a law petition was presented by organizations of women with pgC and TP and was finally passed by the Congress.

Aims: To evaluate the law's requirements.To describe its ethic questioned aspects.

Methods: Law's requirements: 1.Psychophysics protection of women with thrombophilia; 2.Early detection of thrombophilia in women in fertile and prefertile age; 3.Inclusion of tests and treatments as obligatory in public/private health programs.

Results: Ethic questioned aspects:1.Patient's autonomy in demanding HT studies vs medical autonomy in the obligation to prescribe them.2.Universal study of HT in healthy women.3.The use of medication in pregnancy that is "off label" or "non-validated" or what some authors call "innovation".4.The allocation of economic resources in public health. 5.The impacts of health related information in the media.

Conclusions: What happened in our country exposes important bioethics issues related to thrombophilia tests and its treatment in pregnancy:

1. Highlights open unresolved questions such as investigation and regulation of research in pregnant women.
2. Differences of research regulations between countries (we were unable to participate in previous trials SPIN-ALIFE for this reason).
3. Universal demand of genetic studies in healthy women.
4. Distribution of economic resources: The role of Public Health in defining Health Programs and Policies when the population demands government action in areas where scientific evidence do not support this petition.

PB 1546 | Extensive molecular characterization of a family with thrombophilia: implication of multiple genetic alterations of low thrombotic risk profile

M. Carrasco Exposito[1], I. Tirado Garcia[2], L. Romero Roman[2], N. Vilalta Seto[2], J. Mateo Arranz[2], J.A. Millon Caño[2], J. Fontcuberta Boj[2]

[1]Sant Pau Hospital, Unit Hemostasia and Thrombosis, Barcelona, Spain, [2]Sant Pau Hospital, Unit Hemostasia and thrombosis, Barcelona, Spain

Background: Thrombophilia is a complex disease where multiple genetic factors interact with each other and with the environment to generate a gradient of susceptibility to disease.

Aims: Characterize a family with several members with venous thrombosis.

Methods: A biological study of thrombosis in the propósitus was made extending to his relatives. Factor V Leiden mutations, prothrombin gene F2G20210A, factor XII F12C46T, AT Cambridge type II mutation (SER-PINC1G13268T; p.Ala384Ser) and ABO group genotype were included in the study.

Results: The propositus is a female patient with idiopathic popliteal DVT at 79 years old. The thrombosis study resulted in a G / T heterozygous AT Cambridge type II and BO2 of ABO . In her family history of thrombosis: a daughter with popliteal DVT at 30 years old secondary to polytraumatism, at that time in treatment with oral contraceptives and smoker. The genetic study resulted gene F2G20210A heterozygous and A1B of the ABO. Father deceased with a history of paraneoplasic DVT. No other history of thrombosis in rest of the family. A second daughter of the propósitus (currently 49 years): double heterozygote for the mutation F2G20210A and AT Cambridge type II, and A1O2 of the ABO. Grandson of first daughter (currently 30 years): homozygous for F2G20210A and homozygous A1A1 for ABO. His father was also found to have homozygosity for the F2G20210A mutation with no personal or family history of thrombosis in this part of the family. Grandsons by the second daughter (10 and 15 years old at present): both heterozygotes for the AT Cambridge type II mutation, one of them being heterozygous for the F2G20210A mutation and T / T homozygous for F12C46T

Conclusions: In this work we describe a family with Cambridge type II antithrombin in combination with multiple genetic factors. The family had thrombotic clinic in different family members. This example represents the oligogenic composition of thromboembolic disease, where multiple genetic defects coexist modulating the risk of disease.

PB 1547 | Inherited Thrombophilia and Infertility

E. Petkovikj[1], A. Hristova-Dimcheva[1], R. Grubovic[1], R. Apostolovska[1], S. Simeonova-Krstevska[2], M. Jakimovska[1], B. Todorovski[1]

[1]Institute of Transfusion Medicine- Skopje, Skopje, Macedonia, the Former Yugoslav Republic of, [2]University Clinic for Obstetrics and Gynecology, Faculty of Medicine, Ss. Cyril and Methodius University of Skopje, Skopje, Macedonia, the Former Yugoslav Republic of

Background: Increased tendency for thrombosis i.e. hypercoagulability as a result of multiple genetic mutations is called inherited thrombophilia. According to the World Health Organization (WHO), infertility can be described as the inability to become pregnant, maintain a pregnancy, or carry a pregnancy to live birth. Because of the recently reported possibility of association between infertility and inherited thrombophilia, further research is needed.

Aims: Aim of this study is to see the presence of the most common and clinically significant inherited thrombophilias: factor II prothrombin G20210A, factor V Leiden (FVL) G1691A and methylentetrahydrofolate reductase (MTHFR) C677T mutations among the patients with infertility.

Methods: retrospective study, using the data from the outpatient clinic in the Institute of Transfusion medicine- Skopje, Republic of Macedonia. We have examined 39 females with infertility referred to our Institute in the period of June-September 2016. 2ml of venous blood in K2EDTA was collected for genetic evaluation. Detection of point mutations for factor II prothrombin G20210A, factor V Leiden (FVL) G1691A and methylentetrahydrofolate reductase (MTHFR) C667T was performed, using the Operon kit.

Results: We found 23 patients(58.9%) with one thrombophilia, 7 patients(17.9%) with two thrombophilias and only 9 patients(23.1%) do not have any of the tested mutations. Among the tested patients: 15.4% are MTHFR C677T homozygous and 43.6% are MTHFR C677T heterozygous, 17.9% are factor V Leiden (FVL) G1691A heterozygous and 12.8% are factor II prothrombin G20210A heterozygous.

Conclusions: There is strong presence of the most common and clinically significant thrombophilic mutations among the females with infertility. Expanding the tested group and inclusion of a control group is necessary.

PB 1549 | Impact of the Molecular Study of the PROC, PROS1 and SERPINC1 Genes in Patients with Venous Thrombosis

P. Martinho, T. Fidalgo, A.C. Oliveira, C. Pinto, T. Sevivas, R. Salvado, M.L. Ribeiro

Centro Hospitalar e Universitário de Coimbra, Serviço de Hematologia Clínica, Coimbra, Portugal

Background: The prevalence of deficiencies (d) of protein C(PCd), protein S(PSd) and antithrombin(ATd) are low and probably underdiagnosed. The molecular study of the genes *PROC*, *PROS1* and *SERPINC1* increase the diagnostic capacity, allow to establish a genotype/phenotype correlation and to identify patients at venous thrombosis risk.

Aims: To study the these genes in patients (P) with
(i) PCd and/or PSd and/or ATd or with plasma levels at the lower limit
(ii) normal plasma levels but severe history of venous thrombosis.

Methods: We studied 172P with PE (8.1%), VT(33.7%), TA(7%) and obstetric complications(18.6%); 32.6% had a family history of thrombosis. Functional studies: PSL, PCact and ATact - plasma levels compared to age-adjusted reference values, confirmed in 2 different samples. Molecular studies: ASPCR, Sanger sequencing and MLPA.

Results: Among 172P, 130 had: 34.3% PCd, 38.3% PSd and 3.5% ATd; 1 P PCd + PSd; 34normal levels of PC, PS and AT; 7were anticoagulated. In 102 P 26different mutations (mut) - (12*PROC*, 10*PROS1* and 6*SERPINC1*).The p.Ser501Pro(PS Herleen) was found in 46% of PSd. The *PROC* mutation p.Arg199*was identified in 18P with PCd type I and associated with a severe phenotype. The *PROS1* p.Val1191Cysfs*6, p.Ala307Cysfs*22 and p.R451* mut, were found in severe PSd. Two compound heterozygous *PROS1* p.[Pro76Leu+Ala307Cysfs22] were detected in 2P with PSd; 1P showed combined heterozygosity for *PROC*-13A>G, *PROS1* p.N166H,p.A307Cfs*22; two *novel* mut: *PROC*(p.Cys105Arg); *SERPINC1* p.YTyr95Serfs*18; 60% of P with mut in *SERPINC1* and 18.9% in *PROS1* had normal levels.

Conclusions: In PSd and ATd, the success of mut identified was lower, especially in mild deficiencies. Mut. were detected in patients with normal plasma levels, confirming the failure to detect qualitative changes by the available functional assays. The molecular study should be considered in patients with a significant personal/family history of thrombosis, and „normal/borderline" levels of these proteins.

PB 1550 | Cutaneous Necrosis Revealing Paroxysmal Nocturnal Haemoglobinuria

Z. Tazi Mezalek[1,2], W. Ammouri[1], M. Bourkia[1], H. Harmouche[1], N. Bouigua[1], M. Maamar[1], W. Mounfaloti[1], M. Adnaoui[1,2]

[1]Ibn Sina Hospital, Internal Medecine / Hematology, Rabat, Morocco, [2]Mohammed V University, Faculty of Medicine, Rabat, Morocco

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is an acquired clonal disorder of hematopoietic cells characterized by intravascular hemolytic anemia, hypercoagulable state and bone marrow aplasia. Venous thrombosis generally arise in hepatic, intra-abdominal, cerebral, and extremity veins and represent the most common cause of death in patients with PNH. Despite being recognized as a complication, cutaneous thrombosis is uncommon and a variety of findings have been reported.

Aims: We report an exceptional case of cutaneous necrosis of the earlobe and the scalp revealing PNH.

Methods: We report the case of a 37-year-old male patient with minor-thalassemia diagnosed at the age of 5.

Results: He presented with necrotic lesions mainly located in the neck, the scalp and the left earlobe. Laboratory analysis revealed bicytopenia (hemoglobin 9 g/dl; platelet count 33 g/L), with hemolysis and a negative coombs test negative, biological inflammation (CRP of 195 mg/l) and hematuria. There were no other serological, immunological or coagulation alteration. Skin biopsy revealed superficial and deep dermal vessels with foci of necrosis; without vasculitis. Flow cytometry of peripheral blood leucocytes and mononuclear cells confirmed the presence of an PHN clone with 90-95% of positive cells.

Anticoagulant therapy was started with enoxaparin 1 mg/kg twice a day with corticosteroids (prednisone 1 mg/kg/day). After 1 week there were only residual hyperpigmented macules. After 3 years, the patient remains well with VKA treatment and 5mg of prednisone.

Conclusions: PNH is a clonal stem cell disorder resulting from a mutation in the PIG-A (phosphatidyl inositol glycan class A) that block glycosyl-phosphatidyl inositol (GPI) biosynthesis.

Both corticosteroid therapy and anticoagulants may be useful in the treatment of thrombotic episodes and prednisone is used because the complement activation probably initiates thrombosis in patients with PNH. The role of eculizumab in the treatment of acute thrombosis is under consideration.

PB 1551 | Venous Thromboembolism (VTE) in Homozygous Carriers of Factor V Leiden Mutation Patients (FVL)

B. Ceglarek[1], A.J. Sikorska[2], K. Bykowska[3], A. Bućko[4], J. Windyga[2,3]

[1]Institute of Hematology and Transfusion Medicine, Department of Disorders of Hemostasis and Internal Medicine, Warsaw, Poland, [2]Institute of Hematology and Transfusion Medicine, Department of Disorders of Hemostasis and Internal Medicine1, Warsaw, Poland, [3]Institute of Hematology and Transfusion Medicine, Department of Hemostasis and Metabolic Disorders, Warsaw, Poland, [4]Institute of Hematology and Transfusion Medicine, Department of Hemostasis and Metabolic Disorders2, Warsaw, Poland

Background: Risk of venous thromboembolism is increased 50-100-fold in homozygous carriers factor V Leiden mutation patients particularly in the presence of additional congenital and acquired thrombotic risk factors.

Aims: The 21 years retrospective clinical analysis of homozygous FVL patients diagnosed and treated in the IHTM.

Methods: During last 21 years 132 homozygous carriers of FVL mutations were diagnosed in IHTM. We analyzed 103 homozygous FVL mutation patients (74F ; 58M, age 18-64).

DNA was isolated using GeneMatrix kit (Eurx, Poland). The FVL mutation was identified by PCR/RFLP method according to Bertina et al (1994) using restriction enzyme Mnl1 (Eurx, Poland). Prothrombin G20210A mutation was determined according to Poort et al (1966) using Hind III restriction enzyme (Eurx, Poland).

Results:

1. Homozygous factor V Leiden was detected in 74 female (56.1%) and 58 male (43.9%) patients. Deep venous thrombosis (DVT) was observed in 125/132 patients. Heterozygous G20210A mutation of prothrombin gene occurred with FVL in 5/132 homozygous patients.
2. Mean age of female and male patients was similar (30.5 vs.30.7 yrs) at the moment of the first DVT episode (K-16/74 (21.6%) ; M-6/58 (10.3%).
3. Proximal and distal DVT was more often observed in female than male patients.
4. 2-4 episodes of DVT occured in 17/125 pts (13.6%) more often in female patients
(F-11 ; M-6).

5. All the patients had several thrombotic risk factors, particularly age >30 yrs and familiar DVT (K-8/74 ; M-1/58).
6. Deep venous thrombosis untypical localization occurred in 3.03% FVL patients and thrombotic stroke in 8.3% FVL patients. Dominant thrombotic risk factors were familiar DVT.
7. Treatment of all patients was similiar : low molecular weight heparin (LMWH) followed by anticoagulant vitamin K (VKA).

Conclusions: Venous Thromboembolism can occur in carriers of homozygous FVL mutation particularly above 30yrs old if several pathophysiological, environmental and genetic thrombotic risk factors are present.

PB 1552 | Characteristics and Outcomes of Patients with Cerebral Venous Sinus Thrombosis in Oman

K. Al Hashmi[1], K. Al-Wahaibi[2], M. Al-Khabori[3], S. Al Lamki[4]

[1]*Armed Forces Hospital/Sultan Qaboos University, Hemato-Oncology Section, Seeb, Oman,* [2]*Royal Hospital, Internal Medicine Department, Seeb, Oman,* [3]*Sultan Qaboos University, Hematology Department, Al-Khoudh, Oman,* [4]*Royal Hospital, Seeb, Oman*

Background:

1. Cerebral venous sinus thrombosis (CVST) is a rare cause of stroke, usually affecting young to middle aged patients 1. It accounts for 0.5% to 1% of all causes of strokes 1.

Aims:

1. Primary objective: To describe the clinical profile of the patients with CVST, to assess the risk factors involved and the presenting symptoms and signs
2. Secondary objective: The association with inherited thrombophilia and the out come.

Methods:

1. This was a retrospective cohort study which was conducted in 2 tertiary care hospitals in the Sultanate of Oman.
2. The study was reviewed and approved by the ethics committees of the two centers.
3. All Patients admitted with a diagnosis of CSVT were identified using the (ICD-10) coding system of the hospital medical records between Jan 2006 to June 2016.
4. Out of 81 patients were identified, 27 patients were excluded as didn´t meet the inclusion criteria (Omani patients, 14 years or older and radiologically confirmed by CT or MRI).

Results:

1. A total of 54 patients fulfilled the inclusion criteria with radiologically confirmed CVST.
2. The commonest presenting feature was headache (85%); followed by focal motor deficits (48%), and seizures (27%).
3. causes In this cohort were 24% were pregnant or postpartum, 11% had an inherited thrombophilia, 11% were on hormonal therapy, 11% were found to have systemic lupus erythematous, 7% had Antiphospholipid syndrome,13% had infections, and 2% had cancers. 33% there was no cause identified.
4. Thirty-seven percent of patients had multiple sinus thrombosis, 35% had sigmoid and transverse sinus thrombosis.
5. Out come: 30 % had residual neurological deficit on discharge and 2% of patients had died.
6. Age was a predictor for residual neurological deficit (*p=0.003*).

Conclusions:

1. Pregnancy and postpartum were the most common predisposing factors for cerebral venous thrombosis.
2. 30% of patient had residual neurological deficit at discharge.
3. mortality was 2%.
4. further studies needed.

PB 1553 | Anticoagulant Therapy in Disorders in the Fibrinolysis System among Patients with Primary Infertility

I. Kurtov, T. Gritsenko, Y. Berman, V. Kuvaev, A. Kurtova, I. Davydkin

Samara State Medical University, Hematology, Samara, Russian Federation

Background: Currently an important role in the failure of in vitro fertilization, pregnancy complications and infertility of unknown origins belongs to thrombophilia. Early pregnancy losses, that may be connected with disorders in fibrinolysis, are of some interest.

Aims: Identification of disorders of the hemostasis system among patients with primary infertility and also the possibility of using low molecular weight heparins for pregnancy without in vitro fertilization (IVF).

Methods: The study involved 34 women diagnosed primary infertility aged 24 to 38 years, with an increased level of D-dimer in their blood. The timing of primary infertility ranged from 3 to 14 years. 26 women had failures with IVF in the anamnesis. Laboratory tests included: activated partial thromboplastin time, international normalized ratio, fibrinogen, XIIa-dependent fibrinolysis, protein C, protein S, antithrombin III, plasminogen, factor VIII, platelet count, level of plasminogen activator inhibitor type 1, D-dimer. The method of polymerase chain reactions identified: polymorphisms of methylenetetrahydrofolate reductase C677T, prothrombin G20210A, plasminogen activator inhibitor PAI-1, fibrinogen 455G/A, FV Leiden Arg506Gln. The analysis was carried out using nonparametric statistics with the use of U-criterion of Mann—Whitney.

Results: Polymorphism of PAI-1 was revealed among 29 patients (85,3%), including 11 patients with an increased level of PAI-1 (P=0,000005). At the stage of pregravid preparation, all the patients used enoxaparin in the complex therapy, the injections starting before ovulation and continuing until the end of the cycle, for 6 cycles or until pregnancy. Among 34 women included in the study, 7 (20,6%) with an excess of PAI-1 became pregnant.

Conclusions: The fibrinolysis system may play a role in primary infertility. The use of enoxaparin at the stage of pregravid preparation promotes pregnancy in some cases. Further observation is required to develop specific recommendations.

PB 1554 | Pattern of Thrombophilia Testing in Patients with Venous Thromboembolism at a Tertiary Care Hospital

M. Gaddh[1], E. Cheng[2], Y. Lin[2], R. Sharma[1], I. Bodo[1]

[1]Emory Winship Cancer Institute, Atlanta, United States, [2]Emory University, Rollins School of Public Health, Atlanta, United States

Background: Role of thrombophilia testing in patients with venous thromboembolism (VTE) is controversial. With no existing consensus on indications or panel of tests, there may be significant variability in the pattern of testing within and between institutions.

Aims: Determine the pattern of thrombophilia testing in patients with VTE at Emory University Hospital (EUH).

Methods: Patients admitted at EUH in year 2015, for whom a Hematology consult for VTE was requested were identified (N=85) and charts were reviewed retrospectively. Complete thrombophilia workup was defined as testing for all the following: Protein S (PS), Protein C (PC) and Antithrombin (AT) activity, Antiphospholipid antibodies (APLA), Factor V Leiden and PT G20210A gene mutations. Abnormal results for PC, PS and AT activity under conditions known to falsely affect levels were called ‚wrong time'. Statistics were descriptive.

Results: Of the 85 patients, 43 (51%) patients were males; 47% White, 42% African-American. Mean age at first VTE was 52.6 years. Forty-four (52%) underwent thrombophilia testing; 20 (45%) within 2 weeks of VTE event. Thirteen (29%) had complete workup. Reasons for incomplete workup were missed tests in 41, ‚wrong time' in 9 and no repeat testing for APLA in 1. Other tests included JAK 2 mutation in 11, PNH flow cytometry in 7, and fibrinogen, PAI-1, factor 8, factor 9 and factor 11 activity in 18, 3, 2, 1 and 1 patient respectively. Patients who underwent workup had lower mean age at first VTE (51.4 vs 57.7,p=0.045) and higher proportion of unprovoked episodes (52%vs19%,p=0.002) as compared to those who did not get tested. No significant difference in sex, race, clot location or number of episodes were found between the groups. Workup was positive in 10 (23%) and APLA syndrome (n=3) was the most common thrombophilia.

Conclusions: Thrombophilia testing in patients with VTE is common, with significant variability in the pattern of testing. There is need for establishing clear indications for a clinically relevant panel of tests.

PB 1555 | Meaning of Hereditary Thrombophilia in the Diagnosis of Thrombotic Complications during Combat Gunshot Injury

K. Nikolaev[1], S. Kapustin[2], V. Zubritskij[3,4], A. Koltovich[3], I. Zolobov[1]

[1]Main Clinical Hospital of Russian National Guard, Balashicha, Russian Federation, [2]Russian Scientific Research Institute of Hematology and Blood Transfusion of the Federal Medical and Biological Agency, St. Petersburg, Russian Federation, [3]Main Clinical Hospital of the Russian Interior Ministry, Moscow, Russian Federation, [4]Institute of Medical and Social Technology VPO ‚MGUPP', Moscow, Russian Federation

Background: Prevention of complications is needed.

Aims: The aim of the study was to investigate the effect of haemostasis system gene polymorphism on venous thrombosis in the wounded from combat gunshot injury.

Methods: The results of the study of genetic mutations of the haemostatic system components at 46 wounded from combat gunshot injuries from 2013 to 2015 were performed. All patients - men, mean age - 29,5 ± 5,1 years. Mine-blast injured 33 (71.7%), bullet - 13 (28.3%) patients.

All the wounded were classified as high risk for venous thromboembolic complications and had 3 - 4 risk factors for their development.

The study group included 13 (28.3%) patients who during treatment at the hospital were diagnosed with venous thrombosis & the control group - 33 (28,3%) - with no signs of thrombosis.

Studied allelic polymorphism of genes: the factors I, II, V, XII, PAI-1, HPA-1, HPA-2, P2Y12, GpIa C677T (MTHFR).

To assess the reliability between the values used χ^2 test, Fisher´s exact test (two-tailed) to assess the strength of the relationship factors studied - criteria φ (phi) and Cramer´s V.

Results: There were no thromboembolic complica t ions & vascular disease before injury; soldiers were not screened previously for the presence of thrombophilia.

TABLE 1 Distribution of the main polymorphisms of genes in the injured

The name of the mutation	Allelic polymorphism	With thrombosis	No thrombosis	Total	Fisher´s exact test	p	φ & V Cramer
FV Leiden	MN	1	0	1	0.28261	p>0.05	0,2-<0,4
Prt G20210-A	MN	3	0	3	0.01884	p<0.05	0,4-<0,6
HPA-2	AB	8	8	16	0.01400	p<0.05	0,2-<0,4
HPA-2	BB	1	0	1	0.16667	p>0.05	0,4-<0,6
Fibrinogen G/A-455	MUT	5	1	6	0.01318	p<0.05	0,4-<0,6
Fibrinogen G/A-455	MN	2	13	15	0.68566	p>0.05	0,1-<0,2
GpIa C677T	MUT	3	1	4	0.06222	p>0.05	0,2-<0,4
PAI-1	4G/4G	5	8	13	0.46890	p>0.05	0,1-<0,2
P2Y12 ins801A (AP)	MUT	1	1	2	0.44286	p>0.05	0,1-<0,2

The presence of genetic mutations were identified in 42 (91.3%) injured. The data obtained are presented in the table.

Conclusions: We have found that, despite the high prevalence of thrombophilia not all lead to the development of thrombosis. The greatest probability of developing clinical manifestations of thrombosis must be expected for the wounded with combinations of several genetic mutations. It has been found that hereditary thrombophilia Prt G20210-A, HPA-2 and Fibrinogen G/A-455 are risk factors for thrombosis ($p< 0.05$).

The presence of the genotype of the wounded predisposition to thrombosis markers may serve as a basis for the definition of „risk groups" & to make recommendations for the prevention & treatment thrombosis in wounded with prothrombotic genotypes.

PB 1556 | Acquired Thrombotic Thrombocytopenic Purpura (aTTP) in Patient with Decompensated/Uncontrolled Hypertension, Hyperhomocysteinemia, Hypercholesterolemia and Hyperlipidemia

B. Ceglarek[1], A.J. Sikorska[1], K. Bykowska[2], J.M. Teliga Czajkowska[3], A. Bućko[4], J. Windyga[1,4]

[1]*Institute of Hematology and Transfusion Medicine, Department of Disorders of Hemostasis and Internal Medicine, Warsaw, Poland,* [2]*Institute of Hematology and Transfusion Medicine, Department of Hemostasis and Metabolic Disorders2, Warsaw, Poland,* [3]*Medical University of Warsaw, Department for Didactics in Obstetrics and Gynecology, Warsaw, Poland,* [4]*Institute of Hematology and Transfusion Medicine, Department of Hemostasis and Metabolic Disorders, Warsaw, Poland*

Background: Acquired thrombotic thrombocytopenic purpura (aTTP) is characterized by thrombocytopenia and microangiopathic hemolytic anemia (MAHA) of no obvious origin. Microvascular thrombosis is also reported and causes variable degrees of tissue ischemia and infarction .

Aims: A female patient aged 50 admitted to IHTM in poor general condition, conscious without contact, no hemorrhagic disorders, 1brain ischemia attack was observed in the amplitude of vascularization of right and left internal carotid arteries with transient right and left-sided hemihypaesthesia with such symptoms as: confusion, no logical contact, psychomotor agitation.

Methods: Lab tests showed : RBC $1.7x10^6$/L, Hb 5.7 g/dl , HCT 17.0 % , MCV 97.1 fl , platelet 7.0 $x10^3$/L, RBC -poikilocytosis, mikrocytosis, makrocytosis, schistocytes, reticulocytes: 9.03 % , AST: 67.9 U/l , GGTP: 95.4 U/l , LDH: 1 380.3 U/l , bilirubin.5.30 mg/dl, bilirubin direct 1.32 mg/dl , hypercholesterolemia and hyperlipidemia, antinuclear antibodies (ANA3), lupus anticoagulant (LA) were not detected, heterogous MTHFR 677T and hyperhomocysteinemia (20.90 umol/l), ADAMTS 13 activity < 2% and ADAMTS13 inhibitor 41U/ml. Decompensated hypertension and chronic nicotinism.

Results: A 4-week management consisted in administration of : 27 FFP plasmaphereses (1 epileptic attack Grand-Mal was recorded/maintained after 2-nd procedure), steroids (Prednisone, Methyl-Prednisolone), red blood cell infusions-2 units. ADAMTS13 activity increased from 2 to 62% and the inhibitor decreased from 41 to 12U/ml. Remission was observed for the last 58 months. Nowadays: ADAMS 13 activity (44.0%), no hyperhomocysteinemia, hypercholesterolemia, hyperlipidemia and arterial hypertension is under control.

Conclusions: In patients with TTP/aTTPa, heterozygous MTHFR C677T mutation, hyperhomocysteinemia, hypercholesterolemia, hyperlipidemia and uncontrolled hypertension. the plasmapheresis procedure and steroids prove to be an effective therapy.

PB 2293 | External Validation of Generic and Cancer-Specific Risk Stratification Tools for Predicting 30-day Mortality in Patients Presenting with Pulmonary Embolism and Active Cancer

J. Caranfa[1,2], S. Zeichner[3], E. Weeda[2], E. Nguyen[2], C. Coleman[2,4], C. Kohn[2,5]

[1]*University of Connecticut School of Medicine, Farmington, United States,* [2]*UConn/ Hartford Hospital Evidence-based Practice Center, Hartford, United States,* [3]*Emory Winship Cancer Institute, Atlanta, United States,* [4]*University of Connecticut, School of Pharmacy, Storrs, United States,* [5]*University of Saint Joseph, School of Pharmacy, Hartford, United States*

Background: Numerous risk stratification tools exist to predict early post-pulmonary embolism (PE) mortality; however, few were specifically designed for use in cancer patients.

Aims: To evaluate 3 cancer-specific (Registro Informatizado de la Enfermedad TromboEmbólica [RIETE], POMPE-C and criteria by Font et al.) and 3 generic (Hestia, Pulmonary Embolism Severity Index [PESI] and Geneva Prognostic Score [GPS]) risk stratification tools for predicting 30-day post-PE mortality in patients with active cancer.

Methods: We identified consecutive, adult, objectively confirmed PE patients with active cancer presenting to our institution from 11/2010-1/2014. We calculated the proportion of patients categorized as low- or high-risk by each of the 6 risk stratification tools and determined each tools' accuracy for predicting 30-day all-cause mortality.

Results: A total of 124 patients with PE and active cancer (mean age 66.2 years, 46.0% with concurrent DVT, 49.2% with metastatic disease and 46.8%, 16.9% and 11.3% receiving chemotherapy, radiation or both, respectively) were included. Mortality at 30-days occurred in 25 (20.2%) patients. The cancer-specific tools (POMPE-C, RIETE and the criteria by Font et al.) categorized between ~32-43% of patients as low-risk and displayed sensitivities and specificities of 88.0-96.0% and 38.4-52.5%, respectively. The generic PESI and Hestia tools also had sensitivities >96.0% but classified < 19% of patients as low-risk. Specificity of these tools were low (PESI=6.1%; Hestia=23.2%). Although GPS classified 43.5% of patients as low-risk, it did so with a sensitivity of 52.0% and specificity of 42.4%.

Conclusions: When risk stratifying newly diagnosed PE in patients with active cancer, cancer-specific tools appeared to exhibit better

TABLE 1 Prognostic Test Characteristics for 30-Day Mortality

Characteristic	RIETE	POMPE-C	Font	Hestia	PESI	GPS
Low-Risk n (%)	53 (42.7%)	40 (32.3%)	51 (41.1%)	23 (18.5%)	7 (5.6%)	54 (43.5%)
Low-Risk Mortality n/N (%)	1/53 (1.9%)	2/40 (5.0%)	3/51 (5.9%)	0/23 (0%)	1/7 (14.3%)	12/54 (22.2%)
High-Risk Mortality n/N (%)	24/71 (33.8%)	23/84 (27.4%)	22/73 (30.1%)	25/101 (24.8%)	24/117 (20.5%)	13/70 (18.6%)
Sensitivity (95%CI)	96.0% (77.7-99.8%)	92.0% (72.5-98.6%)	88.0% (67.7-96.8%)	100% (83.4-100%)	96.0% (77.7-99.8%)	52.0% (31.8-71.7%)
Specificity (95%CI)	52.5% (42.3-62.6%)	38.4% (28.9-48.7%)	48.5% (38.4-58.7%)	23.2% (15.6-33.0%)	6.1% (2.5-13.2%)	42.4% (32.7-52.8%)
NPV (95%CI)	98.1% (88.6-99.9%)	95.0% (81.8-99.1%)	94.1% (82.8-98.5%)	100% (82.2-100%)	85.7% (42.0-99.2%)	77.8% (64.1-87.5%)
PPV (95%CI)	33.8% (23.3-46.1%)	27.4% (18.5-38.4%)	30.1% (20.2-42.1%)	24.8% (16.9-34.5%)	20.5% (13.8-29.2%)	18.6% (10.6-30.0%)
C-statistic (95%CI)	0.774 (0.679-0.870)	0.806 (0.713-0.899)	0.723 (0.616-0.813)	0.725 (0.623-0.827)	0.754 (0.630-0.878)	0.483 (0.353-0.614)

prognostic accuracy than their generic counterparts. POMPE-C, RIETE and the criteria by Font et al. identified a substantially greater proportion of these PE patients likely to survive to 30-days with comparable sensitivity to the generic tools.

PB 2294 | Predictors of 30-day Mortality among Patients with Cancer-associated Thrombosis in the RIETE Database

A. Tafur[1], H. Fuentes[2], J. Caprini[1], A. Rivas[3], F. Uresandi[4], R. Duce[5], R. Lopez-Reyes[6], A. Visona[7], M. Monreal[8], RIETE Group

[1]NorthShore University Health Systems, Evanston, United States, [2]John Stroger Hospital Cook County, Chicago, United States, [3]Hospital Universitario Araba, Alava, Spain, [4]Hospital de Cruces., Barakaldo, Spain, [5]Ospedale Galliera, Genova, Italy, [6]Hospital Universitari i Politècnic La Fe, Valencia, Spain, [7]Ospedale Castelfranco Veneto, Castelfranco Veneto, Italy, [8]Hospital Universitario Germans Trias i Pujol de Badalona, Barcelona, Spain

Background: Venous Thromboembolism (VTE) is a predictor of fatality among patients with cancer. Identifying who are the pts at the highest risk of 30 d mortality after a cancer-associated thrombosis (CAT), may help us stratify treatment options.

Aims: To derive and validate the variables present at CAT diagnosis which predict 30-day mortality.

Methods: We selected patients with CAT in the RIETE database. The main outcome was mortality within 30d. We analyzed as potential predictors prospectively collected variables including: demographic, comorbidities, cancer specific (type, metastatic, treatment), VTE (location, recurrent), and baseline lab values. We randomly split the database into a derivation (2/3) and validation (1/3) cohort. Data are expressed as mean and percentages, continuous variables categorized in quartiles. To simplify the analysis of high level interactions, we used recursive partitioning and amalgamation (RECPAM) to select groups at risk. We used SPSS 23 for the analysis.

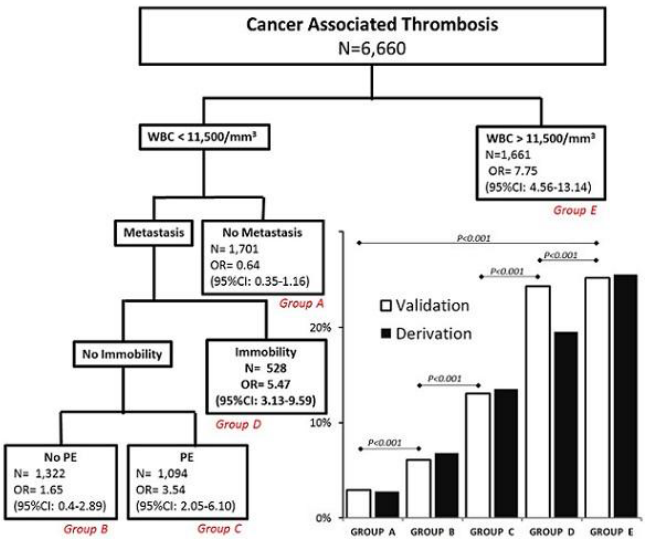

FIGURE 1 Derivation RECPAM and validation mortality rates

Results: In September 2016, there were 10,025 CAT pts (mean age 67, female 47%, metastatic 63%). There were 1,911 (19%) immobile pts for non-surgical reasons at least 4 d prior to diagnosis. The derivation cohort included 6,660 pts of which 827 (12.4%) died within 1 mo. The following variables remained as predictors: WBC > 75th percentile, immobility, metastasis, and pulmonary embolism. RECPAM helped us define 5 risk groups (Fig1). In the validation cohort (n=2,936), 429 (12.7%) of the pts died < 30d. In both the derivation and validation cohorts, there was a significant, incremental risk of death predictable by findings at CAT presentation. The highest risk of death at 30d was among pts with high white count (25%, OR 4.6-13.4) and the lowest probability of death was among pts with no metastases and normal white count (3%, OR 0.4-1.16).

Conclusions: Elevated WBC is more important in predicting CAT early mortality than the combination of PE, immobility, and metastasis.

PB 2295 | Thrombosis after Orthotopic Liver Transplantation for Hepatocellular Carcinoma: Incidence, Implications and Risk Factors

A. Maino[1,2], M. Abbatista[3], P. Bucciarelli[3], A. Artoni[3], S. Bhoori[4], F. Ponziani[4], U. Maggi[5], G. Rossi[5], T. De Feo[6], F. Peyvandi[3], V. Mazzaferro[4], I. Martinelli[3]

[1]Fondazione IRCCS Ca' Granda - Ospedale Maggiore Policlinico, A. Bianchi Bonomi Hemophilia and Thrombosis Center, Milano, Italy, [2]Azienda Provinciale per i Servizi Sanitari - Provincia Autonoma di Trento, Trento, Italy, [3]Fondazione IRCCS Ca' Granda - Ospedale Maggiore Policlinico, Milan, A. Bianchi Bonomi Hemophilia and Thrombosis Center, Milano, Italy, [4]Fondazione IRCCS - Istituto Nazionale Tumori, Gastrointestinal Surgery and Liver Transplantation Unit, Milano, Italy, [5]Fondazione IRCCS Ca' Granda - Ospedale Maggiore Policlinico, Hepatobiliary and Liver Transplant Unit, Milano, Italy, [6]Fondazione IRCCS Ca' Granda - Ospedale Maggiore Policlinico, North Italy Transplant Program (NITp), Organ and Tissue Transplant Immunology, Milano, Italy

Background: Whether thrombosis influences the prognosis of patients with hepatocellular carcinoma (HCC) undergoing orthotopic liver transplantation (OLT) is unknown, as well as the role of inherited thrombophilia in its development.

Aims: To estimate the incidence rate (IR) of thrombosis after OLT for HCC, its influence on mortality and re-transplantation and the role of factor V Leiden (FVL) or prothrombin G20210A mutation, both in donors and recipients.

Methods: Historical cohort of HCC patients enlisted for OLT between 2001 and 2013 in two Northern Italian Liver Units and referred to the North Italy Transplant Program allocation agency. IR of thrombosis, re-transplantation and mortality after OLT were calculated. Hazard ratios (HR) were used to compare patients with and without thrombosis. In a nested case-control study (case:control ratio of 1:3) the association between thrombosis and inherited thrombophilia in donors and recipients was estimated as odds ratio (OR) with 95% confidence intervals (CI).

Results: Of the 460 patients (88% men, mean age 52 yrs) included in the cohort, 430 underwent OLT. During a median follow-up time of 7.2 yrs, 26 recipients (6%) developed thrombosis (19 venous and 7 arterial) for an IR of 1.06 (95%CI 0.71-1.53) per 100 pt-yrs. Mortality rate after OLT did not differ between recipients with and without thrombosis (Table 1). Re-transplantation, conversely, was more common in patients with thrombosis (HR 2.50, 95%CI 0.87-7.17).

The risk of thrombosis was higher in recipients with thrombophilia than in those without (OR 4.23, 95%CI 0.99-18.04), especially when the analysis was restricted to venous thrombosis (Table 2).

The presence of inherited thrombophilia in the donor did not increase the risk of thrombosis.

Conclusions: Thrombosis after OLT for HCC increases the risk of re-transplantation but not mortality. The risk of thrombosis is increased when FVL or prothrombin G20210A mutation is present in the graft recipient but not in the donor.

TABLE 1 IRs of mortality and need of re-transplantation. Adj.HR, hazard ratio adjusted for age at OLT, sex and year of OLT.

	N.	pts-yr	IR per 100 pts-yr (95% CI)	IR ratio	Adj.HR

PB 2296 | Predicting the Risk of Recurrent Venous Thromboembolism in Patients with Cancer: The REMARK Study

N. van Es[1], M. Louzada[2], M. Carrier[3], V. Tagalakis[4], P. Gross[5], S. Shivakumar[6], M. Rodger[3], P.S. Wells[3]

[1]*Academic Medical Center, Department of Vascular Medicine, Amsterdam, The Netherlands,* [2]*London Health Sciences Centre, Department of Medicine, London, Canada,* [3]*Ottawa Hospital Research Institute, Department of Medicine, Ottawa, Canada,* [4]*Jewish General Hospital, Department of Internal Medicine, Montreal, Canada,* [5]*Hamilton Health Sciences, Department of Medicine, Hamilton, Canada,* [6]*Victoria General Hospital, Department of Medicine, Halifax, Canada*

Background: Patients with cancer-associated venous thromboembolism (VTE) often fail (recur) on low-molecular-weight heparin (LMWH). Procoagulant markers may identify high-risk patients and then be used to guide decisions about intensifying anticoagulation.

Aims: To evaluate whether serial measurements of procoagulant markers can identify patients at high risk of recurrent VTE.

Methods: A multicenter, prospective cohort study in which cancer patients with acute symptomatic VTE were enrolled. Patients received standard LMWH therapy. Treatment failure was defined as an extension of VTE, a new VTE, or fatal PE. D-dimer and soluble P-selectin levels were measured at baseline, 1, 4, 5, 12 and 24 weeks post treatment initiation. The relationships between treatment failure and the Louzada risk score, baseline values of the biomarkers, and individual relative changes from baseline were assessed.

Results: We enrolled 117 patients with 19 different cancers (22% lung, 21% colorectal, 9% breast), a mean age of 63 years, equal men and women; 62% had distant metastases. Eleven (9.4%) had recurrent VTE and 23 (20%) died, including 3 fatal PEs and 1 fatal bleeding. VTE recurrence rates were 7.3% with a Louzada score of 0, 8.7% with a score of 1, and 20% with a score of 2 (Figure 1). Median baseline P-selectin levels were higher in patients who recurred (P=0.01), but not D-dimer levels (P=0.12). The area under the ROC-curve was 0.64 (95% CI 0.57-0.81) for baseline D-dimer levels and 0.75 (95% CI 0.60-0.90) for baseline P-selectin levels (Figure 2).

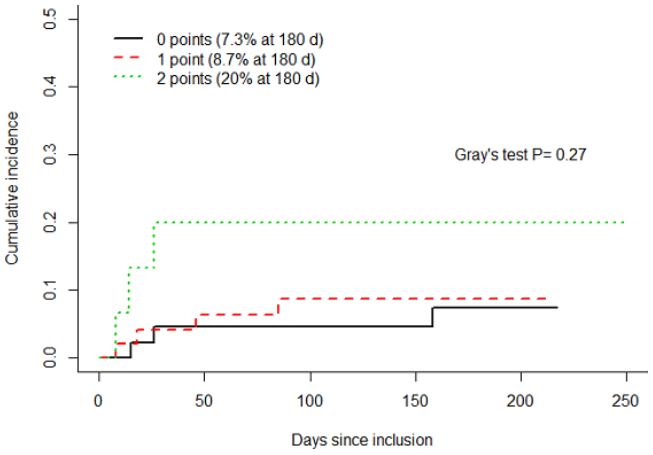

FIGURE 1 Risk of recurrent venous thromboembolism stratified by Louzada score

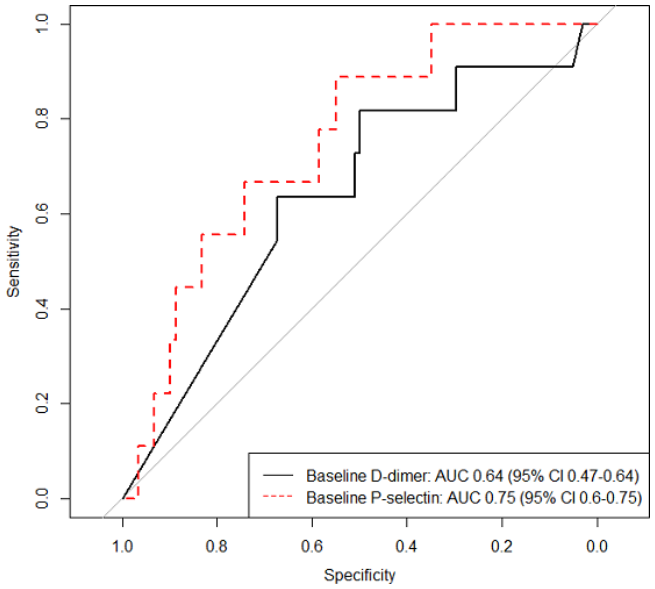

FIGURE 2 ROC-curves for baseline biomarker levels

P-selectin levels at baseline were independently associated with recurrent VTE in competing risk regression analysis, conditional on the risk score (P< 0.01). The decrease in levels of D-dimer and P-selectin from baseline during treatment was not associated with recurrent VTE.

Conclusions: Baseline P-selectin but not D-dimer predict recurrent VTE and may be a valuable addition to clinical prediction rules to select patients for more intensive therapy or closer observation.

PB 2297 | Comparative Analysis of Predictive Models for Thromboembolic Events in Lymphoma Patients

D. Antic[1], N. Milic[2], S. Nikolovski[1], M. Todorovic[1], J. Bila[1], P. Djurdjevic[1], B. Andjelic[1], V. Djurasinovic[1], A. Sretenovic[1], V. Vukovic[1], J. Jelicic[1], B. Mihaljevic[1], Serbian Lymphoma Group

[1]*Clinic for Hematology, Clinical Center of Serbia, Belgrade, Serbia,* [2]*Institute for Medical Statistics and Informatics, Belgrade, Serbia*

Background: The models that evaluate potential thromboembolic risk in lymphoma patients in particular are quite limited.

Aims: In this study we compared diagnostic performance of suggested predictive models for general cancer population /Khorana and Padua score/ and Thrombosis lymphoma /Throly/ score that is specific for lymphoma patients.

Methods: The study population included 1820 eligible lymphoma patients who were treated in the clinics of hematology Clinical Center Serbia, Belgrade and Clinical Center Kragujevac during 9 years period.

Initially, the study population was divided based on a split-sample random method into the model derivation and validation cohorts.

Patient's characterics were evaluated by univariate logistic regression analysis, while the final ThroLy model was developed using a stepwise multivariate logistic regression analysis.

Results: In analyzed population ninety-nine patients (5.4%) developed thromboembolic events. Cohorts were balanced regarding the incidence of events (5.3% and 5.5% in derivation and validation cohort, respectively). The variables included in ThroLy score were: previous venous and/or arterial events, mediastinal involvement, BMI>30 kg/m^2, reduced mobility, extranodal localization, development of neutropenia and hemoglobin level < 100g/L. Based on the risk model score, the population was divided into: low (score 0-1), intermediate (score 2-3), and high (score >3). For patients classified *at risk* according to ThroLy score (intermediate and high-risk scores) in derivation cohort, the model produced negative predictive value of 98.5%, positive predictive value (PPV) of 25.1%, sensitivity of 75.4%, and specificity of 87.5%. In validation cohort PPV for Throly score was 28.9%. Padua and Khorana score had PPV of 15.5% and 14.8% in derivation, and 11.5% and 14.8% in validation cohort, respectively.

Conclusions: ThroLy score is more specific for lymphoma patients than Padua and Khorana score but external validation is required.

PB 2298 | Outcomes of Subsegmental Pulmonary Embolism (SSPE) in Cancer Population

M. Yan[1], C.C. Wu[2], W. Qiao[3], C.M. Rojas-Hernandez[4]

[1]University of Texas Health Science Center at Houston, Internal Medicine, Houston, United States, [2]University of Texas MD Anderson Cancer Center, Diagnostic Radiology, Houston, United States, [3]University of Texas MD Anderson Cancer Center, Biostatistics, Houston, United States, [4]University of Texas MD Anderson Cancer Center, Benign Hematology, Houston, United States

Background: Acute pulmonary embolism (PE) is a significant cause of morbidity and mortality among cancer patients. Modern computed tomographic (CT) scans and CT-pulmonary angiography (CT-PA) has allowed for better visualization of the peripheral pulmonary arteries, resulting in greater detection and incidence of subsegmental pulmonary embolism (SSPE). The clinical significance of SSPE remains unclear, especially among the cancer population.

Aims: To evaluate the incidence of recurrent PE within 6 months of SSPE and overall survival of cancer patients with SSPE.

Methods: We performed a retrospective analysis (2014-2015) of adult cancer patients followed at MD Anderson Cancer Center who were diagnosed with SSPE. The primary outcome was PE recurrence rate within 6 months of SSPE diagnosis. The secondary outcome was overall survival (OS) stratified by SSPE treatment, adjusted for performance status (PS) and tumor stage (TS), and PE recurrence. The study was approved by IRB with consent waiver.

Results: Among 128 patients, 64.1% were male, 75.5% with stage IV disease, and 57.8% were on chemotherapy at time of SSPE diagnosis. The majority of SSPE (73.4%) were diagnosed incidentally by staging CT vs. 26.6% by CT-PA (Table 1).

TABLE 1 Radiographic characteristics of 128 SSPE cancer patients

Characteristic	N	%
Number of SSPE		
- Single	90	70.3
Number of lobes involved		
- Unilobar	98	76.6
Location		
- Unilateral, right	82	64.1
- Unilateral, left	24	18.7
- Bilateral	22	17.2
RV/LV ratio >1	7	5.5

A total of 99 patients (77.3%) were treated with anticoagulation alone, 7 patients (5.5%) had IVC filter placement, 9 patients (7.0%) received both anticoagulation and IVC filter, and 13 patients (10.2%) had no therapy. At 6-month follow-up, 7 of 128 patients (5.5%) had PE recurrence. There was no significant effect of anticoagulation in OS, after adjustment for PS and TS (P=0.11), or by PE recurrence status (P=0.53).

Conclusions: The study showed a similar PE recurrence rate among cancer patients with SSPE treated with anticoagulation when compared to PE outcomes in cancer thrombosis randomized trials. The effect of therapies other than anticoagulation on PE recurrence could not be assessed due to a small number of cases in those subgroups. Anticoagulation did not seem to impact OS in this population.

PB 2299 | Screening for Cancer in Patients with Unprovoked Venous Thromboembolism: A Systematic Review and Individual Patient Data Meta-Analysis

N. van Es[1], G. Le Gal[2,3], H.-M. Otten[4], P. Robin[5], A. Piccioli[6], R. Lecumberri[7], L. Jara-Palomares[8], P. Religa[9,10], V. Rieu[11], M. Rondina[12], M. Beckers[13], P. Prandoni[6], P.-Y. Salaun[5], M. Di Nisio[14], P.M. Bossuyt[15], H.R. Büller[16], M. Carrier[17]

D'Annunzio University, Dipartimento di Medicina e Scienze dell'Invecchiamento, Chieti, Italy, [15]Academic Medical Center, Department of Clinical Epidemiology, Biostatistics,

and Bioinformatics, Amsterdam, The Netherlands, [16]Academic Medical Center, Department of Vascular Medicine, Amsterdam, The Netherlands, [17]Ottawa Hospital Research Institute, Ottawa, Canada

Background: Unprovoked venous thromboembolism (VTE) may be the first sign of occult cancer. Screening is therefore often considered in these patients. However, precise risk estimates are needed as well as better information on the effect of screening strategies and age on occult cancer diagnosis.

Aims: To evaluate the risk of occult cancer overall and in subgroups by age and type of screening received.

Methods: A systematic review searching MEDLINE, CENTRAL, and Embase until January 2016 was performed. Individual patient data was obtained from the prospective studies that have evaluated occult cancer screening strategies in patients with unprovoked VTE and have followed patients for a minimum of 12 months. Risk of bias was assessed using the QUADAS-2 tool. Risk estimates were obtained in one-stage random effect meta-analyses.

Results: Ten eligible studies were identified and individual data were obtained for 2,316 patients. The mean age was 60 years and 1,334 patients (58%) underwent an extensive screening strategy (Table). The risk of a cancer diagnosis was 3.5% (95% CI 2.8-4.5%) at initial screening, 1.6% (95% CI 1.0-2.6%) between screening and 12 months, and 1.0% (95% CI 0.56 to 1.9%) between 12 and 24 months. At screening, cancers were most often diagnosed by medical history and physical examination (37%). The most frequently diagnosed cancers were colorectal (17%), lung (14%), and pancreatic cancer (9%). Of the solid cancers, 41% were early-stage cancers (i.e. stage 0, 1, or 2). An extensive screening strategy at entry was associated with a two-fold increased rate of occult cancer detection (odds ratio 2.0, 95% CI 1.1-3.4). The 12-month risk of cancer diagnosis increased linearly with age (Figure).

Conclusions: Occult cancer is detected in 5.2% of patients within 12 months of an unprovoked VTE diagnosis. Extensive screening detected significantly more cancers than a more limited screening. Whether this translates into improved outcome remains to be elucidated.

PB 2300 | Cancer Cell Derived Extracellular Vesicles Increase Extracellular Vesicle Dependent Tissue Factor Activity of Peripheral Blood Mononuclear Cells in the Presence of Platelets

T. Däullary[1], L. Hell[1], E. Grilz[1], L.-M. Mauracher[1], J. Schmid[2], C. Ay[1], I. Pabinger[1], J. Thaler[1]

[1]Medical University of Vienna, Department of Medicine 1, Vienna, Austria, [2]Medical University of Vienna, Department of Vascular Biology and Thrombosis Research, Vienna, Austria

Background: Tissue factor bearing extracellular vesicles (TF+EV) are thought to be involved in the pathogenesis of cancer-related coagulopathy and thrombosis in certain cancer types. However, the complete pathomechanism and the contributing cells remain to be clarified. In addition to cancer cells, previous studies showed that circulating monocytes express TF under certain circumstances and release EV into the blood.

Aims: The aim of this study was to investigate whether cancer cell derived EV can induce the release of TF+EV by peripheral blood mononuclear cells (PBMC) *in vitro*. Further, the effect of platelets on the release of TF+EV was investigated.

Methods: PBMCs and platelets of healthy donors (n=5) were isolated and co-incubated with supernatant containing EV of a TF+ prostate cancer cell line (DU145). The EV-TF activity in the collected supernatant of each experiment was determined with a factor Xa generation assay.

Results: The EV-TF activity (pg/ml) of PBMCs alone (mean±SD: 0.61±0.77), PBMCs plus platelets (0.25±0.48) and of platelets stimulated with cancer cell derived EVs (0.84±0.11) was low. Increased EV-TF activity was found in the supernatant of PBMCs stimulated with cancer cell derived EVs (1.54±0.63, p=0.039). The co-incubation of PBMCs with platelets and cancer cell derived EVs resulted in a further increase in EV-TF activity (4.84±1.13) compared to PBMCs incubated with cancer cell derived EVs (p=0.003) and to platelets incubated with cancer cell derived EVs (p=0.010).

Conclusions: EVs derived from a cancer cell line increase the extracellular vesicle dependent TF activity of PBMCs and this effect is

enhanced in the presence of platelets. This observation supports an interrelation of cancer cells with platelets and monocytes in activating coagulation in cancer.

PB 2301 | Impact of Regular Physical Activity on the Risk of Cancer-related Venous Thromboembolism - The Scandinavian Thrombosis and Cancer (STAC) Cohort

L.H. Evensen[1,2], M.T. Severinsen[3,4], J. Hammerstrøm[5], S.K. Braekkan[1,2], S.R. Kristensen[4,6], S.C. Cannegieter[7], O.V. Gran[1,2], A. Tjønneland[8], F.R. Rosendaal[1,7,9], H. Skille[1], K. Overvad[10,11], I.A. Næss[12], J.B. Hansen[1,2]

[1]UiT - The Arctic University of Norway, K.G. Jebsen - Thrombosis Research and Expertise Center (TREC), Tromsø, Norway, [2]University Hospital of North Norway, Division of Internal Medicine, Tromsø, Norway, [3]Aalborg University Hospital, Department of Haematology, Aalborg, Denmark, [4]Aalborg University, Department of Clinical Medicine, Aalborg, Denmark, [5]Norwegian University of Science and Technology, Department of Cancer Research and Molecular Medicine, Trondheim, Norway, [6]Aalborg University Hospital, Department of Clinical Biochemistry, Aalborg, Denmark, [7]Leiden University Medical Center, Department of Clinical Epidemiology, Leiden, The Netherlands, [8]Danish Cancer Society Research Center, Diet, Genes and Environment, Copenhagen, Denmark, [9]Leiden University Medical Center, Department of Thrombosis and Hemostasis, Leiden, The Netherlands, [10]Aalborg University Hospital, Department of Cardiology, Aalborg, Denmark, [11]Aarhus University, Department of Public Health, Section for Epidemiology, Aarhus, Denmark, [12]Trondheim University Hospital, Department of Hematology, Trondheim, Norway

Background: Venous thromboembolism (VTE) is a common complication and a predictor of poor prognosis in cancer. Growing evidence suggests that regular physical activity (PA) may reduce the risk of VTE in the general population, but the effect on cancer-related VTE is unknown.

Aims: To investigate the impact of PA on the risk of cancer-related VTE in a population-based cohort.

Methods: A total of 137 780 subjects from the STAC cohort (comprising data from the Tromsø Study, the Nord-Trøndelag Health Study, and the Danish Diet, Cancer and Health Study), were included. Incident cancer and VTE were registered from the date of inclusion (1993-97) until study end (2007-12). Levels of moderate and high intensity PA were dichotomized (≥1 vs < 1 h/week), and hazard ratios (HRs) adjusted for age, sex and BMI were calculated using Cox regression. Cancer-free subjects with PA < 1h/week were used as reference. VTEs occurring from 6 months before to 2 years after a cancer diagnosis were defined as cancer-related. VTEs were classified as unprovoked or provoked based on the presence of provoking factors other than cancer.

Results: There were 2218 VTEs and 13374 cancers during a median follow-up of 11.8 years. Overall, the risk of VTE was 8.5-fold higher in cancer patients (HR 8.5; 95% CI 7.6-9.5) compared to those without cancer, and it was not influenced by the level of PA at baseline. However, in subjects aged < 60 years, the HR of VTE was lower in those engaging in PA ≥1h/week (HR 10.9; 95% CI 8.1-14.8) compared to those engaging in PA < 1h/week (HR 13.5; 95% CI 11.2-16.2). The impact of PA on the risk of VTE among cancer patients was driven by an effect on unprovoked events (HR for PA ≥1h/week 8.9; 95% CI 6.0-13.4 vs HR for PA < 1h/week 12.6; 95% CI 10.0-15.9), with essentially similar effects for deep vein thrombosis (DVT) and pulmonary embolism (PE).

Conclusions: Our findings suggest that moderate and high intensity PA ≥1h/week may affect the risk of VTE among cancer patients, particularly unprovoked VTE, in middle-aged subjects.

PB 2302 | Immunomodulatory Changes at the Tumor Microenvironment Induced by a Kunitz-type Inhibitor Improve Antitumoral Activity CD8$^+$T-dependent Manner on Orthotopic Kidney Tumor Model

J.G. de Souza[1,2], F.V. Pereira[3], P. Boufleur[1], J.M. Sciani[1], C.S. Origassa[3], M. Amano[3], N.O.S. Câmara[3], A.M. Chudzinski-Tavassi[1,2]

[1]Butantan Institute, Biochemistry and Biophysics Laboratory, Sao Paulo, Brazil, [2]Butantan Institute, CENTD- Center of Excellence in New Target Discovery, São Paulo, Brazil, [3]University of São Paulo, Laboratory of Transplantation Immunobiology, Department of Immunology, Institute of Biomedical Sciences IV, São Paulo, Brazil

Background: A Kunitz-type inhibitor domain-containing protein, isolated from the salivary glands of the *Amblyomma cajennense* tick, termed Amblyomin-X, which inhibit coagulation factors, angiogenesis and triggers apoptosis in murine renal adenocarcinoma cells (Renca) by inhibiting the proteasome and endoplasmic reticulum stress.

Aims: Investigation of the immunologic role associated with inhibition of angiogenic factors in the clearance of renal metastasis in lungs.

Methods: Tumor affinity by Amblyomin-X was assessed using orthotopic kidney tumors model, developed in BALB/c by *in vivo* imaging. Its functional and phenotypic immune infiltrate in the tumor microenvironment, apoptosis and cell cycle arrest were evaluated using CBA techniques, flow cytometry and immunohistochemistry. In addition, this model was applied to NSG mice without Amblyomin-X treatment and splenic CD8 T cells from BALB/c mice were adoptively transferred.

Results: herein, we have demonstrated that Amblyomin-X drastically reduced the incidence of lung metastases by inducing cell cycle arrest and apoptosis. In addition, Amblyomin-X treatment modulated cells-immune response and inflammatory cytokines. It increased and activated of CD8T and decreased MDSC´s cells in tumor microenvironment and improves IFNγ and TNFα, as well as decreased IL17 levels. No changes were observed in the IL6 levels. In the *in vivo* imaging analyses, we observed the co-localization of Amblyomin-X with Renca tumor mass for longer time compared to tumor free animal. In NSG mice, Amblyomin-X have shown minor antitumor effect, which was recovered with adoptive CD8$^+$T cells transfer.

Conclusions: In summary, Amblyomin-X has shown antitumor activity with high affinity for tumor cells and dependent on the recruitment of immunologic system to amplify its antitumor property, indicating a strong potential toward a safe drug against cancer and associated thrombosis.

PB 2303 | Elevated Risk of Venous Thrombosis Post Allogeneic Transplantation for Leukemia: Patient Characteristics of a Single Centre Cohort

R. Ikesaka[1], N. Cantor[2], M. Carrier[3], M. Sabloff[4]

[1]University of Ottawa and the Ottawa Hospital Research Institute, Hematology/Thrombosis, Ottawa, Canada, [2]Ottawa Hospital Research Institute, Hematology, Ottawa, Canada, [3]Ottawa Hospital Research Institute at the University of Ottawa, Hematology/Thrombosis, Ottawa, Canada, [4]Ottawa Blood Disease Centre, Hematology, Ottawa, Canada

Background: Leukemia patients undergoing allogeneic hematopoietic stem cell transplant are at increased risk of venous thromboembolism (VTE) due to need for central venous catheter for supportive care, chemotherapy and graft versus host disease(GVHD). This specific post-transplant population is poorly described.

Aims: We sought to describe the rate of events and patient characteristics of individuals who develop VTE in the post allogeneic hematopoietic stem cell transplant period in a cohort of leukemia patients.

Methods: The study was approved by the Ottawa Health Science Network Research Ethics Board. We retrospectively reviewed the charts of all patients diagnosed with acute leukemia at the Ottawa Hospital from January 2007 to September 2015. Patients' demographics, details of transplant and thrombosis characteristics were added to a database of all leukemia patients diagnosed by our centre.

Results: 166 leukemia patients underwent allogeneic bone marrow transplantation. There were 46 venous thrombosis events (27.7%; 95% confidence intervals (CI): 21.1 to 35.2%). Of these events, 15/166 (9.0%; 95%CI: 5.1 to 14.5%) of the transplant population developed a VTE in the post-transplant period. Descriptive statistics are depicted in Table 1.

TABLE 1 Characteristics of patients developing post allogeneic hematopoietic stem cell transplant thrombosis. N=15

	N	%		N	%
Gender			Leukemia Type		
Male	11	73.0	AML	9	60.0
Female	4	27.0	ALL	5	33.3
			Ambiguous Lineage	1	6.7
Mean Age (sd)		47.6 (16.2)			
BMI (sd)		26.07 (3.17)	Stem Cell Source		
			HLA Matched Unrelated Donor	10	66.7
			HLA Matched Related Donor	4	26.7
			HLA Mismatch 7/8 Unrelated Donor	1	6.7

11/15 (73%) of the patients with post allogeneic hematopoietic stem cell transplant VTE had either acute or chronic GVHD. The median time from transplant to diagnosis of VTE was 206 days(range 0-2498 days). There were 6 leukemia relapses post allogeneic hematopoietic stem cell transplant in this population of 15 patients who developed VTE. Thrombosis predated the diagnosis of relapse in 5/6 cases by a mean of 3.35 months (standard deviation 2.20). The site of VTE and first vs recurrent event is depicted in Table 2.

TABLE 2 Site of VTE and First vs. Recurrente VTE event N=15

Site of Thrombosis	N	%	Post Transplant VTE	N	%
PE	1	6.7	First VTE event	6	40.0
DVT	6	40.0	Recurrent VTE	9	60.0
PE+DVT	2	13.3			
Upper Extremity DVT	2	13.3	On DVT prophylaxis at the time of VTE	1	6.7
Upper Extremity Superficial thrombosis	3	20.0			
Portal Vein Thrombosis	1	6.7			

Conclusions: There is a high rate of VTE in the post allogeneic hematopoietic stem cell transplant leukemia population. GVHD is present in a high number of those that develop VTE. Long term prophylaxis strategies in this high risk population should be investigated.

PB 2304 | Combination of Podoplanin Expression and IDH-1 Mutation Status in Primary Malignant Brain Tumors Identifies Patients at Risk of Venous Thromboembolism

J. Riedl, P.M.S. Nazari, M. Preusser, F. Posch, C. Marosi, P. Birner, J. Thaler, G. Ricken, J.A. Hainfellner, I. Pabinger, C. Ay

Medical University of Vienna, Vienna, Austria

Background: Venous thromboembolism (VTE) is common in patients with primary malignant brain tumors. Recently, independent studies have reported intratumoral podoplanin expression and IDH-1 mutation status as novel risk predictors for VTE in these patients. However, the interrelation between podoplanin and IDH-1 mutation and their combined effect on risk of VTE has so far not been investigated.

Aims: We explored the association of podoplanin with IDH-1 mutation status and their combined effect on VTE risk assessment in patients with primary malignant brain tumors.

Methods: Immunohistochemical staining against podoplanin and IDH-1-R132H was performed in brain tumor specimens of 213 adult patients (mostly high-grade gliomas [89%]) included in the Vienna Cancer and Thrombosis Study (CATS), a prospective observational

cohort study of patients with newly diagnosed cancer or progressive disease. Primary endpoint was symptomatic VTE within two years.

Results: Eighty (37.6%) tumor specimens stained medium or highly positive for podoplanin. IDH-1 mutation was found in 42 (19.7%) tumors. IDH-1-R132H mutation was only found in podoplanin negative tumors, while all podoplanin positive tumors were IDH-1-R132H wildtype (wt) (Figure 1A).

During follow-up, 29 (13.6%) patients developed VTE. Expression of podoplanin was associated with a high risk of VTE, while mutant IDH-1-R12H was associated with a very low risk for VTE. In competing risk analysis, a combined variable of podoplanin and IDH-1 mutation predicted risk of VTE (Figure 1B). This association was independent of tumor type: subhazard ratio (SHR) for podoplanin positive plus IDH-1-R132H wt tumors, compared to podoplanin negative plus IDH-1-R132H mutant tumors: 4.69, 95%CI: 1.28-17.17; p=0.020).

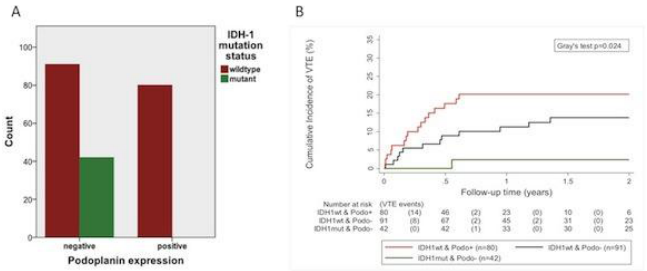

FIGURE 1 (A) IDH-1 R132H mutation according to podoplanin expression. (B) Incidence of VTE according to podoplanin expression and IDH-1 R132H mutation

Conclusions: IDH-1-R132H mutation is only detected in tumors, which are podoplanin negative. Determination of podoplanin and IDH-1-R132H mutation in primary malignant brain tumors identifies patients with both very high and very low risk of developing VTE.

PB 2305 | Podoplanin Promotes Oral Cancer Malignancy by Inducing Intravascular Coagulation in Orthotopic Xenograft Mice Model

H.-Y. Lee[1], J.-C. Cheng[2], C.-P. Tseng[1,3]

[1]*Chang Gung University, Graduate Institute of Biomedical Sciences, Taoyuan, Taiwan, Republic of China,* [2]*China Medical University, Taiwan, Department of Medical Laboratory Science and Biotechnology, Taichung, Taiwan, Republic of China,* [3]*Chang Gung University, Department of Medical Biotechnology and Laboratory Science, Taoyuan, Taiwan, Republic of China*

Background: Tumor-associated thrombosis is a lethal cause in patients with cancer. Podoplanin (PDPN), a small transmembrane glycoprotein, mediated tumor cell-induced platelets aggregation (TCIPA) has been studied in different cancer types. Emerging data also indicated that PDPN is a malignant indicator of human oral squamous cell carcinoma (OSCC).

Aims: To define whether and how PDPN promotes OSCC malignant progression.

Methods: A *luciferase*-expressing PDPN positive (P^+Luc^+) OECM-1 cells was used as our study model. P^+Luc^+shLacZ and P^+Luc^+shPDPN sublines were established by introducing short-hairpin RNA targeting on *b-galactosidase* or *pdpn into* P^+Luc^+ cells, respectively. The cell growth rate and the ability to induce platelet aggregation of these cell lines were analyzed *in vitro*. An orthotopic xenograft animal model was established for functional analysis of PDPN in OSCC. The tumor growth rate was analyzed by *in vivo* image system (IVIS). Indicators of tumor-associated thrombosis were analyzed by immunofluorescence staining for tumor sections and enzyme-linked immunosorbent assay (ELISA) for plasma samples.

Results: *In vitro* analysis revealed no difference for the cell growth or the ability to induce TCIPA of shLacZ and shPDPN cells. In IVIS analysis, the tumor growth rate also had no difference between shLacZ and shPDPN tumor ($p > 0.05$). However, the survival time of the mice bearing shPDPN tumors prolonged when compared to shLacZ tumors ($p < 0.001$). Notably, 29.4% (5/17) of mice bearing shLacZ tumor died suddenly, without any signs of deterioration. Comparing to mice bearing shPDPN tumor, mice with shLacZ tumor was associated with a 2.4-fold increase of platelet infiltration to tumor tissue ($p < 0.05$) and a 1.4-fold increase in the plasma levels of thrombin-anti-thrombin complex ($p < 0.05$).

Conclusions: PDPN promotes disease progression by inducing tumor cells-platelet interactions and intravascular coagulation, which reduce lifespan of the mice with OSCC tumors.

PB 2306 | Thrombin Generation in Patients with Active Multiple Myeloma and Impact of Immunomodulators. The ROADMAP Study

L. Papageorgiou[1], P. Van Dreden[2], D. Fotiou[3], M.S. Guye[4], L. Garderet[4], E. Terpos[3], S. Salta[5], T. Sergentanis[3], M. Dimopoulos[6], A. Larsen[1], I. Elalamy[1,7], G. Gerotziafas[1,7]

[1]*Cancer Biology and Therapeutics, INSERM U 938, Institut Universitaire de Cancérologie (IUC), Université Pierre et Marie Curie (UPMC), Sorbonne Universities, Faculté de Médecine Pierre et Marie Curie, Paris, France,* [2]*Clinical Research, Diagnostica Stago, Gennevilliers, France,* [3]*National and Kapodistrian University of Athens, School of Medecine, Athens, Greece,* [4]*Hôpital Saint Antoine, APHP, Hématologie et Thérapie Cellulaire, Paris, France,* [5]*Service d'Hématologie Biologique, Hôpital Tenon, Hôpitaux Universitaires Est Parisien, Assistance Publique Hôpitaux de Paris, Paris, France,* [6]*National and Kapodistrian University of Athens, School of Medecine, Department of Clinical Therapeutics, Athens, Greece,* [7]*Service d'Hématologie Biologique Hôpital Tenon, Hôpitaux Universitaires Est Parisien, Assistance Publique Hôpitaux de Paris, Paris, France*

Background: Multiple myeloma (MM) and the associated immunomodulatory (IMiD) treatments are associated with an incresed risk of vascular complications. Thrombin generation (TG) assessment reflects the equilibrium between procoagulant and anticoagulant potenties in plasma.

Aims: We conducted a multicenter study, to explore the relationship between stages of MM and alterations of TG profile.

Methods: MM patients (n=129) were recruited from July 2014 to December 2016 and stratified to the following groups: 44 newly

diagnosed treatment naïve patients (ND), 33 patients receiving IMiDs (IM), 45 patients in complete remission (CR) and 7 patients in partial remission on IMiDs (PR/IM). Patients receiving anticoagulant treatment were excluded The control group (CG) consisted of 30 healthy age and sex-matched individuals. Samples of platelet-poor plasma (PPP) were assessed for thrombin generation (TG) with the TF 5pMPPP-Reagent® on Calibrated Automated Thrombogram (Stago,Asnières,France).TG parameters such as Peak, Endogenous Thrombin Potential (ETP) and velocity (MRI) were studied.The upper and lower normal limits (LNL and UNL) were calculated by the mean±2SD.

Results: Patients with ongoing MM (ND, IM, PR/IM) had significantly lower Peak, ETP and MRI values as compared to the CG. In contrast Peak, ETP, MRI values were similar in CG and CR. PR patients had lower ETP and MRI values as compared to the CR group (Table 1). In ND 8% had TG >UNL and 20% had TG< LNL. In IM 9% had TG>UNL and 57% had TG< LNL. None in PR/IM had TG>UNL and 33% had TG< LNL. In CR, 28% had TG>UNL and 14% had TG< LNL.

TABLE 1 Thrombogram parameters in patients with MM and controls (*p<0.05 versus Control; +p<0.05 versus IM; $p<0.05 versus ND; £p<0.05 versus CR)

	Peak (nM)	ETP (nMxmin)	MRI (nM/min)
Control (LNL - UNL)	288±36 (211-359)	1496±191 (1114-1880)	110±24 (61-159)
ND	247±55*$	1229±179*$	103±40
IM	233±54*	1292±532*	86±30*
PR/IM	220±85*	1163±415*£	79±31*£
CR	285±79$+	1591±402$+	114±39+

Conclusions: Patients with active MM showed attenuated TG which was enhanced in the presence of IMiD treatment. Complete remission was associated with TG normalization . This evolutive profile might indicate that TG assay reflects vascular aggression in MM patients which is followed by the release of natural coagulation inhibitors such as thrombomodulin, heparin cofactor II, sEPCR and TFPI.

PB 2307 | Impact of the Extensive Cancer Screening in Patients with a First Episode, Unprovoked Venous Thromboembolism: A Systematic Review and Meta-analysis

C. Chai-Adisaksopha[1], E. Tseng[1], M. Crowther[1], A. Iorio[1], M. Carrier[2]

[1]*McMaster University, Medicine, Hamilton, Canada,* [2]*University of Ottawa, Medicine, Ottawa, Canada*

Background: Diagnosis of malignancy is estimated to be 10% in patients who presents with unprovoked venous thromboembolism (VTE). The impact of extensive cancer screening on mortality in VTE patients remains controversial.

Aims: To explore the benefit of extensive cancer screening among patients with first episode, unprovoked VTE.

Methods: We performed an updated systematic search in MEDLINE, EMBASE and CENTRAL databases, from January 2015 to October 2016. Search strategies were adapted from the recent Cochrane review (CD010837). We included randomised controlled trials evaluating extensive cancer screening (including computed tomography [CT] or a positron emission tomography [PET] scan) versus standard screening in patients with first episode, unprovoked VTE.

Results: We included four randomized trials with 1,644 participants. Median age ranged from 53.4 to 69.3 years. Cancer-associated death occurred in 10 of 817 (1.2%) in patients undergoing extensive screening and 19/827 (2.3%) in control group (4 studies, RR 0.53, 95%CI, 0.25 to 1.14, I^2=0%, P=0.10), Figure 1. All-cause mortality occurred in 20 of 718 (2.8%) patients in extensive group and 25 of 725 (3.4%) in control (3 studies, RR 0.80, 95%CI, 0.45 to 1.42, I^2=0%, P=0.44), Figure 2. Incidence of early malignancy was 2.7% and 1.3% in extensive and control group (4 studies, RR 1.88, 95%CI, 0.90 to 3.95, I^2=0%, P=0.09). Incidence of advanced malignancy was 4.3% and 4.4% in the extensive and the control group (4 studies, RR 1.18, 95%CI, 0.80 to 1.74, I^2=0%, P=0.95).

Conclusions: In patients with a first episode of unprovoked VTE, extensive cancer screening did not significantly reduce cancer-associated mortality and all-cause morality. The meta-analysis did not show differences in the incidence of cancer among patients underwent the extensive screening as compared to the standard of care. The moderate certainty surrounding the effects of the extensive cancer screening warrants further clinical trials.

PB 2308 | Paradoxal Roles of Platelets in Colorectal Cancer Behavior

L. Plantureux, L. Crescence, F. Dignat George, L. Panicot-Dubois, C. Dubois

Aix Marseille Université INSERM UMR 1076 VRCM, Faculté de Pharmacie, Marseille, France

Background: The relationship between thrombosis and cancer is well established. Platelets are able to interact with cancer cells and participate in the development of the tumor and metastasis. To date, Tumor Cell Induced Platelets Aggregation (TCIPA) constitutes the main cellular consequence described following the interactions of platelets and cancer cells.

Aims: We investigated the capacity of colorectal cancer cells to interact independently of TCIPA with platelets and determined the consequences of these interactions *in vivo* during colorectal cancer development.

Methods: The interplay between human and mice platelets and human and mice colorectal cancer cells was analyzed *in vitro* in static and dynamic conditions and *in vivo* by real time intravital microscopy using syngeneic, ectopic or orthotopic, colorectal cancer mice models.

Results: We show, by intratumoral microscopy, that single platelets are present in the microenvironment of a primary tumor in different colorectal cancer models. At the site of the primary tumor, platelets interact with cancer cells mainly through K-cadherin interactions and independent of the TCIPA. This interaction induces the activation, the granule release and the spreading of isolated platelets at the surface of the tumor. This k-cadherin dependent interaction of platelets with cancer cells reduces the growth of the primary tumor. In contrast, when occurring at the lumen of a vessel, this interaction facilitates the binding of cancer cells to the endothelium, mainly through an integrin-dependent pathway.

Conclusions: Our results indicate that platelets play a paradoxal role in tumor behavior: in the tumor microenvironment, platelets reduce tumor growth whereas in the bloodstream platelets facilitate the dissemination of the tumor and the formation of metastasis.

PB 2309 | The Modified Ottawa Score and Clinical Events in Hospitalized Patients with Cancer-associated Thrombosis from the Swiss VTE Registry (SWIVTER)

A. Alatri[1], L. Mazzolai[1], N. Kucher[2], D. Aujesky[3], J.H. Beer[4], T. Baldi[5], M. Banyai[6], D. Hayoz[7], T. Kaeslin[8], W. Korte[9], R. Escher[10], M. Husmann[11], B. Frauchiger[12], R.P. Engelberger[2,7], I. Baumgartner[2], D. Spirk[13]

[1]CHUV, Lausanne University Hospital, Division of Angiology, Lausanne, Switzerland, [2]Bern University Hospital, Swiss Cardiovascular Center, Bern, Switzerland, [3]Bern University Hospital, Division of General Internal Medicine, Bern, Switzerland, [4]Cantonal Hospital Baden, Department of Internal Medicine, Baden, Switzerland, [5]University Hospital Basel, Department of Internal Medicine, Basel, Switzerland, [6]Cantonal Hospital Lucerne, Department of Internal Medicine, Lucerne, Switzerland, [7]Cantonal Hospital Fribourg, Department of Internal Medicine, Fribourg, Switzerland, [8]Cantonal Hospital Obwalden, Department of Internal Medicine, Sarnen, Switzerland, [9]Cantonal Hospital St. Gallen, Department of Internal Medicine, St. Gallen, Switzerland, [10]Regional Hospital Burgdorf, Department of Internal Medicine, Burgdorf, Switzerland, [11]University Hospital Zurich, Clinic of Angiology, Zurich, Switzerland, [12]Cantonal Hospital Frauenfeld, Department of Internal Medicine, Frauenfeld, Switzerland, [13]University of Bern, Institute of Pharmacology, Bern, Switzerland

Background: The modified Ottawa score (MOS) predicted venous thromboembolism (VTE)
recurrence in a cohort of patients with cancer-associated thrombosis mainly managed on an outpatient basis.

Aims: We assessed the prognostic value of the MOS in hospitalized patients with cancer-associated thrombosis.

Methods: In 383 hospitalized patients with cancer-associated VTE from the SWIss Venous
ThromboEmbolism Registry (SWIVTER), 98 (25%) were classified as low-risk, 175 (46%) as intermediate-risk, and 110 (29%) as high-risk for VTE recurrence based on the MOS. Clinical endpoints were recurrent VTE, fatal VTE, major bleeding, and overall mortality at 90 days, estimated with the Kaplan-Meier method, and compared by use of a log-rank test.

Results: Overall, 179 (47%) patients were female, 172 (45%) had metastatic disease and 72 (19%) prior VTE. The primary site of cancer was lung in 48 (13%) patients and breast in 43 (11%). According to the MOS, the rate of VTE recurrence was 4.1% for low, 6.3% intermediate, and 5.5% high risk (p=0.75), the rate of fatal VTE was 0.8%, 1.9%, and 2.0% (p=0.69), the rate of major bleeding was 3.1%, 4.1%, and 3.6% (p=0.92), and the rate of death was 6.1%, 12.0%, and 28.2% (p< 0.001), respectively. None of the MOS items was associated with VTE recurrence: female gender HR 1.26 (95%CI 0.53-2.96), lung cancer HR 1.17 (95%CI 0.35-3.98), prior VTE HR 0.44 (95%CI 0.10-1.91), breast cancer HR 0.83 (95%CI 0.19-3.58), and absence of metastases HR 0.74 (95%CI 0.31-1.74).

Conclusions: In hospitalized patients with cancer-associated VTE, the modified Ottawa score failed to predict VTE recurrence at 3 months but was associated with early mortality.

PB 2310 | Predictive Value of D-dimers and Microparticle-associated Tissue Factor Activity for the Risk of Thrombosis in Pancreatic Cancer

D. Faille[1], N. Ajzenberg[1], E. de Raucourt[2], P. Hammel[2], P. Lévy[2], P. Ruszniewski[2], V. Rebours[2]

[1]CHU Bichat, Paris, France, [2]CHU Beaujon, Clichy, France

Background: Venous Thrombo-embolic Events (VTE) frequently occur in patients with pancreatic cancer and contribute to elevated morbidity and mortality. D-dimers and tissue factor-dependent procoagulant activity of MP (MP-TF) have been proposed to help identifying cancer patients at high risk of thrombosis.

Aims: To compare D-dimer levels and MP-TF in pancreatic cancer and in chronic pancreatitis to determine whether these biomarkers are related to cancer or inflammation and to validate their association with thrombotic risk in a pancreatic cancer population.

Methods: 42 patients with pancreatic cancer, 48 with intraductal papillary mucinous tumor of the pancreas (IPMN), a precancerous lesion, and 50 with chronic pancreatitis were recruited. Plasma D-dimer levels were quantified by immunoturbidimetry (*STA®-Liatest® D-Di*, Diagnostica Stago) and MP-TF was determined by a chromogenic endpoint assay measuring factor Xa generation.

Results: D-dimer levels and MP-TF were significantly higher in cancer patients compared to IPMN or chronic pancreatitis.

TABLE 1 D-dimer levels and MP-TF according to pancreatic disease type

	Pancreatic cancer (n=42)	IPMN (n=48)	Chronic pancreatitis (n=50)	p-value (Chi-square or Kruskal-Wallis)
Age, years, median (IQR)	66 (54-72)	65 (56-71)	47 (39-53)	<0.0001
Gender, male, n (%)	26 (62)	17 (35)	41 (82)	<0.0001
D-dimers, µg/ml, median (IQR)	0.91 (0.57-2.16)	0.27 (0.22-0.44)	0.38 (0.22-0.92)	<0.0001
MP-TF, fM, median (IQR)	24 (11-56)	12 (9-19)	16 (10-23)	0.01

Patients with metastatic cancer (n=26) presented higher D-dimer levels (median [IQR] 1.27 [0.69-2.77] vs 0.56 [0.31-082] µg/ml, p=0.005) and MP-TF (median [IQR] 40 [12-96] vs 12 [9-25] fM, p=0.008) compared to patients with localized lesions (n=18). Cancer patients were followed for a median duration of 159 days [IQR 61-180]. VTE occurred in 9 (20.4%) patients. All had metastatic cancer at the time of thrombosis. In univariate analysis, only elevated D-dimers (cut-off level = 75th percentile 2.16 µg/ml) were significantly associated to the risk of VTE in the next 6 months (HR = 6.2, 95% CI 1.4-27.7, p= 0.017). This was not significant after adjustment for age, sex and metastatic status.

Conclusions: Elevation of D-dimers and MP-TF seems to be related to cancer process and to disseminated cancer stage. D-dimers are associated with the occurrence of future VTE but dependently from metastatic status.

PB 2311 | Venous Thromboembolism Leads to Poor Survival in Patients with High Grade B Cell Lymphoma - A 7-year Single Centre Analysis

M. Grech[1], M. Debono[1], D. Farrugia[1], D.J. Camilleri[1], A. Gatt[1,2]

[1]Mater Dei Hospital, Department of Haemato-Oncology, Msida, Malta, [2]University of Malta, Department of Pathology, Msida, Malta

Background: Venous thromboembolism (VTE) is a recognised complication of cancer. High Grade B cell Lymphoma (HGBCL) carries a significant risk of VTE. However, little is known about the prognostic significance and epidemiology of VTE in these patients

Aims: To assess the risk and prognostic significance of VTE in HGBCL.

Methods: 203 unselected patients with HGBCL diagnosed between 1st January 2010 to 31st December 2016. These included DLBCL and Grade 3 Follicular NHL at all sites. VTE was diagnosed either on CT scan or Doppler US as per standard.

Results: 14 developed a VTE ie 6.9%. 8 patients were female and 6 were male. 4 were pulmonary embolism, one of which directly contributed to patient's death; 1 splanchnic vein clot; 3 upper limb DVT; and 6 lower limb DVT. None of the VTE events were related to indwelling lines. VTE occurred at an average 21.6 days after diagnosis (range -23 to 95 days). The mean Stage and LDH were high at 3.4 and 694.9 respectively and were statistically higher than the non VTE group (P= 0.029 and 0.0014 respectively). The mean age of patients with VTE was 67.1 years and those without was 63.9 years with no statistical significance between the two groups. 10 (71.4%) patients with VTE have died. The median survival of VTE patients was 12.5 months whereas those without VTE have not yet reached median survival (Fig1). When only the Non VTE Stages 3 and 4 (mean 3.6) were compared to the VTE cohort, there was still a significantly worse outcome in the VTE group with a median survival of 64.6 months vs 4.4 months respectively; P = < 0.001). LDH was higher in the VTE group (P=0.028).

Conclusions: 6.9% developed VTE. This occurred very early in their disease with a mean of 21.6 days from diagnosis. VTE patients had a very poor overall survival which was not associated with age or Stage. It remains unclear why VTE is so predictive for overall survival in HGBCL.

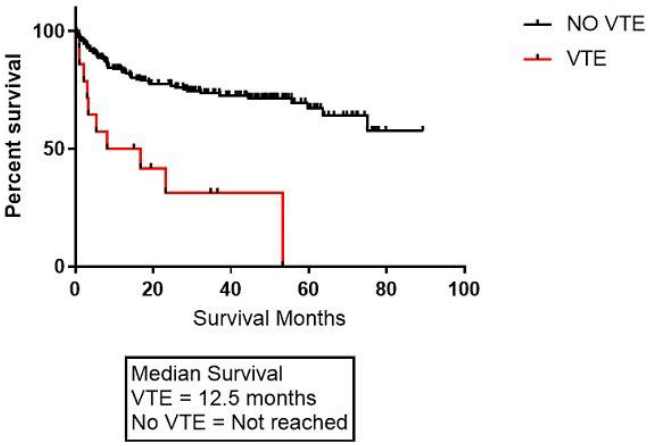

FIGURE 1 Overall Survival in HGBCL patients with VTE and those without VTE

PB 2312 | Performance of Khorana Score Models in Predicting Occurrence of Incidental Venous Thromboembolism (VTE) in Cancer

V.K. Tang[1], C.P. Escalante[2], T.P. Lam[3], M.N. Richardson[3], C.M. Rojas Hernandez[4]

[1]University of Texas Health Science Center at Houston, Internal Medicine, Division Pulmonary/Critical Care, Houston, United States, [2]University of Texas MD Anderson Cancer Center, Department of Internal Medicine, Division of Internal Medicine, Houston, United States, [3]University of Texas MD Anderson Cancer Center, Department of General Internal Medicine, Division of Internal Medicine, Houston, United States, [4]University of Texas MD Anderson Cancer Center, Department of Internal Medicine, Division of Benign Hematology, Houston, United States

Background: VTE is a common complication of cancer and it contributes importantly to morbidity and mortality in this population. The Khorana

score (KS) assesses the risk of developing VTE. In the era of better resolution radiology modalities, clinicians must face the challenge of predicting and managing incidentally found VTE during cancer staging.

Aims: The aim of this study was to evaluate the utility of KS and two modified-Khorana score models in predicting the occurrence of unsuspected VTE in oncology patients.

Methods: The study population included single-institution, prospectively identified ambulatory adult cancer patients scheduled for routine computed tomography (CT) scan of the chest, abdomen and/or pelvis. Exclusion criteria included: prior history of VTE, clinically suspected VTE and/or scheduled for CT scans for suspected VTE, Zubrod performance status score of 4 and current therapeutic anticoagulation therapy. All eligible patient charts were reviewed to assess the KS and two additional previously published KS model modifications. Using non-parametric methods we compared the median of KS, those of the modified models and stratified by incidentally found VTE versus non-VTE patients. Approval by the institutional review board and informed consent from each participant were obtained.

Results: We identified 568 patients with all available information for the calculation of KS and modified models. Of these, 14 had incidental VTE. In the VTE cases, the median score for KS and the modified models were 1.0, 4.0 and 5.0, respectively. KS was unable to predict VTE (p-value of 0.801) whereas the modified models (PROTECHT, Australian) predicted most cases of incidental VTE (Table 1) to be in the "high risk" category, p-value of 0.001 and 0.036, respectively.

TABLE 1 Comparison of Khorana Score (KS) and KS modified models between incidental VTE cases versus controls

Model score	Cases	Controls	Total
Original Khorana score	N (%)	N (%)	N (%)
< 3	13 (2.3%)	536 (94.4%)	549 (96.7)
≥ 3	1 (0.2%)	18 (3.1%)	19 (3.3%)
PROTECHT Model Score			
< 3	2 (0.4%)	267 (47.0%)	269 (47.4%)
≥ 3	12 (2.1%)	287 50.5%)	299 (52.6%)
Australian Model score			
< 3	3 (0.6%)	275 (48.4%)	278 (49.0%)
≥ 3	11 (1.9%)	279 (49.1%)	290 (51.0%)

Conclusions: This study suggests that KS did not predict incidental VTE but adding other characteristics (presence of distant metastases and type of chemotherapy) may improve the performance of KS and potentially identify candidates for VTE prophylaxis.

PB 2315 | Audit: Use of Khorana Score in Newly Diagnosed Patients with Pancreatic Cancer

C. Carson, G. Benson

Belfast Trust, Belfast, United Kingdom

Background: Venous Thromboembolism (VTE) is a well-documented cause of morbidity and mortality in cancer patients. Patients with pancreatic cancer are documented as more likely to experience thromboembolic events than other types of cancer and have been proven to benefit from prophylactic low molecular weight heparin (LMWH). The Khorana score has been validated as one means of risk assessing those patients who would benefit from primary prophylaxis; with guidance of low molecular weight heparin (LMWH) if the Khorana score is ≥ 3.

Aims: To audit if pancreatic cancer patients in the Belfast trust were prescribed primary prophylaxis if they had a Khorana score of ≥3.

Methods: This audit retrospectively looked at all cases of pancreatic cancer discussed at the regional hepatobiliary multidisciplinary meeting (MDM) between January 2014 - December 2017. Belfast trust patients were identified and their Khorana score, evidence of VTE prophylaxis and outcome in terms of VTE was gathered from their notes.

Results: 191 patients were identified from the pancreatic MDM; 89 of whom where in the Belfast trust. Of these 12 developed a pulmonary embolism (PE) none of whom were on primary prophylaxis. 7 developed other forms of VTE, only 1 who was on prophylaxis in the form of an anticoagulant for recurrent deep vein thrombosis. 24 patients were identified to have a Khorana score of ≥3 and of these 5 on chemotherapy and therefore to whom the score could apply. Of these 5 none were prescribed primary prophylaxis and 1 developed a PE.

Conclusions: The Khorana score was only applicable to a small number of pancreatic cancer patients, however in these the standard of primary prophylaxis was not met. The Khorana score was not predictive of PE's however of note; of those to whom the standard was applicable 20% developed a PE in this case without prophylaxis.

PB 2316 | Direct Oral Anticoagulants for the Treatment of Acute Venous Thromboembolism in Patients with Cancer: A Meta-analysis of Randomized Controlled Trials

F. Dentali[1], M.N.D. Di Minno[2], R. Lupoli[2], G. Conte[1], N. Van Es[3], H. Buller[3], W. Ageno[1]

[1]Insubria University, Clinical Medicine, Varese, Italy, [2]Federico II University, Department of Advanced Biomedical Sciences, Naples, Italy, [3]Academic Medical Center, Department of Vascular Medicine, Amsterdam, The Netherlands

Background: Previous meta-analyses have assessed the safety and efficacy of the direct oral anticoagulants (DOACs) in patients with cancer associated venous thromboembolism (VTE). However, in the last year, new evidence from subgroup analyses of pivotal clinical trials has become available, providing separate data on patients with a history of cancer and those with active cancer.

Aims: To estimate the efficacy and safety of the DOACs compared with vitamin K antagonists (VKA) for the treatment of VTE in patients with active cancer and in those with a history of cancer.

Methods: After a systematic review of the literaturel, all RCTs comparing DOACs with VKA in the treatment of patients with acute DVT or PE were included. Patients were classified as patients with active cancer, patients with a history of cancer and patients without active cancer or a history of cancer. Pooled risk ratios (RR) and 95% confidence intervals (CI) were calculated using a random effects model.

Results: Of 27,178 patients (13,593 receiving DOACs and 13,585 VKA) included in 6 randomized controlled trials, 1,496 (5.5%) had active cancer, and 1,605 (5.9%) had a history of cancer. DOACs were significantly more effective than VKA in patients with active cancer in preventing recurrent VTE (RR 0.62, 95% CI 0.43, 0.90) and as effective as VKA in patients with a history of cancer (RR 0.50, 95% CI 0.23, 1.07) and in patients without cancer (RR 1.03, 95% CI 0.87, 1.21). The incidence of major bleeding was significantly lower in the DOAC group than in the VKA group in patients without cancer, but not in patients with active cancer or with history of cancer. However, the absence of heterogeneity among different subgroups suggests a similar, better safety profile of DOACs in comparison to VKA in cancer patients.

Conclusions: The results of this meta-analysis suggest a favorable risk-benefit ratio with the use of the DOACs as compared to VKA in patients with VTE associated with active cancer.

PB 2317 | Podoplanin-dependent Platelet Aggregation Mediated by Human Glioblastoma Cell Lines

P. Mir Seyed Nazari[1], J. Riedl[1], L. Hell[1], C. Brostjan[2], W. Berger[3], D. Lötsch[3], C. Marosi[4], M. Preusser[4], S. Panzer[5], I. Pabinger[1], C. Ay[1]

[1]Medical University of Vienna, Clinical Division of Hematology and Hemostaseology, Department of Medicine I, Vienna, Austria, [2]Medical University of Vienna, Department of Surgery, Vienna, Austria, [3]Medical University of Vienna, Institute of Cancer Research, Department of Medicine I, Vienna, Austria, [4]Medical University of Vienna, Clinical Division of Oncology, Department of Medicine I, Vienna, Austria, [5]Medical University of Vienna, Department of Blood Group Serology and Transfusion Medicine, Vienna, Austria

Background: Primary brain tumor patients are at high risk to develop venous thromboembolism (VTE). Recently, an association between podoplanin (PDPN)-expressing brain tumors, intratumoral platelet aggregates and increased VTE risk was demonstrated. PDPN is a sialomucin-like glycoprotein with the ability to activate platelets via the C-type lectin-like receptor (CLEC)-2.

Aims: To assess the ability of glioblastoma cells to activate human platelets via PDPN *in vitro*.

Methods: Two human glioblastoma cell lines were investigated: Gli16 (PDPN-positive), isolated from a glioblastoma patient (WHO grade IV), who developed pulmonary embolism six months after diagnosis. AMCH (PDPN-negative), isolated from a patient with gliosarcoma (WHO grade IV). Brain tumor cell-induced platelet activation was measured via 1) platelet-leukocyte aggregates in whole blood by flow cytometry, 2) platelet aggregation in platelet-rich plasma by light transmission aggregometry (LTA), and 3) release of the activation marker platelet factor 4 (PF4) by ELISA.

Results: PDPN-positive Gli16 cells induced higher amounts of platelet-leukocyte aggregates compared to PDPN-negative AMCH cells in a dose-dependent manner. Gli16 cell-mediated platelet-leukocyte aggregation was reduced upon addition of the PDPN-specific antibody NZ-1. PDPN-positive Gli16 cells induced significantly higher platelet aggregation than PDPN-negative AMCH cells (median 34.25% vs. 18.9%; p< 0.001), and Gli16 cell-induced platelet aggregation was significantly reduced upon PDPN inhibition via NZ-1 (median 34.25% vs. 2.55%; p< 0.001) (Fig 1). Furthermore, upon co-incubation with PDPN-positive Gli16 cells high release of PF4 from platelets was induced, which was reduced upon NZ-1 addition. In contrast, PDPN-negative AMCH cells caused only minor release of PF4.

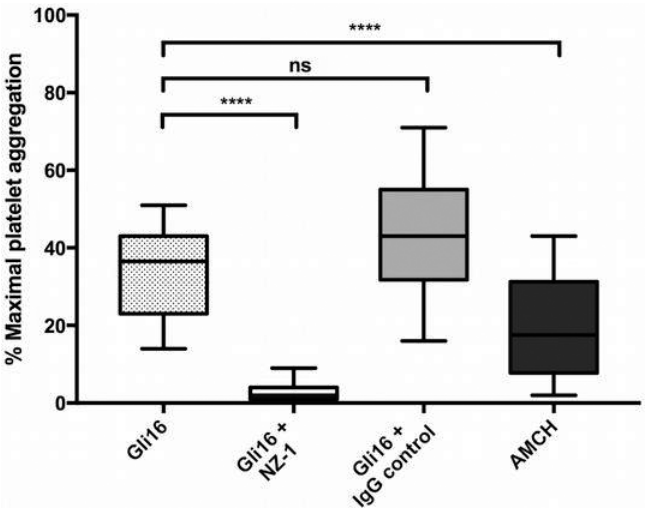

FIGURE 1 Platelet aggregation upon stimulation with human glioblastoma cells in vitro (light transmission aggregometry), ns = not significant

Conclusions: Our results indicate that PDPN plays a crucial role in tumor cell-induced platelet aggregation and thereby might contribute to increased VTE risk in glioblastoma patients.

PB 2318 | Tumor cell-induced Platelet Secretion: Role of Protease-activated Receptors

A. Mitrugno, R.A. Rigg, C. Pui, O.J.T. McCarty

Oregon Health & Science University, Biomedical Engineering, Portland, United States

Background: Paracrine interactions between cancer cells and platelets have been shown to regulate overall tumor growth. We have recently demonstrated that the release of growth factors by activated platelets promotes cancer proliferation through the upregulation of cancer cell oncoproteins. However, the mechanisms through which cancer cells induce platelet activation and secretion of growth factors remain ill-defined. We hypothesize that the generation of thrombin by

procoagulant cancer cells promotes platelet activation and secretion of growth factors through activation of protease-activated receptors (PARs).

Aims: To investigate the role of PAR signaling in tumor cell-induced platelet secretion.

Methods: The procoagulant phenotype of colon cancer cells was explored by monitoring thrombin generation and fibrin formation in a 96 well plate-based absorbance assay. Platelet granule release in response to procoagulant cancer cells was assessed in a 96 well plate-based luminescence assay. The involvement of PAR-4 and PAR-1 in platelet granule release was determined by testing novel PAR-1 and PAR-4 specific antagonists.

Results: Procoagulant colon cancer cells were able to generate thrombin in platelet poor plasma (PPP). Washed platelets enhanced the ability of colon cancer cells to generate thrombin in PPP. Thrombin-induced platelet granule release was selectively inhibited by PAR-1 and PAR-4 inhibitors.

Conclusions: These preliminary findings suggest a potential role for PARs in mediating platelet secretion in response to thrombin which can be produced by procoagulant cancer cells. Future efforts will determine how targeted inhibition of platelet PARs can affect different steps of the metastatic disease without disturbing hemostasis.

PB 2319 | Can NETs or miRNAs Predict Early Surgery-related Pulmonary Embolism in Patients with Intracranial Tumors?

J. Oto[1], E. Plana[1,2], D. Hervás[3], L. Martos[1], L.A. Ramón[1], M.J. Solmoirago[1], Á. Fernández-Pardo[1], F. España[1,4], S. Navarro[1], A. Artoni[5], P. Bucciarelli[5], G. Carrabba[6], G. Merati[5], P. Medina[1]

[1]La Fe Sanitary Research Institute, Haemostasis, Thrombosis, Atherosclerosis and Vascular Biology Research Group, Valencia, Spain, [2]La Fe University and Polytechnic Hospital, Angiology and Vascular Surgery Service, Valencia, Spain, [3]La Fe Sanitary Research Institute, Biostatistics Unit, Valencia, Spain, [4]La Fe University and Polytechnic Hospital, Valencia, Spain, [5]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, A. Bianchi Bonomi Hemophilia and Thrombosis Centre, Milan, Italy, [6]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Neurosurgery Unit, Milan, Italy

Background: Intracranial tumors increase the risk of thrombosis, and often may cause incidental pulmonary embolism (PE) after surgery. New biomarkers are needed to early identify brain cancer patients with high thrombotic risk. Neutrophil extracellular traps (NETs) are highly prothrombotic networks released by neutrophils upon activation. microRNAs (miRs) regulate protein expression.

Aims: To assess the ability of NETs and miRs measured at baseline to predict, the risk of early post-surgical PE in glioma and meningioma patients.

Methods: We recruited and prospectively followed after surgery 10 glioma and 10 meningioma patients. All had negative baseline lung perfusion scan. PE was objectively diagnosed within 7 days after surgery in 5 patients of each group. In plasma samples collected before surgery, we measured NETs markers (DNA, nucleosomes, myeloperoxidase [MPO] and calprotectin), and the expression level of 179 miRs with the Serum/plasma Focus microRNA PCR Panel V4 (Exiqon). Using a multivariable logistic regression model, the predictive ability for post-surgical PE was estimated as the area under the ROC curve (AUC) with R (v3.2.3).

Results: In glioma patients we obtained a good predictive model of post-surgical PE with DNA and MPO as predictors (AUC=0.88 [95%CI: 0.63-1.00], validated AUC=0.77), and also with the expression levels of 8 miRs with Elastic Net. In meningioma patients, NETs markers were not predictors of PE, whilst good prediction was obtained with the expression levels of 6 miRs.

Conclusions: Before surgery, NETs markers (DNA and MPO) might be good predictors of early incidental post-surgical PE in glioma patients. A good prediction could also be obtained with the expression level of 8 and 6 miRs in glioma and meningioma patients, respectively. This information could be useful to tailor post-surgical thromboprophylaxis in these patients. ISCIII-FEDER (PI12/00027, RIC RD12/0042/0029, PIE13/00046, PI14/00079, PI14/00512, FI14/00269, CPII15/00002), GVA (PrometeoII/2015/017), SETH, GR-2011-02347854.

PB 2320 | Thromboprophylaxis Strategy in Cancer Outpatients: CAT AXIS, a Case-vignette Study on Clinical Practice In France

I. Elalamy[1,2], F. Scotte[3], D. Mayeur[4], G. Meyer[5,6]

[1]Tenon University Hospital APHP, Hematology, Paris, France, [2]INSERM UMR S 938, Centre de Recherche Saint-Antoine, Paris, France, [3]Hôpital Européen Georges Pompidou, Medical Oncology and Supportive Care Unit, Paris, France, [4]Hôpital Mignot, Hematology-Oncology and Supportive Care Unit, Le Chesnay, France, [5]Hôpital Européen Georges Pompidou, AP-HP, Department of Respiratory Diseases, Paris, France, [6]Université Paris Descartes, INSERM UMR S 970 and CICEC 1418, Paris, France

Background: Data on venous thromboembolism (VTE) long-term prophylaxis in cancer outpatients remain scarce. In the absence of clear and consistent treatment guidelines, the assessment of clinical practice and recommendations implementation is challenging.

Aims: our objective was to describe and better understand the clinical practice regarding thromboprophylaxis use in this context.

Methods: CAT AXIS was a multicenter cross-sectional study based on the completion of physician-profile questionnaires and the assessment of 10 e-mailed credible clinical scenarios of lung, colon and breast cancers by each of participants using the case-vignettes validated method.

Results: A total of 224 physicians participated allowing the completion and the analysis of 2,085 case vignettes corresponding to 765, 703 and 617 fictive clinical scenarios on lung, colon and breast cancers, respectively. The overall rate of thromboprophylaxis prescription was 680/2085 (32.6%) among participants with a comparable proportion for the three types of cancer. Low-molecular-weight heparin (LMWH) was the most frequently used, by 92.7%, 93.8% and 83.9% of participants for lung, colon and breast cancers, respectively; treatment

duration ≥3 months was prescribed by 74.4% of participants using thromboprophylaxis.

Conclusions: In this case vignette study, physicians of different medical specialties would give prolonged thromboprophylaxis in about 30% of patients with lung, colon or breast cancer. In the absence of clear guidance, thromboprophylaxis use seems not so limited and rather empiric. Furhermore, the choice of LMWH by the majority of participants and treatment duration are appropriate based on available data to date.

PB 2321 | Peripherally Inserted Central Catheter (PICC) Related Thrombosis in 230 Patients with Hematological Malignancies. A 6 Years Single Experience Center

M. Baile[1], A. Veiga[1], M. López-Parra[1], M. Sánchez-Barba[2], N. Arratibel[1], B. Rodríguez[1], M. Sastre[1], O. Del Rey[1], A.Á. Martín[1], M. Cabrero[1], J.R. González-Porras[1], J.M. Bastida[1]

[1]Hospital Universitario de Salamanca, Hematology, Salamanca, Spain, [2]University of Salamanca, Staticals, Salamanca, Spain

Background: The use of peripherally inserted central catheters (PICCs) is widely extended in patients with hematological malignancies who need be treated by chemotherapy. However, catheter-related thrombosis is one of its main complications. We reported the experience of the PICC-related thrombosis (PRT) in our center.

Aims: To analyze the incidence of PRT, describe the clinical characteristics and management of these patients and identify the risk factors of PRT.

Methods: We performed a retrospective chart review of 230 adult patients diagnosed with hematological malignancies, in whom, experimented nurses tunneled PICCs with different technique: blinding Seldinger from 2010 to 2014 and guided by ultrasonography (US) from 2015 to 2016. PRT diagnose was confirmed by Doppler US. Statistical analysis was performed using the SPSS program (v.20).

Results: Baseline patients' characteristics are shown in Table 1. The overall incidence of PRT was 7% (n=16). The main diagnoses related to PTR were acute lymphoblastic leukemia (ALL=6), Non-Hodgkin Lymphoma (5), and Hodgkin Lymphoma (HL=3). All except one had active disease when PICC was tunneled (15/16=94%). Fourteen patients (88%) were treated by chemotherapy based in L-asparaginase (L-ASA), immunomodulatory drugs or other treatment combined with corticosteroids. The median onset of PRT was 26 days, (range: 0-230); and 8 of them (50%) in the first 30 days after insertion. In 11 cases (69%) D-Dimer was elevated. All PICC were removed within 72 hours of PRT and treated with LMWH to a median of 4 months (range: 1-11). Finally, in the univariate analysis ALL, HL and L-ASA had significant impact on PRT (Table 2). However, in the multivariate, HL was the only risk factor of PRT
(OR 8,38; CI 1,05-66,5; p=0,044).

TABLE 1 Baseline patients' characteristics:

Median age (range)	58 years (14-86)
Sex: male / female	128 (56%) / 102 (44%)
Hematological malignancies: n (%)	NHL: 105 (45,7%) / Acute myeloid leukemia and myelodysplastic syndrome: 60 (26,1%) / ALL: 22 (9,6%) / Multiple myeloma and Amyloidosis: 19 (8,3%) / HL: 17 (7,4%) / Others: 7 (3%)
Status disease when PICC was tunneled	Active: 188 (81,7%) / Remission: 42 (18,3%)
Drugs related thrombosis	Immunomodulatory drugs (IMIDS): 24 (10,4%) / L-Asparaginase (L-Asa): 21 (9,1%) / Erythropoietin: 16 (7%)
Thromboprophylaxis	Low Molecular Weigh Heparin (LMWH): 27(9,1%) / ASA: 21 (9,1%) / Oral anticoagulants: 3 (1,3%)
PICCs tunneled technique	Guided by US: 127 (55,2%) / Blinding: 103 (44,8%)
Catheter tip location	Right atrium (RA): 78 (33,9%) / Cava-RA: 152 (66,1)

TABLE 2 Univariate (U) and multivariate (M) analysis to identify risk factors of PRT

	U: OR [IC 95%]; p-value	M: OR [IC 95%] p-value
Male sex	1,36 [0,48-3,87]; 0,57	1,09 [0,358-3,361]; 0,87
Age (>50 years)	2,59 [0,93-7,24]; 0,07	1,28 [0,374-4,396]; 0,69
ALL / HL / NHL	15,75 [2,91-85,12]; 0,001 / 9 [1,38-58,78]; 0,022 / 2,10 [0,39-11,1]; 0,283	4,79 [0,21-110,03); 0,33 / 8,38 [1,06;-66,5]; 0,04 / 2,12 [0,39-11,59]; 0,28
IMIDs / L-Asparaginase / Stimulant growth factors	0,85 [0,1-7,02]; 0,88 / 7,82 [2,453-24,95]; 0,001 / 1,67 [0,6-4,67]; 0,33	1,43 [0,157-13,027]; 0,75 / 3,68 [0,23-59,16];0,38/---

PB 2322 | The Management of Non DVT-PE Cancer-associated Thrombosis: A Single Centre Experience

A. Doyle, D. McClinton, V. McDonald

Guy's and St Thomas' NHS Foundation Trust, Haematology, London, United Kingdom

Background: Thrombosis is a common complication of cancer and its treatment. The management of deep vein thrombosis (DVT) and

pulmonary embolism (PE) is well documented, however the management of other thromboses (non-lower limb DVT or PE thrombosis (NDVTPE)), is less clear.

Aims: To review the natural history and management of patients with cancer-associated NDVTPE thrombosis.

Methods: All patients at a large tertiary hospital for thrombosis and cancer diagnosed with upper limb VTE (ULVTE) or splanchnic veins (SVT) and cancer between June 2014 and December 2015 were identified using an electronic database. Data was collected on tumour type, stage, anti-neoplastic treatment, thrombosis management, complications of anticoagulation and clinical outcome.

Results: 36 (18 male and 18 female) patients were identified, 18 ULVTE and 18 SVT, with results summarised in table 1. The median age and sex distribution were as expected for patients with cancer. Most patients had advanced disease. In addition, 77% for both ULVTE and SVT had cancer near the site of thrombosis suggesting localised effects. Most thromboses were diagnosed at cancer diagnosis or during treatment. The median Khorana score was 2 (range 0-3), with 56% patients having a score of 2 or over. Symptomatic thrombosis was higher in ULVTE (73%) than SVT (50%). No anticoagulation was given in 22% patients with SVT and all others received low molecular weight heparin (LMWH). There were no haemorrhagic complications in this group. 2 patients with ULVTE did not receive anticoagulation, most received LMWH and one received rivaroxaban. Two patients in this group had treatment-related bleeding. Mortality rate was high with a median time to death of 99 days.

TABLE 1 Features of patients in NDVTPE cancer-associated thromboses

	Upper Limb and Neck	Splanchnic
Mean Age (Range)	66.5 (53-90)	64.5 (44-82)
Sex (M/F)	9/9	9/9
Advanced disease (%)	13 (73%)	12 (67%)
Symptomatic (%)	13 (73%)	9 (50%)
Thrombosis at presentation cancer (%)	4 (22%)	5 (27%)
Thrombosis during cancer therapy (%)	9 (50%)	8 (44%)
Thrombosis post-cancer treatment (%)	5 (27%)	5 (27%)
Anticoagulation	16 (88%)	14 (77%)
Bleeding	2	0

Conclusions: These results show that NDVTPE cancer thrombosis are associated with advanced stage cancer and carry a poor prognosis. Many SVT are asymptomatic but are associated with cancer near the site of thrombosis. There are few complications of LMWH treatment but with too little data on other agents.

PB 2323 | Bioinformatic Analysis of Collaborative Interaction between Platelet and Cancer Cell Derived Microparticles in Evolving a Post Code Mechanism for Breast Cancer Metastasis and Identification of CD9 as Potential Drug Resistance Marker

R.K. Vangala, A. Sharma, M. Ghatge

Thrombosis Research Institute, Proteomics and Coagulation Unit, Bangalore, India

Background: Metastasis and drug resistance are the main cause of cancer-related death and major challenge in disease management. The process of tumor cell spreading from primary site to distant tissue is a complex process and involvement of platelets and coagulation factors. However, the mechanisms involved and comprehensive analysis to understand the molecular processes is not yet completely understood in order to evolve with new potential targets or biomarkers.

Aims: We aimed to use patient and cell line based data available from literature and develop a map of molecular pathways and identify potential biomarkers/targets and validate in in-vitro 3D cell culture system.

Methods: The gene expression data of patients (placlitaxel responders vs non responders) were downloaded from Gene Expression Ominibus, drugs and their targets from drug bank database. The gene expression data was analyzed using R-script for LIMMA followed by WGCNA and Cytoscape for network construction. The 3D cell culture was performed in gelatin-hydrogels and MDA MB-231 cells were used for drug resistance assays.

Results: The gene expression and network analysis showed that several novel genes were associated with breast cancer mestasis including WFDC2, WNT6, SMPDL3B, PCOLCE, TNFRSF10A, ST8SIA4, MAPRE2, PIK3R3, DLX4 and CD9 which had similar profiles in 3D cell cultures and non-responder patients. Further microparticles proteome analysis of platelets and cancer cells suggested novel interactome suggesting physical associations between the microparticles possibly leading to larger particles with specific surface protein signature suited for internalization at distal tissues leading to metastasis. These protein signatures could be termed as post code also have CD9 for specific tissues which are targets for metastasis.

Conclusions: Our results for the first time demonstrate that there is a possible mechanism of post code for cancer metastasis and CD9 could be a potential marker also for drug resistance.

PB 2324 | Tumour Microvesicles Interact with Endothelial Cells under Venous Flow in vitro

A. Algarni[1], J. Greenman[2], L. Madden[2]

[1]University of Hull, Biological and Biomedical Sciences, Hull, United Kingdom, [2]University of Hull, Hull, United Kingdom

Background: Tumours shed microvesicles (MV) into the circulation that can then interact at sites remote to the tumour source, particularly those MV that express tissue factor (TF), which are thought to possibly play a role in venous thromboembolism (VTE) in cancer patients. The pathophysiology relating to cancer-induced VTE are not yet fully understood but we have previously shown that tumour MV appear to bind to endothelial cells in static conditions and confer procoagulant activity via tissue factor. This suggests that there may be a role of the endothelium in cancer-related VTE in patients.

Aims: Here, we aimed to investigate the interactions of tumour-MV on human umbilical vein endothelial cells (HUVECs) under shear flow rates.

Methods: MV released from AsPC-1 tumour cells labelled with 5(6)-carboxyfluorescein diacetate N-hydroxysuccinimidyl ester (CFSE) were initially analysed by flow cytometry for degree of CFSE labelling (Figure 1). Having established reproducible, fluorescently-labelled MV they were flowed through a Vena8 Endothelial+™ biochip pre-coated with a confluent monolayer of HUVECs and imaged using a CELLIX imaging system.

Results: CSFE staining of tumour cells was shown to be an effective method of labelling shed MV for a period of up to 48h (Figure 2). The degree of labelling to background was shown to decrease from (29.91%) to (9.38%) over the course of 6 days. When using CFSE-labelled ASPC-1 MV in a shear flow system (under venous shear rates) initial data observed showed a coalescence of tumour MV on HUVECs.

Conclusions: CFSE can be used to label MV released from tumour cells. Based on our initial observations labelled MV appeared to interact with endothelial cells on a biochip, under flow conditions. This may have implications for clot formation in cancer patients.

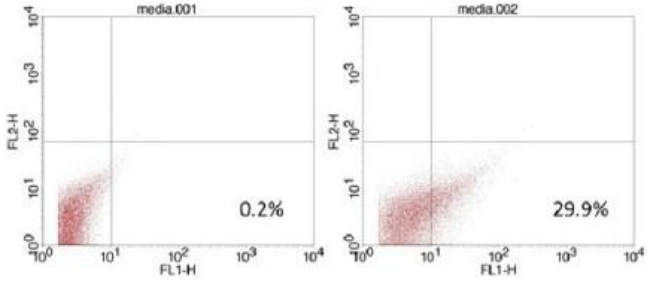

FIGURE 1 Flow cytometry detection of fluorescence intensity of tumour MVs. Right panel shows MVs derived from AsPC-1 cells labelled with 2 µM CFSE wh

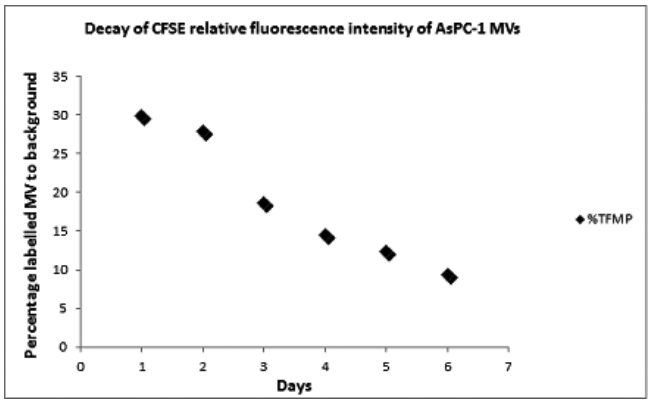

FIGURE 2 Chart shows labelling intensity of MV released by AsPC-1 tumour cells over the course of 6 days.

PB 2325 | The STEP-CAT Cohort Management Study: Step-Down to Prophylactic Doses of Enoxaparin after a Minimum of 3-6 Months of Anticoagulation for the Treatment of Cancer-associated Thrombosis

V. Tagalakis[1,2], T. Djouonang[3], M. Carrier[4], N. Routhier[5], S. Shivakumar[6], S. Solymoss[7], M. Louzanda[8], C. Sperlich[9], S.R. Kahn[1,3]

[1]McGill University, Medicine, Montreal, Canada, [2]Centre for Clinical Epidemiology Lady Davis Institute for Medical Sciences, Jewish General Hospital, Montreal, Canada, [3]Centre for Clinical Epidemiology Lady Davis Institute for Medical Sciences of the, Jewish General Hospital, Montreal, Canada, [4]Ottawa Hospital Research Institute at the University of Ottawa, Medicine, Ottawa, Canada, [5]Universite de Montreal, Hopital du Sacre-Cooeur, Medicine, Montreal, Canada, [6]Nova Scotia Health Authority, Hematology, Medicine, Halifax, Canada, [7]McGill University, Hematology, Medicine, Montreal, Canada, [8]London Health Sciences Centre, Hematology, London, Canada, [9]Hopital Charles LeMoyne, Hematology, Longueuil, Canada

Background: Clinical guidelines recommend a minimum of 3-6 months of anticoagulation with weight-adjusted low molecular weight heparin (LMWH) in cancer patients with acute venous thromboembolism (VTE). There are no recommendations beyond 3-6 months. We hypothesize that prophylactic dose LMWH is a safe option for extended duration secondary prevention of cancer-associated thrombosis (CAT). We therefore propose a pilot study to assess the feasibility of extended duration prophylactic dose LMWH in cancer patients with treated acute VTE. The data obtained from this study will help inform the design of a future trial on prophylactic dose LWMH for secondary prevention of CAT.

Aims: Primary aim is to determine study design feasibility. Secondary aims are to determine the cumulative incidence of VTE recurrence and bleeding.

Methods: This is a multicentre, open-label, single arm pilot study of prophylactic dose enoxaparin in cancer patients with acute VTE after 3-6 months of therapeutic dose LMWH. 150 subjects from 7 Canadian hospital centres with an active malignancy and an objectively confirmed VTE treated with weight adjusted LMWH for 3-6 months will be recruited. Eligible subjects will receive 40 mg daily of enoxaparin

for a maximum of 26 consecutive weeks or until any of the following occurs: recurrent VTE; bleeding necessitating permanent discontinuation of study drug; other adverse event necessitating discontinuation of study drug; or withdrawal of informed consent. Follow up will consist of four visits to determine feasibility and adverse outcomes.

Results: To date one study centre is active and has enrolled 7 patients. The 6 remaining sites will be active by end of February 2017. It is anticipated that enrollment will be completed by April 2018.

Conclusions: Little data exists on reduced dose extended-duration LMWH for secondary prevention of CAT. STEP-CAT will be the first study to assess the feasibility of prophylactic dose LMWH for the treatment of CAT following standard 3-6 months of anticoagulation.

PB 2326 | Myeloma Plasma Cells Express Tissue Factor and Trigger Thrombin Generation

L. Papageorgiou[1], H. Mokrani[1], L. Garderet[2], C. Mazurier[3], A. K.Larsen[4], P. Van Dreden[5], I. El Alamy[6], G. Gerotziafas[1,4]

[1]*Service d'Hématologie Biologique, Hôpital Tenon, Hôpitaux Universitaires de l'Est Parisien, Assistance Publique Hôpitaux de Paris, Paris, France,* [2]*Hôpital Saint Antoine, APHP, Hématologie et Therapie Cellulaire, Paris, France,* [3]*Centre de Recherche Saint Antoine, Oncologie-Hématologie, Paris, France,* [4]*Cancer Biology and Therapeutics, Centre de Recherche Saint-Antoine, Institut National de la Santé et de la Recherche Médicale (INSERM) U 938 and Université Pierre et Marie Curie (UPMC), Sorbonne Universities, Paris, France,* [5]*Clinical Research, Diagnostica Stago, Asnières-sur-Seine, France,* [6]*Service d'Hématologie Biologique Hôpital Tenon, Hôpitaux Universitaires Est Parisien, Assistance Publique Hôpitaux de Paris, Paris, France*

Background: Multiple myeloma is a hematological cancer characterized by clonal expansion of malignant plasma cells within the bone marrow. Myeloma plasma cells (MPCs) occupy and alter the stromal tissue of the bone marrow thereby enhancing their survival and growth. Beyond their key roles in blood coagulation, tissue factor (TF) and thrombin are also involved in cellular cross-talk and modulation of cell proliferation and migration.

Aims: To modelize the procoagulant fingerprint of MPCs by studying their TF expression and effect on thrombin generation (TG) of human plasma.

Methods: TF expression of MPCs was analyzed for TF expression by flow cytometry using anti-TF human murine IgG1 monoclonal antibody (Ref: 4503, American Diagnostics). TG in the presence of MPCS and anti-TF antibody was assessed with the Calibrated Automated Thrombogram assay as described elsewhere (Gerotziafas et al Thromb Res. 2012;129:779-86). In control experiments, TG was assessed in re-calcified normal PPP

(a) in the absence of plasma cells recalcification and

(b) after addition of PPP Reagent® 5pM TF - 4 µM procoagulant phospolipids (PPL) from Diagnostica Stago (France).

Results: MPCs (10^6 cells/ml) express TF (Mean Index of Fluorecence = 6 %) in contrast to normal lymphocytes, neutrophils or HUVECs which expressed no detectable TF. MPCs, accelerated TG in a TF-dependent manner, and increased the Peak and the endogenous thrombin formation (ETP) values compared to the control. However, the procoagulant activity of plasma cells was significantly lower compared to TG triggered by physiologically relevant concentrations of TF (5 pM) and PPL(Table 1).

Conclusions: MPCs express low amounts of TF and induce a mild increase of TG. The identification of the procoagulant fingerprint of plasma cells could lead to new therapeutic strategies aiming to interrupt the cross-talk between MPCs and the surrounding stromal tissue.

TABLE 1 Effect of plasma cells on TG of normal PPP (n = 7). ETP,PEAK ,MRI: mean rate index.*p<0.05 versus control; $ p<005 versus PPP reagent

PB 2327 | Radiotherapy Does Not Affect Coagulation

K.M. Begtrup[1], J.A. Højbjerg[1], B. Offersen[2], A.-M. Hvas[1]

[1]*Aarhus University Hospital, Department of Biochemistry, Aarhus N, Denmark,* [2]*Aarhus University Hospital, Department of Oncology, Aarhus N, Denmark*

Background: Cancer is associated with an increased risk of thromboembolic disease. Thromboembolic disease adds substantially to morbidity and mortality in cancer patients and is the second leading cause of death in cancer patients next to the underlying cancer. Only sparse knowledge exists about the influence of radiotherapy on coagulation and whether radiotherapy itself causes an increased risk of thromboembolic disease.

Aims: The aim was to investigate if adjuvant radiotherapy causes activation of the coagulation system.

Methods: In total 40 women with invasive breast cancer were enrolled after local excision and optionally chemotherapy. The radiotherapy contained up to 50 Gy administrated by 25 radiation fractions. Blood samples were obtained before and immediately after the first, the middle and the last radiation fraction. Platelet function was measured using impedans aggregometry and thrombin generation was determined by calibrated automated thrombogram. Furthermore, von Willebrand factor, factor VIII, fibrinogen, and C-reactive protein (CRP) were measured.

Results: All women had normal platelet aggregation prior to radiotherapy, and means of platelet aggregation stayed within reference interval. Platelet aggregation did not change during a single radiation dose, or throughout the entire radiation period.

Thrombin generation was not affected by radiotherapy, neither by a single radiation dose, nor throughout the entire radiation period. All means of thrombin generation stayed within reference interval. Von Willebrand factor, factor VIII, fibrinogen, and CRP did not change during radiotherapy.

Conclusions: Overall, the coagulation was not affected by radiotherapy. Radiotherapy did not affect the coagulation system nor by a single radiation dose or during the entire radiation period in breast cancer patients receiving adjuvant radiotherapy.

PB 2328 | Usefulness of D-dimer in the Diagnosis of Deep Vein Thrombosis after Neurosurgery for Glioblastoma and Meningioma

M.T. Sartori, F. Boscaro, A. Della Puppa, E. De Bon, F. Dalla Valle, C. Piovella, A. Padoan, R. Scienza, P. Prandoni

University of Padua, Padua, Italy

Background: Patients undergoing craniotomy for high grade glioma and meningioma are at risk for deep vein thrombosis (DVT) despite the use of multimodality prophylaxis. D-Dimer (DD) measurement may help early detection of DVT, but its transient increase after surgery may lead to misinterpretation.

Aims: To verify the diagnostic usefulness of DD variation during postoperative monitoring in the early detection of DVT confirmed by ultrasound (US) in patients undergoing craniotomy for brain tumor.

Methods: Patients undergoing craniotomy for high grade glioma or meningioma were tested for DD before (t0), 3 days (t1) and 7 days (t2) after neurosurgery. Each patient received US of lower limbs before and 7±1 days after surgery to test the presence or absence of DVT. All patients received antithrombotic prophylaxis with elastic stockings, intermittent pneumatic compression and LMWH.

Results: Fifty-seven patients were studied. Eleven patients (19.3%) developed DVT within 7 days after surgery. Median DD levels in patients with and in those without DVT were 147 (125-839) and 142 (77-267) ug/L at t0, 1488 (537-2787) and 572 (313-901) ug/L at t1, 2032 (653-4871) and 416 (242.5-625) ug/L at t2 respectively. Temporal variation of postoperative DD levels was significantly different between patients with and those without DVT (p=0.019). In each patient the t2/t1 ratio in DD values was calculated: using a t2/t1 ratio cut-off level of 1.04 was used, D-dimer ratio demonstrated a sensitivity of 63.6% (95% CI: 0.30-0.89), a specificity of 71.7% (95% CI: 0.56-0.84) and a negative predictive value of 91.2 % (95% CI: 0.75-0.97) for DVT. The t2-t1 difference in DD values was also determined: if a cut-off level of 69 ug/L was used, DD difference demonstrated a negative predictive value of 94.7% (95% CI: 0.82-0.99) for DVT.

Conclusions: In patients undergoing craniotomy for brain tumor a close monitoring of DD during the hospital stay may be useful to exclude a suspicion of DVT.

PB 2329 | Predictors of Mortality in Lung Cancer with Pulmonary Embolism: Concurrence of Pulmonary Embolism with Lung Cancer and Central Emboli

S.-I. Cha, Y.H. Lee, H. Seo

Kyungpook National University Hospital, Daegu, Korea, Republic of

Background: Patients with lung cancer commonly experience pulmonary embolism (PE).

Aims: The aim of the present study was to examine the clinical features of patients with lung cancer and PE and to investigate prognostic factors in these patients.

Methods: This retrospective study divided patients with lung cancer and PE into a group of patients with PE diagnosed concomitantly with lung cancer (concurrent group) and a group with PE detected after lung cancer (sequential group), compared the clinical characteristics of patients in the two groups, and investigated prognostic factors in these patients.

Results: The study population consisted of the concurrent group (27 patients [10.1%]) and the sequential group (240 patients [89.9%]). The concurrent group exhibited higher percentages of stage I cancer at the diagnosis of PE (6 [22.2%] vs. 8 [3.3%], $p < 0.001$) and right ventricular dilation on computed tomography (14 [51.9%] vs. 41 [17.1%], $p < 0.001$), as well as lower rate of small cell carcinoma (1 [3.7%] vs. 49 [20.4%], $p = 0.036$) than the sequential group. PE concurrent with lung cancer (hazard ratio [HR] 2.64, 95% confidence interval [CI] 1.57-4.43, $p < 0.001$) and central PE (HR 1.46, 95% CI 1.02-2.10, p=0.04) were independent predictors of mortality in patients with lung cancer and PE.

Conclusions: PE concurrent with lung cancer is characterized by more severe PE and infrequent small cell carcinoma. PE concurrent with lung cancer and central emboli may be independent prognostic factors in patients with lung cancer and PE.

PB 2330 | Patients with Venous Thromboembolism Events Admitted in a Tertiary Care Hospital: Follow-up for One Year and Correlation with Cancer

F. Sabio[1], L. Gonçalves[2], C. Monteiro[2], C. Marujo[3], C. Koch[2]

[1]Centro Hospitalar São João, Centre of Thrombosis and Hemostasis, Porto, Portugal, [2]Centro Hospitalar de São João - EPE, Centre of Thrombosis and Hemostasis, Porto, Portugal, [3]Centro Hospitalar de São João - EPE, Emergency Department, Porto, Portugal

Background: Venous thromboembolism (VTE) is a significant health problem, especially in cancer patients, as cancer is a strong risk factor for VTE. Also VTE is a well-known marker of occult cancer.

Aims: Evaluate the number of patients admitted in our hospital with acute VTE during 2015, associated risk factors, as cancer, mortality and the incidence of newly diagnosed cancer in the following year.

Methods: A retrospective study of 363 consecutive patients admitted with VTE events during 2015. Pulmonary embolism (PE) with or without deep venous thrombosis (DVT) was diagnosed in 103 (28,4%) patients and DVT alone was diagnosed in 260 (71,6%) patients. Presence of known risk factors, co-morbidities and newly diagnosed cancer during the following year after VTE event were obtained from medical records.

Results: In the PE group the mean age was 69,3 years, 63% females. Known risk factors were present in 32 patients (31%): active cancer in 19 patients (4 under anticoagulants), other risk factors in 13 patients. Idiopathic VTE was diagnosed in 71 patients (68,9%). Twenty-four patients died during follow-up, 10 with previous diagnosed cancer and 2 with newly diagnosed cancer. In the DVT group, the mean age was 50,9 years, 44,2% females. Known risk factors were present in 61 patients (23,4%): active cancer in 56 patients (5 with central venous catheter; 4 of this patients were under anticoagulants), other risk factors in 5 patients. Idiopathic DVT was diagnosed in 191 (73,46%) patients. Six patients died during follow-up, 5 with cancer. Four patients with PE and 2 with DVT developed cancer during the first 6 months of follow-up, all with previous idiopathic thrombotic event.

Conclusions: The number of active cancer in VTE patients was 20,7%, similar to other published studies. The rate of newly diagnosed cancer is lower (1,65%) than published. Though thromboprophylaxis in active cancer is not currently recommended in ambulatory setting, we believe there is a need to identify high-risk patients who will benefit from it.

PB 2331 | Cement Pulmonary Embolism as a Complication of Percutaneous Vertebroplasty in Cancer Patients

A. Mansour[1], H. Abuali[1], S. Salah[2], M. Ma'koseh[3], N. Shaikh-Salem[3], K. Abushalha[3], H. Abdel-Razeq[3]

[1]King Hussein Cancer Center, Radiology, Amman, Jordan, [2]Princess Margret Hospital, Toronto, Canada, [3]King Hussein Cancer Center, Internal Medicine, Amman, Jordan

Background: Vertebroplasty is a minimally invasive procedure commonly performed for compression vertebral fractures secondary to osteoporosis or malignancy. Leakage of bone cement into the paravertebral venous system and cement pulmonary embolism (cPE) are well described, mostly in patient with osteoporosis.

Aims: Little is known about its clinical sequel and outcomes in cancer patients. Here, we report our experience with cPE following vertebroplasty performed in cancer patients.

Methods: All consecutive cancer patients who had vertebroplasty were retrospectively reviewed. Procedure was performed through a percutaneous approach with injection of barium opacified polymethyl-methacrylate cement.

Results: A total of 102 cancer patients, median age 53 (19-83) years, were included. Seventy eight (76.5%) had malignant vertebral fractures while 24 (23.5%) had osteoporotic fracture. Cement PE was detected in 13 (12.7%); 10 (76.9%) had malignant fractures while the 3 others had osteoporotic fractures. Cement PE was mostly asymptomatic; however, 5 (38.5%) had respiratory symptoms that led to the diagnosis. Only the five symptomatic patients were anticoagulated.

Cement PE was more common with multiple myeloma (MM); seen in 7 (18.9%) of the 37 patients included compared to only 3 (7.3%) of 41 patients with other malignancies.

The incidence of cPE was not different in cancer patient with osteoporotic (12.5%) or malignant (12.8%) fractures (HR= 0.972; 95% CI, 0.244-3.86; P= 0.99). However, patient with osteoporotic fractures were older 66 vs. 51 years, P = 0.0076.

Conclusions: Cement PE, mostly asymptomatic, is a relatively common complication following vertebroplasty. Multiple myeloma is associated with the highest risk. Large scale prospective studies can help identify risk factors and clinical outcomes that can lead to better prevention and therapeutic strategies.

PB 2332 | Renal Cell Carcinoma with Neoplastic Thrombosis: A Treatment Challenge for a Rare Entity

V. Pons, P. Raheja, P. Olivera, A. Varela, T. Canals, E. Johansson, V. Cortina, M. Constans, F. Bosch, A. Santamaria

Vall d'Hebron University Hospital, Haemostasis Unit. Haematology Department, Barcelona, Spain

Background: Renal cell carcinoma (RCC) is well known for angiotropism, with up to 10% of tumors presenting extensive neoplastic tumoral thrombosis (NTT). Surgical debulking treatment with thrombectomy sometimes requires an extracorporeal circuit. In this setting, antithrombotic therapy (AT) and its duration are not entirely well defined.

Aims: To describe the clinical profile and management in patients diagnosed with RCC and NTT in a tertiary hospital.

Methods: A retrospective analysis was performed in a consecutive series of patients over the age of 18 with the diagnosis of RCC and NTT in our center between January 2015 and December 2016. We studied demographic characteristics, clinical presentation, oncologic and antithrombotic treatment strategies and outcome.

Results: A total of 9 patients were included in the analysis (6 cases were female and the median age at presentation was 61 years (47-75)). The pathologic diagnosis was of clear cell renal carcinoma in almost all cases (7/9). All patients had tumoral vena cava infiltration, although thrombotic extension was larger involving renal vessels, vena cava and up to the right atrium in 6 patients (66%). Cytoreductive radical surgery (nephrectomy and cavotomy with thrombectomy) was selected in 8 subjects and required cardiopulmonary bypass in 5.

All cases received postoperative incremental doses of low weight heparin (LMWH) with laboratory anti-Xa determination. At discharge and during the oncological therapy (mostly sunitinib, axitinib or bevacizumab), all of them were treated with LMWH. After one year of stable oncologic disease, 3 (33%) patients were on oral anticoagulation, 1 with direct oral anticoagulants and 2 with vitamin K antagonists.

Conclusions: RCC with NTT is a rare entity with extensive thrombotic manifestations. Cytoreductive radical surgery with thrombectomy is feasible and AT with LWMH is the treatment preferred during the first 12 months. Further studies are needed in order to better characterize this specific population.

PB 2333 | Silent Venous Thromboembolism in Patients Undergoing Thoracic Surgery in the Course of Lung Cancer

B. Kazanecka, P. Kuca, M. Dybowska, J. Burakowski, C. Czajka, F. Grzegorczyk, W. Tomkowski

National TB and Lung Diseases Research Institutte, Warsaw, Poland

Background: Venous thromboembolism (VTE) often occurs after thoracic surgery but can even occur before surgery in patients with lung cancer.

Aims: The aim of the study was the investigation of the incidence of silent deep vein thrombosis (DVT) and pulmonary embolism (PE), confirmed by objective imaging tests, before and after thoracic surgery in the course of lung cancer.

Methods: Venous ultrasound (US) imaging was performed to detect DVT before and after thoracic surgery in patients with non-small cell lung cancer. Plasma D-dimer (DD) levels as well as Caprini and Khorana risk scores were examined in all patients. All cases with signs or symptoms of PE after surgery were examined by computed tomography pulmonary angiography (CTPA).

Results: The study was perfomed in 200 patients (M:K = 122:88) with lung cancer and hospitalized for thoracic surgery. All patients received primary antithromobotic prophylaxis by low molecular weight heparins. DVT was detected by US in 3 patients before thoracic surgery. There was no symptoms od DVT and DD Level was elevated in one case.

PE was diagnosed by CTPA in 2 patients after surgery; there was no DVT in these cases.

DD levels were elevated in both cases.

Conclusions: Silent or subclinical VTE may occur before surgical treatment in many patients with non-small lung cell cancer. Risk factors for VTE as well as elevated DD level before treatment might not be sufficient for identification silent DVT in thoracic surgery. PE represent potentially lethal postoperative complication despite pharmacological prevention of VTE.

PB 2334 | Demographic Data and Outcomes of Pediatric Patients with Tumor and Thrombosis

P. Wongmas, P. Komvilaisak, S. Wiangnon, A. Jetsrisuparb

Khon Kaen University, Department of Pediatrics, Faculty of Medicine, Muang, Thailand

Background: Thromboembolic events (TEs) could be occurred in cancers and lead to serious complications. Risk factors of developing thrombosis in cancers is reported including advanced disease, cancer drugs. Regarding to different race and underlying thrombophilia, the cancers associated with thrombosis is conducted in Thailand.

Aims: To describe demographic datas, risk factors, treatment and outcomes

Methods: Cancer patients with TEs age 0-18 years between 1996-2016 in Srinagarind Hospital, Khon Kaen were reviewed.

Results: 57 cancer patients with TEs were included with median age 12 years (3 months-18 years). Most common site of thrombosis was deep vein thrombosis (42.1%). Majority of patients were hematologic malignancies (36.8%) followed by solid tumor (28%) and soft tissue sarcoma (24.6%). The most common risk factor was L-asparaginase. Tumor invasion/compression had increased risk of TEs in children with solid tumor and sarcoma. All of patient with sarcoma and TEs associated with advance diseases (stage III-IV). Two patients had catheter-related thrombosis. More than half of patients were treated by low-molecular weight heparin (53.6%). Other treatment were warfarin(12.6%), aspirin(3.5%), observation (26.8%) and combined treatment(3.5%). 48.2% of all patients improved thromboembolism. The outcome of TEs was categorized into complete (17.5%) and partial (10.5%) resolution, stable (15.8%) and progressive (3.5%) disease. Some patients (14%) with TEs clinically improve with no imaging follow up. 36.8% of patients were not record thromboembolism outcomes due to cancer advance. 61.4% of patients were alive. Two patients (3.5%) died from pulmonary embolism and brain infarct. Most common cause of death was cancer progression.

Conclusions: There were multifactorial in cancer with thrombosis. Adolescence, advance stage of tumor, chemotherapy had increased risk for TEs. Cancer progression was major cause of death in patients with tumor and TEs.

PB 2335 | Retrospective Cohort Study of Venous Thromboembolism (VTE) Rates in Ambulatory Cancer Patients, and Association with Khorana Score

K. Austin[1], J. Borrowman[1], L. Blake[1], M. Scully[1,2], M. Thomas[1,2]

[1]University College London Hospitals NHS Foundation Trust, Department of Haematology, London, United Kingdom, [2]University College London Hospitals NHS Foundation Trust, Cardiometabolic BRC, London, United Kingdom

Background: Guidelines do not recommend cancer outpatients receive thromboprophylaxis unless high VTE risk, with Khorana score suggested for risk stratification.

Aims: To investigate VTE incidence in outpatients with pancreatic, endometrial, colorectal, ovarian and cervical cancer at major cancer centre and role of Khorana score in risk assessment.

Methods: Data from patient records for 1 year after diagnosis Dec 2012-14 (2009-14 pancreatic).

Results: 26/98 pancreatic patients developed non-hospital-associated thrombosis in first year with 30 individual clots (Table 1).13/26

patients were asymptomatic, 11/26 had VTE at diagnosis. 9/160 endometrial patients developed non-HAT VTE with 10 clots. 3/9 were asymptomatic, 3/9 had VTE at diagnosis. 20/212 colorectal patients developed non-HAT VTE with 21 clots. 9/20 were asymptomatic, 0 had VTE at diagnosis. 21/201 ovarian patients had non-HAT VTE with 23 clots. 8/21 were asymptomatic, 3/21 had VTE at diagnosis. 0/95 cervical patients developed non-HAT VTE.

TABLE 1 Site of VTE events by cancer group

	Pancreatic	Endometrial	Colorectal	Ovarian	Cervical
Lower limb DVT	6	1	4	5	0
Upper limb DVT: PICC-associated	3	2	7	4	0
Upper limb DVT: Non-PICC-associated	1	0	0	0	0
Upper limb DVT: Total	4	2	7	4	0
PE	5	7	8	12	0
Intra-abdominal	14	0	2	0	0
IVC	1	0	0	2	0
Total	30	10	21	23	0
Total number of patients	98	160	212	201	95

Excluding those with VTE at presentation, 46/87 pancreatic, 21/157 endometrial, 3/212 colorectal, 26/198 ovarian, 20/95 cervical patients had high-risk Khorana score (≥3). High Khorana score was associated with higher 1 year VTE rate in endometrial [high-risk 3/21 VTE(14.3%) vs. low-risk 3/136(2.2%), p=0.007]; but not pancreatic [high-risk 8/46 VTE(17.4%) vs. low-risk 7/41(17.1%), p=0.97],colorectal [high-risk 0/3 VTE(0%) vs. low-risk 20/209(9.6%), p=0.57], ovarian [high-risk 2/26 VTE(7.7%) vs. low-risk 16/172(9.3%), p=0.79] or cervical cancer [high-risk 0/20 VTE vs. low-risk 0/75].

Conclusions: VTE is a significant burden in pancreatic (26.5%), endometrial (5.6%), colorectal (9.4%) and ovarian (10.4%) cancers. Khorana score predicted VTE risk in endometrial cancer only. A review of factors that can improve prediction of non HAT in cancer require further investigation.

PB 2337 | Subclinical Portal Vein Thrombosis in Liver Cirrhosis Patients Increase Risk of 30 Days Mortality: Preliminary Study

A. Kurniawan, N.P.H. Lugito, M.M. Tjiang, T.A. Yanto

School of Medicine, Pelita Harapan University, Internal Medicine, Tangerang, Indonesia

Background: Portal vein thrombosis (PVT) is a common complication of liver cirrhosis patients with a prevalence ranging from 1% to 16% patients. Mostly PVT was diagnosed radiographic studies as an incidental finding. There is still limited data about the natural history of PVT and its survival in patients with liver cirrhosis.

Aims: The aim of this study is to know 30 days-mortality of PVT in liver cirrhosis patients.

Methods: This was a cohort prospective study evaluating liver cirrhosis patient with PVT in our general hospital, Karawaci, Tangerang, Banten from 2014-2016. Patients with heart failure, chronic kidney disease and cancer other than hepatocellular carcinoma were excluded. Liver cirrhosis patient with or without PVT was followed until 30 days after admitted in our hospital. Diagnosis of liver cirrhosis and PVT were using multi slice CT scan. PVT is defined as occlusive thrombosis of the main portal vein.

Results: Fifty five patients fulfilled the criteria for liver cirrhosis in the study period. Thirty five patients (63.6%) were male. Thirty seven (67.3%) patients were fulfilled Child Pugh B criteria, 10 patients (18.2%) were fulfilled Child Pugh A criteria and others were Child Pugh C criteria. Twenty nine patients (52.7%) had positive hepatitis B infection and 4 patients (7.3%) had hepatitis C infection. Fourteen patients (25.4%) fulfilled criteria of HCC. Five patients with HCC were positive PVT. Four patients with PVTT died in hospital. The mean of D-dimer level using ELISA technique was 5.6 $\pm$ 0.9 g/L. All patients with PVT died within 30 days after they were diagnosed.

Conclusions: All patients with PVT in Liver cirrhosis patients died within 30 days after they were diagnosed. Further study need to be done to confirm this result.

PB 2338 | Relationship of Platelets Parameters with JAK2 V617F Mutation Status and Thrombotic Risk in Myeloproliferative Disorders

D. Bahri, H. Baccouche, A. Chakroun, S. Mahjoub, Z. Manai, N. Ben Romdhane

Rabta Hospital, El Manar University, Department of Hematology, Tunis, Tunisia

Background: Blood count is essential in the diagnosis of myeloproliferative disorders which are closely associated with JAK2 V617F mutation and thrombotic events. The diagnostic and prognostic performance of platelets parameters are not clearly demonstrated in these disorders.

Aims: The aim of this study is to assess the relationship between platelets parameters with both JAK2 mutational status and the thrombotic events.

Methods: 53 patients diagnosed with myeloproliferative disorders were enrolled during a period of 5 years. Arterial and venous thrombotic events were recorded.

Platelets parameters including platelets count (PC), thrombocytocrit (PCT), platelet distribution width (PDW) and mean platelet volume (MPV) were analyzed at diagnosis using automated hematology analyzer SYSMEX XT-4000 i.

JAK2 V617F mutation was detected by allele specific real-time quantitative fluorescence PCR.

Results: The mean age was 62 years [24-92], the sex ratio was 22/31. Thrombotic events were recorded in 13 cases.

Of the 53 MPDs, JAK2 V617F mutation was detected in 44 (83%) patients.

Platelets parameters were compared between patients with JAK2 V617F mutation and wild-type. No significant difference was found between the two groups: PC (611045/mm3 vs 785222/mm3; p=0.17), PCT (0.61% vs 0.71%; p=0.4), PDW (12.17 fL vs 11.13 fL; p=0.24) and MPV (9.78 fL vs 9.5 fL; p=0.6).

There was also no association to thrombotic events: PC (675300/mm3 vs 533923/mm3; p=0.29), PCT (0.65% vs 0.54%; p=0.34), PDW (12.02 fL vs 11.9 fL; p=0.871) and MPV (9.79 fL vs 9.56 fL; p=0.64).

Conclusions: According to this study, there was no impact of platelets parameters on JAK2 mutation status and they were not reliable markers in thrombotic risk assessment. Some studies showed that platelets indices could be predictive of JAK2 mutational status.

PB 2339 | Genetic Forms of a Thrombophilia in Cancer Patients with Recurrent VTE

A. Vorobev, A. Makatsariya, A. Solopova

I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

Background: High rate of the recurrent venous thromboembolism (VTE) as often complication in cancer patients has induced us to carry out association between congenital defects of a hemostasis system and the recurrent VTE in oncogynaecological patients.

Aims: Determination of the rate and structure of genetic forms of a thrombophilia in gynecological cancer patients with recurrent VTE.

Methods: The control group includes 30 women with gynaecological cancer without any VTE episodes and has not family history of VTE.

Laboratory tests: Detection of FV Leiden mutation, prothrombin G20210A mutaton, gene PAI-1 G4/G5 polymorphism, gene MTHFR C677T mutation, genes of platelets glycoproteins polymorphism: GP IIb/IIIa, GP Ia/IIa, GPIba, GP ADP.112 patients with VTE episodes in the past: 62 has ovarian cancer, 30 uterine carcinoma, 20 cervical carcinoma.

Results: We have detected the incidence of FV Leiden mutation is 22 (19,6%); homozygous gene MTHFR mutation is 46 (41,1%); heterozygous gene MTHFR mutation is 58 (51,8%); prothrombin mutaton is 18 (16,1%); gene PAI-1 polymorphism is 32 (28,6%); platelets glycoproteins polymorphism is 50 (44,6%).In control group FV Leiden mutation was in 3 patients (10%); homozygous gene MTHFR in 2 (6,7%), heterozygous gene MTHFR mutation in 5 cases (16,6%); gene PAI-1 polymorphism in 3 (10%) and platelets glycoproteins polymorphism is 3 patients (10%).

Conclusions: Presence of multigenic thrombophilia is the expressed trigger of VTE. So patients with multigenic thrombophilia should be permanently treated by anticoagulats (LMWH) under the control of thrombophilia markers, such as D-dimer, TAT complexes and platelet factor 4.

PB 2340 | Acute Pulmonary Embolism in Cancer Patients: Clinical Findings and Outcome

B. Vitola[1], D. Kigitovica[2], V. Gibietis[1], S. Strautmane[1], A. Skride[3]

[1]Riga Stradins University, Faculty of Medicine, Riga, Latvia, [2]Riga Stradins University, Faculty of Continuing Education, Riga, Latvia, [3]Riga Stradins University, Department of Internal Medicine, Riga, Latvia

Background: As a special group in pulmonary embolism (PE), the baseline characteristics, better therapeutic strategy and prognosis of patients with concurrent malignancy need to be investigated. (*Zhang et al, 2014).*

Aims: To evaluate clinical findings of PE in patients with cancer and to analyse outcome according to prescribed anticoagulation therapy.

Methods: The prospective cohort study included 195 patients (25 patients with cancer) with PE from a single centre in time period from June 2014 till December 2016. The data were analysed by SPSS 21.0.

Results: The overall 6-month mortality in patients with cancer and non-cancer patients was 32% [13.7-50.3] vs 6.6% [2.4-10.8] (p< 0.001). Mean time of death from discharge was 40.25 ± 50.9 [4.9-75.6] days. DVT was localized in lower limbs in 7 cases: 71% [38.0-100.0] - in upper leg, 29% [4.9-62.0]) - in lower leg. Dyspnoea, chest pain and swollen limbs were not significantly associated with malignancy (Relative risk-1.00 and Odds Ratio-1.03), moreover cough was less present in patients with cancer (Risk difference -0.2 [1.0-39.0]).

Mortality rate at 6 months was not significantly associated with clot localization in pulmonary arteries and higher D-dimer value (p=0.093 and p=0.562, respectively).

For long-term treatment after VTE 56% [36.5-75.5] received direct oral anticoagulants (DOAC), 32% [13.7-50.3] - vitamin K antagonist (VKA) and 12% [0-24.7] - low molecular weight heparin (LMWH). 6-month mortality was significantly higher for patients receiving DOACs (n=2; 14% [0-32.6]) compared to VKA (n=5; 63% [29.0-96.0]) (p=0.019). Bleeding during use of anticoagulants occurred in 3 cases (all DOACs; 21% [0-42.9]).

Conclusions: Mortality rate in patients with cancer and PE is significantly higher than in control group - 32% vs 6.6%. Patients who received DOACs had better survival compared to those who used VKA. In real-life practice LMWH is chosen in separate cases instead of being a first choice.

PB 2341 | Subarachnoid Hemorrhage and General Anesthesia Inhibit the Brain (G)Lymphatic System in Mice and Non-human Primates

M. Gauberti[1,2], T. Gaberel[1,3], S. Goursaud[1,4], S. Martinez de Lizarrondo[1], D. Vivien[1,5], C. Gakuba[1,4]

[1]INSERM UMR-S U1237, Caen, France, [2]Caen University Hospital, Department of Diagnostic Imaging and Interventional Radiology, Caen, France, [3]Caen University Hospital, Department of Neurosurgery, Caen, France, [4]Caen University Hospital, Department of Anesthesiology and Critical Care Medicine, Caen, France, [5]Caen University Hospital, Department of Cell Biology, Caen, France

Background: Although we thought that the brain was devoid of a lymphatic system, recent studies demonstrated the existence of a brain

wide circulation of cerebrospinal fluid (CSF) which removes brain extracellular wastes: the glymphatic system. The pathophysiological mechanisms influencing the activity of this glymphatic system remain poorly understood.

Aims: Subarachnoid hemorrhage (SAH) is a frequent disease characterized by the presence of blood in the brain subarachnoid space, commonly leading to severe neurological deficits. We hypothesized that SAH may interfere with the brain glymphatic system by obstructing the CSF circulation routes. Since general anesthesia is associated with an increased deposition of brain extracellular proteins, we also investigated whether general anesthesia influences the glymphatic system activity.

Methods: We first evaluated the circulation of the brain CSF in mice and non-human primates (NHP), using contrast enhanced MRI. Then, animals were subjected to a minimally invasive SAH prior to an MRI evaluation of the impact of SAH on the brain parenchymal CSF circulation. To evaluate the impact of general anesthesia, we developed original methods of MRI and near infrared fluorescence in awake and anesthetized mice.

Results: We first demonstrated in non-human primates that the CSF actively penetrates the brain parenchyma, confirming the existence of the active circulation of CSF first described in rodents. SAH dramatically impaired the brain circulation of CSF, because of paravascular space obstruction by fibrin clots. Regarding the impact of general anesthesia, we demonstrated that the glymphatic system is mainly active during wakefulness and significantly impaired under general anesthesia.

Conclusions: Both subarachnoid hemorrhage and general anesthesia negatively affects the glymphatic system, with potential long-term consequences on extracellular protein accumulation such as the beta-amyloid peptide.

PB 2342 | Association between Hepatic Triglyceride Content and Coagulation Factor Levels: The Netherlands Epidemiology of Obesity (NEO) Study

V.M. Morelli[1], R. de Mutsert[1], A. de Roos[2], H.J. Lamb[2], A. van Hylckama Vlieg[1], M.H.A. Bos[3], F.R. Rosendaal[1,3,4], W.M. Lijfering[1,4], S.C. Cannegieter[1,4]

[1]Leiden University Medical Center, Department of Clinical Epidemiology, Leiden, The Netherlands, [2]Leiden University Medical Center, Department of Radiology, Leiden, The Netherlands, [3]Leiden University Medical Center, Department of Thrombosis and Hemostasis, Leiden, The Netherlands, [4]Leiden University Medical Center, Einthoven Laboratory for Experimental Vascular Medicine, Leiden, The Netherlands

Background: Hepatic triglyceride content (HTGC) has been linked to levels of coagulation factors (F)VIII, IX and XI in one small study. However, it is unclear whether HTGC contributes to coagulation factor levels beyond overall and visceral fat.

Aims: To assess the association between HTGC and levels of fibrinogen, FVIII, FIX, and FXI while taking into account total body fat (TBF) and visceral adipose tissue (VAT).

Methods: In a cross-sectional analysis (NEO study), we included a random subset of participants who underwent magnetic resonance (MR) imaging and MR spectroscopy to measure VAT and HTGC (n=2,075). We excluded participants with missing data on coagulation factors, with liver disease, venous thrombosis or on anticoagulation (n=129). We examined associations between HTGC and coagulation factors by linear regression, adjusted for age, sex, ethnicity, education, alcohol intake, physical activity, smoking, estrogen use and menopause status (first model), adding TBF and VAT in a second model. Consent and ethical approval were obtained.

Results: 1,946 participants (52% men; median age 56 years, IQR 50-61) were analysed. As shown in Table 1, in the first multivariate model, coagulation factor levels increased dose-dependently across HTGC quartiles compared with the lowest quartile (reference category). With further adjustment for TBF and VAT (model 2), the associations between HTGC and levels of fibrinogen, FVIII and FXI across quartiles disappeared, while the association between HTGC and FIX levels, albeit attenuated, remained, as did the dose-response relationship.

Conclusions: HTGC was associated with levels of various coagulation factors of which FIX levels remained associated with HTGC after adjustment for TBF and VAT. Our results shed more light on the relation between obesity and venous thrombosis risk, including the potential that fatty liver contributes to venous thrombosis risk beyond total body and visceral fat.

TABLE 1 Association between hepatic triglyceride content (HTGC) and coagulation factor levels in 1,946 participants from the NEO study

	Mean differences of coagulation factor levels (95% Confidence Interval) compared with the reference category							
	Fibrinogen (mg/dL)		Factor VIII (IU/dL)		Factor IX (IU/dL)		Factor XI (IU/dL)	
HTGC (%) quartiles	Model 1	Model 2	Model 1	Model 2	Model 1	Model 2	Model 1	Model 2

PB 2343 | Portal Vein Thrombosis Associated with Abdominal Inflammatory Conditions

V. Tran[1], A. Acuna-Villaorduna[2], H. Billett[3]

[1]Albert Einstein College of Medicine & Montefiore Medical Center, Bronx, United States, [2]Montefiore Medical Center, Hematology, Bronx, United States, [3]Montefiore Medical Center, Bronx, United States

Background: Portal vein thrombosis (PVT) is an unusual-site thrombosis predisposed by conditions like cirrhosis, malignancies, myeloproliferative neoplasia (MPN) and abdominal inflammatory conditions (AIC). AIC represents the most acute of these etiologies and many patients do not have any other underlying chronic medical conditions. Given that management of patients with PVT is unclear, we investigated whether AIC conditions differed from the others in etiology, therapeutic intervention and prognosis.

Aims: To compare clinical and pathological features of patients with PVT associated with AIC versus other etiologies.

Methods: After IRB approval, medical records from 2005 to 2015 were reviewed by institutional data mining software to identify patients diagnosed with PVT by ICD9. The subgroup of PVT associated with AIC was selected for chart review. AIC was defined as due to an acute event occurring within 60 days preceding PVT diagnosis without history of other chronic diseases associated with PVT.

Results: PVT was identified in 698 patients. The most common etiologies were cirrhosis (198; 28.4%) cirrhosis with concomitant malignancy (198; 28.4%); followed by malignancy (151; 21.6%), idiopathic (95;13.6%), AIC (35; 5%) and MPN (21; 3%). Among AIC, the most common predisposing factors were pancreatitis (10; 28.6%), post-surgical (8; 22.9%), diverticulitis (5; 14.3%), and bacteremia (4; 11.4%). 82.9% received anticoagulation. Follow-up imaging was available for 24 cases with evidence for venous thrombosis recurrence in one case. Patients with AIC were younger, more likely to be black, have higher BMI, and were 3x more likely to receive anticoagulation (Figure 1).

TABLE 1 Baseline characteristics and anticoagulation in patients with PVT

	AIC PVT (n=35)	Non-AIC PVT (n=663)	Total PVT (n=698)	P*
Age, median (IQR25-75)	54 (40-66)	61 (54-69)	61(53-69)	0.0004
Gender, male (%)	14 (40%)	383 (57.8%)	397 (57%)	0.04
Hispanic (%)	11 (31.4%)	282 (43.7%)	293 (42%)	0.15
African-American (%)	14 (40%)	156 (23.5%)	170 (24%)	0.02
BMI, median (IQR 25-75)	29 (23.2-37.1)	26 (23.3-31.7)	26.9 (23.3-32.0)	0.001
Anticoagulation rate (%)	29 (82.9%)	88 (13.3%)	117 (16.7%)	0.0001
Heparin	8 (27.6%)	29 (33%)	37 (31.6%)	0.26
Coumadin with heparin bridge	20 (69%)	48 (54.5%)	68 (58.1%)	
DOACs	1 (3.4%)	11 (12.5%)	12 (10.2%)	

Abbreviations: AIC: abdominal inflammatory conditions; IQR: interquartile range; BMI: body mass index; DOACs: direct oral anticoagulants. P value represents the comparison between AIC and non-AIC PVT.

Conclusions: AIC is most commonly triggered by pancreatitis and surgical procedures. Patients with AIC are more likely to receive anticoagulation and have a low venous thrombosis recurrence rate. Whether the low recurrence rate is due to the presence of a provoked risk factor which abates or due to the increased use of anticoagulation is unclear.

PB 2344 | Role of ADAMTS13 Deficiency in the Pathogenesis of Portal Vein Thrombosis Complicating Liver Cirrhosis

S. Lancellotti[1], M. Basso[1], M. Sacco[1], L. Riccardi[2], M. Pompili[2], R. De Cristofaro[1]

[1]Catholic University of the Sacred Heart School of Medicine, Institute of Internal Medicine, Department of Hematology-Oncology, Roma, Italy, [2]Catholic University of the Sacred Heart School of Medicine, Institute of Internal Medicine, Department of Digestive, Endocrine and Metabolic System, Roma, Italy

Background: Portal vein thrombosis (PVT) dramatically changes the prognosis of cirrhotic patients, especially those waiting for liver transplantation. However, the possible contribution to PVT pathogenesis of von Willebrand factor (VWF) and ADAMTS13, produced by liver stellate cells (LSC), is scarcely documented.

Aims: The aim of our study was to assess the presence of alterations of VWF and ADAMTS13 plasma levels in cirrhotic patients with PVT.

Methods: Thirty patients with PVT (group A) and 60 without PVT (group B) were enrolled and signed an informed consent. Biochemical and haemostatic parameters were measured. ADAMTS13 activity was studied by a synthetic fluorescent 86-amino acid substrate (FRET method). VWF level and activity were analyzed by chemiluminescence assays (Accustar, Werfen) and western blotting agarose gel SDS-electrophoresis.

Results: ADAMTS13 activity was significantly lower in group A (median=16.5% vs. 69.1%, p=0.0047). Group A showed a significantly higher VWF:act, (median:308% vs 203%, p=0.032), whereas no difference was observed for VWF:Ag, FVIII level and presence of thrombophilic factors. In multivariable logistic regression analysis performed on data concerning both group A and B, only the ADAMTS13 activity (p=0.007) resulted to be independently and inversely associated with PVT. ROC analysis showed that a cut-off level of 18% ADAMTS13 could predict the risk of PVT development (AUC 0.709, [SE=0.077, p=0.005])

Conclusions: ADAMTS13 activity is independently and inversely associated with PVT. The decrease of ADAMTS13 activity likely causes an intra-sinusoidal deposition of ultra-large VWF multimers that would favor thrombi formation in sinusoids and PV circulation. Prospective investigations are under way to clarify whether ADAMTS13 level could be considered a predictive biomarker of PVT development in cirrhosis.

PB 2345 | Haemostatic Changes in Cirrhotic Patients Treated with Direct-acting Antiviral Therapy

E. Campello[1], A. Zanetto[2], L. Spiezia[1], C. Radu[1], S. Gavasso[1], A. Ferrarese[2], A.C. Frigo[3], G. Germani[2], M. Senzolo[2], P. Burra[2], F.P. Russo[2], P. Simioni[1]

[1]University of Padua Medical School Department of Medicine, Padova, Italy, [2]University of Padova, Department of Surgery, Oncology and Gastroenterology, Padova, Italy, [3]University of Padua Medical School, Biostatistics, Epidemiology and Public Health Unit, Padova, Italy

Background: Advanced liver disease is characterized by severe alterations of haemostatic balance that can lead to both bleeding and thrombotic complications. Standard coagulation tests failed to detect this disequilibrium. Thrombingeneration test (TG) with and without thrombomodulin (+/- TM) has been reported as the best coagulation test able to quantify the coagulation impairment in patients with liver cirrhosis.

Aims: To evaluate the impact of HCV eradication following direct-acting antiviral (DAA) therapy in coagulation profile of patients with HCV-related liver cirrhosis as well as to correlate these changes with both the improvement of liver function test and the risk of portal vein thrombosis (PVT) development.

Methods: Patients with HCV-related cirrhosis treated with DAA were prospectively enrolled. TG test (+/- TM) was performed at baseline, at the end of therapy and 12 weeks (12W) after the end of therapy. During follow-up, PVT onset was recorded.

Results: Sixty patients were enrolled (Child A/B 50/10). All of them reached 12W after the end of therapy follow-up. Albumin ($p< 0.004$) and platelet count ($p< 0.001$) significantly increased after the end of therapy. Compared to baseline value (0.4), the endogenous thrombin potential ratio significantly improved after the end of treatment (0.8; $p< 0.001$) and 12W after (0.9; $p=0.002$). The 12W after end of treatment-lag time (time to coagulation start in TG test) was significantly longer in comparison to pre-antiviral values ($p< 0.001$). No statistically significant correlation was found between TG parameters and liver function tests at multivariate analysis. Median follow up was 9 months (4-14). During follow-up, one PVT episode was recorded (incidence 2%).

Conclusions: Eradication of HCV is associated with significant changes in TG profile, possibly related to the improvement of liver function. This amelioration may partially correct the disequilibrium of the haemostatic imbalance of liver cirrhosis, leading to a reduction in the risk of PVT development.

PB 2346 | The Risk of Venous Thromboembolism in Women with Polycistic Ovarian Syndrome: An Italian Study

L. Filippi[1], R. Mioni[1], R. Pesavento[1], D. Ceccato[1], A. Dalla Ca'[1], A. Gambineri[2], F. Fruzzetti[3], L. Cervino[1], M.E. Fulghesu[4], R. Vettor[1]

[1]Università degli Studi di Padova, Padova, Italy, [2]Università degli Studi di Bologna, Bologna, Italy, [3]Azienda Ospedaliera Pisana, Pisa, Italy, [4]Università degli Studi di Cagliari, Cagliari, Italy

Background: The risk of venous thromboembolism (VTE) in reproductive-aged women varies from 0.5 to 1.2 cases/1000 patient/year. The polycystic ovarian syndrome (PCOS) affects up to 12-21% of reproductive-aged women. A reduction of global fibrinolytic capacity, increased plasmatic levels of PAI-1 and Ag t-PA has been repeatedly observed in PCOS. Women affected by PCOS show several comorbidities linked to increased cardiovascular and thromboembolic risk as visceral obesity, hyperinsulinism, diabetes mellitus, hypertension, metabolic syndrome. Moreover, they are often treated with long-term hormonal therapy, leading to a further modulation of the thromboembolic risk. Notwithstanding, the clinical relevance of VTE risk in women with PCOS is virtually unknown.

Aims: The objective of the study is to assess both the incidence rate of VTE in women with an objective diagnosis of PCOS and the role of the associated VTE risk factors.

Methods: We have designed a multicenter retrospective cohort study The main inclusion criteria was an objective diagnosis of PCOS, classified in four phenotypes, according to the consensus of AE-PCOS Society. All enrolled patients were scheduled for a follow-up visit to investigate the occurrence of thromboembolic events.

Results: From 1994 to 2016 the data of 1017 consecutive patients with PCOS were collected from 7 centers in Italy. The overall amount of follow-up time was 20034 years. During that time 14 subjects received an instrumental diagnosis of VTE (9 deep venous thrombosis and/or pulmonary embolism and 5 superficial venous thrombosis). Among these, 3 were unprovoked, 4 were associated with non-hormonal risk factors and 7 were associated to hormonal therapy. The overall VTE incidence rate was 0.7/1000 patients/year (95% CI: 0.4-1.2).

Conclusions: These preliminary data show that in our cohort of women affected by PCOS, the disease does not seem to increase the risk of VTE, even in patients treated with hormonal therapy.

TABLE 1 Baseline characteristics

Baseline characteristics	n (SD)
Mean age at menarch	12.2 years (1.54)
Mean BMI	24.6 (5.73)
Mean time of hormonal therapy	62 months (56)
	n (%)
Phenotype A	535 (52.6)
Phenotype B	302 (29.7)
Phenotype C	105 (10.3)
Phenotype D	75 (7.3)
Hormonal therapy users	834 (82)

PB 2347 | Fibrinogen Estimation in Patients with Liver Disease

K. Rizzo[1], K. Vella[2], D. Zammit[2], P. Gatt[3], C. Grima[3], M. Vassallo[4], P. Ellul[4], J. Gerada[4], N. Azzopardi[4], J. Pocock[4], M. Borg Inguanez[5], A. Gatt[6]

[1]University of Malta, Msida, Malta, [2]Mater Dei Hospital, Department of Pathology, Msida, Malta, [3]Mater Dei Hospital, Clinical Perfusion, Msida, Malta, [4]Mater Dei Hospital, Department of Gastroenterology, Msida, Malta, [5]University of Malta, Department of Statistics & Operations Research, Msida, Malta, [6]University of Malta, Department of Pathology, Msida, Malta

Background: Fibrinogen is mainly produced in the liver and hence, conditions like cirrhosis, may affect the levels of fibrinogen, leading to bleeding diatheses. There are different tests that can be used to measure quantitative and qualitative fibrinogen levels however, there is no agreement yet on which test is preferred.

Aims: Comparing 4 different methodologies ie the Clauss Fibrinogen, PT-derived Fibrinogen (PT-Fg), Fibrinogen Antigen (Fib-Ag) and Functional Fibrinogen Thromboelastography (FF-TEG) for estimating fibrinogen levels in patients with liver cirrhosis and healthy controls.

Methods: A total of 55 cirrhosis patients were recruited. 26 were Child Pugh (CP)-A, 14 CP-B and 15 CP-C. 20 healthy control individuals were also enrolled. The FF-TEG was performed using TEG® so as to obtain the estimated functional fibrinogen level (FLEV), whilst the Clauss Fibrinogen, PT-Fg and Fib-Ag were estimated on Sysmex® CS-2100*i*.

Results: All 4 fibrinogen assays gave significantly different fibrinogen levels. However, these assays were strongly and positively correlated with each other in both cohorts. The PT-Fg and the FLEV gave higher results than the Clauss and the Fib-Ag. When grouped according to CP severity score, there was a non significant trend in all assays showing fibrinogen to be raised in CP-A, normal in CP-B and decreased in CP-C when compared to normal. There was only a significant difference between CP-A and CP-C groups using the Fib-Ag, Clauss and PT-Fg but not the FLEV. Of note is that the PT-Fg overestimated fibrinogen levels by a mean of 1.03g/L when compared with Clauss.

Conclusions: Whilst the 4 assays correlate well with each other, there were no apparent differences according to CP severity groups and healthy controls in the FLEV. This is in contrast to the results obtained by the other 3 assays and points to normal fibrin clot strength in liver cirrhosis despite differences in fibrinogen levels.

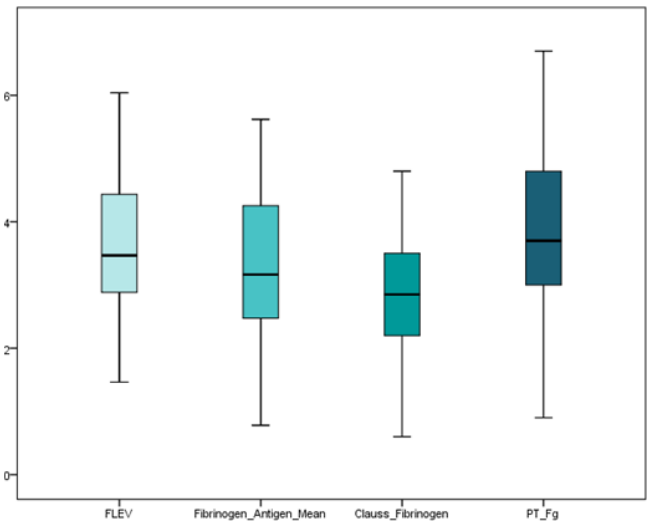

FIGURE 1 Box Plots of FLEV, Fib-Ag, Clauss Fibrinogen and PT-Fg in the liver cirrhosis population

PB 2348 | A Rat Model to Evaluate Formation of Venous Thromboembolism after Prolonged Tourniquet Application

O. Mian[1], J. Gantioqui[1], P. Liao[1], J. Zhou[1], J. Weitz[1], A.K.C. Chan[1,2]

[1]McMaster University and Thrombosis and Atherosclerosis Research Institute, Medicine, Hamilton, Canada, [2]McMaster Childrens Hospital, Pediatric Thrombosis and Hemostasis, Hamilton, Canada

Background: The incidence of symptomatic venous thromboembolism (VTE) in patients undergoing total knee arthroplasty (TKA) is ~10% when no prophylaxis was administered. Despite modern anticoagulant prophylaxis post-operatively, some patients still develop VTE. We previously reported that prolonged tourniquet use during TKA was associated with VTE in the early postoperative period. Hereby, we used a rat model to investigate the pathophysiology of venous clot formation after tourniquet use.

Aims: To determine if deep vein thrombosis is associated with tourniquet application on the ipsilateral thigh of rats.

Methods: Male Sprague Dawley rats were anesthetized with isoflurane. A pneumatic pressure cuff was applied to the leg on the experimental side above the knee for a predefined time at a constant pressure three times above the arterial pressure. The leg without tourniquet served as control. Heparin (500 units) was injected intravenously immediately before block dissection of vessels from the ipsilateral and contralateral sides to prevent perimortem clot formation. Rats were then euthanized. The histology of the harvested vessels was examined after H&E, platelet- and fibrin-specific staining.

Results: The weight of the rats was ~325g. In the experimental leg where the tourniquet was applied for 3 hours at 260 mmHg extensive venous clots were noted whereas no clot was detected in the contralateral leg without tourniquet. Fibrin- and platelet-specific stains confirmed composition of clot in the experimental side but only little fibrin and platelet deposition was found in the control side. Pool of leukocytes was also found at the tourniquet application site.

Conclusions: This animal model will shed light on the pathophysiology of thrombosis caused by the use of hemostatic tourniquet during surgery. Its application during TKA may initiate venous clot formation; therefore, prophylactic dose of anticoagulant administered post-operatively is insufficient to abort clot propagation which then results in thrombotic complications.

PB 2349 | Increased Baseline TF Activity in Women with Unexplained Pregnancy Loss: An Additional Argument for a Basal Endothelial Dysfunction?

E. Pasquier[1], P. Van Dreden[2], A. Rousseau[2], L. de Saint Martin[1], D. Mottier[3], F. Couturaud[1]

[1]EA 3878, Brest University Hospital, Brest, France, [2]Diagnostica Stago, Gennevilliers, France, [3]CIC-INSERM 1412, Brest, France

Background: Tissue factor was identified as a crucial mediator of fetal and placental damage in mouse models of recurrent miscarriage. During pregnancy, an increased level of tissue factor activity (TFa) was reported in women with previous pregnancy loss, compared to healthy women.

Aims: To explore, at distance of pregnancy, the tissue factor pathway in unexplained pregnancy loss.

Methods:

Design: Incident case-control study.Patients: 199 women referred for unexplained pregnancy losses (≥ 2 losses before 21 weeks of gestational age, or at least one later loss), and 201 parous women without pregnancy loss.Intervention: Blood samples collection, at ≥2 months after any obstetric event.

Main outcome measure(s): Plasma levels of thrombomodulin activity (TMa), TFa, free tissue factor pathway inhibitor (f-TFPI).

Results: Among the patients (mean age: 32.5), 182 women experienced early losses and 28 suffered at least one later loss. Controls were significantly older (mean age: 34). When compared to controls, plasma levels of TFa were significantly higher in patients (all patients: OR, 2.2; 95% CI, [1.6-3.1], early loss: OR, 2.2; 95% CI, [1.6-3.1], later loss OR, 2.6; 95% CI, [1.5-4.5]). TMa and f-TFPI were not significantly different between groups. The TFa/ f-TFPI ratio was significantly higher in cases than in controls ($p < 0.001$). Adjusting for age and elapsed time since the last obstetric event did not influence our results.

Conclusions: This study suggests a baseline procoagulant activity in women with history of pregnancy loss. This provides an additional argument for basal vascular dysfunction in women with pregnancy loss.

PB 2350 | HABP2 (PHBP/FSAP) is the Major Plasma Protease that Promote Extracellular Histone Degradation

Y. Amemiya[1], J. Mutoh[1], E. Suzuki[1], K. Hasumi[2]

[1]Tokyo Noko University, Department of Applied Biological Science, Tokyo, Japan, [2]TMS Co., Ltd., Tokyo, Japan

Background: HABP2 (hyaluronan binding protein 2), alternatively designated plasma hyaluronan-binding protein (PHBP) or factor VII activating protease (FSAP), is a circulating single-chain zymogen consisting of an acidic amino acid-rich N-terminal region (NTR), 3 EGF-like domains, a kringle domain, and a serine protease domain. HABP2 converts itself to an active two-chain form, HABP2a, through autoproteolysis, which is triggered by polyanionic or polycationic substances. HABP2 activity is implicated in the regulation of the hemostasis as well as inflammatory processes. Cytotoxic extracellular histones which trigger a systemic activation of both the coagulation cascade and inflammatory pathways, potently promote HABP2 autoactivation.

Aims: To explore the role for HABP2 in histone degradation.

Methods: Histone-binding plasma proteins were identified by PMF analysis. Histone degradation was assayed by measuring fluorescence liberated from immobilized Rhodamine-histones during incubation with human plasma or plasma enzymes.

Results: Human plasma showed significant activity to degrade histones. Histone-binding plasma proteins identified by PMF analysis included prothrombin and HABP2. None of prothrombin, thrombin, protein C, or activated protein C were superior to HABP2 or HABP2a in histone degradation. Immobilized anti-HABP2 or histones removed histone-degrading activity from plasma, and anti-HABP2 inhibited histone degradation in plasma.

Conclusions: HABP2 is a major plasma factor responsible for extracellular histone removal.

PB 2351 | Adjunctive Hemostatic Application of Highly Adhesive Drug Loadable Powder for Partial Hepatectomy Bleeding in a Swine Model

L. Eunhye[1], M. Jin Hee[1], A. Sukyung[1], K. Keunsu[1], L. Don Haeng[1,2]

[1]Utah-Inha DDS and Advanced Therapeutics Research Center, Incheon, Korea, Republic of, [2]Inha University Hospital, Department of Internal Medicine, Division of Gastroenterology & Hepatology, Incheon, Korea, Republic of

Background: Topical agents can be effective as adjuncts to aid in hemostasis when bleeding is not controllable with general methods. UI-SAH is a highly adhesive drug-loadable powder that has been developed for adjunctive hemostatic use. The hemostatic effects are achieved by forming a hydrogel and showing high adhesiveness and biodegradation on bleeding site. And besides, amine containing therapeutic molecules can be easily loaded into UI-SAH without chemical modification.

Aims: The aims of this study were to confirm 1) the effectiveness of the application of UI-SAH powder in hepatectomy bleeding swine model, 2) the prevention of organ adhesion after gelation at the bleeding site and 3) the feasibility of the drug loading capacity.

Methods: Adjunctive hemostatic application of UI-SAH was evaluated by hepatectomy bleeding in a swine model. After inducing bleeding, we topically applied UI-SAH on the bleeding site. The hemostatic effect and organ-adhesive were observed using blood loss, hemostatic time and organ-adhesion. The therapeutic effect of drug-loaded UI-SAH was evaluated in tumor bearing mice model.

Results: Severe bleeding was effectively controlled after applying the UI-SAH and re-bleeding was not observed until 72 h after treatment in a swine. In addition, Hydrogel that were converted from powder immediately after contacting water were act as anti-adhesion barrier.

In a tumor bearing mice model, the tumor volume of anti-cancer drug-loaded UI-SAH group was significantly decreased approximately 50% compared with those of positive control group on day 35 after tumor inoculation.

Conclusions: This study confirmed that the adjunctive hemostatic application of UI-SAH is effective for the in partial hepatectomy bleeding model due to high adhesiveness and the suppression of organ adhesion. Furthermore, tumor suppression can be accelerated by loading of the anti-cancer drug in the UI-SAH. The present study suggests that UI-SAH is promising candidate for adjunctive surgical hemostasis and local anti-cancer therapy.

PB 2352 | The ratio "Tissue Factor / Tissue Factor Pathway Inhibitor" as a Major Determinant of Hypercoagulabilty in Cirrhotic Patients

P. Van Dreden[1], M. Grusse[1], D. François[2], R. Bironien[2], M. Vasse[2,3]

[1]Diagnostica Stago, Clinical Research, Gennevilliers, France, [2]Hôpital Foch, Biology Department, Suresnes, France, [3]UMR 1176, Suresnes, France

Background: Patients with cirrhosis present abnormalities along both procoagulant and anticoagulant pathways, predicting the risk of bleeding or thrombosis is difficult. In this context we evaluated the contribution of thrombin generation assay (TG) and the determinations of Tissue factor pathway inhibitor (TFPI), tissue factor activity (TFa) procoagulant phospholipid (PPL), thrombomodulin activity (TMa) and the Pc pathway system to better understand the haemostasis in cirrhotic patients.

Aims: Analyze the thrombin generation, the expression of TFa , TMa or TFPI, and determine whether their concentrations decrease as liver disease progresses in cirrhotic.

Methods: Blood sample of 42 patients (12 Child A, 19 Child B and 11Child C) with confirmed cirrhosis and 30 healthy subjects were analysed for thrombin generation performed in the presence/absence of thrombomodulin, (Cat Assay, Stago,France), TFa and Thrombomodulin activities, and protein C and S by the Staclot protein C and S, Free TFPI by the Asserachrom Free TFPI (Diagnostica Stago, France).

Results: Comparatively to controls cirrhotic patients have a significant decreased of TG ($p < 0.001$), the ratios of TG in presence and absence of TM were increased ($p < 0.01$) and related to the severity of disease. Proteine C and S were decreased in comparison with controls ($p < 0.01$) and in function of the Child. TFa ,TMa and PPL were significantly increased ($p < 0.01$) whereas TFa and TMa were associated with the severity of disease, PPL did not change between the chlid groups. TFPI levels were comparable between patients and controls, however the ratios TF/TFPI increased with the Child and were significantly different in comparison with controls ($p < 0.01$).

Conclusions: It has been shown that TFPI plasma levels are reduced in congenital and acquired PS deficiency, probably due to the existence of complex between PS and TFPI.The findings may have clinical implication for the treatment or prophylaxis of thrombosis in cirrhotic patients.

PB 2353 | Upper Regulation of Plasma Endocan and D-Dimers in Individuals with Compensated Liver Disease

D. Van Thiel[1], M. George[1], D. Hoppensteadt[2], D. Syed[2], R. Wahi[2], D. Fareed[2], J. Fareed[2]

[1]Rush University, Chicago, United States, [2]Loyola University Medical Center, Pathology, Maywood, United States

Background: Endocan is a unique proteoglycan of endothelial cell origin that increases in response to endothelial dysfunction or injury. Similarly, D dimers in the plasma of individuals with compensated liver disease (CLD) are increased as a consequence of the mixed hyper- and hypo-coagulable state that exists in this population.

Aims: The goals of this investigation were to quantitate endocan and d-dimer levels in the plasma of individuals with CLD and to determine if a relationship exists between d-dimer and endocan in the plasma of individuals with compensated liver disease.

Methods: Sixty four individuals with CLD were identified. Blood samples were collected in both citrate and EDTA, separated by Centrifugation and the plasma was collected and frozen at -70° C until being assayed. Fifty normal healthy volunteers were included as controls. Endocan levels were determined using a commercially available ELISA kit (Lunginov,Nord, France). D-dimer levels were determined utilizing a commercially available kit (Diagnostic Stago, Parsippany, New Jersey, USA). The relationship between these samples of endocan and D-dimers was determined by linear regression analysis.

Results: Endocan levels in CLD were increased (2.3+ or -0.3pg/ml) as compared to the values of the control population (1.4+ or -0.3 pg/ml ($p < 0.05$). D-dimer levels in the plasma of the CLD subjects were markedly increased (2730+ or -610ng/ml) as compared to the values obtained in the healthy controls (230+ or -110 ng/ ml)($p < 0.05$). The relationship between these 2 biomarkers with a positive regression analysis is consistent with a common pathogenic mechanism determining their plasma levels.

Conclusions: Low levels of endotoxin in the portal venous circulation induce an endothelial injury within and limited to the liver that is responsible for the upper regulation of hepatic endothelial cell endocan production and secretion as well as the increased levels of D- dimers.

PB 2355 | Effect of Extract Ethanol of Poguntano Leaves in Hemostasis Disturbances in Alloxan Induced Diabetic Rats

S.S. Widjaja, D. Munir

University Sumatera Utara, Biokimia, Medan, Indonesia

Background: The global prevalence (age-standardized) of diabetes has nearly doubled since 1980, rising from 4.7% to 8.5% in the adult population, and over 1,5 millioon of deaths were caused by the complications of diabetes. The elevated of blood glucose, free fatty acid and insulin resistance will cause the endothelial dysfunction, hemostasis

disturbances that lead to vascular complications that can increased the morbidity and mortality. Poguntano (Picria fel-terrae Merr) from family Scrophulariaceae found in most part of Indonesia, has been used as traditional plant for treatment of diabetes, fever, malaria and cancer.

Aims: The purpose of this study was to investigate the effect of extract ethanol of Poguntano in alloxan induced diabetic rats

Methods: This is an experimental study using alloxan induced diabetic rats, and were divided into three groups (control diabetic group, group given insulin injection and group given Extract ethanol of Poguntano 200 mg/Kg body weight), and control normal group. The duration of study was 4 weeks, blood glucose and Tissue Factor were measured for all groups.

Results: Extract ethanol of Poguntano 200 mg showed significant results ($p< 0.001$) in lowering blood glucose in Alloxan induced diabetic rats at four week after treatment, but did not show superior to insulin group ($p=0.892$). Tissue Factor level were lower significantly in diabetic rats treated with poguntano 200 mg ($p< 0.001$), but did not showed significant results in the insulin group ($p=0.799$).

Conclusions: In our study we have found that extract ethanol of Poguntano 200 mg showed statistical significant in lowering blood glucose and the Tissue Factor level in alloxan induced diabetic rats.

PB 2356 | Recurrent Budd-Chiari Syndrome (BCS) in a Patient with Polycythemia Vera (PV), Protein S Deficiency and Hyperhomocysteinemia (HH) and Abnormal Resistance to Activated Protein (APCR) in the Absence of Factor V Leiden Mutation (FVL) Following Liver Transplant

A. Sikorska[1], B. Ceglarek[1], B. Baran[2], E. Pleban[3], K. Bykowska[2], P. Szopiński[3]

[1]Institute of Hematology and Transfusion Medicine (IHTM), Department of Disorders of Hemostasis and Internal Medicine, Warsaw, Poland, [2]Institute of Hematology and Transfusion Medicine (IHTM), Department of Hemostasis and Metabolic Disorders, Warsaw, Poland, [3]Institute of Hematology and Transfusion Medicine (IHTM), Clinic of Vascular Surgery, Warsaw, Poland

Background: Budd-Chiari syndrome (BCS) is a rare condition recognized in imaging studies and characterized by thrombotic obstruction of the hepatic venous outflow.

Aims: Presentation of the BCS clinical course in a patient with PV and additional trombotic risk factors following liver transplant (LT).

Methods: Factor V Leiden mutation was detected using RFLP/PCR method (EURx,Poland); APCR and protein S deficiency using Siemens reagent.

Results: A 35 year old patient with BCS and PV, progressive fulminant hepatic impairment as result of decompensated liver cirrhosis was subjected to orthotopic cadaveric LT using piggy-back technique. Percutaneous endoscopic jejunostomy (PEJ) was used for nutritional support. Crossmatching was negative as no antibodies against lymphocytes were found in the recipient's serum. The transplanted organ took up function immediately after surgery. On the second day an inferior vena cava (VCI) obstruction was reported just below the right atrium. CT angiography revealed thrombotic obstruction of the hepatic venous outflow, hepatosplenomegaly, ascites that required paracentesis. Gastroscopic findings included oesophageal varices grade 1, reduction in daily urine output, increased blood urea, HH (19.8 mmol/L; n: 5.0-12.0 mmol/l), hypoproteinaemia, hypoalbuminemia, protein S deficiency - 53% (n: 67.5-139%), APCR 0.48 (n: 0.7-1.2); absence of FVL (G1691A) mutation. Balloon technique was applied for VCI obstruction which resulted in resolution of ascites. Successful therapy followed with Enoxaparinum natricum twice a day, hydroxycarbamidum and immunosuppressive corticosteroids, Mycophenolas mofetil and Tacrolimusum.

Conclusions: Protein S deficiency with HH and abnormal APCR in the absence of Leiden mutation may be considered risk factors for recurrence of hepatic vein thrombosis in a patient with PV following liver transplant.

PEDIATRICS

PB 511 | Safety, Efficacy and PK/PD of Rivaroxaban Tablets in Children with VTE. An Einstein Junior Phase II Evaluation

P. Monagle[1], D. Kubitza[2], R. Kumar[3], S. Holzhauer[4], G. Grangl[5], J. Robertson[6], G. Young[7], A.C. Molinari[8], U. Nowak-Goettl[9], S. Willmann[2], K. Thelen[2], M. Becka[2], J.F. Heubach[2], A.W.A. Lensing[2]

[1]Royal Children's Hospital, Department of Clinical Haematology, Parkville, Australia, [2]Bayer AG, Wuppertal, Germany, [3]Nationwide Children's Hospital, Columbus, United States, [4]Universitätsklinikum Charité, Berlin, Germany, [5]Universitätsklinik für Kinder- und Jugendheilkunde, Graz, Austria, [6]Lady Cilento Children's Hospital, South Brisbane, Australia, [7]Children's Hospital Los Angeles, Los Angeles, United States, [8]Giannina Gaslini Children's Hospital, Genova, Italy, [9]University Hospital Schleswig-Holstein, Kiel, Germany

Background: Rivaroxaban is being developed for VTE treatment in children, targeting the exposure of young adults treated with rivaroxaban 20 mg once-daily.

Aims: To investigate the safety and efficacy of rivaroxaban tablets for VTE treatment and to characterize its PK/PD profile.

Methods: Children 6-18yrs with VTE who completed ≥ 2 months of anticoagulation received 30 days of body weight-adjusted once-daily rivaroxaban tablets at a 20 mg equivalent dose, based on physiologically-based PK (PBPK) modeling predictions and Phase I data. Repeat imaging was performed at Day 30 and compared to baseline. PK/PD samples were taken on Day 15 and Day 31. PK results were compared with the pediatric PBPK model predictions and with the adult reference population of VTE patients treated with rivaroxaban 20 mg once-daily. PD results were compared to an adult VTE treatment population.

Results: 24 children (54 sites/10 countries) were enrolled (12-18yrs, n= 11; 6-12yrs, n= 13). No major bleeding or recurrent VTE occurred.

Repeat imaging was improved in 94%. Individual plasma concentrations, as well as AUC, C_{max} and C_{trough} at steady state, were in the prediction range of the PBPK model and the adult reference range of VTE patients. Children < 30 kg tended to have a C_{trough} at the lower end of values observed in adults. Individual values for PT/aPTT were covered by the adult reference range and for both a linear correlation between change from baseline and plasma concentrations was confirmed. A linear relation of anti-factor Xa activity and plasma concentration was observed.

Conclusions: 30 days with once-daily rivaroxaban tablets, at a dose targeting the exposure with rivaroxaban 20 mg once-daily in adults, was safe and efficacious. PK/PD profiles were as predicted. However, C_{trough} levels were at the lower end of the adult distribution in children < 30 kg, suggesting they require a twice-daily rivaroxaban regimen. Our results need confirmation in the Einstein Junior Phase III study.

PB 512 | Safety, Efficacy and PK/PD of a Rivaroxaban Suspension in Children with VTE. An Einstein Junior Phase II Evaluation

A. Chan[1], D. Kubitza[2], A. Santamaría[3], E. Samochatova[4], I. Martinelli[5], P. Connor[6], G. Young[7], C. Male[8], G. Kenet[9], P. Massicotte[10], S. Willmann[2], S. Kraff[2], M. Becka[2], J.F. Heubach[2], A.W.A. Lensing[2]

[1]McMaster University, Hamilton, Canada, [2]Bayer AG, Wuppertal, Germany, [3]University Hospital Vall d´Hebron, Barcelona, Spain, [4]Federal Research and Clinical Centre of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation, [5]IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy, [6]The Noah's Ark Children's Hospital for Wales, Cardiff, United Kingdom, [7]Children's Hospital Los Angeles, Los Angeles, United States, [8]Medical University of Vienna, Vienna, Austria, [9]Sheba Medical Center, Tel-Hashomer, Israel, [10]University of Alberta, Edmonton, Canada

Background: Rivaroxaban is being developed for VTE treatment in children, targeting the exposure of young adults treated with rivaroxaban 20 mg once-daily. A rivaroxaban suspension was developed to enable greater dose flexibility, easier administration, and better acceptance.

Aims: To investigate the safety/efficacy of rivaroxaban suspension for VTE treatment and to characterize its PK/PD profile.

Methods: Children 0.5-12yrs with VTE who completed ≥ 2 months of anticoagulation received 30 days of body weight-adjusted rivaroxaban suspension (1mg/mL) in a 10 mg equivalent dose using a twice-daily regimen, based on physiologically-based PK (PBPK) modeling predictions and Phase I data. Repeat imaging was performed at Day 30 and compared to baseline. PK/PD samples were taken on Day 1, 15 and 31. PK results were compared with pediatric PBPK model predictions and with an adult VTE reference population. PD results were compared to an adult VTE treatment population.

Results: 56 children (81 sites) were enrolled (6-12yrs, n=19; 2-6yrs, n=25; 0.5-2yrs, n=12). No major bleeding or recurrent VTE occurred. Repeat imaging was improved in 91%. Nearly all individual plasma concentrations, as well as AUC, C_{max} and C_{trough} at steady state, were in the prediction range of the PBPK model and the adult reference range. Individual values for PT/aPTT were covered by the adult reference range and for both a linear correlation between change from baseline and plasma concentrations was confirmed. A linear relation of anti-FXa activity and plasma concentration was shown.

Conclusions: 30 days of twice-daily rivaroxaban oral suspension, at a dose targeting the exposure with rivaroxaban 20 mg once-daily in adults, was safe and efficacious. PK/PD profiles were as predicted. The twice-daily rivaroxaban regimen resulted in consistent C_{trough} levels, regardless of body weight. Our results need confirmation in the Einstein Junior Phase III study.

PB 514 | Long-term Outcome in Children on Anticoagulant Therapy after Extracardiac Conduit Fontan Operation (FO)

M. Agazzoni[1], S.S. Meschengieser[1], W. Conejeros-Parodi[2], M.L. Romero[1], M. Barrenechea[1], A.J. Schlichter[2], G.O. Kreutzer[2], R. Pellicciari[2], H. Vazquez[3], M.I. Grippo[3], A. Sánchez-Luceros[1,4]

[1]Hematological Research Institute, National Academy of Medicine, Hemostasis and Thrombosis, Buenos Aires, Argentina, [2]Children's Hospital Ricardo Gutiérrez, Cardiovascular Surgery Division, Buenos Aires, Argentina, [3]Children's Hospital Ricardo Gutiérrez, Cardiology Division, Buenos Aires, Argentina, [4]IMEX-CONICET-National Academy of Medicine, Buenos Aires, Argentina

Background: FO is performed in children with tricuspid atresia and a variety of congenital heart defects. Several modifications have improved early and late mortality and morbidity, mostly due to thromboembolic events (TE) and arrhythmias. The incidence of thrombotic events and the event-related mortality are high, reaches 25-38%. There is no consensus about the best strategy to prevent TE.

Aims: To evaluate the occurrence of TE and/or bleeding events in children prospective cohort with the same type of FO under anticoagulant prophylaxis therapy.

Methods: Between August 1999 and July 2016, we conducted a prospective study to evaluate the occurrence of TE and bleeding events in 114 children (mean age 7.6 years, range 2-21; 60.5% boys) who underwent a modified FO (Fontan-Kreutzer) palliative procedure using a cavopulmonary connection with extracardiac PTFE conduit or none prosthesis. Acenocoumarol was initiated (INR target: 2.0-3.0) immediately after withdrawal of chest tube drainage (mean 6.4 ± 3.8 days, range 2-25). Quality of anticoagulation monitoring was evaluated with Rosendaal´s program. All parents signed informed consent. The protocol was approved by Institutional Ethical Committee.

Results: The total follow-up time was 982 years (mean 8.6 years). Eleven patients were lost to follow-up (mean 34 months, range 6-72). Patients remained in the desired INR range 67.7% of the time, 14% above (>3) and 18.3% below (< 2). At last follow-up, 23 patients had reached adulthood (mean age of 25.6 years, range 22-35). TE and bleeding events are described in table: 2/3 patients presented TE events (one dying) associated to interruption of acenocoumarol due to pneumonia; the third had had poor treatment compliance.

TABLE 1 Thromboembolic events (TE) and bleeding complications after surgery

Major events	Frequency and incidence rate per 100 patient-years	Fatalities related to TE/bleeding (months after surgery)	Events (months after surgery)
TE (N=3)	2.6%, 0.32	pulmonary embolism+ pneumonia (12)	1 case of stroke+ pneumonia (36); 1 case of stroke related to poor anticoagulant compliance (9)
Bleeding (N=4)	3.5%, 0.44	hemoptysis (156)	1 case of pleural puncture procedure and hemothorax (1); 2 cases of hemoptysis requiring cauterization by bronchoscopy with good outcome (36, 60)

Conclusions: Primary prophylaxis with oral anticoagulation, initiated rapidly after modified FO surgery could be considered a a safe and effective therapy in children. Studies on bridging strategies in these patients are necessary in order to limit the morbi-mortality associated.

PB 516 | e-Health Usefulness in Oral Anticoagulation Therapy in Children: Point of Care Instruments and Mobile APPs

R. Berrueco[1], C. Benedicto[2], S. Gassiot[3], A. Ruiz-Llobet[2], A. Català[1], M. Torrebadell[4], M. Camós[4], S. Rives[1]

[1]*Institut de Recerca Pediàtrica Hospital Sant Joan de Déu, Universitat de Barcelona, Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBER ER), Instituto de Salud Carlos III, Pediatric Hematology & Oncology, Esplugues de Llobregat, Spain,* [2]*Institut de Recerca Pediàtrica Hospital Sant Joan de Déu, Universitat de Barcelona, Pediatric Hematology & Oncology, Esplugues de Llobregat, Spain,* [3]*Institut de Recerca Pediàtrica Hospital Sant Joan de Déu, Universitat de Barcelona, Laboratory of Hematology, Esplugues de Llobregat, Spain,* [4]*Institut de Recerca Pediàtrica Hospital Sant Joan de Déu, Universitat de Barcelona, Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBER ER), Instituto de Salud Carlos III, Laboratory of Hematology, Esplugues de Llobregat, Spain*

Background: Use of oral anticoagulation in children has increased during the last decade due to medical and surgical improvements. Point of care (POC) instruments for INR measurements may avoid frequent visits to the hospital and increase time in therapeutic range (TRT). Self-testing is easy to learn. However, self-management generally induces anxiety in caregivers. e-Health instruments as mobile APPs could be useful to overcome it.

Aims: Prospective clinical study in a Pediatric Universitary Hospital to evaluate safety, efficacy and quality of life of a POC instrument (CoaguChek), and a mobile application (TAONet Me).

Methods: After an initial training, patients started self-testing and management of anticoagulation. INR results, drug doses schedule, and questions were introduced in a mobile app. Information was daily reviewed by a pediatric nurse.

Results: A total of 38 patients were included in this program. Of them, 71.1% were boys. The median age was 11 years [range 2-16 years]. Reason for anticoagulation was: 13 mitral mechanic heart valve (MHV), 5 aortic MHV, 1 tricuspid MHV, 1 pulmonar MHV, 14 Fontan surgery, and other reason in 3 cases.

All families successfully completed an initial evaluation test. POC devices and mobile app were considered useful in improving their quality of life, by maintaining a direct communication with professionals, while decreasing medical appointments.

After a follow-up of 6-months, 26 of them had performed >30 INR measurements and were eligible to evaluate TRT. A statistically significant improvement of TRT from 56.1% to 64.1% ($p< 0.05$) was found. No thrombotic or mayor haemorrhagic events were diagnosed during the study.

Conclusions: POC and Mobile app instruments proved to be a useful tool in decreasing caregiver anxiety and improving their quality of life. Moreover, self-control and self-management of anticoagulation resulted in a significant increase in TRT, as compared to previous data.

PB 517 | Feasibility and Safety of Full Dose Anticoagulation Therapy in the Context of Thrombocytopenia in Children with Symptomatic Thromboembolism during Acute Lymphoblastic Leukemia and Lymphoblastic Lymphoma Treatment

M. Bhatt, N. Parmar, J. Fowler, A. Chan, U. Athale

McMaster University, Pediatric Hematology/Oncology, Hamilton, Canada

Background: There are no evidence-based guidelines for anticoagulation therapy (ACT) with low molecular weight heparin (LMWH) in relation to low platelet count.

Aims: To evaluate feasibility and safety of LMWH in children receiving myelosuppressive therapy.

Methods: Medical records of patients who received ACT with LMWH for symptomatic thromboembolism (TE) during ALL/LL therapy between 2007-2015 were reviewed for demographics, details of ALL/LL diagnoses, TE diagnoses and therapy, platelet counts during ACT, LMWH dose modifications, and bleeding episodes. ALL/LL was treated per the Dana-Farber Cancer Institute (DFCI) ALL Consortium protocols. Institutional ACT policy was full dose LMWH for platelets >30x10^9/L, half-dose between 20-30x10^9/L and hold LMWH for platelets < 20x10^9/L. LMWH was held for 24 hours prior to invasive procedure.

Results: Thirty-nine TEs were diagnosed in 33 patients during the study period. Six patients had more than 1 episode. Two patients (6%) were diagnosed with TE during Induction phase, 30 (91%) in asparaginase-intensive Consolidation II, and 1 (3%) during Maintenance; with mean time to TE 5.75 months from ALL/LL diagnosis. Platelets were measured

weekly with a mean count of 264x10^9/L (range 10-1373x10^9/L). On 29 occasions, platelet nadir was < 50x10^9/L and twice it was < 20x10^9/L. Four patients required platelet transfusions to facilitate ACT and 1 patient required LMWH dose adjustment for thrombocytopenia. One (3%) patient had major bleeding episode while on ACT (platelet count: 222x10^9/L). Ninety-two procedures were completed without bleeding complications. Although asparaginase was held with TE diagnosis, 32 patients completed all scheduled doses as per protocol (1 discontinued treatment due to pancreatitis).

Conclusions: Ability to administer full dose LMWH, expected bleeding rate, and completion of asparaginase doses while on ACT shows full-dose ACT is feasible and safe in children with ALL/LL who develop TE while receiving therapy according to DFCI ALL Consortium protocols.

PB 518 | Anticoagulant Effects of Dabigatran in Paediatric Patients Compared with Adults: Combined Data from Three Paediatric Clinical Trials

H. Maas[1], S. Gropper[2], F. Huang[3], J. Stangier[1], I. Tartakovsky[2], M. Brueckmann[2], J. Halton[4], L. Mitchell[5]

[1]*Boehringer Ingelheim Pharma GmbH & Co. KG, Translational Medicine and Clinical Pharmacology, Biberach, Germany,* [2]*Boehringer Ingelheim Pharma GmbH & Co. KG, Clinical Development, Ingelheim, Germany,* [3]*Boehringer Ingelheim Pharmaceuticals, Inc., Translational Medicine and Clinical Pharmacology, Ridgefield, United States,* [4]*Children's Hospital of Eastern Ontario, University of Ottawa, Ottawa, Canada,* [5]*University of Alberta, Edmonton, Canada*

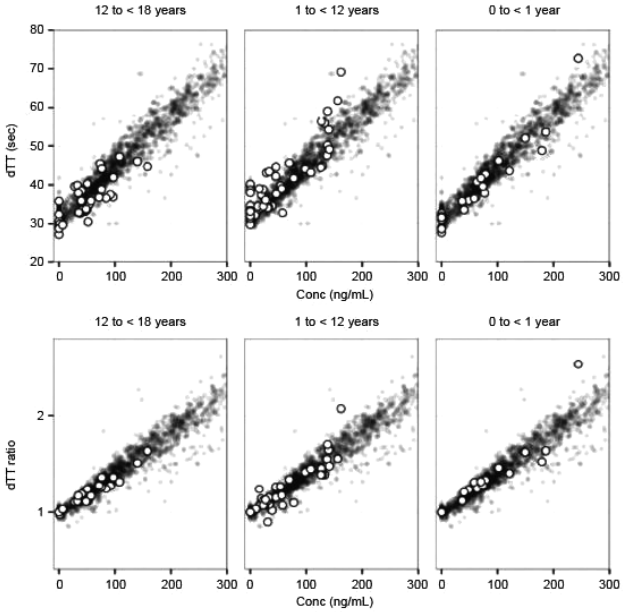
Background: Throughout childhood, physiological age-related changes in the haemostatic system affect responses to anticoagulants and mean coagulation assay responses may differ from those in adults.

Aims: To compare the relationships between plasma dabigatran concentration and coagulation assay results in children treated for venous thrombotic events (VTE) with those in adults.

Methods: Data from three trials in which children (n = 35) of different age groups received age- and weight-adjusted doses of dabigatran etexilate (DE) after standard of care for VTE were compared with those from adult volunteers (healthy or with mild/moderate renal dysfunction in two phase I trials) and adult patients (symptomatic VTE or undergoing hip replacement surgery in two phase III trials). The effects of dabigatran concentration on diluted thrombin time (dTT), ecarin clotting time (ECT) and activated partial thromboplastin time (aPTT) in children and adults were analysed graphically and with modelling.

Results: In the graphical analysis concentration-dTT relationships were consistent in children of all ages and adult volunteers (Figure 1) and patients; for ECT and aPTT, relationships based on ratios over baseline were similar across all ages. However, absolute clotting time data showed the same exposure resulted in longer clotting times in those aged 0 to < 1 year versus adult groups. Modelling showed concentration-clotting time relationships to be largely comparable between adults and children, except in those aged < 2 months (n = 4), in whom there was an upward shift of 10-15% or 10-20% in ECT or aPTT, respectively, relative to adults.

Figure 1. Concentration–dTT relationships for paediatric patients (white circles) and adult volunteers (grey circles) for each of the three paediatric studies



Top row shows untransformed dTT values; bottom row shows dTT expressed as a ratio over baseline.
dTT, diluted thrombin time

Conclusions: The effects of DE on aPTT, ECT and dTT were similar in children and adults with the exception of those aged < 2 months who showed a slight upwards shift in absolute ECT and aPTT relative to adults, although only four subjects were < 2 months. These data suggest that age-related differences in the haemostatic system will have little impact on response to dabigatran.

PB 519 | Factor Levels in Heparinized Critically Ill Pediatric Patients

J. Byrnes[1], J. Palumbo[2]

[1]*Cincinnati Childrens Hospital Medical Center, Cardiology, Cincinnati, United States,* [2]*Cincinnati Childrens Hospital Medical Center, Hematology, Cincinnati, United States*

Background: Activated partial thromboplastin time (aPTT) and anti-factor Xa levels (Xa) are often discordant in critically ill heparinized pediatric patients, and this discordance is associated with morbidity and mortality. This is particularly manifest in patients requiring mechanical circulatory support (MCS). The underlying abnormalities that lead to discordance are poorly understood.

Aims: We sought to:
1) describe the variations in soluble factors associated with discrepancy of the aPTT/Xa ratio in critically ill pediatric patients;
2) describe the impact of MCS on the differences in factor levels.

Methods: Data was pulled from the electronic medical record of all heparinized patients. Statistical comparisons between patients with and without MCS were made using a t-test with unpaired t-test with

unequal variance. To demonstrate the factor variation related to aPTT/anti-Xa ratios, we conducted regression with fixed ranges of anti-Xa (0.2-1 IU/ml) in all patients.

Results: Regression analyses revealed a strong negative correlation between factors V, VII, IX, X. XII and antithrombin and the aPTT/anti-Xa ratio. Only a moderate negative correlation was observed between factors II and XI with the aPTT/anti-Xa.

TABLE 1 Regression Statistics of aPTT/Xa Ratio to Individual Factors in Pediatric Patients. * r = 0.3 to 0.5 or - 0.3 to -0.5; ** r < -0.5 or > 0.5

	m	r
Factor II**	-12.3	0.41
Factor V**	-4.2	0.81
Factor VII**	-12.6	0.57
Factor VIII	-35	0.06
Factor IX**	-10.6	0.57
Factor X**	-8.3	0.67
Factor XI*	-21	0.36
Factor XII**	-2.6	0.51
Antithrombin**	-13.5	0.74

Circulating levels of factors V, VIII, IX, XII were significantly diminished in patients on MCS relative to those not on MCS.

TABLE 2 Variation in Factor Levels between Patients in whom MCS Is/Is Not Applied. *p<0.05

	non-MCS	MCS	p-value
Xa	0.36	0.34	0.81
Factor II	55%	65%	0.3
Factor V	78%	55%	0.02*
Factor VII	59%	55%	0.69
Factor VIII	197%	140%	0.01
Factor IX	76%	62%	0.03*
Factor X	64%	57%	0.49
Factor XI	46%	44%	0.7
Factor XII	63%	44%	0.01

Conclusions: These results imply that consumption of multiple factors is responsible for discrepancies between the aPTT and anti-Xa in heparinized patients. Consistent with contact activation on an artificial surface, loss of factor XII was more significant in patients requiring MCS. The relative loss of factor VIII in MCS is consistent with previous studies showing loss of high molecular weight von Willebrand Factor multimers in MCS. The relative diminution in factors V and IX associated with MCS was unexpected. Future studies will be needed to determine if the loss of factors V and IX is associated with morbidity in this context.

PB 520 | Dosing and Therapeutic Drug Monitoring of Tinzaparin in the Pediatric Intensive Care Unit (PICU)

P.P. Roeleveld[1], D. Hartwich[1], R. de Wilde[1], F. Smiers[2], J. Eikenboom[3], H. Bunker-Wiersma[1]

[1]Leiden University Medical Center, PICU, Leiden, The Netherlands, [2]Leiden University Medical Center, Pediatric Hematology, Leiden, The Netherlands, [3]Leiden University Medical Center, Thrombosis and Hemostasis, Leiden, The Netherlands

Background: Tinzaparin dosing only leads to target anti-Xa levels (AL) after 8.8 (± 7.3) doses in PICU patients when using ACCP guidelines[1].

Aims: By determining the first AL after the first tinzaparin dose we aimed to achieve target AL quicker. Second aim was to describe tinzaparin dosing and therapeutic drug monitoring.

Methods: A retrospective analysis of tinzaparin dosing and AL in PICU patients. The study was approved by the institutional ethics committee.

Results:

Fifty-six children, median age 8.5 months [0-47.5] with newly started therapeutic tinzaparin. In 84% (47/56), the first AL was below target range, 0.22 (±0.13) IU/mL. A dose adjustment was made in 81% (38/47). Target AL were reached after a mean of 4.9 (± 3.0) doses. The dose needed to achieve target AL was significantly higher than the recommended dose in the age groups 0-2 months (p = 0.018), 2-12 months (p = 0.028) and 1-5 years (p = 0.012). Children with edema required a significantly higher final dose (328 ± 63 U/kg) than children without edema (283 ± 37 U/kg, p = 0.030). Patients with inotropes had significantly lower first AL (0.25 ± 0.19 IU/mL vs 0.41 ± 0.17 IU/mL; p = 0.023) and needed more time to reach target AL than patients without inotropes (5.4 days ± 3.0 vs 2.7 days ± 2.0; p = 0.027). Patients with mechanical ventilation had a lower first AL (0.24 ± 0.18 IU/mL vs. 0.38 ± 0.17 IU/mL; p = 0.007) and needed more time to reach target AL (5.7 days ± 2.9 vs 2.5 days ± 1.7; p = 0.002) than patients without mechanical ventilation.

Conclusions: The final tinzaparin dose needed to achieve target AL is significantly higher than recommended by the ACCP in children under 5 years. Edema further impacts on AL warranting an extra 10-15% dose increase. Concurrent use of vasopressors or mechanical ventilation leads to lower first AL and longer time to reach target AL, but a similar final dose. Decreased renal function does not lower tinzaparin dosing requirements. Based on our results, we recommend new starting doses for children admitted to PICU.

TABLE 1 results of tinzaparin drug monitoring

Age	0-2 months (n=15)	2-12 months (n=14)	1 - 5 years (n=18)	5 - 10 years (n=5)	10 - 18 years (n=4)	Total (n=56)
Recommended dose (IU/kg)	275	250	240	200	175

PB 521 | Safety and PK/PD of a Single Rivaroxaban Administration in Children. An Einstein Junior Phase I Evaluation

C. Male[1], K. Thelen[2], L.R. Brandao[3], G. Young[4], A. Santamaría[5], I. Martinelli[6], P. Saracco[7], A. Chan[8], J. Halton[9], P. Monagle[10], S. Willmann[2], M. Becka[2], J.F. Heubach[2], A.W.A. Lensing[2], D. Kubitza[2]

[1]Medical University of Vienna, Vienna, Austria, [2]Bayer AG, Wuppertal, Germany, [3]Hospital for Sick Children, Toronto, Canada, [4]Children's Hospital Los Angeles, Los Angeles, United States, [5]University Hospital Vall d´Hebron, Barcelona, Spain, [6]IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy, [7]A.O.U. Città della Salute e della Scienza di Torino, Torino, Italy, [8]McMaster University, Hamilton, Canada, [9]Children's Hospital of Eastern Ontario, Ottawa, Canada, [10]Royal Children's Hospital, Department of Clinical Haematology, Parkville, Australia

Background: Rivaroxaban is being developed for treatment of venous thrombosis in children.

Aims: To investigate the safety and to characterize the pharmacokinetic (PK)/pharmacodynamic (PD) profile of a single rivaroxaban administration in children.

Methods: Children aged 0.5-18yrs who had completed anticoagulation for any type of thrombosis were eligible. A single body weight-adjusted 10-mg equivalent dose of rivaroxaban was administered as either tablet (6-18yrs) or as oral suspension (0.5-12yrs). Physiologically-based PK (PBPK) modeling was used to predict age-specific weight-adjusted doses of rivaroxaban targeting the adult exposure of 10 mg once-daily. Serial PK and PD samples were taken up to 24 hours after dosing. PD parameters were the prothrombin time (PT), activated partial thromboplastin time (aPTT), and anti-factor Xa (aXa) activity.

Results: 30 children (45 sites/13 countries) were enrolled (12-18yrs, n=4; 6-12yrs, n=13; 2-6yrs, n=7; 0.5-2yrs, n=6). No clinically relevant bleeding occurred. Individual plasma concentrations, AUC, Cmax and C_24h were in line with PBPK predictions and the adult PopPK model. For both PT and aPTT, a linear correlation between change from baseline and rivaroxaban plasma concentrations was found, in line with data obtained in adult healthy volunteers. A linear relationship between rivaroxaban plasma concentration and aXa activity was confirmed.

Conclusions: A single rivaroxaban administration using tablets or oral suspension targeting the adult 10 mg exposure was safe in children. PK data were in line with the PBPK model, validating the model for predicting rivaroxaban doses in children. PD data in children were in line with data from adult healthy volunteers indicating that developmental differences in hemostasis do not influence the PK/PD response of rivaroxaban in children above age 0.5 years. Our results need to be confirmed in the ongoing Einstein Junior phase II study.

PB 522 | Neonatal Portal Vein Thrombosis: Characteristics and Role of Anticoagulation

E. Zapotocka[1], V. Labarque[2], L.R. Brandao[1], S. Williams[1]

[1]Hospital for Sick Children, Division of Pediatric Hematology and Oncology, Toronto, Canada, [2]University Hospitals Leuven, Pediatric Hemato-Oncology, Leuven, Belgium

Background: Portal vein thrombosis (PVT) is a relatively common complication in neonates. The benefit of anticoagulation has not been clearly defined.

Aims: To describe the short and long-term outcomes of neonates with PVT treated according to an institutional protocol (anticoagulation vs no anticoagulation) with respect to thrombus progression, resolution, lobar atrophy, portal hypertension, and bleeding complications.

Methods: Data from all consecutive patients referred to a single Thrombosis Center between Jan 1st, 2008 till Oct 8th, 2015 were retrospectively collected. Institutional review board approved the study. Groups were compared using the chi-test, Fisher exact test, and Mann-Whitney U test, as appropriate.

Results: 221 neonates were included, with median follow up 3.10 years (0.014-8.33). Treatment group (TG) consisted of 112 and

non-treatment group (NTG) of 109 patients; basic data are provided in Table 1. Thrombus burden (Grade 1, 2 and 3) for each case was captured. The rate of progression in the TG was lower than in NTG (p=0.0426). With respect to resolution of the thrombus and development of lobar atrophy no differences between TG and NTG group were observed. After controlling for treatment, thrombus burden was predictive for both thrombus resolution (p< 0.0001) and lobar atrophy (p< 0.0001).

1 case of portal hypertension (incidence 0.45%) was noted (NTG group; 5.5 months since the diagnosis of PVT). Major bleeding occurred in 10 out of 112 (8.93%) of treated patients.

TABLE 1 Basic demographic data

	Treated group (n=112)	Non-treated group (n=109)	P value
Male:female ratio	1.73 (71:41)	1.87 (71:38)	0.8834
Corrected gestational age at the time of diagnosis of PVT; Weeks - median (range)	38 (25-43)	37.5 (25-43)	0.2040
Number of days since insertion of UVC to diagnosis of PVT; median (range)	6 (0-22)	6 (0-29)	0.7948
Follow up, Years - median (range)	3.17 (0.07-8.33)	2.75 (0.014-7.61)	0.4472
PVT grade initial, Number (%)			
Grade 1 (single branch non occlusive)	n=27 (24.1%)	n=52 (47.7%)	0.0126
Grade 2 (single branch occlusive)	n=68 (60.7%)	n=47 (43.1%)	0.1665
Grade 3 (more branches, parenchymal changes)	n=17 (15.2%)	n=10 (9.2%)	0.3077

TABLE 2 Late sequelae - details

	Treatment group (n=112)	Non-treatment group (n=109)	P value
Resolution of the PVT; number (%)			
Complete	68 (60.7%)	83 (76.1%)	0.2928
Partial	14 (12.5%)	6 (5.5%)	0.1077
None	30 (26.8%)	20 (18.4%)	0.2733
Risk of left hepatic lobe atrophy - based on resolution of PVT; number (%)			
Full resolution	10 (14.7%)	10 (12.0%)	0.8119
Partial resolution	4 (28.6%)	0 (0.0%)	0.5392
No resolution	24 (80%)	15 (75.0%)	1.0
Portal hypertension	n=0	n=1	NA

Conclusions: The only significant late sequelae of neonatal PVT, portal hypertension, is a rare event. Anticoagulation was associated with decreased PVT progression. Increased thrombus burden is a predictor of decreased thrombus resolution and increased lobar atrophy. No difference in rate of lobar atrophy and portal hypertension in TG vs NTG was observed.

PB 523 | The Incidence, Assessment and Management of Mental Health Issues in Young People on Anticoagulation Therapy Secondary to Idiopathic Venous Thromboembolism

L. Seneviratna, J. Hislop, S. Jones, F. Newall

Murdoch Childrens Research Institute, Haematology, Melbourne, Australia

Background: Idiopathic venous thromboembolism (VTE), is a relatively rare condition in young people, which necessitates anticoagulation therapy (AT) and resultant lifestyle changes. The impact of commencing AT on the mental health of young people has not previously been reported.

Aims: This study aimed to identify the prevalence of mental health issues in young people diagnosed with idiopathic VTE.

Methods: The retrospective study selected young people (10-19 years) from the warfarin database at The Royal Children's Hospital, Melbourne with idiopathic VTE diagnosed between 2003 and 2014. Demographic details, assessment data and treatment details were extracted from the medical record. A mental health assessment was defined as any written documentation containing details about the patient's mood, specifically symptoms of depression or anxiety.

Results: Thirty eight eligible young people were identified (20 males). Median age was 15 years (range 12-19). Primary diagnoses were: 23 deep vein thrombosis (DVT), 10 pulmonary emboli (PE), and 5 combined DVT and PE. Six patients had a documented HEEADSS assessment (Home environment, Education and employment, Eating and peer-related Activities, Drugs, Sexuality, Suicide/depression and Safety), 3 of which were referred to the Adolescent Medicine department. A mental health assessment was documented for 23.7% of patients. Three patients had pre-existing depression prior to their VTE. 28.9% (11) of patients were referred from Clinical Haematology to a mental health service. Of these, 11 patients 54.5% had a documented mental health diagnosis, including the 3 patients with pre-existing depression.

Conclusions: 15.8% of young people diagnosed with an idiopathic VTE were diagnosed with a mental health disorder, suggesting a higher prevalence of mental health disorders in this sub-population of young people compared to population-based estimates. Furthermore, this study highlights the significant impact idiopathic VTE and AT has upon the mental health of young people.

PB 524 | Investigating the Experience of Parents who Have Given their Children Enoxaparin at Home

S. Monagle[1], H. Gilmore[2], S. Lima[3], F. Newall[2]

[1]Monash Univeristy, School of Medicine, Clayton, Australia, [2]The Royal Children's Hospital, Department of Clinical Haematology, Parkville, Australia, [3]Bendigo Health, Bendigo, Australia

Background: Enoxaparin is commonly used in paediatrics for outpatient treatment and prevention of thrombosis. Parents are often responsible for the safe preparation and administration of enoxaparin when their child goes home. However, little is known about the parental experience of administering enoxaparin to children post-discharge.

Aims: To explore the experience and educational needs of parents whose children require enoxaparin anticoagulation at home.

Methods: A qualitative, descriptive methodology was employed using two focus groups to generate data. An experienced moderator facilitated session with parents who had enoxaparin to their child post-discharge for at least 6 weeks. These sessions were recorded, transcribed and thematically analysed.

Results: 12 parents participated in two focus groups. The figure presents the emergent key themes and subthemes. Without exception, parents described trauma, and felt overwhelmed and distressed at the reality of giving their child clexane injections at home. Furthermore, many reported that they felt insufficiently trained and had particular difficulty preparing the correct dose from manufactured stock solutions. Parents also reported problems with communication, and felt that they were not adequately educated on the practicalities of enoxaparin administration prior to discharge by clinical staff. These practicalities included the supply of weight-appropriate equipment and dosages and rationale for use of subcutaneous injection catheters versus direct injection. Communication problems contributed to the trauma of the experience, as parents felt isolated and uninformed when they were discharged home.

Conclusions: Parents felt unprepared and traumatised when they had to administer enoxaparin to their child at home. Further research is needed regarding the psychosocial impact of parental administration of enoxaparin post-discharge and the optimal approach to supporting this extension of parent care-giving.

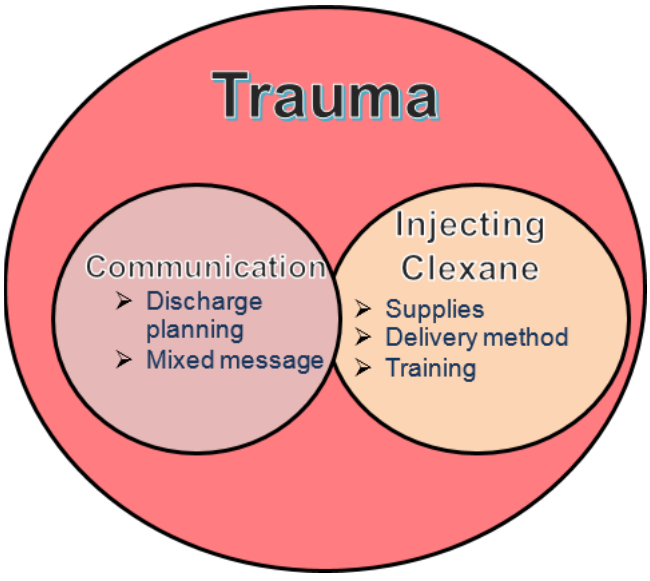

FIGURE 1 Emergent key themes and subthemes

PB 525 | A Pilot Feasibility and Safety Multicenter Trial of Administering Weight Adjusted FIXed Dose of Low Molecular Weight Heparin (Enoxaparin) to Neonates with Thrombosis (FIXET): Study Protocol

M. Bhatt[1], K. Hamilton[1], S. Shivananda[2], K. Kulkarni[3], L. Raffini[4], A. Chan[1]

[1]McMaster University, Pediatric Hematology/Oncology, Hamilton, Canada, [2]University of British Columbia, Neonataology, Vancouver, Canada, [3]Dalhousie University, Pediatric Hematology/Oncology, Halifax, Canada, [4]Childrens Hospital of Philadelphia, Pediatric Hematology/Oncology, Philadelphia, United States

Background: Enoxaparin is a commonly used low molecular weight heparin (LMWH) for the treatment of neonatal thrombosis that is monitored with anti-factor Xa (anti-Xa) levels. The therapeutic range

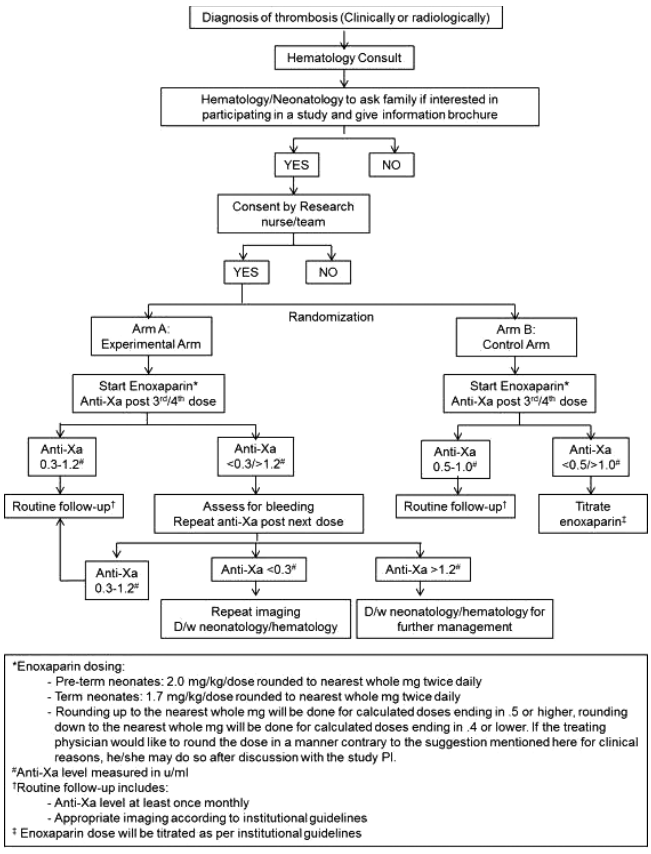

FIGURE 1 Proposed process for screening, recruiting, treating and following a subject

of anti-Xa (0.5 - 1.0 u/ml) was extrapolated from adult studies. The burden of pain to neonates due to venipunctures and of resources to the health care system also warrants an assessment of the utility of monitoring LMWH therapy with anti-Xa levels.

Aims: The aim of this trial is to determine the feasibility and safety of doing a randomized control trial to compare the approach of treating thrombosis in neonates with enoxaparin using weight adjusted fixed dose to variable dose titrated to maintain a pre-determined anti-Xa range (0.5-1.0 u/mL).

Methods: We plan to recruit 20 neonates among four centers over the study period. Figure 1 outlines the study schema.

Premature and term neonates with thrombosis diagnosed by imaging will be included. Key feasibility outcomes include screening/recruitment ratio, recruitment rate, and completeness of data collection. Bleeding and resolution of thrombosis will be measured as secondary outcomes.

Premature and term neonates will receive enoxaparin at a dose of 2.0 and 1.7 mg/kg/dose, respectively, rounded to nearest whole mg twice daily. Patients will have blood sampling for anti-Xa levels drawn after the 3rd or 4th dose from starting or adjustment, followed by at least once monthly. Patients will have appropriate imaging according to institutional guidelines. The duration of enoxaparin therapy will be at the discretion of the treating physician.

The trial has been approved by Hamilton Integrated Research Ethics Board and Health Canada. The trial is registered with clinicaltrials.gov.

Results: The trial has recently started and to date 2 patients have been enrolled and randomized.

Conclusions: We hope to establish feasibility and safety through this pilot study to progress to a full trial and decrease the burden of monitoring in this population.

PB 526 | Secondary Antithrombotic Prophylaxis in Children with Right Atrium Thrombosis

P. Zharkov, N. Ershov, A. Pshonkin, D. Fedorova

Federal Research Clinical Centre of Pediatric Hematology Oncology and Immunology N.A. D. Rogachev, Moscow, Russian Federation

Background: Current recommendations on treatment of right atrium thrombosis (RAT) in children are based mainly on data obtained from studies in infants with cardiac disease. Here we present a retrospective analysis of low molecular weight heparin (LMWH) use in children with RAT hospitalized in large Hematology-Oncology tertiary hospital.

Aims: To analyze efficacy and safety of LMWH use in children with RAT.

Methods: We analyzed retrospective medical data about secondary antithrombotic prophylaxis (SAP) with LMWH in 23 children (13 boys, 10 girls) aged 1-17 years. All patients had confirmed diagnosis of RAT and had at least 2 echocardiography exams to show thrombus size dynamics (change in size for more than 5 mm). Moreover we analyzed presence of symptomatic PE and all clinically relevant bleeding (CRB) episodes occurred 24 hours after LMWH injection. SAP was accepted as effective when there were no increase in thrombus size or pulmonary embolism (PE) episodes and safe when there were no episodes of CRB.

Results: All patients had central venous line (CVL) at the time of diagnosis and no one had any clinical symptoms of thrombosis or cardiac insufficiency. After RAT evaluation, all patients started SAP with LMWH (dalteparin or enoxaparin) at dose of 100 IU/kg twice daily s/c. LMWH dose was reduced to 50% in cases of platelet drop less than 100 10^9/L, and withheld in cases of platelet drop less than 30 10^9/L. During the observation period (5-426 days, Me=55 days), reduction of thrombus size (TS) appeared in 10 (43,5%), increase of TS - in 2 (8,7%) patients, while absence of any TS dynamics was found in 5 (21,7%) children. No PE or CRB episodes were found during the observation period.

Conclusions: Secondary antithrombotic prophylaxis with LMWH in children with right atrium thrombosis is effective and safe.

PB 527 | Thrombotic Storm in an 11 Year Old Boy

S. Singh[1], A. Jindal[1], J. Ahluwalia[2]

[1]PGIMER, Advanced Pediatrics Centre, Chandigarh, India, [2]PGIMER, Department of Hematology, Chandigarh, India

Background: Thrombotic storm was first described by Kitchens in 1998 as a clinical pattern of developing acute to subacute thrombosis over a period of days to weeks with progressive involvement of multiple sites, including several unusual sites.

Aims: To describe the case of a 11 years old boy with thrombotic storm.

Methods: An 11 year old boy presented with progressive headache for 7 days along with facial asymmetry noted on the day of admission. He had had no significant illness in the past and was developmentally normal. At presentation, he was conscious, oriented and alert and had normal vital signs. He had left sided lower motor neuron facial palsy; rest of the physical examination was unremarkable. His further clinical course and laboratory investigations are summarized in Tables 1 and 2 respectively.

Results: Anticoagulation was initiated with intravenous heparin. In view of a clinical possibility of catastrophic antiphospholipid antibody syndrome (elevated IgM anti-β2 GPI antibody titres), he was also given injection methylprednisolone pulse therapy (30 mg/kg/day for 5 days) followed by oral prednisolone. Although he also had low levels of Protein C and Protein S at this time, it was difficult to interpret this finding during the stage of acute thrombosis. Protein C and Protein S levels were also tested in both parents and were in normal range.

Heparin was replaced by oral warfarin and the INR was targeted between 2 to 3.

He has remained well over 14 months of follow-up. Prednisolone has been tapered and stopped. Warfarin is being tapered now. We plan to stop warfarin after 2 months and repeat the procoagulant work-up thereafter.

TABLE 1 Course during hospital stay

Day of hospital stay	Event	Management
Day 1	Cortical sinus venous thrombosis evident on MRI brain	Subcutaneous low molecular weight heparin (LMWH)
Day 2	Status epilepticus	Multiple anti-epileptics and continued on LMWH
Day 4	Pulmonary thrombosis evident on CT angiography (sudden onset respiratory distress and cardiac arrest, requiring cardiopulmonary resuscitation)	Intravenous infusion of unfractionated heparin maintaining aPTT between 70-90s, ventilated from day 4 - day 8
Day 5	Thrombus in right superficial femoral vein and popliteal vein (picked up on ultrasound doppler)	Continued on unfractionated heparin infusion
Day 22	Thrombus in left superficial femoral, common femoral and popliteal vein (symptomatic in form of pain and swelling and confirmed on ultrasound doppler)	Continued on unfractionated heparin infusion
Day 24	Thrombus in right internal jugular vein and external jugular vein (symptomatic in form of neck pain and confirmed on ultrasound doppler)	Continued on unfractionated heparin infusion
Day 34	No new thrombus and recanalization of vessels	Heparin infusion tapered and initiated on oral warfarin
Day 45	Discharged with no neurological deficits	On oral warfarin with target INR between 2-3

TABLE 2 Investigations carried out during admission

Investigation	Result
Haemoglobin	83 gm/L
White blood cell counts	10.8 × 109 /L (P80;L12;M7;E1)
Platelet counts	165 × 109/L
HIV serology by ELISA	Non-reactive
ANA	negative
ANCA	negative
HLA B5	negative
C3; C4	170mg/dl(normal); 53 mg/dl (normal)
Prothrombotic work-up: i)CD55/CD59 (for paroxysmal nocturnal hemoglobinuria); ii)Protein C; iii) Protein S; iv)Factor V Leiden mutation; v)IgG Anticardiolipin antibody (GPLU/mL); vi)IgM Anticardiolipin antibody (MPLU/mL); vii)IgG Anti β2 GPI (U/mL); viii)IgM Anti β2 GPI (U/mL); ix) Serum homocysteine	i)Normal ii)58% (normal range: 63-123) iii)24% (normal range 67-143) iv)Absent v)2.1 (Normal <10) vi)1.1 (Normal <7) vii)1.3 (Normal <5) viii) initially 8.0 (Normal <5); was normal on follow-up after 3 months ix)9.35 µmol/L (Normal: 5-15)

Conclusions: Thrombotic storm is a rare and potentially life threatening condition. It is extremely uncommon in young children. Early and aggressive anticoagulation remains the cornerstone of management.

PB 528 | Variation in Practice in Relation to Antithrombotic Therapy and Monitoring After Paediatric Cardiac Surgery: Results of a United Kingdom Survey

T. Biss[1], J. Alamelu[2], D. Arachchillage[3], E. Chalmers[4], M. Mathias[5], M. Richards[6], M. Williams[7], O. Tunstall[8]

[1]*Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom,* [2]*Evelina London Children's Hospital, London, United Kingdom,* [3]*Royal Brompton Hospital, London, United Kingdom,* [4]*Royal Hospital for Children, Glasgow, United Kingdom,* [5]*Great Ormond Street Hospital for Children NHS Foundation Trust, London, United Kingdom,* [6]*Leeds Children's Hospital, Leeds, United Kingdom,* [7]*Birmingham Children's Hospital NHS Trust, Birmingham, United Kingdom,* [8]*University Hospitals Bristol NHS Trust, Bristol, United Kingdom*

Background: Evidence for dosing, monitoring and intensity of antithrombotic therapy after paediatric cardiac surgery is limited.

Aims: To identify current UK practice.

Methods: A survey was sent by electronic mail to a haematologist in each of the 11 UK centres.

Results: 8/11 centres returned data. Initial post-operative anticoagulation is exclusively with unfractionated heparin (UFH). Initial therapeutic UFH dose is 28 U/kg/hr in infants and 20 U/kg/hr in older children in 6/8 centres. Four centres primarily use APTT and 4 centres anti-factor Xa activity (aXa) to guide dose adjustment. Target range for APTT is 60 to 80, 85 or 90 seconds or ratio 2-2.5 and for aXa is 0.35 -0.7 IU/mL, monitored a minimum of 24 hourly. Prothrombin time and fibrinogen monitoring vary from 1-3 times weekly to 4 hourly. Thresholds for platelet and fibrinogen transfusion are 30-50 $x10^9$/L and 1.0 g/L, respectively. No centre monitors antithombin (AT) levels routinely during therapeutic UFH. AT level is measured when difficult to achieve therapeutic anticoagulation and replacement therapy given at a threshold of 30-100 IU/dL using plasma (1 centre), AT concentrate (3) or either (3). UFH dose is reduced during AT replacement in 3/7. UFH infusion is used to maintain line patency in 5 centres, at a dose of 5-25 U/kg/hr, unmonitored in 2. Two centres give a third group 20 or 28 U/kg/hr UFH, without a target APTT/aXa, monitored only for safety. Low molecular weight heparin (LMWH) is dosed as per international guidelines in 2/8 centres, monitored in all children, timing of aXa levels varying from 2-6 hours post dose. Five centres avoid warfarin in infants. Two have prescribed a direct oral anticoagulant outside of a trial. Antiplatelet therapy, predominantly aspirin, is monitored in selected cases in 4, using a variety of techniques. Five centres use warfarin after uncomplicated Fontan surgery, 4 longterm, the remainder using aspirin.

Conclusions: Variation in practice within the UK exists, highlighting a need for research and guideline provision.

PB 529 | Successful Endovascular Thrombectomy of an Extensive Cerebral Venous Thrombosis with Bilateral Thalamic Infarction in A 16 Year Old Girl: Case Report and Therapeutic Algorithm

S. Holzhauer[1], B. Weschke[2], M. Nikolaus[2], T. Liebig[3], A. Gratopp[4]

[1]*Charité Universitaetsmedizin Berlin, Pediatric Hematology and Oncology, Berlin, Germany,* [2]*Charité University Medicine, Pediatric Neurology, Berlin, Germany,* [3]*Charité Universitaetsmedizin Berlin, Neuroradiology, Berlin, Germany,* [4]*Charité University Medicine, Pediatric Intensive Care, Berlin, Germany*

Background: Cerebral vein thrombosis is a rare but potentially life threatening disease in children. Overall mortality is 10%; prognosis is worse in the presence of thrombosis of the inner cerebral veins or parenchymal lesions. There is uncertainty with regard to the optimal treatment strategy. Endovascular interventions have not been included in treatment recommendations so far.

Aims: To illustrate that mechanic thrombectomy is a successful treatment for selected patients with cerebral venous thrombosis. To present a treatment algorithm considering endovascular thrombectomy as treatment option for pediatric patients with cerebral vein thrombosis.

Methods: Case Report.

Results: A 16 year old girl presented with a 24 hours history of headache, progressive detoriation and decreasing levels of consciousness. MRI revealed a thrombosis of the great cerebral vein, the straight, left sigmoid and transverse sinus. Despite therapeutic anticoagulation with low molecular weight heparin the clinical condition worsened; MRI now showed growing thrombosis with bilateral hemorrhagic thalamic infarction.

Mechanical thrombectomy was performed by combining aspiration of thrombotic material via a microcatheter system (Sofia 5F) and additionally capturing thrombotic material via a stent retriever system (Trevo XP 4/20). Recanalization of the sigmoid and transverse sinus as well as partial recanalization of the great cerebral vein could be achieved and maintained. The clinical condition improved rapidly; one year after the event the patient continues her training as a saleswoman, while still suffering from headaches and impaired vision.

Conclusions: Given the potential benefit, mechanic thrombectomy needs to be considered in patients with (i) progressive thrombosis despite therapeutic anticoagulation (ii) secondary congestive bleeding or (iii) increased bleeding risk. We propose a therapeutic algorithm for children and adolescents with cerebral vein thrombosis treated at our center.

PB 530 | Management of Henoch-Shönlein Purpura in Children with Heparin. Russian Long-term Experience

N. Sokolova[1], N. Vaynyunskaya[2]

[1]*Saint Petersburg State Children Hospital 1, Hematoligical Department, Saint-Petersburg, Russian Federation,* [2]*Saint Petersburg State Children Hospital 1, Saint-Petersburg, Russian Federation*

Background: Henoch-Schönlein purpura (HSP) is an acute immunoglobulin A-mediated disorder characterized by a generalized vasculitis involving the small vessels of the skin, the gastrointestinal tract, the kidneys, the joints. The usuall managemen of itt in many countries includes: steroinds and NSAID. Not much articles are devoted to heparin treatment and bed rest.

Aims: To show one of option for treatment of this disease with good outcomes which is used in Russia as a standard for all childen.

Methods: We have analyzed 242 patients case histories. All patients were admitted to hematological department of State Medical Hospital1 from 2006 to 2016y. All of them had rash, joint and abdominal pain and diagnosis of HSP was made, other conditions was excluded. Children were treated due to Russian standards of care.

Results: All children recieved heparin continuous infusion. Dosage was from 400U/kg/ day to 560U/kg/day. It was controlled by APTT. Bed rest was for 10 days. Steroids was given 2mg/kg prior to tird pain free day. Rash was gone on the 4-9th day (average 5,6), no abdominal pain was on the 4-12th day (average 8,2). Steroids were sropped on the 3-19th(average 6,3). Also hypoallergenic diet was recommended. Only 8 patiens had relapses. No creatinine and urea elevation was found. Only 19 patiens develop urinary syndrome and only 6 required surgical treatment.

Conclusions: We strongly recommend to keep in mind our heparin treatment option. We do not have hemorrhagic complications, we use steriods for shorter period of time. Only 3% of patients develop urinary syndrome. Only 2% need surgical testicular or gastrointestinal complications.

PB 531 | Inherited Antithrombin Deficiency in Children: Treatment of Massive Cerebral Sinus Venous Thrombosis in a Neonate with a Mutation in Gene SERPINC1 (Exon 3 C481c>t)

S. Izquierdo Sebastiá[1], M.Á. Dasí Carpio[1], B. Argilés Aparicio[1], C. García Blanes[2], J. Corral de la Calle[3,4], A. Moscardó Martínez[2], M.T. Santos Díaz[2]

[1]*Hospital Universitari i Politècnic La Fe, Pediatric Hematology Unit, Valencia, Spain,* [2]*Hospital Universitari i Politècnic La Fe, Valencia, Spain,* [3]*Hospital Universitario Morales Meseguer y Centro Regional de Hemodonación, Hematoly and Oncology, Murcia, Spain,* [4]*IMIB, Universidad de Murcia, Murcia, Spain*

Background: Inherited atithrombin deficiency (ATD) is a proven major risk factor of thrombosis. In children with venous thromboembolism (VTE), ATD is described to generate 6.6% of events and cause severe thrombosis in children. Its management is difficult in smaller infants

Aims: To expose the management of a neonate with ATD and severe sinus venous thrombosis (SVT) in a tertiary center

Methods: Clinical case review

Results: A 4 days old neonate with normal pregnancy and delivery, only single coil of umbilical cord, was admitted to hospital with seizures. Cerebral magnetic resonance image (MRI) showed massive SVT and disseminated ischemic injuries. Enoxaparin was started at 2mg/

Kg/12h. First anti-Xa 0.1 UI/mL. His mother had ATD (42-46%). No VTE history. Neonate AT was 18%. We started AT concentrate at 40UI/Kg. Successive AT concentrate doses were modified to obtain AT around 100% (median 109%, [47-169]). Median AT concentrate was 85UI/Kg/day, [70-120]. We achieved adequate anticoagulation with a median of anti-Xa of 0.69 UI/mL, [0.42-1.10]. After 5 weeks of treatment, MRI showed improvement with almost complete resolution of thrombosis, small thrombosis rests. After 59 days of AT treatment, indefinite oral anticoagulation was started. No hemorrhage or new thrombosis were seen. There are no neurological sequels.

Without substitutive treatment infant has AT 46%. A mutation in SERPINC1 gene was detected (exon 3, C481c>t). Five of nine (55%) affected members of the family have developed VTE. Two of them under 10 years old. Only 2 of them showed clear additional risk factors

Conclusions: An early diagnosis of ATD is essential for an adequate management of VTE in children.

Treatment in neonates with ATD must be tailored. Satisfactory clinical evolution in our patient is the result of the maintenance of AT around 100%, that allows adequate anticoagulation controlled with anti-Xa and avoids treatment failure or hemorrhage complications.

It´s difficult to correlate so different phenotype with the same genotype in this family

PB 532 | Venous Thromboembolism Prevention in Children

A.M. Pizzini[1], V. Montemaggiori[2], D. Galimberti[1], M.C. Leone[1], A. Ghirarduzzi[1]

[1]*Arcispedale Santa Maria Nuova, Internal Medicine, Reggio Emilia, Italy,* [2]*Arcispedale Santa Maria Nuova, Orthopedia, Reggio Emilia, Italy*

Background: Venous thromboembolism (VTE) in children has a low prevalence, but prophylaxis in young patients is an emergent issue for increased survival of children at high risk (prematurity, congenital heart disease), wider use of high risk procedures (surgery, central lines) and of prothrombotic drugs

Aims: In adults idiopathic VTE is prevalent, in children VTE is often secondary to transient or permanent risk factors (congenital heart or kidney disease, devices, cancer). These factors should guide us in the choice of the right prophylaxis.

Methods: Between April 2013-March 2014 we evaluated a selected population of diplegic children who underwent orthopedic corrective surgery (fasciotomy, osteotomy). We adopted an internal protocol to uniform the patient/procedure VTE risk and assess when to perform prophylaxis. We considered individual factors (age, puberal development, overweight/obesity, congenital conditions such as thrombophilia), preexistent conditions at risk (previous VTE, chronic inflammatory bowel disease, nephrotic syndrome), active cancer, ipomobility, either preexistent or induced, prothrombotic drugs and devices. Prophylaxis with enoxaparin was adopted when at least 3 factors were present

Results: . We studied 25 children (12 M, 13 F, mean age 14.3 ys) who underwent VTE medium-high risk surgery (osteotomies 36%, fasciotomies 56%) followed by a long immobilization period/cast. We decided to use enoxaparin in 20/25 patients, mechanical prophylaxis in 5. In all the patient on enoxaparin antiXa activity was measured on day 2 to define the right dose: in only 2 children heparin dose had to be modified, mean antiXa levels were 0,345, (in prophylactic range). Follow-up at 1 and 6 months didn‘t show haemorrhages or thrombosis.

Conclusions: Our numbers are too small to be statistically relevant, and our algorithm should be tested on a larger scale to stratify the thrombotic risk in children. Nonetheless we held that VTE prophylaxis should be performed in this setting without a significant bleeding risk.

PB 533 | Development of a Thrombus in Giant Coronary Aneurysm of a Child with Kawasaki Disease - An Unusual Clinical Manifestation

S. Singh[1], A. Jindal[1], M. Singhal[2]

[1]*PGIMER, Advanced Pediatrics Centre, Chandigarh, India,* [2]*PGIMER, Department of Radiodiagnosis and Imaging, Chandigarh, India*

Background: Kawasaki disease (KD) is the most common vasculitic disorder in children. Coronary artery abnormalities (CAA) can develop in up to 15-25% of patients with KD if appropriate treatment is not administered in time. Occasionally, giant coronary aneurysms (diameter>8mm) can also develop. Coronary thrombosis is an unusual, but dreaded, complication that can sometimes be seen in such patients. We describe one such case.

Aims: To describe the case of a young boy with KD and giant coronary artery aneurysm who developed thrombosis on follow-up.

Methods: A 7 year old boy was diagnosed with KD at 3 years of age when he was admitted elsewhere with a febrile illness and left cervical lymphadenopathy. On day 6 of illness, he developed erythematous maculopapular rash, swelling over dorsum of hands with conjunctival congestion. He went on to develop periungual peeling of skin 3 days later. Two dimensional echocardiography revealed ectasia of left main coronary artery. (Table 1). He was treated with intravenous immunoglobulin and aspirin. The fever responded promptly. Follow-up echocardiography revealed a giant aneurysm in distal segment of left anterior descending (LAD) coronary artery (Table 1). Anticoagulation with acenocoumarol was initiated at this stage but the parents discontinued this therapy on their own. He remained clinically well and was referred to us at 7 years of age.

Results: We performed 128 Slice Dual Source CT coronary angiography. It revealed a fusiform aneurysm in mid segment of LAD coronary artery (width 8 mm and length 13.5 mm) with an eccentric hypodense filling defect (3 mm width) in the aneurysm suggestive of coronary thrombosis. He was initiated on low molecular weight heparin (1 mg/kg/ dose twice daily) and aspirin was continued.

Conclusions: CT angiography is an important investigation for detailed assessment of coronary artery complications in patients with KD. Patients with giant coronary artery aneurysms need to be maintained on long-term anticoagulation to prevent thrombosis.

TABLE 1 Two dimensional echocardiography findings

Diameter of coronary arteries	At admission	1 week later	6 months later	3 years
LMCA	5 mm with ectasia of mid portion (> +3Z)	4.2 mm (> +3Z)	-	-
LAD	4 mm (> +3Z)	-	8.7 mm (>+10Z)*	6 mm (>+10Z)*
RCA	3 mm	5 mm (> +3Z)	3.1 mm (+2.8 Z)	-
LCx	3 mm	-	-	-

*Diameter of the aneurysmal segment; Abbreviations- LAD- left anterior descending coronary artery; LCx- left circumflex coronary artery; LMCA- left main coronary artery; RCA- right coronary artery

PB 534 | Management of Anticoagulation Therapy in Patients with Thromboembolism in The Context of Renal Diseases: Case Series and Practical Suggestions

A. Bahabri, V. Belostotsky, A. Chan, M. Bhatt

McMaster University, Pediatrics, Hamilton, Canada

Background: Current guidelines for anticoagulation therapy (ACT), including low molecular weight heparin (LMWH), do not address dosing and monitoring in the context of various renal diseases. LMWH is renally cleared, hence renal dysfunction can cause accumulation of the drug, potentially resulting in increased bleeding risk.

Aims: To describe challenging cases of ACT management in patients with thromboembolism in the context of renal diseases.

Methods: Patient records were reviewed for demographics, details of thromboembolic (TE) diagnosis and therapy, details of renal condition, and bleeding episodes.

Results: A 12 year old girl with steroid resistant nephrotic syndrome developed inferior vena cava thrombus and pulmonary embolism. After initial thrombolytic treatment, she received ACT with enoxaparin, which required multiple dose adjustments based nephrotic syndrome remission or relapse (Table 1).

A 5 year old girl with repaired congenital heart disease developed common femoral and external iliac vein thrombus while on prophylactic enoxaparin for mechanical tricuspid valve. In this case, increasing anti-Xa levels were the first sign of acute kidney injury (AKI). Enoxaparin doses were adjusted until improvement in AKI (Table 2).

Anephric 3 year old boy developed line related superior vena cava thrombus while on hemodialysis. Enoxaparin is renally cleared, hence it was administered once daily post-dialysis and adjusted based on combined peak and trough anti-Xa levels.

Conclusions:

1- Anti-Xa levels should be monitored closely with any disease activity change in nephrotic syndrome patients.

Figure 1. Enoxaparin dosing and monitoring in a hemodialysis patient.

Table 1. Enoxaparin dose adjustments and corresponding anti-Xa levels in a nephrotic syndrome patient with thromboembolism.

Day of Treatment	Enoxaparin	Anti-Xa (U/ml)	Albumin (g/L)	Comment
1	60 mg BID		28 T*	
20	**63 mg BID**	**1.18**	**25**	
21	55 mg BID	1.27		Lower LMWH doses in nephrotic remission
22	50 mg BID	1.13		
27	45 mg BID	0.70	33	
42	**50 mg BID**	**0.39**	**17**	**Higher LMWH doses required in nephrotic syndrome relapse due to lower anti-thrombin levels**
43	**60 mg BID**	**0.33**		
44	**80 mg BID**	**0.44**	**20**	
63	65 mg BID	1.07		

*Post Albumin Transfusion

Table 2. Enoxaparin dosing and monitoring in a patient with thromboembolism who later developed acute kidney injury.

Day of Treatment	Enoxaparin	Anti-Xa (U/ml)	Urea (mmol/L)	Creatinine (umol/L)	eGFR	Comment
7	26 Mg BID	0.82	11.4	50	76.6	
16	29 Mg BID	0.85	9.4	45	85.1	
17	32 Mg BID	0.89				
54	**30 Mg BID**	**2.10**				**Accumulation of LMWH with decreased renal function**
59	**22 Mg BID**	**1.68**				
61	**18 Mg BID**	**1.18**	**36.8**	**77**	**49.7**	
65	**18 Mg BID**	**0.79**	**32.2**	**66**	**58**	
99	20 Mg BID	0.61	15	66	58	

2- Significant changes in anti-Xa levels should prompt investigation of renal function.

3- Enoxaparin can be dosed once daily to maintain a target peak anti-Xa level of 0.5-1.0 U/ml and trough of 0.1-0.3 U/ml in a patient on hemodialysis requiring ACT (Figure 1).

PB 535 | Successful Use of Low Molecular Weight Heparin (LMWH) in Intracardiac Thrombus of a Premature Infant: Case Report

A.M. Vélez Escobar[1], A. Jaramillo Yepez[2], C. Jimenez Alvarez[2], L.N. Builes Restrepo[2,3]

[1]Universidad CES, Antioquia, Medellin, Colombia, [2]Hospital General de Medellin, Antioquia, Medellin, Colombia, [3]Hospital Pablo Tobon Uribe, Antioquia, Medellin, Colombia

Background: Treatment guidelines for Pediatric Atrial Thrombosis are limited. Treatments in neonates include observation, thrombectomy and anticoagulation. Thrombolytic therapy are increasingly being

used to treat intracardiac and arterial thrombosis, but bleeding risks make them unpopular. Currently, optimal treatment modalities are not known.

Aims: We report a premature infant with an Atrial Intracardiac Thrombus which had indication for thrombolysis treatment, because of gestation age, weight and Grade I Ventricular Hemorrhage antecedent, treatment with low molecular weight heparin (LMWH) was used.

Methods: 31 weeks gestation baby, weighted 1002 gr, presented with neonatal respiratory distress syndrome, required INSURE therapy and noninvasive ventilation for 28 hours, venous and arterial umbilical catheter were placed. Grade I Ventricular Hemorrhage was diagnosed at 4 days old. He presented with clinical deterioration and had positive cultures. Echocardiogram showed a 6 x 7 mm mass in the right atrium adhered to the interatrial septum. Treatment was initiated with antibiotics. Follow up echocardiogram showed an increase in size and a new atrial vegetation trough branches of the pulmonary artery were seen. Treatment with LMWH was started (1.5 mu/kg/day). The mass was monitored with serial echocardiograms. After 8 days of treatment, vegetation size is reduced, and by day 15 it disapeared. 5 weeks of anticoagulation and 4 weeks of antibiotics were completed, No hemorrhagic complications presented during the treatment. Interventricular Hemorrhage resolved.

Results: .

Conclusions: Treatments for Thromboembolism in preterm infants are still based on expert opinion. Unfractionated heparin has been the standard treatment in preterm infants with clinically significant and large thrombi that aren´t life-threatening. LMWH is frequently used in post-acute treatment. As with this case, LMWH could be an effective and safe treatment for Acute Right Atrial Thrombosis in preterm Infants.

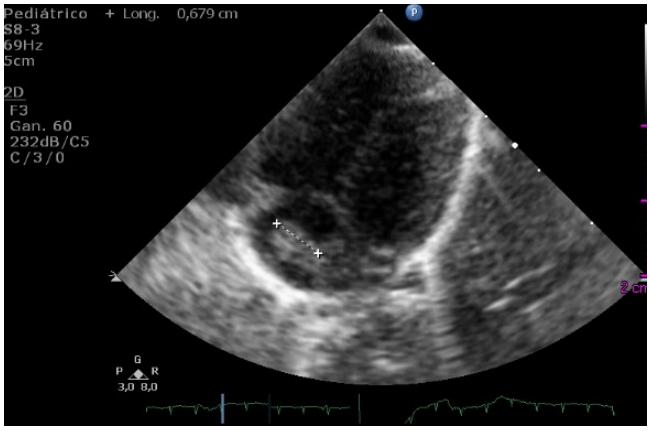

FIGURE 1 echocardiogram showing the intracardiac thrombus in the right atrium.

PB 536 | Petechial Rash and Thrombocytopenia with Unfractionated Heparin (UFH) Use: Heparin Induced Thrombocytopenia (HIT) in a Child with Non-vegetative Infective Endocarditis

M.-P. Schlosser[1], J. Chan[2], J. Halton[2], L. Abbott[2]

[1]*Children's Hospital of Eastern Ontario, University of Ottawa, Pediatrics, Division of Hematology/Oncology, Ottawa, Canada,* [2]*Children's Hospital of Eastern Ontario, University of Ottawa, Division of Hematology/Oncology, Ottawa, Canada*

Background: HIT, a life-threatening complication of heparin therapy, is rare in pediatric patients despite the frequent use of heparin for anticoagulation.

Aims: We present a unique case of HIT in a 10-year old boy being treated with an UFH infusion for multiple venous thrombi.

Methods: Case report.

Results: A 10-year old boy with non-vegetative infective endocarditis and extensive line associated thrombi developed thrombocytopenia and petechial rash after less than 2 days of cumulative exposure to an UFH infusion, approximately one week after initial exposure to heparin. He presented with a rapidly progressive diffuse petechial rash, concurrent drop in platelets (326 to 48x10^9/L over 36 hours), and stable thrombi. Pretest probability of HIT, by the 4T's score, was intermediate. HIT ELISA was positive (optical density of 1.743, inhibition of 87%). Change to bivalirudin, a direct thrombin inhibitor (DTI), was recommended, but not immediately available. Due to the risk of thrombosis progression associated with sudden discontinuation of heparin, UFH was continued for under 12 hours until argatroban was started. Argatroban was titrated from 0.75 mcg/kg/minute to a goal PTT of 50-90 seconds. Within 48 hours, his platelets normalized and rash improved. Anti-platelet factor 4/heparin enzyme immunoassay (IgG EIA) was 1.534, indicating high probability for HIT. A serotonin release assay was indeterminate. The patient required surgery for his underlying cardiac valve disease; once available, bivalirudin was used intra-operatively. Argatroban was restarted post-operatively. He was later switched to warfarin for the remainder of his three-month treatment course. Subsequent ultrasound showed complete thrombi resolution.

Conclusions: Recognition of HIT and management with DTIs rapidly improved the patient's clinical status. DTIs are an effective anticoagulant alternative intra-operatively. Although rare, it is important that clinicians keep HIT on their list of potential risks associated with using heparin in children.

PB 537 | Resolution of Cerebral Sino-venous Thrombosis (CSVT) without Anticoagulation in a Neonate with Co-existing Protein C and Antithrombin Deficiency: A Case Report

V. Khatri[1], A. Chan[2], N. Stein[3], M. Bhatt[2]

[1]*McMaster University, Pediatrics, Hamilton, Canada,* [2]*McMaster University, Pediatric Thrombosis, Hamilton, Canada,* [3]*McMaster University, Pediatric Radiology, Hamilton, Canada*

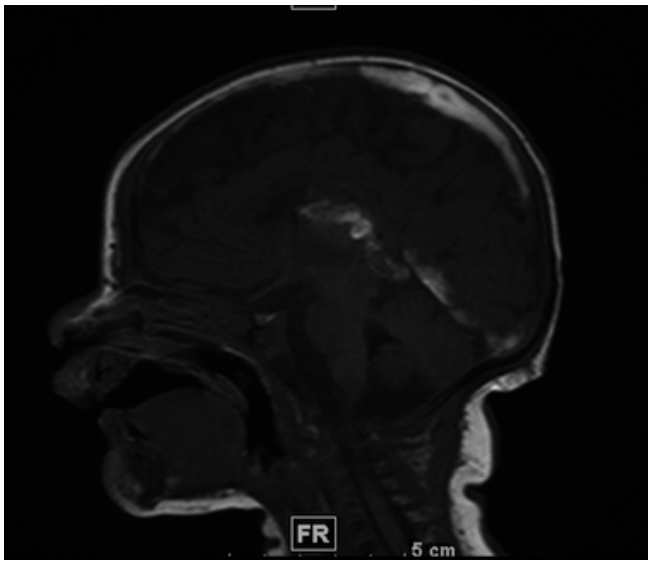

FIGURE 1 Sagittal view of extensive CSVT and bilateral thalamic hemorrhage. Patient 16 days old

Background: There is variability in management of CSVT by age. Evidence supporting anticoagulation (ACT) for adults and older children is established, however conflicting guidelines exist for management of neonatal CSVT. Observational studies have identified reassuring safety profile for ACT in neonates with CSVT, even with pre-existing intra-cranial or intra-parenchymal hemorrhage. However, certain systemic issues (large hemorrhage, infection, coagulopathy) may cause the clinician to manage conservatively.

Aims: We present a novel case of neonatal CSVT with excellent clot resolution despite conservative management in a patient with inherited thrombophilia (protein C and anti-thrombin deficiency).

Methods: Case study verified by healthcare team. Detailed literature review performed using Google Scholar and PubMed from 2000-2017.

Results: The neonate was born at term via vacuum-assisted delivery. At 2 weeks of age, she presented with focal seizure. Head imaging (Figure 1) revealed extensive CSVT. Due to co-existing extensive thalamic and intra-ventricular hemorrhage, the decision for conservative management was made. Follow-up imaging at one year showed complete resolution of CSVT (Figure 2).

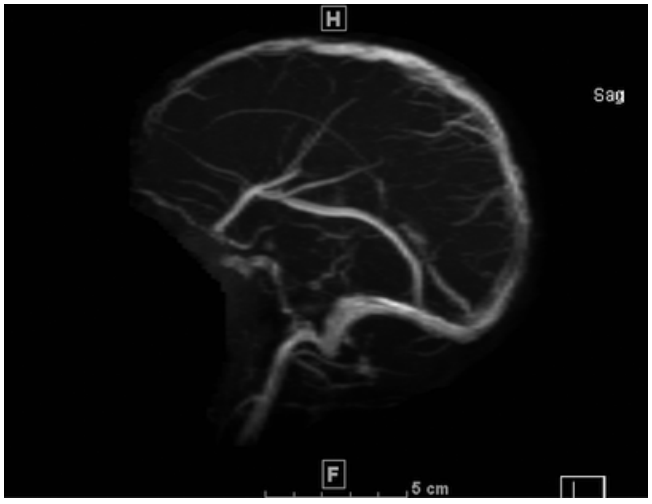

FIGURE 2 Magnetic resonance venography (time of flight) at 1 year old. Shows complete resolution of thrombus

The neonate's father had protein C and anti-thrombin deficiency. Genetic testing at age 10 confirmed same mutation in the patient. The patient is currently 13 years old and has not experienced further thrombotic events.

Conclusions: Neonatal CSVT may resolve completely in some patients without anticoagulation. This highlights the unique thrombogenicity in a neonate as well reassures clinicians who may be pressed to treat a patient conservatively due to above mentioned reasons. However, we acknowledge that resolution of thrombus still remains to be established as a marker of good clinical outcome.

PB 1244 | The Incidence and Assessment of Post-thrombotic Syndrome in Critically Ill Children Two Years Post-central Venous Catheter Placement

S. Jones[1,2,3], J. Rutgers[4], W. Butt[1,5], F. Newall[1,2,3], P. Monagle[1,2,4]

[1]*The University of Melbourne, Department of Paediatrics, Parkville, Australia,* [2]*The Royal Children's Hospital, Department of Clinical Haematology, Parkville, Australia,* [3]*The University of Melbourne, Department of Nursing, Parkville, Australia,* [4]*Murdoch Research Childrens Institute, Haematology Research, Parkville, Australia,* [5]*The Royal Children's Hospital, Paediatric Intensive Care Unit, Parkville, Australia*

Background: Central Venous Catheters (CVCs) are associated with over 50% of thromboses in children. Post-thrombotic Syndrome (PTS) is a long-term complication of thrombosis in children, which can impact quality of life. There is limited data regarding the epidemiology of PTS in children with CVC-related thrombosis, which is further confounded by the wide variance in published PTS rates within pediatric populations (6-64%).

Aims: To determine the frequency and severity of PTS two years following CVC placement in critically ill children and to optimize the scoring criteria for the severity of PTS in children.

Methods: 205 children admitted to a pediatric intensive care unit (PICU) with a CVC in situ participated in a prospective cohort study. Institutional ethics approval and informed consent were obtained. Approximately 24 months after PICU admission and CVC placement, a PTS assessment was performed. Two validated pediatric PTS tools were used independently in conducting PTS assessments in each child: the Manco-Johnson instrument (MJI) and the Modified Villalta scale (MVS).

Results: 126 Children underwent PTS assessment. The same 13 children were classified as having PTS using the MJI and MVS. Two children met the criteria for clinically significant PTS using the MJI, whilst the MVS assessed all PTS cases as mild. The Cronbach's alpha for the MVS and MJI was 0.989 and 0.935, respectively.

Conclusions: The incidence of clinically significant PTS was 1.6% in this cohort, despite 10.3% of children having some degree of PTS. However, only the MJI assessed children to have clinically significant

PTS. This raises the possibility that published estimates of PTS incidence in pediatric populations may overcall the clinical significance of this outcome measure. Based on the findings of this study, MJI may overcall the incidence of clinically significant PTS in younger children. As the MVS is less dependent on measuring pain, it may be more suitable for use in younger children.

PB 1245 | Venous Thromboembolism (VTE) in Pediatric Recipients of Hematopoietic Stem Cell Transplant (HSCT): Principal Findings from a Multicenter Cohort Study

R. Kumar[1], J. Stanek[2], H. Rangarajan[1], S. O'Brien[1]

[1]Nationwide Children's Hospital, Ohio State University, Department of Pediatrics, Division of Pediatric Hematology/Oncology, Columbus, United States, [2]Nationwide Children's Hospital, Division of Biostatistics, Columbus, United States

Background: HCT is the standard of care for a variety of benign and malignant disorders. Placement of central venous catheters (CVC), prolonged hospitalization, infections and graft versus host disease (GvHD) create a pro-thrombotic environment in recipients of HCT. A high incidence of VTE has been described in adult recipients of HCT. Similar data for children is lacking.

Aims: The objective of this retrospective, multicenter cohort study was to estimate the incidence of VTE and describe associated risk factors in recipients of HCT across children's hospitals in the US.

Methods: This study was deemed to be exempt by the IRB at Nationwide Children's Hospital. Data source for this study was the Pediatric Health Information Systems (PHIS), an administrative database that contains clinical and resource utilization data for inpatient and ambulatory surgery patient encounters from 49 free standing children's hospitals in the US. ICD-9 codes were used to identify eligible subjects, VTE, post-HCT complications and CVC placement. All patients who underwent a HCT at one of the PHIS hospitals between 01/01/2010 - 09/30/2014 were eligible for inclusion. Data were analyzed using non-parametric methods.

Results: 4158 unique subjects (3015 allogeneic and 1143 autologous HCT recipients) were included in the analysis. Mean age (±SD) at HCT was 8.8 (±6.5) yrs.1704 (41%) subjects were female. Post HCT, 290 subjects (6.9%) developed VTE. Pre-transplant predictors of VTE are summarized in table 1. GvHD (acute and/or chronic) was the only post-transplant complication associated with VTE [OR (±95% CI): 1.65 (1.2-2.1)]. Among allogeneic transplant recipients, VTE was associated with an increased risk of invasive bacterial and fungal infections. As summarized in table 2, VTE diagnosis in HCT recipients was associated with a worse prognosis.

TABLE 1 Pre-transplant risk factors associated with VTE development

Characteristic	Odds Ratio (95% CI)	p-value
Age ≥ 13 years (compared to < 13)	1.38 (1.08-1.77)	0.0115
Allogeneic (vs Autologous)	1.60 (1.19-2.15)	0.0021

TABLE 2 Morbidity associated with VTE development

Variable	VTE present	VTE absent	P value
Median length of hospital stay	81 days	54 days	p < 0.001
Median length of ICU stay	18 days	12 days	p < 0.001
1-year mortality	13.9% (n=78)	5.9% (n=212)	p < 0.001

Conclusions: Prevalence of VTE in subjects undergoing HCT at tertiary care pediatric hospital's in the US in about 7%. Older age, allogeneic transplants, development of GvHD are associated with VTE.

PB 1246 | Chronic Blood Transfusion Therapy Corrects Abnormalities of Coagulation and Fibrinolysis in Children with Sickle Cell Disease

S. Williams[1], C. Segbefia[2], F. Pluthero[3], W. Kahr[3]

[1]Hospital for Sick Children, University of Toronto, Haematology/Oncology, Toronto, Canada, [2]University of Ghana, Department of Child Health (DCH), Legon, Ghana, [3]Hospital for Sick Children, University of Toronto, Toronto, Canada

Background: Sickle cell disease (SCD) has been described as a hypercoagulable condition. The components and mechanisms of the hypercoagulability of SCD continue to be characterized.

Aims: This study attempts to characterize a specific subset of sickle cell disease patients, patients on chronic transfusion programs for primary or secondary stroke prevention, with thromboelastography (TEG), prior to and following a red blood cell transfusion.

Methods: Thromboelastography profiles prior to and following transfusion, and coagulation parameters (aPTT, INR, fibrinogen, d-dimer) prior to transfusion, were completed in 25 children with SCD presenting for regular transfusion. A retrospective review of clinical history was completed. Neurovascular disease progression was defined as Magnetic Resonance Imaging of brain with increased vessel tortuosity, increased vessel stenosis, or new parenchymal infarct. Descriptive statistics, Student t test and Pearson correlation co-efficient were calculated. Study was approved by institutional review board.

Results: Thromboelastography was completed on 13 males, 12 females, mean age 10 years (5-15 years). Changes in the thromboelastography profile following transfusion were compatible with decreased hypercoagulability (increased K, decreased angle, decreased maximal amplitude). Maximal amplitude on TEG profile prior to transfusion, (p=0.017), d-dimer value pre-transfusion (p=0.048) were significantly associated with neurovascular disease progression.

Conclusions: Transfusion with the intended goal of altering the red blood cell population, significantly altered the hypercoagulable thromboelastography profile in children with sickle cell disease. Thromboelastography may offer an additional monitoring investigation or therapeutic target in the management of chronically transfused patients with sickle cell disease.

TABLE 1 Thromboelastography values prior to and following transfusion in 25 children with sickle cell disease

TEG parameter	Pre-transfusion Median	95% CI	Post-Transfusion Median	95% CI	P value
R(min) Clotting time	7.2	7.2-8.5	7.5	6.7-9.1	NS

PB 1247 | Evaluating the Relationship between von Willebrand Factor, ABO Blood Group and Circulating Lymphoblasts in the Development of ALL-associated Thromboembolism in Children

T. Mizrahi[1], C. Laverdière[1], M. David[1], J.-M. Leclerc[1], Y.-L. Delva[1], L. Thabane[2], A. Chan[3], U. Athale[3]

[1]CHU Sainte-Justine, Pediatric Hematology and Oncology, Montreal, Canada, [2]St Joseph's Healthcare, Biostatistics, Hamilton, Canada, [3]McMaster Childrens Hospital, Pediatrics, Hamilton, Canada

Background: Non-O blood group is known to be an independent prothrombotic risk factor in children with acute lymphoblastic leukemia (ALL), but the exact pathogenesis of its prothrombotic effect is unknown. Von Willebrand factor (vWF) has been contemplated as a pathogenetic mechanism in ABO blood group-related prothrombotic risk. An association of vWF with circulating blasts has been previously shown.

Aims: As a part of a larger study defining risk factors for symptomatic TE (sTE) in children with *de novo* ALL, this sub-study is evaluating the relationship of ABO blood groups, circulating blasts and vWF antigen levels at diagnosis.

Methods: Consenting patients (1-≤18 yrs.) with *de novo* ALL enrolled on the Dana-Farber Cancer Institute 05-01 trial were included and demographic data (ABO blood group, complete blood count, therapy and development of sTE) were collected. Factor VIII:C and vWF antigen were analyzed centrally prior to starting therapy. Regression analyses evaluated relationship between blood group, vWF antigen level and circulating blasts.

Results: Of 131 patients [mean age (range) 6.4 (1-17) yrs.; 70 boys], 21 (16%) developed sTE. Fifty-one patients had blood group O and 76 non-O blood group. Older age [Odds Ratio (OR 1.9, p=0.029] and non-O blood-group (OR 4.27, p=0.028) were identified as independent predictors for development of sTE. Patients with peripheral blasts had higher odds of developing sTE (OR 7.79; p=0.059). There was no interaction between ABO blood group and circulating blasts on vWF levels (p=0.723, Table 1).

TABLE 1 Comparison of vWF levels in patients with and without circulating blasts in patients with O vs. Non-O blood group

		vWF levels at diagnosis (mean [SD]) (range)			
Blood Group	N	Overall	With Blasts	Without Blasts	P value#
O	51	1.697 (0.806) (0.670, 4.430)	1.787 (0.820) (0.780, 4.430)	1.370 (0.688) (0.670, 2.760)	0.130
Non-O	76	1.575 (0.689) (0.710, 4.450)	1.647 (0.745) (0.710, 4.450)	1.344 (0.397) (0.710, 1.970)	0.034
All Participants	127	1.629 (0.731)	1.706 (0.769)	1.368 (0.514)	0.008
P value*		0.3695	0.3876	0.9094	

Conclusions: vWF levels at ALL diagnosis were significantly higher in patients with circulating blasts and among them, in non-O blood group. The relationship between blood group and vWF may be affected by dominant effect of circulating blasts on vWF. However, we showed no interaction between ABO blood group and circulating blasts on the vWF levels. The prothrombotic effect of ABO blood group patients with ALL is thus not yet clear and may deserves consideration in future studies.

PB 1248 | Central Venous Catheter Associated Thrombosis in Congenital Heart Disease Patients: A Preliminary Analysis of the Children's Hospital Acquired Thrombosis (CHAT) Registry

M. Silvey[1], B. Branchford[2], E. Krava[3], J. Jaffray[3], A. Mahajerin[4], S. Carpenter[1]

[1]Childrens Mercy Hospital, Division of Hematology/Oncology, Kansas City, United States, [2]Childrens Hospital of Colorado/University of Colorado, Aurora, United States, [3]Childrens Hospital of Los Angeles, Los Angeles, United States, [4]University of California, Irvine/Childrens Hospital of Orange County, Orange, United States

Background: Central venous catheters (CVCs) are associated with hospital acquired venous thromboembolism (HA-VTE). Congenital heart disease (CHD) patients often have CVC(s) due to multiple surgeries and prolonged hospitalizations.

Aims: To analyze CVC-VTE in hospitalized CHD patients.

Methods: This retrospective study identified and reviewed CHD patients with VTE within the Children's Hospital Acquired Thrombosis (CHAT) registry hospitalized from 2012-2016. CVC VTE was defined as VTE surrounding the CVC, at the CVC tip, or in the same vein where the CVC was placed.

Results: 141 of the 646 HA-VTE pts were found to have CHD. 131 pts had at least one CVC placed during admission. 327 CVCs were placed in CHD pts and most were PICCs, temporary femoral, or temporary jugular lines (Figure 1). Most CVCs were placed in the upper extremity (54%). 106 VTEs were CVC-related with 32% of CVCs developing VTE (Table 1). Multi-lumen CVCs had a higher number of VTE compared to single lumen CVCs. The first CVC placed in each patient had a higher number and percentage of VTE (72 and 54.9%, respectively) compared to subsequent lines (34 and 17.3%, respectively). PICCs had the highest number of VTE (59) while the highest percentage of VTE were with temporary femoral lines (53.7%). 34 patients developed CVC-related VTE despite mechanical, chemical, or combined VTE prophylaxis (Table 1). Of the 85 CVCs placed in these patients, 24.7% developed CVC-VTE (21/85).

Conclusions: CVCs were a main contributor to VTE formation in CHD patients. The most CVC-VTE cases were with the initial CVC, PICCs, and multi-lumen CVCs. Those receiving mechanical and/or chemical prophylaxis had a lower VTE to CVC percentage than the overall cohort, suggesting some protective effect from these prevention strategies. Future analysis will include control patients for direct comparison of purported risk factors.

Figure 1.

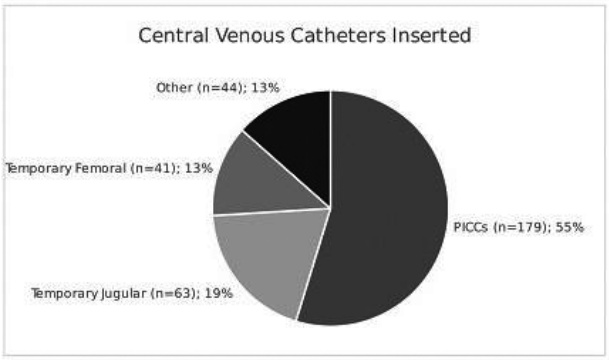

Figure 1. A total of 327 Central Venous Catheters (CVCs) were placed in congenital heart disease patients who developed VTE. The majority of CVCs placed were peripherally-inserted central catheters (PICCs) followed by temporary jugular lines and temporary femoral lines.

FIGURE 1 Central venous catheters placed in congenital heart disease patients who developed VTE

TABLE 1 CVC Related VTE Relating to CVC type, Number of Lumens, and VTE prophylaxis in subjects with congenital heart disease

	CVC Related VTE	Number of CVCs Placed	VTE per CVC percentage
All Lines	106	327	32.4%
PICC Lines	59	179	33%
Temporary Femoral Lines	22	41	53.7%
Temporary Jugular Lines	17	63	27%
Other	8	44	18.2%
Single Lumen	17	70	24.2%
Multi-Lumen	89	258	34.5%
Mechanical and/or Chemical Prophylaxis	21	85	24.7%
No Prophylaxis	85	242	35.1%

PB 1249 | Neutrophil Extracelular Traps (NETs) and Inflammatory Biomarkers in Patients with Hereditary Spherocytosis. Influence of Splenectomy

C. García[1], A. Moscardó[2], S. Izquierdo[1], A.M. Latorre[2], B. Argiles[1], M.T. Santos[2], J. Vallés[2], M.Á. Dasí[1]

[1]*University and Polytechnic Hospital La Fe, Department of Pediatric Hematology, Valencia, Spain,* [2]*Health Research Institute La Fe, Hemostasis, Thrombosis, Atherosclerosis, and Vascular Biology, Valencia, Spain*

Background: NETs formation is part of the immune response but it has been related to thrombotic processes. In patients with hereditary spherocytosis (HS), splenectomy increases risk of sepsis by encapsulated bacteria and probably with a long-term increase in thrombotic risk.

Aims: To analyze NETs (cell-free-DNA, citrullinated histone 3 (CitH3)), and inflammatory markers (RANTES, CXCL5 and HMGB1), in children diagnosed with HS with and without splenectomy, as potential factors involved in potential thrombotic risk increase.

Methods: Children (n=48) were recruited, male 60.5%; mean age 11.1 years (SD 3.9). They were classified into 3 groups: healthy control (n=16), children with HS non-splenectomized (n=16) and children with HS who were splenectomized (n=16). NETs and inflammatory markers were analyzed in plasma by ELISA. Parametric test (ANOVA), non-parametric test (Kruskal-Wallis) and Pearson correlation were used. $P < 0.05$ was considered significant. The study was approved by the ethical Committee of the Hospital La Fe. All patients or their proxy gave their written informed consent.

Results: DNA, HMGB1 and RANTES were significantly elevated in HS vs. controls (Table 1). HS splenectomized patients had higher CitH3 and inflammatory markers when compared to HS patients without splenectomy, except for DNA.

TABLE 1 NETs and inflammatory markers in HS. * HS vs control. # HS+splenectomy vs control. †HS+splenectomy vs HS

		Controls	Patients		P
			HS	HS+ splenectomy	
NETs	DNA	424,5	798,1	645,8	0.0001*#
	CitH3	0,168	0,157	0,207	0.057
Inflammatory markers	CXCL5	89,4	82,5	304,5	0.082
	HMGB1	1,43	1,7	2,38	0.0019#†
	RANTES	242,1	286,9	411,9	0.0087#†

Conclusions: NETs are significantly elevated in patients with HS, particularly in those with splenectomy. There is a link between NETs and inflammatory markers in our patients. The elevation of these biomarkers could be related to the thrombotic risk in patients with HS. Grants. FIS13/00016. ACIF/2016/465. PB 1250 | Paget-Schroetter Syndrome in Children and Young Adults: The Bane of Athletes of Either Gender

D. Warad[1], A. Nageswara Rao[1], R. Pruthi[2], V. Rodriguez[1]

[1]*Mayo Clinic, Division of Pediatric Hematology Oncology, Rochester, United States,* [2]*Mayo Clinic, Division of Hematology, Rochester, United States*

Background: Paget-Schroetter syndrome (PS) or thoracic outlet (TO) venous thrombosis occurs in approximately 2/100,000 individuals and is provoked by excessive overhead activity. Typically, PS occurs in the dominant arm of young athletic males (2:1) 18-30 years of age.
Aims: To review the presentation, management, and outcomes of PS in young individuals < 19 years of age treated at Mayo Clinic between 2000-2016 with a minimum follow-up of 10-weeks.
Methods: Retrospective chart review and analysis.
Results: Of 30 eligible patients, 28 (93%) were athletes or had excessive overhead activity. Median age was 16.8 years (range 12-18.7 years). Gender distribution was nearly equal with similar characteristics.

TABLE 1 Gender-based patient characteristics

Characteristics	Males (n=16)	Females (n=14)	p-value
Median age in years (range)	16.6 (15.0-18.4)	17.2 (12.0-18.7)	0.308
Median body mass index (range)	23.0 (19.1-43.7)	22.5 (19.1-43.7, n=12)	0.403
Dominant hand thrombus (%)	14 (87.5%)	11 (78.5%)	0.051
Athlete or excessive overhead activity (%)	16 (100%)	12 (85.7%)	0.073
Median duration of anticoagulation in weeks (range)	16.5 (7-43.1)	19.1 (4.1-48.3)	0.442
Thoracic outlet decompression surgery (%)	10 (62.5%)	11 (78.6%)	0.333
Median months from thrombosis (range)	1.9 (0.2-7.7)	3.5 (0.3-22.1)	0.098
Median duration of follow-up in months (range)	12.0 (2.64-101)	12.2 (2.82-113.6)	0.819
Complete resolution of thrombus (%)	5 (31.2%)	9 (64.3%)	0.068
Recurrent thrombosis (%)	2 (12.5%)	5 (35.7%)	0.130
Post-thrombotic syndrome (%)	7 (43.7%)	8 (57.1%)	0.463

Symptoms included edema (100%), pain (63%), and discoloration (30%). All patients were anticoagulated (unfractionated/low molecular weight heparin and/or warfarin/rivaroxaban) and 23 (77%) underwent thrombolysis (catheter-directed n=18, pharmacomechanical n=3, systemic n=2) while 21 (70%) underwent TO decompression surgery resulting in complete thrombus resolution in 14 (47%). Median duration of follow-up was 12 months (range 2.6-113.6 months). Recurrent thrombosis noted in 7 (23%) at median 2.25 months (range 0.29-15.6 months) and 15 (50%) had post-thrombotic syndrome. Of the 20 (67%) that had thrombophilia workup, 6 (20%) revealed heterozygous factor V Leiden (n=5), heterozygous prothrombin gene mutation (n=1), or elevated fibrinogen (n=1). Median duration of anticoagulation was longer in known thrombophilia patients at 33.7 weeks (range 16.7-48.2 weeks) compared to those without (14.8 weeks, range 4.1-43.1 weeks), p=0.010.
Conclusions: Young female athletes are prone to develop PS with presentation, course, and outcomes indistinguishable from males. Successful outcomes can be achieved with early recognition and multimodal treatment including anticoagulation, endovascular intervention, and surgical TO decompression.

PB 1251 | The Association between Central Venous Catheter Placement and Central Venous Catheter Related Thrombus

S. Jones[1,2,3], J. Rutgers[4], P. Monagle[1,2,4], W. Butt[1,5], F. Newall[1,2,3]

[1]*The University of Melbourne, Department of Paediatrics, Parkville, Australia,* [2]*The Royal Children's Hospital, Department of Clinical Haematology, Parkville, Australia,* [3]*The University of Melbourne, Department of Nursing, Parkville, Australia,* [4]*Murdoch Research Childrens Institute, Haematology Research, Parkville, Australia,* [5]*The Royal Children's Hospital, Paediatric Intensive Care Unit, Parkville, Australia*

Background: Over 50% of thromboses in children are related to central venous catheters (CVCs). Recently, an increased focus upon concomitant risk factors for CVC-related thrombosis has emerged.

Aims: To describe the contribution site of CVC placement has upon the incidence and sequelae of CVC-related Venous-Thromboembolism (VTE) in acutely unwell children during their pediatric intensive care unit (PICU) admission.

Methods: A prospective cohort study recruited children admitted to a PICU requiring a CVC in the jugular or femoral veins. The study was approved by the hospital ethics committee and informed consent was obtained. Each child had a (blinded) ultrasound of the blood vessel in which the CVC was placed during their admission (Phase I). A second ultrasound was performed approximately 24 months following CVC placement (Phase II).

Results: 21.9% of the children in our cohort developed a CVC-related VTE of which 6.2% (n=2) were symptomatic (both femoral CVCs). This study showed a significantly higher incidence of VTE in children with a femoral CVC at phase II (Table 1). The incidence of clinically significant Post Thrombotic Syndrome (PTS) in was 1.6% (n=2), occurring only in children with femoral CVCs. Despite 18.5% of children with jugular CVCs having radiologically confirmed thrombosis at Phase 1 (all asymptomatic), none developed clinically significant PTS.

TABLE 1 Femoral or Jugular CVC placement and CVC-related Thrombus at Phase I and Phase II

	Normal	Thrombus	P Value (Chi Square)	Odds Ratio (95% CI)
Phase I				
Jugular	92	21	0.72	1.27 (0.16 to 9.9) p=0.8
Femoral	22	11	0.72	1.27 (0.16 to 9.9) p=0.8
Phase II				
Jugular	87	8	0.002	26.17 (1.5 to 443.2) p=0.02
Famoral	17	8	0.002	26.17 (1.5 to 443.2) p=0.02

Conclusions: Children with a femoral CVC have a greater risk of residual CVC-related VTE approximately 2 years post-CVC placement. The study demonstrated no risk of clinically significant PTS in children with asymptomatic jugular vein thrombosis. These findings suggest that children with femoral CVCs present a higher risk of clinically significant thrombosis and thrombosis-associated morbidity at follow up 2 years post CVC.

PB 1252 | Acute Ischemic Stroke in Children on Left Ventricular Assist Device. Is There a Role For Endovascular Treatment?

M. Hunfeld[1], H. van Ommen[2], B. Emmer[3], A. van Es[3], U. Kraemer[4], R.J. Houmes[1], D. Tibboel[1], O. Erdem[1]

[1]Erasmus Medical Center - Sophia Children's Hospital, Intensive Care and Department of Pediatric Surgery, Rotterdam, The Netherlands, [2]Erasmus Medical Center - Sophia Children's Hospital, Department of Pediatric Hematology, Rotterdam, The Netherlands, [3]Erasmus Medical Center, Department of Radiology, Rotterdam, The Netherlands, [4]Erasmus Medical Center - Sophia Children's Hospital, Department of Pediatric Cardiology, Rotterdam, The Netherlands

Background: Left ventricular assist devices (LVADs) are being increasingly used as a bridge to heart transplant in children with end-stage heart failure. However, about 30 to 40% of the children on LVADs develop acute ischemic strokes (AIS). Children with severe neurological deficits are being excluded from a heart transplant. As a consequence, they will die after retrieval of the LVAD. In adults, endovascular treatment has improved outcome in patients with AIS and has become standard of care in patients with an occlusion of a cerebral artery. In children, only case-reports and small case-series are available.

Aims: Despite lack of evidence, endovascular treatment can be considered in children with severe AIS on LVADs to improve outcome.

Methods: A local guideline on endovascular treatment in children on LVAD was developed in the Sophia Children's Hospital ErasmusMC, the nationwide pediatric cardiac transplant center, with 4 children on LVADs a year, in order to quickly detect, diagnose and treat AIS.

Results: Since 2015 3 children on LVAD were identified with severe AIS and underwent endovascular treatment.

Patient 1, was an 11 year old girl, on LVAD day 13 she developed an AIS with an occlusion of the left MCA (M1 and M2). A mechanical thrombectomy was performed with complete neurological recovery. 8 days later she developed a massive intracerebral hemorrhage and as a result she died.

Patient 2, was a 3 year old girl, on LVAD day 17 she developed an AIS with an occlusion of the distal intracranial carotid artery. A mechanical thrombectomy was performed with complete neurological recovery. The following days she developed multiple strokes as a result of a sepsis and died.

Patient 3, was a 14 month old girl, on LVAD day 40 she developed an AIS with an occlusion of the left MCA (M1). A mechanical thrombectomy was performed without any signs of recovery .

Conclusions: Endovascular treatment in children with severe AIS on LVAD is feasible but should be further investigated in international prospective studies.

PB 1253 | Thrombotic and Hemorrhagic Complications in Pediatric Recipients of Hematopoietic Stem Cell Transplant (HSCT): Mayo Clinic Experience

D. Kaur[1], A. Ashrani[2], R. Pruthi[2], S. Khan[1], K. Bailey[3], V. Rodriguez[1]

[1]Mayo Clinic, Pediatric and Adolescent Medicine, Division of Pediatric Hematology/Oncology, Rochester, United States, [2]Mayo Clinic, Divisions of Hematology and Laboratory Medicine & Pathology, Rochester, United States, [3]Mayo Clinic, Biomedical Statistics and Informatics- Health Sciences Research, Rochester, United States

Background: Hemorrhagic (HE) and thromboembolic event (TE) incidences in adult HSCT recipients have been reported; however, these complication rates in pediatric HSCT population are unknown.

Aims: To characterize HE and TE events in pediatric HSCT patients.

Methods: Clinical characteristics, HE, TE and follow up data up to one year were abstracted from medical records on patients aged < 21 years undergoing HSCT between July 2000-June 2015.

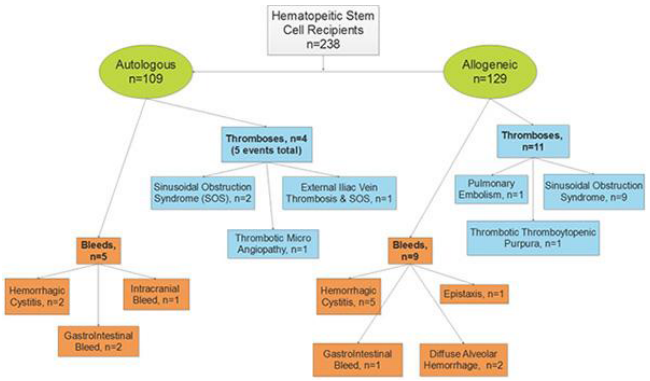

FIGURE 1 Types of Hemorrhagic and Thrombotic Events

Results: During study period, 238 pediatric patients underwent HSCT. Type of HE/TEs are shown in Fig. 1.

Incidence of "HE or TE" was higher in allogeneic HSCT compared to auto HSCT (p=0.02, Table 1). Median time from HSCT to acute TE was 11 days (range; -2 to 59) and 25 days (range; -7 to 46) for acute HE. The proportion of affected patients with ***both*** HE and TE was higher in autologous group (p=0.028). Median time to platelet engraftment for allogeneic and autologous populations was 27 and 29 days, respectively. All patients who had HE had platelets < 50,000 $x10^9$/L and one had platelets < 20,000 $x10^9$/L at time of HE. All patients with hemorrhagic cystitis (n=7) had received cyclophosphamide (Cy). For patients with sinusoidal obstruction syndrome, conditioning had included either busulfan (Bu)/Cy (n=5) or Cy with total body irradiation (n=4), or Thiotepa (n=2). Amongst allogeneic HSCT recipients, 60% of HE and 92% of patients with TE had underlying myeloid neoplasms. HE and TE were managed through supportive medical care. Median time to resolution of symptoms was 8 days (range; 1-53). One patient with thrombotic microangiopathy required renal transplant.

TABLE 1 Patient and Transplant Characteristics (Total Study Population = 238)

Characteristics in Subgroup	Autologous Recipients, n=109	Allogeneic Recipients, n=129	Analyses of Significance
Median Age in yrs. (range)	14.8 (0.9-20.9)	12.3 (0.6-20.9)	
Male sex (%)	66 (60.1%)	75 (58.1%)	
Underlying Diagnoses (%)			
Hematologic	32 (29.4%)	120 (93%)	
Solid tumor	77 (70.6%)	9 (7%)	
Any hemorrhagic or thrombotic complication -	6 (5.5%)	19 (14.7 %)	p= 0.02 for difference in frequency
Hemorrhagic	2 (1.8%)	8 (6.2 %)	
Thrombotic	1 (0.9%)	10 (7.8 %)	
Both Bleed & Thrombosis	3 (2.8%)	1 (0.7 %)	p=0.028 for difference in distribution

Conclusions: Allogeneic pediatric HSCT patients have higher risk of hemorrhagic and thrombotic complications compared to autologous HSCT, perhaps due to intensity of the preparative regimen, especially in the setting of myeloid neoplasms. True incidence of thrombotic complications might be underestimated especially in presence of central venous lines as radiographic surveillance for thromboses is not routine for asymptomatic patients.

PB 1254 | Venous Thromboembolism in Children with Hodgkin´s Lymphoma

D. Evstratov, P. Zharkov, L. Potapenko, A. Pshonkin, N. Myakova

Federal Research Clinical Centre of Pediatric Hematology Oncology and Immunology N.A. D. Rogachev, Moscow, Russian Federation

Background: Data about venous thromboembolism (VTE) epidemiology and risk factors in children with cancer, especially Hodgkin´s Lymphoma (HL) is lacking.

Aims: To estimate frequency and evaluate risk factors of VTE in children with HL.

Methods: Retrospective analysis of medical chart records of 58 inpatients up to 18 yo (3-17.5) with HL, since 1 January 2013 to 1 September 2016 had been performed. All patients had finished treatment according to GPOH-HD-2002 protocol. All episodes of DVT were confirmed by standard radiological methods and ultrasound investigation. Screening for asymptomatic thrombosis was performed before planting and removing of central venous catheters (CVC). All patients had CVCs. Influence of sex, age, stage, B-symptoms, treatment group, involvement of mediastinum, bulky mediastinum had been analyzed using Chi-square test with Yates correction where available (The R Foundation software, The R Project, Vienna, Austria).

Results: During the analyzed period, twelve (20.7%) of 58 patients developed VTE. VTE was symptomatic in 41.7% (n=5) of cases. Most frequently VTE occurred in the basin of v. cava superior (VCS, 66.7%, n=8), less of the patients had VTE in the basin of v. cava inferior (VCI, 16.7%, n=2). In one case there was combined VTE VCI+VCS and one patient had VTE in right atrium. One patient with VCI thrombosis had 2 episodes of PE.

Most of VTE episodes occurred during induction (58,3%, n=7) and consolidation (25%, n=3) of remission period of treatment. One (8,3%) episode was diagnosed at the primary diagnostic and one (8,3%) - during radiation therapy.

VTE was CVC-associated in 75% (n=9) cases. In the rest of 25% (n=3) all episodes were symptomatic and were strongly associated with vein compression by tumor.

None of risk factors, except therapeutic group (p=0.05), had influence on developing of VTE episodes.

Conclusions: VTE is a frequent complication of HL. We consider that advanced stages with big tumor burden can be potential risk factors for big prospective studies.

PB 1255 | Thrombin Generation in Venous Thromboembolism, Arterial Ischaemic Stroke and Bleeding Events in Children

V. Ignjatovic[1,2], S. Thedieck[3], P. Monagle[1,2,4], U. Nowak-Goettl[3]

[1]Murdoch Childrens Research Institute, Haematology Research, Parkville, Australia, [2]The University of Melbourne, Department of Paediatrics, Parkville, Australia, [3]Thrombosis and Haemostasis Treatment Center, UKSH- Campus Kiel und Lübeck, Institute of Clinical Chemistry, Kiel, Germany, [4]Royal Children's Hospital, Department of Clinical Haematology, Parkville, Australia

Background: Venous thromboembolism (VTE), arterial ischaemic stroke (AIS) and bleeding in children are associated with high morbidity and mortality, and significant long-term side effects that impact on quality of life. Whilst previous studies investigated individual haemostatic parameters in these paediatric cohorts, thrombin generation (TG) as a global assay of haemostasis has not been studied in this setting.

Aims: To measure TG in children with clinically relevant thrombotic or haemorrhagic events.

Methods: Blood was collected 6 to 12 mths post first manifestation from children with thromboembolism (VTE/AIS) and inherited bleeding disorders. Asymptomatic siblings (VTE/AIS) or healthy subjects (bleeding) served as controls. Frozen aliquots of platelet free plasma were used for the TG assay (Innovance® ETP test, Siemens) on the BCS-XP analyser (Siemens). The endogenous thrombin potential (ETP) and maximum concentration of thrombin generated (CMax) were calculated.

Results: The total number of participants in each cohort was: controls, n=256; VTE, n=63; AIS, n=56; bleeding, n=50. Samples from siblings were matched for 17 VTE and 18 AIS patients. Figure 1 summarizes the main results. One or both TG parameters were decreased in the setting of VTE, AIS and bleeding, compared to controls. There was no difference in TG in children with VTE compared to their siblings, but CMax was decreased in children with stroke compared to their siblings and when compared to the VTE cohort. ETP was decreased in children with VTE treated with heparin and both TG parameters, were reduced in those treated with VKA, compared to controls.

Conclusions: Clinical events such as VTE, AIS and bleeding have an impact on TG parameters in children. Matching clinical cases to their siblings can be used to study the pathophysiology of thrombosis in children. Whilst more detailed studies are needed, TG has the potential to be used as a clinical tool for identification of children at risk of VTE, AIS or bleeding and/or to guide anticoagulant therapy.

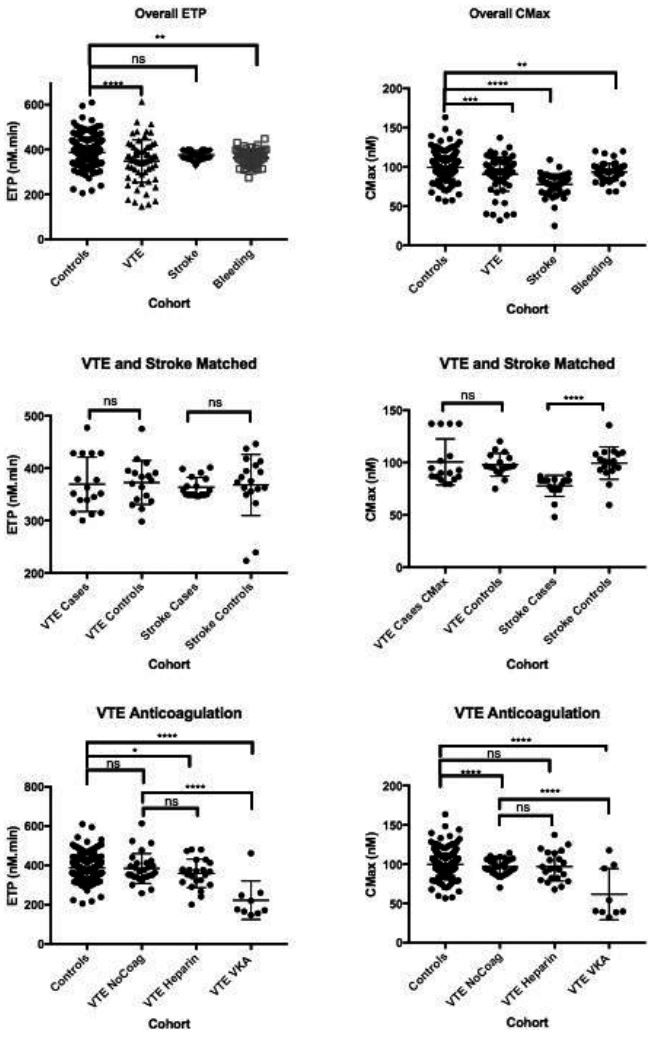

FIGURE 1 Summary of the main results (ETP and CMax)

PB 1256 | Paroxysmal Nocturnal Hemoglobinuria Spectrum among Pediatric Age Group of Patients: Single Center Experience without Any Thrombotic Events

S. Unal, F. Gumruk, M. Cetin

Hacettepe University Faculty of Medicine, Ihsan Dogramacı Children's Hospital, Ankara, Turkey

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is rare in childhood and children with PNH usually presents in the form of aplastic anemia phenotype or overlapping phenotype. Whereas the classical hemolytic form of the disease is less common. PNH is a disease that may cause thrombotic complications and the size of the clone has not been related to predict the risk of thrombotic events.

Aims: PNH is one of the acquired thrombophilic states and the data on the presentational findings and thrombotic events in these patients is limited among children.

Methods: Local Ethical Committee approval is present. Between 2013 and 2016, 14 acquired aplastic anemia patients, 4 patients with undefined hemolytic anemias and 1 patient with recurrent thrombosis of more than 3 times were screened with FLAER for the presence of PNH clones. Two of the patints with aplastic anemia were tested for PNH clones after complete response (CR) to immune-supressive treatment (IST).

Results: None of the patients with undefined hemolytic anemias and the patient with recurrent thrombosis were found to be positive for PNH clones. On the other hand, of the 14 patients with aplastic anemia, 8(57%) were found to be PNH clone positive. The median age of the PNH clone positive patients were 12 years(8-17). CR to IST was 85.7% among clone positive patients, whereas 67% among clone

negative patients. Three patients underwent stem cell transplantation. Of the PNH clone positive 8 patients, 2(25%) were classified as overlapping PNH syndrome and these patients had typically higher clone sizes compared to those with isolated aplastic anemia (median erythrocyte, neutrophil, monocyte clone sizes 17%, 52.5%, 46.5 vs 0.35%, 1.39% vs 0.7%) . None of the patients with clone positivity developed thrombotic events, but one patient who persistently had high clones despite IST response , developed hemolytic attacks in the course and eculizimab was initiated for thrombo-prophylaxis.

Conclusions: In childhood, classical PNH presentations and thrombotic events are rare.

PB 1257 | Incidence and Risk Factors for Childhood Thrombosis: Ten Years Experience of a Paedatric Hematology Center from Turkey

A. Meral Güneş[1], B. Baytan[1], M. Sezgin Evim[1], T. Ersoy Kuzucu[2]

[1]*Uludag University, Pediatric Hematology, Bursa, Turkey,* [2]*Uludag University, Pediatrics, Bursa, Turkey*

Background: Either incidence or knowledge about childhood thrombosis is increasing within the last decades.

Aims: This study evaluated incidence, risk factors, age, gender, family history, symptoms, location and treatment of thrombosis among hospitalized children.

Methods: Clinical and laboratory results of 150 patients diagnosed with thrombosis between 2005-2015 were retrospectively examined.

Results: The annual frequency of thrombosis among hospitalized patients was found 40/10.000. Male/female ratio and the mean age were 60/40 and 83 months (0-338 M), respectively. Of them, 8.6% was neonates. Majority of the events were venous 88.7% and the rest was arterial 11.3%. Thrombosis frequently occurred in cranial 48.7% site followed by lower extremities 26.7% and cardiac 10.7%. Mutation analysis sent from 129 patients. FV Leiden was the most common mutation 20.2%. Congenital and environmental risk factors were simultaneously present in 30.2% of children. No congenital mutation was observed in 8.5% of the cases. Infection 37.6%, catheter 34.1% and congenital heart disease 32.9% were the most frequent environmental risk factors. The majority of children 81.1% were treated with low molecular weight heparin. Four patients with cardiac thrombosis were successfully treated recombinant tissue plasminogen activator. Three neonatals (2.7%) with intraventricular cardiac thrombosis required thromboembolectomy. Treatment-related complication of which was bleeding occurred despite of anti-coagulant therapy. Thrombosis-related mortality was not detected. However, 3% patients were lost due to the underlying disease.

Conclusions: Thrombosis is a multifactorial disorder. In the current data, acquired, respectively. They were combined in 30.2% of children. However, 20.9% of children had none of these factors. Thrombotic disorders during childhood are better defined and treated in our decade with the new approaches.

PB 2162 | ISTH DIC Score is Associated with Mortality in Children with Disseminated Intravascular Coagulation

B. Pongtanakul, C. Wangkittikal, N. Narkbunnam

Faculty of Medicine, Siriraj Hospital, Mahidol University, Pediatrics, Bangkok, Thailand

Background: Disseminated intravascular coagulation (DIC) is an acquired consumptive coagulopathy and intravascular fibrin formation and deposition. DIC is associated with high mortality rate in children. The international society on thrombosis and haemostasis (ISTH) developed ISTH DIC scoring system for diagnosis and prognosis of DIC. However, few of ISTH DIC scoring data was studied in pediatric setting.

Aims: To compare the mortality rate of children who diagnosed with DIC by using ISTH DIC score.

Methods: A retrospective study was performed in children age from 28 days to 15 years who diagnosed with DIC from 2005 to 2014 at Siriraj hospital in Thailand.

Results: Two hundred and forty-four patients (118 boys, 126 girls) were enrolled. One hundred and seventy nine (73.4%) and 65 (26.6%) patients were overt DIC and non-overt DIC, respectively. The common etiologies of DIC were infections (84.4%) followed by tissue injuries (7%) and malignancies (2.9%).The mortality rate of overt DIC patients (76%) was statistically significant higher than non-overt DIC patients (15.4%) ($p< 0.001$). The higher DIC score was correlated with higher mortality rate ($R^2 = 0.89$).

The clinical manifestations that associated with high mortality rate were bleeding and multi-organ dysfunction ($p< 0.001$) but thrombosis was not associated with mortality rate ($p = 0.98$). The laboratories including low platelet count, prolonged prothrombin time and high D-dimer were significantly associated with high mortality rate ($p< 0.01$) but fibrinogen level was not effect on mortality rate ($p = 0.14$). The patients who were admitted in ICU and treated with inotropic drugs, ventilator support, dialysis, albumin and blood component transfusion were significantly increase the mortality rate ($p< 0.001$).

Conclusions: Children with overt DIC had higher mortality rate than children with non-overt DIC. The higher ISTH DIC score was associated with higher mortality. The ISTH DIC score can be used to predict prognosis of DIC in children.

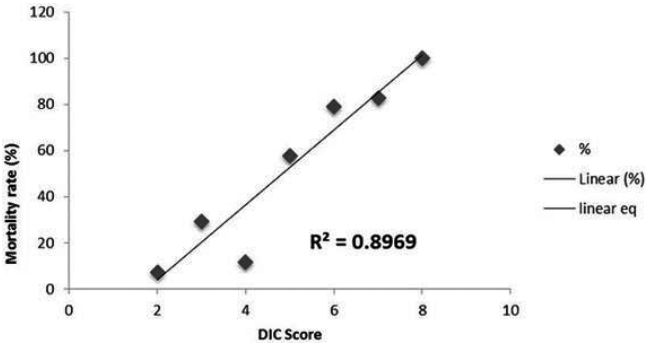

FIGURE 1 Correlation between ISTH DIC score and mortality rate.

PB 2163 | Out of Sight, Out of Mind - The Acquired von Willebrand Syndrome is a Bleeding Cause in Disguise during Congenital Heart Disease Surgery

V. Icheva[1], M. Nowak-Machen[2], C. Schlensak[3], K. Jaschonek[4], U. Budde[5], M. Hofbeck[1], G. Wiegand[1]

[1]University Childrens Hospital Tübingen, Pediatric Cardiology and Intensive Care Medicine, Tübingen, Germany, [2]University Hospital Tübingen, Anestesiology and Intensive Care Medicine, Tübingen, Germany, [3]University Hospital Tübingen, Thoracic, Cardiac and Vascular Surgery, Tübingen, Germany, [4]University Hospital Tübingen, Clinic for Internal Medicine, Tübingen, Germany, [5]Asklepios MVZ Nord GmbH, Hamburg, Germany

Background: Cardiac surgery of the newborn and infant with complex CHD (congenital heart disease) is afflicted by a high rate of intraoperative bleeding complications. In the context of (congenital) cardiac disease, acquired von Willebrand syndrome (AVWS) has previously been associated with patent ductus arteriosus (PDA) or severe valvular stenosis. There is no published data on its intraoperative incidence after cardiopulmonary bypass (CPB) in infants with CHD.

Aims: To investigate the pre- and intraoperative incidence of AVWS in newborn and infants with CHD and its impact on intraoperative bleeding.

Methods: We screened 12 consecutive newborn and infants undergoing complex cardiac surgery for AVWS before and immediately after CPB intraoperatively. The investigated parameters included FVIII-Levels, vWF:Ag, vWF:CB, vWF:RCoF and multimer analysis. The coagulation therapy followed a ROTEM-based algorithm. The intraoperative bleeding was assessed indirectly by comparing the amount of substituted coagulation factors and blood products.

Results: AVWS was detected in 10 out of 12 (83%) patients before surgery. Although vWF:Ag, vWF:CB and vWF:RCoF increased significantly after CPB, still 8 out of 12 patients (66%) were diagnosed with AVWS. The patients with and without intraoperative AVWS did not differ in the volumes of transfused blood products and fibrinogen concentrate, but the ones with AVWS needed significantly higher amount of Prothrombin Complex Concentrate. Nevertheless, all patients were massively transfused due to strong intraoperative bleeding, so it was not possible to detect significant differences in the small cohort.

Conclusions: This data reveal a new possibility to treat intraoperative bleeding during high risk cardiac surgery of the newborn by substitution of von Willebrand Factor concentrate. The high incidence of AVWS is probably due to shear stress caused by valvular or vascular stenosis. Further causes still need to be investigated in a larger cohort.

PB 2164 | International Survey of the Management of Disseminated Intravascular Coagulation among Pediatric and Neonatal Health Care Practitioners

Z. Solh[1,2], R. Rajagopal[3], J. Thachil[4], A. Chan[1], N. Heddle[1], P. Monagle[3]

[1]McMaster University, Hamilton, Canada, [2]Canadian Blood Services, Hamilton, Canada, [3]Royal Children's Hospital, Melbourne, Australia, [4]Manchester Royal Infirmary, Manchester, United Kingdom

Background: ISTH developed a diagnostic scoring system for disseminated intravascular coagulation (DIC) which has been used widely in adult intensive care units. However, controversies exist in pediatric DIC care regarding choice of diagnostic tests.

Aims: To evaluate current practice in pediatric/neonatal DIC management among neonatologists (NICU), pediatric intensivists (PICU), hematologists/oncologists (PHO), emergency physicians, and general pediatricians.

Methods: An online survey (LimeSurvey software) was developed; 3 sections: Respondent Demographics; DIC Diagnosis; DIC Management. It was internationally disseminated via professional societies. Study coordinated by Hamilton (Canada) and Melbourne (Australia) in collaboration with Manchester (England) and members of ISTH Pediatric and DIC SSC. Data collected January - September 2016.

Results: 211 responses: 160 full, 51 partial. 133 (63%) respondents from PHO, 45 (21%) NICU, and 23 (11%) PICU. Geographic distribution: 96 (46%) North America, 56 (27%) Asia, 25 Australia (12%), 24 Europe (11%). The most frequent cause of DIC was sepsis (163/211; 77%), mostly bacterial. To investigate DIC, 79 (42%) respondents use clinical experience only, 52 (28%) use the ISTH guidelines, 28 (15%) use local institutional guidelines. Of those who use only clinical experience, 96% order a platelet count and over 80% order INR, PT, aPTT, fibrinogen, and D dimer. Fibrin degradation products and smears for schistocytes are ordered by 28% and 41%, respectively, while thromboelastography (TEG) is ordered by 6% of respondents. Transfusion of platelets (69%), plasma (64%) and cryoprecipitate (47%) were the most common treatments, while antithrombin (18%), fibrinogen concentrate (16%), antifibrinolytics (9%), unfractionated heparin (9%) and LMWH (5%) were less common. Barriers to using standard DIC guidelines were identified.

Conclusions: Survey reveals variable practices in pediatric/neonatal DIC. Adult guidelines are not widely accepted in pediatrics. Pediatric DIC guidelines are needed.

PB 2165 | Efficiency and Safety of Off-label Use of Recombinant Activated Coagulation Factor VII (rFVIIa) in Pediatric Oncological and Hematological Patients

D. Fedorova, P. Zharkov, A. Pshonkin

Federal Research Clinical Centre of Pediatric Hematology, Oncology, and Immunology named after D. Rogachev, Moscow, Russian Federation

Background: Recombinant FVIIa is often used off-label as a rescue therapy when conventional measures failed. But data on efficiency and safety of off-label rFVIIa use are scarce.

Aims: To analyze efficiency and safety of off-label use of rFVIIa in critically ill children.

Methods: Data were collected retrospectively. Efficacy was scored subjectively on a 3-point scale (complete, partial, or no response). Second endpoints were measurement of transfusion of red blood cells (RBC), platelets, fresh frozen plasma (FFP) in the 24 hours prior to and following use of rFVIIa. All thrombotic events within 7 days from last rFVIIa dose were recorded as adverse events.

Results: Final analysis included 92 cases of rFVIIa use in 65 patients aged from 2 months to 18 years.

TABLE 1 Patient primary context and 30-day mortality

Underlying diagnosis	No. (%)	30-day mortality, No. (%)
Acute leukemia and lymphomas	22 (34)	6 (27)
Primary Immunodeficiency	9 (14)	2 (22)
Congenital and acquired bone marrow failure	8 (12)	5 (63)
Solid malignant tumors	13 (20)	2 (15)
Blood vessel tumors and malformations	4 (6)	1 (25)
Others	9 (14)	1 (11)
HSCT recipients		
Yes	16 (25)	8 (50)
No	49 (75)	9 (18)

In 18 cases rFVIIa was applied to terminate surgical bleeding. Others most frequent indications were gastrointestinal (21 cases), pulmonal (12) and nasal bleeding (12). The median initial therapeutic dose was 75mcg/kg (IQR 44-98). Complete response was achieved in 52% of cases and in 21% there was partial response. There was not statistically significant correlation between severity of thrombocytopenia and efficiency of rFVIIa. In multivariate analysis, only severe hemodynamic instability before administration was independently associated with poor response to first dose. The need of transfusion of RBC declined (13,6 ml/kg VS 0 ml/kg, p=0,0011) after rFVIIa use. But there were no reduction in use of platelets and FFP. Four (6%) of 65 patients developed a thrombotic adverse event (TAE) up to 7 days after rFVIIa application. Initial and total doses of rFVIII in these patients did not exceed the corresponding values in those without thrombosis (p=0,71 and p=0,68, respectively). All patients with TAE were younger than 3 years and had multiple additional risk factors of thrombosis.

Conclusions: Use of rFVIIa is effective and generally safe for management of severe bleeding in children including patients with profound thrombocytopenia.

PB 2166 | Intracranial Hemorrhage in Children with Immune Thrombocytopenic Purpura: A Systematic Review

S. Khaliq[1], M. Rehan[2], S. Saeed[2], L. Zafar[3], Lubna Zafar

[1]*Fauji Foundation Hospital Rawalpindi/Foundation University Medical College, Pathology, Rawalpindi, Pakistan,* [2]*Fauji Foundation Hospital Rawalpindi/Foundation University Medical College, Rawalpindi, Rawalpindi, Pakistan,* [3]*Foundation university medical college, Rawalpindi, Pakistan*

Background: Immune thrombocytopenic purpura (ITP) in children is usually a self-limiting disorder however intracranial hemorrhage (ICH) is its rare but most serious complication which leads to significant morbidity/mortality. The incidence, characteristics, predictive factors and outcome of ICH in children with ITP has not been fully established.

Aims: Systematic review of literature to identify the incidence,age of onset, mean platelet count, predictive factors, clinical characteristics and outcome of ICH in children with ITP.

Methods: Literature search (1954-2016) on ICH in children with ITP was performed by two independent reviewers using PubMed, Embase and Cochrane. Articles were included if they described ICH in children with ITP. Pooled estimates expressed as percentage (%) with 95% Confidence Interval (CI) were generated using the inverse-variance weighted method in random-effect models.

Results: 21 articles met our inclusion criteria (5 institutional surveys, 7 case-series, 1case-control study, 8 case reports). Total 143 children with ICH were identified with an occurrence of 0.9% (95% CI= 0.4-1.3).Median age was 11 years (range = 0-17 years). Mean platelet count at the time of ICH was 9 ± 3 X 10^{9}/L. A total of 34% (95% CI= 20-51) had acute ITP, 19% (95%CI= 8-27) persistent ITP and 47% (95% CI=28-67) had chronic ITP. Only 28 %(95% CI= 18-36) of children had identifiable risk factors, the commonest was head trauma reported in 19% (95% CI= 8-30) of total cases of ICH in childhood ITP. Despite being on treatment ICH was fatal in 37% (95% CI= 19-55) of the children, 12% (95% CI=4-19) had significant neurological sequelae while 51% (95% CI= 36-70) children recovered fully with no neurological sequelae.

Conclusions: ICH in children with ITP tends to occur more frequently during chronic ITP. Large-scale prospective trials are needed to assess possible predictive factors. This systematic review constitute an essential step to identify ICH and the rationales for further clinical studies on ICH in children with ITP.

PB 2167 | Comparison of 3 Current Disseminated Intravascular Coagulation (DIC) Scores in Pediatric Intensive Care Unit (PICU)

R. Natesirinilkul, W. Padungmaneesub, S. Reungrongrat, S. Manowong, S. Inthapaen

Faculty of Medicine, Chiang Mai University, Pediatrics, Chiang Mai, Thailand

Background: DIC is frequently found in ICU. The DIC score defined by International Society on Thrombosis and Haemostasis (ISTH) is used worldwide. Besides ISTH score, Japanese Association for Acute Medicine (JAAM) and Japanese Ministry of Health and Welfare (JMHW) scores have been published and mainly used in adults. The studies of using those 3 scores in children were restricted.

Aims: To compare 3 DIC scores in PICU at Chiang Mai University (CMU) Hospital.

Methods: 100 subjects, aged 1 mo-18 yrs, admitted to PICU >24 hours with underlying diseases predisposing to DIC were enrolled. After the consent, complete blood count (CBC), prothrombin time (PT), fibrinogen and D-dimer were tested in all subjects at 24-48 hrs of admission. DIC was diagnosed when score ≥5 (overt) by ISTH score, ≥4 (acute phase) by JAAM scores and ≥4 and ≥7 in subjects with and without hematopoietic tumors, respectively, by JMHW score. This study was approved by IRB/EC.

Results: Sixty-two per cent were male and mean age (±SD) was 3.6 (±4.4) yrs. The prevalence of DIC by ISTH, JAAM and JMWH were 22, 54 and 16%, respectively. The prevalence of DIC was 56% when 3 scores were combined. Only 12% were diagnosed DIC by all 3 scores and 8/12 had cancers as the underlying diseases. Subjects diagnosed with DIC by ≥1 score had more bleeding symptoms (16/56 vs 4/44, *P*=.0.02) and required more transfusion (37/56 vs 19/44, *P*=.0.02) but did not have higher episodes of thrombosis than non-DIC group. Platelet count was lower (189 vs 278x10^3/uL, *P*= 0.01) and PT was prolonged in subjects with DIC (20 vs 13 s, *P*= 0.01) than in non-DIC group. Subjects with DIC did not have higher chance of death (11/56 vs 6/44, *P*=.0.43) but increase length of stay (LOS)
(99 vs 62 d, *P* = 0.01) than non-DIC group.

Conclusions: JAAM score seemed to be more sensitive than ISTH and JMWH scores for diagnosing DIC in children. Cancers were the most common cause of DIC in this cohort. DIC tends to cause bleeding, blood product use and LOS in children.

PB 2168 | Predictors of Postoperative Bleeding in Children Undergoing Cardiopulmonary Bypass: A Preliminary Italian Study

L. Spiezia, G. Di Gregorio, E. Campello, S. Maggiolo, G. Bortolussi, G. Stellin, P. Simioni, V. Vida

University of Padova, Padova, Italy

Background: Several characteristics such as demographics, pre-existing conditions, surgical procedure, perioperative coagulopathy may predispose children undergoing cardiopulmonary bypass (CPB) to bleeding complications. As yet, studies on risk factors for postoperative bleeding have brought mixed results.

Aims: The purpose of our study was therefore to retrospectively evaluate the parameters able to predict postoperative bleeding in a group of consecutive children undergoing cardiac surgery involving CPB.

Methods: We collected demographic and perioperative laboratory data, as well as intraoperative transfusion requirements and blood loss during the first 24 hours after surgery in a group of consecutive children (aged ≥ 1 month) scheduled for cardiac surgery with CPB at Padua University Hospital between June 2014 and April 2015. Cases were patients who experienced a 24-h postoperative blood loss ≥ 80th percentile.

Results: Eighty-three children (M:F 38:45; age range 1-168 months) were enrolled. In a multivariate logistic regression analysis taking into consideration surgical features, postoperative laboratory data and intraoperative transfusion requirements, age below 7.7 months (p 0.015), postoperative platelet counts lower than 109 x10^9/L (p 0.003) and postoperative D-dimer ≥2350 µg/L (p 0.007) were the variables most significantly and independently associated with excessive 24-h postoperative blood loss.

Conclusions: Although preliminary, our study identified younger age, lower postoperative platelet count and higher D-dimer plasma levels as possible risk factors for postoperative bleeding. As for coagulation parameters, our results suggested consumptive coagulopathy may cause a strong predisposition to postoperative bleeding in children. Further large-scale prospective cohort studies would provide vital insight into the early diagnosis and treatment of CPB-related coagulopathies.

PB 2169 | Clinical Utility and Mechanism of Thrombin Generation in Children with Liver Disease

W. Beatie[1], R. Kremers[2], T. Peters[2], B. de Laat[2], M. Magnusson[3], W. Hardikar[4], P. Monagle[1,5,6], V. Ignjatovic[1,5]

[1]Murdoch Childrens Research Institute, Haematology Research, Parkville, Australia, [2]Synapse BV, CARIM, Maastricht University, Maastricht, The Netherlands, [3]Karolinska Institute, Astrid Lindgren Children's Hospital, Karolinska University Hospital, MMK, Division of Clinical Chemistry and Coagulation & CLINTEC, Division of Paediatrics, Stockholm, Sweden, [4]Royal Children's Hospital, Department of Gastroenterology, Parkville, Australia, [5]The University of Melbourne, Department of Paediatrics, Parkville, Australia, [6]Royal Children's Hospital, Department of Clinical Haematology, Parkville, Australia

Background: Changes in pro- and anti-coagulant factors in children with liver disease result in adverse haemorrhagic and thrombotic events in these patients. Routine coagulation tests provide an incomplete assessment of the bleeding risk, as they are not sensitive to changes in anticoagulant factors. Thrombin generation assay (TGA), as a global measure of haemostasis could be suitable for risk prediction in children with liver disease.

Aims: To: Assess the accuracy of the TGA in predicting the risk of bleeding in children with chronic liver disease; Determine the mechanism of TG in this population, focusing on prothrombin conversion and thrombin inhibition.

Methods: Patients were categorised as having: Severe (PELD > 15) and mild (PELD < 15) disease, or a portal vein obstruction or shunt. Age and gender matched healthy controls were used. The TGA was performed on plasma samples from patients and controls with and without thrombomodulin (TM) and the results were incorporated into a computational model of thrombin decay.

Results: A total of 42 patients (severe, n=5; mild, n=29, obstruction/shunt, n=8) and 20 controls were included. Whilst there was no

correlation between TGA parameters and PELD score, the endogenous thrombin potential (ETP) correlated to the bleeding score in the presence of TM (p = 0.038) across all patient groups. The rate of prothrombin conversion, thrombin-AT formation and the thrombin decay capacity, with and without TM were reduced in severe liver disease, whilst prothrombin conversion and thrombin decay capacity were increased in patients with obstruction/shunts compared to controls.

Conclusions: ETP is an accurate marker of bleeding risk in both liver disease and portal vein obstruction/shunt. The mechanism of TG in children with liver disease is largely dependent on the concentration of prothrombin and it's availability to be converted to thrombin, as well as on the availability of AT as an inhibitor in this process.

PB 2170 | Carotid Intima Media Thickness and Obesity Phenotypes among Children and Adolescents

G. Asghari[1], P. Mirmiran[1], F. Hosseinpanah[2], P. Dehghan[3], M. Tohidi[4], F. Azizi[5]

[1]Nutrition and Endocrine Research Center, Obesity Research Center, Research Institute for Endocrine Science, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of, [2]Obesity Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of, [3]Faculty of Medicine, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of, [4]Prevention of Metabolic Disorders Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of, [5]Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of

Background: Obesity phenotypes and subclinical atherosclerosis are premature complications of excess weight.

Aims: In the current study, we sought to determine the association obesity phenotypes and carotid intima media thickness (cIMT) in overweight and obese pediatrics.

Methods: Sixty-eight overweight and obese children and adolescents (41 boys and 27 girls, age 10.4±1.7, range 7-13 years) were recruited. For the evaluation of arterial IMT, carotid scans were performed by operator according to a standardized scanning protocol for carotid arteries. Obesity phenotypes was defined based on BMI and metabolic status: metabolically healthy obese (MHO): overweight or obese (BMI ≥ 85th percentile) and ≤ 2 parameters of cardio-metabolic risk factors; metabolically unhealthy obese (MUO): overweight or obese (BMI ≥ 85th percentile) and ≥ 3 parameters of cardio-metabolic risk factors.

Results: Forty children were obese (BMI≥95th percentile) and the 28 others were overweight. The mean±SD of cIMT was 0.44±0.05 mm. The prevalence of MHO and MUO were 55.9% and 44.1%, respectively. After adjusting BMI, insulin concentration was higher among MUO phenotype (16.9±1.05 μU/mL) compared to MHO one (12.3±0.93 μU/mL, $P< 0.05$). The BMI-adjusted cIMT was higher in MUO subjects [0.46 (95% CI: 0.43-0.48)] compared to those with MHO phenotype [0.43 (95% CI: 0.41-0.45), P=0.07].

Conclusions: Metabolically unhealthy obese children and adolescents are at higher risk of subclinical atherosclerosis than metabolically healthy obese ones.

PB 2171 | Acquired von Willebrand Syndrome (aVWS) in Severely Ill Pediatric Patients with Bleeding Complications

I. Wieland, K.-W. Sykora

Hannover Medical School, Department of Pediatric Hematology and Oncology, Hannover, Germany

Background: Von Willebrand factor is a multimeric protein which is required for platelet adhesion and plays an important role in haemostasis. Generally, acquired von Willebrand syndrome (aVWS) is associated with a recognizable underlying disorder. In the general population, aVWS is reported with a prevalence of 0.04 to 0.13%. According to the ISTH registry, lymphoproliferative (48%), cardiovascular (21%), myeloproliferative (15%), other neoplastic (5%), and autoimmune disorders (2%) are most common.

Aims: Acquired VWS seems to be an underdiagnosed condition in pediatric patients.

Methods: We report the cases of 14 critically ill paediatric patients who suffered from severe bleeding. In all patients, aVWS was diagnosed. Underlying disorders included dyskeratosis congenita (one boy), posttransplantation lymphoproliferative disease (two girls), sepsis with multiorgan failure and uremia (three patients), congenital heart failure (CHD) with stenosis (6 patients), unknown immunodeficiency (one girl), and progressive familial intrahepatic cholestasis (one boy).

Results: Analyses were performed because of bleeding. In most cases the treatment of bleeding was very difficult, and Treatment with vWF /FVIII concentrates was not sufficient to control bleeding. Then, substitution with rVIIa concentrates was necessary.

Conclusions: Acquired VWS seems to be an underdiagnosed condition in critically ill paediatric patients. The most common causes of avWF in children are congenital heart failure with stenosis, uraemia and lymphoproliferative disease or lymphoma. Microangiopathy, autoimmune disorder, leukocytosis or thrombocytosis were seen as further underlying conditions. Therefore, if there is unexpected bleeding in a critically ill pediatric patient, aVWS should be suspected. Specific treatment can be a challenge, however.

PB 2172 | Thrombopoietin Receptor Agonists for Children with Refractory Immune Thrombocytopenia

J. Zanabili Al-Sibai[1], T. Arias Fernández[1], A. Fernandez[1], L.F. Ávila Idrovo[1], L. Morais Bras[1], C. Castañón Fernández[1], A. Solé Magdalena[1], S. Shehadeh[2], S. González Muñiz[1], M.P. Palomo Moraleda[1]

[1]Hospital Universitario Central de Asturias, Oviedo, Spain, [2]Hospital Alvarez Buylla, Mieres, Spain

Background: Immune thrombocytopenia (ITP) is an autoimmune disease in which antibodies develop against platelets (plts) and dysregulation of cellular immunity result in premature destruction of plts and impaired plt production. For most children, ITP is

a self-limiting disease. Near 10% childs eventually develop refractory ITP (RITP). Thrombopoietin receptor agonists (TPO-RA) stimulate thrombopoiesis and are an alternative to Rituximab (RTX) and splenectomy.

Aims: We present 3 different children with RITP treated with TPO-RA.

Methods:

Case 1: A 5-year-old girl admitted to the hospital due to ITP with mucocutaneous bleeding. She was refractory to corticoids, immune globulin (Ig) and anti-D Ig. RTX was started. After the 3rd dose, she responded temporarily along with fever, renal insufficiency and arterial hypertension probably related to Ig A deficiency, not previously diagnosed. Romiplostim was indicated, reaching response after 2 doses and stopped after the 4th dose. Nowadays, plt count remains within normal limits (pic.1A).

Case 2: A 5-year-old boy was diagnosed of ITP with mucocutaneous bleeding. He received treatment with corticoids and Ig with short response. RTX was indicated. After 4th dose, severe thrombocytopenia and mucocutaneous bleeding persisted. Eltrombopag was started with response after 6 weeks of treatment and bleeding were resolved (pic.1B).

Case 3: A 4-years-old boy with RITP was referred to our hospital. Eltrombopag was begun as 2nd line treatment. He developed response after 4 weeks of treatment. Six weeks later, he presented 600,000plts/μL so the drug was stopped. We observed a quick descent in plts levels and Eltrombopag was restarted with progressive response (pic.1C).

Results: In all cases, splenectomy was avoided due to long-term risk of sepsis, as well as immunosuppressive agents like RTX in 3rd case. In 1st case, TPO-RA was able to stop with sustained response as described in some publications.

Conclusions: In our experience, TPO-RA appear to be efficacy and well tolerated in children.

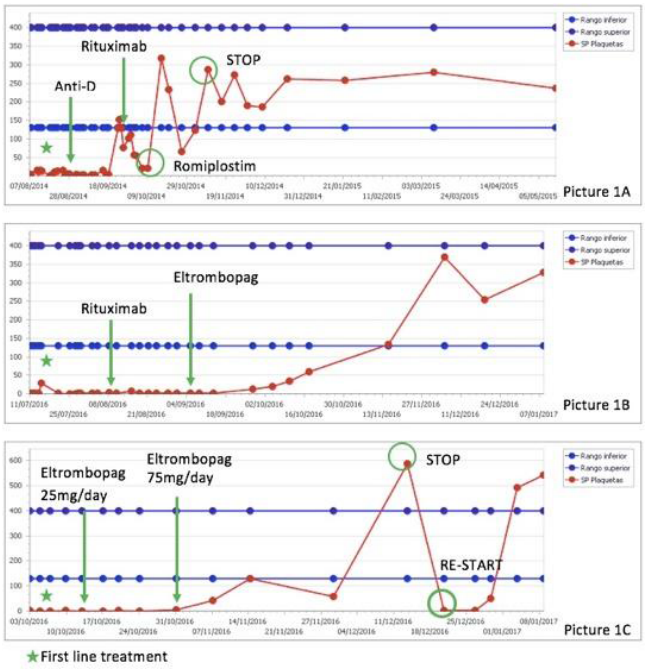

FIGURE 1 Evolution of platelet count

PB 2173 | An Unusual Cause of Bleeding in a Young Girl with Systemic Lupus Erythematosus: Lupus Anticoagulant Hypoprothrombinemia Syndrome

S. Singh[1], A. Jindal[1], N. Kumar[2], J. Ahluwalia[2]

[1]PGIMER, Advanced Pediatrics Centre, Chandigarh, India, [2]PGIMER, Department of Hematology, Chandigarh, India

Background: Lupus anticoagulant hypoprothrombinemia syndrome is an extremely rare clinical entity characterized by isolated acquired Factor II (Prothrombin) deficiency in patients with Lupus Anticoagulant (LA) positivity.

Aims: To describe the case of a young girl with systemic lupus erythematosus (SLE) and LA hypoprothrombinemia syndrome.

Methods: An 8 year old girl presented with 10 days history of fever, arthralgia, swelling over body, chest pain, respiratory distress, epistaxis, melena and bleeding from gums. On examination, she had pallor, anasarca and sub-conjunctival bleed. Chest examination revealed signs of a pleural effusion.

Results: Laboratory investigations revealed anemia, thrombocytopenia, deranged coagulogram with prolongation of both Prothrombin time (PT) and activated partial thromboplastin time (aPTT), and hypoalbuminemia (Table 1). Her blood culture was sterile, IgM dengue serology was negative, IgM scrub typhus serology was negative, serum Widal titres were normal, human immunodeficiency virus serology was negative and no malaria parasite was seen on peripheral smear. She was initiated on intravenous ceftriaxone and cloxacillin and fresh frozen plasma. However, there was no improvement in the coagulopathy and fever. Mixing studies revealed partial correction of PT and specific factor assay revealed very low levels of Factor II (Table 2). Work-up for SLE revealed positive ANA, high anti-dsDNA titres, low complements and positive antiphospholipid antibodies (Table 2). She was diagnosed as SLE with LA hypoprothrombinemia syndrome and was initiated on pulse intravenous methylprednisolone (30 mg/kg/day X 5 days). This led to prompt improvement in her clinical condition and resolution of fever and coagulopathy.

TABLE 1 Laboratory investigations

Investigation	Results
Hemoglobin	58 gm/L
White cell count	69×109cells/L (Polymorphs 71%, Lymphocytes 22%)
Platelet count	101×109/L
Prothrombin time	89 seconds (Normal: 12-14 seconds)
Activated partial thromboplastin time	More than 2 minutes (Normal: 25-32 seconds)
Serum fibrinogen	3.7 gm/L (Normal:2-4)
D- dimer	540
C-reactive protein	33 mg/L (Normal: <6)
Procalcitonin	0.9 ng/mL (Normal <0.5)

TABLE 2 Laboratory investigations

Investigations	Results
Antinuclear antibody	4+ homogenous pattern (indirect immunofluorescence)
Anti-dsDNA antibody titre	1394 IU/mL (Normal <60)
C3;C4	<27 mg/dL; <3 mg/dL
i)Lupus anticoagulant; ii)Anti β2 GPI (IgM and IgG); iii)Anti cardiolipin (IgG and IgM)	i)Positive; ii)Positive (IgG); iii) Positive IgM and IgG
24 hour urine protein	40 mg/m2/hour
Direct Coomb's test	Negative
Factor II assay	6% (60-160%)
Factor V assay	85.5% (Normal: 60-160%)
Factor X assay	105.3% (Normal: 60-160%)

Conclusions: LA hypoprothrombinemia syndrome is an uncommon condition and may be associated with SLE. Mixing studies and specific Factor II assay will establish the diagnosis. Immunosuppressant medications lead to prompt improvement of coagulopathy.

PB 2174 | Cost-benefit Relationship of the Collagen-binding Assay on von Willebrand Disease Study in Children

P. Zúñiga Contreras[1], J.G. Martínez Órdenes[1,2], G. Muñoz Silva[1], P. Sepulveda Mercado[1]

[1]*Pontificia Universidad Católica de Chile, Pediatria, Santiago, Chile,* [2]*Universidad de Santiago de Chile, Pediatria, Santiago, Chile*

Background: Von Willebrand disease (vWD) is the most frequent inherited bleeding disorders in children. In our institution the diagnosis is made by quantification von Willebrand factor (vWF:Ag), factor VIII (FVIII:c), Ristocetin cofactor (CoR) and collagen binding assay (vWF:CB), defined as complete vWD study (EC-vWD). Data published in adults show that vWF:CB contributes 23% to the diagnosis of vWD. In our country, vWF:CB is not codified by social health system which increases the cost of the study.

Aims: To evaluate whether EC-vWD improved capacity of diagnosis in children between 0 and 18 years evaluated in the hemostasis laboratory of our institution.

Methods: A retrospective study that reviewed the database of EC-vWD assays from 2008 to 2012. We reviewed a total of 464 records. The results were classified according to the diagnostic criteria of vWD (Quiroga, 2014): Normal (N), Normal Low (NL), Possible vWD (P-vWD) and vWD. Data was analyzed with Graph Pad Prims 6®. Statistical analysis: Fisher´s exact test for differences between criteria and Spearman-rank tests for correlations. Statistical significance: $p < 0.05$.

Results: Of the 464 EC-vWD analyzed, the mean age was 8.4±4.7 years. The proportion of women was 49.1%. EC-vWD results were:

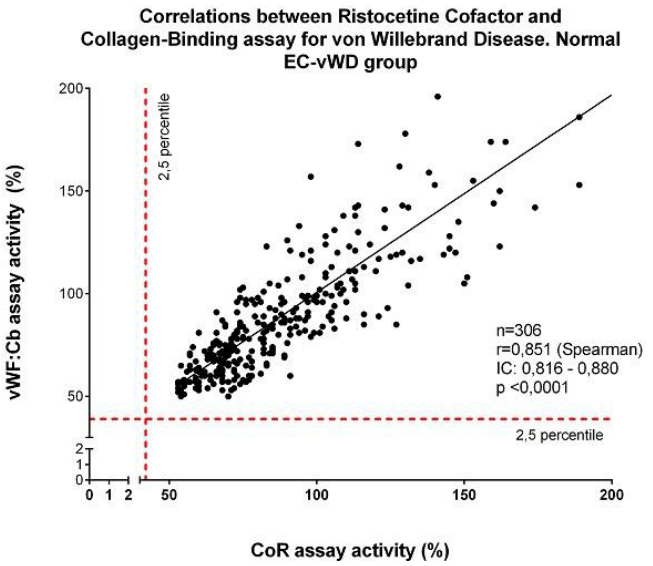

FIGURE 1 Correlations between CoR and vWF:CB assays. Normal children group

N: 65.9%; NL: 15.9%; P-vWD: 8.8% and vWD: 9.4%. The correlation between CoR and vWF:CB was significant in all groups (N r=0.85; NL r= 0.70; p-vWD r= 0.93 & vWD r= 0.82, all $p < 0.001$; fig 1 & 2.

To comparing contribution of CoR and vWD:CB for the all diagnostic categories there were no differences in any categories.

Conclusions: According to the analysis vWF:CB alone did not increase the research of vWF cases in children. These results differ from those of Quiroga et al., who showed that vWF:CB improves the vWD diagnosis on 23% in adults. This allows us to point out that for the diagnosis of vWD in children the initial approach may omit the vWF:CB

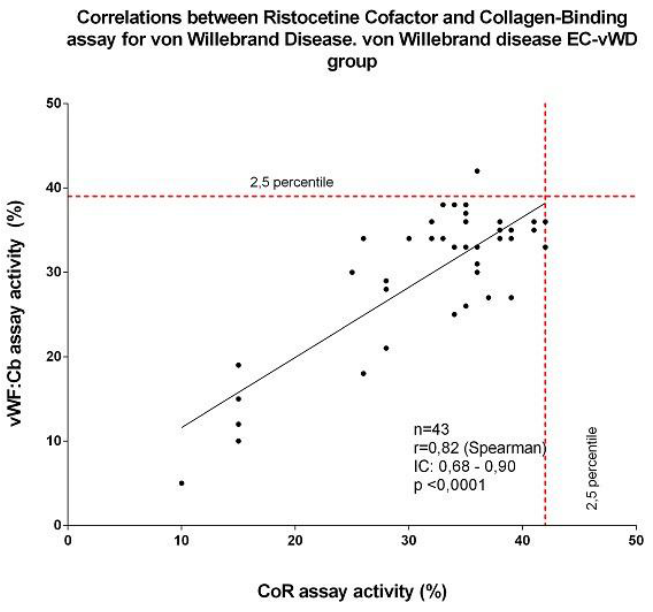

FIGURE 2 Correlations between CoR and vWF:CB assays. groupvon Willebrand Disease children group

assay, which does not alter the diagnostic capacity of vWD and reduces the cost of study vWD. EC-vWD could be used as a second-line study.

PB 2175 | Severe Factor VII Deficiency in Lebanon: The Impact of Molecular Studies, Prenatal Diagnosis and Primary Prophylaxis

R. Farah[1], J. Al Danaf[2], H. Farhat[3], M. Giansily-Blaizot[4]

[1]Saint George Hospital University Medical Center, Pediatric Hematology/Oncology, Beirut, Lebanon, [2]LAU-Rizk Hospital, Pediatrics, Beirut, Lebanon, [3]LAU-Rizk Hospital, Laboratory Medicine, Beirut, Lebanon, [4]CHU de Montpellier, Hematology Laboratory, Montpellier, France

Background: Congenital deficiency of Factor VII is rare but is the most common autosomal recessive hemorrhagic disorder. The clinical phenotype varies from asymptomatic forms to lethal hemorrhagic diathesis characterized by central nervous system (CNS) and gastrointestinal (GI) hemorrhages occurring commonly during the neonatal period. Severe phenotypes account for 10-15% of symptomatic FVII deficient patients. Some mutations are consistently associated to the severe clinical phenotype, mostly specific missense and invariant AG or GT splice site mutations.

Aims: We are presenting a case series of several Lebanese offsprings of consanguineous marriages homozygous for the same *F7*:c.291+1G>C splice site mutation known to be associated with life-threatening bleeding phenotype and evaluating the impact of prenatal diagnosis and primary prophylaxis on the outcome of these children.

Methods: In our series, five children from four different families, presented as a first symptom with GI bleeds (n=4) or CNS bleed (n=1) within the first two months of life (range Day 1 to Day 40 of life). Among them, three could not receive the assigned rFVIIa prophylactic regimen and CNS bleeds recurred in all of them leading either to death (n=2) or sequelae (n=1).

Results: Three children from affected families were diagnosed prenatally via amniocentesis analysis at 16 weeks of maternal gestation, and in homozygous patients prophylaxis with rFVIIa was started at the dose of 30 µg/kg 2-3 times a week right after birth with excellent outcome in terms of bleeding prevention. When continued, this regimen was very well tolerated, and was shown to avoid any life-threatening bleed allowing the patient to lead a normal life.

Conclusions: Early diagnosis and, if possible, prenatal diagnosis is of paramount importance in these severe variants and primary prophylaxis starting at birth should be considered the management of choice in this clinical setting, to avoid life-threatening bleeds and disability, at least till gene therapy becomes available.

PB 2177 | Genetic Confirmation and Identification of Novel Mutations in Glanzmann Thrombasthenia and von Willebrand Disease Families by Diagnostic Exome Sequencing

Y.J. Shim[1], E.M. Choi[1], H.S. Kim[1], J.M. Lee[2]

[1]Keimyung University School of Medicine and Dongsan Medical Center, Pediatrics, Daegu, Korea, Republic of, [2]Yeungnam University College of Medicine, Pediatrics, Daegu, Korea, Republic of

Background: Congenital platelet function disorders and von Willebrad disease (vWD) are very heterogeneous group resulting in primary hemostatic defects. Physicians generally have difficulty to confirm them due to complicated diagnostic technique.

Aims: We intended to apply diagnostic exome sequencing (DES) for genetic confirmation and finding causative variants in children with primary hemostatic problems.

Methods: Library preparation was performed with TruSight One sequencing panel (Illumina, USA), which enriches about 4,800 genes with clinical relevance. Massively parallel sequencing was conducted with NextSeq (Illumina). Variants were annotated with population databases (1000 Genomes Project, Exome Variant Server, Exome Aggregation Consortium) and disease databases (OMIM). For missense variant, in-silico analysis was done with SIFT, PolyPhen-2, and MutationTaster. Candidate variants were confirmed by Sanger sequencing and family study. For *VWF* gene, multiplex ligation dependent probe amplification assay was also done.

Results: Twelve children with easy bruising, frequent epistaxis, or menorrhagia and their family members were enrolled. Two unrelated children were confirmed as Glanzmann thrombasthenia (GT). One proband had compound heterozygous variants of c.1913+5G>T and c.1451G>T (p. Gly484Val) in *ITGB3*. The former was pathogenic which results in aberrant splicing and the latter is novel. The other proband had homozygous variant of c.1913+5G>T in *ITGB3*. Three unrelated children were confirmed as vWD. One proband had compound heterozygous variants of c.2574C>G (p.Cys858Trp) and c.3390C>T (p.Pro1127_Gly1180delinsArg) in *VWF*, especially the latter synonymous variant previously confirmed to be resulted in exon 26 skipping. Another proband had a novel variant, c.2008C>T (p.Arg670Cys). The last proband had a known *VWF* pathogenic variant of c.1728G>T (p.Met576Ile).

Conclusions: DES is a valuable method to confirm GT or vWD. Further study is needed to find out unidentifiable mutations by this strategy.

PB 2178 | Application of Different Technologies during Prenatal Diagnosis in Glanzmann´s Thrombasthenia

J. Ding[1], M. Jiang[2], L. zhou[2], H. Li[1], C. Ruan[2]

[1]Suzhou Municipal Hospital, Center for Reproduction and Genetics, Suzhou, China, [2]The First Affiliated Hospital of Soochow University, Suzhou, China

Background: Glanzmann´s thrombasthenia is a bleeding disorder caused by qualitative and/or quantitative defects of platelet

membrane glycoprotein (GP) IIb/IIIa complex. The disease is inherited in an autosomal recessive manner.

Aims: This report describes the prenatal diagnosis performed using flow-cytometry and DNA sequencing technologies.

Methods: The high-throughput capture sequencing technique and PCR-Sanger sequencing were used to detect pathogenic mutations in the proband of this family and analyze the whole family at the genomic level. After the genetic cause was clarified, fetus blood sample was collected by direct puncture of the umbilical vein from the proband´s mother who was pregnant for 22 weeks. Both DNA sequencing and GPIIb/IIIa complex quantified by flow-cytometry were applied for prenatal diagnosis.

Results: The proband carried compound heterozygous mutations of p.Tyr220Cys and p.Leu872fs in the GPIIb gene. Pedigree analysis showed that the two mutations were inherited from the mother and father, respectively. DNA sequencing showed that the fetus inherit the mutation p.Tyr220Cys from mother and had a new mutation which had not been reported. Using flow-cytometry, GPIIb/IIIa complex on fetus platelets was quantified, which is about half of normal controls. The fetus was proved to be a carrier of Glanzmann´s thrombasthenia.

Conclusions: Combined DNA sequencing and flow cytometry can attain more reliable and accurate results of prenatal diagnosis in Glanzmann´s thrombasthenia.

PB 2179 | Continuous Infusion of Recombinant Factor IX in a Neonate with Severe Hemophilia B and A Vascular Ring Requiring Surgical Correction

C. Hugge[1], C. Huddleston[2], L. Cerny[1], N. Hillman[1], J. Puetz[3]

[1]St. Louis University School of Medicine, Pediatrics, St. Louis, United States, [2]St. Louis University School of Medicine, St. Louis, United States, [3]St. Louis University, Pediatrics, St. Louis, United States

Background: Infusion of continuous coagulation factor in patients with hemophilia undergoing major surgery is an effective strategy for maintaining consistent hemostatic levels. Very little data exists for the use of continuous infusion in neonates, in particular those with hemophilia B receiving recombinant Factor IX (rFIX).

Aims: To report the case of a neonate with severe hemophilia B who required a high infusion rate of continuous rFIX during and after surgery for correction of a vascular ring.

Methods: The subjects medical and laboratory record were reviewed and relevant data extracted.

Results: A one week old infant with severe hemophilia B was diagnosed with a congenital vascular ring with planned surgical correction on the tenth day of life. Factor concentrate replacement via continuous infusion was planned for the perioperative period. A goal factor level of 1.0 IU mL^{-1} was set. Continuous rFIX infusion was started at a dose of 6 IU/kg/hr after a 150 IU/kg bolus. The infusion was begun 24 hours prior to surgery. Four hours after beginning the infusion, a factor IX of 0.6 IU mL^{-1} was obtained. Over the subsequent 18 hours the patient´s rate was adjusted based on serial examination of factor IX levels. A preoperative level of 0.94 IU mL^{-1} was obtained on a dose of 15 IU/kg/hr. No bleeding complications were noted during or after surgery and the factor level remained above 1.0 IU mL^{-1} at this rate until intermittent dosing was started on POD 2. Factor IX inhibitor titers measured 4 and 11 months later were negative.

Conclusions: Coagulation factor replacement by continuous infusion has advantages for hemophilia patients undergoing major surgery. Our experience suggests that neonates with hemophilia B require higher infusion rates in comparison to older patients and supports individualized dosing based on serial factor evaluations in the preoperative period. Using this approach, hemostatic levels of factor IX can be achieved and maintained in the newborn.

PB 2180 | Tailored Prophylaxis in Children with Hemophilia A: A New Approach for the Future

S. Pasca[1], P. Cogo[2], M. Milan[1], L. Sarolo[1], E. Zanon[1]

[1]University Hospital of Padua, Hemophilia Center, Padua, Italy, [2]University Hospital of Udine, Pediatric Clinic, Udine, Italy

Background: Primary prophylaxis started early at dosage of 25-40 IU/kg three times/week is considered the gold standard for the treatment of children with severe hemophilia, improving their quality of life (QoL) and reducing bleeds. In the last years a new approach to prophylaxis based on annual bleeding rate (ABR), presence of target joints, pharmacokinetics (PK) or lifestyle of each patient has begun to be adopted in hemophilia treatment.

Aims: To evaluate whether in a group of children with severe or moderate hemophilia A (HA) a tailored approach may be used to replace the standard therapy.

Methods: PK evaluation was carried out in eight children with severe or moderate HA referred to Hemophilia Center of Padua and previously receiving recombinant factor VIII, octocog alfa (20-80 IU/kg), using a computing program (Bayesian approach). For each patient a tailored prophylaxis was estimated with the same program considering a trough level of 1% (severe HA) or 3% (moderate HA).

Results: PK evaluations of six children with severe HA (FVIII < 1%) previously on prophylaxis and of two children with moderate HA (FVIII 2-3%) and ABR >5, previously treated on-demand, were carried out. Bayesian curve was created for each child. Afterwards a tailored prophylaxis was assessed individually employing PK data: clearance and half-life of FVIII, steady state volume, time to reach +1% from basal FVIII. Following our results, the previously on-demand treated pts were placed on prophylaxis and their ABR decreased significantly. Based on trough level data, the weekly frequency of infusions may be reduced in three patients with severe HA, while may be increased in two children. As to the remaining child, it may be to change only the dosage (Fig. 1).

Conclusions: A therapeutic approach based on PK and clinical characteristics of each patient could change the standard treatment. Based on our results tailored prophylaxis could be another effective option for children with HA, improving their QoL.

			Previous treatment		Pharmacokinetics				Tailored prohylaxis	
ID	Age (yr)	Weight (kg)	Dose (IU/kg)	Frequency	Clereance (dl/hr/kg)	Hal-life (hr)	Steady State Vol. (dl/kg)	Time (hr) to reach +1 %	Dose (IU/kg)	Frequency

PB 2181 | Normal aPTT in Children with Mild Factor XI Deficiency

J. Puetz[1], C. Hugge[1], K. Moser[2]

[1]*Saint Louis University, Pediatric Heme/Onc, St. Louis, United States,* [2]*Saint Louis University, Pathology, St. Louis, United States*

Background: Hemophilia C is a bleeding disorder caused by factor XI deficiency. Unlike hemophilia A or B the bleeding pattern is variable.Patients are screened for factor XI deficiency because of abnormal bleeding and/or an abnormal aPTT. It has been suggested that patients with factor XI deficiency may have a normal aPTT. Unfortunately, there are few data in the medical literature to confirm this notion.

Because clinicians rely on the aPTT in diagnostic algorithms when evaluating patients with abnormal bleeding, it is essential to determine if a normal aPTT eliminates the need for factor XI activity testing. This is especially true in children where phlebotomy and specimen volume constraints can be significant.

Aims: To determine if children at our center with factor XI deficiency have ever had a normal aPTT.

Methods: We queried our bleeding disorders database for all children diagnosed with factor XI deficiency (defined as more than one abnormal result). The subject's electronic medical record (EMR) was then extracted for bleeding symptoms/scores, demographic information, treatments given, and all available aPTT and factor XI measurements. This study was deemed exempt research by the Institutional Review Board of Saint Louis University.

Results: Our pediatric bleedings disorder center is located in the central United States with a referral region covering 3 million people. Seven children were identified as having factor XI deficiency. All had mild deficiency (0.21 to 0.39 IU/ml[1]). Their median bleeding score was 5. Four of the subjects received antifibrinolytics or plasma for surgery or abnormal bleeding. Three of the 7 subjects had a normal aPTT at the time of diagnosis, and 4 of 7 ever had a normal aPTT recorded.

Conclusions: The majority (57%) of subjects with mild factor XI deficiency had a normal aPTT. This supports the hypothesis that children with mild factor XI deficiency can have a normal aPTT. Pediatricians should incorporate this evidence in their diagnostic algorithm for children with abnormal bleeding.

PB 2182 | Impact of SIPPET [Survey of Inhibitors in Plasma-product Exposed Toddlers] Study on Clinical Practice in United States: A Survey of Hemophilia and Thrombosis Research Society [HTRS] Members

A. Al-Huniti[1], A. Sharathkumar[1], P. Ten Eyck[2]

[1]*University of Iowa Carver College of Medicine, Stead Family Department of Pediatrics, Iowa City, United States,* [2]*Unversity of Iowa, Institute of Clinical and Translational Research, Iowa City, United States*

Background: Factor VIII product class (recombinant versus VWF containing plasma derived factor VIII) and its role in inhibitor development among PUPs with hemophilia A was debated over years. SIPPET study addressed this question and showed that recombinant factor VIII (rFVIII) almost doubled the risk of inhibitor development compared to plasma derived factor VIII (PDFVIII) after adjusting for known high risk factors. These findings have created confusion among health care providers.

Aims: Understand the impact of SIPPET results on clinical practice in United States.

Methods: An anonymous web-based survey of HTRS members.

Results: Forty-nine percent [61/130] of pediatric hemophilia treaters completed the survey. Majority(94%) worked at HTCs. All providers treated racially diverse population with inhibitors. Majority (80%) used rFVIII while remaining customized their product choice based on family preference and a priori risk of inhibitor. Eighty-five percent were uncertain about the protective role of VWF against inhibitor development. Sixty percent [37/61] expressed concerns about study design primarily related to ethnicity differences followed by product choice of first and second generation concentrates versus third generation in US. Fifty percent shared SIPPET study with all PUPs while only a third discussed the results with all patients seen in comprehensive clinic. Seventy percent [48/61] admitted that the results of SIPPET study will influence their clinical practice and 35%[17/48] will consider using plasma derived concentrates to all PUPs while 54%[26/48] will use it for high-risk PUPs. About 80% of them will subsequently switch to rFVIII after 50 exposures. For PUP with minimal exposure to rFVIII and genetic predisposition for inhibitor, only 40% will switch to PDFVIII while 30% were uncertain and remaining 30% will continue with rFVIII.

Conclusions: Despite the concerns about SIPPET study design, the results of the study will influence the clinical practice of majority of pediatric hemophilia treaters in US.

PB 2183 | Intraosseous Infusion of Recombinant Factor IX

C. Hugge, J. Puetz, R. Fleming

St. Louis University School of Medicine, Pediatrics, St. Louis, United States

Background: Obtaining vascular access can be challenging in the neonate. The use of the intraosseous route has been well described as a viable way to administer a variety of medications. To our knowledge, the administration of recombinant Factor IX (rFIX) by intraosseous infusion has not been reported.

Aims: To report a case of a neonate with severe hemophilia B requiring and safely receiving intraosseous infusion of rFIX.

Methods: The subjects medical and laboratory record were reviewed and relevant data extracted.

Results: The 2 day old infant presented with persistent post circumcision bleeding as well as persistent bleeding from a heel stick site. Laboratory values included a PTT >100s, Factor IX< .01 IU mL^{-1}, and a hemoglobin decline from 15 g/dL to 10 g/dL within a 24 hour period. Attempts at obtaining vascular access including umbilical and peripheral vessels were unsuccessful. A left tibial intraosseous line was placed to facilitate factor replacement. A single infusion of 100 IU/kg of rFIX was administered which resulted in excellent hemostasis. The intraosseous line was removed within 24 hours and no complications were noted. Factor IX inhibitor titers measured 4 and 11 months later were negative.

Conclusions: We report the successful administration of rFIX via the intraosseous route. We believe this represents the first report of rFIX concentrate being administered in such a fashion. Although we could not determine the recovery of rFIX, the rapid cessation of bleeding indicates adequate factor IX recovery. Our experience suggests that intraosseous infusion of factor concentrate is a viable option in emergencies.

PB 2184 | The Differential Diagnosis of Acute Rheumatic Fever in a Hemophilic Child

M. Sezgin Evim, A. Meral Güneş, B. Baytan

Uludag University, Pediatric Hematology, Bursa, Turkey

Background: Acute rheumatic fever (ARF) is a pediatric age disease. Most occurred ages is between 5-15 years. The incidence of ARF is 30-50/100.000 in developing countries.Migratory nature of arthritis is specific for ARF. Hemophilia-A and ARF togetherness is rare.

Aims: Discriminative diagnosis of acute rheumatic fever from hemophilic arthritis.

Methods: Ten years old boy diagnosed as severe Hemophilia-A was on factor VIII prophylaxis. The patient was admitted with systemic fever, swollen right ankle. Factor VIII was applied due to spontaneously swollen left knee two days ago. His joint condition seemed to improve but, his right ankle started to swell and became painful. On admission right ankle was found swollen and warm. His left knee symptoms was resolved.

Results: His laboratory results; white blood cell: 22.500 /$mm^{3,}$ absolute neutrophil count: 18.700/mm^3, fibrinogen: 740 mg/dl, C-reactive protein: 24.7 mg/dl, erythrocyte sedimentation rate: 53 mm/hour, and Antistreptolysin-O:1420 U/ml . Antibiotic therapy and factor replacement were given concurrently. He was found inhibitor free. His left ankle started to swell under treatment. ARF was diagnosed according to Modified Jones Criteria with no carditis. Fever and arthritis were resolved and acute phase reactants decreased after adding prednisolone as anti-inflamatuar.

Conclusions: The main challenge for ARF diagnosis in hemophilic patients is to differentiate arthritis from acute hemorrhage. Prednisolone and oral penicillin prophylaxis can be preferred instead of ASA and intramuscular penicillin due to high risk of bleeding.

PB 2185 | Proteomic Analysis of Changes Induced by Infant Cardiopulmonary Bypass

U. Nag[1], J. Otto[2], C. Mccoy[1], H. Leraas[3], J. Kim[1], C. Brady[4], J. Turek[5], J. Lawson[1], E. Tracy[1]

[1]Duke University Medical Center, Surgery, Durham, United States, [2]Duke University, Surgery, Durham, United States, [3]Duke University School of Medicine, Durham, United States, [4]Duke University, Durham, United States, [5]University of Iowa Carver College of Medicine, Surgery, Iowa City, United States

Background: Bleeding and thrombotic events cause significant morbidity and mortality in children on extracorporeal membrane oxygenation (ECMO) or cardiopulmonary bypass (CPB). Existing laboratory studies fail to reliably predict and guide management of these events.

Aims: To better characterize the complex and overlapping interactions that make the pediatric coagulome and its response to vascular injury, we performed an unbiased proteomic analysis of infants undergoing CPB.

Methods: Blood samples were collected from infants (0-12 months) at initiation of CPB, and at 1, 4, and 24 hours after initiation. 2D-difference gel electrophoresis (2-DIGE) was utilized to identify changes in plasma protein concentrations across time points. Inflammatory cytokines and vascular injury markers were assessed by ELISA.

Results: Ten infants with congenital cardiac anomalies were enrolled with mean age 125±121 (range 3-330) days (Table 1). No immediate complications were observed. Using 2D-DIGE, >1400 individual protein spots were observed, and 89 proteins demonstrated significant concentration change (>30%, $p < 0.02$). 70/89 proteins were upregulated at one or more time points after initiation of CPB, while 19/89 were downregulated. 29/89 protein spots were identified by mass spectrometry (Table 2). These included multiple proteins not previously described as hemostatic proteins, with at least 7 identified as novel proteins with unknown functions. Of the cytokines analyzed with ELISA, IL-2, IL-8 and IL-10 were elevated at 4h after initiation of bypass and IL-6 was elevated at both 4 and 24 hours after initiation of bypass.

TABLE 1 Characteristics of infants undergoing CPB

Diagnosis	Operation	Age (days)	Sex	BSA (m^2)	CPB time (min)	Circulatory arrest time (min)	Survival
HLHS	Glenn shunt, PA plasty	161	M	0.2	176	53	Yes
TGV	Arterial switch	3	M	0.27	174	0	Yes
VSD	VSD closure	195	F	0.3	67	34	Yes
AVSD	AVSD repair	120	F	0.34	125	0	Yes
DORV	Bidirectional Glenn shunt	330	M	0.36	85	0	Yes

ASD	ASD repair	288	M	0.34	62	0	Yes
AVSD	AVSD repair	135	F	0.27	152	0	Yes
Pulmonary Atresia	RV-PA conduit	6	M	0.2	40	0	Yes

HLHS = Hypoplastic left heart syndrome,; TGV = Transposition of the great vessels; VSD = Ventricular septal defect; AVSD = Atrioventricular septal defect; DORV = Double outlet right ventricle; ASD = Atrial septal defect

TABLE 2 Changes in Plasma Protein Concentrations at Time Points From Baseline at Initiation of CBP.

Protein Name	1h	4h	24h	Function
Antithrombin III	---	48%	42%	Anticoagulant
Fibrinogen gamma chain	---	88%	106%	Hemostasis
α-2 HS glycoprotein	---	-40%	-29%	Acute phase reaction protein
α 1-acid glycoprotein	-284%	-409%	-174%	Acute phase reaction protein
α 1-antichymotrypsin	---	---	266%	Acute phase reaction protein
α1-B glycoprotein	---	37%	---	Acute phase reaction protein
Apolipoprotein E	---	-59%	-42%	Maintenance of lipoprotein particle
Apolipoprotein A1i	-55%	---	---	Maintenance of lipoprotein particle
Hemopexin precursor	59%	61%	---	Heme scavenger
Amyloid P component, serum	---	55%	112%	Cell free DNA scavenger
SPT2 chromatin protein domain containing 1	---	---	242%	Histone chaperone
Rho guanine nucleotide exchange factor 11	---	---	-263%	Second messenger signaling
Serine/threonine-protein kinase PDIK1L	-23%	-41%	---	Protein kinase
LBH domain-containing protein-1 LBHD1	---	-68%	-49%	Unknown
Integrator complex subunit 7 INTS7	---	56%	39%	Unknown
Transmembrane protein 78 TMEM78	---	-73%	-53%	Unknown
Novel protein DKFZp779N0926	---	---	82%	Unknown
Novel protein CAF16400	---	51%	43%	Unknown
Novel protein CAE91331	---	---	107%	Unknown
Novel protein CAE98668	---	---	48%	Unknown

Conclusions: In response to CPB in infants, changes are observed in the concentrations of numerous plasma proteins. Associating these plasma protein changes with clinically significant bleeding and thrombotic events that occur during the course of support may provide predictive biomarkers for better management of bleeding and thrombosis in these infants.

PB 2186 | Spatial Clot Propagation in Neonates and Adults

A. Schlagenhauf, S. Pohl, E. Zoehrer, B. Leschnik, H. Haidl, W. Muntean, S. Gallistl

Medical University of Graz, Department of General Pediatrics and Adolescent Medicine, Graz, Austria

Background: The hemostatic balance of neonates is more fragile than that of adults due to lower levels of clotting factors but also inhibitors. Nonphysiologically high tissue factor concentrations in conventional clotting assays result in apparent hypocoagulation with neonatal samples, but with low levels of tissue factor neonatal and adult hemostasis is almost comparable. This finding can be explained by lower concentrations of inhibitors resulting in rapid clot propagation after onset of clot formation. The Thrombodynamics assay uses immobilized tissue factor and video analysis for separate determination of initial and stationary rate of clot formation, thus, modelling the initiation and propagation phase of coagulation.

Aims: We aimed to test neonatal, cord, and adult samples with this assay and to compare results with data from Calibrated Automated Thrombography (CAT).

Methods: Plasma from cord blood (N=30), and venous blood of healthy neonates (N=10) as well as adults (N=20) was measured with the Thrombodynamics assay. All samples except venous blood from neonates were also measured with CAT.

Results: Initial (Vi) and stationary rates (Vs) of clot formation in the Thrombodynamics assay were significantly higher in neonatal than in adult samples (Vi: 69.54±5.32 µm/min vs. 54.93±5.47 µm/min P< 0.001; Vs: 52.17±12.93 µm/min vs. 31.14±5.62 µm/min, P< 0.001). No differences were observed between cord blood and neonatal venous blood. CAT parameters showed shorter lag times in cord blood samples than in adult samples (4.79±0.78 min vs. 6.94±1.5 min, P< 0.05), but a significantly lower enodgenous thrombin potential (714,8±130,7 nM*min vs. 1643±187 nM*min, P< 0.001).

Conclusions: Although the thrombin formation capacity is significantly lower in cord samples than in adult samples, the rate of clot propagation in the Thrombodynamics assay is faster. Hence, the Thrombodynamics assay, depicts the clinical picture of neonatal coagulation better than CAT and conventional clotting assays by mimicking a damaged vessel wall.

PB 2187 | Platelet-leukocyte Aggregates as Possible Biomarkers of Thrombotic Risk in Children with Hereditary Spherocytosis and Splenectomy

C. García[1], A. Moscardó[2], S. Izquierdo[1], A.M. Latorre[2], B. Argiles[1], M.T. Santos[2], J. Vallés[2], M.Á. Dasí[1]

[1]*University and Polytechnic Hospital La Fe, Department of Pediatric Hematology, Valencia, Spain,* [2]*Health Research Institute La Fe, Hemostasis, Thrombosis, Atherosclerosis, and Vascular Biology, Valencia, Spain*

Background: Hereditary spherocytosis (HS) is a chronic hemolytic disease caused by a pathologic structure of the erythrocyte membrane that causes their splenic sequestration. Splenectomy is the treatment used in severe forms, but implies the risk of encapsulated bacterial sepsis and recently has been suggested a long-term increased risk of thrombosis.

Aims: To study platelet activation markers (platelet-leukocyte (PL) and platelet-monocyte (PM) aggregates) as potential factors involved in the risk of thrombosis.

Methods: Forty-eight children were included in the study, 60.5% male, mean age 11.1 years. Control (n=16), with HS non-splenectomized (n=16) and with HS who were splenectomized (n=16). The 3 groups had similar sex and age. PL and PM aggregates were analyzed

by flow cytometry. ANOVA, Kruskal Wallis, Pearson correlation and multiple linear regression analysis were used. The study was approved by the ethical Committee of the Hospital La Fe. All patients or their proxy gave their written informed consent.

Results: When compared with the control group, the PL aggregates were 2-fold increased in the HS group, and 3-fold in the HS group with splenectomy (Table 1). The PM aggregates were also elevated in the patients (Table 1).The number of platelets was significantly correlated ($p < 0.05$) with the formation of PL and PM. The multiple linear regression adjusted by platelet number, showed a significant increase in PL aggregates in both groups, which was greater in the splenectomized group. For each increase of 100,000 platelets/ml, a 2.7% increase in PL aggregates was observed ($P < 0.05$).

TABLE 1 PL and ML aggregates in HS

	Control	HS	HS+ Splenectomy	P
PL aggregates (%)	7.3 (SD 3.5)	14.6 (SD 5.9)	21.9 (SD 9.2)	0.0001
PM aggregates (%)	25.1 (SD 21.3)	50.4 (SD 23.3)	55.4 (SD 13.4)	0.0006

Conclusions: Platelet activation is elevated in children with HS, which is greater in children with HS who were splenectomized, adjusted by the number of platelets. PL aggregates may be a useful biological marker of thromboembolic risk in patients with HS. Grants. FIS13/00016. ACIF/2016/465. PB 2188 | Pediatric Chronic Kidney Disease: Assessment of Endothelial Function and Hemostasis

L. Dusse[1], R. Silva[1], L. Sousa[1], C. Loures[1], M. Carvalho[1], E. Reis[2], A. Simões-Silva[3]

[1]Federal University of Minas Gerais, Department of Clinical and Toxicological Analysis, Belo Horizonte, Brazil, [2]Federal University of Minas Gerais, Department of Statistical, Belo Horizonte, Brazil, [3]Federal University of Minas Gerais, Department of Pediatric, Belo Horizonte, Brazil

Background: Chronic kidney disease/CKD is associated with cardiovascular diseases and impairment of patient´s quality of life. These problems are more serious in childhood because affect not only the course of CKD but also triggering complication in adult life. Endothelial dysfunction plays a critical role in the development of atherosclerosis, which may be a common pathogenesis pathway for CKD and cardiovascular disease.

Aims: To evaluate in CKD patients, the endothelial activation through the biomarkers levels, E-selectin, Vascular/VCAM-1, Intercelular adhesion molecule-1/ICAM-1, Vascular Endothelial Growth Factor/VEGF and the hemostasis by D-Dimer levels.

Methods: This study was conducted in accordance with the declaration of Helsinki and local committee of ethics. It included 38 CKD pediatric patients (6-18 years old) and 31 healthy volunteers match for age and sex. Soluble E-selectin, VCAM-1, ICAM-1, VEGF and D-dimer plasma levels were evaluated by ELISA. Mann-Whitney test was used for comparison between groups and Spearman for biomarkers and glomerular filtration rate (GFR) correlation.

Results: Higher endothelial activation was found in CKD patients comparing to volunteers; sE-selectin 40.39(32.95) vs 32,87(15.16) P=0.005; sVCAM 925.6(340.5) vs 511.7(145.2)P< 0.0001); sICAM 254.1(128.5) vs 202(109,2)P=0.007; VEGF 253.7(155.1) vs 111(86.15) P=0.0001. As well, a hipercoagulability was found in CKD patients vs healthy volunteers; D-Di 343.7(329.9) vs 287.9(158.4) P=0.022. Considering all participants, correlations were found among the endothelial activation biomarkers each other, as well as between D-Di and GFR.

Conclusions: Our findings show endothelium dysfunctional in CKD pediatric patients. High D-Di levels reinforce the early predisposition to hypercoagulability in these patients. The studied markers can be useful for pediatric CKD management .Clinical measures are needed to prevent or postpone atherosclerosis and cardiovascular disease in these patients.

PB 2189 | Derivation of a Clinical Prediction Rule to Use with D-dimer to Exclude Pulmonary Embolism in Children

J. Kanis, J. Pike, C. Hall, J. Kline

Indiana University School of Medicine, Emergency Medicine, Indianapolis, United States

Background: Pulmonary embolism (PE) rarely occurs in children. Prior work suggests a frequent delay in diagnosis. D-dimer testing offers non-high pretest probability to exclude PE in adults, but little evidence exists regarding utility in children.

Aims: We sought to derive criteria for a clinical prediction rule (CPR) to guide D-dimer use in children with suspected PE.

Methods: Records of children aged 5-17 years who had D-dimer or pulmonary vascular imaging (PVI) were collected by query of admin databases from Jan 2004 to Dec 2014 from a large multi-center US hospital system. Chart review confirmed that D-dimer was sent to evaluate PE with a random sample (>15%) to examine interobserver variability (Cohen's K). Criterion standard for venous thromboembolism+ (VTE+) required diagnostic PVI or deep vein thrombosis on ultrasound. Predictor variables were examined by univariate analysis and retained variables used to test the provisional CPR without and with D-dimer ordered as part of standard care.

Results: The search identified 525 children aged 5-17 tested for PE with D-dimer or PVI (K=0.95 for random sample of 100); 51 had PE and 5 had isolated DVT (56/525 VTE+ (10.6%, 95% CI 8-14%)). Children with PE+ had higher mean heart (HR) and respiratory rate (RR) and a lower pulse oximetry (SaO2%) and hemoglobin concentration. Five conditions were more frequent in PE+ versus no PE: surgery, central line, limb immobility, cancer, and prior PE or DVT; and, 23.5%

of patients who were PE+ were currently prescribed an anticoagulant. Without D-dimer, a provisional CPR(-) requiring HR< 100, RR< 22, SaO2%>94, and no cancer, central line, recent surgery, limb immobility, prior VTE+, or leg swelling had diagnostic sensitivity of 93% (83-97%) and specificity of 44% (40-48%). The CPR(-) with D-dimer normal had a sensitivity of 100% (91-100%) and specificity of 39% (35-44%).

Conclusions: We found VTE+ rate among children to be high, and D-dimer is frequently used. A preliminary CPR with normal D-dimer was 100% sensitive and 39% specific.

PB 2190 | Thrombin Generation in Pediatric Patients with Generalized Infectious Diseases and Multiple Organ Dysfunction Syndrome

L. Papayan[1], O. Smirnova[1], O. Golovina[1], L. Alekseeva[2], A. Vilnits[2], S. Bessmeltsev[3]

[1]*Russian Research Institute of Haematology and Transfusiology, Laboratory of Blood Coagulation, Saint Petersburg, Russian Federation,* [2]*Pediatric Research and Clinical Center for Infectious Diseases, Saint Petersburg, Russian Federation,* [3]*Russian Research Institute of Haematology and Transfusiology, Saint Petersburg, Russian Federation*

Background: Severe sepsis is associated with systemic activation of coagulation and increased thrombin generation, which can result in thrombosis. Coagulation parameters, such as prothrombin time (PT) or aPTT, poorly reflect the activation of blood coagulation. The Calibrated Automated Thrombography (CAT) is a more useful tool for the testing of the haemostatic system. It can be performed with thrombomodulin (TM) addition, and in this case, the method becomes sensitive to the protein C system disorders.

Aims: The aim of our study was to evaluate the possibility of CAT using for assessment of the hypercoagulability in pediatric patients with multiple organ dysfunction syndrome (MODS).

Methods: The study involved 5 patients with MODS and 30 healthy adults. PT, aPTT, fibrinogen level and antithrombin activity were measured in all patients. The thrombin generation (TG) was measured by CAT according to Hemker et al. with PPP plasma +/- rh-TM reagent. We analyzed the following parameters: endogenous thrombin potential (ETP, nM*min), thrombin peak height (Peak, nM), and such parameter as sensitivity to TM - the reducing rate of the ETP and Peak thrombin after the addition of rh-TM.

Results: It is known that children have lower TG than adults. The results of CAT without rh-TM showed that ETP in all children did not differ from the adults, and Peak was increased in 3 of 5 patients. In the study of CAT with rh-TM ETP was increased in 4 of 5 cases, and Peak - in all samples. The sensitivity to TM was markedly reduced in all patients, which reflects the serious disturbances in the protein C system (table 1).

At the same time, the usual coagulation parameters were within the normal range in 4 of 5 patients. Only one child demonstrated decreased antithrombin activity (32%).

Conclusions: Our results show that CAT performed with and without TM is the good instrument for the early detection of hypercoagulability. One of the causes of hypercoagulability in pediatric patients with MODS is a disturbance in the system of a protein C.

PB 2191 | A New ADAMTS13 Mutation and Pharmacokinetic Properties in Congenital Thrombotic Thrombocytopenic Purpura (TTP)

J.D.A. Carneiro[1], D.M. Celeste[1], M.N.P.F. Oliveira[1], G.A.C. Zanatta[2], T.R.F. Rocha[3], M.P. Garanito[1]

[1]*Unidade de Onco-Hematologia - Instituto da Criança - Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo, Pediatrics, São Paulo, Brazil,* [2]*Unidade de Terapia Intensiva do ITACI - Instituto da Criança - Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo, Pediatrics, São Paulo, Brazil,* [3]*Unidade de Doenças Trombo-Hemorrágicas - Serviço de Hematologia - Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo, Hematology, São Paulo, Brazil*

Background: Congenital TTP is a rare and potentially fatal disease secondary to constitutional deficiency of ADAMTS13. TTP is characterized by platelet aggregation in the microvasculature that results in microangiopathic hemolytic anemia and isquemia in various organs.

Aims: To report the case of a patient with a new ADAMTS13 mutation and evaluate pharmacokinetic (PK) properties after plasma infusion.

Methods: ADAMTS13 activity was measured by ELISA Technozym test and genetic study was done by gene sequencing (Illumina HiSeq/Nextera Exome Capture).

Results: A three-year-old girl, the first offspring of non-consanguineous parents, was hospitalized presenting as pale and apathetic, with petechiae and ecchymosis, vomiting and fever. Laboratory evaluation showed schistocytic hemolytic anemia, thrombocytopenia and

TABLE 1 The thrombin generation parameters in pediatric patients with MODS

CAT parameters	Normal range in healthy adults (Me, 95% CI)	Patient 1, 12 years	Patient 2, 3 years	Patient 3, 3 years	Patient 4, 3 years	Patient 5, 4 years
ETP without rh-TM, nM*min	1756,0 (1220,6-2159,9)	1941,5	2016,5	1722.5	1269.0	1717,0
ETP with rh-TM, nM*min	878,0 (538,8-1381,0)	1846,5	1924,0	1698.0	1252.5	1627,0
Sensitivity of ETP to TM, %	51,5 (22,9-64,4)	5,0	4,0	2,0	1,0	5,0
Peak without rh-TM, nM	293,9 (198,7-376,1)	396,5	427.7	387.9	324,9	341,9
Peak with rh-TM, nM	174,5 (113,8-310,0)	341,9	416.0	386.1	325,4	336,7
Sensitivity of Peak to TM, %	35,8 (14,8-53,1)	2,0	3,0	0,4	0	2,0

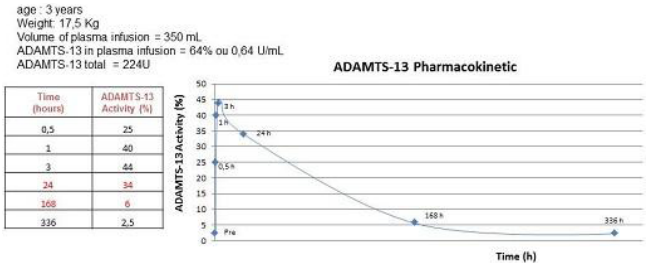

FIGURE 1 ADAMTS13 Phamacokinetics

renal dysfunction. Hemoglobin 9.4g/dl (11.7-14.4); Platelets 8,000/µL (150,000-450,000); Reticulocytes 8.9% (0.8-2.1); BUN 103mg/dl (11-38); Creatinine 1.47mg/dl (0.31-0.47); LDH 715U/L (160-370); ADAMTS13 activity < 5% (≥70%). Patient evolved with seizure and was treated with plasma infusions, dialysis and supportive care. After patient recovery, ADAMTS13 PK study after plasma infusion showed a half-life of 57.5 hours (Fig.1) and a recovery of 146%. Genetic analysis detected a compound heterozygous status: Chr9:136.307.625C>T(p.Arg692Cys) and Chr9:136.314.904G>GT(p.Trp955Leu fs*33) a new mutation. Patient is going well on prophylaxis with plasma infusion each two weeks without relapses.

Conclusions: This case report showed a high recovery and long half-life of ADAMTS13 in a Brazilian child with congenital TTP that presented a new ADAMTS13 gene mutation. These findings are important to individualize plasma infusion prophylaxis and for considering future treatment with recombinant ADAMTS13 concentrate.

PB 2192 | Thromboelastographic (TEG) Parameters in Newly Diagnosed Pediatric Patients with Acute Lymphoblastic Leukemia (ALL) and Central Venous Catheters (Cvcs)

R. Ko[1], L. Ji[2], R. Carmona[3], F. Goodarzian[4], R. Sposto[2,3], G. Young[3,5]

[1]*Genentech, Inc., US Medical Affairs, South San Francisco, United States,* [2]*University of Southern California Keck School of Medicine, Preventive Medicine, Los Angeles, United States,* [3]*Children's Hospital Los Angeles, Pediatrics, Los Angeles, United States,* [4]*Children's Hospital Los Angeles, Radiology, Los Angeles, United States,* [5]*University of Southern California Keck School of Medicine, Pediatrics, Los Angeles, United States*

Background: One of the most common adverse events in children with newly diagnosed ALL is VTE. Many of these patients have CVCs, which are the most common risk factor in children for developing VTE. TEG is a global hemostasis assay that measures various parameters of coagulation including clot initiation and propagation. This study prospectively monitored TEG parameters in patients with newly diagnosed ALL and CVCs during Induction.

Aims: To investigate if TEG can detect and monitor hypercoagulability in patients with newly diagnosed ALL and a CVC and predict VTE development.

Methods: This study was approved by the IRB. Patients with newly diagnosed ALL and CVCs who consented/assented had blood sampled at baseline (pre-treatment/Day 0) and then weekly throughout Induction (Days 7, 14, 21, 28) unless they presented with a symptomatic VTE. TEG was performed on citrated blood that was not activated. Patients who did not have symptomatic VTEs had an ultrasound performed on the extremity with the CVC at the end of Induction. Random-effects interval-data regression models were used to assess whether there was a significant difference in TEG parameters between VTE+ patients and VTE- patients, or among blood samples collected at different time points.

Results: Patient demographics are shown in Table 1. TEG parameters of R time, K time, and MA all showed statistically significant decreases over time ($p < 0.001$ for all TEG parameters, Figure 1). There were no differences between VTE+ and VTE- patients in any of the TEG parameters.

Conclusions: TEG parameters of R time, K time, and MA all showed statistically significant decreases over time in patients with newly diagnosed ALL and CVC during Induction, indicating that TEG can detect and monitor hypercoagulability. There were no differences in TEG parameters between patients who did and did not develop VTE, though the number of subjects was small. Other labs collected (markers of thrombin generation) may indicate differences.

PB 2193 | Look, Feel, Move: A Case of Idiopathic Femoral Artery Thrombosis in a Neonate

C. Williams[1], C. Mayes[2], C. Macartney[1]

[1]*Royal Belfast Hospital for Sick Children, Haematology, Belfast, United Kingdom,* [2]*Royal Jubilee Maternity Hospital, Neonatal Unit, Belfast, United Kingdom*

Background: True idiopathic thrombosis is extremely rare in children. Most thrombi occur secondary to iatrogenic causes. We present a case of successfully treated idiopathic thrombosis with low molecular weight heparin (LMWH).

Aims: To highlight the features of spontaneous femoral artery thrombosis resulting in peripheral limb ischaemia in a neonate.

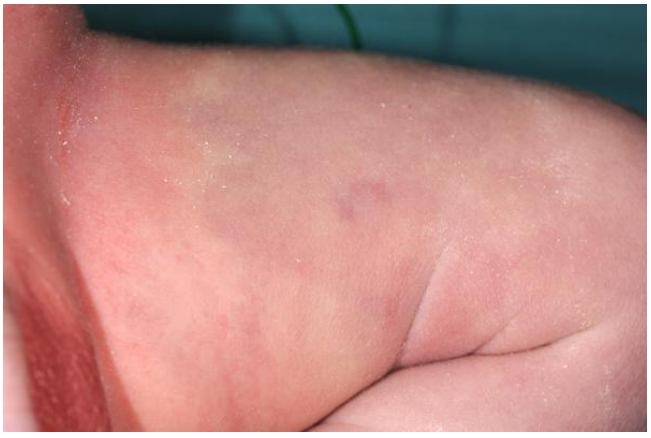

FIGURE 1 The appearance at birth of demarcated left upper leg

Methods: An infant boy was born at term via vaginal delivery and immediately after birth was noted to have a pale left leg. The left limb was also cold to touch, had a capillary return of six seconds and the left femoral pulse was weak while distal pulses were absent. Leg movement was normal. There was an irregular area of demarcation distal to the femoral arterial region.

Urgent Doppler ultrasound studies were undertaken which showed reduced arterial flow within the left femoral, popliteal and posterior tibial arteries. Reduced blood flow was also noted within the venous system of the left lower limb.

Results: LMWH injections were commenced twice daily as per haematology. A repeat ultrasound three days later showed chronic thrombosis of the left femoral artery with dilated collaterals in the inguinal region.An echocardiogram did not detect any abnormalities.

Enoxaparin was continued twice daily until discharge whilst monitoring the Factor Xa levels to keep within a target range of 0.5-1 IU/ml lower limb perfusion improved gradually. The left leg had a normal appearance by day 5 but was still cooler to touch and peripheral pulses remained difficult to palpate.

Following discharge LMWH was continued for three months and a follow up scan performed at this time showed a normal Doppler flow with no evidence of thrombosis.

A thrombophilia screen showed the boy to be heterozygous for FV Leiden and not thought to be a causative factor.

Conclusions: Our case highlights the importance of careful inspection of the neonate post-delivery and of appropriate investigation of abnormal findings.

PLATELETS – BASIC

PB 538 | Selected Expression and Functional Importance of alpha4a-Tubulin in Platelet Biogenesis

C. Strassel[1], A. Hovasse[2], S. Moog[1], M. Mageira[3], M. Batzenschlager[1], C. Schaeffer-Reiss[2], B. Kile[4], C. Gachet[1], C. Janke[3], F. Lanza[1]

[1]Université de Strasbourg, INSERM, EFS Grand Est, BPPS UMR-S 949, FMTS, Strasbourg, France, [2]Université de Strasbourg, Laboratoire de Spectrometrie de Masse BioOrganique, IPHC, UMR 7178, Centre National de la Recherche Scientifique, Strasbourg, France, [3]Institut Curie, Orsay, France, [4]The Walter & Eliza Hall Institute, Parkville, Australia

Background: Platelets are produced from mature megakaryocytes (MK) following a profound cellular reorganization. This includes the assembly of microtubules (MT) into a unique submenbranous coiled structure, the marginal band (MB). This process is thought to depend on a specific αβ-tubulin isotype repertoire. Whereas the MK-restricted-β1-tubulin is already known to be important for platelet biogenesis, the implication of other tubulin isotypes is currently unknown.

Aims: Our goal was to establish the αβ-tubulin repertoire in platelets and during megakaryopoiesis and to evaluate the implication of selected isotypes in platelet formation.

Methods: We used a combination of RT PCR and proteomic analyses in human platelets and in human CD34+-derived MK to establish an exhaustive and quantitative list of the tubulin isotypes. The function of a selected α isotype (α4A) in MK and platelets was explored in an ENU mutant mouse model.

Results: β-6, β-5 and α1c -tubulin transcripts were already present in CD+34 cells and decreased during the final stages of megakaryopoiesis. β-1, α4A- and α-8tubulin transcripts were only observed later during MK differentiation and in platelets. Quantitative LC-SRM mass spectrometry revealed an important expression of the α4A -isotype in platelets. In mice carrying a point mutation in *tuba4a* (V260E) we observed a thrombocytopenia (25%) and enlarged platelets with a decreased number of MT coils (1-3/plt). α4A -tubulin was not detected in these platelets and MT were hyper-tyrosinated. Molecular modelling predicted that the mutation would result in a steric clash with neighboring residues.

Conclusions: This study reveals new information on the evolution of the tubulin isotype repertoire in platelet formation pointing to a role of less-widely expressed α-isotype.

PB 539 | Redundant and Non-redundant Roles of RhoA and Cdc42 in Platelet Biogenesis and Function

D. Cherpokova[1,2], M. Popp[1], S. Dütting[1], P. Nurden[3], I. Pleines[1], M. Morowski[1], A. Baig[1], K. Aurbach[1], G. Krohne[4], C. Brakebusch[5], B. Nieswandt[1]

[1]Institute of Experimental Biomedicine I, University Hospital and Rudolf Virchow Center, University of Würzburg, Würzburg, Germany, [2]Boston Children's Hospital, PCMM, Boston, United States, [3]IHU LIRYC, Hopital Xavier Arnozan, Pessac, France, [4]University of Würzburg, Würzburg, Germany, [5]BRIC, Biomedical Institute, University of Copenhagen, Copenhagen, Denmark

Background: Small GTPases of the Rho family, such as RhoA and Cdc42, are critically involved in the regulation of cytoskeletal rearrangements during platelet activation. We have previously shown that megakaryocyte (MK)/platelet-specific RhoA deficiency leads to moderate thrombocytopenia and impaired platelet responses downstream of G-protein coupled receptors, whereas lack of Cdc42 was associated with moderate thrombocytopenia and enhanced agonist-induced platelet granule release. Despite partially overlapping downstream signaling pathways, little is known about the specific roles and functional redundancy of both proteins in platelet biogenesis and function.

Aims: We investigated functional redundancies of RhoA and Cdc42 in platelet production and function.

Methods: MK/platelet-specific (Pf4-Cre) RhoA/Cdc42 double knockout (DKO) mice were generated by intercrossing the respective single KO mice. MK and platelet morphology was analyzed by different microscopy techniques. Platelet functions were assessed by biochemical methods in vitro, or in vivo in models of arterial thrombosis and by hemostatic assays.

Results: Combined deficiency of RhoA and Cdc42 led to severe macrothrombocytopenia associated with pronounced alterations in MK morphology and generation of platelets of heterogenous size and granule content. The life span of circulating RhoA/Cdc42 DKO platelets was markedly reduced due to enhanced platelet clearance, whereas the rate of platelet production after antibody-induced platelet depletion was unaltered compared to wild-type littermates. RhoA/Cdc42-deficient platelets exhibited an overall reduction of agonist-induced integrin activation, but unaltered granule secretion. Despite severe hemostatic defects, $FeCl_3$-induced formation of occlusive thrombi was largely unaffected in RhoA/Cdc42 DKO mice.

Conclusions: These results implicate the existence of both distinct and overlapping roles of RhoA and Cdc42 in platelet production and function.

Research was funded by the DFG.

PB 540 | PDK1 is Crucial to Proplatelets Formation and Thrombopoiesis

B. Walker-Allgaier[1], P. Münzer[1], S. Geue[1], D. Eißler[1], F. Lang[2], H. Schulze[3,4], M. Gawaz[1], O. Borst[1]

[1]*University of Tuebingen, Cardiology and Cardiovascular Medicine, Tuebingen, Germany,* [2]*University of Tuebingen, Physiology, Tübingen, Germany,* [3]*Research Center for Experimental Biomedicine, Rudolf Virchow Center, Würzburg, Germany,* [4]*University of Würzburg, Department of Experimental Haemostaseology, Würzburg, Germany*

Background: Megakaryopoiesis is a complex process including megakaryocytes (MKs) maturation and differentiation. Finally, MKs form proplatelets within the bone marrow (BM) and release platelets in BM sinusoids. PDK1 has been shown to be highly expressed in platelets and megakaryocytes and is required for Ca^{2+}-dependent platelet activation, but its role in the regulation of platelet biogenesis has not been investigated so far.

Aims: The present study explored the role of PDK1 in the regulation of thrombopoiesis and platelet survival in a platelet- and megakaryocyte (MK) specific knockout approach.

Methods: PDK1-floxed mice were crossed with PF4-Cre mice to generate platelet-specific PDK1 deficient mice (*pdk1*$^{-/-}$) and wildtype littermates (*pdk1*$^{fl/fl}$); FACS analysis; Western Blot; RT-PCR; ploidy assay; proplatelets formation assay; immunohistological analysis.

Results: MK/platelet-specific PDK1-deficient mice (*pdk1*$^{-/-}$) developed a significant macrothrombocytopenia as compared to wildtype (*pdk1*$^{fl/fl}$) mice. As revealed by immunohistological analysis, *pdk1*$^{-/-}$ mice further displayed a remarkable MK hyperplasia as well as a significantly increased extramedullary thrombopoiesis. However, the size of spleen and liver was comparable between *pdk1*$^{-/-}$and *pdk1*$^{fl/fl}$ mice. While platelet lifespan was not significantly affected, *pdk1*$^{-/-}$ MKs have less contact to bone marrow sinusoids and displayed a drastic increased number of MKs with a significant lower size within the bone marrow. However, there was no significant difference in plasma TPO levels in *pdk1*$^{-/-}$ mice as compared to *pdk1*$^{fl/fl}$ mice. Further examination of bone marrow MKs revealed no significant difference in the ploidy of *pdk1*$^{-/-}$ MKs as compared to *pdk1*$^{fl/fl}$ MK, though *pdk1-null* MKs produced significantly less proplatelets indicating that PDK1 is required for proplatelet formation.

Conclusions: The present observations unraveled PDK1 as an important signaling molecule in proplatelet formation and thrombopoiesis.

PB 541 | Inhibition of MAP Kinase-interacting Kinase-1 (Mnk1) Regulates Platelet Functional Responses and Protein Synthesis in Megakaryocytes

B. Manne[1], R. Campbell[1], R. Badolia[2], S.P. Kunapuli[2], A. Weyrich[1], M. Rondina[1,3,4]

[1]*University of Utah, Molecular Medicine, Salt Lake City, United States,* [2]*Temple University School of Medicine, Philadelphia, United States,* [3]*University of Utah, Internal Medicine, Salt Lake City, United States,* [4]*George E. Wahlen VAMC GRECC, Salt Lake City, United States*

Background: MAPK-interacting kinases (Mnks) are serine/threonine kinases that control protein synthesis in neurons and neutrophils. The expression and function of Mnks in megakaryocytes (MKs) and platelets is unknown.

Aims: To evaluate the role of Mnk1 in MKs and platelets.

Methods: We used ETP-45835 (Mnk1 specific pharmacological inhibitor) to evaluate the role of Mnk1 in MKs and platelets.

Results: Mnk1, but not Mnk2, is expressed in human and murine MKs and platelets (Fig. A). Inhibiting Mnk1 activation in MKs with ETP-45835 reduced proplatelet formation. As protein synthesis is essential for proplatelet formation, we next examined the mechanisms by which Mnk1 regulates protein synthesis in MKs. We identified that CYFIP1, which repress translational in neurons through eIF4E, is expressed in MKs. Activation of Mnk1 in MKs was sufficient for eIF4E phosphorylation and release of CYFIP1 from eIF4E, thus permitting translation. Mnk1 inhibition reduced global protein synthesis by ~30%

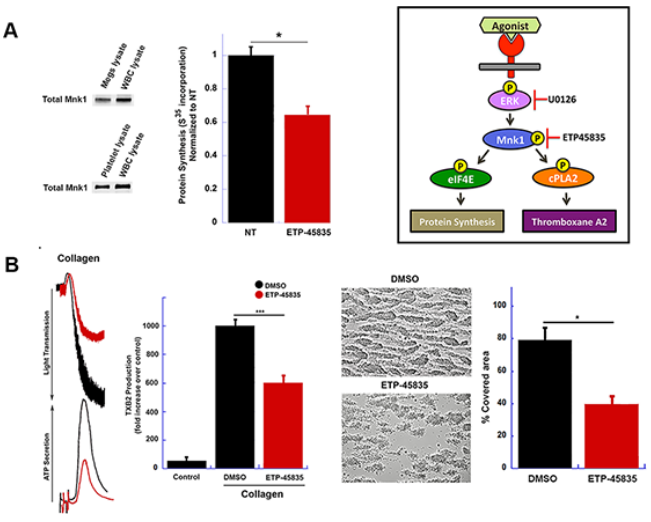

FIGURE 1 Mnk1 regulates platelet activation and protein synthesis in megakaryocytes

(Fig. A), as assessed by S[35]methionine, and prevented CYFIP1 dissociation from eIF4E. We next determined the role of Mnk1 in platelets. Mnk1 was activated in stimulated platelets (e.g. collagen, ADP). Mnk1 activation was abolished with U0126, an Erk1/2 specific inhibitor, indicating that Erk regulates Mnk1 activation in platelets. When Mnk1 activity was specifically inhibited with ETP-45385 *ex vivo*, platelet aggregation, secretion, TxB2 generation, and adhesion to collagen under flow was inhibited (Fig. B). Concordantly, treating mice with ETP-45385 *in vivo* prevented collagen and epinephrine induced pulmonary embolism. The addition of arachidonic acid to ETP45385-treated platelets *ex vivo* fully rescued platelet aggregation and TxB2 generation, demonstrating that Mnk1 activation in platelets regulates the arachidonic acid pathway.

Conclusions: Mnk1 controls proplatelet formation and protein synthesis in MKs. In platelets, Mnk1 regulates platelet activation responses and thrombosis through thromboxane dependent mechanisms.

PB 542 | On-track to Producing Commercially-Feasible cGMP-Compliant Human Platelets from induced Pluripotent Stem Cells at Clinical Scale

J. Thon[1,2], B. Dykstra[1,2], L. Beaulieu[2], C. Peters[2], J. Italiano[1,2]

[1]*Brigham and Women's Hospital, Medicine, Boston, United States,* [2]*Platelet BioGenesis, Dorchester, United States*

Background: Platelets are the principal blood cells responsible for clot formation at sites of active bleeding, and are critical for treatment of cancer, trauma, and surgery. Nevertheless, donor-derived platelet transfusions are significantly limited by: donor shortages and recipient access; usable shelf life of only 1.5 - 2 days due to a 5-day storage limit at room temperature and a 2-day screening period for microbial growth and donor-specific pathogens; risk of bacterial and viral transmission; and wide functional variability among units and donors, leading to over-transfusion to insure effective bleeding control limit the effectiveness of donor-derived platelets.

Aims: The production of lab-generated human platelets is necessary to extend platelet transfusions beyond major cities in first-world countries and meet present and future transfusion needs.

Methods: We are advancing a cGMP-compliant; 1) serum- and feeder-free cell culture protocol to differentiate human induced pluripotent stem cells into megakaryocytes; and 2) automated scalable microfluidic device that supports continuous media perfusion and parallelization, maximizes cell zonal distribution and trapping, and allows independent control of pressure, shear stress, and stretch force exposure to trigger platelet production.

Results: We have developed a cGMP-compliant process that can produce >3x10^8 human platelets per business card-sized bioreactor, and is amenable to clinical and commercial scale up to produce an apheresis-equivalent platelet unit for < $5,000. Morphology, ultrastructure and function of our megakaryocytes and bioreactor platelets is ongoing, and consistent with donor platelets.

Conclusions: We can generate functional human megakaryocytes and platelets from cGMP-compliant human induced pluripotent stem cell cultures at costs/yields necessary to make production of a platelet transfusion unit clinically and commercially feasible.

PB 543 | Disruption of the Cholesterol Efflux Transporters ABCA1 and ABCG1 Alters Megakaryocyte Proplatelet Production

A.B. Ouweneel[1], M. van der Stoep[1,2], H.F. Heijnen[2], C. Strassel[3], M. Van Eck[1], S.J.A. Korporaal[2]

[1]*Leiden Academic Centre for Drug Research, Leiden University, Division of Biopharmaceutics, Cluster BioTherapeutics, Leiden, The Netherlands,* [2]*University Medical Center Utrecht, Center for Circulatory Health, Department of Clinical Chemistry and Haematology, Utrecht, The Netherlands,* [3]*INSERM, Université de Strasbourg, EFS ALCA, BPPS UMR-S 949, FMTS, Strasbourg, France*

Background: Platelets, produced by megakaryocytes in the bone marrow, play an important role in the onset and development of atherosclerosis and atherothrombosis. Platelet numbers and functionality are affected by hypercholesterolemia in mice and humans.

Aims: We investigated whether disruption of cholesterol efflux influences megakaryocyte proplatelet production.

Methods: Proplatelet production was studied in bone marrow explants from mice lacking ATP-Binding cassette transport A1 (ABCA1 KO), G1 (ABCG1 KO) or both (ABCA1/ABCG1 double KO (dKO)) and wildtypes.

Results: Explant cultures of both ABCA1 KO and ABCG1 KO bone marrow showed lower amounts of megakaryocytes at the periphery of the explants (-52±4% ($p < 0.01$) and -32±3% ($p < 0.001$) resp.), indicating that reduced cholesterol efflux capacity negatively influences either megakaryocyte maturation from progenitor cells, or their migratory capacity. Interestingly, ABCA1 and ABCG1 deletion had differential effects on proplatelet formation. ABCA1 deficiency inhibited proplatelet formation (-67±16%, $p < 0.001$). In contrast and despite the lower amount of megakaryocytes, a clear increase in proplatelet formation was observed in ABCG1 KO explants (+243±77%, $p < 0.001$). In line with the notion that ABCA1 and ABCG1 independently modulate megakaryocyte maturation and/or migration, the amount of visible megakaryocytes was even further reduced in bone marrow explants from ABCA1/ABCG1 dKO mice (-75±3%, $p < 0.001$). In further support, the marked increase in proplatelet formation resulting from ABCG1 deficiency was diminished upon additional deletion of ABCA1, leading to only a mild increase in proplatelet formation (+42±15%, $p < 0.05$) in dKO compared to wildtype megakaryocytes.

Conclusions: In conclusion, absence of cholesterol efflux transporters ABCA1 and ABCG1 alters proplatelet production by megakaryocytes. Moreover, our studies suggest that modulation of individual cholesterol efflux transporter function may translate into an overall differential effect on platelet production.

PB 544 | Environmental Chronic Stress Induces Abnormal Megakaryopoiesis Predisposing to Thrombosis: Protective Effects of Apocynin

L. Sandrini[1,2], A. Ieraci[1], P. Amadio[2], M. Popoli[1], E. Tremoli[2], S.S. Barbieri[2]

[1]*Università degli Studi di Milano, Dip. Scienze Farmacologiche e Biomolecolari, Milan, Italy,* [2]*Centro Cardiologico Monzino, Milan, Italy*

Background: Environmental chronic stress (ECS) has been identified as a trigger of acute coronary syndromes (ACS). Changes in redox balance, enhanced reactive oxygen species (ROS) production, and platelet hyper-reactivity were detected in both ECS and ACS. However, the mechanisms by which ECS predisposes to thrombosis are not well known.

Aims: We analysed the impact of ECS on megakaryopoiesis and platelet activation in mice and the effect of Apocynin, an inhibitor of NADPH oxidase, in this experimental setting.

Methods: Forced swimming for 4 days (5 min twice/day) and FeCl3 arterial injury were used as model to induce ECS and to assess thrombosis in mice, respectively. Megakaryocytes and platelets were analyzed by flow cytometry. Apocynin was administrated 2.4 mg/ml in drinking water for 4 days.

Results: We show that ECS leads to an abnormal megakaryopoiesis increasing the number of BM megakaryocytes (MKs) and affecting circulating platelets. MKs of stressed mice show an advanced maturation state (e.g. expression of CD42d), and an enhanced ability to produce ROS. Interestingly, a higher number of large and reticulated platelets with marked functional activation (e.g. integrin $a_{IIb}b3$ and P-selectin expression, and platelet/leukocyte aggregates) is detected after ECS. In addition, Apocynin decreases the total number of MKs and prevents their ability to generate ROS without affecting the percentage of $CD42d^+$ cells.

Finally, Apocynin reduces the hyper-activation of platelets and the enhanced susceptibility to $FeCl_3$-induced arterial thrombosis in stressed mice.

Conclusions: Apocynin treatment, reducing ROS generation in MKs, restores the physiological bone marrow megakaryopoiesis and platelet behaviour, and it prevents the detrimental effect of chronic stress on atherothrombosis. These data suggest a potential use of NADPH oxidase inhibitors in the occurrence of thrombosis associated with chronic stress. Studies in human will verify the clinical impact of these findings.

PB 546 | CCalcium/calmodulin-dependent Protein Kinase II (CamKII) Regulates Platelet Formation

R. Campbell[1], D. Shi[1], J. Winters[1], S. Bhatlekar[1], B. Manne[1], A. Jiang[1], S. Saperstein[1], M. Rondina[1,2,3], P. Bray[1,2], A. Weyrich[1,2]

[1]*University of Utah, Molecular Medicine, Salt Lake City, United States,* [2]*University of Utah, Internal Medicine, Salt Lake City, United States,* [3]*George E. Wahlen VAMC GRECC, Salt Lake City, United States*

Background: CamKII is a known regulator of actin polymerization. Calcium fluxes result in phosphorylation of CamKII and activation of downstream Rho family small GTPases such as Rac-1 causing actin polymerization. While CamKII has been demonstrated to regulate dendrite formation in neurons, it's role in platelet formation has never been studied.

Aims: We hypothesized that calcium signaling through CamKII would regulate proplatelet formation in megakaryocytes.

Methods: We examined the Platelet RNA And eXpression-1 (PRAX-1) data set to determine if *CamKII* expression correlated with platelet counts in humans. RNA-seq was performed on murine megakaryocytes (MKs) and platelets to assess *CamKII* expression. Calcium fluxes were inhibited in cultured murine Mks and CamKII phosphorylation levels and proplatelet formation was determined. Mice were treated *in vivo* with KN93, a specific CamKII inhibitor, and platelet counts were followed over time.

Results: Human and murine MKs and platelets express both isoforms of *CamKII* (gamma and delta). *CamKII delta* expression in humans positively correlated with platelet counts ($p=0.03$). Concordantly, *CamKIIdelta* expression significantly increased during human MK maturation and proplatelet formation *in vitro*. The calcium chelators EDTA and BAPTA significantly inhibited CamKII phosphorylation ($p< 0.01$) and reduced proplatelet formation by 45% ($p< 0.01$). Specifically inhibiting CamKII with KN-93 significantly blocked CamKII phosphorylation, proplatelet formation by 90% ($p< 0.001$), and decreased Rac1-GTP activity, a downstream substrate of CamKII, two-fold. Activation of CamKII through brain-derived neutrophic factor increased proplatelet formation by 50%. Inhibiting CamKII *in vivo* with KN-93 significantly decreased platelet counts by 42% ($p< 0.05$).

Conclusions: Our data demonstrate, for the first-time, calcium signaling regulates proplatelet formation through the activation of CamKII and its subsequent interactions with Rac-1.

PB 547 | Presence and Absence of Platelet Proteins in Differentiating Megakaryocytes

J.M. Koornneef[1], F.P.J. van Alphen[2], C. van der Zwaan[1,2], M. Hansen[3], E. van den Akker[3], K. Mertens[1,4], M. van den Biggelaar[1], A.B. Meijer[1,4]

[1]*Sanquin Research, Department of Plasma Proteins, Amsterdam, The Netherlands,* [2]*Sanquin Research, Department of Research Facilities, Amsterdam, The Netherlands,* [3]*Sanquin Research, Department of Hematopoiesis, Amsterdam, The Netherlands,* [4]*Utrecht Institute for Pharmaceutical Sciences, Utrecht University, Department of Pharmaceutics, Utrecht, The Netherlands*

Background: Generation of functional platelets from in vitro cultured megakaryocytes (MKs) remains a challenge. The function and protein content of MKs at their final stage of differentiation should closely reflect that of platelets. Insight into differences between cultured MKs and platelets may therefore contribute to the development of protocols to obtain functional platelet-generating MKs.

Aims: We aim to compare the proteome and function of platelets with in vitro maturating MKs.

Methods: Hematopoietic progenitor cells from peripheral blood were differentiated along the MK lineage until formation of proplatelets was observed. The changes in protein levels were assessed using label-free quantitative mass spectrometry analysis, and compared with the proteome of normal platelets. In addition, maturing MKs were stimulated with platelet agonists to assess the release of granule content.

Results: MK stimulation with platelet agonists induced surface expression of P-selectin and secretion of VWF already at an early stage of MK differentiation. This shows that the secretory machinery is already developed in immature MKs. Proteomics data of the immature MKs also revealed the presence of platelet proteins that contribute to signaling, degranulation, and coagulation. These proteins were strongly upregulated upon further differentiation along the MK lineage. Several proteins were identified in platelets but not in cultured MKs, including Factor V (FV), EGF, and VEGFC. Absence of FV may be expected as it is endocytosed by MKs and the culture media did not contain FV. Other proteins may not be identified because they originate from endocytosis as well, or because their transcription trigger is absent in cultured MKs.

Conclusions: We show that cultured MKs resemble platelets in that they support granule release and express the required proteins for this. Platelet proteins that are not detected in MKs represent attractive targets for future investigations directed towards obtaining functional platelet-generating MKs.

PB 548 | Platelet Factor 4 (PF4) Levels Correlate with Platelet Count and Ability to Inhibit Megakaryopoiesis in Pediatric Patients with ITP

E. Tkaczynski, A. Arulselvan, M. Lambert

The Children's Hospital of Philadelphia, Philadelphia, United States

Background: Immune Thrombocytopenia (ITP) is a relatively rare disorder resulting in significant thrombocytopenia. Mechanisms that determine degree and duration of thrombocytopenia are not well understood. Our previous work has shown that platelet (p)PF4 levels are inversely correlated with platelet count and that PF4 released by megakaryocytes in a damaged bone marrow inhibits megakaryocyte proliferation. We hypothesized that PF4 levels may influence meg biology and platelet count in patients with ITP.

Aims: Determine the relationship between pPF4 levels and platelet count in pediatric ITP patients as well as to determine whether this would influence lymphocyte profiles.

Methods: As a pilot study, we collected blood on 15 patients with ITP and examined the relationship between platelet count and pPF4 level using a PF4 ELISA kit. We also cultured megakaryocytes to determine whether PF4 levels would influence cell growth and differentiation using murine PF4 knockout bone marrow.

Results: Patient platelet count did not correlate with megakaryocyte growth from bone marrow. However, there was an inverse relationship between pPF4 level and megakaryocytes cultured from murine bone marrow (R^2=0.45, p= 0.04). In contrast, pPF4 levels correlated with platelet count (R^2=0.71, p=0.003) in contrast to control populations where PF4 levels were inversely correlated with PF4 levels (historical data). Finally, patients with ITP had significantly higher numbers of CXCR3B (receptor for PF4 on lymphocytes) positive lymphocytes in the peripheral blood compared to controls.

Conclusions: Platelet PF4 levels in pediatric patients with ITP determine megakaryocyte proliferation from bone marrow. In contrast to the general pediatric population, platelet PF4 levels in this patient population correlate with platelet count. The PF4 level may influence various lymphocyte markers and may help modulate the immune response. Further studies will need to examine whether platelet PF4 levels influence bleeding or response to therapy.

PB 549 | Role of NOD-like receptors (NLRs) in Megakaryo/thrombopoiesis

L.P. D'Atri[1], M. Centurión[2], S. Negrotto[1], M. Schattner[1]

[1]Institute of Experimental Medicine, CONICET-National Academy of Medicine, Laboratory of Experimental Thrombosis, Buenos Aires, Argentina, [2]Hospital Bernardino Rivadavia, Endocrine Gynecology and Reproduction Section, Buenos Aires, Argentina

Background: Toll-like receptors are expressed in megakaryocytes and platelets, providing a link between the inflammatory response and megakaryo/thrombopoiesis. Recently, the expression and functionality of other pattern recognition receptors (PRRs) such as the NOD-like receptors (NLRs): NOD2 and NLRP3, were described in platelets, however its role in megakaryocytes remain unknown. NOD2 is an intracellular receptor for muramyl dipeptide (MDP), the minimal bioactive peptidoglycan motif common to all bacteria. The NLRP3 activation is triggered by endogenous damage signals such as monosodium urate crystals (MSU) and also by PRRs agonists. NLRP3 recruits

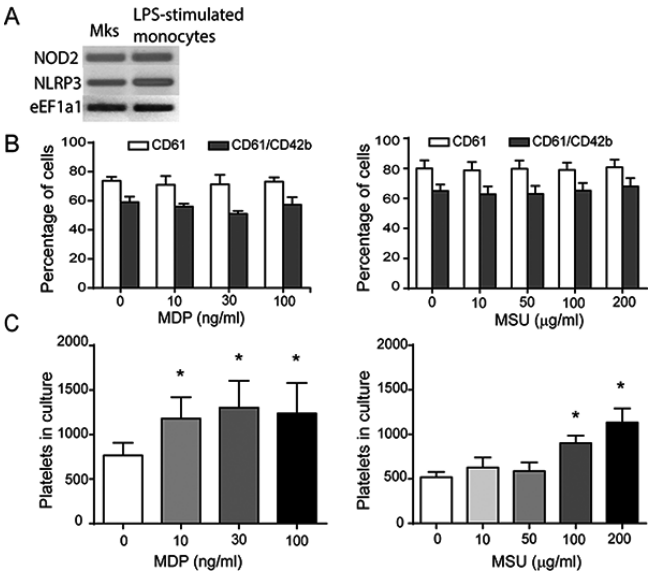

FIGURE 1 *p<0.05 vs. without agonist, n=5

caspase-1 to assemble the inflammasome and process Interleukin-1 beta.

Aims: We here aimed to study the expression and functionality of NOD2 and NLRP3 inflammasome in human megakaryo/thrombopoiesis.

Methods: NOD2 and NLRP3 expression were determined by semi-quantitative RT-PCR in human $CD34^+$-derived megakaryocyte progenitors and LPS-stimulated monocytes as positive control. Surface expression of CD61 and CD42b as indicators of megakaryocyte differentiation and maturation, respectively, and the number of cultured-derived platelets were determined by flow cytometry. Data was analyzed by ANOVA.

Results: We found that megakaryocytes progenitors constitutively expressed NOD2 and NLRP3 (Fig. 1A). Stimulation of cells with MDP failed to affect megakaryocyte survival, proliferation, differentiation or maturation (Fig. 1B). Similar results were observed after MSU stimulation. However, both MDP and MSU significantly increased platelet generation in culture (Fig. 1C).

Conclusions: These findings show that the activation of two NOD-like receptors regulate thrombopoiesis without altering megakaryopoiesis, suggesting that these pathways could be involved in reactive thrombocytosis caused by bacterial infections.

PB 550 | *In vitro* Generation of Functional Megakaryocytes Derived from Induced Pluripotent Stem Cells of Parahaemophilia Patients

C. Radu[1], M. Trevisan[2], C. Bulato[1], E. Campello[1], F. Sartorello[1], L. Spiezia[1], L. Barzon[2], P. Simioni[1]

[1]University of Padua, Department of Medicine, Padua, Italy, [2]University of Padua, Department of Molecular Medicine, Padua, Italy

Background: Congenital factor V (FV) deficiency (parahaemophilia) is a rare autosomal recessive bleeding disorder. The ability of obtaining induced Pluripotent Stem Cells (iPSCs) derived megakaryocytes (MK) from parahaemophilia patients represents a powerful technology to study the mutant gene function, to characterize platelet FV and consequently to develop a gene therapy to correct the genetic defects.

Aims: For the development of patient-specific *in vitro* MK cell model for FV deficiency, by using iPSCs, and for the investigation of genotype-phenotype correlates of the disease.

Methods: Peripheral mononuclear blood cells were isolated and cultured to expand into erythroblast cells and then were transduced with Sendai Virus vectors or episomal plasmids technique, expressing the factors OCT4, SOX2, KLF4 and cMyc. To verify the differentiation potential of iPSCs, the Embryoid Bodies test was performed and gene expression of markers belonging to the three germ layers was analysed by RT-PCR. The iPSCs obtained from healthy and parahaemophilia subjects were differentiated into the MK lineage. iPSC-MK were analysed for the expression of CD41 and FV by immunofluorescence technique.

Results: iPSC-MK were capable of platelet formation *in vitro*, showing no major differences in morphology and function with respect to blood-derived MK. iPSC-MK cells were stained with CD41 and the confirmed that these iPSC-MK were indeed MK-like cells. iPSCs-MK from healthy subjects were positive for the expression of FV. In the contrary, iPSC-MKs from parahaemophilia patients were negative.

Conclusions: The ability of obtaining iPSCs-MK from parahaemophilia patients represents a useful tool to study the underlying mechanisms of disease, for drug screening tests, as well as a source of pluripotent cells, that could be modified with gene editing tools to rescue the phenotype of the disease, the mutant gene function, to characterize platelet FV and consequently to develop a gene therapy to correct the genetic defects.

PB 553 | The Application of High throughput Sequencing to the Diagnosis of Thrombocytopenia

R. Wheeler, J. Cutler, M. Mitchell

Viapath Analytics at Guy's & St. Thomas' Hospitals, Molecular Haemostasis, London, United Kingdom

Background: Inherited platelet disorders are a heterogeneous group of rare diseases associated with altered platelet structure and/or function, reduced platelet count and mucocutaneous bleeding of varying severity. The published frequency of 1/10000 individuals is likely to be an underestimate as there is currently no consensus approach to diagnosis. We have performed molecular analyses in 68 patients diagnosed with macrothrombocytopenia or familial thrombocytopenia in whom BSS and GT had been excluded. We analysed a subset of genes known to be associated with platelet function and were able to identify a causative mutation in 34 cases. This leaves 50% of patients without a molecular diagnosis.

Aims: To date over 50 genes have been implicated in the aetiology of platelet disorders. Screening this number of genes using conventional methodologies is neither practical nor cost-effective. Therefore we have set up a pilot study to investigate the application of high throughput sequencing to the molecular diagnosis of thrombocytopenias.

Methods: We used the Agilent SureSelect focused exome to investigate 12 patients analysed previously (6 with an identified mutation and 6 without). The Agilent NGS Bravo platform was used for library preparation and target enrichment. Sequencing was performed on an Illumina MiSeq. VCF files were generated using the Broad Institute Best Practice guidelines. The Ingenuity Variant Analysis Package was used to identify and prioritise potential disease-causing variants.

Results: All 6 previously identified mutations were recapitulated. We were also able to identify potential causative mutations in a number of patients for whom diagnosis had previously been unavailable. These are being investigated further in family members.

Conclusions: We have shown that high throughput sequencing using a focused exome allows rapid molecular diagnosis of patients with inherited thrombocytopenia even in the absence of detailed phenotypic data. This information will improve patient treatment and prognosis.

PB 554 | PEAR1 Methylation Is a Determinant of Platelet and Plasma P-selectin Levels, Platelet-leukocyte Aggregates and Platelet Distribution Width

B. Izzi[1], F. Gianfagna[2,3], K. Cludts[1], A. De Curtis[2], P. Verhamme[1], A. Di Castelnuovo[2], C. Cerletti[2], G. de Gaetano[2], M. Hoylaerts[1], L. Iacoviello[2,3], Moli-family Investigators

[1]University of Leuven, Department of Cardiovascular Sciences - CMVB, Leuven, Belgium, [2]IRCCS Istituto Neurologico Mediterraneo NEUROMED, Department of Epidemiology and Prevention, Pozzilli, IS, Italy, [3]University of Insubria, Department of Medicine and Surgery, Varese, Italy

Background: Platelet Endothelial Aggregation Receptor 1 (PEAR1) is a transmembrane receptor involved in platelet activation and megakaryopoiesis. *PEAR1* variants were associated with differential platelet response to activation with possible implications for cardiovascular disease onset. *PEAR1* expression during megakaryopoiesis is driven by DNA methylation.
Aims: To investigate *PEAR1* DNA methylation changes as determinants of platelet phenotype and function variability in a cohort of large families with or without myocardial infarction (MI) at young age.
Methods: Moli-family is an Italian family-based cohort including 732 subjects (aged 43±19 SD, 44% men) from 54 extended pedigrees (23 families with familiarity for MI at young age and 31 matched control families). *PEAR1* methylation (32 CpG sites) was investigated for 605 Moli-family participants, for whom plasma P-selectin levels and blood counts were available. Whole blood platelet function was assessed through platelet P-selectin and platelet-leukocyte mixed aggregates measurements. We performed principal factor analysis (PFA) to identify groups of CpG sites with similar methylation estimates (eigenvalue > 1.0), and multivariable linear regression analysis (using age, sex, smoking, and familiarity for MI as covariates) to assess their relation with each of the platelet specific variables measured.
Results: We discovered a methylation factor (PEAR1-F1) characterized by positive loadings of previously identified megakaryocyte-specific CpG sites (Izzi et al. Blood 2016) including CpG 7_8, 19_20, 15_16, 25_26 and 31_32. PEAR1-F1 was inversely significantly associated with platelet ($p< 0.0001$) and plasma ($p=0.0004$) P-selectin and both platelet-monocyte ($p=0.0002$) and platelet-PMN ($p=0.0065$) aggregates in whole blood, while it was positively associated with PDW ($p=0.0022$).
Conclusions: This large *PEAR1* epigenetic analysis, performed in the framework of the Moli-family epidemiological study, for the first time links methylation changes to platelet function variability.

PB 555 | Single Cell Transcriptome Analysis in Living Human Platelets

C. Zara, R. D'Alessandro, M. Brambilla, E. Tremoli, M. Camera

Centro Cardiologico Monzino IRCCS, Milano, Italy

Background: Platelets (PLT) are involved in other functions besides hemostasis, ranging from inflammation, immunity to angiogenesis and tumor metastasis. It is reasonable that within circulating PLTs there are subsets committed to play these different functions by means of a specific proteome and transcriptome. Transcriptome analysis on the whole platelet population does not allow to characterize subsets.
Aims: To identify PLT subsets taking advantage of Smartflare technology that allows the identification of mRNA in single living PLTs by flow cytometry.
Methods: Single cell expression of 50 mRNA involved in inflammation and hemostasis was assessed in PLTs isolated from 10 healthy subjects aged 30±10 years. Experimental conditions were optimized in order to reach an uptake of the control probe in more than 90% of PLTs. PLTs were then incubated with nanoparticles conjugated to an oligonucleotide complementary to a specific mRNA. Analysis was performed by imaging flow cytometer in order to assess the fluorescence intensity related to mRNA expression only in PLTs with internalized probes.
Results: Among the analyzed mRNA, 10 were undetectable, while 3/4 of transcripts involved in hemostasis, like P-selectin, and only 1/4 of genes involved in inflammation, like C-C motif chemokine ligand 5, were found in more than 70% of PLTs (86±7 and 97± 4 %). Conversely, 3/4 of genes related to inflammation, like COX1, and 1/4 of mRNA related to hemostasis, like tissue factor, were found in a reduced percentage of PLTs (49±8 and 44±10%). Housekeeping genes like GAPDH, 18S and actin-β were expressed in more than 90% of PLTs.
Conclusions: These results show for the first time that in healthy subjects a differential enrichment of specific mRNA occurs in platelet subsets. It is tempting to speculate that the relative abundance of both mRNA as well as the platelet subsets may change in pathological condition.

PB 556 | Uncovering GEnetic NEtworks Underlying Platelet Response to Thienopyridines by EXome Sequencing of Extreme Phenotype Patients: Discovery and Validation Results

J.-L. Reny[1,2], M. Ibberson[3], B. Stevenson[3], Y. Daali[2], M. Docquier[2], I. Xenarios[3], T. Cuisset[4], M.-C. Alessi[5], P. Fontana[2]

[1]University Hospital Geneva, Geneva, Switzerland, [2]Geneva University Hospitals and Faculty of Medicine, Geneva, Switzerland, [3]Swiss Institute of Bioinformatics, Lausanne, Switzerland, [4]Marseille University Hospital, Cardiology, Marseille, France, [5]Marseille University Hospital, Hemostasis Laboratory, Marseille, France

Background: The genetic determinants of the platelet reactivity (PR) phenotype in clopidogrel-treated subjects play an important role (heritability, $h^2=0.73$) but previous GWAS approaches have identified very few variants, explaining only 5-12% of PR variability. Pilot studies relying on whole exome sequencing have identified candidate genes and pathways.
Aims: To validate, in independent cohorts, genes and pathways that contribute to the variability of PR observed in response to clopidogrel treatment.
Methods: Based on previous whole exome sequencing (WES) findings in 96 extreme PR phenotype patients from a 534 clopidogrel-treated

outpatients a network was built. Genes and pathways were tested in an independent population of 96 extreme PR phenotype patients Compliance to clopidogrel was confirmed by the quantification of clopidogrel carboxylic acid in the serum in both populations. Average coverage of the exome bait region was 70-fold, with more than 98% of bases having at least 10x read-depth coverage.

Results: Exome analysis samples of the discovery cohort yielded 585 variants in 418 genes with a different frequency between LPR and HPR patients (adjusted p-value< 0.05). Principal component analysis showed complete discrimination of the two extreme PR groups, which was not dependent on the known CYP2C19*2 variant. Interestingly, the previously identified B4GALT2 c.909C>T variant was not detected in the discovery cohort. Based on literature search and gene annotation a network of 40 genes was built with several known CYP-P450 2C19, 2C19, 2C18 genes, Thrombospondin, apoptosis related genes (BAX, CASP9, SORBS3 and BIRC6) and CLASP2 (Cytoplasmic linker associated protein 2) involved with stabilization of microtubules. In the validation population the network genes from the top of the list were confirmed, mostly Cytochrome genes.

Conclusions: The candidate genes and pathways identified in the WES population network were confirmed in the validation population but most of the information is restricted to Cytochrome genes.

PB 557 | Poorly Controlled Diabetes Mellitus Is Associated with Decreased Aspirin-mediated Acetylation of Platelet Cyclooxygenase-1 (COX-1) at Serine 529

F. Finamore[1], J.-L. Reny[2], S. Malacarne[3], P. Fontana[4], J.-C. Sanchez[1]

[1]University of Geneva, Human Protein Sciences, Geneva, Switzerland, [2]Geneva University Hospital, Division of Internal Medicine and Rehabilitation, Geneva, Switzerland, [3]Geneva University Hospitals, Endocrinology, Diabetology and Nutrition Unit, Geneva, Switzerland, [4]Geneva University Hospitals, Division of Angiology and Haemostasis, Geneva, Switzerland

Background: Diabetes is a major risk factor for cardiovascular diseases. Although aspirin is considered as a cornerstone of the prevention and treatment of the atherothrombosis-related ischemic events, this antiplatelet drug appears to be less effective in poorly controlled diabetic patients. It has been suggested that glycation of platelet proteins plays a pivotal role in poor responsiveness to aspirin. However, a direct effect on the critical residue (serine 529, or Ser529) of the catalytic pocket of cyclooxygenase 1 (COX-1) has never been demonstrated.

Aims: This study aimed to elucidate the impact of hyperglycaemia on the aspirin acetylation of platelet COX-1 from poorly controlled diabetes mellitus.

Methods: We used targeted mass spectrometry to measure the level of acetylation of platelet cyclooxygenase-1 (COX-1) at serine 529 on control (HbA1c < 6%) and diabetic (HbA1c ≥ 8%) subjects.

Results: Using a targeted mass spectrometry approach, we found that hyperglycaemia only had a direct impact on the level of acetylation of the Ser529 residue, whereas the overall COX-1 acetylation level remained unchanged. Also, the functional aspirin-induced inhibition of COX-1 was dose-dependently impaired as glucose concentrations increased.

Conclusions: These results provide new insights into the interplay between glucose and aspirin and their effects on platelet COX-1; they provide a mechanistic explanation for the phenomenon of poor response to aspirin in diabetic patients.

PB 559 | A Combination of Biochemical and Functional Approaches Shows a Hyperactivation of Src Family Kinases-mediated Signaling Pathways in Platelets from Obese Patients

M.N. Barrachina[1,2], A.M. Sueiro[3], F.F. Casanueva[4], M. Pardo[5], Á. García[1,2]

[1]Center for Research in Molecular Medicine and Chronic Diseases (CIMUS) University of Santiago de Compostela, Platelet Proteomics, Santiago de Compostela, Spain, [2]Instituto de Investigación Sanitaria de Santiago (IDIS), Santiago de Compostela, Spain, [3]Instituto de Investigación Sanitaria de Santiago (IDIS), Servicio de Endocrinología, Xerencia de Xestión Integrada de Santiago (XXS), Santiago de Compostela, Spain, [4]Instituto de Investigación Sanitaria de Santiago (IDIS), Grupo de Endocrinología Molecular y Celular, Santiago de Compostela, Spain, [5]Instituto de Investigación Sanitaria de Santiago (IDIS), Grupo Obesidómica, Santiago de Compostela, Spain

Background: Central obesity constitutes a relevant risk factor for the development of atherothrombosis and coronary artery disease. Platelets play a fundamental role in this increased cardiovascular risk since they show hyperactivation and lower sensitivity to antiplatelet therapy in obese patients.

Aims: The main goal of this study was to identify platelet biomarkers related to the risk of suffering atherothrombosis in obese patients without cardiovascular disease, confirm the platelet activation levels in these patients, and identify those activation pathways more altered.

Methods: The study was done by a combination of proteomic and functional analyses. For the former, platelets were obtained from ten obese patients (BMI>40), with no associated comorbidities or chronic treatments, and ten age- and sex-matched lean controls. Proteome analyses were based on two-dimensional differential in-gel electrophoresis (2D-DIGE) and mass spectrometry. Validations were by western blotting and functional studies by aggregation assays.

Results: Following the proteomic analysis, we detected 55 differences that varied between obese and lean groups. From those, 38 were successfully identified by MS, corresponding to 28 open-reading frames. Most proteins were involved in platelet activation and aggregation, such as integrin alpha-IIb, alpha actinin-1, actin, and vinculin. Since proteomic data pointed towards alteration in Src family kinases (SFKs)-mediated signaling pathways, we explored the levels of the active form of Src (pTyr418) in a cohort of obese patients and lean controls, and found this form was up-regulated in the obese group. Moreover, aggregation studies showed platelets from obese patients were hyper-reactive in response to collagen and collagen-related

peptide (CRP) pointing towards GPVI signaling as one of the altered pathways.

Conclusions: In conclusion, our results suggest a higher activation state of SFKs-mediated signaling pathways in platelets from obese patients, with a primary involvement of GPVI signaling.

PB 560 | First Quantitative Proteomic Approaches of Platelet Protein Expressions and Networks in Human MYH9-Related Disorders

N. Schlegel[1], M. Le Gall[2,3], A. Vincenot[1], O. René[1], V. Salnot[2,3], M. Leduc[2,3], C. Broussard[2,3], M.-F. Hurtaud-Roux[1], S. Binard[1], S. Crosnier[4], M. Canton[4], P. Ohlmann[4]

[1]National Reference Center on Inherited Platelet Disorders and Service d'Hématologie Biologique, Hôpital Robert Debré, Paris, France, [2]INSERM U 1016 Institut Cochin, CNRS UMR 8104, Plateforme Protéomique 3P5, Paris, France, [3]Université Paris Descartes, Sorbonne Paris Cité, Paris, France, [4]Agro-Bio R and D, La Ferté Saint Aubin, France

Background: MYH9-Related Disorders (MYH9-RD) - rare autosomal dominant disorders characterized by decreased platelet count but giant platelets, leukocyte inclusions, and, in some cases, various combinations of hearing loss, nephropathy and cataracts - are due to mutations in *MYH9* gene coding the non muscle myosin-IIA heavy chain (MYH9). A proteomic approach of the molecular role of wild-type (WT) MYH9 has been reported in rare extra-platelet studies, (Hays 2014, Zhang 2015). The consequences of *MYH9* mutations on platelet proteins expression is poorly known.

Aims: To identify modifications of MYH9 partners expression and networks within MYH9-RD platelets compared to healthy donors using different proteomic approaches.

Methods: Platelets from MYH9-RD patients (n=4, platelet count mean= 54G/L, large platelets mean : 21%, all mutations located in the tail domain) and from healthy donors (n=4) were isolated from Platelet Rich Plasma. Proteomic study of platelet crude extracts was performed by 2D-DIGE and Label Free analysis. Bioinformatic analysis of the results was performed using Ingenuity and Pathway Studio software.

Results: From 1,756 platelet proteins identified and quantified, Label Free analysis showed altered expression of 128 proteins in patients while the 2D-DIGE analysis highlighted 23 altered proteins (ANOVA $p< 0.05$). We identified an association between mutated MYH9 and an altered expression (either up- or down- fold changes) of proteins co-acting with cytoskeleton signaling - such as FLNA, VCL, TLN, TUBB, MSN - and main functional networks. Other myosins such MYL6 and MYL12A were also found affected.

Conclusions: For the first time we identified alterations in MYH9 interacting proteins and networks within MYH9-RD platelets as compared to MYH9-WT ones. Despite the small number of patients these results contribute to amplify the understanding of MYH9 functioning and provide molecular data on the des-organization of MYH9-RD platelets.

PB 562 | Platelets in Severe Aortic Stenosis Have an Altered Protein Profile and Are More Vulnerable upon Activation Compared to Coronary Artery Disease

C. Christersson[1], A. Dimberg[2], U. Alström[2], E. Ståhle[2]

[1]Uppsala University, Department of Medical Sciences, Cardiology, Uppsala, Sweden, [2]Uppsala University, Department of Surgical Sciences, Thoracic Surgery, Uppsala, Sweden

Background: Patients with severe aortic stenosis (AS) have impaired von Willebrand factor and the altered coagulation might contribute to a bleeding tendency. Platelets are sensitive to high shear stress.

Aims: The aim was to evaluate the platelet proteome in severe AS and platelet response to activation compared to patients with coronary artery disease (CAD).

Methods: Platelets were purified from whole blood from AS (n=10) and CAD (n=10) upon admission before surgery. After preparation the proteins were analyzed by mass spectrometer. Whole blood was

TABLE 1 Platelet proteins in aortic stenosis compared to coronary artery disease

Protein name	LOG2 ratio AS/CAD	P-value	Protein name	LOG2 ratio AS/CAD	p-value
Protein CVD3 homolog	-0.31	0.003	Platelet endothelial aggregation receptor 1	-0.34	0.044
Dematin	-0.44	0.006	Microtubule-associated protein RP/EB family member 1	0.38	0.010
Septin-6	-0.36	0.007	Rho GDP-dissociation inhibitor 2	0.31	0.010
Bifunctional ATP-dependent dihydroxacetone kinase/FAD-AMP lyase	-0.55	0.016	Ras-related protein Rab-1B and 1C	0.36	0.014
ATP synthase subunit d. mitochondrial	-0.35	0.017	Tubulin alpha-8 chain	0.29	0.015
Hematopoetic lineage cell-specific prrotein	-0.26	0.010	HLA class I histocompatibility antigen	0.43	0.035
Filamin-A	-0.28	0.033	Integrin alpha-6	0.36	0.036
cGMP-dependent protein kinase	-0.68	0.039	Ras-related protein protein Rab-27B	0.35	0.043
Protein G6b	-0.50	0.042	Glycine-tRNA ligase	0.45	0.047

activated ex vivo by CRP-XL and ADP and the expression of fibrinogen, CD62P, and CD63 on platelets were evaluated.

Results: A total of 1567 protein groups were included in the quantitative analysis and 16 proteins were downregulated in the AS compared to CAD groups and 12 proteins were upregulated.

Upon activation with CRP-XL the fibrinogen expression tended to be higher in the AS group (p=0.062) and similar results were found after stimulation with ADP. CD62P expression but not CD63 were increased after ADP activation in the AS group (p=0.047).

Conclusions: Several of the platelet proteins which are different in AS compared to CAD are involved in the cytoskeleton function and microtubule formation which could contribute to the increase of platelet aggregation and release of alpha granule found in AS. The vulnerable platelets might function as a compensatory mechanism in an altered primary hemostasis in aortic stenosis.

PB 563 | Characterization of Large and Small Platelets

S. Handtke[1], J. Conrad[2], L. Steil[2], R. Palankar[1], M. Ferrara[1], S. Cauhan[1], U. Völker[2], A. Greinacher[1], T. Thiele[1]

[1]Institut für Immunologie und Transfusionsmedizin, Universitätsmedizin Greifswald, Greifswald, Germany, [2]Interfaculty Institute for Genetics and Functional Genomics, University of Greifswald, Greifswald, Germany

Background: The mean platelet volume (MPV) is a composite of large and small platelets in the circulation. The MPV increases in situations of increased platelet turnover. Little is known, whether small and large platelets from the same individual differ in their functional characteristics.

Aims: To characterize functional and proteome differences in platelets with different MPV.

Methods: Platelet fractions with high and low MPV were separated from healthy blood donors by differential centrifugation. Platelet function was determined by flow cytometry (CD62P expression after stimulation with TRAP). Platelet adhesion and spreading was measured on collagen functionalized micro patterned arrays by live imaging and quantitative fluorescence microscopy. Cytosolic proteins were isolated and identified using a shotgun LC-MS/MS approach.

Results: Large and small platelet fractions significantly differed in MPV: 12.03 fl ± 0.88 vs. 7.76 fl ± 0.53, $p< 0.0001$. Large platelets showed higher CD62P-expression after stimulation with TRAP compared to small platelets: 29.81 MFI ± 8.575 vs. 21.22 MFI ± 6.996; p< 0.0039.Single large platelets covered a 1.4 fold larger area on a collagen surface: 63.76 μm^2 ± 21.13 in vs. 45.69 μm^2 ± 17.9 $p < 0.0001$. Out of 894 proteins identified in the cytosolic fraction, 19 proteins showed significantly different abundance in large and small platelets. Four proteins were more abundant in large platelets (ADP-ribosylation factor 1/3, Voltage-dependent anion-selective channel protein 3, Guanylate cyclase soluble subunit alpha-3, GTP-binding protein SAR1a) and 15 proteins were more abundant in small platelets (e.g. Apolipoprotein A-II, Alpha-1-antitrypsin).

Conclusions: We provide a method to separate large and small platelets for functional analyses. Platelets with high and low MPV of healthy volunteers differ in their proteome, and large platelets show enhanced functional capacities compared to small platelets.

PB 564 | TREM-like Transcript-1: A More Sensitive Marker of Platelet Activation than P-selectin Detectable in the Core and Shell of Thrombi

C.W. Smith, Z. Raslan, L. Parfitt, P. Patel, Y.A. Senis, A. Mazharian

University of Birmingham, Institute of Cardiovascular Sciences, Birmingham, United Kingdom

Background: Recent findings suggest thrombi can be divided into a core of tightly packed, highly activated P-selectin-positive platelets, and a shell of loosely packed, P-selectin negative platelets. TREM-like transcript-1 (TLT-1) is an immunoreceptor tyrosine-based inhibition motif (ITIM)-containing receptor highly expressed in α-granules of platelets, which gets rapidly up-regulated to the surface upon activation. TLT-1 has been proposed to bind fibrinogen and facilitate platelet activation. However, the function of TLT-1 in thrombus formation and stability remains undefined.

Aims: To determine the expression of TLT-1 in activated platelets relative to P-selectin during platelet activation and thrombus formation.

Methods: TLT-1 and P-selectin surface expression were analysed in thrombin-activated human and mouse platelets *in vitro* by flow cytometry, and during thrombus formation following laser injury of cremaster arterioles in mice.

Results: Activation of platelets with 0.1 U/ml thrombin results in a more rapid and robust up-regulation of TLT-1 surface expression compared with P-selectin. This was seen at all concentrations of thrombin tested between 0.01-1 U/ml. TLT-1 was also found to more rapidly translocate to the surface of activated platelets compared with P-selectin during thrombus formation following laser injury of cremaster arterioles in mice. TLT-1 expression was detected throughout the entire thrombi compared with P-selectin, which was only observed in a highly localized region within the core of the thrombus, directly adjacent to the site of injury.

Conclusions: Findings from this study demonstrate more rapid up-regulation and peak surface expression of TLT-1 compared to P-selectin, in thrombin-activated human and mouse platelets *in vitro*, and during thrombus formation in mice following laser injury of arterioles. Moreover, they suggest platelet activation in the shell region of growing thrombi occurs more rapidly and to a greater extent than previously thought.

PB 565 | WASH-complex Subunit Strumpellin Selectively Regulates Integrin αIIbβ3 Expression

Y. Schurr[1], L. Reil[1], B. Nieswandt[1], L. Machesky[2], M. Bender[1]

[1]University Hospital and Rudolf Virchow Center, Department of Experimental Biomedicine, Würzburg, Germany, [2]Cancer Research UK Beatson Institute, Glasgow, United Kingdom

Background: Endocytosis in megakaryocytes (MKs) and platelets is crucial for loading of granule cargos, such as the uptake of fibrinogen from plasma by αIIbβ3 integrin, and thus platelet effector function. However, the underlying mechanisms of cargo sorting and receptor trafficking are poorly understood, and key regulatory proteins remain to be identified. Strumpellin is a component of the Wiskott-Aldrich syndrome protein and Scar homologue (WASH) complex, the major endosomal actin polymerization-promoting complex. In other cell types, the WASH-complex is recruited to subdomains of early endosomes and generates an actin network thereby coordinating endosomal protein sorting. The function of WASH complex in MKs and platelets is unknown.

Aims: The aim of this study was to investigate the role of Strumpellin in platelet biology.

Methods: Mice lacking Strumpellin in MKs and platelets were analyzed using flow cytometric, histologic and immunoblot analyses as well as confocal and transmission electron microscopy.

Results: Strumpellin deficient mice had normal platelet count and size. Flow cytometric analysis revealed a 20% decrease in integrin αIIbβ3 surface expression on resting platelets. By contrast, the expression of other receptors (e.g. GPV, GPIb, α2 and β1 integrins) was unaltered compared to wild-type controls. P-selectin exposure and integrin αIIbβ3 activation after platelet stimulation was moderately reduced. Furthermore, a reduced number of αIIbβ3 integrins could be mobilized to the surface upon activation indicating a decreased internal pool of αIIbβ3 in knockout platelets. However, these platelets showed unaltered integrin αIIbβ3-dependent spreading on fibrinogen. Mutant bone marrow MKs displayed normal ploidy and morphology, but integrin αIIbβ3 surface expression was reduced suggesting a MK intrinsic defect.

Conclusions: These data point to a distinct role of Strumpellin in maintaining integrin αIIbβ3 expression in MKs and platelets, and provide new insights into regulatory mechanisms of platelet integrins.

PB 566 | Mechanisms of Platelet Adhesive-receptor Shedding in Platelet Populations in Thrombus Formation

C.C.F.M.J. Baaten[1], F. Swieringa[1,2], T. Misztal[1,3], T.G. Mastenbroek[1], M.A.H. Feijge[1], P.E. Bock[4], M.M.P.C. Donners[5], P.W. Collins[6], P.E.J. van der Meijden[1], J.W.M. Heemskerk[1]

[1]Maastricht University / Cardiovascular Research Institute Maastricht (CARIM), Department of Biochemistry, Maastricht, The Netherlands, [2]Leibniz Institute for Analytical Sciences - ISAS-e.V., Department of Bioanalytics, Dortmund, Germany, [3]Medical University of Bialystok, Department of Physical Chemistry, Bialystok, Poland, [4]Vanderbilt University School of Medicine, Department of Pathology, Microbiology and Immunology, Nashville, United States, [5]Maastricht University / Cardiovascular Research Institute Maastricht (CARIM), Department of Pathology, Maastricht, The Netherlands, [6]Cardiff University, Arthur Bloom Haemophilia Centre, School of Medicine, Cardiff, United Kingdom

Background: The platelet adhesive receptors, glycoproteins (GP)Ibα and GPVI, are cleaved by members of the family of A Disintegrin And Metalloproteases, ADAM10 and ADAM17. The signaling mechanisms and functional consequences of receptor shedding are poorly understood.

Aims: We hypothesized involvement of four distinct activation mechanisms in adhesive receptor shedding: elevated Ca^{2+}, protein kinase C (PKC), phospholipid scrambling and caspase activity. The contribution of these mechanisms was assessed in agonist-stimulated platelets and in thrombi formed under flow.

Methods: Shedding of both GPVI and GPIbα (GPIX as control) was measured in activated platelets by multi-color flow cytometry or in thrombi formed under arterial flow conditions by confocal microscopy.

Results: Agents raising Ca^{2+} caused complete cleavage of GPIbα and GPVI, with similar kinetics, in a distinct population of phosphatidylserine (PS)-exposing platelets. Shedding was abolished by inhibition of ADAM10/17, but not of calpain or caspases. Surprisingly, shedding occurred independently of PS exposure, as it was unchanged in Scott syndrome platelets (no PS exposure). PKC stimulation caused incomplete cleavage of only GPIbα, which was annulled by kinase inhibition and overruled by Ca^{2+} elevation. Shedding of both glycoproteins with the apoptotic agent ABT-737 was mostly confined to a PS-positive platelet population and relied on caspase activity and (partially) Ca^{2+} elevation. Shedding induced by mitochondrial uncoupling was also Ca^{2+}-dependent. In thrombi formed on collagen, ADAM-dependent shedding of GPIbα and GPVI relied on high-Ca^{2+} and coincided with PS exposure. Platelets with shed receptors showed an increased ratio of prothrombin/VWF binding and detached normally.

Conclusions: Glycoprotein shedding is primarily mediated by Ca^{2+} elevation and caspase activity, along with but not via PS exposure; and enhances the platelet procoagulant activity.

PB 567 | The GYPSIE (GlYcoProtein Six in Stroke) Study: GPVI-dimer Level is Increased in Ischaemic Stroke Patients, But Total GPVI Is Not

H. McKinney[1,2], P. Thomas[1,2], I. Induruwa[3], J. Batista[1,2], C. Kempster[1,2], A. Bonna[4], K. Soejima[5], W.H. Ouwehand[1,2], E.A. Warburton[3], K. Downes[1,2], R.W. Farndale[4], M. Moroi[4], S.M. Jung[4]

[1]University of Cambridge, Department of Haematology, Cambridge Biomedical Campus, Cambridge, United Kingdom, [2]NHS Blood and Transplant, Cambridge Biomedical Campus, Cambridge, United Kingdom, [3]University of Cambridge, Biomedical Campus, Department of Clinical Neurosciences, Cambridge, United Kingdom, [4]University of Cambridge, Biochemistry, Cambridge, United Kingdom, [5]Chemo-Sero-Therapeutic Research Institute, Kaketsuken, Research Department, Kumamoto, Japan

Background: Platelet glycoprotein VI (GPVI) binds to subendothelial collagen exposed by vessel injury or plaque rupture, initiating signalling culminating in thrombus formation. The collagen-binding form of

GPVI is a dimer of two GPVI-molecules (GPVI-dimer), which is constitutively present on resting platelets. This suggests that GPVI-dimer levels, not total GPVI, may be related to the incidence of ischaemic stroke.

Aims: To determine if GPVI-dimer levels, compared to total GPVI, are elevated in ischaemic stroke patients.

Methods: Blood samples were obtained from stroke patients at admission with informed consent and used for all tests within 2 h. GPVI was measured by flow cytometry in triplicate (as MFI) using the non-inhibitory, GPVI-dimer-specific antibody 204-11 Fab and pan GPVI antibody HY101; appropriate control antibodies and fluorescently labelled secondary antibodies were used. P-selectin expression was also measured by flow cytometry.

Results: Ischaemic stroke patients showed significantly higher GPVI-dimer level (P< 0.0001) on day of admission (n=70) and at the 90-day follow-up (n=27) compared to healthy controls (n=90). In contrast, levels of total GPVI did not differ between the patients (0- and 90-day) and the healthy controls. GPVI-levels tended to be elevated in strokes classified as large artery strokes (LAS), cardioembolic strokes (CES), and small vessel occlusions (SVO). Compared to healthy controls, resting platelets of stroke patients showed increased P-selection expression compared to healthy controls, suggesting the presence of activated platelets. This is an ongoing study, with further patient data to be added by the time of presentation.

Conclusions: GPVI-dimer levels, not total GPVI, are elevated in ischaemic stroke. This suggests that GPVI-dimer could serve as a future biomarker and pharmacological target in patients with ischaemic stroke.

PB 568 | Gradient-dependent Modulation of Platelet Stimulatory G-protein Coupled Receptors (GPCR) Signaling

A. Macwan, N. Boknäs, S. Ramström, S. Berg, L. Faxälv, T. Lindahl

Linköping University, Linköping, Sweden

Background: The hemostatic activity of platelets is usually confined to the vicinity of an injured vessel. Factors or intracellular mechanisms responsible for this spatiotemporal regulation of platelet activation are not well understood.

Aims: To verify and characterize the agonist gradient dependent desensitization of platelets receptors as a mechanism for adaptive modulation of platelet GPCR signaling.

Methods: We assessed the effect of agonist gradients on different aspects of platelets activation such as aggregation, alpha-granule release and calcium mobilization by aggregometry, flowcytometry, and fluorimetry, respectively. Western blotting was used to assess the phosphorylation status of VASP in platelets treated with different gradients.

Results: We show that gradient-dependent desensitization is a common feature of stimulatory GPCRs, modulating the response to agonist stimulation by a mechanism involving phosphorylation of vasodilator-stimulated phosphoprotein (VASP) and protein kinase A. Different GPCRs display distinct patterns of gradient-dependent desensitization. Protease-activated receptor 1 (PAR1) and the ADP receptors desensitize rapidly and require higher temporal agonist concentration gradients than PAR4 and thromboxane receptors. In contrast, signaling from a collagen receptor, the non-GPCR glycoprotein VI, does not exhibit gradient dependence. We also show that platelets from surgical patients undergoing cardio-pulmonary bypass exhibit activation responses suggestive of desensitization of signaling from PAR1 but not PAR4, consistent with our observation *in vitro* that PAR1 is more susceptible to gradient-dependent desensitization.

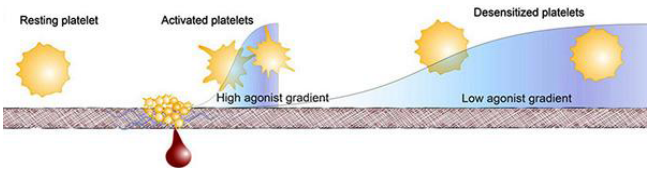

FIGURE 1 Illustration showing the platelet response to different concentration gradients

Conclusions: Platelet activation by stimulatory GPCRs is not dependent only on the concentration of the agonist but also on how rapidly the concentration changes (Fig. 1). Our findings suggest that gradient-dependent desensitization could represent a new clinically relevant mechanism for hemostatic regulation in platelets.

PB 569 | Activation of αIIbβ3 Integrin Involves the Cys608-Cys655 Disulfide Bond and the Electrostatic Network of the β-tail Domain

R. Mor-Cohen[1,2], L. Levin[3], E. Nachliel[3], M. Gutman[3], Y. Tsfadia[3], Y. Einav[4]

[1]Amalia Biron Research Institute of Thrombosis and Hemostasis, Chaim Sheba Medical Center, Tel Hashomer, Israel, [2]Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel, [3]Faculty of Life Sciences, Tel Aviv University, Department of Biochemistry and Molecular Biology, Tel Aviv, Israel, [4]Faculty of Engineering, Holon Institute of Technology, Bioengineering Department, Holon, Israel

Background: Integrin αIIbβ3 needs to be activated to mediate platelet aggregation. The β3 subunit of the integrin contains four EGF-like domains and a β-tail domain (βTD) which are rich in cysteine residues that form a network of disulfide bonds. Some of these bonds, such as the βTD 608-655 bond, were suggested to regulate integrin activation through disulfide bond exchange. Expression studies showed that the C655S mutation leads to αIIbβ3 activation, while the C608S mutation keeps the integrin inactive.

Aims: To examine the role of the 608-655 disulfide bond in αIIbβ3 activation.

Methods: Molecular dynamics simulations were conducted using β3 fragments comprising the βTD and the EGF-4 and EGF-3 domains, for either wild-type (WT) or one of the mutations disrupting the 608-655 bond, sometimes combined with the nearby Asp606 residue (C655S, C608S, C655S/D606A and C608S/D606A). Each of the WT and the

mutated β3 subunits were expressed in cells together with WT αIIb. The activity state of WT and mutated integrins was measured by flow cytometry.

Results: In the C655S simulation, the free thiol of Cys608 distanced from Ser655 and approached Asp606, causing a separation between the βTD α-helix 1 and β-strand 4, which further leaded to an opening of the angle between the βTD and the EGF-4 domain. In the C608S simulation, the thiol of Cys655 became very close to Asp606 enabling it to make a strong polar bond which kept α-helix 1 and β-strand 4 in close proximity, not allowing further conformational rearrangements. In the C655S/D606A and C608S/D606A double mutants simulations no strong polar bonds between α-helix 1 and β-strand 4 were shown. When expressed in cells, only the WT and the C608S integrins were non active while the other mutants were constitutively active.

Conclusions: Electrostatic interactions in the βTD are important for stabilization of the inactive αIIbβ3 conformer and interruption of this electrostatic network by disrupting the 608-655 bond is probably involved in normal activation of the integrin.

PB 570 | Clathrin Mediated αIIbβ3 Endocytosis Plays an Important Role in Platelet Activation

X. Fan[1], W. Gao[2], P. Shi[1], X. Chen[1], L. Zhang[1], K. Wang[1], X. Luo[2], J. Liu[1]

[1]Shanghai Jiao Tong University School of Medicine, Shanghai, China, [2]Huashan Hospital of Fudan University, Shanghai, China

Background: Dynamic endocytic and exocytic trafficking of integrins is an important mechanism for cell migration, invasion and cytokinesis. Endocytosis of integrin can be classified as clathrin dependent and clathrin independent manners. And rapid delivery of endocytic integrins back to the plasma membrane is key intracellular signals and is indispensable for cell movement. Integrin αIIbβ3 plays a critical role in thrombosis and haemostasis. Although previous studies have demonstrated that internalization of fibrinogen-bound αIIbβ3 may regulate platelet activation, the roles and mechanisms of integrin αIIbβ3 endocytosis in platelet activation are unclear.

Aims: To reveal the roles and mechanisms of integrin αIIbβ3 endocytosis in platelet activation.

Methods: A novel selective clathrin terminal domain inhibitor pitstop2 was used to study the role of clathrin-mediated endocytosis in platelet activation. Platelet activation were assessed by flow-cytometry, aggregometry and spreading on immobilized fibrinogen *in vitro*. The dynamic location of αIIbβ3 was traced by Alexa488-Fg uptake or fluorescence labeled αIIbβ3 internalization and distribution.

Results: We found that pitstop2 inhibited human platelet aggregation and spreading on immobilized fibrinogen. Pitstop2 significantly extended the occlusion time in vivo arterial thrombosis model. Mechanism studies revealed that pitstop2 did not block the endocytosis of αIIbβ3, but inhibit the recycling of αIIbβ3 to plasma membrane during platelet or CHO cells bearing αIIbβ3 spreading on immobilized fibrinogen. And pitstop2 enhanced the association of αIIbβ3 with clathrin and AP2 indicate that pitstop2 inhibit platelet activation is probably due to disturb the dynamic dissociation of αIIbβ3 from clathrin and AP2. Further study demonstrated that Src/PLC/PKC was the key pathway to trigger the endocytosis of αIIbβ3 during platelet activation.

Conclusions: Our findings suggest integrin αIIbβ3 endocytosis is clathrin-dependent and plays a critical role on platelet activation.

PB 571 | An Inhibitory Mutant of Snake Venom Rhodocytin Blocks CLEC-2/Podoplanin Interaction-dependent Platelet Aggregation and Experimental Lung Metastasis

T. Sasaki[1], T. Shirai[1], N. Tsukiji[1], S. Otake[1], S. Tamura[2], M. Osada[3], K. Satoh[4], Y. Ozaki[5], K. Suzuki-Inoue[1]

[1]University of Yamanashi, Faculty of Medicine, Department of Clinical and Laboratory Medicine, Chuo, Japan, [2]Nagoya University Graduate School of Medicine, Department of Pathophysiological Laboratory Sciences, Nagoya, Japan, [3]Gumma Paz College, Faculty of Health Science, School of Medical Technology, Takasaki, Japan, [4]Yamanashi University Hospital, Division of Laboratory Medicine, Chuo, Japan, [5]Fuefuki Central Hospital, Fuefuki, Japan

Background: The snake venom rhodocytin (also called aggretin), produced by the Malayan pit viper (*Calloselasma rhodostoma*), induces platelet aggregation through its binding to the platelet receptor CLEC-2. CLEC-2 is a physiological target protein, podoplanin expressed on some types of tumor cells, indicating that it is involved in podoplanin-induced platelet aggregation and tumor metastasis. Accumulating evidence suggests that CLEC-2 is a promising target for both anti-platelet and anti-metastasis drugs without increasing bleeding risk. We noticed that rhodocytin could be used not only as a research tool but also as a lead protein in order to develop anti-CLEC-2 drugs. In previous ISTH 2015 Congresses, we have reported for the first time generation of functional recombinant rhodocytin (rRhodo).

Aims: The aim of this study is to validate mechanism of platelet activation through CLEC-2 using mutagenesis analysis on rRhodo.

Methods: We constructed mutant α or β subunit of rhodocytin using site-directed mutagenesis. These purified mutant rRhodo were analyzed for the formation of multimer with Blue-native PAGE, the induction/inhibition of platelet aggregation with aggregometer, and the binding to CLEC-2 with FACS. In addition, we investigated whether mutant rRhodo could suppress podoplanin-induced metastasis in an experimental lung metastasis model in mice.

Results: Blue-native PAGE showed that wild-type rRhodo and native rhodocytin formed heterooctamer. Mutagenesis analysis showed that D4 in α subunit was one of critical sites for platelet aggregation through CLEC-2. Moreover, mutant rRhodo αWTβR53A/K56A formed heterotetramer. This mutant bound to CLEC-2 without platelet aggregation, and inhibited CLEC-2/PDPN interaction-dependent platelet aggregation and experimental lung metastasis.

Conclusions: We revealed that the formation of octamer and critical sites for platelet activation on rhodocytin. These findings provide strong support that mutant rRhodo can be a potential source for therapeutic agents that target CLEC-2.

PB 572 | Human and Murine Neonatal Platelets Display Reduced CLEC-2 and GPVI Expression and Function Profiles Compared with Adult Platelets

V. Palma-Barqueros[1], A.T. Hardy[2], R. Teruel-Montoya[1], J.E. Blanco[3], E. Caparros-Pérez[1], R. Guijarro-Campillo[3], V. Vicente[1], M.L. Lozano[1], S.K. Watson[2], Y. Senis[2], S.P. Watson[2], F. Ferrer-Marin[1,4], J. Rivera[1]

[1]Servicio de Hematología y Oncología Médica, Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, CB15/00055-CIBERER, Murcia, Spain, [2]Institute of Cardiovascular Sciences, College of Medical and Dental Sciences, University of Birmingham, Birmingham, United Kingdom, [3]Servicio de Ginecología y Obstetricia, Hospital Universitario Virgen de la Arrixaca, Murcia, Spain, [4]Universidad Católica de San Antonio-UCAM, Murcia, Spain

Background: Newborn platelets (NP), *vs*. adult platelets (AP), are hyporreactive by unclear and likely multifactorial mechanisms. The role of ITAM/ITIM-containing receptors, i.e GPVI, FcγRIIA and CLEC-2/G6bB and PECAM-1, in NP hyporreactivity is unknown.

Aims: To compare the expression and the function of ITAM/ITIM-containing receptors of NP and AP in human and in mice.

Methods: Human adult and cord blood and murine blood samples, at distinct pre- and postnatal ages, were assessed for:

1) Levels of GPs Ibα, αIIbβ3, αIIβ1 and ITAM-ITIM receptors by flow cytometry;

2) Functional status of GPCR and ITAM receptors, by measuring P-selectin expression and fibrinogen (Fg) binding upon platelet stimulation with agonists (PAR-1, PAR-4, ADP, CRP, CD9 and rhodocytin in human; PAR-4, CRP and rhodocytin in mice;

3) GPVI and CLEC-2 signaling in human washed NP and AP activated with CRP or rhodocytin, by immunobloting of phosphorylated PLCγ2 and Syk in platelet lysates.

Results: Human NP showed lower levels of GPVI, CLEC-2, PECAM-1 and αIIbβ3 than AP. Changes in these receptors were also observed in murine embryos and neonates compared to adults.

In both species, NP had impaired response to ITAM and GPCR stimulation, this hyporesponsiveness being more marked for GPVI and CLEC-2 agonists.

In human NP Fg-binding was reduced in response to all agonists, while severe impairment in P-selectin secretion was restricted to CRP and rhodocytin suggesting a defect in the first steps of GPVI and CLEC-2 signaling. Concordantly, human NP showed reduced CRP- and rhodocytin- induced phosphorylation of PLCγ2 and Syk.

Conclusions: Our study shows changes in platelet receptors during development both in human and mice, including reduced GPVI and CLEC-2 levels. This, in addition to impaired ITAM receptor signaling,

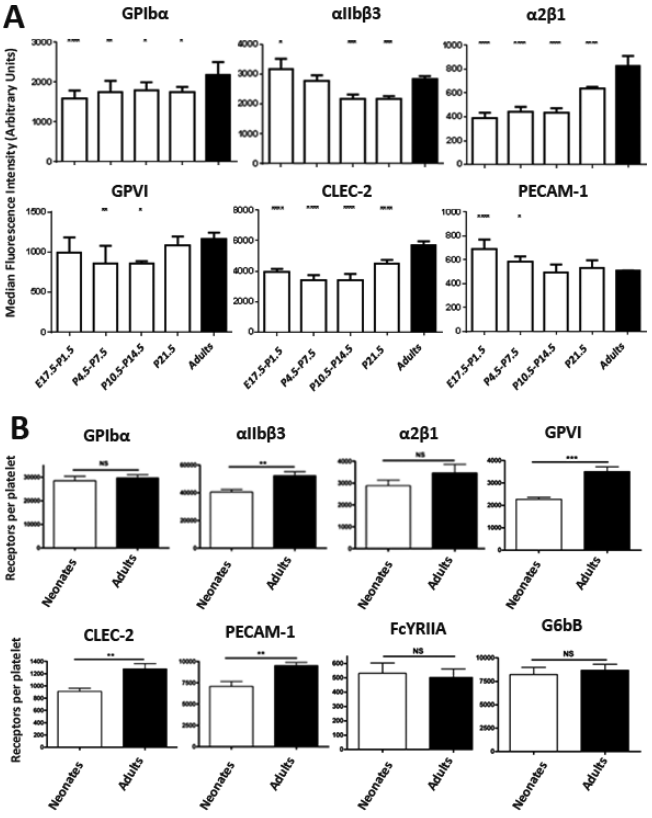

FIGURE 1 Receptor expression in adult and neonate platelets from mice (a) (n≥3), and humans (b) (n≥8)

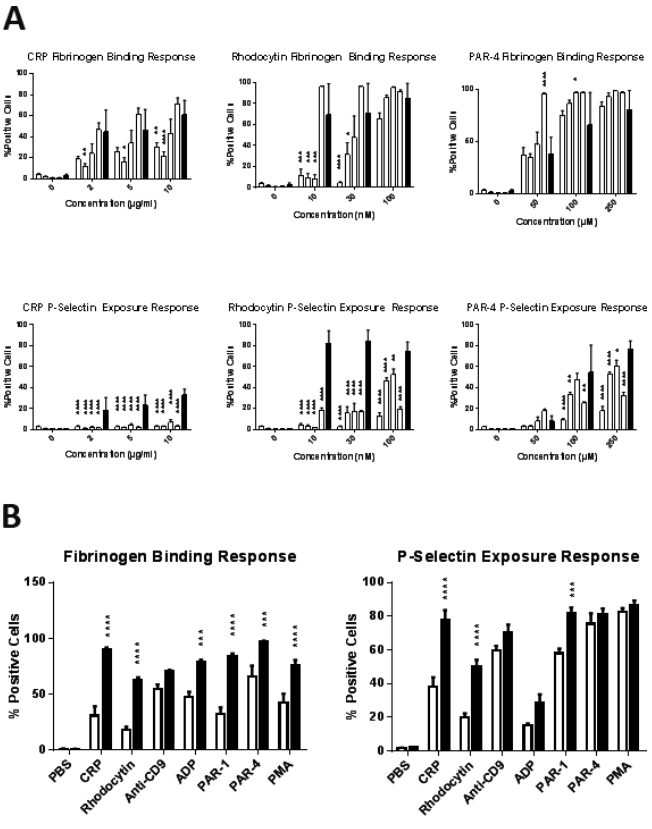

FIGURE 2 Fibrinogen binding and P-Selectin exposure response of platelets from mice (a) (n≥3) and human (b) (n≥8) neonates and adults.

contributes to defective reactivity of NP to GPVI and CLEC-2 agonists. A GPVI defect seems to play a major role in the well-known neonatal platelet hyporreactivity to collagen. *ISCIII&Feder (PI14/01956).*

PB 573 | DCBLD2 but Not GARP Has A Minor Role in Thrombus Formation in Mice which is Not in Line with the Findings in Zebrafish

E. Vermeersch[1], B. Nuyttens[1], K. Broos[1], W. Maes[1], S.F. De Meyer[1], K. Vanhoorelbeke[1], D. Unutmaz[2], H. Fujii[3], C. Tersteeg[1], H. Deckmyn[1]

[1]*KU Leuven Campus Kulak Kortrijk, Laboratory for Thrombosis Research, Kortrijk, Belgium,* [2]*The Jackson Laboratory for Genomic Medicine, Farmington, United States,* [3]*Osaka University, Chromatin Biochemistry Research Group, Combined Program on Microbiology and Immunology Research Institute for Microbial Diseases, Osaka, Japan*

Background: Functional genomics in zebrafish identified a role for GARP (or LRRC32) in the promotion and DCBLD2 in the inhibition of thrombus formation (Blood 2009;113:4754-62).

Aims: To unravel the role of GARP and DCBLD2 in murine thrombus formation.

Methods: Platelet and endothelial specific *GARP*$^{-/-}$ mice (generated using Cre-loxP recombination) and full *Dcbld2*$^{-/-}$ mice were used. Surface expression of GPIb, GPVI and integrin αIIb and the function of platelets without GARP or DCBLD2 was measured by flow cytometry and aggregometry after activation with PAR4-activating peptide, collagen related peptide or adenosine diphosphate. *In vivo* tail bleeding time, as well as occlusion time of the mesenteric and carotid artery after $FeCl_3$-induced thrombosis, were determined in *GARP*$^{-/-}$ and *Dcbld2*$^{-/-}$ mice and their wildtype littermates.

Results: Platelets lacking DCBLD2 or GARP expression had normal platelet numbers and size and normal surface expression of GPIb, GPVI and integrin αIIb. Platelets without GARP displayed normal agonist induced activation and aggregation responses. Platelets lacking DCBLD2 demonstrated a stronger activation and aggregation towards suboptimal agonist levels. Nevertheless, in platelet specific *GARP*$^{-/-}$ mice, endothelial specific *GARP*$^{-/-}$ mice as well as in *Dcbld2*$^{-/-}$ mice, neither tail bleeding time nor occlusion time in the carotid- and mesenteric artery after $FeCl_3$-induced thrombus formation were affected.

Conclusions: Evidence is provided that platelet and endothelial GARP expression is not important in hemostasis and thrombosis in mice. DCBLD2 has a minor role in downregulating platelet activation and aggregation, which however is not translated into significant effects *in vivo*. These results are not in line with the observations previously made in zebrafish. Thus, zebrafish are a useful *in vivo* model to perform a first screening on gene function in thrombosis, but mammalian models are needed to evaluate biological relevance.

PB 574 | The Association of PAR4 Polymorphism with Human Platelet Reactivity in Japanese

Y. Morikawa[1], H. Kato[1], N. Nishiura[1], K. Akuta[1], H. Kashiwagi[1], S. Honda[2], Y. Kanakura[1], Y. Tomiyama[3]

[1]*Osaka University Graduate School of Medicine, Department of Hematology and Oncology, Suita, Japan,* [2]*National Cerebral and Cardiovascular Center, Department of Molecular Pathogenesis, Suita, Japan,* [3]*Osaka University Hospital, Department of Blood Transfusion, Suita, Japan*

Background: Thrombin is the most important agonist to activates human platelets via two thrombin receptors, PAR1 (protease activated receptor 1) and PAR4. However, the details of PAR system in human platelets are still obscure mainly due to the different receptor expression between human and mouse. Especially, in contrast to PAR1 which has been established as a major thrombin receptor, the role of PAR4 in human platelet activation is not clear.

Aims: To elucidate the role of PAR4 in human platelets, we analyzed inter-individual variation of platelet activation and signaling induced by PAR4 in Japanese subjects.

Methods: We analyzed detailed platelet aggregation, integrin αIIbβ3 activation, granule release, calcium mobilization, and protein phosphorylation induced by PAR4-AP (PAR4-activating peptide) using human platelets obtained from healthy volunteers. PAR4 sequence was analyzed and investigated the association with platelet reactivity. We further analyzed the role of PAR4 in 293T cells transfected PAR4 expression vector.

Results: Sequencing analysis revealed PAR4 polymorphism p.Ala120Thr (c.533G>A) and the frequencies of 120A/A, A/T, and T/T in 202 Japanese were 56.9, 37.1, and 5.9% respectively. The concentration of PAR4-AP inducing irreversible platelet aggregation was significantly lower in 120T/T than those in 120A/A. PAR4-AP induced αIIbβ3 activation, granule release, and calcium mobilization were induced at lower concentration of PAR4-AP in 120T/T than 120A/A. Western blot analysis revealed PAR4-AP induced ERK phosphorylation, but not MLC phosphorylation, was enhanced in 120T/T platelets. 293T cells transfected with PAR4-120T or -120A confirmed that PAR4-AP induced calcium mobilization is much greater in PAR4-120T than PAR4-120A 293T cells.

Conclusions: We demonstrate that PAR4-120T/T platelets are much more sensitive to PAR4-AP stimulation than PAR4-120A/A.

PB 575 | Engineering scFvs (Single Chain Variable Fragments) to Platelet Glycoprotein VI

S. Hamaia, M. Moroi, R.W. Farndale, S.M. Jung

University of Cambridge, Biochemistry, Cambridge, United Kingdom

Background: The display of antibodies as Fabs or scFvs on filamentous phage was first described in 1990 (McCafferty et al.). It provides a powerful technique for selecting a specific antibody from a mixed population of antibodies together with the gene that codes for it.

Large and diverse libraries now in use are capable of generating large panels of diverse, high affinity (sub-nanomolar) antibodies to a given antigen. As phage display is an *in vitro* technique, it also allows a wide range of standard DNA manipulation procedures to be used. Another advantage of working with antibodies in the form of recombinant DNA is the flexibility it allows over choice of final format. An antibody can be expressed as a scFv or Fab fragments or as fusion proteins with other protein domains attached.

Aims: Selecting large panels of diverse, high affinity **single chain variable fragments scFv** to both monomeric and dimeric GPVI.

Methods: Our methods include scFv selection on monomeric GPVI (depleted on Fc fusion GPVI) and Fc fusion GPVI, i.e, dimeric (depleted on monomeric GPVI) using Cambridge University phage library, isolation, and cloning the sequence of eluted phages in expression vector, scFv expression, antigen screening, and platelet aggregation, flow cytometry and real-time adhesion.

Results: Our screening on monomeric and Fc fusion GPVI showed that some clones are dimer-specific, few are either monomer-specific or bind to both forms of GPVI. Most of the clones recognized platelet GPVI in real-time platelet adhesion using xCELLigence RTCA Roche. In addition, we found that some of the clones were activating (aggregate platelets) and others inhibit platelet binding to Collagen Related Peptide (CRP).

Conclusions: Using phage display technology we selected scFv specific to glycoprotein VI forms, and some of them are inhibitory and others are activating.

PB 576 | Activation of Human Blood Platelets through CLEC2 is Slackened due to the Diffusion of Receptors into the Signalosome Region, but Still Can Induce Cytosolic Calcium Spiking in Single Platelets

A. Martyanov[1,2], M.A. Panteleev[1,2,3], A.N. Sveshnikova[1,2,3]

[1]*Lomonosov Moscow State University, Physics Faculty, Moscow, Russian Federation,* [2]*Center for Theoretical Problems of Physicochemical Pharmacology, Russian Academy of Sciences, Moscow, Russian Federation,* [3]*National Scientific and Practical Centre of Pediatric Hematology, Oncology and Immunology named after Dmitry Rogachev, Moscow, Russian Federation*

Background: Platelet surface receptor CLEC2 has a significant role in maintaining blood vascular integrity during inflammation. It shares signaling pathways with GPVI receptor. However, CLEC2 activation is notably delayed comparing to GPVI and the nature of this delay remains obscure. Different concepts of CLEC2 signaling have been proposed, for example Hughes et al. (Blood, 2015) believe that activation of Syk kinase lies upstream of SFK and Btk, while Manne et al. (J. Biol. Chem. 2015) assume the opposite. And whether CLEC2 activation affects platelet calcium signaling remains questionable.

Aims: Systems biology analysis of intracellular signaling after ligation of CLEC2 in single platelets.

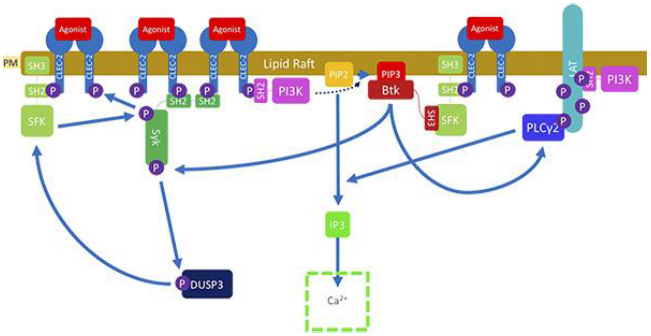

FIGURE 1 Model of CLEC-2 signalisation

Methods: A comprehensive 3D model of CLEC2 signaling was constructed based on experimental data and solved in VCell software (vcell.org). Fucoidan (Sigma 9072-19-9) was utilised as CLEC2 agonist in all experiments. For single platelet analysis Fura-2 loaded platelets were immobilised on fibrinogen and analised by TIRF microscopy. Alternatively, spreading of platelets on immobilized fucoidan was observed by the same technique. For model validation platelet activation by fucoidan was analised by aggregometry, flow cytometry and spectrofluorimetry.

Results: The model describes diffusion of CLEC2 molecules to the lipid raft and recruitment of downstream proteins to the signalosome. Signaling scheme is described in fig 1. Changing cholesterol saturation of cell membrane affected diffusion speed of the CLEC2 molecules, thus slowing down formation of the CLEC2 cluster. The model predicted cytosolic calcium spiking, which was confirmed in experiments with single platelets.

Conclusions: Slow activation of platelets by CLEC2 is due to the diffusion of it's oligomers to the signalosome, where a lipid raft prevents the cluster from the dissolving. CLEC2 activation leads to cytosolic calcium oscillations in single cells. Suggested scheme explains initial CLEC2 signaling stages and ties up representations of Hughes et al. and Manne et al.

PB 577 | Decompensated Heart Failure Patients Demonstrate Shedding of Platelet Receptors Glycoprotein (GP) Ibα and GPVI in Contrast to Stable Heart Failure Patients

J.M.L. Casan[1], J.F. Arthur[2], R.K. Andrews[2], E.E. Gardiner[3], J. Shaw[4], A.K. Davis[1]

[1]*The Alfred Hospital, Haematology Unit, Melbourne, Australia,* [2]*Monash University, Australian Centre for Blood Diseases, Melbourne, Australia,* [3]*Australian National University, John Curtin School of Medical Research, ACRF Department of Cancer Biology, Canberra, Australia,* [4]*The Alfred Hospital, Cardiology Unit, Melbourne, Australia*

Background: Pathological shedding of platelet receptors glycoprotein (GP)-VI and GPIbα may contribute to platelet dysfunction and increased bleeding risk. Such changes have been demonstrated in patients with circulatory support devices associated with high shear

such as ventricular assist devices and extracorporeal membrane oxygenation. Surprisingly, we have also previously detected similar findings in patients with decompensated heart failure. Pathophysiologic mechanisms beyond altered shear forces may include inflammation or fibrin-mediated effects.

Aims: To investigate whether shedding of platelet receptors GPVI and GPIbα occurs in stable patients with compensated systolic heart failure, whether changes in von Willebrand factor (VWF) multimers were present, and how these patients compared to patients with decompensated heart failure and healthy donors.

Methods: 20 outpatients with compensated heart failure were recruited for measurement of platelet count, coagulation parameters, VWF multimers and assessment of platelet receptor status by flow cytometry or ELISA methods.

Results: Levels of shed GPVI (sGPVI), high molecular weight VWF multimers and platelet surface GPVI and GPIbα in stable heart failure patients were not significantly different to healthy controls. In contrast, patients with decompensated heart failure demonstrated significantly increased shedding of GPVI and GPIbα.

Conclusions: Stable heart failure patients appear to have similar platelet receptor expression profiles to healthy controls. However, heart failure patients developing clinical decompensation demonstrate increased shedding of platelet GPVI and GPIbα. The underlying mechanisms are not clear but may include alteration in shear stresses, differential expression of inflammatory mediators or effects of increased fibrin. Further research elucidating the pathobiology of these observations could potentially identify critical factors related to decompensation in heart failure.

PB 578 | Switching Integrin Alpha IIb-beta3 Conformations under Physiological and Stress Conditions

U. Janke[1,2], M. Delcea[1,2]

[1]*University Greifswald, Institute for Biochemistry, Greifswald, Germany,* [2]*ZIK HIKE, Greifswald, Germany*

Background: The heterodimeric transmembrane platelet receptor integrin alpha IIb-beta 3 (αIIbβ3) plays a crucial role in haemostasis and is involved in the autoimmune disease Immune Thrombocytopenia (ITP). ITP patients develop a higher bleeding risk due to autoantibody mediated platelet destruction. The immunogenicity (i.e. capacity of the immune system to induce an immune response) is potentially related to different conformations of αIIbβ3.

Aims: We aim to study the influence of mutations, external stress factors (e.g. pH and temperature) and binding partners on the αIIbβ3 conformation (e.g. closed, open and intermediate) in a membrane environment.

Methods: Integrin αIIbβ3 is incorporated into 1,2-Dimyristoyl-sn-glycero-3-phosphorylglycerol (DMPG)/ 1,2-dimyristoyl-sn-glycero-3-phosphocholine (DMPC) liposomes. Binding affinity and specificity of αIIbβ3 to binding partners (e.g. fibrinogen) is quantified under different conditions using surface plasmon resonance (SPR) and quartz crystal microbalance (QCM). Further the binding of specific antibodies to different αIIbβ3 conformations is investigated using enzyme-linked immunosorbent assay (ELISA).

Results: Different incorporation protocols are compared with regards to liposome- αIIbβ3 conjunction. We show using SPR and QCM that manganese ion concentration modifies the conformation of αIIbβ3. Our results indicate a higher binding affinity to interaction partners, e.g. fibrinogen, in presence of manganese ions.

Conclusions: Our results reveal that the biophysical methods SPR and QCM allow studying interactions between αIIbβ3 and ligands under native conditions. Future experiments could show the changing in binding properties of αIIbβ3 to ITP autoantibodies due to external factors or mutations.

PB 579 | C-Type Lectin-like Receptor 2 Promotes Hematogenous Tumor Metastasis and Prothrombotic State in Tumor-bearing Mice

T. Shirai[1], O. Inoue[2], S. Tamura[3], N. Tsukiji[1], T. Sasaki[1], H. Endo[4], K. Satoh[5], M. Osada[5,6], H. Sato-Uchida[7], H. Fujii[8], Y. Ozaki[1], K. Suzuki-Inoue[1]

[1]*University of Yamanashi, Faculty of Medicine, Department of Laboratory Clinical Medicine, Chuo, Japan,* [2]*Yamanashi University Hospital, Infection Control Office, Chuo, Japan,* [3]*Nagoya University Graduate School of Medicine, Department of Pathophysiological Laboratory Sciences, Nagoya, Japan,* [4]*University of Shiga Prefecture, School of Human Cultures, Department of Food Science and Nutrition, Hikone, Japan,* [5]*Yamanashi University Hospital, Division of Laboratory Medicine, Chuo, Japan,* [6]*Gumma Paz College, Faculty of Health Science, School of Medical Technology, Takasaki, Japan,* [7]*University of Yamanashi, Faculty of Medicine, Department of Clinical Nursing, Chuo, Japan,* [8]*University of Yamanashi, Faculty of Medicine, First Department of Surgery, Chuo, Japan*

Background: C-type lectin-like receptor 2 (CLEC-2) is a platelet activation receptor of sialoglycoprotein podoplanin, which is expressed on the surface of certain types of tumor cells. CLEC-2-podoplanin interactions facilitate hematogenous tumor metastasis. However, direct evidence of the role of CLEC-2 in hematogenous metastasis and cancer progression is lacking.

Aims: The aim of this study is to examine the role of CLEC-2 in podoplanin-expressing cancer progression.

Methods: We generated platelet-specific CLEC-2-depleted mice using rat anti-mouse CLEC-2 monoclonal antibody 2A2B10. Podoplanin-expressing B16F10 mouse melanoma cells were used to evaluate hematogenous tumor metastasis, tumor growth, and overall survival.

Results: Hematogenous tumor metastasis was significantly inhibited in CLEC-2-depleted mice. B16F10 cells co-cultured with wild-type platelets, but not with CLEC-2-deficient platelets, showed increased proliferation. However, B16F10 cell proliferation was not inhibited in CLEC-2-depleted mice. Histological analysis showed that thrombus formation in tumor vessels was significantly inhibited and functional vessel density was significantly increased in CLEC-2-depleted mice. These data suggest that CLEC-2 deficiency may inhibit thrombus formation in tumor vessels and increase the density of functional vessels,

thus improving oxygen and nutrient supply to tumors, indirectly promoting tumor proliferation. Furthermore, the overall survival of CLEC-2-depleted mice was significantly prolonged, which may be due to the suppression of thrombus formation in the lungs and subsequent inhibition of systemic inflammation and cachexia.

Conclusions: Targeted inhibition of CLEC-2 as a new strategy for preventing hematogenous tumor metastasis and for inhibiting cancer-related thromboembolism. This study was published in *J Thromb Haemost* in 2016.

PB 580 | αIIb or Not IIb: Novel Insights into the Regulation of αIIb Expression and Localization in Activated Platelets

A. Mitrugno[1], A.T.P. Ngo[2], J. Pang[2], M.L.D. Thierheimer[2], O.J.T. McCarty[2]

[1]Oregon Health & Science University, Biomedical Engineering, Portland, United States, [2]Oregon Health & Science University, Biomedical Engeneering, Portland, United States

Background: Integrin αIIbβ3 plays a crucial role in hemostasis and thrombosis, mediating platelet adhesion to extracellular matrix proteins, aggregation and thrombus formation; therefore appropriate regulation of integrin αIIbβ3 activity and quantity is essential to maintain platelet homeostasis. However, while much is known about the regulation of αIIbβ3 activation and derived signaling, comparatively little is known of the biochemical mechanisms that modulate its surface expression and localization in platelets.

Aims: To establish if the expression and localization of αIIb is modulated upon platelet activation.

Methods: Immunofluorescence (IF) microscopy was used to compare platelet αIIb spatial distribution on surfaces of fibrinogen following activation with thrombin and in the presence of various platelet pharmacological inhibitors. Western blot analysis was used to determine changes in platelet αIIb expression following activation with thrombin or ADP alone and in the presence of protein translation inhibitors.

Results: We show increased αIIb expression upon activation of platelets with thrombin or ADP. IF imaging revealed the presence of αIIb clusters in the center of thrombin-stimulated platelets adhering on fibrinogen. Inhibition of thrombin-activated platelets with PAR1 and PAR4 antagonists was not sufficient to prevent the formation of centralized αIIb clusters. Interestingly, inhibition of GPIb with the blocking antibody SZ2, but not AK2, abrogated αIIb centralization and clustering. Blockade of αIIb with integrilin had a mild inhibitory effect on αIIb relocalization, which was enhanced in the presence of apyrase, an ADP chelator.

Conclusions: Our results suggest that αIIb expression and localization can be regulated in platelets in a fashion dependent on GPIb, ADP and integrin signaling. Future efforts will define molecular routes of trafficking of αIIb in platelets.

PB 1258 | A Default in Acetyl-CoA Carboxylase Phosphorylation Increases Thrombus Growth *in vitro* and *in vivo*, and in a Collagen-dependent Manner

S. Lepropre[1], S. Kautbally[1], L. Bertrand[1], G.R. Steinberg[2], B.E. Kemp[3], A. Hego[4], O. Wéra[4], S. Brouns[5], F. Swieringa[5], J. Heemskerk[5], C. Oury[4], C. Beauloye[1], S. Horman[1]

[1]Université Catholique de Louvain, Brussels, Belgium, [2]McMaster University, Hamilton, Canada, [3]University of Melbourne, Victoria, Australia, [4]Université de Liège, Liège, Belgium, [5]University of Maastricht, Maastricht, The Netherlands

Background: We have previously shown that AMPKα1 is activated in thrombin- or collagen-stimulated murine platelets. Accordingly, acetyl-CoA carboxylase (ACC), the bona-fide substrate of AMPK, is phosphorylated/inhibited upon platelet stimulation but its role in platelets has never been investigated. ACC is a central regulator of lipid metabolism. Given the primary roles of lipids in platelets, namely structural, energy storage and signaling, we hypothesized that acute ACC phosphorylation could affect platelet functions.

Aims: To determine the impact of acute ACC phosphorylation on platelet functions and investigate its contribution to haemostasis and thrombosis.

Methods: Platelets were isolated from a knock-in mouse model (KI) expressing a genetically modified ACC that can no longer be phosphorylated/inhibited by AMPK. *In vitro*, platelet adhesion and thrombus formation were measured using a flow chamber-based assay. Haemostasis was assessed via the measurement of bleeding time. Thrombosis was studied upon ferric chloride-induced carotid artery injury.

Results: ACC phosphorylation was unchanged in non-stimulated KI relative to control (WT) platelets. Thrombin or collagen stimulation led to a rapid and significant increase in ACC phosphorylation in WT, but not in KI platelets. This effect was accompanied by a prolonged presence of calcium in the cytosol of stimulated KI platelets. Most importantly, thrombus formation on collagen-coated surface was effectively augmented under flow, in the absence of ACC phosphorylation. Accordingly, KI mice had a subsequent shorter bleeding time. They also showed increased thrombus growth reflected by a higher increment in thrombus surface area over a 10-minute time interval, compared to WT mice ($7242\mu m^2 \pm 1265$ versus $2520\mu m^2 \pm 1219$ for WT mice).

Conclusions: Overall, our study defines a new and important role for platelet ACC phosphorylation in regulating thrombus formation *in vitro* and *in vivo*, and in a collagen-dependent manner.

PB 1260 | Fibrin Activation and Not GPCR Activation Induces Shedding of Platelet GPVI: Soluble GPVI is Elevated in Thermal Injury and ICU Patients

S.J. Montague[1], C. Delierneux[2], C. Lecut[3], N. Layios[2,4], R.J. Dinsdale[5,6], N.S. Poulter[7], R.K. Andrews[8], P. Hampson[5,6], C.M. Wearn[5,6], C. Lee[1], N. Maes[9], J. Bishop[10], A. Bamford[6], C. Gardiner[11], N. Moiemen[6], S.P. Watson[7], C. Oury[2], E.E. Gardiner[1], P. Harrison[5,6]

[1]*Australian National University, Dept. Cancer Biology and Therapeutics, Canberra, Australia,* [2]*University of Liège, GIGA-Cardiovascular Sciences, Liege, Belgium,* [3]*University Hospital of Liege, Laboratory of Hematology, Liege, Belgium,* [4]*University Hospital of Liege, General Intensive Care, Liege, Belgium,* [5]*Univeristy of Birmingham, Scar Free Foundation for Burns Research, Birmingham, United Kingdom,* [6]*Univeristy of Birmingham, Institute of Inflammation and Ageing, Birmingham, United Kingdom,* [7]*University of Birmingham, Institute of Cardiovascular Sciences, Birmingham, United Kingdom,* [8]*Monash University, Australian Centre of Blood Diseases, Melbourne, Australia,* [9]*University Hospital of Liege, Biostatistics and Medico-Economic Information, Liege, Belgium,* [10]*University of Birmingham, NIHR Surgical Reconstruction and Microbiology Centre, Birmingham, United Kingdom,* [11]*University College London, Department of Haematology, London, United Kingdom*

Background: Upon activation of the major platelet collagen and fibrin receptor, glycoprotein VI (GPVI), the sheddase ADAM10 is activated and cleaves GPVI, releasing a soluble GPVI (sGPVI) fragment into plasma.

Aims: To determine whether sGPVI levels are elevated in patients with injury, assess sGPVI associations with clinical parameters, and whether fibrin induces GPVI shedding.

Methods: Plasma sGPVI levels were measured in thermal injury patients (n=99) and patients admitted to ICU (n=83) by ELISA. Washed platelets from healthy controls were stimulated with fibrin and G-protein coupled receptor (GPCR) agonists to induce GPVI shedding. Intact and cleaved GPVI was quantitated by western blot and densitometry.

Results: sGPVI levels at admission were associated with 28- and 90-day mortality of ICU patients (p=0.02 and 0.005). sGPVI was elevated day 14 post thermal injury (p< 0.005) and was higher in patients who developed sepsis (p=0.002). sGPVI positively correlated with D-dimer levels (fibrin degradation products) at day of admission for ICU patients (r=0.41) and at day 14 in thermal injury patients (r=0.46). Platelet activation by GPCR agonists, PAR-1, PAR-4, U46619 and ADP did not induce GPVI shedding. However, platelet activation by thrombin under conditions supporting fibrin formation induced metalloproteolytic GPVI shedding reducing intact GPVI to 33% of control GPVI levels (100%). Fibrin-mediated shedding was independent of integrin αIIbβ3 and ADAM10 but required fibrin polymerisation. GPVI signalling through Src and Syk, did not have a major role in fibrin-mediated GPVI shedding. Together this data suggests roles for multiple sheddases or alternative mechanisms including shear or Factor X activation.

Conclusions: Elevated sGPVI was predictive of mortality in injured patients, where minimal collagen exposure is assumed. Fibrin degradation strongly correlated with sGPVI in both patient cohorts. Fibrin induces GPVI shedding and may explain elevated sGPVI levels observed in patient plasma.

PB 1261 | A Humanized Monoclonal Antibody that Inhibits Platelet-surface ERp72 Reveals a Role for ERp72 in Platelet Function and Thrombus Formation

L.-M. Holbrook, G. Sandhar, P. Sasikumar, M. Schenk, A. Bye, A. Stainer, K. Sahli, G. Flora, A. Bicknell, J. Gibbins

University of Reading, ICMR, School of Biological Sciences, Reading, United Kingdom

Background: We have previously reported that multiple thiol isomerases are released by platelets and growing evidence supports the importance of PDI, ERp5 and ERp57 in the regulation of platelet activation. The role of ERp72, which is released and binds to the activated platelet surface, however has not been established.

Aims: To investigate if ERp72 inhibition using enzyme activity-blocking antibodies impacts on platelet functional responses and thrombus formation.

Methods: Humanized anti-ERp72 antibodies were generated using Human Combinatorial Antibody Library (HuCAL) phage-display technology. Eleven ERp72-selective antibodies were screened for their ability to inhibit both enzyme activity and platelet aggregation. One antibody (anti-ERp72) was selected for further study. Platelets were pre-incubated with anti-ERp72 or control immunoglobulin (Ig) prior to stimulation with collagen (1μg/mL) or CRP-XL (0.5μg/mL). Platelet aggregation and granule secretion were measured using lumi-aggregometry and flow cytometry. Platelet adhesion was measured by ELISA and thrombus formation in mice examined using intravital microscopy.

Results: Anti-ERp72 (10-25μg) caused a concentration-dependent reduction in platelet aggregation compared to control Ig (25μg). Anti-ERp72 also diminished platelet adhesion on collagen and fibrinogen and decreased dense and α-granule secretion. Fibrinogen and PAC-1 binding were substantially inhibited suggesting that ERp72 may regulate integrin αIIbβ3 function or outside-in signaling through this receptor. Anti-ERp72 significantly delayed thrombus formation in mice.

Conclusions: In this study we generated humanized antibodies that blocked ERp72 enzyme activity, inhibited platelet responses and delayed thrombus formation in mice. These data demonstrate that like PDI, ERp5 and ERp57, ERp72 is an additional thiol isomerase of importance for haemostasis and thrombosis and may represent an important target for antithrombotic therapies.

PB 1262 | Patient Derived HLA Monoclonal Antibodies Induce Fcγriia Dependent Platelet Activation

M. Rijkers[1], F.H.J. Claas[2], A. Mulder[2], L. Porcelijn[3], F.W.G. Leebeek[4], J. Voorberg[1], A.J.G. Jansen[1,4], M. de Haas[2,3]

[1]Sanquin-AMC Landsteiner Laboratory, Department of Plasma Proteins, Amsterdam, The Netherlands, [2]Leiden University Medical Center, Department of Immunohaematology and Blood Transfusion, Leiden, The Netherlands, [3]Sanquin, Department of Immunohaematotology Diagnostics, Amsterdam, The Netherlands, [4]Erasmus University Medical Centre, Department of Hematology, Rotterdam, The Netherlands

Background: Pregnancy or transfusion can lead to the development of alloantibodies against MHC class I (HLA) molecules. As yet it is difficult to predict the clinical significance of HLA antibodies; in the majority of patients the presence of HLA antibodies does not result in a decline in platelet numbers or function after transfusion. In a subset of patients HLA antibodies coincide with refractoriness following platelet transfusion.

Aims: Evaluate the effect of HLA antibodies on platelet activation and clearance.

Methods: Human HLA IgG monoclonal antibodies (mAbs) with specificities for different HLA subtypes were incubated with platelets obtained from healthy donors with known HLA typing. Platelet activation (CD62P surface exposure, von Willebrand factor (VWF) and SPARC release) and platelet aggregation were measured. Binding of HLA mAbs to the platelets and HLA expression levels on platelets were determined.

Results: While all HLA mAbs bound to HLA matched platelets, 3 out of 11 induced platelet activation. CD62P membrane exposure was upregulated upon incubation with WIM8E5 (directed against A1/A10/A11/A9/A29/A30/A31/A33/A28), SN607D8 (A2/A28) and GV5D1 (A1/A9) with platelets expressing these MHC class I alleles. Also release of SPARC and VWF was observed upon incubation with WIM8E5, SN607D8 and GV5D1. These mAbs also induced platelet aggregation although at a rate that was 10 times lower than observed for collagen. Upon incubation with IV.3 (a blocking antibody directed towards FcγRIIa) WIM8E5, SN607D8 and GV5D1 induced aggregation and α-granule release was completely blocked. Blocking of downstream signaling from FcγRIIa employing Syk inhibitor IV also interfered with mAb induced α-granule release.

Conclusions: We provide evidence for FcγRIIa dependent activation of platelets by patient derived HLA mAbs. We suggest that these HLA antibodies contribute to enhanced clearance of transfused platelets from the circulation.

PB 1263 | Platelet PN-1 Regulates Clot Structure and Retraction

S. Loyau, Y. Boulaftali, L. Venisse, V. Arocas, M.-C. Bouton

INSERM U 1148, LVTS, Paris, France

Background: Serpin E2 or Protease Nexin-1 (PN-1), a cellular serpin, is a strong inhibitor of serine proteases. We recently established platelet PN-1 as a negative regulator of thrombin generation and thrombosis. The mechanical properties of clot are dependent of thrombin-induced platelet activation and fibrin formation. Altered clot architecture and retraction are known to be associated with abnormal thrombin generation. We hypothesize that platelet PN-1 can regulate clot architecture.

Aims: To evaluate the role of platelet PN-1 on clot structure and retraction.

Methods: Clot retraction was assessed after recalcification in glass tubes of human platelet-rich plasma (PRP) incubated or not with a PN-1-blocking IgG, or of PRP obtained from wild-type (WT) or PN-1 knock-out (PN-$1^{-/-}$) mice. Clot architecture was evaluated with confocal microscopy of human or mice platelet-rich clots (PRC) supplemented with Alexa647-fibrinogen and Alexa488 anti-CD41, a platelet marker. Clot viscoelasticity properties were analysed with rotational thromboelastometry test (ROTEM).

Results: Surprisingly, clot weight was increased by 66% in human PRC incubated with a blocking anti-PN-1 IgG and by 40% in PN-$1^{-/-}$ PRC compared to their respective controls, indicating a positive effect of PN-1 on clot retraction. Confocal microscopy images showed that the fibrin network structure was more porous in PRC from PN-$1^{-/-}$ mice or in human PRC incubated with a blocking anti-PN-1 IgG. TEMograms showed that the blocking anti-PN-1 IgG induced a 26% decrease of the maximum clot elasticity, a clot strength parameter. In our experimental conditions, no difference was observed in PRC incubated with tranexamic acid and in platelet-poor clots indicating a direct role of PN-1 in platelet contractile force.

Conclusions: Despite its anti-thrombin effect, platelet PN-1 accounts for the formation of a tight structure of PRC. We thus identify a critical positive role of PN-1 on platelet-driven clot retraction.

PB 1264 | Statins Inhibit Platelet Function and Attenuate Clot Structure

M.M. Jalal, F.P. Coxon, N.J. Mutch

University of Aberdeen, Institute of Medical Sciences, School of Medicine, Medical Sciences and Nutrition, Aberdeen, United Kingdom

Background: Inhibition of the mevalonate pathway by statins impairs prenylation of proteins by depleting cells of lipid geranylgeranyl diphosphate (GGPP). One such protein is Rab27b, a GTPase involved the secretion of platelet dense granules.

Aims: To investigate the impact of statins on prenylation of Rab27b in platelets and downstream effects platelet function.

Methods: Whole blood pre-treated with atorvastatin (ATV) was analysed by thromboelastography. ADP was quantified as a marker of dense granule secretion in thrombin-stimulated ATV treated platelets. P-selectin exposure and fibrinogen-binding to thrombin-stimulated platelets ± ATV was analysed by flow cytometry. Fibrin clot formation in platelet-rich plasma (PRP) ± ATV was examined by confocal microscopy. Unprenylated Rab27b was detected in the aqueous fraction of platelet lysates by Western blot. All samples were treated with increasing concentrations of ATV (0, 10, 20 and 40 μM) for 24 h at 37°C.

Results: ATV significantly increased clot formation time at 20 μM ($p< 0.005$). Clot firmness was attenuated by ATV at 20 μM (39.6 mm) ($p< 0.005$) compared to untreated (51.8 mm). Incubation of PRP with ATV (20 μM) significantly ($p< 0.001$) attenuated clot retraction. Fibrinogen-binding and P-selectin exposure were significantly lower ($p< 0.05$) in stimulated platelets treated with 40 μM ATV. Similarly, confocal microscopy of PRP clots revealed a reduction in fibrin binding to platelet aggregates following ATV treatment. ATV induced a dose-dependent accumulation of unprenylated Rab27b and inhibition of ADP release from activated platelets. Exogenous GGPP partially rescued the ADP release defect in ATV treated platelets suggesting these changes arise from attenuated prenylation of Rab27b.

Conclusions: Statins attenuate fibrinogen-binding to activated platelets, clot retraction, a-granule and dense granule secretion. Statins modulate fibrin binding to platelet aggregates, suggesting a potential alternative cardiovascular protective mechanism for these drugs *in vivo*.

PB 1265 | Cyclophilin D Restricts the Lytic Susceptibility of Fibrin via Modulation of Platelet Functions

V.J. Farkas[1], L. Kőhidai[2], L. Szabó[3], C. Chinopoulos[1], L. Polgár[2], K. Kolev[1], I. Varjú[1,4,5]

[1]*Semmelweis University, Department of Medical Biochemistry, Budapest, Hungary,* [2]*Semmelweis University, Department of Genetics, Cell- and Immunobiology, Budapest, Hungary,* [3]*Institute of Materials and Environmental Chemistry, Research Centre for Natural Sciences, Hungarian Academy of Sciences, Department of Functional and Structural Materials, Budapest, Hungary,* [4]*Boston Children's Hospital, Program in Cellular and Molecular Medicine, Boston, United States,* [5]*Hungarian Academy of Sciences, Budapest, Hungary*

Background: In growing thrombi platelets are exposed to a variety of stimuli, resulting in morphologically and functionally distinct platelet subpopulations. Platelet activation by ‚strong' stimuli results in opening of the mitochondrial permeability transition pore (mPTP). Cyclophilin D (CypD), an enhancer of mPTP has been previously suggested as a suitable target to influence thrombosis. However, its role in ‚mild' platelet activation as well as in the platelet-driven stabilization of fibrin is unknown.

Aims: To compare the effects of CypD in platelet activation by ‚strong' (thrombin+collagen-analogue convulxin) and ‚mild' (ADP) stimuli, and to define the role of CypD in the lytic susceptibility of fibrin.

Methods: CypD function was blocked using pharmacologic inhibition (cyclosporin A, CsA) in human and genetic ablation in murine platelets. Platelet morphology was assessed with transmission- (TEM) and scanning electron microscopy (SEM). Adhesion and spreading were followed using an impedance-based assay. Platelet-platelet interactions were studied with optical aggregometry. Fibrinolysis was evaluated in a turbidimetric assay.

Results: TEM and SEM evidenced that ‚strong' stimulus-induced organelle-swelling (5-fold increase in the normalized organelle area index of human platelets) and membrane fragmentation were reverted by CsA. The rate of ADP-induced platelet spreading in $CypD^{-/-}$ and CsA-treated platelets was doubled compared to their respective controls. CsA but not the genetic ablation of CypD increased both the rate (+92%) and maximal values (+28%) of ADP-induced platelet aggregation. The fibrin-stabilizing effect of wild type platelets was abolished in clots containing $CypD^{-/-}$ platelets according to our fibrinolysis assays.

Conclusions: Any anti-thrombotic strategy that targets CypD function should consider the opposing consequences of CypD inhibition that depend on the stimulus and stage of platelet activation.

PB 1266 | Biomechanical Mechanisms of Platelet-fibrin Interactions as a Basis of Blood Clot Contraction

R.I. Litvinov[1], O.V. Kim[2], M.S. Alber[2], J.W. Weisel[1]

[1]*University of Pennsylvania Perelman School of Medicine, Philadelphia, United States,* [2]*University of California Riverside, Riverside, United States*

Background: Contraction is a final stage of blood clot maturation that strengthens hemostatic clots, enhances wound healing and restores blood flow past otherwise obstructive thrombi. Despite biological and clinical importance, the physical mechanisms of clot contraction are largely unknown.

Aims: To unveil and quantify the structural biomechanics of clot contraction at various spatial scales from a single cell/single fiber level up to the network and macroscopic levels.

Methods: We used confocal microscopy and rheometry to perform concurrent 3D dynamic measurements of the platelet-fibrin meshwork over the course of clot contraction.

Results: We found that activated platelets bend and shorten individual fibrin fibers via cellular filopodia that undergo sequential extension and retraction, pulling hand-over-hand. Platelets also induce compaction of fibrin fibers into platelet-attached agglomerates. By pulling on multiple, closely-set fibrin fibers, platelets move toward each other and form secondary clusters. Contracting platelets remodel a fibrin network by increasing its density causing enhanced clot stiffness. Kinetic analysis revealed at least three distinct phases that differ in duration and rate constants. All the observed changes were reduced or abrogated in the presence of inhibitors of non-muscle myosin IIA (blebbistatin) and the integrin $\alpha_{IIb}\beta$ (abciximab), indicating that cell contractility and platelet-fibrin interactions are crucial for contraction of blood clots. Finally, blood clot contraction was found to be a spatially non-uniform process with faster compression of the clot edge and slower deformation of the clot interior.

Conclusions: We discovered structural mechanisms by which local platelet-fibrin interactions result in dramatic modifications of the whole clot architecture. The mechanisms of blood clot contraction that were revealed demonstrate an important new biological application of cell motility principles.

PB 1267 | Non-genomic Effects of the Pregnane X Receptor: Inhibition of Platelet Functions

G.D. Flora, K.A. Sahli, A.R. Stainer, A.J. Unsworth, P. Sasikumar, L.M. Holbrook, T. Sage, J.M. Gibbins

University of Reading, School of Biological Sciences, Reading, United Kingdom

Background: Platelets, despite being enucleated, express nuclear receptors that are capable of regulating platelet activity. The pregnane X receptor (PXR) is a nuclear receptor, involved in the detoxification of xenobiotic compounds. Recently, its presence was reported in the human vasculature and its ligands were proposed to exhibit anti-atherosclerotic effects.

Aims: To explore the presence of PXR in human platelets and evaluate the role of its ligands in regulating platelet function.

Methods: Western blotting and immunoprecipitation were performed to examine the expression of PXR. Platelet aggregation and dense granule secretion were studied on washed platelets with and without treatment with PXR ligands (rifampicin or SR12813). The extent of fibrinogen binding and α-granule secretion was analysed using flow cytometry. Calcium mobilisation was measured by spectrofluorimetry in FURA-2AM loaded platelets and integrin $\alpha_{IIb}\beta_3$ outside-in signalling was studied by measuring clot retraction. The effects of PXR ligands on thrombus formation *in vitro* (whole blood) were tested in $DiOC_6$ loaded platelets.

Results: The expression of PXR in human platelets was confirmed using western blotting and immunoprecipitation. Platelets treated with rifampicin or SR12813 (10,20,50 & 100μM) reduced collagen or thrombin-mediated platelet aggregation and dense granule secretion. PXR ligands attenuated CRP-XL or thrombin-stimulated fibrinogen binding and P-selectin exposure, indicating a reduction in integrin $\alpha_{IIb}\beta_3$ up-regulation and α-granule secretion, respectively. Calcium mobilisation and clot retraction were also inhibited upon treatment with either of the ligands. Lastly, significant reduction in thrombus formation under arterial flow conditions *in vitro* was observed, demonstrating the potential role of the ligands in regulating thrombosis.

Conclusions: PXR exist in human platelets and exposure to its ligands inhibits platelet function. Future work will determine the specificity and mechanisms by which PXR ligands function in platelets.

PB 1268 | A Potential Role of Platelet Activation in the Progression of Atrial Fibrillation

S. Dolleman, H. de Boer, A.J. van Zonneveld

Leiden University Medical Center, Internal Medicine (Nephrology), Leiden, The Netherlands

Background: Atrial fibrillation (AF) progresses in time and is associated with microvascular destabilization, tissue fibrosis and an increased risk for heart failure. AF is associated with low grade inflammation, a hypercoagulable state and activated platelets.

Aims: Our working hypothesis links AF progression to microvascular destabilization via hypercoagulability. To elucidate how this affects the integrity of the microvasculature, tissue factor (TF)-mediated coagulation on endothelial cells (ECs) was studied in the absence or presence of platelets (PLTs).

Methods: Primary ECs were treated with 1 ng/ml tumor necrosis factor α (TNFα). TF-induced coagulation was determined using a FXa generation assay. The role of PLTs was studied by adding PLTs to an EC-monolayer or to isolated extracellular matrix (ECM), which becomes exposed when the integrity of the monolayer is lost. TF protein was determined with an antibody (10H10) recognizing cryptic/proteolytically inactive TF (cTF). Expression of protein disulphide isomerase (PDI) was determined, which is involved in decryption/activation of TF.

Results: Without TNFα, ECs do not show TF-activity nor cTF protein expression (Figure A1 vs B1) and this is not altered when PLTs are added (A3 vs B3). PLT incubation on TNFα-stimulated ECs significantly increase TF-activity coinciding with a decrease in cTF protein (A4 vs B4), indicating decryption of TF. Interestingly, PLTs incubated on ECM±TNFα showed a similar protein pattern (B7-8 vs B3-4), but a synergistically potentiating effect on activity (A8 vs A4). Although PDI is constitutively expressed in ECs (B1-4), only the addition of PLTs resulted in significant FXa generation, suggesting that PLT-PDI is responsible for the decryption of TF. While resting PLTs express low amounts of PDI (B9), they increase PDI expression when encountering ECM (B7-8 vs B5-6).

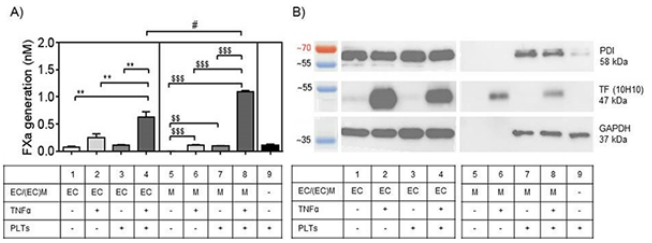

FIGURE 1 FXa generation (A) and immunoblots (B) on ECs and ECM from the same source. One-way ANOVA P<0,05, within EC (*) or ECM ($) and between EC and ECM (#)

Conclusions: We show that PLTs may aggravate the pro-coagulation state in AF. These data indicate that patients with AF may benefit from treatment with platelet inhibitors.

PB 1269 | Analysis of Microparticles Associated with Procoagulant Platelets by Imaging Flow Cytometry

E.C. Reddy[1], H. Wang[1], S.J. Israels[2], K.W.A. Bang[3], M. Rand[4]

[1]*The Hospital for Sick Children, Physiology and Experimental Medicine Program, Toronto, Canada,* [2]*University of Manitoba, Department of Pediatrics and Child Health, Winnipeg, Canada,* [3]*Sinai Health System, Lunenfeld-Tanenbaum Research Institute, Toronto, Canada,* [4]*The Hospital for Sick Children; University of Toronto, Physiology and Experimental Medicine Program & Division of Haematology; Department of Laboratory Medicine and Pathobiology, Toronto, Canada*

Background: A procoagulant platelet subpopulation, distinguished by phosphatidylserine (PS) surface membrane exposure, is formed upon activation. In a study of the physical characteristics of PS-exposing platelets, we made the novel observation that the majority of PS-positive (+) platelets had one or more associated microparticles (MPs).
Aims: To evaluate MPs associated with PS-exposing platelets using imaging flow cytometry.
Methods: Washed platelets were stimulated with 1U/mL thrombin and 10μg/mL collagen (T+C) or 3μM A23187, and labeled for the platelet marker glycoprotein (GP)IX with anti-CD42a-eFluor450, and for the platelet activation markers: activated αIIbβ3 with PAC1-FITC; P-selectin with anti-CD62P-PE; and PS exposure with annexin A5-Alexa Fluor647. At least 150,000 cells/sample were acquired on the Amnis ImageStream^X Mark II imaging flow cytometer and analyzed with IDEAS software. Values are mean±SEM, n=4.
Results: The majority of PS+ platelets produced by T+C stimulation (92.0±1.6%) or A23187 stimulation (97.1±0.7%) possessed at least one associated MP; % PS-negative platelets with associated MPs was negligible. The number of associated MPs per platelet ranged from 1-8, with the majority of PS+ platelets possessing 1 or 2 MPs (T+C: 80.2±1.0%; A23187: 72.8±2.5%), with diameters 20-25% of that of the parent platelet. Platelet-associated MPs were heterogeneous as indicated by the expression of GPIX and the activation markers in various combinations of up to all 4 markers. Those positive for GPIX, P-selectin, and PS, and not expressing activated αIIbβ3, were in the highest proportion: 23.1±5.2% (T+C) and 29.4±4.0% (A23187).
Conclusions: As demonstrated by imaging flow cytometry, almost all PS+ platelets have associated MPs that show heterogeneous marker expression. These MPs are not detectable by traditional flow cytometry. Whether the MPs are the result of blebbing of the platelet membrane, or have been released from platelets and subsequently re-associate with a platelet surface, has yet to be determined.

PB 1270 | Controlled Adhesion of Endothelial Cell and Platelets onto Patterned CoCr Alloy Surfaces by Direct Laser Interference Patterning Technique for Cardiovascular Applications

M. Pino[1], R. Schieber[2,3,4], F. Lasserre[4], M. Hans[4], M. Fernández-Yagüe[2,3], M.P. Ginebra[2,3,5], F. Mücklich[4], M. Pegueroles[2,3], G. Escolar[1], M. Diaz-Ricart[1]

[1]Centre de Diagnòstic Biomèdic (CDB), Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Hospital Clínic, Universitat de Barcelona, Hemotherapy-Hemostasis, Barcelona, Spain, [2]Biomaterials, Biomechanics and Tissue Engineering Group, Department of Materials Science and Metallurgical Engineering, Technical University of Catalonia (UPC), EEBE, Barcelona, Spain, [3]Centre for Research in NanoEngineering (CRNE), UPC, EEBE, Barcelona, Spain, [4]Chair of Functional Materials, Faculty of Natural Sciences and Technology, Saarland University, Saarbrücken, Germany, [5]Institute for Bioengineering of Catalonia (IBEC), Barcelona, Spain

Background: Stent restenosis and thrombosis are the main drawbacks of current carfiovascular bare-metal stents. Nano- and micro-scale modification of implant surfaces is a strategy to recover the functionality of the artery by stimulating and guiding molecular and biological processes at the implant/tissue interface.
Aims: To explore changes in the adhesion of endothelial cells (EC) and platelets on CoCr surfaces due to modifications via Direct Laser Interference Patterning (DLIP).
Methods: CoCr alloy surfaces were modified via DLIP to create a lineal patterning with different periodicities (≈ 3, 10, 20 and 32 μm) and depth (≈ 20 and 800 nm). Changes in surface topography, chemistry and wettability were characterized by scanning electron microscopy, X-ray photoelectron spectroscopy, and sessile drop method, respectively, before and after modification. The effect of the different DLIP patterns on both the growth of human umbilical vein EC and the adhesion of platelets on the CoCr surfaces were explored, by using immunofluorescence and perfusion techniques with flowing blood.
Results: Patterned surfaces with low depth presented a chemical rather than topographical lineal pattern, while high depth surfaces appeared chemically homogeneous. Adhesion and spreading properties of HUVECs were similar on all patterned and plain CoCr surfaces. However, high depth series induced EC elongation and alignment along the pattern lines. Platelet adhesion and aggregation of platelets, under flow conditions, decreased on all the patterned surfaces compared to the CoCr control, mainly due to changes in wettability.
Conclusions: These results provide evidence of the potential of DLIP topographies to modify the surface of metal stents to foster endothelialization without enhancing platelet adhesion.

PB 1271 | Authophagy of Microparticles by Platelets is Partially Mediated through TLR-4 and Enhances Thrombogenicity

I. Lopez-Vilchez, R.M. Hernandez, P. Molina, M. Pino, M. Diaz-Ricart, G. Escolar

Hospital Clinic of Barcelona, Centre of Biomedical Diagnosis (CDB), Institute of Biomedical Research August Pi i Sunyer (IDIBAPS), University of Barcelona, Department of Hemotherapy and Hemostasis, Barcelona, Spain

Background: Cardiovascular disease involves multiple inflammatory processes, including activation of innate immunity toll-like receptors (TLR). Circulating microparticles of platelet origin (PMP) are the most abundant (70-90%). PMPs contribute to the activation of inflammatory cells, accompanied by formation of heterotypic aggregates (HA) between platelets and leukocytes. Platelets play a key role in ischemic complications and can internalize procoagulant microvesicles, fostering their thrombogenicity.
Aims: We have investigated the association of PMP with platelets, and explored the involvement of TLR-4.
Methods: PMPs were separated by ultracentrifugation of expired platelets concentrates. We assessed: 1) Interactions of PMPs with platelets using confocal microscopy; 2) Association between platelet-PMP and formation of HA, by flow cytometry; and 3) Modifications in

thromboelastometry parameters of blood enriched with platelets exposed to PMPs, by ROTEM technology. Effects of a specific antibody to TLR-4 were also evaluated.

Results: Confocal microscopy studies demonstrated uptake of PMP by platelets. Flow cytometry revealed PMP-platelet associations (86.1±6.7% vs. 2% control; p< 0.01) and increased HA formation (34.4±7.0% vs. 29.7±6.7% control; p< 0.05). Incubation of platelets with anti-TLR4 prior to exposure to PMPs decreased both, PMP-platelet associations (57.1±7.9% vs. PMP without anti-TLR4; p< 0.05) and prevented HA formation. Addition of 30% platelets containing PMPs accelerated the clotting time (54.6±4.9 sec. vs. 62.1±5.2 sec. control; p< 0.05), and the clot formation time (79.4±5.8 sec. vs. 119.6±6.1 sec. control; p< 0.05) in the ROTEM system. The anti-TLR4 normalized alterations in the latter parameters.

Conclusions: We demonstrate autophagic activity of platelets to their procoagulant microparticles, a process partially mediated by innate immunity receptor TLR-4 and with implications in platelet thrombogenicity.

Grants: *RD12/0042/0016;FIS-PI13/00517;PIE15/00027;DTS16/00133*

PB 1272 | Analysis of Venous and Arterial Hemostatic Plugs Reveals Strikingly Similar Composition and a Gradient of Platelet Activation

C. Matzko[1], M. Tomaiuolo[1], I. Poventud-Fuentes[1], L. Nettey[1], J. Weisel[2], L. Brass[1], T. Stalker[1]

[1]*University of Pennsylvania, School of Medicine, Philadelphia, United States,* [2]*University of Pennsylvania, Philadelphia, United States*

Background: Prior experiments in the mouse microvasculature have established that the architecture of hemostatic plugs is characterized by a gradient of platelet activation with heterogeneous packing density and platelet activation.

Aims: To determine and compare the architectural composition of hemostatic plugs in large arteries and veins.

Methods: We developed a new methodology to study hemostasis in large veins and arteries that combines scanning electron microscopy (SEM), confocal/two-photon microscopy, and histological sections. Hemostatic plugs in mouse jugular veins and carotid arteries were produced by needle injuries, then fixed and imaged in situ from either the intraluminal or extraluminal side.

Results: Our results revealed great similarity in platelet morphology and packing density in the jugular vein and carotid artery. Hemostatic plugs in both vessel types were composed almost entirely of platelets, which varied in activation state depending on spatial localization in the platelet mass. The extravascular portion in both cases was composed primarily of densely packed, highly activated, platelet-derived microvesicles and fibrin. In both the vein and artery, there was little fibrin observed on the intravascular side, suggesting thrombin activity is primarily restricted to the extravascular portion of the plug. A gradient of platelet activation extending from the injury site was observed on the intravascular side of both vein and artery hemostatic plugs. Though flow rates differ in the carotid and jugular, bleeding times were similar.

Conclusions: In conclusion, our results show that platelet rich hemostatic plugs in both large arteries and veins display a gradient of platelet activation, with a drastic difference between the appearance and composition of the internal and external surface of the plug in both vessel types. These novel findings suggest localized spatial distribution of thrombin and other platelet agonists at a site of vascular injury.

PB 1273 | Platelet Reactivity and Receptor Density in Platelets with Different MPV

A. Södergren[1], S. Ramström[2,3]

[1]*Linköping University, Department of Clinical and Experimental Sciences, Linköping, Sweden,* [2]*Linköping University, Department of Clinical Chemistry and Department of Clinical and Experimental Medicine, Linköping, Sweden,* [3]*Örebro University, School of Medical Sciences, Örebro, Sweden*

Background: It is often stated that larger platelets (plt) are more reactive than smaller ones. However, most studies only describe associations between a high mean platelet volume (MPV) and different clinical conditions. The fact that activated plt undergo substantial reorganisation which impact on plt size complicates studies to prove the hypothesis. Pre-analytical activation may also contribute to these problems.

Aims: To investigate if plt reactivity and receptor density varies between resting plt with different MPV.

Methods: Blood from healthy donors was centrifuged (150g, 15 min) and the fractions containing the largest and smallest plt were separated. MPV and numbers of PAR1, GPIb and GPVI receptors were determined. Plt reactivity was investigated by agonist stimulation, with surface exposure of activation markers P-selectin, active GPIIb/

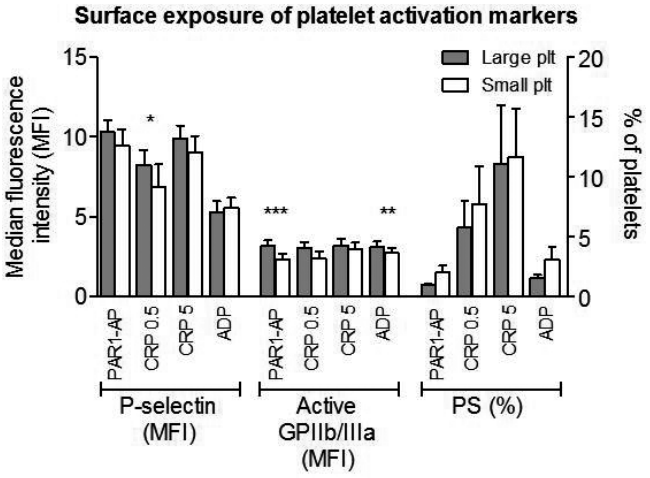

Figure 1. Plt were stimulated with PAR1-activating peptide (AP; 30μM), collagen-related peptide (CRP; 0.5 or 5μg/ml) or ADP (5μM). Mean ± standard error of the mean, n=6. * Indicate statistically significant differences between large and small plt.

FIGURE 1

IIIa and phosphatidylserine (PS) evaluated with flow cytometry. T-test was used to compare large and small plt.

Results: We successfully separated plt with different MPV. A low resting P-selectin exposure verified that pre-analytical plt activation was low and thus did not influence the results, table I. Receptor numbers were higher in large plt. However, if plt were assumed to be spherical, the resulting number of receptors/μm^2 were higher in small plt, table I. Only small differences in plt reactivity was found, with higher exposure of P-selectin and active GPIIb/IIIa in large plt at some conditions. Exposure of PS did not differ between large and small plt. These results, although non-significant, rather indicate a higher PS exposure in small plt, figure 1.

Conclusions: Centrifugation allowed successful separation of plt with different MPV, while maintaining a resting state. Large plt were slightly more reactive than small plt regarding P-selectin and active GPIIb/IIIa, but not PS. It can however be questioned whether such minute differences are physiologically relevant and can explain the reported associations between platelet size and different clinical conditions.

TABLE I Features of resting platelets.

	Large platelets	Small platelets
MPV (fL)	9.2 ± 0.5	7.8 ± 0.5 **
P-selectin (%, resting plt)	8.1 ± 1.0	7.6 ± 1.0
GPIb (receptors/plt)	28283 ± 1346	25338 ± 1013 *
PAR1 (receptors/plt)	1792 ± 166	1430 ± 184 **
GPVI (receptors/plt)	6204 ± 517	3986 ± 368 **
GPIb (receptors/μm2)	14.22 ± 0.59	15.95 ± 0.66 **
PAR1 (receptors/ μm2)	0.84 ± 0.03	0.95 ± 0.04 **
GPVI (receptors/ μm2)	4.00 ± 0.17	4.49 ± 0.19 **

Mean ± standard error of the mean, n=6. * Indicates statistically significant differences between large and small plt.

PB 1274 | Connexin 62 Hemichannels and Gap Junctions Regulate Platelet Function

K.A. Sahli, G.D. Flora, A. Bye, A. Stainer, S.K. Alouda, P. Sasikumar, L.M. Holbrook, M. AboHassan, T. Sage, J.M. Gibbins

University of Reading, School of Biological Sciences, Reading, United Kingdom

Background: Connexin (Cx) is a large family of proteins, expressed in numerous mammalian cells. Cxs oligomerise into hexameric structures [hemichannels, (HCs)] in the plasma membrane. These HCs on adjacent cells can dock together, forming gap junctions (GJs) that regulate trafficking of molecules between cells. Previously, we reported the presence of Cx37 and Cx40 in human platelets and that selective inhibition, or deletion, attenuates platelet functions. Notable levels of Cx62 transcripts were also reported in megakaryocytes.

Aims: The objective of this study was to determine the role of Cx62 in human platelets.

Methods: The presence of Cx62 in human/mouse platelets was examined by immunoblotting. A ^{62}Gap27 targeting Cx62 and scrambled control were designed. Platelet aggregation and dense granule secretion was studied in washed platelets, and the degree of fibrinogen binding and α-granule secretion measured through flow cytometry. Calcium mobilisation was measured by spectrofluorimetry in FURA-2AM loaded platelets. Integrin $\alpha_{IIb}\beta_3$ outside-in signalling was analysed by clot retraction. In vitro thrombus formation was examined in DiOC6 labelled platelets.

Results: Western blotting confirmed the expression of Cx62 in human/mouse platelets. ^{62}Gap27 but not scrambled control inhibited CRP-XL or thrombin-stimulated platelet aggregation and dense granule secretion. CRP-XL or thrombin-stimulated fibrinogen binding and P-selectin exposure was also reduced by ^{62}Gap27. Platelets treated with ^{62}Gap27 displayed reduced calcium mobilisation and clot retraction. Thrombus formation *in vitro* (arterial flow conditions) was inhibited substantially by ^{62}Gap27 suggesting probable role of Cx62 in regulating haemostasis and thrombosis.

Conclusions: Cx62 is present in human/mouse platelets and exposure to ^{62}Gap27 dampens platelet function. Work is ongoing to identify the nature of the molecules trafficking through Cx62 HCs (isolated platelets) or GJs (within thrombus) along with the mechanisms through which their conductance is regulated.

PB 1275 | Chloride Intracellular Channel 1 Cooperates with Integrins to Promote Thrombus Formation and Angiogenesis

L.M. Knowles, E. Ampofo, P. Niewald, A. Drawz, I. Müller, H. Eichler, J. Pilch

Saarland University Medical Center, Homburg / Saar, Germany

Background: Chloride intracellular channel 1 (CLIC1) has been shown to be involved in thrombus formation as well as angiogenesis but its role in these processes is largely unknown.

Aims: To determine if CLIC1 supports cell adhesive processes that are relevant for endothelial and platelet function.

Methods: Human umbilical venous endothelial cells (HUVEC) were probed for cell proliferation on plastic and cell invasion/survival after embedding in fibrin after transfection with siCLIC1. The subcellular localization of CLIC1 in HUVEC as well as platelets was analyzed with fluorescence microscopy following treatment with the synthetic CLIC1 inhibitor IAA94, which was also used to assess the effect of CLIC1 on integrin activation and platelet aggregation. The role of CLIC1 on thrombus formation *in vivo* was assessed by intravital fluorescence microscopy in a mouse dorsal skin fold chamber model.

Results: Knocking down endothelial CLIC1 with siRNA caused a defect in cell spreading that was associated with decreased cell proliferation, invasion and survival. The effects of CLIC1 inhibition could be traced back to diminished CLIC1 cell membrane expression, which, in turn, resulted in disorganized lamellipodia formation. Paralleling these results, we detected integrin-dependent CLIC1 membrane relocation in platelets. Treatment of platelets with the synthetic CLIC1 antagonist

IAA94 targeted membrane CLIC1 and, in the process, reduced integrin αIIbβ3 activation. As a consequence, inhibition of CLIC1 impaired platelet aggregation *in vitro* and vaso-occlusion in a mouse model of photo-chemical thrombus formation *in vivo*.

Conclusions: CLIC1 cooperates with integrins during cell adhesion and as such mediates functions related to thrombus formation, endothelial homeostasis and angiogenesis.

PB 1276 | A Novel Role for the Membrane Protein G6f in Platelet Activation Induced by Weak Stimulation

A. Amirkhosravi, M. Davila, L. Robles-Carrillo, M. Brodie, M. Rivera-Amaya, J. Francis

Florida Hospital, Center for Thrombosis Research, Winter Park, United States

Background: The lymphocyte antigen 6 complex locus protein (G6f) is a type I transmembrane protein of the immunoglobulin super family that is expressed on the surface of human platelets. The intracellular tail of G6f contains a single tyrosine in a single YXXI motif, which undergoes phosphorylation in response to GPVI and αIIbβ3-mediated platelet activation. This leads to the binding of the adaptor protein Grb2 to G6f. G6f is currently considered to be platelet-specific, but its function remains unknown.

Aims: In this study, we investigated if antibodies against this membrane protein can influence platelet activation and aggregation caused by various agonists.

Methods: Washed platelets were stimulated with low doses of agonists: thrombin (0.03-0.05 U/ml), ADP (10 μM), IgG immune complexes (IC, 40-100 nM) and collagen related peptide (CRP, 0.25-1 μg/ml) with or without anti-G6f antibodies. Platelet aggregation and dense granule release were assessed by aggregometry and the serotonin release assay, respectively.

Results: Platelet aggregation and granule release induced by low dose thrombin, ADP (aggregation only) and IC were strongly inhibited (>80%) by the anti-G6f antibodies whereas CRP-induced platelet activation was inhibited by 40%. These effects were not observed with higher agonist concentrations.

Conclusions: Our results suggest a novel role for G6f in platelet activation caused by a broad range of agonists. The results also indicate that anti-G6f antibody promotes an inhibitory effect against agonist-induced platelet activation and aggregation. G6f may therefore represent a possible anti-thrombotic target. However, additional mechanistic studies are required to address this.

PB 1277 | Biomimetic Surfaces for Studying Neutrophil-platelet Interactions

L. Erpenbeck[1], J. Spatz[2], R.K. Andrews[3], M.P. Schön[1], S. Kruß[4]

[1]*Universitätsmedizin Göttingen, Dermatology, Allergology and Venerology, Göttingen, Germany,* [2]*Max Planck Institute for Intelligent Systems, and Institute of Physical Chemistry, Department of New Materials and Biosystems, Heidelberg, Germany,* [3]*Monash University, Department of Clinical Haematology, Melbourne, Australia,* [4]*Georg August University Göttingen, Physical Chemistry, Göttingen, Germany*

Background: Neutrophils play a central role in cardiovascular disease and thrombosis. They interact with platelets through receptor-ligand interactions such as neutrophil L-selectin and PSGL-1 as well as integrin Mac-1 and platelet glycoprotein Ibα (GPIbα). The presentation of L-selectin as well as GPIbα varies under different physiological and pathophysiological conditions. However, the biological consequences of these dynamic changes remain poorly understood and hard to assess. I*n vivo* models are often too complex for the isolated observation of single receptor-ligand interactions while classical *in vitro* systems do not allow precise tuning of local receptor density and, simultaneously, hydrodynamic shear stress.

Aims: Therefore, our aim was to develop a nanotechnology-based platform for studying ligand-receptor interactions under realistic biophysical conditions.

Methods: A nanopatterning/site-directed biofunctionalization approach allowed the presentation of surface receptors in their natural orientation as well as precise adjustment of the local and global surface density of these receptors. Additionally, these biofunctionalized surfaces can be integrated into a microfluidic system, enabling the imitation of physiological flow conditions. We employed this method to mimic interactions between neutrophil Mac-1 and surface-bound GPIbα as well as between L-selectin and PSGL-1.

Results: Under physiological flow conditions, neutrophils required minimum spacings of GPIbα to successfully adhere. Under low shear stress, adhesion to GPIbα was similar at all tested densities, however receptor spacings differentially regulated neutrophil spreading kinetics and locomotion. For the interaction between L-selectin and PSGL-1, attachment of cells increased with higher ligand densities.

Conclusions: We were able to show that initial attachment and rolling of neutrophils increases at higher ligand densities. For complex cellular behaviors such as spreading and migration there is an optimum density at medium ligand concentrations.

PB 1278 | Heparin Decreases Thrombin Induced Procoagulant Platelet Formation via a Direct Platelet Effect

S. Wang[1], M. Bourcy[2], H. Campbell[2], V. Chen[2,3]

[1]*University of New South Wales, Sydney, Australia,* [2]*ANZAC Research Institute, Sydney, Australia,* [3]*Concord Hospital, Haematology, Sydney, Australia*

Background: Lack of procoagulant platelets is associated with bleeding while excess is associated with atherothrombosis. Heparins are known to bind to exosite II on thrombin and a direct inhibition thrombin induced platelet activation has been postulated.

Aims: Determine if heparin has a direct effect on procoagulant platelet formation.

Methods: We adapted a procoagulant platelet flow cytometry assay based on novel cell death agent, GSAO (Hua et al,Blood, 2015) to measure procoagulant platelet formation ex vivo. Whole blood from healthy volunteers was pre-incubated with varying doses of unfractionated heparin (UFH) or vehicle prior to thrombin stimulation. In some experiments, washed human platelets were stimulated without plasma, or resuspended in anti-thrombin III deficient plasma or autologous plasma prior to preincubation with UFH. Comparison was made with preincubating with anticoagulants with structural similarity to heparin but variable binding to thrombin: enoxaparin, the heparinoid danaparoid (which acts on FXa); and structurally dissimilar anticoagulants: fondaparinux, rivaroxaban and apixaban. Procoagulant platelets were defined as being GSAO+/CD62P+ by FACS.

Results: UFH demonstrated a dose dependent inhibition of procoagulant platelets within the therapeutic range, and abrogated response at high doses (13.3±8vs1.81±0.5,p< 0.001). Inhibition was reproduced with washed platelets and platelets resupended in anti-thrombin III deficient plasma indicating a direct effect on platelets (fold change 0.1±0.05, p< 0.001). Heparin based anticoagulants enoxaparin, and the heparinoid indirect FXa inhibitor, danaparoid, reproduced these findings (fold change 0.46±0.1,p< 0.01 and 0.61±0.11,p< 0.05), while the structurally dissimilar pentasaccharide, fondaparinux and direct FXa inhibitors did not.

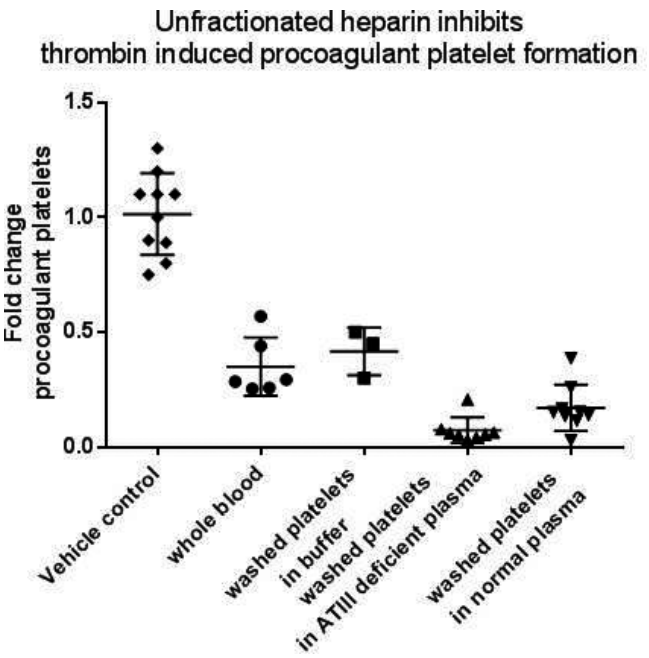

FIGURE 1 UFH or vehicle control was preincubated prior to thrombin stimulation and measurement of procoagulant platelets

Conclusions: Anticoagulants with structural similarity to heparin inhibit procoagulant platelet formation independent of the anticoagulant activity. Exploration of the mechanism could give insight into new therapeutic targets.

PB 1279 | Changes in Platelet Surface Receptor Expression upon Activation Are Mainly Contributed by Large Platelets

M. Moroi, S.M. Jung

University of Cambridge, Biochemistry, Cambridge, United Kingdom

Background: Upon activation, platelets undergo a shape change, including filopodia protrusion. Thus more plasma membrane, along with receptors, may be exposed on the surface.

Aims: We determined if surface receptor expression changes upon platelet activation and if larger platelets show a greater change.

Methods: Receptors in resting, CRP, Cvx, or thrombin activated platelets were measured by an Accuri C6 flow cytometer, as MFI, using specific primary Abs and Alexa fluor 488-anti-mouse Fab. In the analyses, the total platelet population (P1) was divided in half: smaller ones (P3) and larger ones (P2).

Results: In activated platelets, P1 showed increased integrin $\alpha 2\beta 1$ and $\alpha IIb\beta 3$, no change in GPVI, and decreased GPIb (Ib). P2/P1, the ratio of the MFI value in P2 and P1, was calculated for each receptor in activated platelets. The ratios for $\alpha 2\beta 1$, $\alpha IIb\beta 3$, Ib, and GPVI were increased from about 130% to 190% in PRP and 130% to 160% in washed platelets. The ratio for CD62P and $\alpha IIb\beta 3$ increased to >300% after thrombin activation. P3 (smaller platelets) showed much lower changes in expression. Immunoblotting of the platelet supernatant and confocal imaging showed that decrease in GPIb expression was due to shedding, while decreased GPVI expression was caused by internalization.

Conclusions: More receptors are exposed on the surface of platelets when they become activated, corresponding to platelet shape change and filopodia extension. Changes in receptor expression are mainly contributed by large platelets (P2), while small ones (P3) show only slight changes. These results indicate it is mainly the population of large platelets that become activated, supporting the recently proposed hypothesis that large mean platelet volume (MPV) is a risk factor for cardiovascular incidents. Further, these results suggest that flow-cytometric measurement of P2 platelets for increased receptor expression would be a more sensitive method to detect activated platelets.

PB 1280 | Autophagy Inhibitors Reduce Platelet Function by Preventing Granule Exocytosis

D. Groeneveld, J. Adelmeijer, T. Lisman

University Medical Center Groningen, Surgical Research Laboratory, Department of Surgery, Groningen, The Netherlands

Background: A critical role for autophagy, the process by which cells eliminate excess or damaged content, in platelet activation and thrombosis has recently been shown using mice deficient in autophagy proteins. Given its role in regulating protein secretion, autophagy may regulate platelet function by regulating granule exocytosis. This

mechanism has been suggested to explain the platelet inhibitory effects of chloroquine (CQ), but experimental evidence in support of this mechanism is lacking.

Aims: Our aim was to elucidate by which mechanism inhibition of the autophagy machinery decreases platelet function.

Methods: Platelet-rich plasma (PRP) or whole blood from healthy volunteers was treated with different concentrations of CQ, bafilomycin A1 (BAF), 3-methyladenine (3MA), or vehicle. Lumiaggregometry was used to simultaneously measure release of ATP and platelet aggregation. P-selectin expression was measured with flow cytometry. Release of platelet factor 4 (PF4) and Platelet-derived Growth Factor (PDGF) were assessed. Platelet adhesion and aggregation to collagen, von Willebrand factor (VWF), and fibrinogen was studied using a flow chamber model, and were recorded in real-time using fluorescent microscopy.

Results: We observed a dose-dependent decrease in ADP and ADP/TRAP-induced P-selectin expression, PF4 -, and PDGF release in PRP treated with CQ or 3MA. CQ and 3MA also dose-dependently inhibited platelet aggregation and ATP release in suspension induced by different agonists. Platelet aggregation to collagen and VWF under flow was severely reduced in whole blood treated with CQ or 3MA. However, there was no difference in platelet adhesion to fibrinogen, which is independent of platelet secretion. We did not observe any effects on platelet function using BAF.

Conclusions: Disruption of the autophagy machinery using CQ or 3MA leads to impaired platelet function by decreasing the release of α- and δ-granule content. It seems that autophagy has however, no effect on secretion-independent functions of platelets.

PB 1281 | Kinetics of Prothrombin Interaction with Subpopulations of Activated Platelets

N. Podoplelova[1], S. Obydennyi[1,2], M. Canault[3], F. Ataullakhanov[1,2,4], M.-C. Alessi[3], M. Panteleev[1,2,4]

[1]Dmitry Rogachev National Scientific and Practical Center of Pediatric Hematology, Oncology and Immunology, High School of Molecular and Experimental Medicine, Moscow, Russian Federation, [2]Center for Theoretical Problems of Physicochemical Pharmacology, Moscow, Russian Federation, [3]Aix-Marseille Université, Inserm, Inra, NORT, Marseille, France, [4]Moscow State University, Faculty of Physics, Moscow, Russian Federation

Background: One of the major reactions of blood coagulation is membrane-dependent activation of prothrombin to thrombin by prothrombinase. There are at least two activated platelet subpopulations with dramatically different procoagulant properties. Systematic kinetic studies for the binding of a prothrombin to the membranes of activated platelet subpopulations are lacking.

Aims: We aimed to characterise the binding of a prothrombin to the membranes of activated platelet subpopulations.

Methods: Platelets were isolated from whole blood by washing and gel-filtration. Written informed consent was given by all participants, and the study was approved by the institutional ethical committee. They were stimulated with thrombin (100 nM), subpopulations were identified with Fura Red is dye for cytosolic calcium Flow cytometry and confocal microscopy were used to investigate interaction of fluorescein-labeled prothrombin with the membranes of activated platelets.

Results: In agreement with previous reports, prothrombin was predominantly bound to the phosphatidylserine-positive subpopulation of activated platelets. This interaction was high-affinity and calcium-dependent. Binding to the phosphatidylserine-negative platelets was several-fold less and calcium-independent binding. Prothrombin was bound to platelets of patients with Glanzmann´s thrombasthenia with the same parameters as for the platelets of healthy donors indicating that binding to phosphatidylserine-negative subpopulation did not depend on integrin $\alpha_{2b}\beta_3$. Apparent equilibrium binding of prothrombin to phosphatidylserine-positive platelets was specific, with 10,000±2,500 binding sites per platelet and apparent k_d of 1.5 ±0.4 microM (n=3). The association/dissociation data were fitted to an exponential decay model with rates of k_+= 1.8±0.3 microM^{-1}s^{-1} and k_- = 0.96 ±0.04 s^{-1}.

Conclusions: Here, we quantitatively characterized interaction of prothrombin with the two subpopulations of activated platelets from healthy donors and patients with Glanzmann´s thrombasthenia.

PB 1282 | Inhibition of MRP4 Mediated Transport Reduces Platelet Function in a cAMP-cGMP Independent Manner

L. Alemanno[1], V. Klaus[2], I. Massimi[1], G. Maria[1], D. Angiolillo[3], F.M. Pulcinelli[1]

[1]Sapienza University of Rome, Dept. of Experimental Medicine, Rome, Italy, [2]University of Wuerzburg-Julius-Maximilians, Wuerzburg, Germany, [3]University of Florida, College of Medicine, Division of Cardiology, Jacksonville, United States

Background: Platelet Multidrug Resistance Protein4 (MRP4) overexpression has a role in reducing the pharmacodynamics effects of aspirin. In platelets obtained from aspirin treated patients, high on aspirin residual platelet reactivity (HARPR) positively correlated with MRP4 levels.

Aims: We studied the effects of an MRP4 mediated transport inhibitor, cilostazol, on collagen induced platelet activation.

Methods: All studies were performed in platelets obtained from healthy volunteers (HV; N=10) and patients under chronic aspirin treatment (N=45). Platelet aggregation (PA) was evaluated and the results are reported as percent of aggregation observed after 4 min stimulation (%PA) in response to collagen (threshold concentration). ATP release (luciferin-luciferase assay) was measured to evaluate platelet secretion. We evaluated the phosphorylation status of VASP on the Serine 239 through Western Blot. As cilostazol is also a cAMP elevating agent (PDE inhibitor), to separate the effect on MRP4 and PDE, platelets were treated at different time points.

Results: An inhibitory effect on PA and secretion was found when platelets were activated immediately (T0) after addition of cilostazol (6.4±2.4 vs 88.8±1.9 PA%; 2.4±1.6 vs 26.8±2.2 ATP-release %).

VASP phosphorylation was absent at this time (T0), indicating that inhibition is not cAMP-cGMP correlated. The effect of Cilostazol on PA is dependent on MRP4 inhibition, as similar PA reduction was obtained using an MRP4 selective inhibitor, Ceefourin1(6.4±5.8 vs 84.1±5.5 PA%).

Cilostazol effect was evident also in aspirin treated platelets. A reduction of PA and secretion were observed (38.8±16 vs 61.8±17 PA%; 14.9±8.2 vs 20.9±10.8 ATP-release %).

Inhibition of MRP4 reduces HARPR, in patients under chronic aspirin treatment.

Cilostazol treatment reduces collagen induced PA (17.5 ±7.7 vs 53.2±7.8 PA%) in patients with HARPR.

Conclusions: The inhibition of MRP4-mediated transport reduces residual platelet function in patients with HARPR in cAMP-cGMP independent manner.

PB 1283 | Single Platelet Screening Platform Based on Cytoskeletal Adhesion Morphology

S. Lickert, I. Schön, V. Vogel

ETH Zurich, Department for Health Sciences and Technology, Zurich, Switzerland

Background: For sealing injured blood vessels, platelets respond to biophysical and biochemical stimuli by remodeling the cytoskeleton. How this reorganization gives rise to a highly contractile phenotype that drives clot contraction remains poorly understood. In vitro, spreading platelets form unique self-organized cytoskeletal patterns, but whether these correlate with platelet function under pathophysiological settings is elusive.

Aims: We aimed at establishing a mid-throughput imaging platform to systematically classify single platelet morphologies and test how these respond to known effectors of platelet aggregation.

Methods: Washed platelets were cultured in the presence of ADP on fibrinogen-coated glass, fixed and stained for F-actin and vinculin. Morphological parameters of single cells were extracted from confocal images by advanced image analysis. Super-resolution fluorescence and SEM were used to obtain further structural insights.

Results: Platelets from healthy subjects predominantly adopted a polarized and highly aligned cytoskeletal organization with strong F-actin bundles anchored at peripheral adhesion sites. This morphology was exclusively observed on fibrinogen or fibronectin, but not on collagen I or laminin. The specific integrin $\alpha_{IIb}\beta_3$ inhibitors RUC-4 and Eptifibatide induced an isotropic cytoskeletal organization in a dose-dependent manner before affecting spreading area. Platelets from a patient with Glanzmann thrombasthenia formed actin rings and very slowly proceeded to a more polarized organization. Differences between morphologies were statistically highly significant with $p << 10^{-10}$.

Conclusions: Our results show that outside-in signaling of the platelet integrin $\alpha_{IIb}\beta_3$ determines the cytoskeletal organization on fibrinogen. Our assay sensitively distinguishes between different platelet phenotypes that are representative for platelet aggregation behavior. The developed platform will be further explored for a clinical screening of platelets.

PB 1284 | Systemic Alteration of Platelet Activity during Each Trimester of Normal Pregnancy

S. Cullen[1], M.A. Alobaidly[1], C. Regan[2], N. Moran[1]

[1]Royal College of Surgeons in Ireland, Molecular and Cellular Therapeutics, Dublin, Ireland, [2]Coombe Women & Infants University Hospital,Cork St. Dublin 8, Dublin, Ireland

Background: Markers of platelet activation are elevated during normal pregnancy. However, the clinical significance of platelet activation during pregnancy is not understood.

Aims: In this study we therefore aim to compare platelet function in healthy pregnant women with non-pregnant donors.

Methods: 20 healthy pregnant women were recruited with informed consent at their first-trimester hospital visit. A 12 ml blood sample was donated at each trimester (T1: 9-15 weeks, T2: 16-24 weeks, T3: 25-36 weeks gestation), and within 8 weeks of delivery.

Platelet aggregation was measured in response to a collagen related agonist (CRP), a thrombin-derived activator peptide (TRAP), and a thromboxane mimic (U46619). In parallel platelet ATP/ADP secretion assays were performed using dose-ranges of agonists to quantify changes in platelet sensitivity.

Results: The results of this study shows differential modulation of platelet activation during normal healthy pregnancy. Specifically platelet aggregation in response CRP is enhanced (>two- fold) compared to non-pregnant controls. In parallel the potency of CRP to induce a secretion response is significantly altered (EC_{50} 0.34+/-0 .05 ug/ml vs 8.72 +/-2.77 ug/ml) in T1 pregnancy vs control (Figure 1). Differences in potency persist in T2 and T3 and revert to normal levels in postpartum samples. These alterations in responsiveness may reflect the physiological importance of collagen in critical stages of pregnancy. In parallel, responsiveness to other soluble platelet agonists shows

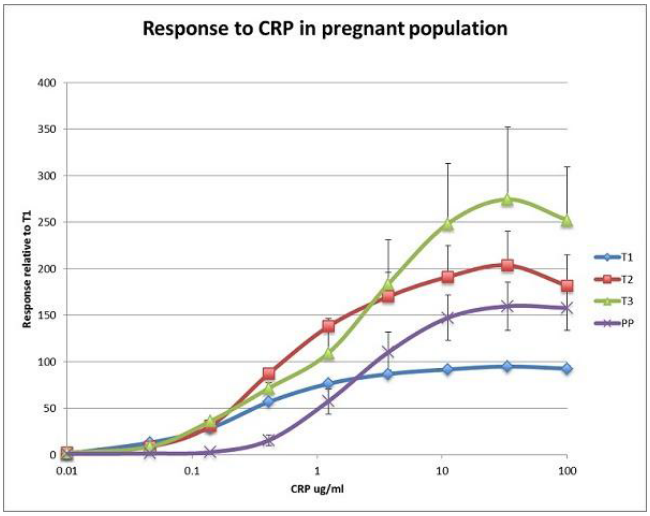

FIGURE 1 Platelet ATP secretion was data from pregnant donors in response to doses of CRP. All data is normalized to data obtained from trimester 1

modulation throughout gestation. In contrast platelet aggregation and secretion in response to U46619 and TRAP was greater at T3 than T1.
Conclusions: From this study we hypothesize that this subtle regulation of platelet responsiveness during pregnancy reflects a nuanced regulation of platelet function that is necessary for a normal healthy pregnancy.

PB 1285 | The Inhibitory Effect of Protamine on Arterial Thrombosis and Platelets in Rats

J. Miklosz, B. Kalaska, D. Pawlak, A. Mogielnicki

Medical University of Bialystok, Department of Pharmacodynamics, Bialystok, Poland

Background: Protamine-induced thrombocytopenia (PIT) is a new immuno-hematological and thrombotic disorder described in patients treated with unfractionated heparin (UFH) and protamine (PRT) during cardiopulmonary bypass (CPB). We previously found elevated anti-protamine IgG antibodies (PLoS One 2015) and erythrocyte-platelet aggregates in lungs of mice treated with UFH followed by PRT (UFH/PRT) (Front Pharmacol 2016).
Aims: We aimed to investigate the effect of PRT alone or in complex with UFH on arterial thrombosis and platelets in rats.
Methods: Wistar male rats were divided into 4 groups treated with vehicle, UFH, PRT and UFH/PRT. Platelet aggregation and platelet count were assessed one hour after single administration. In the chronic experiment, UFH/PRT administration was repeated 5 times, once weekly. Arterial thrombosis was electrically-induced in the carotid artery of rats after the last injection. We assessed: thrombus weight, platelet count and aggregation in whole blood, aPTT, PT, fibrinogen, prostacyclin metabolite and D-dimer concentrations in rat plasma.
Results: The platelet aggregation was inhibited, while no changes in platelet number occurred one hour from a single injection of PRT (Table 1). In the chronic experiment, PRT slightly inhibited thrombosis development (0.83±0.17 vs. 1.09±0.22 mg in the vehicle; p< 0.05), but it did not affect the platelet count and platelet aggregation in rats. There were no changes in other parameters.
Conclusions: PRT inhibits directly platelets activity, without decreasing the platelet count, while UFH slightly weakens this effect. We showed an antithrombotic rather than prothrombotic potential of PRT in a repeated-dose experiment in healthy rats. We suggest that PIT and thrombotic complications after PRT treatment could depend on the individual cardiovascular risk, interactions between UFH/PRT/CPB and other drugs, rather than PRT alone.
Funding: National Science Centre, 2016/23/N/NZ7/00442.

PB 1286 | The Role of Neuraminidases in Platelet Function

D.E. van der Wal, A.M. Davis, M. Mach, D.C. Marks

Australian Red Cross Blood Service, Product Development and Storage, Sydney, Australia

Background: Platelets contain many glycans capped by sialic acid, and its cleavage has been implicated in clearance of senescent and cold-stored platelets as well as in immunothrombocytopaenia. The majority of glycans are attached to the platelet adhesion receptor glycoprotein (GP)Ibα. So far, 4 human sialidases (neuraminidase, NEU1-4) have been identified: NEU1 being lysosomal and NEU2 cytosolic.
Aims: To investigate the role of neuraminidases in platelet function.
Methods: Donors were consented to donate either whole-blood to prepare platelet rich plasma (PRP, n=6) or apheresis platelets (n=8). Platelets were stimulated with ristocetin (3mg/ml), ADP (20μM) and arachidonic acid (AA, 800μM). NEU1 and NEU2 surface expression was measured by flow cytometry, as were platelet-attached glycans using Ricinus Communis Agglutinin-1 (RCA-1; detecting galactose-residues) and Wheat Germ Agglutinin (WGA; detecting sialic acid and N-acetyl-D-glucosamine, GlcNAc-residues). GPIIb/IIIa-integrin and/or GPIbα mediated signalling was inhibited by RGDS, GlcNAc or O-sialo-glyco-endopeptidase respectively. Apheresis platelets were studied on collection day (D0) and day 1, 2, 5, 7, 9 post-collection.

TABLE 1 Platelet count and platelet aggregation after one hour experiment. Results are shown as mean ± SD, n = 6-7 * P<0.05 Mann-Whitney test

		VEHICLE	UFH	UFH+PRT	PRT
Platelet count (10^3/mm^3)	-5 min	609 ± 103	609 ± 103	609 ± 103	609 ± 103
	15 min	583 ± 138	549 ± 167	605 ± 159	622 ± 58
	30 min	595 ± 196	607 ± 213	605 ± 146	630 ± 162
	60 min	563 ± 196	639 ± 56	621 ± 82	643 ± 40
Platelet aggregation	Maximal extension	8.2 ± 1.8	9.2 ± 1.6	7.0 ± 3.3	5.4 ± 2.1*
	Slope of platelet aggregation	3.8 ± 0.6	4.4 ± 0.7	3.5 ± 1.4	3.0 ± 0.7*
	Lag phase	146.0 ± 38.0	141.0± 36.0	191.0 ± 64.0	219.0 ± 48.0*
	Area under the curve	18.4 ± 6.2	21.9 ± 6.4	14.0 ± 12.2	8.2 ± 5.7*

Results: Ristocetin stimulation induced a 3-fold increase in RCA-1 binding ($p < 0.05$), and reduced WGA binding ($p < 0.05$), ADP and AA had no effect. Interestingly, basal platelet membrane expression of both NEU1 and 2 was observed, which was increased by 5- and 3-fold respectively following ristocetin stimulation ($p < 0.05$). RGDS inhibited NEU1 expression by 40%; however, GPIbα inhibition decreased both NEU1 and NEU2 by 80%. In apheresis platelets, binding to all lectins, without or with ristocetin stimulation was highly variable between donors.
Conclusions: These results show a potential novel role for NEU1 and NEU2 in platelet activation, which is highly dependent on GPIbα-mediated signalling. The significance of the variation in apheresis platelet products requires further investigation.

PB 1287 | Platelet Procoagulant Activity Development and Thrombin Generation in Recalcified ADP-supplemented Platelet-rich Plasma

E. Artemenko, F. Ataullakhanov, M. Panteleev

Center for Theoretical Problems of Physicochemical Pharmacology, Moscow, Russian Federation

Background: Only upon strong CRP- or thrombin-induced stimulation, phosphatidylserine(PS)-positive platelet subpopulation is formed. However, ADP can regulate the number of procoagulant platelets, modulate action of other agonists and potentiate thrombin generation in recalcified platelet-rich plasma.
Aims: The objective of this study was to investigate possible formation of the PS-positive platelets in recalcified plasma following ADP-induced platelet activation and contribution of ADP-stimulation and thrombin generation in this process.
Methods: Whole blood was collected from healthy donors into sodium citrate. We used flow cytometry to investigate the formation of PS-positive and PS-negative platelet subpopulations.
Results: In accordance with previously published data, ADP-induced stimulation of washed platelets caused no formation of PS-positive platelets. The same ADP-induced stimulation of platelets in plasma caused formation of PS-positive platelet subpopulation as detected by annexin V binding. The formation of PS-positive platelets in plasma upon ADP-induced platelet activation was only due to spontaneous thrombin generation, because this effect was completely inhibited by irreversible thrombin inhibitor D-Phe-Pro-Arg-chloromethylketone (PPACK).
Conclusions: Our data indicate that ADP-induced activation of platelets in plasma can lead to formation of PS-positive activated platelets only due to indirectly generated thrombin.

PB 1288 | Role of HSP47 in Platelet Collagen Interaction

S. Alouda, K. Sahli, P. Sasikumar, L. Holbrook, J. Gibbins

University of Reading, School of Biological Sciences, Reading, United Kingdom

Background: Heat shock protein 47 (HSP47) belongs to the heat shock protein superfamily, which is involved in chaperoning activities within secretory system of cells to maintain protein folding and configuration. HSP47 is unusual in that its chaperoning activities are confined to collagen and procollagen monomers. We reported presence of HSP47 within and on the surface of platelets for the first time in proteomic analysis of platelet peripheral membrane proteins. Through the use of agents that disrupt interactions between HSP47 and collagen we demonstrated its importance in the control of platelet function.
Aims: To understand the mechanism by which HSP47 modulates platelet-collagen adhesion.
Methods: Immunofluorescence and sucrose density gradient subcellular platelet fractionation were used to determine HSP47 location in human platelets. Quantification of HSP47 was achieved using quantitative western blotting. The actin polymerisation inhibitor (latrunculin-A) was used to test the dependency of HSP47 mobilisation on actin polymerisation. Release of HSP47 was tested using immunoblotting and flow cytometry.
Results: The presence of HSP47 in platelets was confirmed in immunofluorescence confocal microscopy where it was found to colocalise with the dense tubular system (DTS) within platelets. Consistent DTS association, HSP47 was also seen in low-density sucrose gradient fractions. HSP47 was expressed at around 10,000 copies per platelet and its mobilisation to the cell surface was shown to be dependent on actin polymerisation following platelet activation. Immunoblotting of platelet releasate confirmed the release of HSP47 from human platelets in a soluble form and on platelet-derived microvesicles.
Conclusions: HSP47, located in the DTS is mobilised to the platelet surface in a manner that is dependent of cytoskeletal reorganisation. Our future priority will be to determine to what is HSP47 binds on platelet surface, and its ability to influence collagen-stimulated cell signalling.

PB 1289 | Assessment of Platelet Procoagulant State - Significance of Different Methods

S.A. Fiedler, A.-C. Junker, G.J. Praefcke, C. Grundmann, R. Seitz, U. Salge-Bartels

Paul-Ehrlich-Institut, Federal Institute for Vaccines and Biomedicines, Hematology and Transfusion Medicine, Langen, Germany

Background: Platelets are key players in hemostasis. During primary hemostasis platelets adhere to injured endothelium and to exposed subendothelial matrix proteins. In consecutive steps, coagulation factors are bound to phosphatidylserine rich sites in the platelet membrane thereby facilitating the progression of the clotting cascade. Platelet microvesicles (MV) shedded in the course of activation also play an intensifying and spreading role.

Aims: The objective of our study was to determine platelet coagulant status by use of different methods and to evaluate conditions that could induce the release of MV.

Methods: Platelets were either prepared from citrated whole blood obtained from healthy donors or from pooled platelet concentrates obtained from a blood bank at day 5 of preparation. Flow cytometry was applied to measure binding of fluorescently-labeled Annexin V (AV). Thrombin generation assay (TGA) triggered with tissue factor, and thrombelastometry (TEM) were performed. As exogenous challenge, different shear rates were applied by passage through a flow chamber.

Results: Annexin V binding was found on platelets and MV. Shear forces reduced the AV binding on platelets and increased AV binding in the MV fraction. In TGA the whole platelet samples clearly enhanced thrombin generation. A major part could be attributed to the effect of MV. Application of shear forces was particularly suitable to generate activated states in conjunction with MV release.

Conclusions: TGA provides a sensitive and valuable quantitative method for the determination of the platelet procoagulant status. Complementary data can be obtained by flow cytometry which allows the direct comparison of AV binding to platelets and MP. Together with the application of shear forces a measure of the platelet procoagulant status and of platelet integrity can be acquired.

PB 1290 | Exploration of additional parameters of multiple electrode aggregometry is encouraged

M.T. Skipper, P. Rubak, O.H. Larsen, A.-M. Hvas

Aarhus University Hospital, Clinical Biochemistry, Aarhus, Denmark

Background: Platelet function evaluated by multiple electrode aggregometry is increasingly employed. Area under the curve (AUC) of the platelet aggregation signal is at present the only reported parameter in the literature. However, other parameters of platelet aggregation are readily available and may provide further insight on platelet function.

Aims: To provide reference intervals of maximum aggregation amplitude and aggregation velocity in order to facilitate future exploration of these parameters.

Methods: 121 healthy individuals were included. Multiple electrode aggregometry was performed in hirudin whole blood using ADP, arachidonic acid, collagen and ristocetin (RISTOlow and RISTOhigh). Day-to-day variation was investigated, and the associations of the aggregation parameters with platelet count, white and red blood cell counts were explored.

Results: Reference intervals were established for maximum amplitude and aggregation velocity, and will be presented at the congress. Day-to-day variation was ≤11% for both parameters except when using RISTOlow (30 and 18% respectively). In contrast to the AUC and velocity, the maximum amplitude was not associated with the platelet count inside the reference interval in all assays (p-values ≥ 0.4) except RISTOHigh (p=0.001). Similar to the AUC, a positive association with white blood cell count was found using all agonists (p-values ≤ 0.02) except RISTOhigh. No associations with red blood cell count or haematocrit were observed (p-values > 0.08).

Conclusions: Reference intervals for maximum aggregation amplitude and aggregation velocity were established. The day-to-day variation was acceptable. The presented data facilitates future exploration of these parameters that may provide further insight on platelet function and therefore should be encouraged in research settings.

PB 1293 | Nicotine Suppresses the Collagen-induced Platelet Aggregation

Y. Suganuma[1], T. Kano[1,2], K. Ikemoto[1], C. Ichinose[1], T. Matsui[3], K. Kondo[1]

[1]Fujita Health University School of Medicine, Department of Pharmacology, Toyoake, Japan, [2]Fujita Health University, Graduate School of Medicine, Toyoake, Japan, [3]Fujita Health University School of Health Sciences, Department of Biology, Toyoake, Japan

Background: Nicotine is reported to have various physiological activities, but little is known about its effect on platelets.

Aims: We investigate the effect of continuous nicotine loading on hemostatic processes, especially on platelet activation.

Methods: Male ICR mice of 6 months old were administered with nicotine (100 μg/mL) by supplementation in drinking water for 4 weeks. (1) Loading dose was calculated from amount of water intake. (2) Systolic blood pressure and heart rate were measured by tail cuff method. (3) Citrated blood was collected from inferior vena cava, cells number was counted using cell counter. (4) The whole blood sample was centrifuged at 200 *g* for 10 min to obtain platelet-rich plasma (PRP), and platelet poor plasma (PPP) was obtained by further centrifugation (1,500 *g*, 10min). PRP was adjusted to 250,000 platelets per mL with PPP, and stimulated with collagen (4~10 μg/mL) or ADP (1~10 μM) to evaluate platelet aggregation by light transmission (MCM HEMA TRACER 712, MC Medical). (5) Prothrombin time (PT) and activated partial thromboplastin time (aPTT) were measured using CA-104 (Sysmex).

Results:

(1) Nicotine intake of each mouse was calculated to be 12.2±0.2 mg/kg body weight/day.

(2) Nicotine loading did not affect systolic blood pressure and heart rate,

(3) nor blood cells counting.

(4) Nicotine loading inhibited platelet aggregation induced by collagen (5 μg/mL) from 77.1±3.5% of vehicle control (0.2% saccharin containing d.w.) to 46.4±9.4% (n=12), while ADP-induced one showed no significant suppression.

(5) Nicotine loading did not affect PT and aPTT.

Conclusions: These results indicate that nicotine supplementation suppresses platelet activation, especially when stimulated by collagen. Our interest is focusing toward the intracellular mechanism of nicotine on the platelet activation.

PB 1294 | Platelets Enhance Freshly Isolated Lymphocytes Adhesion to Fibrin

O. Solpova[1], A. Solpov[2]

[1]Chita State Medical Academy, Normal Physiology Department, Chita, Russian Federation, [2]Chita State Medical Academy, Chita, Russian Federation

Background: The processes of primary hemostasis, which are caused by adhesion, aggregation and subsequent retraction of the platelet plug can't be viewed in isolation from coagulation. The damaged part of the vascular wall is always expressed tissue factor, which triggers the extrinsic pathway of coagulation and by PF4 initiated an internal pathway of prothrombinase and fibrin clot formation. In a previous study we demonstrated that CD4+lymphocytes interacted with platelets and formed heterotypic lymphocyte-platelet aggregates (LPA).

Aims: The aim was to determine the role of fibrin in the interaction of lymphocytes and platelets isolated from blood of healthy donors with the adhesive surface in static conditions.

Methods: We used the Millipore filters coated with fibrin. Filters impregnated with Na CL 0,9% served as 1-st control and autologous platelet poor plasma 2-nd control. At the bottom of the wells plastic plate placed filters and added to a previously prepared lymphocyte-platelet suspension was extracted from the blood of 12 healthy individuals on Ficoll gradient. After incubation in static conditions in the wells and subsequent washing, the cell pool resuspended and counted in a light microscope. The numbers of lymphocyte-platelet aggregates remaining in the cell suspension were counted.

Results: We observed that after incubation of platelets and lymphocytes to the filter surface with fibrin their number in the suspension was reduced to nearly 2.5 times as compared with filters impregnated NaCL 0,9% or platelet poor plasma. This reduces the average number of platelets per one lymphocyte and total lymphocyte count ($p < 0.05$). Reduction of the number of LPA in a suspension showed the ability of lymphocytes in aggregates with platelets adheres to surface coated by fibrin.

Conclusions: Thus, lymphocytes are able to contact with fibrin, while they forming coagregates with platelets. Moreover, we proved a leading role of fibrin, but not blood plasma in this process.

PB 1295 | Synergistic Inhibitory Effect of Capsaicin and Dihydrocapsaicin on the Arachidonic Acid Pathway of Platelet Aggregation

S. Almaghrabi[1], K. Ahuja[1], D. Geraghty[1], M. Adams[1,2]

[1]University of Tasmania, School of Health Sciences, Launceston, Australia, [2]Murdoch University, School of Veterinary and Life Sciences, Perth, Australia

Background: Capsaicinoids, including capsaicin (CAP) and dihydrocapsaicin (DHC), the pungent principles of chilli peppers, individually inhibit *in vitro* platelet aggregation. However, their effects when present in the relative proportions that they are found in different fruits, i.e., 60:40 CAP:DHC, are not known.

Aims: To determine the effects of CAP and DHC, alone and together, on platelet aggregation, platelet count, and thromboxane B2 (TXB2) formation.

Methods: The individual (12.5 μM) and combined (CAP+DHC, 3.75+2.5, 7.5+5 μM) effects of CAP and DHC were determined on arachidonic acid (AA; 300μg/mL), ADP (5 μM), and collagen (4μg/mL) induced aggregation (AggRAM aggregometer; %AUC normalised to aggregation in the absence of capsaicinoid, mean±SEM), platelet count (Sysmex 1000i analyser) and TXB2 release (ELISA) (n=4 healthy donors). Data were analysed using ANOVA/linear regression.

Results: Compared to vehicle, CAP and DHC (12.5 μM) each inhibited AA-induced aggregation (by 23.2 and 25.3%, respectively; both $p< 0.01$). In combination, CAP+DHC inhibited AA-induced aggregation (CAP+DHC, 3.75+2.5 μM by 36.5%, $p=0.01$; CAP+DHC, 7.5+5 μM by 57.5%, $p< 0.001$), compared to vehicle (Fig 1). In contrast to AA-induced aggregation, neither CAP nor DHC individually, or in combination, significantly inhibited ADP- or collagen-induced aggregation. Incubation of platelets with CAP or DHC (12.5 μM), and in combination, for up to 2 hours did not significantly affect the platelet count. The 60:40 CAP+DHC (7.5+5 μM) combination significantly inhibited TXB2 formation ($p< 0.001$), compared to the individual capsaicinoids.

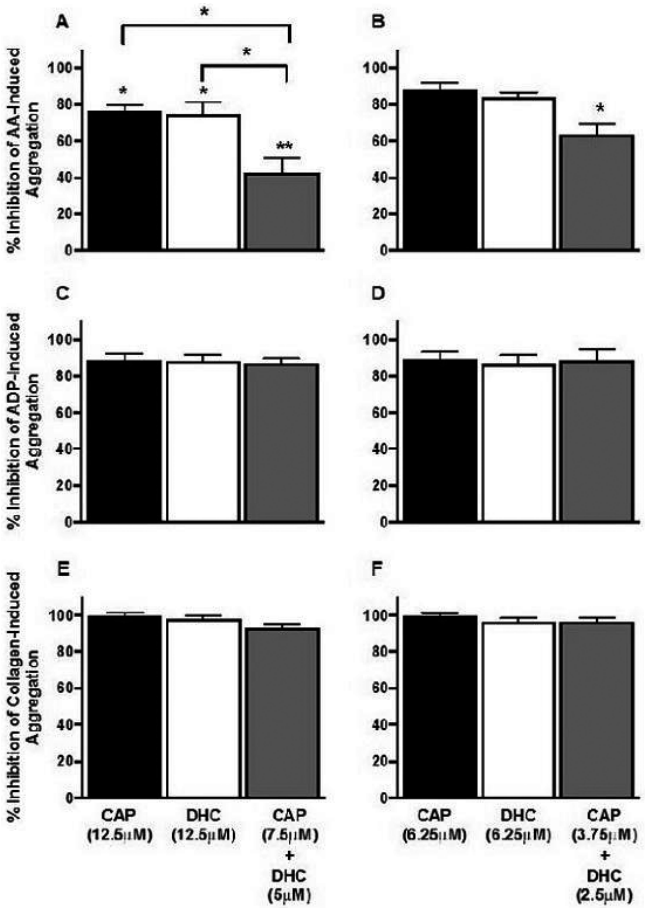

FIGURE 1 Effect of CAP, DHC, and their combination, on AA- (A & B), ADP- (C & D) and collagen- (E &F) induced aggregation. * $p<0.05$, ** $p<0.001$

Conclusions: The combination of CAP+DHC in the proportions they are present in chilli peppers, produces a significantly greater inhibitory effect against AA-induced platelet aggregation and TXB2 formation, compared to the individual capsaicinoids. Further investigations are warranted to determine whether these capsaicinoids may be exploited for therapeutic benefit by dampening platelet activity via the AA-pathway.

PB 1296 | Crosstalk between PI3K Pathway and MAPK Pathway Regulates Platelet Activation and Protein Synthesis via Phosphoinositide-dependent Kinase-1

B. Manne[1], P. Munzer[2], R. Badolia[3], R. Campbell[1], S. Kunapuli[3], O. Borst[2], A. Weyrich[1,4], M. Rondina[1,4,5]

[1]*University of Utah, Molecular Medicine, Salt Lake City, United States,* [2]*University of Tuebingen, Cardiology and Cardiovascular Medicine, Tuebingen, Germany,* [3]*Temple University School of Medicine, Philadelphia, United States,* [4]*University of Utah, Internal Medicine, Salt Lake City, United States,* [5]*George E. Wahlen VAMC GRECC, Salt Lake City, United States*

Background: Phosphoinositide-dependent protein kinase 1 (PDK1) is known to regulate PAR4 induced platelet activation and thrombus formation through GSK3b. However, whether PDK1 signaling also involves the ADP receptor and, if so, downstream functional consequences are unknown.

Aims: To evaluate the role of PDK1 in ADP-induced platelet activation and protein synthesis.

Methods: We employed both pharmacologic (e.g. the selective PDK1 inhibitor, BX795) and genetic (platelet specific deletion of PDK1) approaches to dissect the role of PDK1 in ADP-induced platelet activation and protein synthesis.

Results: Inhibition of PDK1 with BX795 reduced 2MeSADP-induced platelet aggregation by abolishing thromboxane generation. Similar results were observed in PDK1-/- mice (Fig A). Inhibition of PDK1 protected mice from collagen and epinephrine-induced pulmonary embolism (Fig B). PDK1 was also necessary for the phosphorylation of MEK1/2, Erk1/2 and cPLA2, indicating that PDK1 regulates an upstream kinase in MAPK pathway. We next identified that this upstream kinase is Raf1 (necessary for the phosphorylation of MEK1/2), as pharmacologic inhibition and genetic ablation of PDK1 was sufficient to prevent Raf1 phosphorylation (Fig C). Pharmacologic inhibition and genetic ablation of PDK1 blocked MAPK- and mTORC1-dependent protein synthesis in platelets through a mechanism requiring the phosphorylation of S6K and eIF4E. Concordantly, PDK1 is necessary for signal-dependent synthesis of the protein bcl3, which is under mTORC1-dependent control (Fig C).

Conclusions: Taken together, our findings show for the first time that PDK1, a master kinase in the PI3K pathway, directly governs thromboxane generation, thrombosis, and protein synthesis in platelets through regulating MAPK and mTORC1 pathways.

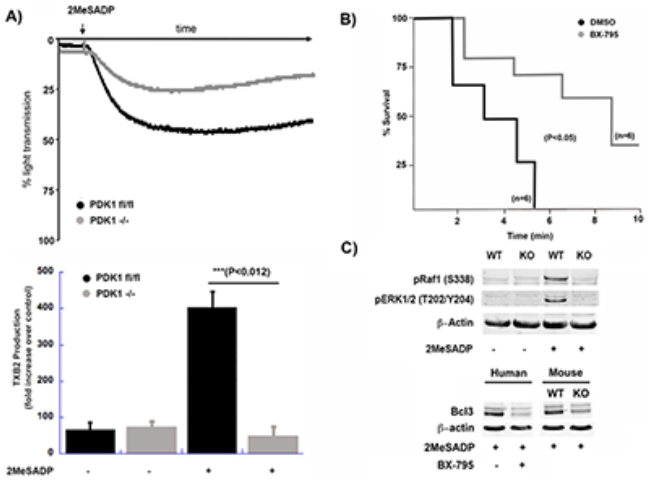

FIGURE 1 PDK1 regulates platelet aggregation, TxB2 generation, and thrombosis through the MAPK kinase pathway

PB 1298 | Diacylglycerol Kinase Zeta is a Negative Regulator for GPVI-Mediated Platelet Activation

A. Moroi[1], H. Zhi[1], M. Riese[1,2], P. Newman[1,2]

[1]*Blood Research Institute, BloodCenter of Wisconsin, Milwaukee, United States,* [2]*Medical College of Wisconsin, Milwaukee, United States*

Background: Diacylglycerol kinases (DGK) are a family of enzymes that catalyze the conversion of diacylglycerol (DAG) into phosphatidic acid (PA). Removal of DAG, a potent activator of protein kinase C, from the metabolic pool has the effect of dampening platelet activation. Human platelets contain mRNA transcripts encoding many of the isoforms of DGK, and an inhibitor of DGKα, β and γ, R59949, has been shown to amplify platelet activation induced by collagen, but not thrombin. These data support a role for DGKs is suppressing platelet activation, however the specific identity of the DGK isoforms that function in platelets is unknown.

Aims: The aim of this study is to determine which DGK isoforms play a role in platelet production and function.

Methods: Platelet count and function from mice lacking the ζ isoform of DGK was determined using standard biochemical and cell biological techniques.

Results: DGKζ-KO mice are born in normal Mendelian ratio, and show normal platelet counts and volume. Flow cytometric analysis revealed a 50% increase in surface expression of GPVI, whereas expression of integrins α2β1 and αIIbβ3 were normal. Platelet activation responses to the GPVI agonists, collagen and collagen-related peptide (CRP) was potentiated in DGKζ-/- platelets; and the onset of platelet activation was earlier. Consistent with this, signaling events downstream of GPVI activation, including phosphorylation of PLCγ2 and ERK, was significantly increased in DGKζ-/- platelets. Interestingly, in contrast to GPVI-mediated platelet activation, thrombin-mediated activation was reduced.

Conclusions: Taken together these data support the notion DGKζ is a selective negative regulator of GPVI-, but not thrombin-, mediated platelet activation. Pharmacologic suppression or genetic deletion of this DGK isozyme might prove useful in producing platelets that exhibit improved hemostatic effectiveness without inducing overt pathological thrombosis.

PB 1299 | ELMO1 Negatively Regulates Glycoprotein VI-mediated Signaling by RhoG in Platelets

A. Patel[1], J. Kostyak[1], R. Badolia[1], D. Bhavanasi[1], C. Dangelmaier[1], S. Kim[1], J. Aslan[2], S. Merali[1], S. Kunapuli[1]

[1]*Temple University School of Medicine, Philadelphia, United States,* [2]*Oregon Health & Science University, Portland, United States*

Background: PI3-kinase is an important signaling molecule activated upon platelet activation leading to generation of Phosphatidylinositol (3,4,5)-trisphosphate (PIP_3) in turn recruiting pleckstrin homology (PH) domain containing proteins to the membrane. We screened for proteins that interacted with PIP_3 and among these proteins we found engulfment and cell motility-1 (ELMO1). ELMO1 is a scaffold protein with no catalytic activity and is well known to regulate actin cytoskeleton involved in cell motility and cell spreading in nucleated cells. ELMO1 is expressed in platelets and interacts with active RhoG however the function of ELMO1 is not known.

Aims: The focus of this study is to determine the function of ELMO1 in platelets.

Methods: We utilized $ELMO1^{-/-}$ mice to characterize the function of ELMO1 in platelets using *ex vivo* and *in vivo* methods.

Results: Platelet aggregation and dense granule secretion was enhanced in $ELMO1^{-/-}$ platelets in response to GPVI agonists, CRP (Figure 1A & B) and collagen, but unaltered using PAR4 agonist (AYPGKF). Surface expression of GPVI and Glycoprotein IIb/IIIa (GPIIb/IIIa) were normal, suggesting that ELMO1 plays a specific role downstream of GPVI. $ELMO1^{-/-}$ platelets exhibited enhanced clot retraction and spreading indicating its role in GPIIb/IIIa-mediated outside-in signaling. Whole blood from $ELMO1^{-/-}$ mice perfused over collagen under arterial shear conditions exhibited enhanced thrombus formation. $ELMO1^{-/-}$ mice showed reduced survival compared to control following pulmonary embolism. $ELMO1^{-/-}$ mice also exhibited shorter time to occlusion using the ferric-chloride injury model and shorter bleeding times compared to control. This indicates that ELMO1 plays an important role in hemostasis and thrombus formation *in vivo*. At the molecular level, RhoG activity was enhanced within 1 minute in $ELMO1^{-/-}$ murine platelets (Figure 1C) compared to control in response to CRP.

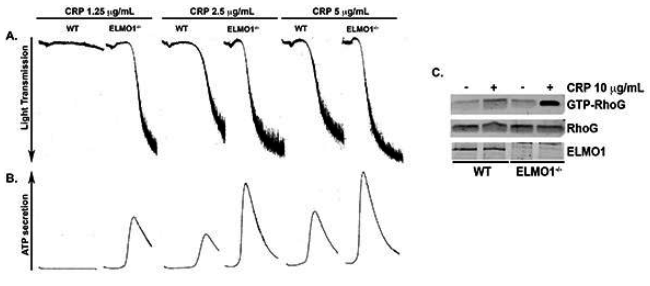

FIGURE 1 Representative figure of (A) platelet aggregation, (B) dense granule secretion, and (C) active RhoG pull-down by GST-ELMO1 from platelets.

Conclusions: ELMO1 negatively regulates GPVI-mediated thrombus formation possibly by RhoG.

PB 1300 | All Roads Lead to Filamin A: Ligand Binding and Shear Force Signal to Calpain-mediated Cleavage of Filamin A upon Platelet Activation

C.L. Buitrago, B. Coller

Rockefeller University, New York City, United States

Background: Responding to mechanical stimuli is a critical function of living cells. Filamin A (FlnA) is a 280 kD highly conserved protein. It has been implicated in cytoskeletal integrity and mechanotransduction. As an essential scaffolding protein that physically links membrane-bound glycoproteins (GP) to the actin cytoskeleton, it has been implicated in platelet aggregation under conditions of shear as both integrin alphaIIbbeta3 and GPIb-V-IX receptors have been shown to interact with FlnA through its C-terminal region.Nonetheless, many aspects of FlnA's signaling mechanisms and functions remain unknown.

Aims: Study signaling mechanism leading to Filamin A cleavage.

Methods: Use of human platelets and monoclonal antibodies to GPIb (6D1), and alpha2beta1 (6F1), as well as the small molecule inhibitor of alphaIIbbeta3 RUC-4.

Results: When platelets are activated by thrombin-receptor activating peptide (T6), ADP, or convulxin (Cnx), FlnA is cleaved downstream of ligand binding to integrin alphaIIbbeta3 in a PKC dependent fashion. On the other hand, inducing von Willebrand factor binding to GpIb with ristocetin or collagen binding to integrin alpha2beta1 results in FlnA cleavage without a PKC requirement. Cleavage generates a 180 kD N-terminal fragment, while the 100 kD C-terminal is further cleaved into 90 and 10kD fragments. We also demonstrate that FlnA cleavage requires not only receptor activation but ligand binding since RUC-4 inhibits cleavage in platelets treated with the alphaIIbbeta3 activating antibody PT25 or DTT in the presence of fibrinogen. Furthermore, platelet activation and Ca^{++} mobilization *per se* are not sufficient to induce FlnA cleavage as treating platelets with PMA in combination with RUC-4 inhibits it. Finally, we demonstrate that FlnA cleavage occurs only under aggregating conditions since stirring is required in combination with activation by T6, ADP, collagen, Cnx or ristocetin.

Conclusions: FlnA cleavage is an essential outcome of ligand binding and platelet aggregation under shear force.

PB 1301 | Kindlin-3 identified as a key negative regulator of the small Rho GTPase, Cdc42 during platelet spreading

D. Ghalloussi[1,2], L. Vidal[1], M. Poggi[1], P. Saultier[1], F. Peiretti[1], L. Limozin[3], H. Chambost[1,4], M.-C. Alessi[5], M. Canault[1]

[1]Aix-Marseille Université, Inserm, Inra, NORT, Faculté de Médecine Timone, Marseille, France, [2]University of North Carolina at Chapel Hill, Bergmeier Lab, Chapel Hill, United States, [3]Aix-Marseille Université, Inserm, CNRS, Laboratoire Adhésion & Inflammation, Marseille, France, [4]Service d'Hématologie et Oncologie Pédiatrique, Hôpital Timone Enfants, APHM, Aix Marseille Univ, Marseille, France, [5]Aix-Marseille Université, Inserm, Inra, NORT, CRPP, Faculté de Médecine Timone, Marseille, France

Background: Integrin bidirectional signaling allows the fine regulation of platelet functions in hemostasis and thrombosis. Upon stimulation, integrin ligation and clustering trigger outside-in signaling, which is critical for platelet spreading and retraction. These processes depend on Rho family small GTPases (RhoA, Cdc42 and Rac1) that regulate actin-binding proteins and actin dynamics. Kindlin-3 (K3) is described as an essential regulator of platelet integrin inside-out signaling and recent studies suggest roles for kindlins in outside-in signaling. Previously, we identified a patient with a complete K3 deficiency suffering LAD-III, characterized by strong defect in platelet inside-out $\alpha_{IIb}\beta_3$ signaling.
Aims: Taking advantage of the K3 deficiency in platelets of the LAD-III patient, we studied its role in $\alpha_{IIb}\beta_3$ integrin outside-in signaling and in cytoskeleton changes during spreading.
Methods: Platelet adhesion and spreading, confocal and reflection interference contrast fluorescence microscopy, Cdc42 activation assay.
Results: We found that K3-deficient platelets normally elongate filipodia and perform early steps of spreading but cannot extend lamellipodia and form stress fibers. Platelet treatment with a combination of ADP and Mn^{2+} restores soluble fibrinogen binding and partial aggregation. However, impairment of spreading and clot retraction persists. Conversely to healthy platelets, K3-deficient ones are stuck at the level of actin nodule formation. These nodules are abnormal since they lack $\alpha_{IIb}\beta_3$ integrin, Cdc42 and Rac1 clusters and show impaired protein phosphorylation (Ser-Thr and Tyr). Interestingly, increased and prolonged Cdc42 GTP-binding is noticed in K3-deficient platelets and full lamellipodia extension is restored by CASIN, a selective Cdc42 inhibitor.
Conclusions: This study points out K3 as key negative regulator of Cdc42 activity and actin cytoskeleton organization during $\alpha_{IIb}\beta_3$ integrin outside-in signaling in human platelets.

PB 1302 | RGS-insensitive G Proteins as a Model to Study G Protein-dependent Signaling

S. Gupta, D. DeHelian, L. Brass, P. Ma

University of Pennsylvania, Department of Medicine, Philadelphia, United States

Background: We first reported that the duration of G protein signaling in platelets is limited by RGS proteins. A mutation (G184S) in G_{i2} renders the α subunit resistant to accelerated turn-off by all RGS proteins, and therefore confers a gain of function for platelet activation. Using the alternative gene knockout approach, knocking out either RGS10 or RGS18 in mice results in a gain of platelet function.
Aims: The gain of function in RGS-insensitive G_{i2}(G184S) appears to be confined to G_{i2} signaling in platelets. Here we examine for the first time RGS-insensitive G_q as an in vivo probe of G protein regulation.
Methods: Using CRISPR-Cas9 genome-editing, we have recently generated a transgenic mouse line in which a substitution (G188S) in G_q subunit renders it resistant to accelerated turn-off by all RGS proteins. Platelet function was examined by flow cytometry.
Results: G_q(+/G188S) mice are grossly normal in appearance and have a normal platelet count. Western blot analysis show that there is no difference in G_q expression levels among G_q(G188S/G188S), G_q(+/G188S) and WT control. Flow cytometry using Jon/A to detect $\alpha_{IIb}\beta_3$ activation show that the dose/response curve for the PAR4 agonist peptide, AYPGKF, was shifted to higher concentrations in the G_q(+/G188S) platelets. The platelet response to U46619 or ADP was also impaired in the G_q(+/G188S) platelets. In contrast, responses to collagen-related peptide, which is not a G protein coupled receptor agonist, were unaffected. Similarly, α-granule secretion in the G_q(+/G188S) platelets was attenuated in response to AYPGKF, but not collagen.
Conclusions: In contrast to enhanced G_{i2} signaling in G_{i2}(G184S) mutant platelets, we observed decreased platelet activation in G_q(+/G188S) mutant platelets, indicating that regulation of G_q signaling is more complex than that of G_i signaling. This new G_q(G188S) mutant mouse may provide novel insight into how G_q signaling is regulated differently from G_i signaling.

PB 1303 | Arp2/3 is Critical for Platelet Homeostasis but Dispensable for Hemostatic Plug Formation

D.S. Paul[1], C. Casari[1], C. Wu[2,3], R. Piatt[1], S. Pasala[4], R. Campbell[5], R.H. Lee[1], B.C. Cooley[6], K.R. Machlus[7], J.E. Italiano Jr.[7,8], A. Weyrich[9], J.E. Bear[2,3], W. Bergmeier[1,4]

[1]University of North Carolina at Chapel Hill, McAllister Heart Institute, Chapel Hill, United States, [2]University of North Carolina at Chapel Hill, Lineberger Comprehensive Cancer Center, Chapel Hill, United States, [3]University of North Carolina at Chapel Hill, Department of Cell Biology and Physiology, Chapel Hill, United States, [4]University of North Carolina at Chapel Hill, Department of Biochemistry and Biophysics, Chapel Hill, United States, [5]University of Utah, Program in Molecular Medicine, Salt Lake City, United States, [6]University of North Carolina at Chapel Hill, Rodent Advanced Surgical Core, Chapel Hill, United States, [7]Brigham and Women's Hospital, Harvard Medical School, Division of Hematology, Boston, United States, [8]Children's Hospital Boston, Program in Vascular Biology, Department of Surgery, Boston, United States, [9]University of Utah, Program in Molecular Medicine, Department of Internal Medicine, Salt Lake City, United States

Background: Actin reorganization regulates key processes in platelet activation including shape change, spreading, aggregation and granule secretion. The contribution of actin filament branching to platelet biology, beyond spreading, is poorly understood.
Aims: Here we examined the role of the Actin Related Protein 2/3 complex (Arp2/3), an essential component in actin branching, in platelet function and homeostasis.

Methods: Deletion of the Arp2/3 complex in mice results in early embryonic lethality; therefore we employed the Cre/Lox gene targeting strategy to generate mice with a megakaryocyte/platelet-specific deletion of the *Arpc2* gene, which encodes the p34 subunit of the Arp2/3 complex (*Arpc2*$^{fl/fl}$*PF4-Cre*). Loss of p34 subunit expression results in disruption of the entire Arp2/3 complex.

Results: Deletion of the Arp2/3 complex resulted marked thrombocytopenia (~60% reduction in the peripheral platelet count) and a significant decrease in platelet size, reminiscent of the micro-thrombocytopenia documented for Wiskott-Aldrich syndrome patients. Microthrombocytopenia in *Arpc2*$^{fl/fl}$*PF4-Cre* mice was a consequence of premature platelet release into the bone marrow compartment and impaired platelet survival in circulation. *Arpc2*$^{fl/fl}$*PF4-Cre* platelets exhibited alterations in their actin cytoskeleton and their peripheral microtubule coil, resulting in altered morphology of resting platelets. Thrombocytopenia was alleviated following clodronate liposome-induced macrophage depletion in *Arpc2*$^{fl/fl}$*PF4-Cre* mice. *Arpc2*$^{fl/fl}$*PF4-Cre* platelets failed to spread on a fibrinogen matrix and showed a mild defect in integrin activation, alpha-granule secretion and aggregation. However, no significant differences in hemostasis or thrombosis were observed between *Arpc2*$^{fl/fl}$*PF4-Cre* and control mice.

Conclusions: Our studies support a critical role for Arp2/3 in platelet homeostasis but, unexpectedly, not vascular hemostasis or thrombosis.

PB 1304 | Cold-induced Binding of von Willebrand Factor Facilitates Fast Clearance of Refrigerated Platelets

W. Chen[1], S.A. Druzak[1], K.M. Hoffmeister[2], J. Ware[3], R. Li[1]

[1]*Emory University, Aflac Cancer and Blood Disorders Center, Children's Healthcare of Atlanta, Department of Pediatrics, Atlanta, United States,* [2]*Blood Center of Wisconsin, Milwaukee, United States,* [3]*University of Arkansas for Medical Sciences, Department of Physiology & Biophysics, Little Rock, United States*

Background: Refrigerated platelets are rapidly cleared after transfusion, but the underlying mechanism is not entirely clear. Enzymatic removal of the N-terminal domain of GPIbα on refrigerated murine platelets abrogated fast removal of these platelets mediated by Ashwell-Morell receptors, but the N-terminal domain of murine GPIbα contains no N-glycosylation sequence (Asn-X-Ser/Thr). Recently we demonstrated that botrocetin-mediated binding of VWF to GPIbα under shear induces unfolding of the mechanosensory domain (MSD) in GPIbα, leading to platelet clearance. It was reported previously that VWF binding to platelets was increased after refrigeration.

Aims: To investigate the role of VWF in the fast clearance of refrigerated platelets.

Methods: Freshly obtained murine and human platelet-rich plasmas were stored in gas-permeable bags at 4°C for 24 hours. VWF binding, MSD unfolding, GPIb-IX signaling events, and post-transfusion recovery and survival of platelets were measured by flow cytometry as previously reported.

Results: After cold storage binding of VWF to both human and murine platelets was significantly increased. Uniform shear treatment of cold-stored murine and human platelets resulted in increased MSD unfolding, β-galactose exposure and phosphatidylserine exposure on the platelet. Furthermore, post-transfusion recovery and survival of cold-stored VWF$^{-/-}$ platelets was significantly increased than that of cold-stored WT platelets.

Conclusions: These results suggest that cold-induced VWF binding to GPIbα critically induces GPIb-IX signaling and fast clearance of cool-stored platelets. Inhibition of the VWF/GPIbα interaction during cold storage may potentially enable cold storage of platelets.

PB 1305 | RGS Proteins Shape the Hemostatic Response by Regulating the Platelet Signaling Networks

S. Gupta[1], S. Sampietro[1], D. Dehelian[1], V. Tutwiler[1,2], A. Tang[1], T. Stalker[1], L. Brass[1], P. Ma[1]

[1]*University of Pennsylvania, Department of Medicine, Philadelphia, United States,* [2]*School of Biomedical Engineering, Science, and Health Systems, Drexel University, Philadelphia, United States*

Background: Regulator of G protein Signaling (RGS) proteins limit the duration of G protein signaling by accelerating the hydrolysis of GTP on Gα. Platelets express RGS10 and RGS18. In resting platelets, RGS proteins are sequestered by scaffold protein, spinophilin. RGS18 deletion in platelets leads to gain of function.

Aims: To define the role of RGS10 in the hemostatic response to injury.

Methods: RGS10$^{-/-}$ mice were generated and evaluated for platelet function *in vitro* and *in vivo*. Free RGS10 levels in platelets were measured using novel assay.

Results: An increase in free RGS10 levels was observed in platelets upon activation by thrombin or rendered resistant to activation by PGI_2. Integrin $a_{IIb}b_3$ activation and α-granule secretion in the absence of secondary wave mediators revealed a marked gain of function by RGS10$^{-/-}$ platelets in response to G protein coupled receptors (GPCR) signaling agonists: PAR4 activating peptide, ADP and TxA_2 (U46619). Notably, while the dose/response curve for the PAR4 agonist was shifted to lower concentrations in the RGS10$^{-/-}$ platelets with no change in the maximum response, the dose/response curve for U46619 and ADP showed a substantial increase in maximal response. Intracellular calcium mobilization was also enhanced in response to GPCR agonists. Hemostatic thrombi formed in the RGS10$^{-/-}$ mice revealed a smaller core of fully activated platelets and a larger shell of partially activated loosely packed platelets. The decreased platelet packing density was confirmed in intra thrombus transport studies using fluorescent albumin. In line with augmented GPCR signaling, phosphorylation of serine/threonine kinase Akt and myosin light chain kinase was also enhanced in RGS10$^{-/-}$ platelets.

Conclusions: RGS10 is key regulator by limiting platelet activation downstream of GPCR signaling. RGS10 affects response sensitivity

and amplitude and is agonist selective. RGS10 regulates both Gi- and Gq-dependent signaling in platelets and, appears to have a role that is independent of RGS18.

PB 1306 | A Spatial Systems Approach to Identifying Roles for the Rho-specific Guanine Nucleotide Dissociation Inhibitor (RhoGDI) Ly-GDI in Platelet Function

A.T.P. Ngo[1], M.L.D. Thierheimer[1], Ö. Babur[2], A.D. Rocheleau[1], T. Huang[1], R.A. Rigg[1], A. Mitrugno[1], J. Burchard[2], X. Nan[1], E. Demir[2], O.J.T. McCarty[1], J.E. Aslan[3]

[1]Oregon Health & Science University, Biomedical Engineering, Portland, United States, [2]Oregon Health & Science University, Computational Biology, Portland, United States, [3]Oregon Health & Science University, Knight Cardiovascular Institute, Portland, United States

Background: Platelets undergo specific morphological alterations critical to hemostasis via actin cytoskeletal reorganizations driven by the Rho GTPases Rac1, Cdc42 and RhoA. While these Rho GTPases are known to be critically sequestered and regulated by Rho-specific guanine nucleotide dissociation inhibitor proteins (RhoGDIs) in other cell types, roles for RhoGDIs in platelet activation and hemostatic function remain uncharacterized.

Aims: Here we aim to determine how and whether RhoGDI proteins regulate Rho GTPase-driven platelet functions downstream of platelet integrin and glycoprotein receptors.

Methods: Through an approach combining pharmacology, cell biology and systems biology tools, we investigate roles for RhoGDI proteins in platelet function.

Results: We find that platelets express two RhoGDI family members, RhoGDI and Ly-GDI. Functional interference and platelet spreading experiments suggest a specific role for Ly-GDI in platelet function. Intracellular staining assays demonstrate that Ly-GDI displays an asymmetric, polarized pattern that largely colocalizes with Rac1 and Cdc42 as well as microtubules and protein kinase C (PKC) in platelets adherent to fibrinogen. Signaling studies rooted in quantitative phosphoproteomics and pathways analyses also support a regulatory role for Ly-GDI in platelets, as Ly-GDI is phosphorylated at PKC substrate motifs in a PKC-dependent manner in response to the platelet collagen receptor glycoprotein (GP)VI-specific agonist collagen-related peptide. Notably, inhibition of PKC diffuses the polarized organization of Ly-GDI in spread platelets relative to its colocalization with Rac1 and Cdc42.

Conclusions: Together, our results support roles for Ly-GDI as a localized regulator of Rho GTPases in platelets and link PKC and Rho GTPase signaling systems in the orchestration of the platelet activation program.

PB 1307 | RhoGAP6 and RhoGEF2 Are Novel Regulators of RhoA in Platelets

S. Comer[1], Z. Nagy[2], S. Gambaryan[3], U. Walter[4], R. Zahedi[5], K. Jurk[4], A. Smolenski[1]

[1]UCD Conway Institute, UCD School of Medicine, University College Dublin, Dublin, Ireland, [2]Centre for Cardiovascular Sciences, University of Birmingham, Birmingham, United Kingdom, [3]Sechenov Institute of Evolutionary Physiology and Biochemistry, Russian Academy of Sciences, St. Petersburg, Russian Federation, [4]Center for Thrombosis & Hemostasis, Universitätsklinikum der Johannes Gutenberg-Universität Mainz, Mainz, Germany, [5]Leibniz-Institut für Analytische Wisschenschaften, ISAS, Dortmund, Germany

Background: RhoA, a Rho family small GTPase, is the bridge between extracellular signals and cytoskeletal restructuring of platelets during activation. Vascular endothelium releases prostacyclin (PGI_2) and nitric oxide (NO) leading to platelet inhibition. PGI_2 and NO upregulate cAMP and cGMP which activate cAMP/cGMP-dependent protein kinases (PKA and PKG). PKA and PKG then phosphorylate unknown substrates causing RhoA inhibition and restricting platelet function.

Aims: To identify Rho GTPase activating proteins (RhoGAPs - terminate RhoA signalling) and Rho guanine nucleotide exchange factors (RhoGEFs - activate RhoA) as substrates of PKA and PKG that convert PGI_2/NO signals into RhoA inhibition.

Methods: Platelet phosphoproteome screening (Beck et al Blood 2014 and 2017) presented RhoGAP6 and RhoGEF2 as candidate substrates for PKA and PKG. Protein analysis includes quantitative mass spectrometry, mutagenesis studies, pulldown assays, PhosTag and SDS-PAGE/Western blotting in human platelets and transfected cells.

Results: We show that RhoGAP6 and RhoGEF2 proteins are expressed in human platelets and regulate RhoA activity. Both proteins are phosphorylated by PKA and PKG on serine/threonine residues. We give evidence of an interaction of RhoGAP6 with the phosphoserine/threonine binding protein 14-3-3. RhoGEF2 phosphorylation on serine 886 stimulates binding of RhoGEF2 to 14-3-3. Further interaction partners of RhoGAP6 and RhoGEF2 are being investigated while RhoGAP6 and RhoGEF2 protein complex regulation by PKA and PKG is being characterized.

Conclusions: This data shows two new RhoA regulatory proteins in platelets, RhoGAP6 and RhoGEF2 that are novel targets for PKA and PKG phosphorylation. Investigation of the implications of phosphorylation of these two proteins will provide a better understanding of endogenous platelet regulation by PGI_2 and NO.

PB 1308 | A Role of TNF Receptor-associated Factor 3 in Platelets A and Thrombosis

R. Zhang[1], G. Zhang[1], B. Xiang[1], P. Xie[2], Z. Li[1]

[1]University of Kentucky, Lexington, United States, [2]Rutgers University, Rutgers, United States

Background: Platelets express CD40 and its ligand (CD40L) and are a major source of soluble CD40L. CD40L has been shown to potentiate platelet activation and thrombus formation, involving both

CD40-dependent and -independent mechanism. CD40L-mediated platelet activation requires the family of member of TNF receptor-associated factor 2 (TRAF2). However, the mechanism of platelet activation by CD40L has not been fully understood.

Aims: Identifying the expression and function of a novel member of the TNF receptor-associated factor family, the TRAF3, in platelets.

Methods: Western blot was used to verify the expression of TRAF3 in platelets. The function of TRAF3 in platelets was evaluated by various in vitro platelet function assays, tail-bleeding time assay, and FeCl3-induced carotid artery thrombosis assay.

Results: Here we show that platelet also express TRAF3, which plays a negative role in regulating platelet activation. Thrombin- or collagen-induced platelet aggregation and secretion are increased in TRAF3 knockout mice. The expression of integrin aIIbb3, GPVI, and PAR4 was similar between TRAF3 knockout platelets and wild type controls, suggesting that increased platelet activation in the TRAF3 knockout mice is not due to increased expression of platelet receptors. TRAF2 expression was not affect by deletion of TRAF3 either. Using the $FeCl_3$-induced arterial thrombosis model, we found that time to formation of thrombi in was significantly shortened in TRAF3 knockout mice.

Conclusions: TRAF3 plays a negative role in platelet activation and in thrombus formation in vivo.

PB 1309 | Annexin A7 (ANX7) Regulates Collagen-dependent Platelet Ca2+ Increase and Activation

S. Geue[1], B. Walker-Allgaier[1], D. Eißler[1], P. Münzer[1], F. Lang[2], M. Gawaz[1], O. Borst[1]

[1]University Hospital of Tübingen, Cardiology and Cardiovascular Medicine, Tübingen, Germany, [2]University of Tübingen, Department of Physiology, Tübingen, Germany

Background: Activation of platelets by subendothelial collagen results in an increase of cytosolic Ca^{2+} concentration ($[Ca^{2+}]_i$) and is followed by platelet secretion, aggregation and thrombus formation with consecutive vascular occlusion.

Aims: This study aimed to determine the role of ANX7 in collagen-dependent platelet Ca^{2+} signalling and function in platelets from ANX7 knockout (*anx7*$^{-/-}$) mice.

Methods: Fura-2-AM spectrofluorometric Ca^{2+} measurements, *in vitro* flow chamber approaches, light transmission aggregometry and PGE_2 ELISA were performed using *anx7*$^{-/-}$ and *anx7*$^{+/+}$ platelets.

Results: Stimulation of the collagen receptor glycoprotein VI (GPVI) by collagen or collagen-related peptide (CRP) leads to platelet activation due to increased intracellular calcium concentration ($[Ca^{2+}]_i$). Fura-2-AM spectrofluoriometric Ca^{2+} measurements revealed that ANX7 deficiency strongly blunted Ca^{2+} mobilisation from intracellular stores as well as extracellular Ca^{2+} influx following activation with CRP or collagen. As platelet activation is linked with integrin $\alpha_{IIb}\beta_3$ activation and subsequent aggregation, light transmission aggregometry was performed uncovering a significant impaired platelet aggregation in *anx7*$^{-/-}$ platelets compared to *anx7*$^{+/+}$ platelets after stimulation with CRP or collagen. Furthermore, platelet dense granule secretion (reflected by ATP release) in response to CRP or collagen as well as *in vitro* thrombus formation under high arterial shear rates (1700 s^{-1}) on collagen-coated surfaces were significantly diminished in *anx7*$^{-/-}$ platelets as compared to *anx7*$^{+/+}$ platelets. In addition, *anx7*$^{-/-}$ platelets exhibit increased PGE_2 levels under resting conditions as well as upon activation with CRP and collagen.

Conclusions: In conclusion, ANX7 plays an important role upon GPVI-triggered platelet activation and thrombus formation due to impaired activation-dependent increase of $[Ca^{2+}]_i$. Impaired Ca^{2+}-dependent platelet activation results, at least in part, from increased PGE_2 levels in *anx7*$^{-/-}$ platelets.

PB 1310 | Four-receptor Platelet Signaling Computational Model Reveals a New Role of Protein Kinase A in the Control of Platelet Response

A. Sveshnikova[1,2], F. Balabin[1], E. Shylov[2], S. Shakhidzhanov[1,3], J. Dunster[4], J. Gibbins[4], M. Panteleev[1,2,3]

[1]Faculty of Physics, Lomonosov Moscow State University, Biophysics, Moscow, Russian Federation, [2]National Scientific and Practical Centre of Pediatric Hematology, Oncology and Immunology named after Dmitry Rogachev, Moscow, Russian Federation, [3]Center for Theoretical Problems of Physicochemical Pharmacology, Russian Academy of Sciences, Moscow, Russian Federation, [4]University of Reading, School of Biological Sciences, Reading, United Kingdom

Background: Under physiological conditions, platelets are stimulated by several agonists simultaneously. Moreover, receptor network can be important even when not all of them are occupied by ligands.

Aims: We developed a computational systems biology model of platelet signaling encompassing receptors PAR1, PAR4, $P2Y_{12}$, $P2Y_1$ and pathways to integrin activation and procoagulant activity in order to investigate the interplay of G_q- and G_i-dependent signaling.

Methods: Kinetics of fibrinogen and annexin V binding to Fura Red-loaded platelets were investigated by continuous flow cytometry, confocal and total internal reflection fluorescence microscopy. The model comprised set of ordinary differential equations integrated in COPASI software (www.copasi.org).

Results: The model included about one hundred reactions governing signal transduction after ligation of G-protein coupled receptors and leading to cytosolic calcium increase and protein kinase A (PKA) inactivation. PKA and calcium then influenced CalDAGGEFI activation and subsequent Rap1b-GTP formation and integrin activation.

The validation of the model was conducted using experiments on cytosolic calcium, fibrinogen and annexin V binding dynamics after platelet stimulation with a combination of ADP and thrombin or PAR-activating peptides. The model predicted that ADP would increase the frequency of calcium oscillations, the levels of fibrinogen binding and procoagulant activity, and $P2Y_{12}$ antagonists would decrease them even when platelets are stimulated via PAR1 only. The predictions were confirmed experimentally.

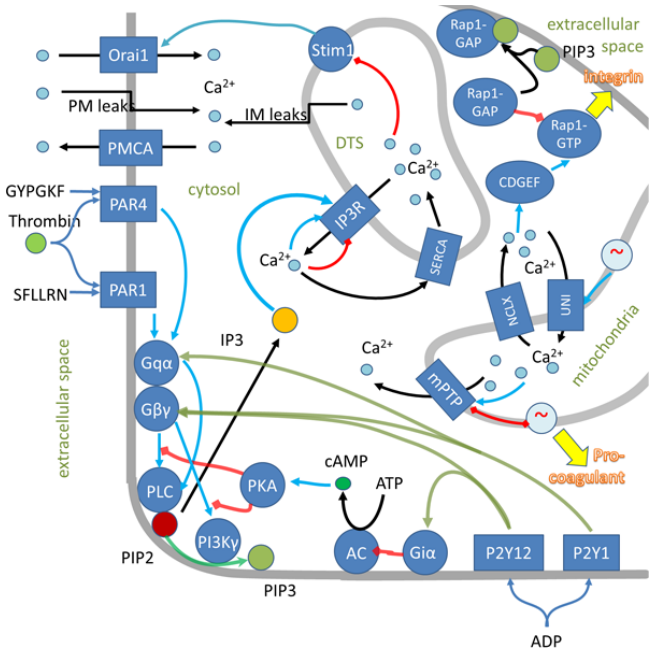

FIGURE 1 Scheme of the 4-receptor platelet signaling model]

Conclusions: Here we presented the first comprehensive model describing platelet intracellular signaling after simultaneous activation by ADP and thrombin. PKA is a crucial controlling element in platelet response even when stimulating signal comes though PAR receptors and does not contain ADP.

PB 1311 | Disabled-2 Controls Platelet Activation Through a Regulatory Circuit Involving Multiple Interacting Proteins

H.-J. Tsai[1], K.-Y. Chien[2,3], H.-R. Liao[4], Y.-H. Chiang[1], J.-C. Cheng[5], C.-P. Tseng[1,6]

[1]Chang Gung University, Department of Medical Biotechnology and Laboratory Science, Taoyuan, Taiwan, Republic of China, [2]Chang Gung University, Department of Biochemistry and Molecular Biology, Taoyuan, Taiwan, Republic of China, [3]Chang Gung University, Clinical Proteomics Core Laboratory, Taoyuan, Taiwan, Republic of China, [4]Chang Gung University, Graduate Institute of Natural Products, Taoyuan, Taiwan, Republic of China, [5]China Medical University, Department of Medical Laboratory Science and Biotechnology, Taichung, Taiwan, Republic of China, [6]Chang Gung Memorial Hospital, Department of Laboratory Medicine, Taoyuan, Taiwan, Republic of China

Background: Platelet Disabled-2 (Dab2) is a key haemostatic regulator involving in thrombin signaling, integrin activation, and fibrinogen uptake. The underlying mechanism of Dab2 in platelet function has not yet been completely elucidated.

Aims: Dab2-interacting proteins (Dab2-IPs) in the resting and thrombin-stimulated human platelets were unveiled with an aim to elucidate Dab2 function in human platelet activation.

Methods: Dab2 was immunoprecipitated from the resting and thrombin-stimulated platelet lysates followed by differential labeling of $^{12}C_2{}^{1}H_6$ and $^{13}C_2{}^{1}H_2{}^{2}D_4$, respectively. A liquid chromatography system coupled with an Orbitrap Elite hybrid mass spectrometry was used for identification of Dab2-IPs. The biological processes regulated by Dab2-IPs were defined by GO enrichment analysis.

Results: There were a total of 10 Dab2-IPs exclusively present in the resting but not in thrombin-stimulated platelets. Additional 32 Dab2-IPs were present in both resting and thrombin-stimulated platelets. Among them, Dab2 had an increased interaction with one Dab2-IPs, a decreased interaction with 16 Dab2-IPs, and no alteration for the interaction with 15 Dab2-IPs when platelets were stimulated with thrombin. GO enrichment analysis of the 32 Dab2-IPs revealed the top 3 GO terms were vesicle mediated transport (n = 18), endocytosis (n = 13) and complement activation (n = 8). Notably, thrombin stimulation resulted in a decrease in Dab2-clathrin interaction which was known to regulate fibrinogen uptake. These findings were confirmed by immunoprecipitation of Dab2 followed by Western blotting of clathrin and consistent with the notion that Dab2 acts as a clathrin sponge and sequesters clathrin from its interaction with membrane receptor.

Conclusions: Dab2 controls platelet activation through a regulatory circuit involving multiple Dab2-IPs. Thrombin-stimulated dissociation of Dab2-clathrin protein complex provides a new function of Dab2 in the regulation of human platelet activation.

PB 1312 | Sustained Inhibition of Acetyl-CoA Carboxylase Decreases Platelet Dense Granules Secretion and Aggregation

S. Lepropre[1], M. Octave[1], S. Kautbally[1], G. Muccioli[1], V.M. Darley-Usmar[2], L. Bertrand[1], C. Beauloye[1], S. Horman[1]

[1]Université Catholique de Louvain, Brussels, Belgium, [2]University of Alabama at Birmingham, Birmingham, United States

Background: Acetyl-CoA carboxylase (ACC) regulates fatty acids synthesis and oxidation. Our results show that ACC is phosphorylated in platelets of patients with coronary artery disease. ACC phosphorylation results in its inhibition. Given the primary roles of lipids in platelets structure, metabolism and signaling, we hypothesize that a sustained inhibition of ACC could affect platelets bioenergetics and functions.

Aims: To investigate the effect of a sustained ACC inhibition on platelets functions, signaling and metabolism.

Methods: Platelets were treated with TOFA, an ACC inhibitor, for 2 hours before thrombin stimulation. We measured lipogenesis via ^{14}C-acetate incorporation into fatty acids. Platelet functions were assessed by aggregometry and flow cytometry. Platelet signaling was investigated via western blot analysis, and metabolism, via the measurement of oxygen consumption rate.

Results: We show that TOFA significantly decreased lipogenesis. This reduction was associated with an inhibition of thrombin-induced dense granules secretion and platelet aggregation whereas αIIbβ3 activation and α-granules secretion were not affected, suggesting that the default in aggregation resulted from a lower autocrine effect of ADP. Mechanisms involved in the modulation of dense granules secretion implied PKC, in particular PKC-δ, and their

substrates, cytohesin-2 and protein kinase D (PKD). Platelet metabolism was also affected by a sustained ACC inhibition, as shown by the TOFA-induced decrease in reserve capacity and ATP-linked respiration.

Conclusions: A sustained inhibition of platelet ACC decreases lipogenesis and affects dense granule secretion and aggregation through (i) a PKC/PKC-δ dependent mechanism, and (ii) an alteration of platelets bioenergetics. We believe that it could affect thrombus stability in atherosclerotic patients.

PB 1313 | The G12/13 Signaling Pathway Contributes to the Racial Difference in PAR4 Signaling

B. Tourdot[1], H. Stoveken[1], D. Trumbo[1], P. Bray[2], G. Tall[1], M. Holinstat[1]

[1]University of Michigan, Ann Arbor, United States, [2]University of Utah, Salt Lake City, United States

Background: Atherothrombotic disorders disproportionally burden blacks relative to whites. One of the independent risk factors for atherothrombosis is enhanced platelet reactivity. Compared to platelets from white donors, platelets from black donors were hyper-responsive to activation of the thrombin receptor Protease-Activated Receptor-4 (PAR4), which was at least partially due to an increase in Gαq signaling. It remains unknown if the difference in PAR4 signaling by race was due solely to differences in Gαq signaling or whether Gα12/13 also contributed to the racial difference in PAR4-mediated platelet activation.

Aims: Determine if the activation of both signaling pathways known to be regulated by PAR4, Gαq and Gα12/13, are enhanced in platelets from blacks compared to whites.

Methods: To determine if there was a racial difference in the Gα12/13 pathway in PAR4-stimulated platelets, RhoA activation, actin polymerization, shape change, and spreading were measured in washed human platelets from white and black donors. Moreover, PAR4-mediated Gq and G12/13 protein activation was directly measured in prepared membranes expressing recombinant human PAR4 with mutations known to be differentially expressed by race.

Results: PAR4 receptor with the Thr120 variant, a variant more commonly expressed in black donors, enhanced the activation kinetics of Gq and G12/13 compared to the Ala120 (white) variant. Similarly, RhoA activation, shape change, and spreading were enhanced in PAR4 stimulated platelets from blacks compared to whites.

Conclusions: The increased signaling through PAR4 observed by race, which is controlled in part by genotype differences, was not due to biased signaling toward Gaq. Rather an overall increased activity of the receptor leads to increased kinetic activation of both the Gαq and Gα12/13 signaling pathways in platelets.

PB 1314 | Changes in Gene Expression Levels in Immune Thrombocytopenia Patients Treated with Eltrombopag

J.M. Bastida[1], J.M. Hernández-Sánchez[2], A.E. Rodríguez[2], D. Alonso-López[2], E. Lumbreras[2], A. Díaz[2], R. Bueno[2], V. Gutiérrez[2], J.M. Hernández-Rivas[1,2], J.R. González-Porras[1]

[1]Hospital Universitario Salamanca - IBSAL, Hematologia, Salamanca, Spain, [2]IBSAL, IBMCC, CIC, Universidad de Salamanca-CSIC, Salamanca, Spain

Background: Eltrombopag (ETP) is small non-peptide molecule, which interacts with the transmembrane domain of thrombopoietin receptor, initiating a JAK/STAT signaling pathway inducing the proliferation and differentiation of the megakaryocytes to increase platelets production.

Aims: To assess the gene expression profile (GEP) and the underlying signaling pathways modified before and during the ETP treatment in chronic immune thrombocytopenia (ITPc) patients.

Methods: ITPc patients (n=14) treated with ETP were evaluated (Table 1). Complete response (CR) was defined as a platelet count of ≥100x10^3/mm^3. RNA was isolated from mononucleated cells pre/post ETP treatment. Thus, 28-paired samples were hybridized in Affymetrix´s. The robust microarray analysis algorithm was used for normalization and signal expression was calculated by significance analysis of microarray to provide a robust statistical inference. The pathways and upstream regulators related with the most differentially expressed genes were analyzed by *in silico* analysis tools: IPathwayGuide and DAVID.

Results: Baseline patients' characteristics (Table 1). Median platelet counts and white blood cells increased after treated by ETP. All but two patients achieved CR (Table 1).

TABLE 1 Baseline characteristics of ITPc treatments included in the study

Age: median (range)	77,5 (35-87) years
Treatments before start Eltrombopag:	One: 5 (35,7%) / ≥2: 9 (64,3%) / Splenectomy: 3 (21,4%)
Blood cells count (BCC) basal: median (range). Platelets (P) and WBC in (x10^3/mm^3); Hb in g/dL	P: 14,45 (1,9-73,8) / WBC: 6,85 (2,2-19,3) / Hb: 13,85 (8,7-16,2)
BBC at day 14: median (range). P and WBC in (x10^3/mm^3); Hb in g/dL	P: 119,5 (4,7-230) / WBC: 7,58 (1,9-14,4) / Hb: 12,85 (8,6-16,3)
BBC at day 28: median (range). P and WBC in (x10^3/mm^3); Hb in g/dL	P: 132 (1,9-173,8) / WBC: 9,1 (2,7-14,1) / Hb: 13,35 (8,1-15,4)
Treatment response (n,%):	Complete: 12 (85,7%) / Failure: 2 (14,3%)
Doses response (n,%)	50 mg: 9 (64,3%) / 75mg: 3 (21,4%) / Failure: 2 (14,3%)
Day of response (n,%):	+14 day: 10 (71,4%) / +28 day: 4 (28,6%)

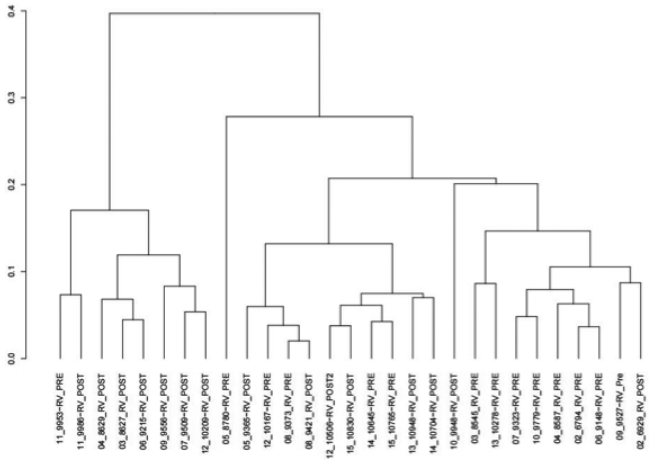

FIGURE 1 Samples distribution provide robust statistical inference of the most significant genes:

In silico analysis revealed that ETP treatment modified the expression of 147 genes, all of them were overexpressed after treatment. These genes cluster (2 groups), samples pre/post ETP treatment are shown in Figure 1. Mainly, genes (38) were involved in the maintenance of hemostasis and almost all of them were related to platelet activation (*PTGS1*, *GP1BA* or *GP6*). Interestingly, the paired GEP pointed out *E2F1 and GFI1B* as possible leaders of the increase of the megakaryopoiesis. The main signaling pathways overexpressed by ETP are downstream routes of PI3K/Akt (*GFI1B*) and platelet activation.

Conclusions: In ITPc patients, ETP not only induced overexpression of many genes related with platelet activation and megakaryopoiesis but also signaling pathways such as JAK/STAT and PI3K/Akt.

PB 1315 | Calcium Homeostasis in Platelets in Pregnancy Women with Preeclampsia

V.D. Bichan[1], A.V. Bakunovich[2], A.A. Krivolap[1], V.N. Sidorenko[3], L.M. Lobanok[3], K.Y. Bulanova[2]

[1]Belarusian State University, Minsk, Belarus, [2]International Sakharov Environmental Institute of Belarusian State University, Minsk, Belarus, [3]Belarusian State Medical University, Minsk, Belarus

Background: Platelet function is abnormal in preeclampsia. Changes of platelet functional activity associated with adhesion and aggregation, leading to increased bleeding and thrombus formation or enhance the development of pathological changes in blood flow. Ca^{2+} is required in platelets for many functions such as shape change, secretion and aggregation.

Aims: The aim of the study was to investigate changes in calcium homeostasis in platelets of pregnant women with preeclampsia.

Methods: Venous blood samples of obtained from 21 pregnant women with preeclampsia and 23 of healthy pregnant women, for platelets study. Informed consent was obtained from every study subject. No participants had taken any antiplatelet drugs in the previous 2 week. Intracellular Ca^{2+} concentration in the platelets was determined using the fura 2-AM.

Results: The resting platelet Ca^{2+} in a group of women with preeclampsia was higher (82,1±4,2) nM than in the control group (60,6±3,5) nM. Different Ca^{2+} transport mechanisms can to be altered in platelets from patients with preeclampsia, including the sarcoendoplasmic and plasma membrane Ca^{2+}-ATPases, plasma membrane Ca^{2+} channels, or the Na^{+}/Ca^{2+} exchanger. This study confirmed that in pregnant women with preeclampsia, platelets have increased basal Ca^{2+} and larger agonist-stimulated Ca^{2+} response compared with those in normal subjects. Ca^{2+} leak from the dense tubular system or the acidic stores, induced by a low concentration of thapsigargin or 2,5-di-(t-butyl)-1,4-hydroquinone (TBHQ), respectively, was clearly greater in pregnant women with preeclampsia than in control. Furthermore, it was found that in preeclampsia, the direction and activity of the platelet Na^{+}/Ca^{2+} exchanger was altered.

Conclusions: Platelets from patients with preeclampsia show abnormalities in intracellular Ca^{2+} homeostasis that are involved in platelet hyperaggregability and the development of thrombotic complications.

PB 1316 | PDK1 Regulates Platelet Activation through Phosphorylating of S6K on Thr229

W. Gao[1], K. Wang[2], L. Zhang[2], J. Liu[2], X. Luo[1], X. Chen[2]

[1]Huashan Hospital of Fudan University, Shanghai, China, [2]Shanghai Jiao Tong University School of Medicine, Shanghai, China

Background: Phosphoinositide-dependent kinase 1 (PDK1) regulates platelet activation through Akt-Thr308/Gsk3β-Ser9 signaling pathway. It is still unknown whether PDK1 could activate other substrates during the process of platelet activation.

Aims: The Aims of this study were to find out whether PDK1 regulated platelet activation through other substrates, to identify the role of S6K Thr229 in platelet activation.

Methods: Platelet aggregation and secretion test; platelet spreading; clot retraction; immublotting; Statistical analysis.

Results: Here, we reported that PDK1 played inhibitory roles in collagen and ADP induced platelet aggregation and secretion while Akt/Gsk3β signaling was blocked by the pharmacologic Gsk3β inhibitors. Moreover, PDK1 regulated collagen induced platelet aggregation partially through suppressing the secretion of ADP from dense granules. Further results demonstrated that the p70 ribosomal S6 kinases (S6K) was phosphorylated by PDK1 on Thr229 in the resting platelets and dephosphorylated in response to agonists stimulation. S6K inhibitor promoted platelet aggregation and secretion induced by collagen. S6K Thr229 phosphorylation might function as a regulator keeping platelets from activation. Thus, the diminished platelet aggregation in response to collagen stimulation caused by PDK1 was partially due to the phosphorylation of S6K on Thr229. Compared to thrombin, collagen induced the decrease of S6K Thr229 phosphorylation was restored by the Gsk3β inhibitor, which explained the different roles of Gsk3β in thrombin and collagen induced platelet aggregation.

Conclusions: Together, these results indicate that PDK1 negatively regulates collagen induced platelet activation through affecting phosphorylation of S6K on Thr229.

PB 1317 | Reverse Phosphorylation of the Protein Phosphatase 2A Inhibitor α-endosulfine (ENSA) at Two Distinct Sites (S67, S109) in Activated and Inhibited Human Platelets

E. Walter[1], O. Pagel[2], S. Makhoul[1], R.P. Zahedi[2], A. Smolenski[3], S. Gambaryan[1,4], U. Walter[1], K. Jurk[1]

[1]*University Medical Center of the Johannes Gutenberg University Mainz, Center for Thrombosis and Hemostasis (CTH), Mainz, Germany,* [2]*Leibniz-Institut für Analytische Wisschenschaften - ISAS - e.V., Dortmund, Germany,* [3]*UCD Conway Institute, UCD School of Medicine, University College Dublin, Dublin, Ireland,* [4]*Sechenov Institute of Evolutionary Physiology and Biochemistry, Russian Academy of Sciences, St. Petersburg, Russian Federation*

Background: α-endosulfine (ENSA; ARPP19-e) belongs to the cAMP-regulated phosphoprotein (ARPP) family. In *Xenopus*, PKA evokes ENSA S109 phosphorylation which keeps the oocyte in prophase whereas S67 phosphorylation is necessary for M-phase entry (Vigneron et al. Int J Dev Biol. 2016). In *Drosophila* and *Xenopus*, Greatwall kinase (MASTL in mammals) phosphorylates ENSA at S67 and converts it to a potent protein phosphatase 2A (PP2A) inhibitor resembling okadaic acid. Little is known about ENSA in platelets.

Aims: To elucidate the regulation and function of ENSA S67/S109 phosphorylation in human platelets.

Methods: Platelet proteomic studies were carried out as published (Burkhart et al. Blood. 2012; Beck et al. Blood. 2017). ENSA cloned from human platelets was expressed in HEK293 cells and *E.coli* BL21. ENSA phosphorylation was studied with intact human platelets, platelet extracts and recombinant proteins and mutants.

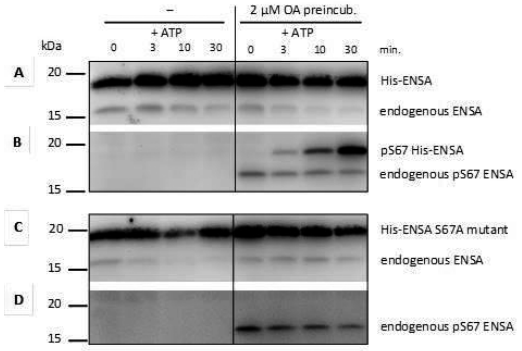

Figure 1: Demonstration of specific ENSA S67 protein-kinase activity in soluble extracts of human platelets. Washed human platelets were pre-treated without (-) or with 2 µM okadaic acid (OA) for 15 minutes at 30°C. Then, platelets were lysed by an EDTA/EGTA containing NP40 buffer at 0°C and recombinant His-tagged ENSA protein (wildtype and the S67A mutant as control) was added to the soluble platelet extracts. The phosphorylation reaction of endogenous protein kinase(s) was started by the addition of $MgCl_2$/ATP (0 min) and incubated at 30°C. Aliquots were removed from the reaction mixture before ATP addition (0 min) and after 3, 10 and 30 minutes of incubation. Western blots were probed for the presence of endogenous (~ 17 kDa) and recombinant His-tagged (~ 19 kDa) ENSA with a general antibody against human ENSA (A and C; cell signalling) and for the presence of phosphorylated endogenous and His-tagged pS67-ENSA with a phosphospecific antibody (B and D; cell signalling).

FIGURE 1 Demonstration of specific ENSA S67 protein-kinase activity in soluble extracts of human platelets

Results: ENSA and PP2A, but not MASTL, were detected in human platelets at significant protein levels. Quantitative phosphoproteomics showed strong ENSA S109 phosphorylation in response to cAMP- (Iloprost) and cGMP-elevating (NO-donors, Riociguat) platelet inhibitors whereas ADP and selective GPIb-stimulation decreased S109 phosphorylation. ENSA S67 phosphorylation was elevated upon phosphatase PP1/PP2A inhibition while decreased by cyclic nucleotide-elevating platelet inhibitors. Using recombinant ENSA wild type and mutant proteins a strong kinase activity towards S67 was observed in human platelet extracts (see Fig). Okadaic acid, a powerful pharmacological PP2A inhibitor, strongly inhibited various agonist responses in human platelets.

Conclusions: Our data demonstrate that in human platelets ENSA S67 is phosphorylated by a kinase other than MASTL. With its regulated phosphorylation sites S67 (essential for PP2A inhibition) and S109 (both PKA and PKG) ENSA represents an important signaling node in human platelets.

PB 1318 | Integration of Platelet Agonist Signaling during the Hemostatic Response in vivo

J. Shen[1], S. Sampietro[2], J. Wu[2], J. Tang[3], C. Matzko[2], C. Tang[1], Y. Yu[3], L.F. Brass[2], L. Zhu[4], T.J. Stalker[2]

[1]*Cyrus Tang Hematology Center, Soochow University, Suzhou, China,* [2]*University of Pennsylvania, Perelman School of Medicine, Philadelphia, United States,* [3]*Tianjin Medical University, Tianjin, China,* [4]*Soochow University, Suzhou, China*

Background: The local microenvironment within an evolving hemostatic plug shapes the distribution of soluble platelet agonists, resulting in a gradient of platelet activation emanating from the site of injury. While thrombin and ADP mediated platelet activation are clearly critical for establishment of this gradient, it remains unclear to what extent there is overlap of these and other platelet signaling pathways in time and space.

Aims: We sought to determine whether single agonists dominate the platelet activation state within specific regions of a hemostatic plug, or whether multiple agonist pathways are integrated to produce the platelet activation gradient observed. We also examined the relationships among different agonists in the face of anti-platelet or anti-coagulant therapy.

Methods: A combination of genetic and pharmacologic approaches was used in the mouse cremaster laser injury model to examine how thrombin, thromboxane A_2 (TxA_2), $P2Y_{12}$ and epinephrine signaling are coordinated in time and space to regulate the development of platelet activation gradients in vivo.

Results: We found that 1) inhibition of either TxA_2 or $P2Y_{12}$ signaling specifically attenuated accumulation of minimally activated platelets in the outer shell region of hemostatic plugs; 2) dual anti-platelet therapy was similar to inhibition of either TxA_2 or $P2Y_{12}$ signaling alone; 3) epinephrine signaling was completely dispensable for hemostatic plug formation; and 4) thrombin mediated, robust platelet activation does not require positive feedback via $P2Y_{12}$.

Conclusions: In conclusion, accumulation of minimally activated platelets requires integration of both TxA_2 and $P2Y_{12}$ signaling pathways, while maximal platelet activation requires thrombin mediated signaling. These data shed new light on the way multiple platelet signaling pathways are integrated during the hemostatic response, and predict the outcome of therapeutically targeting specific platelet signaling pathways alone and in combination on hemostatic plug organization.

PB 1319 | The Identification and Characterization of a Novel, Selective Platelet-surface ERp57 Inhibitor that Modulates Platelet Function Independently of Outside-in Signaling through Integrin αIIbβ3

L.-M. Holbrook[1], E. Brunt[1], A. Stainer[1], A. Bye[1], A. Feldenzer[2], C. Galinski[2], D. Kennedy[2], J. Gibbins[1]

[1]*University of Reading, ICMR, School of Biological Sciences, Reading, United Kingdom,* [2]*Western New England University, College of Pharmacy, Boston, United States*

Background: Inhibition of platelet-surface ERp57 using function-blocking antibodies results in the inhibition of platelet function and *in vivo*, ERp57 controls thrombus growth. Despite ERp57 being an important antithrombotic target, to date, a selective ERp57 small molecule inhibitor is not available.

Aims: To use newly identified selective inhibitors of ERp57 to explore the role of ERp57 in platelet signaling through the integrin αIIbβ3.

Methods: 3641 compounds were screened for inhibition of ERp57 by insulin turbidity assay, the most potent that was selective for ERp57, CGP13501 (CGP) was selected for further investigation. Human platelets were incubated with CGP (7.5-300μM) or vehicle for 5 minutes prior to stimulation with CRP-XL (1μg/mL), U46619 (1μM) or thrombin (0.1U/mL). Platelet aggregation and granule secretion was measured using lumi-aggregometry and by flow cytometry. Calcium mobilisation from intracellular stores was measured by fluorescence-based assay, platelet spreading and thrombus formation were measured using confocal microscopy.

Results: CGP inhibited ERp57 enzyme activity but not the activity of PDI, ERp5, ERp72 or thioredoxin. CGP (7.5-300μM) concentration-dependently inhibited platelet aggregation in response to CRP-XL, U46619 and thrombin. Calcium mobilisation, dense-and alpha-granule secretion and platelet spreading on collagen and fibrinogen were similarly affected. CGP decreased substantially the size of thrombi formed under arterial flow conditions using human and murine blood and in blood from transgenic (diYF) mice that display defective integrin αIIbβ3 outside-in signaling.

Conclusions: CGP is a potent inhibitor of ERp57 that inhibits thrombus formation through a mechanism that is not dependent on outside-in signaling by integrin αIIbβ3. Small molecule inhibitors of ERp57 such as CGP provide additional means to explore the role of ERp57 in platelet function and may prove useful for the development of future antithrombotic therapies.

PB 1320 | Platelet Proteomic Profiling in a Patient with Severe Platelet Dysfunction Associated to an Anti-αIIbβ3 Autoantibody Triggering Outside-in Signaling

M. Fiore[1], X. Pillois[2], M. Jandrot-Perrus[3], F. Cognasse[4], A. Debesset[5], A. Chansavang[5], S. Claverol[6], B. Payrastre[7], S. Laradi[4]

[1]*University Hospital of Bordeaux, Reference Center for Platelet Disorder, Hematology Laboratory, Pessac, France,* [2]*University Hospital of Bordeaux, Pessac, France,* [3]*Unité Mixte de Recherche S 1148, INSERM, Université Paris Diderot, Centre Hospitalier Universitaire Bichat, Paris, France,* [4]*French Blood Establishment (EFS) Rhône-Alpes-Auvergne, Saint-Etienne, France,* [5]*University of Bordeaux, Bordeaux, France,* [6]*Proteome Platform, CGFB, University of Bordeaux Segalen, Bordeaux, France,* [7]*INSERM, U 1048 and Université Toulouse 3, Institut des Maladies Métaboliques et Cardiovasculaires (I2MC), Toulouse, France*

Background: Acquired platelet dysfunction may be caused by anti-$\alpha_{IIb}\beta_3$ autoantibodies.

Aims: We report the case of a patient who has developed an atypical severe platelet disorder associated with an IgM antibody that induces integrin $\alpha_{IIb}\beta_3$ outside-in signaling.

Methods: We performed several functional assays (e.g. PAC-1 binding) to investigate the mechanism leading to platelet dysfunction. We also investigated the proteome of platelets (Label-Free quantitative analysis LC-MS/MS method), from the patient (n=3) and three unrelated controls. Functional analysis was performed using IPA software.

Results: The patient is a 53-year-old man with chronic refractory immune thrombocytopenia. Platelet function testing showed much reduced aggregation using all agonists, but normal agglutination with ristocetin. Expression of $\alpha_{IIb}\beta_3$ was reduced and there was nearly no activation of GPIbα or P-selectin. Surprisingly, an IgM antibody was strongly detected in permeabilized platelets, suggesting that this antibody was internalized. Patient´s platelet poor plasma activated $\alpha_{IIb}\beta_3$ of control platelets as evidenced by increased PAC-1 binding. We also demonstrated that constitutive activation of $\alpha_{IIb}\beta_3$ triggers outside-in signaling, as shown by the phosphorylation of β_3 Tyr773 and the autophosphorylation of FAK. In the same way, PRP clot retraction was conserved in our patient. Using a proteomic approach, 932 proteins were identified in our samples from which 306 were differentially expressed. Most of them are involved in platelet signaling or protein ubiquitination pathways. The signaling activation pathway appeared diminished, while proteins in the ubiquitination pathway were augmented.

Conclusions: We present the case of a patient with a severe platelet disorder associated with the presence of an IgM anti-$\alpha_{IIb}\beta_3$ autoantibody triggering outside-in signaling.

Paradoxically, others signaling activation networks were diminished, probably due to a proteolysis phenomenon linked to the proteasome system.

PB 1321 | STAT3 Phosphorylation Is Regulated by Thromboxane A2 Receptor in Platelets

A.M. Latorre[1], J. Vallés[1], M.T. Santos[1], S. Bonanad[2], A. Moscardó[1]

[1]*Health Research Institute La Fe, Hemostasis, Thrombosis, Atherosclerosis, and Vascular Biology, Valencia, Spain,* [2]*University and Polytechnic Hospital La Fe, Department of Hemostasis and Thrombosis, Valencia, Spain*

Background: Thromboxane A2 (TXA2) synthesis is part of the amplification loop of platelet activation. This effect is mediated by the action of TXA2 on its receptor on platelet membrane. However, signal transduction mechanisms related to TXA2-R are largely unknown. STAT3 is present in platelets, and is phosporylated in response to thrombopoietin (TPO) and collagen.

Aims: To investigate the implication of STAT3 phosporylation in TXA2-induced platelet activation.

Methods: Washed human platelets were stimulated with different agonists (collagen, thrombin, TXA2 analogs U46619 or IBOP, ADP and r-TPO). STAT3 phosphorylation were performed by immunoblotting. TXA2-R, ADP receptor P2Y12 and GPIIbIIIa were blocked with SQ29,548, 2MeSAMP and RGDS, respectively. STAT3 was inhibited with STA21.

Results: Platelet aggregation induced by collagen, thrombin, U46619 and IBOP, but not ADP, dose and time-dependently induced STAT3 phosphorylation. In all cases this phosphorylation was lower than those induced by TPO. TXA2-R blocking suppressed STAT3 phosphorylation induced with all agonist, and only partially reduced TPO-induced phosphorylation. Similar results were obtained when TXA2 synthesis was blocked by aspirin, suggesting that TXA2-R plays an important role in STAT3 phosphorylation. U46619-induced STAT3 phosphorylation was independent of aggregation or ADP release as demonstrated by GPIIbIIIa or P2Y12 receptors blocking. Incubation with STA21 reduced U46619-induced STAT3 phosphorylation, although only reduced platelet aggregation at low concentrations of agonist. Finally, TXA2-R and STAT3 were co-immunoprecipitated both from resting and activated platelets.

Conclusions: STAT3 phosphorylation induced by different platelet agonists is mainly related to TXA2 receptor. These results described for the first time a new signal transduction mechanism linked to TXA2 receptor. Grants. FIS13/00016. ACIF/2016/465. PB 1322 | Guanosine Exerts Antiplatelet and Antithrombotic Properties through cAMP-PKA Signaling and Independently of Platelet Adenosine Receptors

E. Fuentes[1], M.A. Alarcón[1], I. Palomo[1], L. Badimon[2], G. Vilahur[2], T. Padro[2], K.-N. Klotz[3], S. Kachler[3], M. Fuentes[1]

[1]*Universidad de Talca, Talca, Chile,* [2]*Centro de Investigación Cardiovascular (CSIC-ICCC), Barcelona, Spain,* [3]*University of Würzburg, Würzburg, Germany*

Background: Guanosine is a natural product and an endogenous nucleoside that has shown to increase during myocardial ischemia. Platelets are critically involved in ischemic coronary events. It remains unknown, however, whether guanosine may affect platelet activation and function.

Aims: We sought to investigate the potential antiplatelet and antithrombotic properties of guanosine and decipher the mechanisms behind.

Methods: We firstly assessed the effects of guanosine on platelet activation/aggregation upon stimulation with several platelet agonists includingadenosine diphosphate (ADP), collagen, arachidonic acid (AA), and TRAP-6. Guanosine antithrombotic potential was also evaluated both *in vitro* (Badimon perfusion chamber) and *in vivo* (murine model). In addition we assessed any potential effect on bleeding. At a mechanistic level we determined the release of thromboxane B2, intraplatelet cAMP levels, the binding affinity on platelet membrane, and the activation/phosphorylation of protein kinase A (PKA), phospholipase C (PLC) and PKC.

Results: Guanosine markedly inhibited platelet activation/aggregation -challenged by ADP and, although to a lesser extent, also reduced platelet aggregation challenged by collagen, AA and TRAP-6. Guanosine significantly reduced thrombus formation both *in vitro* and *in vivo* without significantly affect bleeding. Guanosine antiplatelet effects were associated with the activation of the cAMP/PKA signaling pathway, and a reduction in thromboxane B2 levels and PLC and PKC phosphorylation. The binding affinity assay revealed that guanosine effects on platelets were adenosine receptor independent.

Conclusions: Guanosine effectively reduces ADP-induced platelet aggregation and limits thrombotic risk. These antithrombotic properties are associated with the activation of the cAMP/PKA signaling pathway and are independent of adenosine receptors.

PB 1323 | Anti-thrombotics from Snake Venom as Selective Inhibitor of $\alpha_{IIb}\beta_3$ Outside-in Signaling

Y.-J. Kuo[1], W.-J. Chuang[2], T.-F. Huang[1]

[1]*College of Medicine, National Taiwan University, Graduate Institute of Pharmacology, Taipei, Taiwan, Republic of China,* [2]*National Cheng Kung University Medical College, Department of Biochemistry, Tainan, Taiwan, Republic of China*

Background: Current $\alpha_{IIb}\beta_3$ antagonists are efficacious anti-thrombotics but have significant bleeding risk.

Aims: To address the issue, we examined whether two purified antagonists, TMV-2 and TMV-7, from *Trimeresurus mucrosquamatus* snake venom, prevent thrombosis without causing bleeding via selectively inhibiting $\alpha_{IIb}\beta_3$ outside-in signaling.

Methods: We investigated the relationship between structure activity and the capacity of binding to $\alpha_{IIb}\beta_3$ on mutually exclusive binding of cytosolic protein talin and $G\alpha_{13}$ to β_3 cytoplasmic domain among TMV-2, TMV-7 and its derivative by immunoprecipitation and binding study.

Results: We reported the purified Arg-Gly-Asp (RGD)-containing disintegrin TMV-7 endows with a binding motif toward aIIb b-propeller

domain of αIIbβ3, different from those of another disintegrin TMV-2 and abciximab, with advantages in that TMV-7 selectively inhibits Gα13-binding without affecting talin-binding to β3 in human and mouse thrombin-activated platelets. Compared with TMV-2 and abciximab, TMV-7 had minor effect on clot retraction, processes of hemostasis driven by talin. TMV-7 potently inhibited FeCl3-induced occlusive thrombosis in vivo, but did not affect bleeding time measured by tail bleeding time model, compared to abciximab and TMV-2. To mimic hemorrhage during surgical procedures, we used ROTEM method of surgical hemorrhage. In contrast to abciximab and TMV-2, TMV-7 had no effect on human whole blood coagulation-indexes even at higher dose. Additionally, we mutated the RGD-domain of TMV-7 from ARGDNP to AKGDXX, and found that this AKGDXX mutant (XX) also acts as a selective inhibitor of Gα13-mediated outside-in signaling and exhibits a higher potency in inhibiting platelet aggregation and preventing thrombosis in vivo, and its safety index is raised to 70-time higher than TMV-7.

Conclusions: Taken together, TMV-7 and XX prevent thrombosis by a mechanism different from that of all other tested $\alpha_{IIb}\beta_3$ antagonists, acting as efficacious antithrombotic agents with minimal bleeding risk.

PB 1324 | The Involvement of $\alpha_{IIb}\beta_3$ Integrin on the Release of Extracellular Vesicles and the Chemokines CXCL4 and CCL5 by Platelets

A.C.A. Heinzmann, T. Vajen, J.W.M. Heemskerk, J.M. Cosemans, T.M. Hackeng, R.R. Koenen

Maastricht University / Cardiovascular Research Institute Maastricht (CARIM), Biochemistry, Maastricht, The Netherlands

Background: Platelets release extracellular vesicles upon activation as well as spontaneously during prolonged storage. Platelets represent a major source of extracellular vesicles (EV) and have been recognized to be involved in inflammatory diseases. Stimulation of platelets results in activation of $\alpha_{IIb}\beta3$ integrin, which enables ligand binding and subsequent outside-in signaling. Previous studies have shown that $\alpha_{IIb}\beta3$ integrin is involved in platelet EV release. Besides the release of platelet EV, platelets are a rich source of chemokines i.e. platelet factor 4 (CXCL4) and RANTES (CCL5), which can be secreted through the α-granules and are involved in the inflammatory recruitment of leukocytes. However, the exact mechanism behind the involvement of $\alpha_{IIb}\beta3$ integrin in the release of platelet EV and chemokines is currently unknown.

Aims: To identify the underlying mechanisms of platelet EV- and chemokine CXCL4 - and CCL5 - release by activated platelets

Methods: Platelets were isolated from healthy volunteers and stimulated with convulxin and TRAP-6. The release of platelet EV and chemokines (CXCL4 and CCL5) was determined by a prothrombinase-based assay and by ELISA, respectively. The mechanism of extracellular release was studied with several inhibitors e.g. eptifibatide.

Results: Convulxin-activated platelets increased the release of platelet EV compared to non-activated platelets. Chemokine CXCL4 and CCL5 levels were increased upon convulxin and TRAP-6 platelet activation. Pre-treatment with the $\alpha_{IIb}\beta3$ inhibitor eptifibatide reduced platelet EV release triggered by convulxin and attenuated CCL5 release, but did not affect TRAP6- activated platelets. Interestingly, CXCL4 release was not affected by eptifibatide pre-treatment of platelets.

Conclusions: These data conclude that the $\alpha_{IIb}\beta3$ integrin is involved in the release of platelet EV and the chemokine CCL5. Interestingly, the release of CXCL4 appears not to be dependent on the action of $\alpha_{IIb}\beta3$ integrin.

PB 1325 | Neuromedin U Potentiates ADP and Epinephrine Activation of Human Platelets

C. Grippi[1], B. Izzi[2], F. Gianfagna[1,3], A. Di Pardo[4], M.B. Donati[1], G. de Gaetano[1], M.F. Hoylaerts[2], L. Iacoviello[1,3], C. Cerletti[1]

[1]IRCCS Neuromed, Department of Epidemiology and Prevention, Pozzilli, Italy, [2]Center for Molecular and Vascular Biology, University of Leuven, Department of Cardiovascular Sciences, Leuven, Belgium, [3]University of Insubria, Department of Medicine and Surgery, Varese, Italy, [4]IRCCS Neuromed, Centre for Neurogenetics and Rare Diseases, Pozzilli, Italy

Background: Neuromedin U (NmU), a pleiotropic hypothalamic neuropeptide involved in the gut-brain axis, interacts mainly through NMUR1 and NMUR2 receptors coupled to $G\alpha_{q/11}$ and $G\alpha_{i,}$, respectively. Transcriptome analysis shows evidence for expression of NmU and its receptor in human platelets, but the functional effect of NmU on these cells is unclear.

Aims: To explore whether NmU plays a role in platelet activation and to detect the presence in platelets of NMUR1, the receptor preferentially involved in NmU activity on peripheral cells.

Methods: Platelet aggregation was studied in a PAP-8E (Bio/Data Corporation) aggregometer; platelet rich plasma was stimulated with human NmU (Abcam, Cambridge-UK) alone or combined with ADP, epinephrine, serotonin, with(out) platelet inhibitors. Human anti-NMUR1 antibody (H-45; 1:200) was used in western blots of platelets.

Results: NmU itself (to 10μM) did not induce any measurable platelet aggregation, but significantly and concentration-dependently (10-100nM) potentiated ($p< 0.003$) platelet aggregation by submaximal ADP-concentrations (0.625-2.5μM). This effect was more pronounced when NmU was added 1-2 min prior to ADP. Neither aspirin (200μM, 15 min), nor MRS2179 (50μM, 5 min), a $P2Y_1$ inhibitor, modified the NmU effect on ADP. NmU also increased (mean 37%; CI 95% 23.3-52.2; $p< 0.0002$) aggregation by low epinephrine concentrations (0.078-1.25μg/ml), but did not affect serotonin (20μM)-induced aggregation. YM-254890, a specific inhibitor of Gαq receptors (1μM), abrogated the NmU/epinephrine-induced platelet activation. NMUR1 was detected in platelets from six donors.

Conclusions: This is the first description of the potentiating effect of NmU on platelet activation by several agonists. This effect is COX-1 and $P2Y_1$ independent; NmU/epinephrine acts through NMUR1, coupled to $G\alpha_q$ in platelets. NmU released during vascular activation and/or injury may enhance platelet responses to classical agonists, *via* NMUR1-signaling.

PB 1326 | Real-time Flow Cytometry Can Identify Differences in the Kinetics of Platelet Activation in Response to Different Agonists

J.L. Mitchell, C.I. Jones

University of Reading, ICMR, Reading, United Kingdom

Background: The kinetics of platelet activation may be important in determining the size and structure of a forming thrombus. Real-time flow cytometry accurately measures the dynamics of platelet activation over time and can identify variations in response to different agonists.

Aims: To identify differences in the rate of platelet activation in response to stimulation via different signalling pathways.

Methods: Platelet-rich plasma was used in real-time flow cytometry to detect binding of FITC-labelled fibrin(ogen) antibodies in response to cross-linked collagen related peptide (CRP-XL; 0.1mg/ml), thrombin (0.3U/ml), ADP (1mM) and epinephrine (0.5mM). Data was collected over 300 seconds and a loess curve of fluorescence intensity vs. time was plotted in R and used to calculate a range of metrics, including maximum fibrinogen binding, maximum rate and acceleration of fibrinogen binding, and the time points at which these maximums occurred.

Results: In 300s platelets bound greater levels of fibrinogen when stimulated with ADP (3.8FU; P< 0.05 vs. CRP-XL) and epinephrine (4.4FU; P< 0.001 vs. CRP-XL) compared to CRP-XL (2.9FU) or thrombin (3.6FU). In contrast, the maximum acceleration of fibrinogen binding revealed the highest rates in response to CRP-XL ($15.1x10^{-4}$ FU/min) and thrombin ($11.79\ x10^{-4}$ FU/min) when compared to ADP ($7.68\ x10^{-5}$ FU/min; P< 0.05 vs. CRP-XL) and epinephrine ($3.59\ x10^{-5}$ FU/min; P< 0.0001 vs. CRP-XL), but occurred at later time points. These data indicate that ADP and epinephrine induce rapid platelet activation at a steady rate leading to high maximal fibrinogen binding at 300s. Stimulation with CRP-XL begins at a slow rate initially, before accelerating to a high activation rate, leading to lower levels of fibrinogen binding at 300s.

Conclusions: The rate of platelet activation and time to reach full activation varies depending on the signalling pathway. These measurements could determine how efficiently platelets are recruited into forming thrombi and how this would affect thrombus architecture.

PB 1327 | Interplay between Calcium and Zinc: Implications for Platelet Activation

K. Taylor[1], N. Pugh[2]

[1]Imperial College London, London, United Kingdom, [2]Anglia Ruskin University, Cambridge, United Kingdom

Background: At sites of vascular injury, Zn^{2+} is released from damaged cells, activated platelets and inflammatory cells. At high concentrations, Zn^{2+} acts as a direct platelet agonist. At low concentrations, Zn^{2+} potentiates platelet activation. However, the underlying mechanism(s) of Zn^{2+}-induced platelet activation remain unclear.

Aims: The aim of this work was to determine the mechanisms by which Zn^{2+} gains access to the platelet cytosol, and to investigate the mechanism by which Zn^{2+} effects platelet aggregation.

Methods: Zn^{2+}-induced platelet activation was investigated in washed platelet suspensions using various channel blockers. Zn^{2+} entry into the platelet cytosol was assessed using the Zn^{2+}-sensitive dye FluoZin-3. Fluctuations of intracellular Ca^{2+}, activation of integrin $a_{IIb}b_3$ and expression of P-selectin, LAMP-3 and phosphatidylserine were assessed by flow cytometry.

Results: Blockade of the sodium/calcium exchanger (NCX) and transient receptor potential (TRP) family members, resulted in reduced aggregation in response to Zn^{2+}. Co-application of TRP and NCX blockers abrogated aggregation. Further experiments revealed reduced aggregation responses to CRP and thrombin in the presence of these drugs. Pre-incubation of platelets with sub-activatory Zn^{2+} reduced intracellular Ca^{2+} responses, likely by impairment of release of Ca^{2+} from the dense tubular system. However, CRP- and thrombin-induced detection of activation markers (i.e. P-selectin, LAMP-3 and intergrin activation) was not significantly altered in the presence of subactivatory Zn^{2+}.

Conclusions: TRP channels and NCX are implicated in coordinating platelet responses to Zn^{2+}. Low concentrations of Zn^{2+} reduce agonist-induced Ca^{2+} responses, likely via reduction of Ca^{2+} release from the intracellular store. Given that the expression of activation markers was not affected by Zn^{2+}, these data indicate a potentiatory role for Zn^{2+} during platelet activation.

PB 1329 | Btk Kinase Activity is Not Critical for Platelet Activation by GPVI

P.L.R. Nicolson[1], S. Watson[1], C.E. Hughes[2], A.P. Bye[2], J.M. Gibbins[2], A.T. Hardy[1], C.N. Watson[1], S. Montague[1], M.G. Tomlinson[1], G.E. Pratt[3], S.P. Watson[1]

[1]University of Birmingham, Institute of Cardiovascular Sciences, Birminhgam, United Kingdom, [2]University of Reading, Institute for Cardiovascular and Metabolic Research, Reading, United Kingdom, [3]Queen Elizabeth Hospital Birmingham, Department of Haematology, Birmingham, United Kingdom

Background: Ibrutinib and acalabrutinib, two inhibitors of the non-receptor protein tyrosine kinase Btk, are used to treat B cell malignancies. They bind irreversibly to Cys481 of Btk, preventing it from phosphorylating itself and other substrates. Patients treated with ibrutinib have increased bleeding events and this correlates with inhibition of platelet aggregation downstream of the collagen receptor GPVI. Patients treated with acalabrutinib do not bleed excessively.

Aims: We sought to investigate this discrepancy between the two Btk inhibitors.

Methods: Aggregometry, tyrosine phosphorylation and Ca^{2+} mobilisation assays were performed in washed platelets pre-treated with ibrutinib or vehicle. Aggregometry was also performed with platelet rich plasma (PRP) from patients taking ibrutinib 420mg daily, acalabrutinib 100mg twice daily or a control treatment.

Results: Ibrutinib (40nM) blocked GPVI-induced phosphorylation of Btk on Y223 and PLCg2 Y759 and 1217, but only caused a slight delay

in aggregation and had no effect on Ca^{2+} mobilisation. Complete inhibition of aggregation, Ca^{2+} mobilisation and total tyrosine phosphorylation occurred at concentrations greater than 1μM ibrutinib. PRP from patients taking ibrutinib did not aggregate in response to GPVI ligation whereas PRP from patients taking acalabrutinib aggregated normally.

Conclusions: Our results confirm that ibrutinib blocks GPVI-induced platelet aggregation *in vitro* and *ex vivo* but that, contrary to current understanding, this is due to off-target effects. We hypothesise that reducing the dose of ibrutinib given to patients would abolish its off-target effects and therefore reduce bleeding. This is supported by the fact that the more specific Btk inhibitor acalabrutinib, which does not have a bleeding side effect, does not block aggregation to GPVI *ex vivo*.

Acknowledgement: This work was supported by the British Heart Foundation.

PB 1330 | ERK5 Associates Casein Kinase II to Regulate GPIb-IX-mediated Platelet Activation via PI3K/Akt Pathway

Z. Cheng[1], X. Fan[2], X. Chen[2], H. Mei[1], J. Liu[2], Y. Hu[1]

[1]Institute of Hematology, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, WuHan, China, [2]Shanghai Key Laboratory of Tumor Microenvironment and Inflammation, Shanghai Jiao Tong University School of Medicine, Department of Biochemistry and Molecular Cell Biology, Shanghai, China

Background: The platelet adhesion receptor, the glycoprotein (GP) Ib-IX complex play essential roles in thrombosis and hemostasis. Although mitogen-activated protein kinases (MAPKs) p38 and ERK1/2 have been shown to be crucial in GPIb-IX-mediated platelet adhesion and aggregation, the function and mechanisms of ERK5 (extracellular signal-regulated kinase 5) in GPIb-IX-mediated platelet activation remain unknown.

Aims: To study the function and mechanisms of ERK5 in GPIb-IX-mediated platelet activation.

Methods: The effects of ERK5 inhibitor on Botrocetin/vWf or Ristocetin/vWf induced human platelet two-phase aggregation and on platelet adhesion to VWF under shear stress were assessed. The ERK5 associated proteins were identified by co-immunoprecipitation and mass spectrometry analysis from CHO cell expressing HA-ERK5 and were confirmed by immunoprecipitation and western blot in human platelet. The role of ERK5 associated proteins in GPIb-IX-mediated platelet activation were clarified by specific inhibitor.

Results: Phosphorylation levels of ERK5 were significantly enhanced in human platelets stimulated by Botrocetin/vWf or Ristocetin/vWf. ERK5 inhibitor XMD8-92 significantly suppressed the second phase of Botrocetin/vWf or Ristocetin/vWf induced human platelet aggregation, and inhibited human platelet accumulation on immobilized VWF under shear stress. Immunoprecipitation and mass spectrometry analysis revealed that ERK5 associates with CKII (casein kinase II) in CHO cells expressing HA-ERK5 and in human platelets. CKII inhibitor TBB, similar as ERK5 inhibitor XMD8-92, specifically restrained the phosphorylation of PTEN, therefore suppressed Akt phosphorylation in human platelet treated with Botrocetin/vWf or Ristocetin/vWf.

Conclusions: ERK5 associates CKII to play critical roles in GPIb-IX-mediated platelet activation via PI3K/Akt Pathway.

PB 1331 | Agonist-induced Protein Disulfide Isomerase Activity in Platelets: Different Effect of Different Agonists

R. Mor-Cohen[1,2], J. Mostafa[1,2], U. Seligsohn[1,2]

[1]The Amalia Biron Research Institute of Thrombosis and Hemostasis, Chaim Sheba Medical Center, Tel Hashomer, Israel, [2]Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel

Background: Protein disulfide isomerase (PDI) resides mainly in the endoplasmic reticulum but is also displayed on the surfaces of various cells including platelets. PDI is released from platelets following activation and facilitates platelet aggregation and thrombus formation in mice thrombosis models.

Aims: To investigate the effect of different agonists on PDI activity in human platelets and explore whether this effect correlates with platelets activation.

Methods: Washed platelets were prepared from healthy controls´ blood samples. Enzymatic reductase activity in platelets that were either activated or not by various agonists was assayed by measuring the kinetics of eosin 5-isothiocyanate-coupled glutathione disulfide (Di-E-GSSG) reduction. The contribution of PDI to reductase activity was assessed by adding a specific PDI inhibitor, quercetin-3-rutinoside (rutin). Platelet activation by the various agonists was measured by flow cytometry (FACS) using antibodies against the platelets activation markers P-selectin and active αIIbβ3.

Results: Resting platelets displayed basal reductase activity that was significantly increased following incubation with thrombin, TRAP, convulxin, ionophore and U46619. In contrast, collagen and ADP at low and high concentrations did not increase platelets reductase activity and did not further increase reductase activity induced with TRAP and U46619. Addition of rutin, significantly decreased reductase activity induced by the different agonists and also of resting platelets. FACS analysis showed that most agonists profoundly increased both P-selectin expression and αIIbβ3 activation; however, collagen and ADP caused smaller increase of both markers.

Conclusions: Resting human platelets harbor active PDI on their surfaces and platelets strong activation by some agonists induces the release of additional active PDI. Other agonists that caused lesser activation of platelets did not induce PDI release from platelets, indicating that PDI release requires strong platelets activation.

PB 1332 | Dose-dependent Inhibitory and Stimulatory Effects of Sphingosine-1-phosphate on Platelet Adhesion to Endothelium

B. Knoop[1], B. Levkau[2], A. Ayhan[1], A. Mohring[1], L. Dannenberg[1], M. Kelm[1], T. Zeus[1], A. Polzin[1]

[1]Heinrich Heine University Medical Center Düsseldorf, Division of Cardiology, Pulmonology, and Vascular Medicine, Düsseldorf, Germany, [2]University Hospital Essen, Centre for Medical Biotechnology, Essen, Germany

Background: Sphingosine-1-phosphate (S1P) is a biologically active sphingolipid with important cardiovascular functions. Activated platelets release large amounts of S1P locally during thrombus formation, whereas S1P itself induces platelet aggregation. In endothelial cells, S1P leads to P-selectin activation and enhances P-selectin-dependent leucocyte rolling. However, the effects of S1P on platelet adhesion to endothelium under flow are unknown.

Aims: To investigate the effect of different S1P concentrations on platelet adhesion to endothelial cells under flow.

Methods: Human umbilical vein endothelial cells were grown in microfluidic channels (Bioflux 200) until a monolayer was formed. Cells were stimulated with S1P in different concentrations (0.1µM, 1µM, 10µM). Whole blood of healthy individuals was perfused over the monolayer using pulsatile flow for 10 min. Thrombus formation was assessed using area coverage in percent. Data are mean ± standard deviation.

Results: Stimulation with 1µM S1P significantly decreased platelet adhesion to endothelial cells (20.1±4.9% vs. 16.3±3.7%, p< 0.0001), while 0.1µM S1P had no effect (19.1±4.5% vs. 20.2±4.4%, p=0.64). In contrast, 10µM S1P significantly increased platelet adhesion to endothelial cells (17.8±3.6% vs. 25.4±6.7%, p= 0.007). The S1P1 receptor antagonist W146 abolished the decrease in platelet adhesion by 1µM S1P (Control: 28.7±6%, 1µM S1P: 23.7±7%, 1µM S1P+W146: 33.8±4%) but had no effect on the increase in platelet adhesion by 10µM S1P (Control: 27.3±7%, 10µM S1P: 40.7±9%, 1µM S1P+W146: 38.7±11%). The enhanced adhesion by 10µM S1P was abrogated by a P-selectin blocking antibody (Control: 19.4±5%, 10µM S1P: 27±8%, 10µM S1P+anti-CD62P: 21.3±5%).

Conclusions: S1P affects platelet adhesion to endothelial cells dose-dependently. Physiological S1P concentrations suppress platelet adhesion to the endothelium through S1P1, whereas high S1P concentrations enhance adhesion independently of S1P1 and by activating P-selectin.

PB 1333 | Calcium Signalling Patterns in Adherent Single Platelets during Activation with Collagen-related Peptide

S. Obydennyi[1,2], F. Ataullakhanov[1,2,3], M. Panteleev[1,2,3]

[1]Center for Theoretical Problems of Physicochemical Pharmacology, Russian Academy of Sciences, Moscow, Russian Federation, [2]Dmitry Rogachev National Research Center of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation, [3]Moscow State University, Moscow, Russian Federation

Background: Platelet activation with thrombin, SFLLRN, ADP induces cytoplasmic calcium oscillations, while that with fibrillar collagen results in calcium increase without perceptible oscillations. Calcium patterns in single platelets activated with CRP are not well-characterized.

Aims: To study dynamics and dose-dependence of platelet calcium signalling upon CRP stimulation.

Methods: Whole blood was collected into sodium citrate. Platelets were loaded with Fura Red, immobilized on a fibrinogen surface for 20 min, followed by activation and real-time confocal microscopy. Annexin V and tetramethylrhodamine were used for detection of PS and mitochondrial potential.

Results: Calcium response during activation with different concentrations of CRP was concentration-dependent, and two types of dynamics were observed: short (~100 sec) high increase in calcium with following decrease and transition to stationary level (higher than rest level) for high concentrations of agonist, and the same dynamics without short increase but with low-speed one to the same stationary calcium level for low concentrations of agonist. All platelets had calcium spikes after activation that could be halted after a while. Calcium increase was delayed for decades of seconds for low agonist concentrations and was immediate for high concentrations of CRP. Formation of procoagulant platelets was accompanied by their mitochondrial collapse.

Conclusions: Activation of platelets with CRP leads to emergence of calcium oscillations distinct from responses induced by either thrombin, ADP, or collagen.

Study was supported by RFBR grant 16-34-01342.

PB 1334 | Reelin Modulates PLCγ2 Phosphorylation upon Platelet Activation and Integrin Outside-in Signaling

I. Krüger[1], N.S. Gowert[1], M. Klier[2], H.H. Bock[3], M. Elvers[1]

[1]University Clinic of the Heinrich-Heine-University Düsseldorf, Research Group Molecular Hemostasis, Düsseldorf, Germany, [2]University Hospital, Research Group Experimental Vascular Medicine, Düsseldorf, Germany, [3]Heinrich-Heine-University Düsseldorf, Clinic for Gastrenterology, Hepatology and Infectiology, Düsseldorf, Germany

Background: Reelin is known as an extracellular matrix protein mediating cell migration in brain development. Recent studies provide evidence that Reelin is expressed in platelets as co-localized to F-Aktin. Moreover, Reelin binds to the receptors amyloid precursor protein (APP) and apolipoprotein E receptor 2 (ApoER2) and is important for thrombus formation under high shear conditions suggesting that Reelin modulates glycoprotein(GP)Ib signaling in platelets. Consequently, defective thrombus formation protects Reelin-deficient mice (Reeler) against arterial thrombosis.

Aims: To analyze the role and the signaling mechanisms of Reelin in platelet cytoskeletal reorganization, activation and aggregation.

Methods: In vitro and in vivo analysis of Reeler mice.

Results: Reelin activated small GTPases of the Rho family and was shown to be important for the phosphorylation of Rho target proteins such as PAK1/2 supporting lamellipodia formation upon spreading on fibrinogen. Furthermore the adhesion and cytoskeletal reorganization of Reeler platelets on a collagen-related peptide (CRP) matrix was found to be reduced. Likewise strongly reduced phosphorylation of PLCgamma2 and Syk in response to CRP was detected in reeler platelets. Furthermore, platelet adhesion to immobilized reelin was significantly reduced when the collagen receptor GPVI was blocked. For further analysis of outside-in signaling of integrin αIIbβ3 clot retraction experiments were performed showing strongly reduced retraction of the clot in Reeler platelet rich plasma (PRP). Taken together these data provide first evidence for Reelin to mediate signaling through GPVI and to modulate integrin outside-in signaling suggesting that Reelin is a modulator of PLCgamma2 phosphorylation in platelets.

Conclusions: Our study reveals an important role for Reelin in hemostasis and arterial thrombosis, thus being a promising therapeutic target for antithrombotic therapy.

PB 1335 | Calcium Monitoring in Platelets: Tool for Diagnosing Platelet Function Defects

A. Aliotta, D. Bertaggia Calderara, L. Alberio

CHUV, University Hospital and University of Lausanne, Department of Hematology, Lausanne, Switzerland

Background: Laboratory tests currently used to investigate a bleeding diathesis may fail to reveal the underlying hemostatic disorder. Flow cytometry analysis (FCA) improved our tools for exploring platelet (PLT) function and profiling defects associated with bleeding diathesis.

Aims: To hone standard FCA by extending investigations to intracellular signaling, here monitoring free intracellular Ca^{2+} upon PLT activation.

Methods: Platelet-rich plasma was obtained from buffered citrated whole blood. PLTs were activated with increasing concentrations of thromboxane analogue U-46619, ADP, thrombin (THR), TRAP6 (PAR-1 agonist), AYPGKF (PAR-4 agonist), convulxin (CVX, GPVI agonist), and ionophore. PLT activation end-points for FCA were P-selectin expression and PAC-1 binding. Intracellular free Ca^{2+} was detected by its indicator Fluo-3 AM. After measurement of a stable baseline, PLTs were activated with agonists and Fluo-3 fluorescence was acquired over time.

Results: Optimal dose-response concentrations were determined for each agonist, and Ca^{2+} monitoring following PLT activation was performed. Strong and sustained cytosolic Ca^{2+} increase was observed after PLT activation with ionophore and CVX. THR induced an initial strong Ca^{2+} response, which slowly declined. Both TRAP6 and AYPGKF demonstrated a strong intracellular Ca^{2+} increase with a rapid decline. Their combined action was not able to fully replicate THR effect. Weak Ca^{2+} mobilization was observed with U-46619 and ADP. With Ca^{2+}-supplemented buffer, we observed both an increased Ca^{2+} mobilization and a qualitatively different response for THR and CVX combined either together or with U-46619 and ADP. Preliminary results indicate an increased calcium mobilization after *in vivo* desmopressin treatment.

Conclusions: The present work highlights the use of continuous Ca^{2+} monitoring to complement FCA of PLT function. This technique sharpens the ability to investigate agonist synergies and PLT signaling defects in bleeding patients investigated for PLT function disorders.

PB 1336 | Modelling Intracellular Zinc Release in Platelets

N.S. Ahmed, N. Pugh

Anglia Ruskin University, Cambridge, United Kingdom

Background: Zinc ions (Zn^{2+}) are released into the cytosol from intracellular stores of a number of different cell types in response to external stimulation, in a similar manner to intracellular calcium (Ca^{2+}) release. Platelets are small blood cells that are involved in the haemostatic response to vascular injury.

A hallmark of platelet activation is increased intracellular Ca^{2+} levels as a result of store release and influx through membrane channels. The role of Zn^{2+} release in platelets has yet to be studied in detail. Ionophores which enable ion transfer across membranes are often used to mimic intracellular ion release. Here we used zinc-specific ionophores to examine the effect of increased Zn^{2+} concentration on platelets.

Aims: The primary objective of this project is to examine the role of increases in intracellular Zn^{2+} in platelet processes, and to determine the potential store and release of Zn^{2+} in platelets.

Methods: The effects on platelets of Zn^{2+}-specific ionophores, clioquinol and pyrithione were compared with that of the calcium ionophore, A23187.

Results: A23187 induced platelet shape change followed by full platelet aggregation. Clioquinol induced shape change followed by sub maximal aggregation, whilst pyrithione caused significant platelet shape change without aggregation. Pre-treatment of platelets with the Zn^{2+} chelator, TPEN reduced the effects of Zn^{2+} ionophores in the platelets. The mechanism of ionophore-induced shape changes was examined using Cytochalasin D (Cyt D), which inhibits actin polymerization. Cyt D significantly reduced the shape change induced by Zn^{2+} ionophores.

Conclusions: These data suggest that intracellular Zn^{2+} is able to influence platelet responses in particular the cytoskeletal rearrangement that occurs during platelet shape change upon platelet activation. We hypothesis that during platelet activation, Zn^{2+} is released from intracellular stores to modulate platelet responses.

PB 1337 | Role of Heterotrimeric G Proteins in Platelet Activation and Clot Formation in Platelets Treated with Integrin $\alpha_{IIb}\beta_3$ Inhibitor

I. Budnik[1], B. Shenkman[2], H. Hauschner[3], U. Martinowitz[2], N. Savion[4]

[1]Sechenov First Moscow State Medical University, Department of Pathophysiology, Moscow, Russian Federation, [2]Sheba Medical Center, National Hemophilia Center, Tel-Hashomer, Israel, [3]Sheba Medical Center, Amalia Biron Research Institute of Thrombosis and Hemostasis, Tel Hashomer, Israel, [4]Tel Aviv University, Goldschleger Eye Research Institute, Sackler Faculty of Medicine, Tel Aviv, Israel

Background: Mechanisms of platelet activation are triggered by soluble agonists which induce signaling via heterotrimeric Gαq, Gαi, and Gα12/13 proteins.

Aims: To investigate the contribution of the G proteins to platelet activation and clot formation in the presence of eptifibatide, excluding outside-in signaling caused by integrin αIIbβ3 engagement.

Methods: The study was approved by the research ethics committee, and each volunteer signed a written informed consent. Blood was drawn and diluted by 40% with Tris-buffered saline. Platelet-rich plasma or reconstituted whole blood were prepared and pretreated with 25 μg/mL eptifibatide. Selective and combined activation of the G proteins was achieved by using combinations of platelet agonists and inhibitors. Platelet activation was evaluated by P-selectin expression using flow cytometry. Clot formation was assessed by rotation thromboelastometry.

Results: Selective signaling of Gαq or Gαi but not Gα12/13 promoted P-selectin expression. Further increase in P-selectin expression was achieved by ADP-induced combined signaling of Gαq and Gαi and to more extent by combined signaling of Gαq and Gα12/13. The maximal P-selectin expression was achieved by TRAP-induced combined signaling of Gαq, Gαi, and Gα12/13. In ROTEM, selective activation of Gαq, Gαi, or Gα12/13 failed to affect blood clotting. Combined signaling of Gαq and Gαi or Gαq and Gα12/13 or all three G proteins shortened the clotting time and stimulated clot strength. Pretreatment of platelets with acetylsalicylic acid did not change the effect of ADP but inhibited the effect of TRAP. Signaling of Gαq and Gα12/13 triggered by U46619 (1.5 μM) also stimulated clot formation.

Conclusions: Combined signaling of either Gαq and Gαi or Gαq and Gα12/13 stimulates maximal platelet activation and clot formation in platelets treated with inhibitor of integrin αIIbβ3. It could be suggested that outside-in signaling is not necessarily required to fulfill these platelet functions.

PB 1338 | *In vitro* Assessment of Catecholamines to Restore Platelet Aggregation in the Presence of Ticagrelor and Aspirin

A.-C. Martin[1,2,3], T. Nunes[1,2], B. Decouture[1,2], P. Gaussem[1,2,4], A. Godier[1,2,5], C. Bachelot-Loza[1,2]

[1]Inserm UMR-S1140, Faculté de Pharmacie, Paris, France, [2]Université Paris Descartes, Sorbonne Paris Cité, Paris, France, [3]Hôpital d'Instruction des Armées Percy, Service de Cardiologie, Clamart, France, [4]AP-HP, Hôpital Européen Georges Pompidou, Service d'Hématologie Biologique, Paris, France, [5]Fondation Rothschild, Service d'Anesthésie-Réanimation, Paris, France

Background: Ticagrelor, a $P2Y_{12}$ antagonist increases bleeding. No antidote is available and platelet transfusion is probably ineffective. However, catecholamines, epinephrine (EPI) and norepinephrine (NOR) activate platelets, thus could be considered to restore antiplatelet agents-induced platelet inhibition.

Aims: To assess *in vitro* the efficacy of EPI and NOR to restore platelet aggregation in the presence of ticagrelor and aspirin (ASA).

Methods: Platelet rich plasma (PRP) from volunteers was incubated with ticagrelor (n=16) or ASA (n=16). Platelet aggregation (spectrophotometry-based technique) was assessed using various agonists: ADP (2μM), EPI (1nM to10μM) or NOR (1nM to 0.4mM), and a mix of ADP+EPI or ADP+NOR with ticagrelor, and arachidonic acid (AA) (1mM), EPI or NOR, and a mix of AA+EPI or AA+NOR with ASA. Results are expressed in percentage of maximal aggregation.

Results: Compared to control, ticagrelor and ASA inhibited ADP- and AA-induced platelet aggregation respectively (8 vs 60%, p< 0.01, 10 vs 95%, p< 0.01). EPI or NOR concentration-dependently induced platelet aggregation in samples incubated with ticagrelor. However, the level of aggregation didn't return to baseline corresponding to the ADP-induced aggregation in the absence of ticagrelor (38% and 40%, vs 60%, p< 0,01, respectively). A combination of EPI (1μM) or NOR (10μM), and ADP completely restored platelet aggregation, to a similar level as ADP-induced platelet aggregation in the absence of ticagrelor. Similar results were observed with ASA. Catecholamines also potentiated the effects of the other agonists: the resulting aggregation from catecholamines+ADP or AA was greater than the sum of the aggregation response induced by catecholamines and ADP or AA.

Conclusions: EPI and NOR, in combination with ADP or AA, completely restored *in vitro* platelet aggregation in the presence of ticagrelor or ASA, respectively. Thus, EPI and NOR could potentiate the effects of ADP and TXA2 *in vivo* and thereby circumvent the effects of ticagrelor and ASA.

PB 1339 | Emerging Role for TLT-1 at the Interception of Inflammation and Hemostasis

J. Morales[1], F. Reyes[2], F. Staback[1], O. Santiago[3], A. Pacheco[1], C. Con Yost[4], M. Rondina[5], A. Washington[1]

[1]*University of Puerto Rico, Biology, San Juan, United States,* [2]*University of Puerto Rico, Medical Sciences Campus, San Juan, United States,* [3]*Ponce Medical School, School of Medicine, Ponce, United States,* [4]*University of Utah School of Medicine, Department of Pediatrics/Neonatology and Molecular Medicine, Salt Lake, United States,* [5]*University of Utah School of Medicine, Department of Medicine, Salt Lake, United States*

Background: TREM like transcript 1 (TLT-1) is a membrane receptor released from platelet α-granules upon activation. *Treml1*$^{-/-}$ mice bleed in response to various immune challenges where their wild type (WT) counterparts do not.

Aims: This study aims to evaluate TLT-1's role in the modulation of inflammatory associated hemorrhage.

Methods: We used an acute lung injury model, transmigration assays, and the cremaster muscle model to evaluate TLT-1 function.

Results: Using a LPS derived acute lung injury model we can demonstrate that administration of lipopolysaccharide (LPS:10µg) by nasal inhalation causes bleeding in the lungs, delayed neutrophil transmigration, but increased neutrophil accumulation in the bronchoalveolar lavage of mice suggesting that the neutrophils from *treml1*$^{-/-}$mice may cause the bleeding problems at the endothelial barrier (n=16,p≤0.01). To evaluate neutrophil function, we used whole mount staining of the cremaster muscle treated with CXCL2. Our results demonstrate that neutrophils from *treml1*$^{-/-}$mice accumulate at the endothelial barrier where their WT counterparts transmigrate, supporting the idea that these neutrophils are delayed in transmigration (n=10, p≤0.001). *In vitro* transmigration assays using neutrophils from WT or *treml1*$^{-/-}$mice with platelets from *treml1*$^{-/-}$mice platelets demonstrate that these platelets have difficulty in releasing from the transmigrated neutrophil and increased cell death as confirmed by flow cytometry and propidium iodine staining (p≤0.001). Those neutrophils (WT and *treml1*$^{-/-}$mice) incubated with WT platelets transmigrate alone and with a greater survival percentage. Moreover, addition of soluble TLT-1 intra venously protected mice from inflammatory associated hemorrhage in the lung upon nasal LPS challenge (n=18, P< 0.001).

Conclusions: These data suggest a potential role for TLT-1 in mediating platelet derived modulation of inflammatory associated bleeding.

PB 1340 | Uptake of Influenza Virus by Platelets Occurs via Sialic Acid Binding

A.J.G. Jansen[1,2], H. Low[3], J. van den Brand[4], D. van Riel[4], A. Osterhaus[3], E. van der Vries[3]

[1]*Erasmus Medical Center, Department of Hematology, Rotterdam, The Netherlands,* [2]*Sanquin-AMC Landsteiner Laboratory, Plasma Proteins, Amsterdam, The Netherlands,* [3]*University of Veterinary Medicine Hannover, Research Center for Emerging Infections and Zoonoses, Hannover, Germany,* [4]*Erasmus Medical Center, Department of Viroscience, Rotterdam, The Netherlands*

Background: Thrombocytopenia is a common symptom during influenza virus infection. We have recently shown that influenza A/H1N1 virus load is significantly correlated with a lower platelet count.

Aims: In this study, the relationship between platelets and influenza infection was studied further *in vivo* and *in vitro*.

Methods: To study influenza induced thrombocytopenia *in vivo*, 120 ferrets were inoculated intratracheally (1x10E6 TCID50) with an influenza A/H3N2 (n=30), A/H1N1 (n=30), or A/H5N1 virus (n=30). Platelet counts were measured at day 1-4. To assess direct platelet influenza virus interaction *in vitro* electron microscopy was performed on isolated human platelets incubated for 1 minute with influenza virus (A/PR/8/34). Additionally, platelet characteristics after virus uptake were measured, including membrane expression of the GPIb-IX-V complex, CD62P, surface sialic acid and GlcNac using flowcytometry and functional capacity employing aggregometry using agonists collagen, thrombin and ADP. Finally influenza virus uptake was measured in platelets after neuraminidase treatment.

Results: All ferrets had thrombocytopenia at day 3 post infection. The decrease in platelet count was significant in the A/H5N1 infected ferrets (p< 0.05). In these animals, influenza virus antigen was also detected in the liver and spleen at day 3 after infection. By electron microscopy we observed platelets with virus containing vacuoles, suggesting that platelets had rapidly phagocytosed the virus. Uptake of influenza virus had no effect on expression of GPIba, GPIX, P-selectin, surface sialic acid and GlcNAc or functional capacity of these platelets. Finally, desialylated platelets could not take up influenza virus.

Conclusions: Our study shows that sialic acid is essential for uptake of influenza by platelets. This mechanism may play an important role in the occurrence of thrombocytopenia during influenza infection and may be part of the host response mechanism by which viruses are cleared in the liver.

PB 1341 | Platelets Express and Release Immune-modulatory CXCL14 upon Activation

A. Witte, J. Lu, M. Gawaz

Universitätsklinikum Tübingen, Medizinische Klinik III, Kardiologie, Tübingen, Germany

Background: Platelets are the source of a variety of chemokines with immune-modulatory activity. The chemokine CXCL14 is expressed in immune cells with pro-inflammatory atherogenic impact. Expression of CXCL14 in platelets was unexplored.

Aims: The current study investigated whether platelets express and release CXCL14 upon activation. Furthermore a possible autocrine, immune-modulatory paracrine function of platelet derived CXCL14 was explored.

Methods: Flow cytometry, immunoblot, ELISA, monocyte migration, phagocytosis, and endothelial scratch assays (HUVECs) were performed.

Results: Western Blot analyses show that human as well as murine platelets express the chemokine CXCL14. Upon activation with

agonists CXCL14 surface expression and milieu release were significantly enhanced on human platelets. Furthermore, activation of platelets with increasing concentrations of Collagen Related Peptide (CRP) corresponded with CXCL14 surface expression. Recombinant (r) CXCL14 had no effect on agonist induced platelet activation. CXCL14 is chemotactic for $CD14^+$ monocytes. Currently we observed that CXCL14 present in activated platelet supernatant induced monocyte migration, counteracted upon CXCL14 neutralization with a neutralizing antibody. Moreover, blocking the chemokine receptor CXCR4, but not CXCR7 reduced the number of migrated monocytes towards rCXCL14, suggesting the involvement of CXCR4 in the CXCL14 directed monocyte chemotaxis.

In addition, a scratch assay with HUVECs indicates that platelet-derived CXCL14 counteracts the angiogenic effect of VEGF on these endothelial cells, which might be of importance during wound healing and angiogenesis.

Conclusions: Platelets are a hitherto unrecognized source of CXCL14 and release it upon activation. Platelet derived CXCL14 induces monocyte migration and counteracts the angiogenic effect of VEGF on HUVECs.

PB 1342 | CD8 T Cells Are Important Mediators of Platelet Refractoriness

C. Maier[1], S. Patel[1], C. Arthur[1], A. Bennett[2], A. Duncan[1], S. Stowell[1]

[1]*Emory University School of Medicine, Atlanta, United States*, [2]*Emory University, Atlanta, United States*

Background: Platelet refractoriness remains a significant clinical problem, yet the mechanisms by which it occurs are multifactorial and incompletely understood. Immune-mediated platelet clearance by anti-platelet alloantibodies plays a significant role, and patients with detectable alloantibodies can be managed with transfusion of HLA-matched platelets. Still, many patients are platelet refractory even after receiving HLA-matched platelets. We have previously shown that CD8 T cells play a direct role in platelet clearance. Allogeneic platelets are cleared within 24 hours post transfusion in B cell-deficient μMT recipient mice (ie in the absence of anti-platelet alloantibodies), whereas syngeneic platelets are not. Platelet clearance is dependent on CD8 T cells, as CD8 depletion, but not NK cell depletion, prevents clearance.

Aims: However, whether minor antigen differences can mediate CD8 T cell-dependent platelet clearance remains unknown.

Methods: To test this possibility we examined platelet refractoriness using mOva and OT I transgenic mice.

Results: We found that transfusion of mOva platelets into OT I mice, whose CD8 T cell receptors recognize a specific ovalbumin peptide in the context of MHC class I H2Kb, results in significant platelet clearance as compared to transfusion with wildtype platelets. Clearance kinetics demonstrate platelet loss starting at 8 hours and peaking at 24 hours, and are similar whether OT I mice are naïve or previously primed with mOva splenocytes. In addition, OT I CD8 T cells show increased expression of activation markers at 24 hours post transfusion. Mechanistic studies examining the role of common cell-mediated cytolytic molecules, such as perforin and granzyme, are underway.

Conclusions: This work extends the ability of CD8 T cells to mediate platelet clearance to a minor antigen, providing insight into the mechanisms underlying platelet refractoriness with significant implications for treatment of non-antibody-mediated platelet clearance.

PB 1343 | Endothelial Expression of TLT-1 Binding Pockets Mediate Platelet-endothelial Interaction, Leukocyte Transmigration, and Angiogenesis

Y. Ferrer-Acosta[1], J. Morales[1], K. Lugo-Citron[1], J. Thon[2,3], B. Madera[1], A.V. Washington[1]

[1]*University of Puerto Rico, San Juan, Puerto Rico*, [2]*Bingham and Women's Hosptial, Boston, United States*, [3]*Harvard Medical School, Boston, United States*

Background: Trem like transcript (TLT)-1 is one of the most abundant platelet proteins, yet its true function remains an enigma. TLT-1 is a receptor, stored in the a-granules, and expressed and released as a soluble fragment (sTLT-1) upon activation.

Aims: Our recent characterization of TLT-1 antibodies showed that a greater amount of TLT-1 co-localized with pro-angiogenic VEGF-containing (31±9%) than anti-angiogenic endostatin-containing α-granules (8±4%), leading to the hypothesis that TLT-1 has angiogenic properties

Methods: To test this, we used HUVECs to demonstrate that sTLT-1 mediates filopodia formation and actin polymerization when compared to control proteins and that labeled sTLT-1 can be up-taken into the early endosomes as denoted by co-localization with the early endosomal marker EEA where labeled BSA is not.

Results: The functional consequences of sTLT-1 interactions with endothelial cells (ECs) were demonstrated by a marked increase of IL-6 ($p \leq 0.005$) and IL-8 ($p \leq 0.0005$) compared to controls. Soluble TLT-1 also markedly increased angiogenic structures of endothelial cells ($p \leq 0.005$). Both the increased cytokine production and angiogenic features induced by sTLT-1 were reversed in the presence of anti-TLT-1, suggesting that TLT-1 mediates EC activation. *In vivo* evaluation using the *treml1*$^{-/-}$ mouse and a Lewis Lung Carcinoma model demonstrated that while no growth differences were witnessed, *treml1*$^{-/-}$ mice (n=12) demonstrated greater survival compared to wild type (*wt*; n=13; 66.6% verse 23.1%; p≤0.023). *Treml1*$^{-/-}$ mice demonstrated a dramatic absence in pecam staining compared *wt* mice (7% vs 1% of total area). The addition of anti-TLT-1 to *wt* mice markedly decreased vessel formation while sTLT-1 significantly increased vessel formation in null mice, suggesting that TLT-1 affects the endothelium *in vivo*.

Conclusions: Use of a TLT-1 fc chimera demonstrates that endothelial cells express TLT-1 binding sites allowing us to conclude that ECs recruit platelets to mediate their function.

PB 1344 | Extracellular Vesicles from Activated Platelets: A Quantitative Cryo-electron Microscopy and Immuno-Gold Labeling Study

A. Brisson[1], S. Tan[1], R. Linares[1], C. Gounou[1], S. Mornet[2]

[1]University of Bordeaux, UMR-CBMN, Pessac, France, [2]UPR-ICMCB, Pessac, France

Background: Upon activation, blood platelets release two types of extracellular vesicles (EV), namely µm-large EV named microparticles characterized by the presence of phosphatidylserine (PS) at their surface, which supports their role in hemostasis and in thrombosis[1], and small EV (50-100 nm) called exosomes characterized by the exposure of CD63[2].

Aims: This study aims at providing a quantitative description of the size, phenotype and relative amount of PS+, CD41+ and CD63+ EV, using cryo-electron microscopy (EM) and immuno-gold labeling[3].

Methods: Peripheral blood was collected over citrate from four healthy adult donors after informed consent. Activation of platelet rich plasma (PRP) was performed with thrombin, TRAP and CRP-XL. Gold nanoparticles conjugated with annexin-5 or with anti-CD41 or anti-CD63 antibodies were synthesized to label PS+ EV, platelet-derived EV and CD63+ EV, respectively[3]. Cryo-EM was performed as described[3].

Results: EV activated by the three agonists presented a similar size distribution, about 50% of them ranging from 50 to 400 nm. About 60% EV were found to expose CD41, a majority of them exposing also PS. Several mechanisms of EV formation are proposed to explain the presence of large amounts (40%) of CD41-negative or PS-negative EV of large size, as well as large EV containing organelles, principally mitochondria or granules[4] .

In addition, we found that the majority of EV in activated platelets exposed CD63. Two populations of CD63+ EV were distinguished, namely large EV with low labeling density and small EV, likely the exosomes, with high labeling density.

Conclusions: This study provides an unprecedented description of EV from activated platelets.

PB 1345 | Renal Denervation Decreases the Platelet Activation Status in Hypertensive Patients

M.T.K. Zaldivia[1,2], D. Hering[3,4], P. Marusic[3,4], Y. Sata[4], R. Lee[4], M. Esler[4], N. Htun[1], J. Duval[4], L. Hammond[4], U. Flierl[1], M. Schlaich[3,4], K. Peter[1,2]

[1]Baker Heart and Diabetes Institute, Atherothrombosis and Vascular Biology, Melbourne, Australia, [2]Monash University, Department of Medicine, Melbourne, Australia, [3]University of Western Australia, School of Medicine and Pharmacology - Royal Perth Hospital Unit, Perth, Australia, [4]Baker Heart and Diabetes Institute, Neurovascular Hypertension and Kidney Disease, Melbourne, Australia

Background: Hypertension is associated with increased arterial thrombotic events. Increased shear stress and sympathetic tone can affect platelet activity, a key player in the pathophysiology of atherothrombotic complications. Renal denervation (RDN) reduces sympathetic activity and blood pressure (BP) in patients with resistant hypertension. However, its effect on platelet activity has not been investigated.

Aims: To determine whether RDN-induced reduction in sympathetic nerve activity affects platelet activation in patients with hypertension.

Methods: Ambulatory BP, and platelet activation markers P-selectin expression, glycoprotein αIIbβ3 (GPIIb/IIIa) activation (binding of antibody Pac-1), monocyte-platelet aggregate formation (MPA) and soluble P-selectin were measured at baseline, 3 months, and 6 months after RDN in 41 patients.

Results: RDN significantly reduced ambulatory BP at 3 months (150.6±11.2 / 81.0±11.3 mmHg to 144.7±11.8 / 77.9±11.0 mmHg; $P< 0.05$), which was sustained at 6 months (144.7±13.8 / 78.6±11.1 mmHg; $P< 0.05$). Expression of P-selectin on the platelet membrane, the most sensitive platelet activation marker, significantly decreased at 3 months ($P< 0.05$) and 6 months ($P< 0.05$), indicative of a reduction in platelet activation. Soluble P-selectin was also reduced at 3 months ($P< 0.05$) and 6 months ($P< 0.05$). MPA was reduced at 3 months ($P< 0.05$) after RDN. The GPIIb/IIIa activation status showed a non-significant trend of reduction. Notably, patients who received aspirin as part of their medication regime did not show reduction in P-selectin expression following RDN.

Conclusions: Our results indicate that RDN can effectively reduce BP and at the same time have an additional beneficial effect on platelet activation. In patients on aspirin medication, RDN does not show further reduction of the platelet activation status. These results provide additional mechanistic explanations by which RDN can have favourable results in reducing cardiovascular complications.

PB 1346 | Upregulation of Inflammatory Transcripts in Platelets of Patients with Nonalcoholic Fatty Liver Disease (NAFLD): Role of Platelets in the „Inflammatory Network“ of NAFLD

M.A. Alberelli[1], L. Miele[2], G. Marrone[2], A. Liguori[2], M. Biolato[2], R. Landolfi[3], A. Gasbarrini[2], A. Grieco[2], E. De Candia[4]

[1]Fondazione Policlinico Universitario A. Gemelli, Catholic University of Rome, Area of Haematology/Oncology, Rome, Italy, [2]Fondazione Policlinico Universitario A. Gemelli, Catholic University of Rome, Internal Medicine and Gastroenterology Area, Rome, Italy, [3]Fondazione Policlinico Universitario A. Gemelli, Catholic University of Rome, Internal Medicine and Emergency Area, Rome, Italy, [4]Fondazione Policlinico Universitario A. Gemelli, Catholic University School of Medicine, Area of Haematology/Oncology, Rome, Italy

Background: Non alcoholic fatty liver disease (NAFLD) and non alcoholic steatohepatitis (NASH) are associated with a significant increase of cardiovascular events that represent the major cause of mortality. The presence of a systemic proinflammatory/prothrombotic state, contributing to the cardiovascular events, has been hypothesized in these diseases.

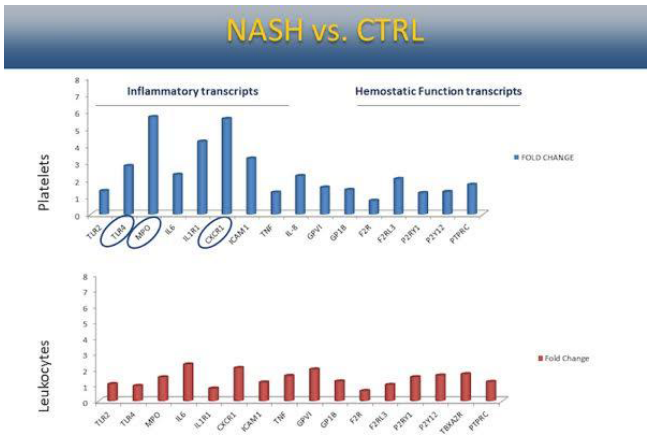

FIGURE 1 Fold changes of inflammatory and hemostatic transcripts in NASH vs controls. a) platelet b) leukocytes

Aims: The aim of this study was to assess whether chronic inflammatory stimuli in NAFLD are associated with proinflammatory/prothrombotic changes in platelets by investigating the expression of platelet inflammatory and hemostatic transcripts.

Methods: Twenty patients with histologic diagnosis of NASH, 10 patients with NAFLD and 15 healthy volunteers were recruited. The differential expression of hemostatic (GPVI, GPIB, F2R, F2RL3, P2Y1, P2Y12, TBXA2R) and of inflammatory transcripts (TLR2, TLR4, IL6, IL1R1, MPO, CXCR1-the IL8 receptor-, ICAM1, TNF) was investigated in platelets of patients and controls. Plasma levels of inflammatory cytokines TNF-alpha, leptin, IL6 and LPS were measured in the three groups.

Results: NASH patients had increased expression of CXCR1, TLR4, ICAM1, MPO and IL1R1 platelet inflammatory transcripts compared to controls. Expression of CXCR1 was significantly increased in NASH compared to NAFLD patients. The hemostatic transcripts of platelets were similar in the three populations. Surprisingly, the inflammatory transcripts were unchanged in leukocytes of NAFLD and of NASH subjects compared to controls. Plasma markers of inflammation, such as leptin and IL6, and plasma LPS levels were significantly higher in NASH and NAFLD patients compared to controls.

Conclusions: In NASH patients a pro-inflammatory phenotype of platelets was associated with elevation of systemic inflammatory markers and of LPS, suggesting that platelets play a role in the inflammatory network of the disease. The platelet pro-inflammatory phenotype might represent a link between inflammation and increased cardiovascular risk of NAFLD.

PB 1347 | Characterization of PF4-heparin Complexes by Photon Correlation Spectroscopy and Zeta Potential

S. Bertini[1], J. Fareed[2], L. Madaschi[1], G. Risi[1], G. Torri[1], W. Jeske[3], A. Naggi[1]

[1]Institute for Chemical and Biochemical Research, G Ronzoni, Milan, Italy, [2]Loyola University Medical Center, Maywood, United States, [3]Loyola University Medical Center, Thoracic and Cardiovascular Surgery, Maywood, United States

Background: Heparin-induced thrombocytopenia (HIT) is associated with antibodies to complexes between heparin and platelet factor 4 (PF4). HIT antibodies preferentially recognize macromolecular complexes formed between PF4 and polyanionic heparins over a limited range of molar ratios.

Aims: To investigate the complexes that human PF4 forms with heparins from various species and organs, along with different low molecular weight heparins (LMWHs) at several stoichiometric ratios to evaluate their sizes and charges by Photocorrelation Spectroscopy and Zeta Potential.

Methods: PF4, from human platelets (hPF4), was purchased from ChromaTec, Greifswald, Germany. The porcine heparin, Medefil (Glendale Heights, IL), Bioiberica (Barcelona, Spain) and Hepalink (Shenzhen, China), LMWH included enoxaparin (Sanofi Aventis, Paris, France) Lovenox; tinzaparin, (LEO-Pharma, Ballerup, Denmark) and dalteparin, (Pharmacia AB, Uppsala, Sweden). Bovine mucosal heparin was provided by Bioiberica (Madrid, Spain). Ovine heparin was provided by Kin Master (Passo Fundo -RS, Brazil). The pentasaccharide (fondaparinux) was from GlaxoSmithKline (Verona, Italy).

Results: The resulting data of the PF4 complexes with heparins (UFHs), LMWHs and their fractions, and components suggest that the size of aggregates is not only a simple function of average molecular weight (MW) but also of the MW distribution. At lower concentrations, ovine mucosal heparin formed large PF4/heparin complexes as compared to porcine and bovine heparin.

Conclusions: Generally the largest complexes occur at the molar ratios that lead to charge neutralization. Discrepancies are observed when samples are too small to bind more than one molecule of PF4 as in case of oligomers smaller than decasaccharides or when, because of polydispersion of the MW, small chains compete with longer chains for binding to PF4. The size of the aggregate is not a simple function of average MW but it is also affected by the MW distribution of the sample.

PB 1348 | Acetylsalicylic Acid Differentially Limits Activation and Apoptosis of Human Platelets Exposed to Various Staphylococcus aureus Strains

A. Chabert[1], P. Damien[1], P.O. Verhoeven[1,2], F. Grattard[1,2], P. Berthelot[1,2], F. Zeni[1,3], L. Panicot-Dubois[4], S. Robert[4], F. Dignat-George[4], M.-A. Eyraud[5], B. Pozzetto[1,2], B. Payrastre[6], F. Cognasse[1,5], O. Garraud[1,7], H. Hamzeh-Cognasse[1]

[1]Université de Lyon, EA 3064 - GIMAP, Saint-Etienne, France, [2]CHU de Saint-Etienne, Laboratoire des Agents Infectieux et d'Hygiène, Saint-Etienne, France, [3]CHU de Saint-Etienne, Service Réanimation Polyvalente, Saint-Etienne, France, [4]Université Aix Marseille, INSERM UMR-S 1076, VRCM, Marseille, France, [5]French Blood Establishment (EFS) Rhône - Alpes - Auvergne, Scientific Dpt, Saint-Etienne, France, [6]I2MC, Inserm/UPS UMR 1048, Toulouse, France, [7]INTS - Institut National de la Transfusion Sanguine, International Affairs, Paris, France

Background: In addition to their haemostatic functions, platelets alter their inflammatory response according to the bacterial stimulus. *Staphylococcus aureus* is associated with exacerbated inflammation

during sepsis and poor prognosis as it induces thrombocytopenia. Acetylsalicylic acid and statins are active against platelet aggregation and decrease the mortality rate in sepsis patients.

Aims: Therefore, it is crucial to investigate these molecules, which have antiplatelet activities and protect platelets exposed to *S. aureus*, to limit thrombocytopenia and inflammatory responses.

Methods: Platelets were exposed to live clinical and reference strains of *S. aureus* in the presence or absence of acetylsalicylic acid or fluvastatin. Platelet viability, expression of activation markers, aggregation, and release of soluble CD62P, soluble CD40L, RANTES and GROα, which are the major pro-inflammatory platelet factors, were assessed. Apoptosis was evaluated by analyzing mitochondrial membrane potential, phosphatidylserine exposure and platelet microparticle release.

Results: All *S. aureus* strains induced platelet activation (increased expression of CD62P and CD63) and the release of RANTES and GROα; however, none altered platelet aggregation. Staphylococcal strains triggered platelet death via a decrease in the mitochondrial membrane potential and an increase in phosphatidylserine exposure, but no changes in platelet microparticle formation were found. We next observed that acetylsalicylic acid, but not fluvastatin, limited platelet activation and inflammatory factor release and restored platelet count by protecting platelets from *Staphylococcus*-induced apoptosis.

Conclusions: This study demonstrates that acetylsalicylic acid limits several of the effects induced by clinical strains of *S. aureus* on platelets in vitro. These results suggest new strategies to prevent bacteremia associated-inflammation.

PB 1349 | Tyrosine Kinase Inhibitor Pazopanib Inhibits Platelet Procoagulant Activity in vitro and in Renal Cell Carcinoma Patients

B.M.E. Tullemans[1], M. Nagy[1], S. Sabrkhany[2], M.G.A. Oude Egbrink[2], M.J. Aarts[3], J.W.M. Heemskerk[1], M.J.E. Kuijpers[1]

[1]*Maastricht University / Cardiovascular Research Institute Maastricht (CARIM), Biochemistry, Maastricht, The Netherlands,* [2]*Maastricht University / Cardiovascular Research Institute Maastricht (CARIM), Physiology, Maastricht, The Netherlands,* [3]*Maastricht University Medical Center +, Medical Oncology, Maastricht, The Netherlands*

Background: Pazopanib is an oral tyrosine kinase inhibitor (TKI) used for cancer treatment. Mild bleeding has been reported in patients treated with pazopanib.

Aims: As tyrosine kinases are essential for platelet signaling, the effects of pazopanib on platelet function were investigated in vitro and in renal cell carcinoma (RCC) patients.

Methods: Whole blood, platelet-rich plasma or isolated platelets from healthy volunteers (controls) were incubated with pazopanib or vehicle. In addition, blood was obtained from 6 patients diagnosed with metastatic RCC, both before and at 14 days on-treatment with pazopanib. Light transmission aggregometry, whole blood perfusion over collagen, flow cytometry, western blotting, and changes in $[Ca^{2+}]_i$ were measured.

Results: In control platelets, pazopanib reduced collagen- and ADP-receptor induced integrin activation and secretion, as well as aggregation and rises in $[Ca^{2+}]_i$, accompanied by diminished GPVI-dependent tyrosine phosphorylation of multiple proteins. After whole blood perfusion over collagen at high shear rate, thrombus height, size and phosphatidylserine (PS) exposure were reduced by pazopanib. Reduced GPVI-induced PS exposure by pazopanib was confirmed by flow cytometry. Pazopanib treatment
(14 days) moderately, but significantly decreased platelet count in the patients. In blood from patients on-treatment, thrombus formation under flow was altered by a marked reduction in PS exposure with limited effects on thrombus height and size.

Conclusions: Administration of pazopanib in vitro suppresses key GPVI-induced platelet activation responses, including thrombus formation, tyrosine phosphorylation, $[Ca^{2+}]_i$ rises and PS exposure. In treated cancer patients, pazopanib effects are confined to a reduction in GPVI-dependent PS exposure. Together with the mild reduction in platelet count, this may contribute to the higher bleeding tendency observed in patients treated with this TKI.

PB 1350 | Tunable Activation of Therapeutic Platelet-Rich Plasma by Pulse Electric Fields: Differential Effects on Clot Formation, Growth Factor Release and Platelet Morphology

A.J. Gerrits[1], V.B. Neculaes[2], T. Gremmel[1,3], A.S. Torres[2], A. Caiafa[2], S.L. Carmichael[1], A.D. Michelson[1], A.L. Frelinger III[1]

[1]*Boston Children's Hospital, Dana-Farber Cancer Institute, Harvard Medical School, Center for Platelet Research Studies, Division of Hematology/Oncology, Boston, United States,* [2]*GE Global Research Center, Niskayuna, United States,* [3]*Medical University of Vienna, Department of Internal Medicine II, Vienna, Austria*

Background: Activation of platelet-rich plasma (PRP) by pulse electric fields (PEFs) produces gels and releases growth factors which promote wound healing.

Aims: To determine the parameters of platelet gel strength and the profile of released factors following activation of PRP with different PEF conditions and characterize the mechanism of PEF-induced factor release.

Methods: Concentrated PRP from normal donor blood (n=5) was activated by different PEFs (condition A or B) in the presence of $CaCl_2$. Clot formation was evaluated by thromboelastography (TEG), platelet surface exposure of markers of degranulation of α-granules (P-selectin) and T-granules (TLR9 and protein disulfide isomerase [PDI]) by flow cytometry, growth factors and soluble PDI by ELISA and morphology by transmission electron microscopy (TEM).

Results: By TEG, time to initial clot formation was shorter with thrombin (< 1 min) than with PEF A (4.4 min) and B (8.7 min, $p < 0.05$), but clot strength was greater with PEF B (80.7 mm) than with either thrombin (40.9 mm) or PEF A (40.6 mm, $p < 0.05$). Supernatants of PRP activated with PEF A had higher epidermal growth factor (EGF) levels than supernatants from all other conditions. Platelet surface TLR9 and PDI were higher after thrombin than after PEF A or B, whereas

the supernatant contained higher levels of PDI after PEF A than after thrombin. By TEM, platelets in PEF-treated samples had a distinct morphology and retained a subset of granules.

Conclusions: PEF conditions can be modulated to produce therapeutic platelet gels as strong or stronger those produced by thrombin, and this is tunable to produce growth factor profiles enhanced in specific factors important for different stages of wound healing. Moreover, the distinct morphology and the pattern of growth factor release suggest PEF initiates regulated release of contents rather than mechanical fracturing.

PB 1351 | Bacteria Educated Platelets (BEPs) - Altered RNA expression in Human Platelets Induced by Gram Negative Bacteria

A.V. Fejes[1], W.A. van der Heijden[2], M.G. Best[3], A. Vancura[3], Q. de Mast[2], T. Wurdinger[3], C. Mannhalter[1]

[1]Medical University of Vienna, Vienna, Austria, [2]Radboud University Medical Center, Nijmegen, The Netherlands, [3]VU University Medical Center, Amsterdam, The Netherlands

Background: Blood platelets contain ~9500 different mRNAs, different classes of non-coding RNAs and ~ 16 kb mitochondrial DNA. They are unable of de novo gene transcription, but contain mRNA splicing and translation machinery to produce functional proteins.

Aims: The aim of the study was to analyze the platelet transcriptome following exposure to E.coli bacteria, paying specific attention to changes, that could have a functional effect.

Methods: Citrated blood of healthy donors (n=4) was used to isolate platelets by OptiPrep density gradient centrifugation. Washed platelets were incubated with the non-pathogenic E. coli K12 and the pathogenic E.coli O18 strain in 1:5 or 1:1 platelet to bacteria ratio for 3 hours. Platelet RNA was isolated by the Trizol method and sequenced on the Hiseq 2500 Illumina platform. Platelet surface proteins were analyzed by flow cytometry on BD FACSCalibur using anti-CD41-APC, anti-P-selectin and anti- CD63 antibodies.

Results: Analysis of the intron-spanning reads (log counts per million > 3) allowed the identification of 136 genes that were differentially expressed in the K12 treated platelets, compared to the control ones. In the O18 treated platelets the expression of 176 genes was affected. (P-value < 0.05). Thirty-two genes overlapped between the two strains, the rest of them was strain specific. Most RNAs show a 4-8 log-fold decrease. Different RNA entities were affected by lower and high bacteria concentrations. Evaluation of pre-mRNA splicing is in progress in addition to detailed pathway analysis.

By flow cytometric analysis we found, that incubation of platelets (ratio 1:5) with K12 shows higher P-selectin level on the surface than after O18 incubation (~20 vs.~13%).

Conclusions: Pathogenic and non-pathogenic E.coli strains have common as well as strain specific effects on the platelet transcriptome. The effect is also dependent on the platelet to bacteria ratio. This could be an indication of a different role of platelets when exposed to lower or large number of bacteria.

PB 1352 | Ascorbic Acid on Platelet Activation. New Functions for an Old Drug

P.C. Ivani[1,2], M. Schattner[1], S. Suarez[2], M.A. Marti[2], R.G. Pozner[1,2]

[1]Institute of Experimental Medicine - CONICET/National Academy of Medicine, Ciudad Autonoma de Buenos Aires, Argentina, [2]Universidad de Buenos Aires, Facultad de Ciencias Exactas y Naturales, Quimica Biologica, Ciudad Autonoma de Buenos Aires, Argentina

Background: Early studies have shown that ascorbic acid (Asc), inhibits platelet (Plt) by reducing the levels of reactive oxygen species. However, recent studies revealed that excessive vitamin C consumption may aggravate cardiovascular diseases in susceptible populations.

Aims: We evaluated Plt responses at normal or low concentration of classical agonist.

Methods: Plt aggregation was quantified by LTA, fibrinogen binding and p-selectin externalization were evaluated by FACS. The level of HNO, an interesting reactive nitrogen specie, produced by Plt was determined by the classical spectral changes in a manganese(III) prophyrin and by a new HNO-selective electrode (based on a cobalt(II) porphyrin).

Results: Plt aggregation induced by AA 0.9mM or PAR1-AP 6μM were significantly inhibited when Asc 10mM was added to the aggregometer cuvette (49±10 or 24±9% of inhibition for AA or PAR1-AP, respectively). This effect was dependent on GPIIbIIIa activation, revealed by a similar inhibition of fibrinogen binding obtained in the presence of Asc. Moreover, p-selectin externalization was also abrogated by Asc. All the inhibitory effects on the Plt activation responses tested were dependent on the concentration of Asc.

Surprisingly, when Plt were stimulated with non-aggregating concentrations of the agonists, the presence of Asc resulted in an aggregatory response (60±5 or 45±6% of aggregation for AA 0.2mM or PAR1-AP 3μM, respectively, p< 0.05).

HNO was produced concomitantly with the aggregation induced by AA 0.9mM or PAR1-AP 6μM (290±20 or 216±36nM, respectively). Interestingly, the HNO production was significantly higher in the presence of Asc (963±146 or 980±126nM). However, HNO was not detected when Plt were stimulated by non-aggregating concentrations of agonists.

All these responses were dependent on the concentration of Asc.

Conclusions: Altogether, these results present Asc as a dual modulator for Plt aggregation and present evidence of HNO production in primary cell as a new endogenous negative regulator for Plt function.

PB 1353 | Lipopolysaccharide Do Not Affect Platelet Activation in vitro

A.S. Maiorov[1,2], T.O. Shepelyuk[2,3], A.N. Sveshnikova[1,2,4]

[1]Lomonosov Moscow State University, Faculty of Physics, Moscow, Russian Federation, [2]Center for Theoretical Problems of Physicochemical Pharmacology, Russian Academy of Sciences, Moscow, Russian Federation, [3]Lomonosov Moscow State University, Faculty of Fundamental Medicine, Moscow, Russian Federation, [4]National Scientific and Practical Centre of Pediatric Hematology, Oncology and Immunology named after Dmitry Rogachev, Moscow, Russian Federation

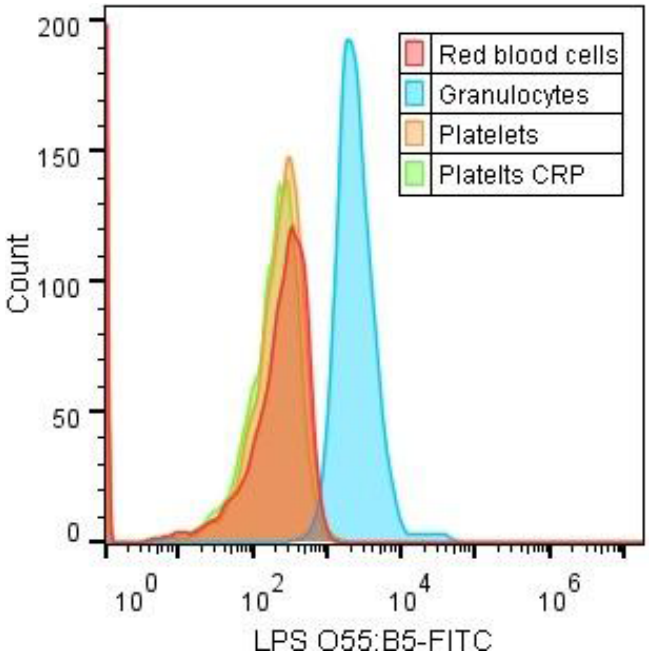

FIGURE 1 Binding of LPS by different cells

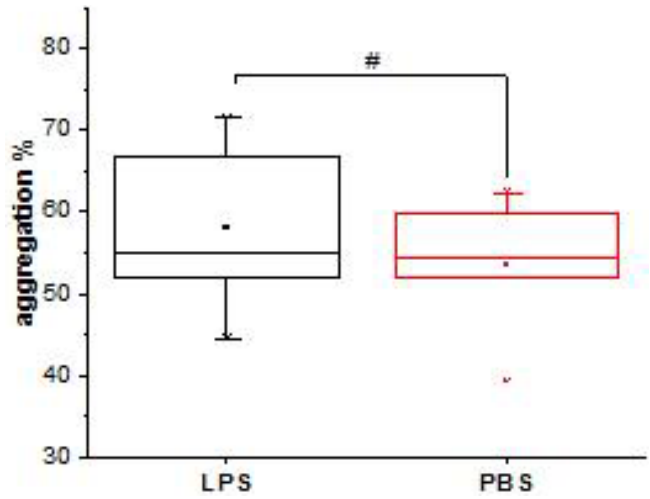

FIGURE 2 Aggregometry assay

Background: During severe infection bacteria get into the bloodstream where they can directly or indirectly influence coagulation system functioning. In the last decade many studies reported platelets interaction with bacteria through different pathways. One of the most controversial of them is activation of platelets through toll like receptor 4 (TLR4) by lipopolysaccharides (LPS) of gramnegative bacteria.

Aims: Throughout investigation of platelet pre-activation by bacterial endotoxins.

Methods: Platelet activation was assessed by aggregometry, spectrofluorimetry, flow cytometry and confocal microscopy of Fura-Red loaded platelets. Experiments were conducted with LPS O55:B5 or O111:B4 from Sigma. Also a non-pathogenic Escherichia coli XL was used as a model LPS-containing surface. Whole blood, platelet rich plasma (PRP) or washed platelets were incubated with 1-100 ug/ml LPS 0-2 hours with gentle mixing at room or body temperature prior to activation with 1-10 uM ADP or 0.03-10 ug/ml collagen related peptide. Computational modeling of platelet activation by LPS through TLR4 receptor was used to assess capabilities of this signaling pathway.

Results: LPS binding to platelets were not detected by flow cytometry (Fig.1). No significant difference of PRP treated/untreated with LPS was detected in aggregometry assay with ADP (Fig. 2). CRP - induced α- or δ-granule release, integrin activation or phosphatidylserine exposure were not significantly different for platelets incubated with LPS at all conditions. Platelets interaction with E.coli in confocal microscopy was not observed. Changes in form, behavior or cytosolic calcium concentration of immobilized on fibrinogen single platelets after incubation with LPS were not observed. Our calculations predict that due to very low concentration of soluble CD14 in healthy blood platelet activation by LPS should take up to 24 hours.

Conclusions: We are forced to conclude that there is no significant direct pre-activation of platelets by LPS in vitro.

PB 1354 | Intercellular Signalling between Platelets and a Myeloid Leukemic Cell Line

T. Iftikhar, C. Vial, M.P. Mahaut-Smith

University of Leicester, Molecular and Cell Biology, Leicester, United Kingdom

Background: Platelets play a role in cancer metastasis however the mechanisms whereby they modulate circulating tumour cells remains unclear.

Aims: To explore the intercellular signalling between human platelets and a human megakaryocytic/erythroleukemic cell line (HEL) via changes in the ubiquitous second messenger, intracellular Ca^{2+} ($[Ca^{2+}]_i$).

Methods: $[Ca^{2+}]_i$ responses were measured in fura-2-loaded stirred suspensions of HEL cells and platelets using dual excitation spectrofluorimetry. Measurements were made from a pure population of each cell type and in a mixed population in which only one cell type was loaded with fura-2. Extracellular ATP was measured using a luciferin-luciferase luminescence assay. P2 receptor expression was determined using quantitative PCR.

Results: Thrombin evoked a transient increase in $[Ca^{2+}]_i$ in both platelets and HEL cells. Following co-incubation, the platelet $[Ca^{2+}]_i$ increase was unaffected while the HEL cell response was significantly potentiated (2.2 ± 0.23 fold). PAM_3CSK_4 (Toll-like receptor 2/1 agonist) caused a $[Ca^{2+}]_i$ increase in HEL cells only when co-incubated with platelets. Both agonists evoked ATP release from platelets, but not HEL cells, over a time course that mirrored the enhanced Ca^{2+} responses. HEL cells showed robust $[Ca^{2+}]_i$ responses to both ADP and ATP and expressed multiple P2 receptor subtypes (P2X4>P2Y11>>P2X1>P2X7>P2X6>P2Y12>P2Y13>P2Y2). The platelet-dependent HEL cell responses were unaffected by inhibition of P2X1 with NF449 but significantly reduced by the P2Y11 antagonist NF157. An increase in type VII apyrase (0.32 to 3.2U/ml) converted the platelet-induced

HEL cell response into a biphasic response, which can be explained by conversion of ATP to ADP.

Conclusions: These experiments demonstrate synergistic interactions between platelets and a myeloid cancer cell line at the level of Ca^{2+} signalling. Release of ATP and ADP followed by activation of P2Y11 receptors can at least partially explain the underlying mechanism.

PB 1355 | An Optimized Protocol for Platelet Rich Plasma Preparation to Improve its Angiogenic and Regenerative Properties

J. Etulain[1], H.A. Mena[1], R.P. Meiss[2], S. Negrotto[1], M. Schattner[1]

[1]*Laboratory of Experimental Thrombosis, Institute of Experimental Medicine, CONICET-National Academy of Medicine, Capital Federal, Argentina,* [2]*Division Experimental Pathology, National Academy of Medicine, Capital Federal, Argentina*

Background: Although platelet rich plasma (PRP) is used for regenerative medicine as source of platelet-derived growth factors, its effectiveness remains controversial partially due to the absence of PRP preparation methods based on regenerative role of platelets.

Aims: We aimed to optimize PRP current protocols analyzing PRP dilution (to reverse the antiangiogenic effect of plasma factors); 4°C preincubation (as low T° increases platelet degranulation); and supplement with fibrin cryoprecipitate (as provisional matrix for regeneration) by evaluating angiogenic and regenerative responses. Optimization was compared with current PRP-preparation methods (37°C, no PRP dilution or supplements).

Methods: PRP pure or 25% diluted with saline, incubated at 37 or 4°C 30min, with or without supplementation with cryoprecipitate from frozen plasma were activated with $CaCl_2$ (22mM). Then, supernatants were used to induce: angiogenesis *in vitro* (HMEC-1 proliferation, migration and tubule formation), *in vivo* (chorioallantoic membrane, CAM) and skin mice regeneration of full-thickness excisional wounds (perimeter closure and histology). ANOVA, n=6-12, P< 0.05.

Results: We found that plasma-free platelets supernatants induced higher angiogenesis than PRP. The antiangiogenic effect of plasma was decreased by diluting PRP (Table). Moreover, angiogenesis was improved by both PRP preincubation at 4°C and by cryoprecipitate supplementation (Table). Combination of optimizing variables exerted an additive effect increasing angiogenesis not only *in vitro*, but also *in vivo* (optimized-PRP, Table). Furthermore, optimized PRP treatment induced a faster (3-7 days) and more efficient skin mice wound repair (determined by wound closure, angiogenesis, and epidermal thickness and granulation tissue reduction) compared to non-optimized PRP (7-14 days).

Conclusions: Our findings indicate that 25% PRP dilution, 4°C preincubation and cryoprecipitate supplementation improve angiogenic and regenerative properties of PRP compared to current methods.

PB 1357 | Treatment of Patients with Autologous Platelet Rich Fibrin is Dependent on the Composition of Peripheral Blood Cells: Dental Implant Stability is Associated with Red Blood Cells and Not with Platelets

J.A. Remijn[1], S. Buis[1,2], A. Karanzai[2], J. Konings[3,4], P.G. de Groot[3], B. de Laat[3,4], J.E.I.G. Brouwers[2]

[1]*Gelre Hospitals, Clinical Chemistry and Hematology, Apeldoorn, The Netherlands,* [2]*Institute for Dental Implantology, Amersfoort, The Netherlands,* [3]*CARIM, Maastricht University, Synapse Research Institute, Maastricht, The Netherlands,* [4]*CARIM, Maastricht University, Department of Biochemistry, Maastricht, The Netherlands*

Background: Platelet Rich Fibrin (PRF) is a platelet-fibrin membrane clot clinically used to accelerate wound healing and bone regeneration. PRF membranes are prepared from the patient's own blood using a dedicated centrifugation protocol. In dental implantology PRF has been used to improve osseointegration of dental implants achieving implant stability.

TABLE 1 Angiogenesis mediated by supernatants from different PRP-preparation protocols

	Non-optimized PRP (100%, 37°C, without cryoprecipitate)	Washed Platelets	Diluted PRP (25%)	PRP (100%) 4°C preincubation	PRP (100%) supplemented with plasma cryoprecipitate	Optimized-PRP (diluted + 4°C preincubation + cryoprecipitate)
HMEC-1 Proliferation (pnpp)(in vitro)	1.7±0.2*	2.4±0.2*#	2.4±0.2*#	2.4±0.2*&	1.9±0.1*	4.2±0.2*Ŧ
HMEC-1 Migration (wound healing)(in vitro)	2.0±0.1*	4.0±0.5*#	3.5±0.3*#	2.5±0.3*	2.3±0.2*	5.1±0.3*Ŧ
HMEC-1 Tubule Formation (matrigel)(in vitro)	6.0±0.5*	8±1*#	8±1*#	6±1*	11±1*¥	12±1*Ŧ
CAM (in vivo) Blood vessel Branch Points	1.4±0.1*					2.4±0.2*Ŧ

Results are expressed as fold of unstimulated control. ANOVA n=6-12.*p<0.05 vs unstimulated; #p<0.05 vs PRP without dilution (or 100%); &p<0.05 vs 37°C; ¥p<0.05 vs without cryoprecipitate; Ŧp<0,05 vs non-optimized PRP.

Aims: We have introduced PRF for several years (N=250 patients) and we experience improved osseointegration of oral implants in patients treated with PRF. How PRF improves dental implantation is unknown and therefore we analyzed the influence of the composition of PRF on dental implant stability.

Methods: PRF membranes were prepared with different centrifugation protocols. The composition of PRF was analyzed with scanning electron microscopy. We included 90 patients to study the effect of blood cell- and fibrinogen levels on PRF. Correlation with clinical outcome was investigated in 20 patients by measuring the Implant Stability Quotient (ISQ) 17 weeks after treatment with PRF.

Results: We found that the PRF composition was influenced by the centrifugation method and the composition of peripheral blood cells. PRF membrane length was significantly inversely correlated to hemoglobin, hematocrit and erythrocytes, while leucocytes were not associated with PRF membrane length. PRF membrane length was increased with increased platelet count. Furthermore, we found that the ISQ value in patients, 17 weeks after implantation with PRF, was significantly correlated with increased red blood cells and not with fibrinogen, platelets and leukocytes.

Conclusions: The composition of PRF is significantly correlated to the composition of patient‘s blood. We show that red cell number was the dominant factor that determines implant stability. ISQ was not correlated with platelets, leukocytes and fibrinogen. Our findings give new insights into the mechanisms how PRF affects osseointegration and are the first steps to develop an optimal protocol for the use of PRF in oral implantology.

PB 2194 | Inhibitors of Apoptosis Signal-regulating Kinase 1 (MAP3K5), as Anti-thrombotic Agents

M. Naik[1], X. Chen[2], J. Wu[3], T. Stalker[3], D. Maloney[4], A. Jadhav[4], U. Naik[2]

[1]Thomas Jefferson University, Medicine, Philadelphia, United States, [2]Thomas Jefferson University, Philadelphia, United States, [3]University of Pennsylvania, Philadelphia, United States, [4]NIH National Center for Advancing Translational Sciences, Bethesda, United States

Background: Recently, we showed that ASK1 is rapidly activated by physiological agonists in human platelets. Ablation of *Ask1* gene results in impaired platelet functions making it an important target for thrombosis.

Aims: To evaluate the effect of two structurally distinct ASK1 inhibitors; IPTB and GS-4997 on thrombosis.

Methods: ASK1 activation was determined by western blotting. Tail bleeding or laser-induced injury was used to assess hemostasis. $FeCl_3$-induced arterial thrombosis and pulmonary thromboembolism were used as thrombosis models.

Results: We found that GS-4997 and IPTB dose-dependently (100nM-5mM) inhibited thrombin-induced ASK1 and its downstream effector p38 MAPK activation, aggregation, and spreading of human platelets as well as clot retraction. Pretreatment of the whole blood with these inhibitors significantly (P=0.001) reduced thrombus formation under arterial flow without affecting platelet adhesion to collagen. *In-vivo* thrombosis assay revealed that C57BL/6 mice injected with IPTB (100mg/kg) or GS-4997 (100mg/kg), showed a significantly increased time of occlusion (P=0.028 and P=0.005 respectively). Furthermore, IPTB or GS-4997 protected mice against collagen/epinephrine-induced pulmonary thromboembolism. Out of 26 saline-treated mice only 3 survived whereas, 10 out of 11 mice treated with GS-4997 (100mg/kg) survived (P=0.0002). In case of IPTB 9 out of 12 treated mice survived (P=0.0028). Interestingly, hemostasis assays revealed that C57BL/6 mice treated with IPTB (1mg/kg) or GS-4997 (1mg/kg), had no effect on bleeding time or platelet accumulation as observed by tail bleeding or laser-induced injury model respectively, suggesting that both inhibitors had no effect on *in-vivo* hemostasis.

Conclusions: Our results strongly suggest that both IPTB and GS-4997 protect the mice from thrombosis without affecting hemostasis. Further development of these inhibitors as a potential therapeutic agent to combat thrombotic disorders is highly warranted.

PB 2195 | The Oral Bruton’s Tyrosine Kinase Inhibitor Ibrutinib Selectively Blocks Atherosclerotic Plaque-induced Platelet Thrombus Formation

B. Kristina, J. Janina, W. Siess

Ludwig-Maximilians-University, Institute for the Prevention of Cardiovascular Diseases (IPEK), Munich, Germany

Background: Platelet glycoprotein VI (GPVI) interaction with plaque collagen is essential to trigger atherothrombosis under arterial flow conditions, whereas platelet integrin α2β1 interaction with native collagen is critical for hemostasis after vessel wall injury. GPVI signals through Bruton´s tyrosine kinase (Btk) activation. Btk can selectively and irreversibly be blocked by ibrutinib, approved as anti-proliferative drug with a remarkable long term safety profile.

Aims: We explored the potential of ibrutinib as an oral GPVI-targeting plaque-selective antiplatelet drug.

Methods: Ibrutinib was studied *in vitro* and in blood from patients on oral ibrutinib therapy in static platelet assays and arterial flow models of human atherosclerotic plaque- and collagen-induced platelet activation.

Results: Ibrutinib suppressed GPVI-mediated static platelet aggregation in blood exposed to plaque homogenate and collagen fibers by -84% and -92% at 1μM, respectively, and with similar IC_{50} values. In contrast, platelet aggregation stimulated by thrombin-receptor-activating-peptide (-31%) or ADP (-13%) was only slightly compromised. Under arterial flow conditions ibrutinib dose-dependently inhibited platelet thrombus formation onto plaque homogenate (-98%) and plaque tissue (-76%) but not onto collagen fibers (+8%). Ibrutinib did not impair integrin α2β1-mediated platelet adhesion to immobilised soluble collagen. Moreover, in patients taking ibrutinib platelet thrombus formation under arterial flow onto plaque homogenate (-100%)

and plaque tissue sections (-83%) but not onto collagen fibers (+8%) was suppressed. *In vitro* bleeding time was not significantly increased in patients on ibrutinib.

Conclusions: Btk inhibition by ibrutinib suppresses GPVI-dependent platelet thrombus formation on atherosclerotic plaque from flowing blood, but spares hemostatic platelet function. It holds promise as lesion-focused antiplatelet drug that may complement established dual antiplatelet therapy.

PB 2196 | The anti-asthma therapeutic zafirlukast is a broad spectrum thiol isomerase inhibitor that inhibits platelet function

L.-M. Holbrook[1], S. Nock[1], S. Ryan[1], J. Romanowski[2], D. Kennedy[2], J. Gibbins[1]

[1]*University of Reading, School of Biological Sciences, Institute for Cardiovascular and Metabolic Research, Reading, United Kingdom,* [2]*Western New England University, College of Pharmacy, Boston, United States*

Background: Several members of the thiol isomerase family of enzymes are present in, and released by platelets, inhibition of these enzymes results in inhibition of platelet responses including aggregation, adhesion and thrombus formation. To date, few pan thiol isomerase inhibitors have been characterised. The most studied, bacitracin is known to be nephrotoxic which limits its therapeutic usage. Therefore it is desirable to identify novel broad spectrum inhibitors of these enzymes.

Aims: In this study we screened compound libraries of existing therapeutics to identify compounds which inhibit thiol isomerase activity, and determined their effects on platelet function.

Methods: 3641 compounds were screened for inhibitory effects on the redox activity of ERp5, PDI, ERp57, ERp72 and thioredoxin (TRX) in an insulin turbidity assay. The most potent compound, zafirlukast (ZFL) was selected for further investigation. Human platelets were incubated with ZFL (0.1-10μM) or vehicle for 5 minutes prior to stimulation with collagen or CRP-XL (1μg/mL). Platelet aggregation and granule secretion were measured by lumi-aggregometry and flow cytometry. Spreading and thrombus formation under arterial flow conditions were measured by confocal microscopy.

Results: Compound library screening revealed that the cysteinyl leukotriene receptor antagonist ZFL inhibits the enzyme activity of PDI, ERp57, ERp72, TRX and ERp5. When applied to platelets, ZFL caused a concentration-dependent inhibition of platelet aggregation and granule secretion. Platelet spreading on collagen and thrombus formation was also inhibited in the presence of ZFL.

Conclusions: We demonstrate that the anti-asthma compound ZFL is a potent broad spectrum platelet thiol isomerase inhibitor which broadens the repertoire of compounds available to further study the role of thiol isomerases in platelet function and may represent a novel antithrombotic compound. Investigations are underway to establish the effects of ZFL on thrombosis and haemostasis in mice.

PB 2197 | Potentiation of TRAP-6-induced Platelet Dense Granule Release by Blockade of P2Y12 Signaling with MRS2395

A. Mitrugno[1], R.A. Rigg[1], N.B. Laschober[1], A.T.P. Ngo[1], J. Pang[1], C.D. Williams[2], J.E. Aslan[3], O.J.T. McCarty[1]

[1]*Oregon Health & Science University, Biomedical Engineering, Portland, United States,* [2]*Oregon State University, School of Pharmacy, Portland, United States,* [3]*Oregon Health & Science University, Computational Biology Program, Portland, United States*

Background: The release of ADP from platelet dense granules and its binding to platelet P2Y12 receptors is crucial for amplifying the initial hemostatic response and propagating thrombus formation. P2Y12 has thus emerged as a therapeutic target to safely and effectively prevent secondary thrombotic events in patients with acute coronary syndrome or a recent history of stent placement. However, the response to P2Y12-targeted anti-platelet therapy is variable and some patients are still at risk for cardiovascular events. Several mechanisms of resistance to anti-P2Y12 therapy have been proposed, including, paradoxically, the increased release of ADP by platelet dense granules in response to anti-P2Y12 therapy.

Aims: To explore whether targeting of P2Y12 ADP receptor results in the release of its autocrine ligand.

Methods: Human washed platelets were treated with MRS2395 or ticagrelor, two P2Y12 inhibitors, and assessed for agonist-induced platelet dense granule release and calcium generation by employing 96-well plate luminescence and fluorescence assays, respectively. The effect of MRS2395 and ticagrelor on agonist-induced platelet dense granule trafficking was visualized by Superresolution Structured Illumination Microscopy (SR-SIM). Platelet molecular pathways downstream of P2Y12 inhibition were studied via pharmacology- and biochemistry-based approaches.

Results: Our results show that in platelets activated with the PAR-1 agonist TRAP-6 (thrombin receptor-activating peptide), inhibition of P2Y12 with the antagonist MRS2395, but not ticagrelor, potentiated human platelet dense granule trafficking to the plasma membrane and granule secretion, intracellular cytosolic Ca2+ influx and phosphorylation of GSK3β-Ser9 through a PKC-dependent pathway.

Conclusions: These results suggest that inhibition of P2Y12 with MRS2395 may act in concert with PAR-1 signaling and result in the aberrant release of ADP by platelet dense granules, thus reducing or counteracting the anticipated anti-platelet efficacy of these inhibitors.

PB 2198 | Discovery and in vitro Pharmacology of BAY-386 - A Novel, Reversible PAR-1 Antagonist

C. Gerdes[1], M. Jeske[2], M.J. Gnoth[1], E. Bender[1], K. Zimmermann[1], A. Buchmueller[1], P. Ellinghaus[1], A. Itakura[3], V. Laux[1], O.J. McCarty[3]

[1]*BAYER AG, Drug Discovery, Wuppertal, Germany,* [2]*BAYER AG, Catalysis & Chemical Technology, Leverkusen, Germany,* [3]*Oregon Health & Science University, Biomedical Engineering, Portland, United States*

Background: Antiplatelet therapy represents a cornerstone in the prevention of ischemic cardio- and cerebrovascular events. Protease activated receptor-1 (PAR-1) is the dominant receptor for thrombin, the most potent platelet activator.

Aims: Our aim is to identify novel antiplatelet agents to overcome efficacy and safety limitations of standard therapy. Specifically, we set out to find a potent, selective and reversible PAR-1 antagonist with the potential for oral activity.

Methods:

- Ultra high-throughput chemical library screening (uHTS) using TRAP- (thrombin receptor activating peptide) induced calcium release in HEK293 cells
- High affinity TRAP radioligand binding assay
- Human platelet aggregation induced by TRAP, thrombin, PAR-4 agonist, ADP, and collagen
- High shear (1000/s) human whole blood perfusion over collagen; measurement of downstream platelet activation
- Thrombin-induced cytokine mRNA and protein expression on cultured human umbilical vein endothelial cells (HUVEC)
- In vitro drug metabolic and pharmacokinetic characterization (DMPK)

Results:

- uHTS: phenylpiperidine class of compounds further optimized to BAY-386 (IC_{50}: 0.01 μM)
- Specific binding to PAR-1 on human platelet membranes (IC50: 0.056 μM)
- Inhibition of human platelet-rich plasma (PRP) aggregation by BAY-386 at IC_{50} of 0.43 and 0.14 μM against TRAP and thrombin, respectively
- No inhibition of PAR-4 agonist- or ADP- or collagen-induced aggregation
- Abrogation of inhibition of PRP aggregation by a standard platelet washing procedure
- Complete prevention of downstream platelet activation in whole blood flowing at high shear over collagen by BAY-386 (IC_{50} 5.6 μM)
- Block of thrombin-induced pro-inflammatory cytokine mRNA and protein expression by HUVEC, including MCP-1 and CXCL1
- In vitro DMPK profile compatible with oral activity.

Conclusions: BAY-386 is a potent, specific and reversible PAR-1 antagonist with the potential for oral treatment of arterial thrombosis.

PB 2199 | Selective Serotonin Reuptake Inhibitors Inhibit Convulxin- and Fibrinogen-induced Phosphorylation of Syk in Human Platelets

Y.-L. Tseng[1], J.P.-C. Chang[2], H.-Y. Lane[2]

[1]*Taipei Tzu Chi Hospital, Department of Psychiatry, New Taipei City, Taiwan, Republic of China,* [2]*University Hospital and College of Medicine, China Medical University, Department of Psychiatry, Taichung, Taiwan, Republic of China*

Background: We previously reported that selective serotonin reuptake inhibitors (SSRIs) reduce platelet aggregation induced by collagen. Collagen and convulxin induce platelet aggregation through glycoprotein VI (GPVI)-FcRγ chain-Syk signaling pathway. In addition, fibrinogen induces platelet activation through αIIbβ3 integrin-FcγRIIa-Syk signaling pathway.

Aims: To investigate the effects of SSRIs on GPVI- and αIIbβ3 integrin-mediated signaling pathway.

Methods: Citalopram and escitalopram, two relatively pure SSRIs, were used in this study. Platelet aggregation was measured by aggregometry. The expression of αIIbβ3 integrin was measured by flow cytometry. Fibrinogen binding-induced activation was examined by the spreading assay on immobilized fibrinogen. Signaling pathways were evaluated by immunoprecipitation and Western blotting.

Results: Citalopram and escitalopram both concentration-dependently inhibited convulxin-induced platelet aggregation and the activation of αIIbβ3 integrin. Convulxin-induced phosphorylation of Syk, LAT, and Akt was inhibited by citalopram and escitalopram. Citalopram inhibited the interaction between FcRγ and Syk, whereas the phosphorylation of FcRγ in response to convulxin remained unchanged. Further, citalopram inhibited the increase of the interaction between serotonin transporter and Syk induced by convulxin. In the presence of Mn^{2+}, escitalopram inhibited the formation of filopodia and lamellipodia on immobilized fibrinogen. Escitalopram did not influence the binding of fibrinogen to platelets. It inhibited the phosphorylation of Syk, LAT, and PAK2 triggered by the adhesion on fibrinogen.

Conclusions: Our data demonstrate that citalopram and escitalopram inhibit GPVI- and αIIbβ3 integrin-mediated platelet activation. The mechanism of the inhibitory effect of citalopram or escitalopram is not the influence on the activation of GPVI and the interaction between fibrinogen and αIIbβ3 integrin, but the interaction between Syk and its upstreaming molecules.

PB 2200 | Citalopram Inhibits Platelet Function through a SERT-Independent Mechanism

H.G. Roweth[1], R. Yan[1], A.H. Watson[1], R.W. Farndale[2], G.E. Jarvis[1]

[1]*University of Cambridge, Department of Physiology, Development and Neuroscience, Cambridge, United Kingdom,* [2]*University of Cambridge, Biochemistry, Cambridge, United Kingdom*

Background: Selective serotonin reuptake inhibitor (SSRI) antidepressants reduce the rate of serotonin (5-HT) uptake by the serotonin reuptake transporter (SERT). Since platelets also express SERT, SSRIs may modify platelet function and influence myocardial infarction risk. However, the cardiovascular benefits and risks of SSRIs are poorly characterised and *in vitro* data is limited. The SSRI citalopram is a racemate, the (*S*)-isomer being a more potent SERT inhibitor. Although citalopram has been shown to inhibit platelets *in vitro*, it is unclear whether this is mediated via SERT blockade.

Aims: To determine if citalopram inhibits platelet function via SERT blockade.

Methods: Washed platelets (WP) were prepared from citrated blood from healthy volunteers.

Platelet aggregation was quantified using turbidimetric aggregometry. Static adhesion to various ligands was measured by detecting acid phosphatase from lysed adherent WP. SERT activity was quantified by adding exogenous 5-HT (1 μM) to WP and determining the fall in supernatant 5-HT concentration over time. 5-HT concentrations were quantified using high-pressure liquid chromatography.

Results: Citalopram and its isomers inhibited platelet aggregation (pIC_{50} ≈ 4.2) and static adhesion (pIC_{50} ≈ 3.9), with no significant difference in the *S*:*R* isomer potencies. By contrast, 5-HT uptake was more potently inhibited by (*S*)-citalopram (pIC_{50} ≈ 8.6) than (*R*)-citalopram (pIC_{50} ≈ 7.4), giving an *S*:*R* potency ratio of approximately 16-fold.

Conclusions: 5-HT uptake into platelets was completely blocked by both citalopram isomers at concentrations that had no effect on platelet aggregation or adhesion. Despite an *S*:*R* potency ratio of 20 for 5-HT uptake, (*R*)-citalopram was equally potent at inhibiting platelet aggregation and adhesion. These findings strongly suggest that inhibition of platelet function *in vitro* by citalopram is not mediated via SERT blockade. Alternative mechanisms of action are necessary to explain the pharmacological effects of citalopram on platelets.

PB 2202 | What is the Optimal Treatment Option for A Patient with X-linked Thrombocytopenia?

M. Gresikova[1], T. Freiberger[2], B. Ravčuková[2]

[1]*Clinic of Hematology and Oncology for Children, Children Faculty Hospital, Department of Hematology and Transfusion, Bratislava, Slovakia,* [2]*Genetic Laboratory, Center for Cardiovascular Surgery and Transplantation, Brno, Czech Republic*

Background: X-linked thrombocytopenia (XLT) is an allelic variant of the Wiskott-Aldrich syndrome (WAS) which presents with a milder phenotype with bleeding but not the immune dysregulation as demonstrated in patients with WAS. XLT patients have profound thrombocytopenia, small platelets, hemorrhage is a major problem. Stem cell transplantation at an early age is the treatment of choice for patients with WAS, therapeutic options for patients with XLT are controversial.

Aims: We asked whether eltrombopag, a thrombopoietic agent would increase platelet counts and / or reduce beeding in XLT patient.

Methods: We report the first patient with XLT in Slovak republic carrying a novel missense mutation p.Y88H (c.296T>C). Platelet (PLT) count was very low since the birth (6-29x10^9/l). Major problem of patients is bleeding, he received repeated platelet transfusion for severe traumatic hemorrhage. We asked whether a thrombopoietic agent-eltrombopag- would increase platelet counts, and/or reduce bleeding in WAS/XLT patients.

Results: Our patient was 6-yeard old and platelets were very low (PLT:6 x10^9/l) at the time of starting treatment. Eltrombopag (50 to 75 mg) was administered orally once daily and dosing was adjusted to maintain the platelet count >50×10^9/L. Eltrombopag treatment was well tolerated and resulted in an increased platelet count (in 8 week-PLT:45×10^9/l, in 16 week- PLT-84×10^9/l), but less that in control (5 pediatric chronic immune thrombocytopenia patients). Platelet activation was assessed by whole blood flow cytometry. Agonist-induced platelet surface activated glycoprotein GP IIb/IIIa were proportional to platelet size and therefore decreased compared with controls. Immature platelet fraction was significantly less increased compared with controls.

Conclusions: In XLT patients, eltrombopag may reduce the risk of hemorrhage by increasing the platelet count and/or platelet turnover until a more definitive therapy is available or while awaiting the effectiveness of other therapy.

PB 2203 | The Effect of Vorapaxar on Platelet-mediated Inflammatory Response

A. Tsouka, I. Moschonas, S. Papadaki, A. Tselepis

University of Ioannina, Atherothrombosis Research Centre/Laboratory of Biochemistry, Department of Chemistry, Ioannina, Greece

Background: Apart from their important role in haemostasis and thrombosis, platelets also participate in inflammatory reactions, through mechanisms that may involve the CD40 ligand (CD40L), P-selectin and cell-to-cell interactions with leukocytes. Vorapaxar is a specific antagonist of the protease-activated receptor-1 (PAR-1) that potently inhibits platelet aggregation and thrombosis.

Aims: We investigated the possible vorapaxar effects on various platelet activation markers and on platelet-leukocyte interactions.

Methods: Whole blood of healthy volunteers was incubated with vorapaxar at various concentrations (0.1μM to 2μM) for 60min at 37°C and then activated with 50μM TRAP-6 or ADP. Platelet activation was evaluated by flow cytometry, determining the membrane expression of P-selectin and CD40L using the monoclonal antibodies, anti-CD61-PerCP, anti-CD154-FITC and anti-CD62P-PE. CD40L was expressed as the percentage of $CD61^+$/$CD154^+$ cells, whereas P-selectin was expressed as Mean Fluorescence Intensity. Formation of platelet-monocytes and platelet-neutrophil conjugates was determined by dual labelling with anti-CD61-PerCP and anti-CD14-FITC or anti-CD45-PE, respectively. The platelet-monocyte and platelet-neutrophil conjugates were assessed as the percentage of $CD61^+$/$CD14^+$ and $CD61^+$/$CD45^+$ particles, respectively.

Results: Vorapaxar significantly inhibited the TRAP-6-induced membrane expression of P-selectin and CD40L, in a dose dependent manner showing IC50 values of 0.80μM and 0.64μM , respectively. Furthermore, vorapaxar (1μM) reduced by 100% and 86% the formation of platelet-neutrophil and platelet-monocyte conjugates, respectively induced by TRAP-6. Vorapaxar did not significantly influence the ADP effect on all the above parameters.

Conclusions: Vorapaxar potently attenuates platelet-mediated inflammatory response followed by PAR-1 activation an effect that may contribute to the reduction of acute limb ischemia and peripheral revascularization observed in patients with peripheral artery disease.

PB 2204 | APAC, a Dual Antiplatelet and Anticoagulant Attenuates Collagen-induced Platelet Aggregation and Fibrin Elasticity in Blood

A. Jouppila[1], M. Lemponen[2], K. Barreiro[3], R. Lassila[4]

[1]*Helsinki University Central Hospital Research Institute, Helsinki, Finland,* [2]*Helsinki University Hospital Laboratory Services, Helsinki, Finland,* [3]*Helsinki University, Helsinki, Finland,* [4]*Helsinki University Hospital, Comprehensive Cancer Center, Department of Hematology, Coagulation Disorders Unit and Laboratory Services, Helsinki, Finland*

Background: APAC, a semisynthetic mimetic of heparin proteoglycans, inhibits both collagen-induced platelet aggregation and procoagulant activity *in vitro* and *in vivo* (Lassila&Jouppila STH 2014). In two baboon models of arterial thrombosis, collagen-coated shunt (Oregon, USA) and 30-90% stenosis model of injured femoral artery (FA) (Bloemfontain, SA) APAC reduced platelet thrombus formation, and maintained vessel patency. In PET labeling APAC retained in rat FA anastomosis site for 48 -120h.

Aims: We further characterized the effects of APAC on platelet aggregation in whole blood and platelet-rich plasma (PRP), and in global coagulation (ROTEM®) *in vitro.*

Methods: APAC-spiked citrated blood of healthy volunteers was challenged to collagen (3.2 µg/ml), ristocetin (0.77 mg/ml) and ADP (6.4 µM) in Multiplate®, and to collagen (0.5 µg/ml) in PRP and in ROTEM® for INTEM, EXTEM, FIBTEM (with cytochalasin D) and HEPTEM (with heparinase) activation.

Results: Overall, APAC dose-dependently prolonged lag time and decreased slope of aggregation. In blood APAC (150 µg/ml) inhibited collagen- and ristocetin (but not ADP) -induced aggregation by 58 ±15% (mean ± SD) and by 25 ±2%, respectively, unlike UFH. In PRP APAC specifically inhibited collagen-induced aggregation already at 1 µg/ml by 55 ±31%, 3 µg/ml by 75 ±15%, and 30 µg/ml by 85 ±11%. The inhibition of maximal aggregation varied, but improved in all donors by an increase of APAC dose. In ROTEM® APAC (3 µg/ml) uniquely prolonged all EXTEM, INTEM and FIBTEM clotting times (CT), 4.5-8-fold, while UFH (3 µg/ml) prolonged mainly INTEM. However, APAC prolonged INTEM CT 2-fold in comparison to UFH. Anticoagulation was abolished in HEPTEM.

Conclusions: APAC, inhibits collagen-, but not ADP-induced, platelet aggregation in citrated blood and PRP. In all donors APAC attenuated the initial aggregation. Moreover, in ROTEM® APAC globally attenuates platelet procoagulant activity and fibrin elasticity.

PB 2205 | Citrated Iron Oxide Nanoparticles Inhibit Thrombin-evoked Ca2+ Signalling in Human Platelets

S. Moise[1,2], N. Telling[1], A. Harper[1]

[1]*Keele University, Institute for Science and Technology in Medicine, Stoke-on-Trent, United Kingdom,* [2]*University of Nottingham, School of Pharmacy, Nottingham, United Kingdom*

Background: Previous work in our lab has suggested that platelet Ca^{2+} signalling is potentiated through a pericellular recycling system.[1,2] This allows Ca^{2+} removed into the Open Canalicular system (OCS) to accumulate and recycle back into the cytosol through Ca^{2+}-permeable ion channels potentiating Ca^{2+} signals.[2] Localised buffering of Ca^{2+} within the OCS could interrupt this system and provide a new method to inhibit agonist-evoked changes in platelet function.

Aims: Here we aim to assess whether the absorption of citrate onto the surface of the nanoparticles may inhibit agonist-evoked by providing localised Ca^{2+} buffering in the pericellular region of the platelet.

Methods: Platelets were isolated from healthy volunteers under informed consent and with local ethical committee approval. Thrombin-evoked changes in cytosolic- and extracellular Ca^{2+} concentration were monitored in Fura-2-loaded platelets and washed platelet suspensions containing 2.5 µM Rhod-5N salt respectively, using our previously published methodologies.[2] Thrombin-evoked aggregation was assessed using absorbance changes on a microplate reader.

Results: Human platelets preincubated with 300 µM citrated iron oxide nanoparticles could be observed to bind nanoparticles under light microscopy. This treatments also buffered thrombin-evoked rises in extracellular Ca^{2+} concentration (50.4 ± 14.9% of control; n = 6; $P < 0.05$). In addition, pre-treatment with nanoparticles also significantly inhibited thrombin-evoked rises in cytosolic Ca^{2+} concentration (41.8 ± 4.0% of control; n = 6; $P < 0.05$), aggregation (27.6 ± 8.1% of control; n = 6; $P < 0.05$) and clot retraction (51.0 ± 12.2% of control; n = 7; $P < 0.05$)

Conclusions: These studies provide further support for the pericellular Ca^{2+} recycling hypothesis[1,2] and suggest that Ca^{2+} chelator-loaded nanoparticles targeted to human platelets might provide novel antiplatelet therapies.

Refs: [1]Walford *et* al.,(2016). Br *J Pharmacol* **173**, 234-247. [2]Sage *et al*., (2013).*Physiol Rep***1**, e00085.

PB 2206 | Induction of Diabetes Attenuates the Antithrombotic Effect of Clopidogrel in Apolipoprotein E-deficient Mice

A. Sugidachi[1], K. Ohno[1], J.A. Jakubowski[2], Y. Ito[1], A. Tomizawa[1], M. Mizuno[1]

[1]*Daiichi Sankyo Co., Ltd., Rare Disease and LCM Laboratories, Tokyo, Japan,* [2]*Eli Lilly and Company, Lilly Research Laboratories, Indianapolis, United States*

Background: Several studies have demonstrated that patients with diabetes mellitus (DM) exhibit an impaired platelet inhibitory response to clopidogrel. This impaired response may contribute to their increased risk of recurrent atherothrombotic events, despite the use of dual antiplatelet therapy. However, the mechanisms for the impaired response have not been fully elucidated.

Aims: To compare the effects of clopidogrel on thrombus formation in wild type (WT), apolipoprotein E-deficient (apoE KO) and diabetic apoE KO mice.

Methods: DM was induced by injection of streptozotocin (STZ) at 55 mg/kg/d (i.p., x 5 days) in 9-week old mice. Antithrombotic effects of clopidogrel at 10 mg/kg/d (p.o., x 5 days) were determined in a carotid arterial thrombosis model induced by $FeCl_3$ at 21 weeks. Antiplatelet effects were also determined by flow cytometry.

Results: Similar antithrombotic effects of clopidogrel were observed in WT and apoE KO mice. However, in diabetic apoE KO mice, clopidogrel's effects were attenuated compared to WT and non-diabetic apoE KO mice: Percent inhibition of thrombus area (μm^2) by clopidogrel was 85.5% for WT, 75.0% for apoE KO and 1.9% for diabetic apoE KO mice. The time to occlusion and lumen stenosis also reflected significant losses of clopidogrel's antithrombotic effects in diabetic apoE KO mice. Ex vivo platelet reactivity, assessed by ADP-induced activated GPIIb/IIIa expression, was inhibited similarly and completely by clopidogrel in all three mice groups, whereas the effects of clopidogrel on ex vivo platelet P-selectin expression induced by PAR4-activating peptide were diminished in diabetic apoE KO mice compared to WT and non-diabetic apoE KO mice.

Conclusions: These data suggest that STZ-induced diabetic apoE KO mice would be a useful model to further study the impaired responses to clopidogrel in DM patients, whose condition may in part reflect a reduction of clopidogrel's effect on thrombin-induced platelet activation.

PB 2208 | With an ASA Dose that Inhibits Prostacyclin Formation, Clopidogrel Has a Lesser Antithrombotic Effect

R. Ni[1], N. Vaezzadeh[1], J. Zhou[1], J.I. Weitz[1], M. Cattaneo[2], P.L. Gross[3]

[1]Thrombosis and Atherosclerosis Research Institute and McMaster University, Hamilton, Canada, [2]Medicina 3, Ospedale San Paolo, Dipartimento di Scienze della Salute, Università degli Studi di Milano, Milan, Italy, [3]Thrombosis and Atherosclerosis Research Institute and McMaster University, Department of Medicine, McMaster University, Hamilton, Canada

Background: Dual-antiplatelet therapy (DAPT), the standard-of-care in acute coronary syndromes, combines acetylsalicylic acid (ASA) and a $P2Y_{12}$ antagonist to inhibit thromboxane A_2 (TXA_2)- and adenosine diphosphate (ADP)-mediated platelet activation. Both agents also influence platelet levels of cyclic adenosine monophosphate (cAMP), an inhibitor of platelet activation. Higher doses of ASA inhibit endothelial prostacyclin (PGI_2) formation, which otherwise would increase platelet cAMP levels, while $P2Y_{12}$ antagonists block the inhibitory effect of ADP on cAMP formation. Thus higher doses of ASA may be less effective than lower doses of ASA when combined with a $P2Y_{12}$ antagonist.

Aims: To determine in the context of DAPT with clopidogrel, whether an ASA dose that preserves endothelial formation of PGI_2, but inhibits platelet TXA_2 formation, provides greater antithrombotic effect than a higher dose of ASA.

Methods: Mice were dosed orally with ASA, clopidogrel or both. Platelet aggregation was evaluated using the Multiplate Analyzer. The effects of ASA on TXA_2 and PGI_2 were monitored by measuring arachidonic acid (AA)-induced platelet aggregation and plasma levels of 6-keto-PGF1α, respectively. Platelet cAMP levels were measured by an ELISA. Thrombus formation was evaluated using the laser-injury cremaster arterial model.

Results: ASA at 10 and 40 mg (0.15 and 0.6 mg/kg body weight) inhibited AA-mediated platelet aggregation to a similar extent, but only ASA 10 mg preserved PGI_2 formation. PGI_2 elevated cAMP levels and reduced platelet aggregation in thrombin-stimulated, clopidogrel-treated platelets, but not in platelets not treated with clopidogrel. Thrombi in mice given clopidogrel alone or DAPT with 10 mg ASA were smaller than in mice given DAPT with 40 mg ASA.

Conclusions: We provide animal evidence against the use of higher doses of ASA in DAPT, which inhibit PGI_2 formation, which otherwise would favour cAMP-mediated platelet inhibition in presence of $P2Y_{12}$ antagonism.

PB 2209 | Inhibition of Human Platelet Aggregation by Some Newly Synthesized S-Esters of Thiosulfonic Acid

T. Halenova[1], I. Nikolaeva[2], A. Nakonechna[3], V. Lubenets[3], O. Savchuk[1]

[1]Taras Shevchenko National University of Kyiv, Kyiv, Ukraine, [2]Taras Shevchenko National University of Kyiv, Biochemistry, Kyiv, Ukraine, [3]Lviv Polytechnic National University, Lviv, Ukraine

Background: According to the current understanding, the hyperactivation of platelet may lead to increased intravascular coagulation and thrombosis. Today a relevant issue is the searches for new antithrombotic agents that are able to modulate the processes of platelet activation and aggregation. Previously, we described two low molecular weight compounds 1, 2 (Fig.1), which were effective inhibitors of rabbit platelet aggregation induced by ADP (IC_{50} ~ 12mM and 10mM, respectively).

Aims: The aim of this study was to investigate the effects of these thiosulfonate derivatives on human platelet aggregation.

Methods: All experiments using human subjects were approved by the ethical committee of Taras Shevchenko National University of Kyiv. Only healthy volunteers without taking any nonsteroidal anti-inflammatory drugs for at least 14 days were recruited and written informed consent was obtained before blood collection. Platelet aggregation was assessed within the first 3 hours after blood sampling using photo-optical aggregometer AT-02 (Medtech, Russia). In order to investigate the IC50 values of these compounds, their increasing concentrations (1-100 mM) were added to human PRP ($2,5\times10^5$platelet/ml) and incubated for 2 minutes prior to determination of ADP (5×10^{-6}M) or collagen (2 μg/ml) induced aggregation.

Results: The degree of inhibition exerted by these compounds was found to be proportional to their concentration. The identified dithiocarcamates were shown to have similar efficacy that was evidenced by their close IC50 values: 10-12 μM for ADP-dependent aggregation and 1.5-2.5 μM for aggregation induced by collagen.

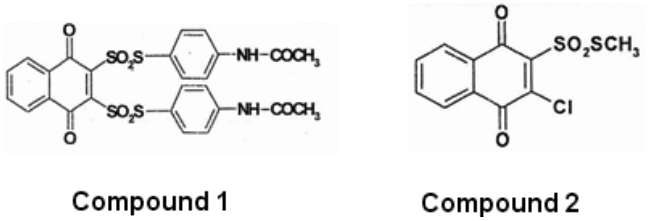

FIGURE 1 The structures of studied thiosulfonate derivatives

Conclusions: The findings suggest that these thiosulfonic acid S-ester derivatives are potent anti-platelet agents and the mechanism underlying their antiaggregation action needs more careful study.

PB 2210 | Looking for the Best Experimental Conditions for Studying the Effect of Aspirin on Murine Hemostasis

B. Decouture[1], B. Dizier[1], P. Gaussem[1,2], C. Bachelot-Loza[1]

[1]*Paris Descartes University, INSERM UMR_S 1140, Paris, France,* [2]*AP-HP, Hôpital Européen Georges Pompidou, Service d'Hématologie Biologique, Paris, France*

Background: Aspirin (ASA) is an anti-inflammatory and anti-platelet agent that irreversibly inhibits the cyclooxygenase (COX) and, thus thromboxane (TX) generation. However, there are some discrepancies in pre-clinical studies regarding the ASA antiplatelet effect *in vivo* and *ex vivo*.

Aims: Define the appropriate experimental model (dose, route…) for the *in vivo* and *ex vivo* study of the effect of ASA administration on mouse hemostasis.

Methods: FVB and C57Bl6 mice were injected with ASA (10 or 100 mg/kg) or vehicle by oral route 30 min or 3 h before tail bleeding assay, or blood cardiac puncture to assess *ex vivo* washed-platelet aggregations (5 µg/ml collagen and 100 µM arachidonic acid (AA)) and TXB2 production (ng/10^9 platelets).

Results: Our results demonstrate that oral administration of ASA 10 mg/kg is not sufficient to obtain a maximum ASA-induced inhibition of hemostasis regarding bleeding time, TXB2 synthesis and collagen-induced aggregation. At ASA 100 mg/kg, platelet aggregation and TXB2 generation induced by collagen were significantly inhibited at 30 min (44% ± 12 and 69% ± 4, respectively) and at 3 h (51% ± 15 and 85% ± 5) after ASA oral administration. Paradoxically, no inhibition was observed on AA-induced aggregation, even if the TXB2 generation was fully inhibited (0,21 ± 0,05 for ASA vs 2,33 ± 1,13 for vehicle at 30 min post-ASA; 0,14 ± 0,02 for ASA vs 1,13 ± 0,48 for vehicle at 3h post-ASA). Interestingly, the effect of ASA on bleeding assay was more significant when performed 30 min after oral administration than after 3 h, and more specifically when considering bleeding time rather than blood loss.

Conclusions: Although the inhibitory effect of ASA (100 mg/kg) is observed *ex vivo* on collagen-, but paradoxically not on AA-, induced platelet aggregation at 30 min and 3 h after administration of ASA, its inhibitory effect *in vivo* is only observed at 30 min.

PB 2211 | Platelet Microvesicle Formation during the Hemostatic Response is Regulated by P2Y12 Signaling

M. Tomaiuolo[1], C. Matzko[1], I. Poventud-Fuentes[1], J. Weisel[2], L. Brass[1], T. Stalker[1]

[1]*University of Pennsylvania Perelman School of Medicine, Medicine, Philadelphia, United States,* [2]*University of Pennsylvania, Cell and Developmental Biology, Philadelphia, United States*

Background: Previous studies have shown that hemostatic plugs formed in the mouse microvasculature have a characteristic architecture in which the extent of platelet activation reflects gradients in platelet agonist distribution radiating outwards from the injury site. In that setting, there is minimal overlap of thrombin and ADP signaling.

Aims: Here, we sought to characterize the architecture of hemostatic plugs in large vessels and determine the role of $P2Y_{12}$ signaling in regulating architecture development.

Methods: Correlative microscopy integrating fluorescence with scanning electron microscopy was used to image hemostatic plugs in situ in mouse jugular veins from 1 to 20 min after needle injury.

Results: Our findings show in detail the intraluminal and the extravascular portions of the hemostatic plug, and reveal what could previously only be inferred (Fig. 1). Platelet size, morphology, and packing density varied remarkably depending on spatial localization within the platelet plug. The intraluminal portion was composed almost exclusively of platelets. Platelets closest to the injury edge had a highly activated morphology, including P-selectin surface expression, dense packing, and microvesicle formation. Platelets farther from the injury site often remained discoid. The extravascular portion was rich in densely-packed microvesicles intertwined with fibrin. The microvesicles were CD41, P-selectin, and annexin V positive, indicating they originated from highly activated platelets. In the presence of a $P2Y_{12}$ inhibitor, hemostatic plugs were significantly smaller, the platelet

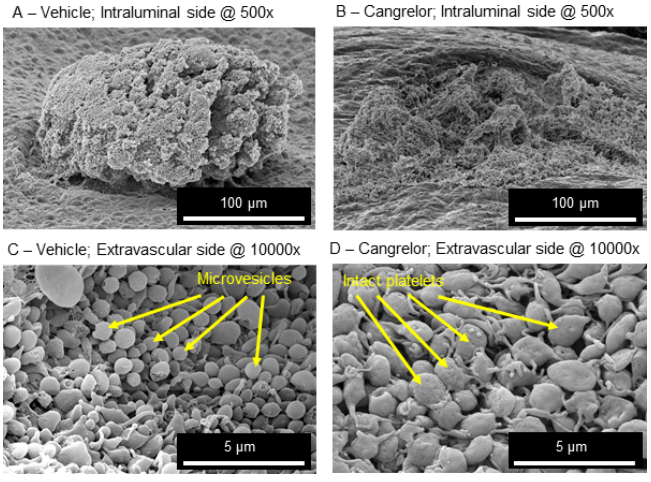

FIGURE 1 Jugular vein hemostatic plugs from mice treated with vehicle (A,C) or cangrelor (B,D) shown from the intraluminal or extravascular side

activation gradient was less apparent, and notably, microvesicle formation was greatly reduced.

Conclusions: Our findings indicate that

1) the development of a platelet activation gradient is conserved across vessels of different sizes,

2) platelet microvesicle formation is a prominent feature of the hemostatic response, and

3) clinically relevant platelet signaling pathways regulate the platelet activation gradient.

PB 2212 | Convection through Platelet Thrombi

S. Kobayashi[1], M. Komatsu[1], D. Ku[2]

[1]*Shinshu University, Faculty of Textile Science and Technology, Ueda, Japan,* [2]*Georgia Institute of Technology, School of Mechanical Engineering, Atlanta, United States*

Background: Growth of macroscopic high shear thrombosis may stem from thrombi dominated by diffusion in the core or high-shear convection of whole blood reactants.

Aims: We measure the velocity of blood cells through the pores of the growing high-shear platelet thrombus.

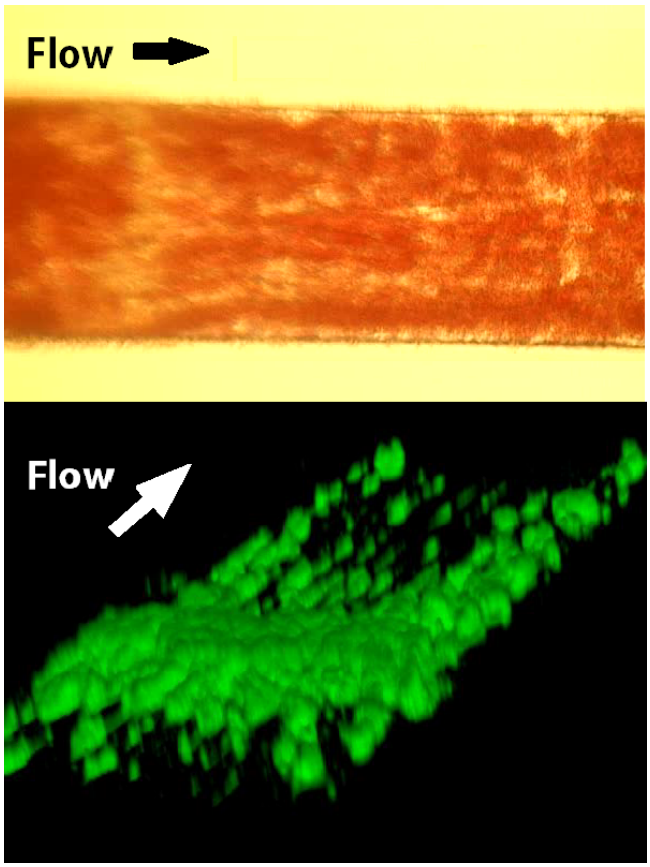

FIGURE 1 Microscopic images of test section. Upper: Picture of whole blood thrombus at 170s, Lower: Confocal image of thrombus at 170s (PRP)

Methods: Whole blood (WB) is perfused through a stenotic microfluidics chamber mimicking an atherosclerotic artery. Platelet adhesion and aggregation is imaged until full occlusion. A light microscope provides an *en face* image in real-time that is captured by a CCD video camera. Confocal images of mepacrine-labelled platelets are captured using a laser scanning microscope.

Results: A white thrombus forms under high shear rates (>3000/s). Platelet arrest on the collagen surface was instantaneous with little rolling. Rapid accumulation occurred between 30 and 200 seconds after perfusion began. Thrombus appeared in ridges in the stream-wise direction that were spaced approximately 30 μm peak to peak. Blood cell motion in the valleys proceeded at high velocity of >250 μm/s. The high velocities during growth imply a high Peclet number, low Damkohler number, and Reynolds number of 10^{-8}. At ~170 s, the velocities suddenly slowed to 50 μm/s with persistent velocities after 600s throughout the thrombus. Fluid motion indicates a volume porosity of 30% within the thrombus. As RBC velocities approached zero, red clot became prominent in the sections upstream and downstream of the stenosis, but less within the test section. Confocal imaging confirmed the 3-D structure of the thrombus as growing mountain peaks with interspersed valleys.

Conclusions: Thrombus formation forms by stream-wise ridges, with long porous valleys that create high velocity RBC passage long after thrombus fills the lumen. High resolution video can be used as a velocimeter to quantify convection within the platelet thrombus. The images of internal convection appear to contradict the stagnation build-up or core-shell hypotheses for growth suggested by some.

PB 2213 | Different Prothrombotic Phenotypes of Atherosclerosis-prone Apoe-/-and Ldlr-/- Mice

J.P. van Geffen[1], F. Swieringa[1,2], J.C. Sluimer[3], E.A.L. Biessen[3], J.W.M. Heemskerk[1], M.E.J. Kuijpers[1]

[1]*Maastricht University / Cardiovascular Research Institute Maastricht (CARIM), Department of Biochemistry, Maastricht, The Netherlands,* [2]*Leibniz Institute for Analytical Sciences - ISAS-e.V., Department of Bioanalytics, Dortmund, Germany,* [3]*Maastricht University / Cardiovascular Research Institute Maastricht (CARIM), Department of Pathology, Maastricht, The Netherlands*

Background: *Apoe*$^{-/-}$ and *Ldlr*$^{-/-}$ mice have elevated plasma lipids, are prone to atherosclerosis and have a prothrombotic tendency. Feeding a western-type diet is crucial for the atherosclerotic propensity of *Ldlr*$^{-/-}$ but not *Apoe*$^{-/-}$ mice.

Aims: Given the suggested roles of platelets and coagulation in these processes, we determined the phenotype of *Apoe*$^{-/-}$ and *Ldlr*$^{-/-}$ mice, using multi-parameter tests of platelet/coagulant function.

Methods: Analysis of blood, lipids and coagulation parameters of wild type (C57BL/6), *Apoe*$^{-/-}$ and *Ldlr*$^{-/-}$ mice with(out) high-fat diet. Thrombotic potential in whole blood flowed over collagen/tissue factor (TF). Platelet phenotyping of thrombi formed on collagen. Heat maps of normalized data of thrombus size and activation parameters. Assessment of coagulation in plasma by calibrated automated thrombin generation (TF stimulation) and thrombin-anti-thrombin(TAT)-complexes.

Results: Compared to blood from wildtype mice, blood from both *Apoe*$^{-/-}$ and *Ldlr*$^{-/-}$ mice displayed an increased prothrombotic potential, measured as enhanced platelet-dependent clot formation under high-shear, arterial, flow conditions ($p < 0.05$). For both genotypes, the increased clot formation was independent of age (2-18 months) or diet (high/low fat). Coagulant activity was significantly increased in plasma from *Apoe*$^{-/-}$ but not *Ldlr*$^{-/-}$ mice (circulating TAT complexes and plasma thrombin generation). Multi-parameter assessment of platelet thrombus formation under flow (without coagulation) indicated a stronger gain-of-function of *Ldlr*$^{-/-}$ platelets than of *Apoe*$^{-/-}$ platelets compared to wild-type platelets.

Conclusions: The prothrombotic phenotypes of *Apoe*$^{-/-}$ and *Ldlr*$^{-/-}$ mice are age- and diet-independent, and link to a different gain-of-function of platelet activity (*Ldlr*$^{-/-}$ > *Apoe*$^{-/-}$) and coagulant activity (*Apoe*$^{-/-}$ > *Ldlr*$^{-/-}$). This study provides novel insight into the mechanisms of linking atherosclerosis to thrombosis.

PB 2214 | PCSK9, Not only A Modulator of Cholesterol Levels but Also of Platelet Function

L. Rossetti[1], N. Ferri[2], S. Marchianò[3], B. Canciani[1], D. Trabattoni[1], F. Santilli[4], G. Davì[4], E. Tremoli[1], M. Camera[1,3]

[1]*Centro Cardiologico Monzino IRCCS, Milano, Italy,* [2]*Università degli Studi di Padova, Dept. di Scienze del Farmaco, Padova, Italy,* [3]*Università degli Studi di Milano, Dept. of Pharmacological and Biomolecular Sciences, Milano, Italy,* [4]*Università degli Studi di Chieti, Dept. of Medicine and Aging Sciences, Chieti, Italy*

Background: The serine protease Proprotein convertase subtilisin/kexin 9 (PCSK9) is a main player in cholesterol homeostasis inducing degradation of the LDL cholesterol receptor (LDLR). PCSK9 plasma levels predict recurrent cardiovascular events in stable angina (SA$^+$) patients. PCSK9 contribution to cardiovascular events might be mediated by mechanisms occurring via unknown LDLR-independent pathways. Platelets (PLT) play a key role in the acute complications of atherosclerosis and the hyperreactive phenotype of PLT in type-2 diabetes mellitus (DM) patients is well known. Interestingly PLT count is positively associated with plasma PCSK9 in SA$^+$ patients and increased serum PCSK9 is directly associated with PLT reactivity in acute coronary syndrome patients. No study has evaluated whether PCSK9 affects PLT function.

Aims: To evaluate whether PCSK9 modulates PLT activation and to assess whether PCSK9 is expressed by PLT from healthy subjects (HS) and SA$^+$ patients, DM$^+$ or DM$^-$.

Methods: The effect of PCSK9 (5μg/mL) on epinephrine(0.6μM)-induced PLT activation was assessed by aggregation assay and by whole blood flow cytometry (FC) evaluation of P-selectin, PAC-1, Tissue Factor (TF). PCSK9 levels in PLT lysates from 30 SA$^+$ (15 DM$^+$, 15 DM$^-$), 10 DM$^+$SA$^-$ patients and 10 HS, who gave informed consent, were assessed by ELISA.

Results: PCSK9 potentiates PLT aggregation induced by epinephrine (+40%AUC;+78%Slope;-15%LagTime;+15%MaxAggregation) and increases PAC-1, P-selectin and TF expression (+50%,+40%,+25%;$p < 0.05$). ELISA assay showed that PLT from SA$^+$DM$^+$ patients contained twice the amount of PCSK9 compared to the other groups (21.6±7.7pg/μg protein,$p < 0{,}001$). No difference in plasma PCSK9 levels were found among the groups.

Conclusions: These data show for the first time that PCSK9 is expressed in human PLT and significantly higher levels are found in SA$^+$DM$^+$ patients. Moreover PCSK9 plays a role in PLT activation and aggregation. These findings may help to understand the molecular basis of PLT hyperreactivity in SA$^+$DM$^+$ patients.

PB 2215 | Increased Platelet P2Y12 Expression in Diabetes and the Therapeutic Implication of Inverse Agonist for Antiplatelet Therapy

L. Hu, L. Chang, Z. Ding

School of Basic Medical Sciences, Fudan University, Key Laboratory of Metabolism and Molecular Medicine, Ministry of Education and Department of Biochemistry and Molecular Biology, Shanghai, China

Background: Platelet of diabetes patients are hyperactive, which contributes to not only the increased prevalence of cardiovascular complications, but also the inadequate response to currently available antiplatelet agents leading to increased cardiovascular death. The underlying mechanism is still not completely understood.

Aims: The aim of this study was to explore the mechanisms for increased platelet P2Y12 expression in diabetes patients and patients with upregulated $P2Y_{12}$ may gain more benefit from antiplatelet agents with potent $P2Y_{12}$ inverse agonist activity.

Methods: No clinical trial.

Results: Using real time PCR and Western blotting we show that platelet from diabetes patients express dramatically higher $P2Y_{12}$ than healthy subjects. $P2Y_{12}$ expression correlates well with ADP-induced platelet aggregation. Upregulated $P2Y_{12}$ of diabetic platelet is constitutively activated. Though both AR-C78511, a potent $P2Y_{12}$ inverse agonist, and cangrelor have similar antiplatelet efficacy on platelets from healthy subjects, AR-C78511 exhibits superior antiplatelet effects on diabetic platelet over cangrelor, a neutral $P2Y_{12}$ receptor antagonist we previously reported. Furthermore, we recapitulated the findings from diabetic patients using diabetic Goto-Kakizaki (GK) rats. Importantly, using two kinds of thrombosis models, we found that the superior antiplatelet effect of the inverse agonist can be translated into superior antithrombotic effect on diabetic GK rats. Using megakaryocytes from diabetic rats and high glucose-treated megakaryocytic cell line, we provided evidences suggesting that high glucose-ROS-NFκB pathway upregulates platelet $P2Y_{12}$ receptor in diabetes.

Conclusions: Platelet $P2Y_{12}$ receptor is significantly increased and constitutively activated in T2DM patients, which contributes to platelet hyperactivity and dampened antiplatelet efficacy in T2DM. $P2Y_{12}$ inverse agonists may have superior antiplatelet effects than cangrelor in diabetic patients, especially in patients with increased platelet $P2Y_{12}$ expression.

PB 2216 | Elevated Activity of Fibrinogen-like Protein 2, (FGL2/fibroleukin) in Platelets of Cancer Patients

E. Rabizadeh[1], Y. Zimra[1], I. Cherny[1], R. Gorion[2]

[1]Rabin Medical Center and FMRC Tel Aviv University, Hematology Lab, Petah Tikva, Israel, [2]Rabin Medical Center, Tel Aviv University, Hematoligy Institute, Petah Tikva, Israel

Background: Fibrinogen-Like Protein 2 (FGL2), a recently discovered trans-membrane procoagulant, is believed to play a central role in cancer development. Similar to factor Xa, FGL2 is capable of exerting prothrombinase activity however, independent of the classical coagulation pathway.
Aims: To investigate if platelets can directly induce coagulation via FGL2 activity and if FGL2 activity in platelets has the potential to be used as a malignancy biomarker.
Methods: Blood samples were collected from healthy individuals and patients with malignancies. Platelet rich plasma, were generated and washed to obtain factor X free samples. FGL2 activity, mRNA, protein levels and the expression of FGL2 Antigen on platelets were determined.
Results: We found a strong correlation between FGL2 prothrombinase activity and the number of platelets. Immunoprecipitation and immunoblotting analyzes proved the absence of factor X prothrombinase and presence of FGL2 in the samples. We showed that FGL2 is present in the membrane of the platelets as well as in peripheral blood mononuclear cells (PBMC). We demonstrated that FGL2 prothrombinase activity was higher in several malignancies compared to healthy controls. Moreover, remission in B cell lymphoma patients is correlated with reduced FGL2 activity levels.
Conclusions: We show for the first time that FGL2 prothrombinase is located in platelets as well as in PBMC. The exerted FGL2 activity is entirely dependent on platelets, despite being also expressed by T cells and macrophages. Therefore, we claim that platelets are capable of directly inducing coagulation, probably locally, via FGL2 activity beyond the classical coagulation route. In view of our findings, the measured activity of FGL2 in platelets has a potential to be employed as a malignancy biomarker. More study is needed to establish the role of FGL2 in thrombophilia-prone diseases.

PB 2217 | Dynamics of Single Platelet Dense Granule Release Induced by Various Concentrations of Thrombin and ADP

T. Shepelyuk[1,2,3], D. Nechipurenko[1,2,3], M. Panteleev[1,2,3], F. Ataullakhanov[1,2,3]

[1]Center for Theoretical Problems of Physicochemical Pharmacology, Moscow, Russian Federation, [2]Lomonosov Moscow State University, Moscow, Russian Federation, [3]Dmitry Rogachev National Research Center of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation

Background: Primary hemostatic response to vascular injury involves platelet recruitment, aggregation and activation, the latter being strongly dependent on the action of ADP, thrombin and "outside-in" signaling through platelet integrins. However, spatiotemporal aspects of platelet activation, granule release, and distribution of agonists concentration during thrombus formation remain unclear. Platelet dense granule secretion is considered to be important source for ADP, though, the kinetics of dense granule release in response to thrombin and ADP remains a matter of controversy.
Aims: To assess the dynamics of dense granule release by single surface-attached platelet in response to various concentrations of thrombin and ADP.
Methods: We used confocal microscopy to image dense granules of platelets upon their loading with mepacrine (quinacrine). Briefly, citrated blood was perfused through the flow chamber, adhered platelets then were washed with buffer, followed by buffer with calcium (2 mM) and agonist. Experiments were performed under the wide range of conditions: on fibrinogen and/or von Willebrand factor-coated coverslips; at different thrombin and/or ADP concentrations (from 100 nM to 0.01 nM; from 100 uM to 0.1 uM, respectively, and combinations); in absence and presence of various shear stresses (from 100 to 1000 s-1); with platelets aggregated from blood, PRP or washed gel-filtered platelets.
Results: The kinetics of dense granule release depends on type and concentration of thrombin or ADP, the kind of surface protein and the shear rate. In particular, with decreasing concentrations of thrombin the number of granules released by platelets and the percentage of such platelets are decreased (from 5-8 to 1-2 and from 95-100% to 15-10%, respectively), while the mean time of granules release is increased (from 1-2 to 500-600 s).
Conclusions: Here we have shown for the first time concentration- and time-dependencies of single platelet dense granule release under a wide range of experimental conditions.

PB 2218 | Comparison of Reticulated and Non-reticulated Platelet Function and Releasates

M.A. Hayman, P.C. Armstrong, T.D. Warner

William Harvey Research Institute, London, United Kingdom

Background: Within the general platelet population there exists a subpopulation of platelets known as reticulated platelets, so called because of the presence of RNA within their cytoplasm. Reticulated platelets account for roughly 10% of the total platelet population in healthy subjects but can be markedly increased in specific patient groups. Critically to cardiovascular health, reticulated platelets are thought to be more reactive than their nonreticulated counterparts.
Aims: To isolate reticulated platelets and directly interrogate their functional capacity and lipid release profiles.
Methods: Thiazole orange (TO) staining of PRP coupled with flow cytometry was used to isolate reticulated platelets, intermediate platelets and nonreticulated platelets. mRNA content in each subpopulation was quantified using qRT-PCR. Platelet aggregate formation was assessed using imaging flow cytometry. To investigate

subpopulation releasates, mass spectrometry, ELISA and luciferase based assays were used.

Results: Reticulated platelets, defined as those with the highest TO staining intensity, corresponded with platelets containing the highest mRNA content. Aggregation studies revealed that reticulated platelets are disproportionally recruited into forming aggregates and locate towards the centre. In addition, reticulated platelets express a higher level of cell-surface P-selectin upon activation.

Conclusions: Reticulated platelets display increased reactivity and part-take more readily in aggregate formation than non-reticulated platelets. Thus this sub-population of platelets may be early drivers of thrombus formation and could be a contributing factor in the failure of anti-platelet prophylaxis.

PB 2219 | Platelet S1P: Evidence for the Involvement of the Membrane Transporter MRP4 during its Secretion, and Identification of Surface Receptors

B. Decouture[1], P. Thérond[2], E. Dréano[1], D. Pidard[1], J.-S. Hulot[3,4], P. Gaussem[1,5], C. Bachelot-Loza[1]

[1]Paris Descartes University, INSERM UMR_S 1140, Paris, France, [2]AP-HP, Hôpital Bicêtre, Service de Biochimie, Le Kremlin Bicêtre, France, [3]AP-HP, Institute of Cardiometabolism and Nutrition (ICAN), Pitié-Salpêtrière Hospital, Paris, France, [4]Sorbonne Universités, UPMC University, Paris, France, [5]AP-HP, Hôpital Européen Georges Pompidou, Service d'Hématologie Biologique, Paris, France

Background: Sphingosine-1-phosphate (S1P) is a bioactive lipid metabolite that plays key roles in vascular development and homeostasis. Most vascular roles of S1P have been attributed to activation of G protein-coupled S1P receptor (S1P1-5) signaling. In a previous study, we showed that sphingosine kinase deficiency in megakaryocytes and platelets impairs platelet activation and spreading, and reduces the availability of S1P for activation of vascular receptors during systemic inflammation. However, the mechanisms of S1P export from activated platelets and its mechanism of action on platelets remain to be fully defined.

Aims: To address mechanisms of S1P export from mouse platelets, and the expression and function of S1P receptors on mouse and human platelets.

Methods: S1P levels were quantified in serum, plasma and supernatants of activated platelets from MRP4-deficient mice and controls by LC-MS/MS. S1P receptor expression was assessed in wild-type mouse and human platelets by immuno-precipitation/-detection. The role of S1P signaling in platelet activation was addressed with pharmacological tools and in S1P1-deficient mouse platelets.

Results: While plasma S1P levels in MRP4-deficient mice were similar to wild-type controls, MRP4-deficient mice showed a significant reduction in S1P levels in serum and in supernatants from activated platelets. Immunodetection was most robust for S1P1 and S1P5 in mouse and human platelets, respectively. However, addition of S1P or S1P receptor agonists did not modify platelet aggregation. PAR4-ap-, collagen-, U46619- and ADP-induced platelet aggregation was not sensitive to S1P receptor antagonists and did not differ between platelets from platelet S1P1-deficient and littermate control mice.

Conclusions: Our results show that MRP4 contributes significantly although not exclusively to activation-induced S1P export from mouse platelets, but do not so far support a role for S1P signaling in mouse platelet activation.

PB 2220 | The Framingham Heart Study (FHS): Results from >900 Individuals with Detailed Platelet Function Testing

J. Huffman[1], M.-H. Chen[1], C. Wallace de Melendez[1], A. Lachapelle[1], C. Song[1], P. Sutherland[2,3], M. Hayman[4], P. Armstrong[4], M. Chan[4], T. Warner[4], A. Johnson[1]

[1]National Heart, Lung and Blood Institute's The Framingham Heart Study, Population Sciences Branch, Framingham, United States, [2]Boston University, Boston, United States, [3]National Heart, Lung and Blood Institute's The Framingham Heart Study, Framingham, United States, [4]The William Harvey Research Institute, Barts and The London School of Medicine & Dentistry, Queen Mary University of London, London, United Kingdom

Background: There are few large studies of platelet reactivity, limiting investigation of the genetic and environmental drivers in the general population.

Aims: We describe early results and analysis from an ongoing deep platelet study with respect to technical factors and cardiovascular risk factors (final projected n~3,800).

Methods: Fasting blood (sodium citrate+hirudin) is drawn. A bleeding history is taken by a modified ISTH Bleeding Assessment Tool (BAT). Whole blood platelet function measurements include impedance aggregometry (AA/ADP/collagen/ristocetin/TRAP-6 amide) and flow cytometry (FC) (CD61/CD63/CD62P/PAC1) after 20*u*M ADP. PRP is used for: (1) FC (as above), (2) traditional LTA (AA/ADP/collagen/epinephrine/ristocetin/TRAP-6 amide), and (3) Optimul absorbance assays (AA/ADP/collagen/epinephrine/ristocetin/TRAP-6 amide/U46619). Steps are taken to reduce variability (e.g., large agonist lots) and track technical factors (e.g., draw/test time). Detailed anthropometric measurements, biomarkers, clinical and sub-clinical measures are available on FHS participants.

Results: To date, of 939 participants with fasting blood draws (57.1% female, mean age 53.5 years), 60 (6.3%) were known diabetics. BAT results include: bleeding disorder (0.9%), discontinuation of medication for bleeding concerns (1.4%), serious bleeding issue after surgery (1.0%), some family history of bleeding (8.0%), and history of menorrhagia with medical attention (10.0% of women). In initial analysis, female sex was strongly associated with higher platelet reactivity across agonists, with other factors assessed showing much weaker or no association in multivariable models.

Conclusions: The Framingham platelet study will provide a previously unprecedented scale of population-level data on platelet function, bleeding history, and its relation to -omic and environmental factors. Systematic differences in platelet reactivity by sex require further study and may affect anti-platelet treatment responses in clinical settings.

PB 2221 | Polyphosphate Nanoparticles on the Platelet Surface Trigger Contact System Activation

J.J.F. Verhoef[1], A.D. Barendrecht[2], K.F. Nickel[3], K. Dijkxhoorn[2], E. Kenne[4], L. Labberton[4], O.J. McCarty[5], R. Schiffelers[2], A.P. Hendrickx[6], H. Schellekens[1], M.H. Fens[2], S. de Maat[2], T. Renne[4], C. Maas[2]

[1]Utrecht Institute for Pharmaceutical Sciences, Utrecht University, Department of Pharmaceutics, Utrecht, The Netherlands, [2]University Medical Center Utrecht, Clinical Chemistry and Haematology, Utrecht, The Netherlands, [3]University Medical Center Hamburg, Institute of Clinical Chemistry and Laboratory Medicine, Hamburg, Germany, [4]Karolinska Institutet and University Hospital, Molecular Medicine and Surgery, Stockholm, Sweden, [5]Oregon Health & Science University, Biomedical Engineering, Cell & Developmental Biology, Portland, United States, [6]University Medical Center Utrecht, Medical Microbiology, Utrecht, The Netherlands

Background: Polyphosphate (polyP) is an inorganic polymer that has diverse effects on blood coagulation and fibrinolysis. The secretion of polyP by platelets is linked to thrombosis via factor XII (FXII) activation. However, the small polymer size of secreted platelet polyphosphate limits its capacity to activate FXII in vitro. This leaves the exact mechanisms by which platelet polyP and FXII interact in thrombosis unclear.

Aims: To investigate the nature of platelet polyP.

Methods: We studied subcellular localization of polyP in platelets under flow by live-cell imaging, confocal fluorescence microscopy and scanning electron microscopy (SEM). Biophysical characterization was performed by ultracentrifugation fractionation, dynamic light scattering and electrophoresis. Plasma contact system activation was studied in plasma with chromogenic substrates and specific ELISAs.

Results: Live-cell imaging studies revealed that platelets retain polyP on their surface under flow (Fig. 1A). This occurs when single platelets secrete their contents on von Willebrand factor or during aggregation on collagen. Ultracentrifugation fractionation studies show that cell-associated polyP forms stable insoluble spherical nanoparticles. Confocal microscopy and SEM confirmed the presence of these nanoparticles on the platelet surface after degranulation (Fig. 1B). The chelating agent EDTA disrupts polyP nanoparticles, indicating that divalent metal ions are critical for their stability. Electrophoretic studies suggest that the apparent polymer size of membrane-associated polyP exceeds that of secreted polyP. This is associated with calcium complexation. In contrast to short-chain soluble polyP, polyP nanoparticles strongly activate FXII and the contact system in plasma.

Conclusions: Membrane-associated polyP is present on the platelet surface in a nanoparticle state. We propose that these polyP nanoparticles mechanistically link the procoagulant activity of platelets with activation of coagulation FXII.

PB 2222 | Analysis of Integrin β3 Clustering and Kindlin Association Using a Novel STORM Microscopy Method

M. Abo Hassan, C. Jones

Institute for Cardiovascular and Metabolic Research,University of Reading, Reading, United Kingdom

Background: Integrin αIIbβ3 activation and clustering is a vital part of platelet activation and is mediated in part through the association of kindlin with integrin β3.

Aims: To develop a Stochastic Optical Reconstruction Microscopy (STORM) method for measuring clustering in non-adherent platelets and investigate the time course of integrin β3 clustering and association with kindlin.

Methods: Platelet-rich-plasma was activated with thrombin (1U/ml) in the presence of GPRP (0.5mg/ml) for 0, 15, 30, 60, 90, 120, 180 and 300s, fixed with 2% (v/v) formal saline and permeablised with BD Phos Flow Perm Buffer III. Kindlin and integrin β3 were identified with primary and alexa fluor 647 and 555 labelled secondary antibodies, respectively. Labelled platelets were washed then adhered overnight to poly-D-lysine coated slides before 3D dSTORM imaging. Images were reconstructed using Nikon NIS Elements. The localization of integrin β3 and kindlin were analysed using the ImageJ plugin ThunderSTORM and a novel cluster analysis method that analysed the density of β3 molecules within 50nm of each β3 and kindlin molecule.

Results: The density of β3 molecules surrounding each β3 molecule (a measure of clustering) showed a biphasic pattern increasing from a low in resting platelets to peak at 60s, falling at 90s, then increasing again by 180s before again declining by 300s (P=0.026). The density of β3 molecules surrounding each kindlin molecule showed the opposite trend for the first 30s (decreasing from a high in resting platelets) and then followed the same pattern as β3 clustering (P=0.008). The kindlin-β3 and β3-β3 densities were positively associated after 30s stimulation (slope=0.32, r^2=0.22, P=0.047) but not in the first 15s (slope=-0.28, r^2=0.57, P=0.08).

Conclusions: We have developed a STORM microscopy method and used it to quantify kindlin-β3 and β3-β3 clustering in platelets. β3-β3 clustering was biphasic and associated with kindling-β3 clustering over time.

PB 2223 | Shear-mediated Platelet Activation (SMPA) Yields a Differing "Activation Signature" than that of Biochemical Agonists

Y. Roka-Moiia[1], N. Bajaj[1], D.E. Palomares[1], A. Dimasi[2], A. Redaelli[2], D. Bluestein[3], M.J. Slepian[1,3]

[1]Sarver Heart Center, University of Arizona, Department of Medicine, Tucson, United States, [2]Politecnico di Milano, Department of Electronics, Information and Bioengineering, Milan, Italy, [3]Stony Brook University, Department of Biomedical Engineering, Stony Brook, NY, United States

Background: Supraphysiologic shear stress is the major driver of platelet activation within mechanical circulatory support devices (MCSD), leading to postimplantation thromboembolic events.

Aims: To define and compare the effect of constant shear vs biochemical agonist stimulation on platelet phosphatidylserine externalization (PSE), α-granule secretion and procoagulant activity.

Methods: Human gel-filtered platelets were exposed to constant shear (30, 50, 70 dynes/cm^2 for 10 min) generated by a hemodynamic shearing device [Girdhar, 2012]. Biochemical activation and aggregation were induced by ADP, TRAP6, collagen, thrombin or arachidonic acid (AA). Aggregatory activity was evaluated via optical aggregometry. Platelet annexin V binding and P-selectin exposure were analyzed by flow cytometry, as PSE and α-granule exocytosis markers, respectively. Procoagulant activity was detected using the chromogenic platelet activation state assay [Jesty, 1999].

Results: ADP, TRAP6, collagen all induced P-selectin exposure and aggregation but did not affect platelet annexin V binding. Platelet stimulation with thrombin or AA led to massive α-granule secretion, annexin V binding and high-amplitude aggregation. In contrast, platelets exposed to high shear stress demonstrated high PSE levels and low secretory activity. The % of the platelet population binding annexin V grew quantitatively in parallel with the degree of shear exposure, while surface P-selectin barely increased. As well as PSE, thrombin generation was induced with shear (PAS assay), though with biochemical agonists was only noted with AA.

Conclusions: Constant shear, but not most biochemical agonists, induced massive PSE and subsequent thrombin generation on the platelet surface thus promoting the prothrombotic state formation. In contrast, SMPA was not associated with α-granule exocytosis, as was observed with biochemical activation. Our findings suggest a possible diagnostic signature for SMPA and provide data to further its mechanistic understanding in MCSD.

PB 2225 | Investigating Platelet Functional Heterogeneity Using Droplet Microfluidics

M.S.A. Jongen, N.A. Englyst, J.J. West

University of Southampton, Faculty of Medicine, Southampton, United Kingdom

Background: Platelets have long been known to be heterogeneous in size, volume and density. Functional heterogeneity has been suggested in several studies. However, there are currently no methods available to investigate platelet function on a single cell level. Single platelet research is needed to study intrinsic heterogeneity without the influence of adjacent cells and associated amplification mechanisms. Such a method should study platelets in isolation, with high throughput, to detect potentially rare phenotypes, without interfering with normal platelet function. To this effect, this study implements droplet microfluidics to investigate single platelet functionality.

Aims: The study aims to develop a high throughput droplet microfluidic protocol to investigate single platelet function to measure intrinsic functional heterogeneity.

Methods: The innovative droplet microfluidic protocol involves compartmentalizing and activating platelets without paracrine signalling. This is coupled with flow cytometry and imaging to quantify platelet response to agonists using three endpoints; integrin $\alpha_{IIb}\beta_3$ activation, degranulation and membrane inversion.

Results: Platelets are singularly encapsulated in 25-mm-diameter monodisperse (CV of 1-4%) water-in-oil droplets at a frequency of 4 kHz, with droplets containing a single platelet produced at a rate of 0.25 kHz (following a Poisson distribution). Isolated platelet stimulation excludes activation propagation by paracrine signalling between platelets, resulting in reduced active platelet numbers yet with enhanced activation levels caused by autocrine signalling. Platelet functional heterogeneity in response to agonists has a strong intrinsic heterogeneity component.

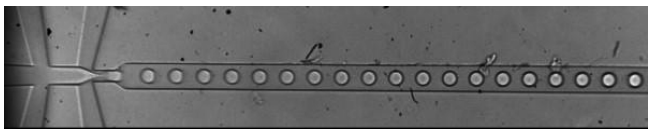

FIGURE 1 Monodisperse droplet formation

Conclusions: This study demonstrated the value of single platelet compartmentalisation in droplet microenvironments to determine system heterogeneity and ultimately unravel the intrinsic, pre-programmed states that drive platelet ensemble activation in health and potentially in disease.

PB 2226 | Sickle Cell Disease Patients under Regular Transfusion Program Have Decreased in vitro Platelet Aggregation

R.C. Saez[1,2], G.G. Yamaguti-Hayakawa[1], B.K.L. Duarte[1], J.O.F. Guanaes[1], S. Ospina[1], S.S. Medina[1], F.F. Costa[1,2], M.C. Ozelo[1,2]

[1]University of Campinas, INCT do Sangue Hemocentro UNICAMP, Campinas, Brazil, [2]University of Campinas, Department of Internal Medicine, Faculty of Medical Sciences, Campinas, Brazil

Background: Sickle cell disease (SCD) results in chronic inflammatory response with frequent endothelium activation. Activated endothelial cells induce inflammatory pathway signaling with increased production of inflammatory mediators and expression of adhesion molecules.

Aims: This study aims to evaluate the adhesive and inflammatory properties of endothelial cells and platelets from SCD patients under regular transfusion, compared to healthy individuals.

Methods: Endothelial colony-forming cells (ECFCs) were isolated from peripheral blood mononuclear cells and seeded on collagen with conditioned media. Platelets were obtained by centrifugation of platelet rich plasma. ECFCs were incubated with or without platelets and in the presence or absence of TNF-α. Inflammatory and adhesion molecules levels were evaluated in culture's supernatants by Luminex (sCD40L, IL-1B, IL-8, PDGF-AA, PDGF-AB/BB, ADAMTS13, sICAM-1, sVCAM-1, sP-Selectin, thrombospondin-1). Endothelial adhesion molecules were analyzed by flow cytometry (VCAM-1, ICAM-1, P and E-selectin).

Results: SCD platelets under regular transfusion (N=4) showed a significantly decreased response to the aggregating agents ADP (p=0.003), epinephrine (p< 0.001) and ristocetin (p=0.001), compared to control platelets (N=7). The expression of adhesion molecules VCAM-1 and P-selectin on ECFCs (regardless of the group) increased significantly after co-incubation with control platelets (p< 0.001 and p=0.01, respectively). This co-culture supernatant also presented with higher levels of soluble VCAM-1 and P-selectin, compared to co-cultures with SCD platelets (p=0.003 and p=0.007, respectively). The addition of TNF-α lead to similar results. No differences were detected in the expression and release of adhesion molecules in control ECFCs (N=6) and SCD ECFCs (N=6).

Conclusions: Our results showed, for the first time, that regular transfusions in SCD patients can alter platelet function, reducing endothelial activation capacity and therefore, the risk of vaso-occlusive event.

PB 2227 | Microthrombocytopenia and Defective GPVI/ITAM Signaling in Mice Lacking the Small GTPase RhoB

K. Aurbach[1,2], S. Dütting[1,2], C. Brakebusch[3], U.G. Knaus[4], I. Pleines[1,2], B. Nieswandt[1,2]

[1]*Institute of Experimental Biomedicine, University Hospital Würzburg, Würzburg, Germany,* [2]*Rudolf Virchow Center, University of Würzburg, Würzburg, Germany,* [3]*BRIC, Biomedical Institute, University of Copenhagen, Copenhagen, Denmark,* [4]*UCD Conway Institute, UCD School of Medicine, Dublin, Ireland*

Background: Cytoskeletal rearrangements are critical for platelet production by megakaryocytes as well as for proper platelet function. We have previously shown that mice lacking the small GTPase RhoA in megakaryocytes exhibit a macrothrombocytopenia and reduced platelet activation in response to agonists coupling to G_{13}/G_q. In contrast, the role of the Rho subfamily member RhoB in megakaryocytes and platelets remains unknown.

Aims: We investigated the functional role of RhoB in platelets in vitro and in vivo.

Methods: Taking advantage of constitutive RhoB knock-out mice, platelet function and cytoskeletal rearrangements were assessed in vitro using biochemical, flow cytometric and microscopy based assays. Platelet in vivo function was studied by the tail bleeding assay and models of arterial thrombosis.

Results: In contrast to the macrothrombocytopenia observed in RhoA-deficient animals, loss of RhoB led to a decrease in both platelet count and size, indicating a distinct role for RhoB in platelet biogenesis. RhoB-deficient platelets displayed a selective activation defect downstream of the *immunoreceptor tyrosine based activation motif* (ITAM) coupled collagen receptor GPVI resulting in reduced activation of phospholipase (PLC) γ2 in line with impaired aggregate formation on collagen under flow. Interestingly, spreading on fibrinogen was unaltered in RhoB-deficient platelets, whereas F-actin assembly upon stimulation with collagen-related peptide and convulxin as well as microtubule reassembly were severely defective. *In vivo*, these defects translated into a marked protection from arterial thrombus formation and variable tail bleeding times.

Conclusions: Our results reveal an unexpected critical role of RhoB in platelet biogenesis and function in vitro and in vivo.

PB 2228 | Characterization of in Vitro Cell-free Induced Fibrillar Fibronectin: Morphology Dependent Effects on Platelet Function

K. Huynh[1], P. Le[1], N. Mai[1], V. Stoldt[2], H. Nguyen[1], T. Vo[1]

[1]*International University - Vietnam National University HCMC, Biomedical Engineering, Ho Chi Minh, Viet Nam,* [2]*Heinrich Heine University Medical Center, Experimental and Clinical Hemostasis, Hemotherapy, and Transfusion Medicine, Duesseldorf, Germany*

Background: Insoluble fibrillar fibronectin is the active form of fibronectin, an essential component of extracellular matrix that plays important roles in many cellular processes.

Aims: This study aimed to synthesize fibronectin fibrils under cell-free conditions and characterize the relationship between fibril morphology and platelet adhesion in hemostasis.

Methods: To induce fibrillogenesis, purified fibronectin at 4 concentrations (0.25 mg/ml, 0.5 mg/ml, 0.75 mg/ml and 1 mg/ml) were dialyzed against urea 2 M in 16 h followed by dialysis against PBS pH 7.3 to subsequently remove urea. Morphology of synthesized fibrils was characterized by fluorescence microscopy. To evaluate the effect of fibronectin fibrils on platelet function, platelet adhesion assays on fibronectin fibrils were performed.

Results: Microscopic images revealed that urea induced heterogeneous formation of fibronectin fibrils with various morphologies ranging from aggregation to fibrillar form. Fibrillar fibronectin that have diameter in range 30 µm - 130 µm tend to interact to form matrix while fibronectin aggregates with size around 50 µm suspend in solution. Our data showed that among 4 tested concentrations, 1mg/ml is the best condition for fibronectin polymerization which yields the most aggregated fibronectin and fibrillar matrix. At lower concentrations, less fibronectin fibrils were formed and they did not link together to form a matrix. Platelet adhesion assay indicated a stronger platelet adhesion on fibronectin fibrils coated surfaces than surfaces coated with untreated plasma fibronectin.

Adherent platelets clustered into small groups around aggregated fibronectin and separate fibrils. In contrast, platelets appeared to adhere much more on fibrillar matrix and link to one another forming a layer.

Conclusions: Mild denaturation of plasma fibronectin by urea induces irreversible heterogeneous formation of fibronectin fibrils. Microscopic analyses revealed that fibril morphology affects platelet adhesion.

PB 2229 | Extracellular Histones Stimulate Clot Retraction and Induce Resistance to Fibrinolysis

C.T. Ammollo, N. Semeraro, M. Colucci, F. Semeraro

Aldo Moro University of Bari, Dept. Biomedical Sciences and Human Oncology, Bari, Italy

Background: Histones possess prothrombotic properties among which platelet activation. Interaction between activated platelets and fibrin(ogen) underlies the process of clot retraction, which can contribute to thrombogenesis by increasing clot resistance to fibrinolysis.

Aims: To evaluate the influence of histones on clot retraction and lysability.

Methods: Platelet-rich plasma (PRP) was clotted with $CaCl_2$ ± calf thymus histones for 2 h at 37°C. Retraction was assessed by clot area decrease and fibrinolytic resistance by release of FITC-fibrin degradation products at 2 hours after addition of t-PA to the milieu surrounding the retracted clot.

Results: In PRP, histones increased clot retraction in a dose-dependent manner (EC50, 0.43 µg/mL), with maximal stimulation at 40 µg/mL (85.9±0.8% vs 47.4±3.9% in controls). A mixture of recombinant histone subtypes produced a similar effect. Enhancement of clot retraction by histones was independent of thrombin generation increase as it persisted with clots induced by high tissue factor (25 pM) or thrombin (1 U/mL). In the presence of the anti-GPIIb/IIIa antibody abciximab (5 µg/mL), clot retraction amounted to only 6.2±3% in control PRP and to 41.8±4.4% in histone-PRP ($P<0.01$), suggesting a histone-mediated resistance to anti-GPIIb/IIIa. The extent of t-PA-mediated lysis of histone-treated PRP clots was 39.7±2.7% as compared to 57.8±7.3% in control clots ($P<0.05$), indicating an increased resistance to lysis. No effect on fibrinolysis was seen when histones were incorporated into platelet-poor plasma clots. Histone/DNA complexes (40 µg/mL each) behaved like histones, whereas DNA alone had no effect on either clot retraction or lysis.

Conclusions: Enhancement of clot retraction and resistance to fibrinolysis may represent additional mechanisms accounting for the thrombogenic activity of histones. Moreover, resistance to GPIIb/IIIa inhibitors may have clinical and therapeutic implications.

PB 2230 | Evaluation of the Total Thrombus-formation System (T-TAS): Application to Human and Mouse Blood Analysis

R. Al Ghaithi[1], J. Mori[2], L. Hardy[3], H. Philippou[3], E. Hethershaw[3], N.V. Morgan[2], Y.A. Senis[2], P. Harrison[1]

[1]Institute of Inflammation and Ageing, University of Birmingham, Birmingham, United Kingdom, [2]Institute of Cardiovascular Sciences, University of Birmingham, Birmingham, United Kingdom, [3]Leeds Institute of Cardiovascular and Metabolic Medicine LIGHT Laboratories, University of Leeds, Leeds, United Kingdom

Background: The Total Thrombus-formation Analyser System (T-TAS) is a whole blood flow chamber system for the measurement of *in vitro* thrombus formation under different shear stress conditions.

Aims: To evaluate the utility of the T-TAS for the measurement of thrombus formation within human and mouse blood.

Methods: T-TAS microchips (collagen, PL chip; collagen/tissue thromboplastin, AR chip) were used to analyse platelet or fibrin-rich thrombus formation respectively. Blood from humans and wildtype (WT), CD148, CSK, and CsK/CD148 platelet-specific knockout (KO) mice were tested.

Results: Thrombus growth (N=22) increased with shear within PL (4:40±1.11, 3:25±0.43 and 3:12±0.48 mins [1000, 1500 and 2000s^{-1}]) or AR chips (3:55±0.42 and 1:49±0.19 [240s^{-1} and 600s^{-1}]). AUC on the PL chip was also shorter at 1000s^{-1} than at 1500/2000s^{-1}(260±51.7, 317± 55.4 and 301±66.2 respectively). In contrast no differences in the AUC between 240s^{-1} and 600s^{-1} were observed in the AR chip (1593±122 and 1591±158). The intra-assay CV (n=10) in the PL chip (1000s^{-1}) and AR chips (240s^{-1}) were T_{10}14.1%, T_{60}16.7%, $T_{10\text{-}60}$22.8% and AUC_{10}24.4% or T_{10} 9.03%, T_{80}8.64%, $T_{10\text{-}80}$23.8% and AUC_{30}5.1%. AR chip thrombus formation was inhibited with rivaroxaban (1µM), but not with the ticagrelor (10µM). PL chip thrombus formation was totally inhibited with the ticagrelor. T-TAS shows agreement with LTA in about 82% of patients tested so far (n=14). The onset (T_{10}) of thrombus formation in WT mice (N= 4) was shorter when compared to humans e.g. PL chip (1000s^{-1}) T_{10} were 02:02±00:23 and 03:30±0:45 respectively). All three KO mouse models exhibited no measurable thrombus formation in PL chips with delayed onset of thrombus formation in AR chips.

Conclusions: T-TAS measures *in vitro* thrombus formation within 2 different chips and can be used for monitoring antithrombotic therapy in patients. It can also be applied to investigating thrombus formation within patients and mouse models.

PB 2231 | The Mechanisms Underlying Core-and-Shell Architecture of Arterial Thrombus and it´s Dynamics Described with Computational Modeling

V.N. Kaneva[1], D.Y. Nechipurenko[1,2,3], F.I. Ataullakhanov[1,2,3], M.A. Panteleev[1,2,3]

[1]Lomonosov Moscow State University, Moscow, Russian Federation, [2]Center for Theoretical Problems of Physicochemical Pharmacology, Moscow, Russian Federation, [3]Dmitry Rogachev National Research Center of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation

Background: Under high shear conditions primary hemostatic response involves GPIb-mediated interaction between platelets and von Willebrand factor as well as platelet interaction through surface integrins which strongly depends on platelet activation. Despite the abundance of experimental data covering various features of those interactions, the origin of spatio-temporal heterogeneity of platelet thrombus and the mechanisms limiting its size are not clearly understood.

Aims: In order to get a deeper insight into complex mechanics of platelet thrombus formation and the origin of specific dynamics of thrombus shell observed in vivo we developed and analyzed the computational model of arterial thrombus formation.

Methods: We created a 2d computational model of arterial thrombus formation which considers two types of platelet interactions: through GPIb (vWF-mediated) and through αIIbβ3 integrins (fibrinogen and vWF-mediated). Platelets were represented by discoid particles 2 μm in diameter. Two types of inter-platelet interaction were described differently: interaction via GPIb and Von Willebrand factor was modeled by stochastic springs, while interaction via αIIbβ3 and fibrinogen/vWf was described using deterministic Morse potential. Platelet activation process was described with simple residence-time based model. Blood was considered as incompressible Newtonian fluid.

Results: The dynamics of thrombus formation described with our model has several features:

1) the height of the thrombus is limited by specific dynamics of its outer layers (shell) which flow pass the stable inner layers (core) due to transient nature of GPIb-vWF-mediated interactions and only partial integrin activation

2) the interplay between integrins activation kinetics and the dynamics of thrombus shell influences the evolution of thrombus core.

Conclusions: Our stochastic model of thrombus formation describes complex mechanics of thrombus shell and offers new mechanism of thrombus size regulation.

PB 2232 | Effects of pH and Concentration of Sodium Citrate Anticoagulant on Platelet Aggregation Measured by Light Transmission Aggregometry Induced by Adenosine Diphosphate

K. Germanovich[1], E.A. Femia[1], C. Cheng[1], N. Dovlatova[2], G.M. Podda[1], M. Cattaneo[1]

[1]*Unità di Medicina III, ASST Santi Paolo e Carlo - Dipartimento di Scienze della Salute, Università degli Studi di Milano, Milano, Italy,* [2]*Thrombosis and Haemostasis Group, Clinical Neurosciences, University of Nottingham, Nottingham, United Kingdom*

Background: The 2013 ISTH-SSC guidelines for the standardization of light transmission aggregometry (LTA) were largely based on expert consensus, as studies directly comparing LTA methodologies were lacking.

Aims: We experimentally tested the cogency of ISTH-SSC recommendations pertaining to use of anticoagulant, in particular whether:

1) buffered citrate (BC) is preferable to un-buffered citrate (C);

2) the 2 recommended concentrations of sodium citrate (109 and 129 mM) are equivalent in terms of platelet aggregation (PA).

Methods: Blood from 16 healthy volunteers was collected into BC and C 109 and 129 mM. PA was measured by LTA in platelet-rich plasma (PRP) stimulated by ADP (2 μM) immediately after PRP preparation and up to 4 hours after blood collection; pH and platelet count in PRP were measured in parallel.

Results: pH in PRP increased with time up to about 8 for all anticoagulants, although it was lower in BC than in C at all times. In BC PA was lower at 45 min, but equivalent at all other times. PA was higher and more stable in sodium citrate 109 mM than in 129 mM at all times. The extent of PA did not change up to 2 hours since blood collection, and subsequently dramatically decreased.

Conclusions: In contrast with ISTH-SSC recommendations,

1) BC does not show advantages compared to C;

2) 109 mM citrate is preferable to 129 mM, because it better supports PA;

3) LTA studies should be completed within 2 hours of blood collection, instead of the recommended 4 hours.

PB 2233 | Idelalisib and Platelet Aggregation in Patients with Chronic Lymphocytic Leukemia (CLL)

A. Artoni[1], P. Bucciarelli[1], R. Cassin[2], S. Lamarca[1], A. Lecchi[1], G. Reda[2], A. Cortelezzi[2], F. Peyvandi[1]

[1]*Fondazione IRCCS Ca' Granda - Ospedale Maggiore Policlinico, A. Bianchi Bonomi Hemophilia and Thrombosis Center, Milan, Italy,* [2]*Fondazione IRCCS Ca' Granda - Ospedale Maggiore Policlinico, Oncohematology, Milan, Italy*

Background: Idealisib and ibrutinib are novel therapies for chronic lymphocytic leukemia (CLL). It has been reported that ibrutinib induces a platelet dysfunction that increases bleeding in 50% of patients. Knowledge about potential bleeding complications associated with the use of idelalisib are important for CLL patients management.

Aims: To assess the potential side effects of idelalisib on bleeding tendency in patients with CLL.

Methods: Ten patients with CLL (M/F: 6/4; median age 71 y) who started treatment with idelalisib were included in an observational prospective study. Bleeding Severity Score (BSS) was administered and primary and secondary hemostasis tests were performed before and after 1 and 3 months starting therapy with idelalisib.

Results: No bleeding episodes were observed in patients treated with idelalisib and BSS remainde below 5. All patients had normal coagulation tests at all three time points, while platelet count was below 100.000/mm^3 at baseline in 5 patients. At baseline, in 9/10 patients platelet aggregation were abnormal with at least 2 of the 4 aggregating agents tested and platelet secretion was impaired, particularly using ADP (8/10 patients). In 8 patients intraplatelet ATP/ADP ratio was abnormal, suggesting a delta storage pool disease. At 1 month, 5/9 patients with abnormal baseline platelet aggregation tests had an improvement of

platelet aggregation and one worsened. At 3 months, 3 further patients had an improvement of platelet aggregation. At 3 months, 7 patients reached complete remission and 2 a partial remission of CLL.

Conclusions: Idelalisib treatment appears safe in patients with CLL at increased bleeding risk. Platelet function tests improved after beginning of therapy.

PB 2234 | Platelet Investigations in Patients with Essential Thrombocytosis

O.H. Pedersen[1,2], M.L. Larsen[1,2], P.H. Nissen[2], P.K. Niekerk[3], S. Bønløkke[3], E.L. Grove[1,4], S.D. Kristensen[1,4], A.M. Hvas[2,4]

[1]Aarhus University Hospital, Department of Cardiology, Aarhus, Denmark, [2]Aarhus University Hospital, Centre of Haemophilia and Thrombosis, Department of Clinical Biochemistry, Aarhus, Denmark, [3]Aarhus University, Department of Hematology, Aarhus, Denmark, [4]Aarhus University, Faculty of Health, Institute of Clinical Medicine, Aarhus, Denmark

Background: Patients with essential thrombocytosis (ET) are characterized by an increased platelet count, and provide a biological model for studying platelet function in patients with accelerated platelet turnover. ET patients have an increased risk of thromboembolic events, partly explained by the increased platelet count. An increased proportion of reactive immature platelets may also be important.

Platelet function analysed by impedance aggregometry is dependent on platelet count but flow cytometry allows for evaluating of platelet function independently of platelet count.

Aims: To investigate associations between platelet count, platelet turnover and platelet function in ET patients.

Methods: In 24 ET patients, platelet aggregation was measured by impedance aggregometry using the Multiplate® Analyzer. Arachidonic acid (AA), Thrombin-Receptor-Activating-Peptide (TRAP) and adenosine diphosphate (ADP) were used as agonists. Platelet surface expression of P-selectin, CD63 and fibrinogen were measured with flow cytometry (Navios®) after activation with the same agonists. The results were reported as median fluorescence intensity of marker-positive platelets.

Immature platelet count (Sysmex®) was used as marker of platelet turnover.

Results: Platelet count correlated significantly with aggregation induced by AA (r=0.43, P=0.04), TRAP (r=0.46, P=0.03) or ADP (r=0.60, P=0.003).

After activation by AA and ADP, the median fluorescence intensity of expressed fibrinogen, CD63 and P-selectin were significantly increased in ET patients compared to healthy individuals (P< 0.03).

The immature platelet count was significantly higher in ET patients compared to healthy individuals (median 12.3 [IQR 9.8-18.7] vs median 6.9 [IQR 5.5-10.3], P< 0.0001).

Conclusions: ET patients have an increased aggregation potential compared to healthy individuals illustrated with a higher median intensity of activating-dependent surface markers. This is likely explained by an increased platelet count and increased proportion of immature platelets.

PB 2235 | Computational Analysis of Shear Stress Distribution during Thrombus Formation in a Blood Vessel and Parallel Plate Flow Chamber

A. Megalinskiy[1], D.Y. Nechipurenko[1,2,3], F.I. Ataullakhanov[1,2,3], M.A. Panteleev[1,2,3]

[1]Lomonosov Moscow State University, Physics, Moscow, Russian Federation, [2]Center for Theoretical Problems of Physicochemical Pharmacology, Moscow, Russian Federation, [3]Dmitry Rogachev National Research Center of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation

Background: Unrevealing the mechanisms governing the regulation of arterial thrombus size is one of the long-standing problems of biorheology. Studies on thrombus formation ex vivo usually involve perfusion of whole blood through especially designed flow chambers. In such experiments activators are usually applied to a sufficiently large surface area, leading to the formation of multiple thrombi which affect local hydrodynamics.

Aims: In order to identify the differences between local hydrodynamic conditions in case of thrombus formation in a blood vessel and during flow chamber experiment the computational fluid dynamics analysis was performed.

Methods: Thrombi in microvessel were represented by semi-ellipsoids of various sizes, the boundary conditions corresponded to constant pressure drop. The geometry of multiple platelet thrombi in the flow chamber was taken from experimental data obtained by whole blood perfusion over collagen at 1000 s-1. Platelet thrombi were represented by semi-ellipsoids, and the stationary flow fields corresponding to different time points of experiment were computed for constant inflow boundary conditions. The blood was treated as Newtonian fluid, while thrombi were considered as solid impermeable barriers.

Results: Computation results showed significant differences in the dynamics of shear stress magnitude at the surface of growing thrombi in the studied systems: the initial stage of thrombi formation inside the flow chambers was characterized by decrease of surface shear rate, while in the blood vessel shear rate at thrombus surface rapidly increases with initial thrombus growth. At later stages of thrombi formation within the flow chamber there is a strong decrease of shear rates in between the thrombi associated with redistribution of blood flow and increase of shear rates at thrombi apexes.

Conclusions: CFD analysis shows non-physiological dynamics of thrombus surface shear rate in parallel-plate flow chamber experiments.

PB 2236 | Platelet Function during Prolonged Targeted Temperature Management after Cardiac Arrest: A Randomised Clinical Trial

A. Jeppesen[1], H. Kirkegaard[2], S. Ilkjær[1], A.-M. Hvas[3]

[1]Aarhus University Hospital, Department of Anaesthesiology and Intensive Care Medicine, Aarhus, Denmark, [2]Aarhus University Hospital, Research Centre for Emergency Medicine, Aarhus, Denmark, [3]Aarhus University Hospital, Centre for Haemostasis and Thrombosis, Department of Clinical Biochemistry, Aarhus, Denmark

Background: Current guidelines recommend to lower the body core temperature in patients resuscitated after out-of-hospital cardiac arrest. Previous studies investigating the effect of mild hypothermia on platelet function were small and showed conflicting results. Moreover, the platelet function during prolonged hypothermia in humans has not been investigated.

Aims: Investigate whether prolonged duration of targeted temperature management impaired the platelet function compared with standard duration.

Methods: We randomized 82 out-of-hospital cardiac arrest patients to either 24 hours (standard, n=42) or 48 hours (prolonged, n=40) of targeted temperature management at 33±1°C. Blood samples were obtained 22±2, 46±2 and 70±2 hours after targeted temperature management was reach. Platelet function was analysed by impedance aggregometry (Multiplate®Analyzer) using COL®test, TRAP®test, ADP®test and ASPI®test as agonists. Use of antithrombotic drugs was systematically registered from medical records. Informed content was obtained and the study was approved by the research ethics committee.

Results: The platelet function was below the reference interval at all time points, independent on the agonist used. No differences in platelet function were observed between groups in the 22-hour sample. In the 46-hour sample, where only the standard group had been rewarmed, the prolonged group had a 24% (95% confidence interval (-10%;-37%), p=0.002) decreased platelet function when using the COL®test compared with the standard group, but no difference were observed between groups when using TRAP®test, ADP®test, or ASPI®test. Moreover, no differences were observed between groups in any of the agonist used at the 70-hour sample where all patients had been rewarmed.

Conclusions: Prolonged duration of targeted temperature management did not induce a pronounced impaired platelet function when compared with standard duration.

PB 2237 | An Absence of Platelet Activation Following Thalidomide Treatment *in vitro* or *in vivo*

J. Qiao[1,2], Y. Wu[1], X. Wu[1], Y. Liu[1], X. Li[2], W. Ju[2], L. Zeng[1], E. Gardiner[3], R. Andrews[4], K. Xu[1,2]

[1]*Xuzhou Medical University, Xuzhou, China,* [2]*The Affiliated Hospital of Xuzhou Medical University, Department of Hematology, Xuzhou, China,* [3]*Australian National University, Canberra, Australia,* [4]*Monash University, Melbourne, Australia*

Background: Increased risk of thromboembolism and platelet hyperreactivity has been reported in patients receiving thalidomide therapy. Whether thalidomide induces platelet activation directly or through other factors remains unclear.

Aims: The aim of this study was to evaluate the effect of thalidomide on platelet activation under resting conditions *in vitro* and *in vivo*.

Methods: Isolated human or mouse platelets were treated with different concentrations of thalidomide (10, 50 and 100 μg/ml) for 60 min at 37°C followed by analysis of platelet surface expression of platelet receptors GPIbα, GPVI, $\alpha_{IIb}\beta_3$ and P-selectin, and PAC-1 or fibrinogen binding, by flow cytometry and collagen- or ADP-induced platelet aggregation. In addition, thalidomide (200 mg/kg) was intraperitoneally injected into mice for analysis of the effect of thalidomide on platelet activation *in vivo*.

Results: No increased expression of P-selectin, PAC-1 or fibrinogen binding was observed in either human and mouse platelets after thalidomide treatment *in vitro* for 60 min at 37°C. Thalidomide treatment also did not affect expression of GPIbα, GPVI or $\alpha_{IIb}\beta_3$, nor did it affect collagen- or ADP-induced platelet aggregation at threshold concentrations. However, while mice injected with thalidomide displayed no increased surface expression of platelet P-selectin or $\alpha_{IIb}\beta_3$, there was a significantly shortened tail bleeding time, thrombin time, prothrombin time together with higher levels of Factor IX and fibrinogen.

Conclusions: Thalidomide at therapeutic doses does not directly induce platelet activation under resting conditions *in vitro* or *in vivo*, but results in increased procoagulant activity, which could explain the thalidomide-dependent prothrombotic tendency in patients.

PB 2238 | Reduced Left Ventricular Function Compared to Preserved Function after Myocardial Infarction is Associated with a Different Platelet Pattern

C. Christersson[1], Å. Thulin[2], A. Siegbahn[2]

[1]*Uppsala University, Cardiology, Uppsala, Sweden,* [2]*Uppsala University, Clinical Chemistry, Uppsala, Sweden*

Background: Heart failure is associated with increased risk of thromboembolic events such as stroke.

Aims: The aim was to compare the platelet activity in patients with reduced left ventricular ejection fraction (LVEF) and normal LVEF after a recent myocardial infarction (MI).

Methods: MI patients were included in an observation study 3-5 days after the index MI. Platelet-monocyte (PMA) and platelet-ganulocyte (PGA) complexes, defined as the amount of monocyte/granulocyte with surface expression of CD41 or CD62P, platelet derived microparticles (PMP) and the amount of single platelets with surface expression of CD42b, CD49b, CD62P were evaluated in whole blood at inclusion and after 3 months. LVEF was calculated (n=84) after the index MI before discharge and LVEF < 0.52 for men and < 0.54 for women were defined as reduced LVEF.

Results: Reduced LVEF was found in 26% (n=22) of the MI patients. The proportions of aspirin, P2Y12-inhibitor, anticoagulant and statin treatment were similar in the group with reduced compared to normal LVEF. After 3 months the CD41+MPs tended to persist lower in the reduced compared to normal LVEF group (p=0.090). No differences were found comparing the other platelet measurements after 3 months.

Conclusions: The observation that patients with reduced LVEF have lower concentrations of circulating PMPs and single platelets expressing adhesion proteins early after the MI might be explained by their adherence to the damage myocardium. Activated P-selectin expressing platelets forming complexes with monocytes induce production of

TABLE 1 Platelet markers at inclusion after MI separated by LVEF

	LVEF reduced (n=22)	LVEF normal (n=62)	p-value
CD41+MPs (n/10000 platelets)	2492 (1580-2985)	3086 (2318-4127)	0.018
CD49b (%)	7.10 (5.46-10.91)	10.70 (8.58-14.02)	<0.001
CD42b (%)	6.78 (5.10-10.44)	10.17 (8.29-13.72)	<0.001
CD62P (%)	14.26 (12.30-17.44)	12.58(8.64-18.70)	0.183
PMA CD41+ (%)	3.63 (2.88-4.25)	3.30 (2.73-4.08)	0.600
PMA CD62P+ (%)	4.71 (3.81-5.37)	3.98 (3.10-4.69)	0.015
PGA CD41+ (%)	4.11 (3.60-5.46)	3.94 (3.23-5.00)	0.302
PGA CD62P+ (%)	8.72 (6.58-10.20)	7.34 (5.62-9.31)	0.170

cytokines and tissue factor which could contribute to the increased risk of thromboembolism in patients with reduced LVEF.

PB 2240 | Lymphocyte-platelet Adhesion and Clusters Formation in Patients Infected with Influenza A/H3N2

A. Emelianov[1], A. Emelianova[2], N. Belozerceva[2], O. Solpova[1], A. Solpov[1], Y. Vitkovsky[1]

[1]Chita State Medical Academy, Normal Physiology Department, Chita, Russian Federation, [2]Chita State Medical Academy, Infectious Diseases Department, Chita, Russian Federation

Background: Recent studies have accumulated evidence that platelets, besides their haemostatic activity, participate in inflammation, immunity and atherosclerosis. In a previous study we demonstrated that platelets interacted with T-lymphocytes and formed heterotypic aggregates. Also it support CD4+ lymphocyte adhesion to the subendothelial extracellular matrix under flow conditions by formation of heterotypic clusters that are dependent on platelet adhesion and aggregation and mediated by CD40L, PSGL-1 and dependent integrins. Previously, we found that the number of lymphocyte-platelet aggregates (LPA) increased in patients with influenza A/ H1N1 (2009).

Aims: The aim was to investigate LPA number and lymphocyte-platelet clusters (LPC) formation in patients infected with influenza A/ H3N2 in blood circulation.

Methods: In control group we used the blood of 14 healthy donors. The blood of patients was taken in the acute phase of the disease (1-2 days) and after antiviral and symptomatic treatment (5-6 days). Lymphocytes were isolated by ficoll-urografin gradient and then counted percent of LPA and number of LPC (rel. u.).

Results: The number of LPA in control was 11,7 ± 3,6%, and LPC 1,9 ± 1,03 rel. u. It has been found that the amount of LPA and LPC increased in the acute phase of the disease versus control (2.4 and 3.9 times, respectively, p < 0.001). Also the average numbers of platelets on lymphocytes surface increased in 2.7 times (p < 0.05). We didn't find differences in these parameters on 5-6 days of the disease.

Conclusions: Thus, lymphocytes increased ability to form heterotypic coaggregates and clusters with platelets in patients with acute phase of influenza A/H3N2. Probably the clusters forming process is mediated by platelet and leukocyte adhesion molecules.

PB 2241 | Detection and Characterization of Extracellular Vesicles at Different Stages of Platelet Concentrate Storage Using High-resolution Flow Cytometry

Background: Platelet-derived extracellular vesicles are formed due to platelet activation. Increased level of these vesicles in the bloodstream is observed in various pathological processes.

Aims: To analyze platelet-derived extracellular vesicles in platelet concentrate samples at the different stages of storage using high-resolution flow cytometry.

Methods: 65 samples of platelet concentrates prepared from donors' blood according to the standard protocols were selected. Samples were fractionated by differential centrifugation and composition of the fractions was characterized by flow cytometer CytoFLEX/ BecmanCoulter using fluorescence-labeled antibodies against specific markers of different cell types-platelets(CD41,CD62P), erythrocytes(CD235a), leukocytes(CD45), endotheliocytes(VEGFR2).

Results: Analysis showed that the fractions contain minor amounts(< 0.01%) of objects carrying CD45 or CD235a and are substantially free of VEGFR2 carriers. Platelets were detected as objects of 1-2.5μm, bearing CD41(99% of all objects). Platelet-derived extracellular vesicles were defined as the objects, which bear CD41, and were represented by two populations of objects, which have size 0.1-1μm (71% of all CD41 positive objects with size < 1μm) and 0.03-0.1μm. The substantial proportion of platelet-derived extracellular vesicles (54%) was positive for surface marker of activated platelets CD62P/P-selectin. Levels of platelet-derived extracellular vesicles as well as extracellular vesicles from erythrocytes and leukocytes increased in platelet concentrate on the 7th day compared with the 2nd day.

Conclusions: Thus, during platelet concentrate storage the number of platelet-derived extracellular vesicles increases progressively, reflecting platelet activation and changing of platelet concentrate quality. The findings are of practical importance for blood banking and transfusion medicine, since they indicate the advantages of 2nd day versus 7th day concentrate. Supported by grant of Russian Foundation for Basic Research №16-04-01142.

PB 2242 | New Opportunities in Express-evaluation of Living Platelets

I. Vasilenko[1,2], E. Vlasova[1,2], V. Metelin[1,2], A. Balkanov[1], R. Lifenko[2], V. Khvatov[3], M. Makarov[3]

[1]M.F.Vladimirsky Moscow Regional Clinical and Research Institute, Moscow, Russian Federation, [2]A.N. Kosygin Russian State University, Moscow, Russian Federation, [3]N.V.Sklifosovsky Research Institute of Emergency Medical Treatment, Moscow, Russian Federation

Background: Platelets play a critical role in cancer progression, thrombosis, and markers of platelet-tumor cell interaction are candidates as biomarkers for cancerprogression and thrombosis risk.

Aims: The aim of our study was to evaluate living platelet size, function and morphology simultaneously in unactivated and activated states in patients with cancer using method of Quantitative Phase Imaging (QPI).

Methods: We examined 79 healthy volunteers and 75 patients (average age 67,3+/-9,1 years) with oropharynx cancer of I-II and III-IV stage, brain metastasis or glioblastoma. We observed the optic-geometrical parameters of each isolated living cell and the distribution of platelets by sizes to detect the dynamics of cell population heterogeneity using Computer-aided Phase-Inteference Microscope.

Results: Simultaneously we identified 4 platelet forms that have different morphological features and different parameters of size distribution. We found out that morphological platelet types correlate with morphometric platelet parameters. In the fluorescence microscope we observed the platelet concentration; the relative content of platelet granule (%); concentration of platelet granules; morphofunctional activity (in points); adhesive activity (in % or points); morpho-functional status of platelets (in points). In this method we used staining platelet which were painted with trypaflavine and acridine orange in Zerensena phosphate buffer (pH = 7.3).

We fixed the platelet activation using both methods. The degree of platelet activation is connected with initial tumor stage and metastases. The vital colorant allowed to obtain a differential glow of cell cytoplasm and granule in the fluorescence microscope. No light granules in platelets are associated with activation of cells or damage.

Conclusions: According to our results we suggest that both methods can serve criteria of the efficiency of the radio- and chemotherapy and can be express methods to detect the activation status of platelets.

PB 2243 | Comparing Platelet Reactivity in Patients with Chronic Kidney Disease to that in Healthy Volunteers

H.E. Allan, M.V. Chan, P.C. Armstrong, M.M. Yaqoob, T.D. Warner

William Harvey Research Institute, London, United Kingdom

Background: The 10-year mortality risk in patients with non-dialysis requiring chronic kidney disease (CKD) is 5 fold higher than the general population. This elevated mortality rate is strongly linked to atherothrombotic disease.

Aims: Here we aim to determine if changes in platelet reactivity may be a causative factor in the increased incidence of atherothrombotic disease in CKD patients.

Methods: Blood was obtained by venepuncture from healthy volunteers (n=20) and CKD patients (n=18, stage 4-5, eGFR=15±1) into 3.2% sodium citrate. Flow cytometry was used to determine P-selectin expression and platelet-leukocyte interactions in whole blood. Platelet rich plasma and platelet poor plasma were obtained by centrifugation and aggregation in response to arachidonic acid, collagen, TRAP-6 amide (ligand for thrombin receptor, PAR-1), U46619 (ligand for thromboxane A_2 receptor, TP), epinephrine and ristocetin, was determined using light transmission aggregometry (LTA) and Optimul aggregometry. Percentage aggregation was calculated and data were analyzed by ANOVA. Data is reported as mean±s.e.m.

Results: Basal P-selectin expression on platelets in whole blood was not different between CKD patients and healthy controls. LTA indicated increased platelet aggregation in CKD patients compared to healthy controls. For instance, aggregation to arachidonic acid (1mM) was 88±2% in CKD patients vs. 73±1% in controls; ADP (20 μM) 85±2% vs. 70±1%; collagen (10 μg/ml) 86 ±3% vs. 72±1%; TRAP-6 amide (25 μM) 87±2% vs. 71±1%; U46619 (10 μM) 87±2% vs. 72±1%; $p< 0.05$ for all.

Conclusions: Initial observations indicate increased platelet reactivity in CKD patients compared to healthy controls which may contribute to the increased risk of atherothrombotic disease.

PB 2244 | Disaggregation Following Agonist-induced Platelet Activation in Patients on Dual Antiplatelet Therapy

P.P. Wadowski[1], B. Eichelberger[2], C. Kopp[1], J. Pultar[1], D. Seidinger[1], R. Koppensteiner[1], I.M. Lang[3], S. Panzer[2], T. Gremmel[1]

[1]Medical University of Vienna, Division of Angiology, Department of Internal Medicine II, Vienna, Austria, [2]Medical University of Vienna, Department of Blood Group Serology and Transfusion Medicine, Vienna, Austria, [3]Medical University of Vienna, Division of Cardiology, Department of Internal Medicine II, Vienna, Austria

Background: Light transmission aggregometry (LTA) is considered the historic gold standard method for the assessment of platelet function. The difference between maximal and final aggregation by LTA indicates the stability of platelet aggregates. A small difference means low disaggregation, whereas a great difference between the two values reflects high disaggregation, i.e. a low stability of platelet aggregates.

Aims: In this study, we evaluated the extent of disaggregation after platelet stimulation with 5 different agonists in patients on dual antiplatelet therapy.

Methods: LTA was performed in 323 patients with daily aspirin (100mg/d) and clopidogrel (75mg/d, n=256), prasugrel (10mg/d, n=47) or ticagrelor (180mg/d, n=20) therapy after angioplasty and

stenting using the following agonists: ADP (10μM), arachidonic acid (AA; 0.5mg/ml), collagen (190μg/ml), epinephrine (5.5μM) and thrombin receptor-activating peptide-6 (TRAP-6; 25μM).

Results: Significant differences between maximal and final aggregation values were observed with all agonists throughout the groups (all p< 0.001). Disaggregation was highest using AA (clopidogrel: 36.5% (18.2%-66.3%); prasugrel/ticagrelor: 100% (100%-100%)) and ADP (clopidogrel: 21.7% (5.1%-44.6%); prasugrel: 100% (81.3%-100%), ticagrelor: 100% (85.0%-100%)). In contrast, low disaggregation was observed after platelet stimulation with collagen and TRAP-6 in clopidogrel-treated patients (collagen: 8.8% (1.8%-28.9%); TRAP-6: 2.5% (0.7%-9.2%)), and after platelet stimulation with collagen (prasugrel: 3.0% (2.1%-5.5%); ticagrelor: 3.3% (2.2%-6.5%)) and epinephrine (prasugrel: 4.8% (0.0%-12.5%); ticagrelor: 5.0% (0.5%-17.4%)) in prasugrel- and ticagrelor-treated patients.

Conclusions: Pathways of platelet activation that are not inhibited by standard antiplatelet therapy allow persisting platelet aggregation and may at least in part be responsible for adverse ischemic events during antithrombotic secondary prevention.

PB 2245 | *In vitro* Study on the Effects of Ibrutinib (Ibr) on Platelet (Plt) Function via Light Transmission Aggregometry (LTA): Platelet Aggregation (PA) Results

J. Ninomoto[1], A. Mokatrin[1], T. Kinoshita[1], C. Marimpietri[1], B.Y. Chang[1], J. Sukbuntherng[1], D.F. James[1], M. Crowther[2]

[1]*Pharmacyclics LLC, an AbbVie Company, Sunnyvale, United States,* [2]*McMaster University, Department of Pathology and Molecular Medicine, Division of Hematology & Thromboembolism, Hamilton, Canada*

Background: Ibr is a first-in-class, once-daily inhibitor of Bruton's tyrosine kinase (BTK). BTK is expressed in human plts and is involved in signaling via collagen receptor glycoprotein VI. Bleeding events, mostly Gr 1/2 bruising and petechiae, are common with ibr (ibr PI, 2017) and other BTK inhibitors (Walter Blood 2016; Byrd NEJM 2016).

Aims: This in vitro study evaluated ibr effects on plt function.

Methods: Four cohorts (cht) of subjects (sbj) without known cancer were included: healthy, taking aspirin, taking therapeutic warfarin daily for ≥60 days, or with renal dysfunction on hemodialysis. Plt-rich plasma isolated from peripheral blood was incubated with 0-10 μM ibr and exposed to the following plt agonists: arachidonic acid (AA), adenosine diphosphate (ADP), collagen, ristocetin, and thrombin receptor-activating peptide 6 (TRAP-6). In vitro PA was measured by percent of maximum aggregation (% MA) obtained by LTA.

Results: Among 56 sbj, 8 per cht had evaluable samples. Only collagen-induced PA was meaningfully inhibited, occurring in a concentration-dependent manner with ibr 10 μM resulting in >50% PA inhibition in healthy, warfarin, and renal chts. In the aspirin cht, inhibitory effects of ibr on collagen-induced PA was also observed, but was less pronounced as collagen-induced PA was reduced in control (ie, without ibr). No measurable PA was noted to AA in aspirin cht control. In all chts, the reduction in PA was < 30% (ie, no appreciable inhibition) with ibr concentrations up to 10 μM for the remaining agonists.

Conclusions: In this in vitro study, ibr inhibited collagen-induced PA in samples from sbj who were healthy, on therapeutic warfarin, or had renal dysfunction. The magnitude of ibr inhibition of collagen-induced PA in sbj on aspirin was less pronounced since collagen-induced PA was already reduced in the aspirin control (ie, without ibr). PA induced by the agonists AA, ADP, ristocetin, and TRAP-6 were not substantially inhibited by ibr 10 μM.

PB 2246 | The Use of Laser Therapy for Muscle Bleeding in Glanzmann Thrombasthenia - A Case Report

B. Choinska[1], P. Laguna[1], K. Scipio del Campo[2], M. Matysiak[1]

[1]*Medical University, Dep. Ped. Hematology and Oncology, Warsaw, Poland,* [2]*Medical University, Dep. Ped. Cardiology, Warsaw, Poland*

Background: Glanzmann thrombasthenia (GT) is a rare autosomal recessive disorder, caused by quantitative or qualitative defect of the membrane integrin αIIbβ3, a platelet receptor binding adhesive proteins in the initial stage of the coagulation proces. The primary objective of this study was to describe clinical effects observed in laser treatment in muscle bleeding in patient with GT.

Aims: A 13-year-old male with GT was admitted to the hospital due to a burgeoning bleeding in the right thigh caused by a fall from a bicycle. During physical examination, a haematoma was detected. The difference of 15cm in the circuit was observed between the lower limbs. The thigh was aching and an extensive bruise was noticeable. Platelet transfusions were ineffective so rFVIIa was successfully used to terminate the bleeding. Nonetheless the extensive, painful haematoma could have still been observed.

Methods: The biostimulation with *semiconductor laser generating a beam of monochromatic light (visible bright red) with the wavelength of 650 nm and the dose of 2J/cm* was used to accelerate the regression of hematoma. Furthermore, rehabilitation exercises were conducted in parallel.

Results: The reduction of hematoma and the cessation of patient's complaints were observed already after administrating the first dose. The *average reduction* in circumference per day was about 1cm. Adverse effects were observed as well though.

Conclusions: This case report describes the succesful use of laser therapy in the treatment of muscle haematoma in GT. The laser biostimulation is safe and can help to accelerate treatment and improve patient management.

PB 2247 | Amniotic Fluid-derived Mesenchymal Stem Cells (AF-MSCs) Decrease Agonists Platelet Response

M. Fernández-Arrausi[1], D. Iyu[1], E.G. Navarro[1], J.J. Cerezo-Manchado[2], M. Rodríguez-Valiente[2], A.I. García-Guillén[1], J.M. Moraleda[2,3], F. García-Candel[2,4], N.M. Atucha[1]

[1]University of Murcia. IMIB-Arrixaca, Physiology, El Palmar, Spain, [2]Hospital Clínico Universitario Virgen de la Arrixaca, Hematology, El Palmar, Spain, [3]University of Murcia.IMIB-Arrixaca, El Palmar, Spain, [4]IMIB-Arrixaca, El Palmar, Spain

Background: When mesenquimal stromal cells are administered intravenously, they produce adverse events, mainly thrombotic disorders. These have been related to tissue factor (FT) expression, which gives them procoagulant activity. Moreover, these cells have the ability to interact with other cells, including platelets, key elements in haemostasis and homing.
Aims: The objetive was to evaluate in vitro, the effect of amniotic fluid-derived mesenchymal stem cells (AF-MSCs) on platelet function.
Methods: AF-MSCs were isolated from amniotic fluid obtained in deliveries by planned caesarean. They were cultured at 37 °C and 5% CO_2 with Amniomax medium supplemented with fetal bovine serum and antibiotics. AF-MSCs were tripsinized on passage 4-5 and mesenchymal markers (CD90, CD105, CD73) and FT expression was measured by flow-cytometry. Whole blood of control subjects was incubated *in vitro* with AF-MSCs (150.000/300.000 cell/mL, 15 min at 37 °C) and the platelet response was quantified by impedance aggregometry (multiplate; ADP and TRAP tests), flow cytometry (platelet activation marker P-selectin expression), and platelet function analyzer (PFA-100). Also, clotting tests were performed in plasma obtained from in vitro blood incubations.
Results: AF-MSCs cultures showed high proliferation and viability. The AF-MSCs expressed mesenchymal markers CD105 (88%), CD90 (60%) and CD73 (97%) and tissue factor (43%), being negative for the hematopoietic markers CD45 and CD34. The incubation of peripheral blood with AF-MSCs shorted PTTa; augmented EPI-collagen closure time and decreased impedance platelet aggregation response to ADP and TRAP (even in the presence of the antithrombin, hirudin), without modification of PTa, ADP-collagen clousure time, or P-selectin expression.
Conclusions: Platelet function is modified by AF-MSCs. The mechanisms involved will require further studies.

PLATELETS – CLINICAL

PB 690 | Obesity and ADAMTS13 Deficiency as Risk Factors for TTP

L. Geys[1], E. Roose[2], I. Scroyen[3], C. Tersteeg[2], K. Vanhoorelbeke[2], R. Lijnen[3]

[1]KULeuven, Center for Molecular and Vascular Biology, Leuven, Belgium, [2]KULeuven, Laboratory for Thrombosis Research, Kulak, Kortrijk, Belgium, [3]KULeuven, Center for Molecular and Vascular Bioogy, Leuven, Belgium

Background: Thrombotic thrombocytopenic purpura (TTP) is caused by absence of ADAMTS13 activity. Thrombocytopenia is presumably related to formation of VWF and platelet rich microthrombi. Obesity may be a risk factor for TTP; it is associated with abundance of macrophages that may phagocytose platelets.
Aims: To evaluate the role of obesity and ADAMTS13 deficiency in TTP, and to establish whether macrophages contribute to thrombocytopenia.
Methods: Lean or obese ADAMTS13 deficient (*Adamts13*$^{-/-}$) and wild-type (WT) mice were triggered with 250 U/kg of recombinant human VWF, and TTP characteristics were evaluated 24h later. In separate experiments, macrophages were depleted in the liver and spleen of lean and obese WT or *Adamts13*$^{-/-}$ mice by injection of 10 µl/g body weight of clodronate-liposomes, 48h before injection of rVWF.
Results: Obese *Adamts13*$^{-/-}$ mice had a lower platelet count than lean mice (894±35x10^3 *versus* 1010±35x10^3 platelets/µL; p< 0.05) suggesting that they might be more susceptible to TTP development. Lean *Adamts13*$^{-/-}$ mice triggered with VWF did not develop TTP, while typical TTP symptoms developed in obese *Adamts13*$^{-/-}$ mice, including severe thrombocytopenia (35±13x10^3 *versus* 803±113x10^3 platelets/µL, p=0.0001) and higher LDH levels (630±123 *versus* 329 ± 57 mU/mL; p< 0.05). Removal of macrophages by clodronate injection in obese *Adamts13*$^{-/-}$ mice before treatment with VWF resulted in preservation of platelet counts 24h after the trigger (1327±80x10^3/µL *versus* 187±47x10^3/µL for control PBS liposomes; p=0.008). *In vitro* experiments with cultured macrophages confirmed VWF dose-dependent increase of platelet phagocytosis.
Conclusions: Obese *Adamts13*$^{-/-}$ mice are more susceptible to induction of acute episodes of TTP than lean mice. Phagocytosis of platelets by macrophages contributes to thrombocytopenia after VWF triggering in this model.

PB 691 | Acute Thrombotic Thrombocytopenic Purpura (TTP) - Diagnostic and Prognostic Implications of Highly Sensitive Troponin Assays, ECG and ECHO

I. Karpha, T. Dutt

Royal Liverpool University Hospital, Liverpool, United Kingdom

Background: Whilst cardiac involvement is a recognised feature of acute TTP, clinical symptoms are not consistent. The development of highly sensitive troponin (hs-cTnT) assays allows detection of subtle elevations with diagnostic and prognostic implications. Identification of myocardial injury is crucial as patients may benefit from early, aggressive treatment; however, the value of standard cardiac investigations is unclear.
Aims: To evaluate hs-cTnT levels and electro/echocardiographic changes in patients with acute TTP, and their correlation with disease severity and outcome.
Methods: A retrospective review of registry data from a Regional TTP centre and data collected on hs-cTnT levels, electrocardiogram (ECG), echocardiography findings in acute TTP.

Results: 29 patients with 32 hospital episodes (2011-2016) were reviewed. The M:F ratio was 1:1.4, mean age 52 years (28-83). 22/32 episodes had an abnormal hs-cTnT at presentation (>14ng/L). 18/22 episodes with an elevated hs-cTnT had an ECG, of which none demonstrated any acute abnormality. Echocardiography was performed in 13/32 episodes. 8/10 were performed in patients with an abnormal hs-cTnT but only 1/8 showed acute change - RV overload and dilated RV. 7/8 described chronic changes such as left ventricular hypertrophy.

Abnormal hs-cTnT levels were associated with a lower ADAMTS13 activity, higher ADAMTS13 IgG inhibitor level and lower presenting platelet count. Outcomes were poorer in those with abnormal hs-cTnT, including 4 deaths. All deaths were in patients with a hs-cTnT >100ng/L, irrespective of other cardiac investigation results (see table).

TABLE 1 HS-cTnT and TTP Severity/Outcomes

	Normal Presenting hs-cTnT (<14ng/L, n=10)	Abnormal Presenting hs-cTnT (>14ng/L, n=22)
Median presenting platelet count (x109/L)	22	11
Median ADAMTS 13 Activity (%)	26.5	<1
Median IgG ADAMTS13 Inhibitor (units)	8.5	61
Acute ECG/ECHO change	0	1
Deaths	0	4 (18%)

Conclusions: hs-cTnT assays allow early confirmation of myocardial involvement in acute TTP. Abnormal hs-cTnT levels correlate with disease severity and poor outcome. ECG and ECHO findings do not appear to correlate with hs-cTnT levels or represent acute cardiac involvement. Further study is required to determine the value of routine cardiac investigation and alternative cardiac imaging that may inform management.

PB 692 | Plasmin Cleavage of ADAMTS-13 Enhances its Activity

M.M. Mebius[1], C.C. Clark[1], S. de Maat[1], A.G.M. Tielens[2], P.G. de Groot[1], R.T. Urbanus[1], R. Fijnheer[1], J.J. van Hellemond[2], C. Maas[1]

[1]*University Medical Center Utrecht, Clinical Chemistry and Haematology, Utrecht, The Netherlands,* [2]*Erasmus Medical Center, Medical Microbiology & Infectious Diseases, Rotterdam, The Netherlands*

Background: Thrombotic thrombocytopenic purpura (TTP) is associated with a deficiency of ADAMTS-13 (a disintegrin and metalloproteinase with a thrombospondin type 1 motif, member 13), which degrades von Willebrand Factor (VWF) multimers to control thrombogenicity. Plasmin has protective properties in TTP: it degrades platelet-VWF complexes and stimulation of plasmin activity has therapeutic value in a TTP mouse model. However, prolonged exposure (hours) of ADAMTS-13 to plasmin destroys it. This leaves the overall contribution of plasmin in thrombotic microangiopathy unclear.

Aims: To investigate the short-term effects of plasmin on ADAMTS-13 in plasma.

Methods: We studied how plasmin influences ADAMTS-13 activity in plasma using the FRETS-VWF73 assay. Direct binding studies were performed to investigate the influence of plasmin on the binding properties of ADAMTS-13 to immobilized VWF.

Results: Plasminogen activation in plasma (30 min.) increases ADAMTS-13 activity as measured by FRETS-VWF73 (25.0% ± 3.6%, p=0.0625) (Fig. 1A). This is unrelated to direct effects of plasmin on this substrate, as inhibition of plasmin prior to measurement still results in increased ADAMTS-13 activity (21.2% ± 6.9%, p=0.0313). We found that increased ADAMTS-13 activity is accompanied by plasmin-mediated cleavage of ADAMTS-13. We next investigated the influence of plasmin on the binding of ADAMTS-13 to immobilized VWF. Normally, a single species of ADAMTS-13 binds to VWF (Fig. 1B). After plasmin activity, full-length ADAMTS-13, multiple disulfide-linked cleaved forms-, and a truncated form of ADAMTS-13 are captured (Fig. 1C).

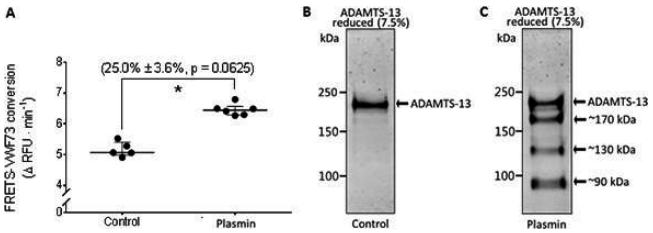

FIGURE 1 A) The effect of plasmin on ADAMTS-13 activity. B,C) Binding of ADAMTS-13 to immobilized VWF before (B) or after (C) plasmin activity.

Conclusions: We report the unexpected finding that plasmin stimulates ADAMTS-13 activity in plasma, which is accompanied by binding of cleaved forms of ADAMTS-13 to VWF. We propose that cleavage or truncation of ADAMTS-13 by plasmin alters protein conformation with functional consequences. This could reflect a physiological rescue mechanism to enhance ADAMTS-13 activity.

PB 694 | Unraveling Immunoprofiles of Acquired TTP Patients Using Anti-idiotypic Antibodies

A.-S. Schelpe[1], E. Roose[1], F. Peyvandi[2], B. Joly[3], I. Pareyn[1], H. Deckmyn[1], J. Voorberg[4], P. Coppo[5], A. Veyradier[3], S.F. De Meyer[1], K. Vanhoorelbeke[1]

[1]KU Leuven Campus Kulak Kortrijk, Laboratory for Thrombosis Research, Kortrijk, Belgium, [2]Università degli Studi di Milano, Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico and Department of Pathophysiology and Transplantation, Milan, Italy, [3]Université Paris Diderot, Service d'Hématologie Biologique and EA 3518-Institut Universitaire d'Hématologie, Groupe Hospitalier Saint Louis-Lariboisière, Assistance Publique-Hôpitaux de Paris, Paris, France, [4]Sanquin, Department of Plasma Proteins, Sanquin-AMC Landsteiner Laboratory, Amsterdam, The Netherlands, [5]Université Pierre et Marie Curie, Département d'Hématologie Clinique, Hôpital Saint Antoine, Assistance Publique-Hôpitaux de Paris, Paris, France

Background: In acquired (a)TTP patients, anti-ADAMTS13 autoimmune responses are polyclonal but with clear immunodominant epitopes in the ADAMTS13 spacer domain. A detailed analysis of immunoprofiles in aTTP patients is not available yet. However, insight into immunoprofiles of patients with other autoimmune disorders provided crucial diagnostic and prognostic information.

Aims: By using anti-idiotypic Abs that recognize specific anti-spacer autoAbs, we aim at getting insight into the anti-spacer immunoprofiles in aTTP patients.

Methods: Mice were immunized with three different categories of cloned human anti-spacer autoAbs: autoAb1, 2 and 3 with a strong, weak or no inhibitory effect on ADAMTS13 function respectively, to generate anti-idiotypic Abs. Fifty-six plasma samples of acute aTTP patients were analyzed via ELISA where the three anti-idiotypic Abs were coated to capture their respective category of anti-ADAMTS13 autoAbs. In this way, anti-spacer immunoprofiles were determined.

Results: We successfully developed three anti-idiotypic Abs that specifically captured autoAb 1, 2 or 3. Screening aTTP patient plasma on these three anti-idiotypic Abs revealed that 43% (24/56) of the patients had autoAb1 group Abs, 41% (23/56) had autoAb2 group Abs and 30% (17/56) had autoAb3 group Abs. Identifying which autoAb groups are present in the plasma of individual aTTP patients allowed us to setup immunoprofiles. Immunoprofile 1 (autoAb1 group Abs) was present in 7.14% of the patients, profile 2 (autoAb2) in 14.29%, profile 3 (autoAb3) in 5.36%, profile 4 (autoAb1 and 2) in 10.71%, profile 5 (autoAb1 and 3) in 8.93%, profile 6 (autoAb2 and 3) in 0%, profile 7 (autoAb1, 2 and 3 group) in 16.07% and profile 8 (none of the autoAb groups) in 37.5%.

Conclusions: We have developed a powerful tool to determine anti-spacer immunoprofiles in aTTP patients. We now will determine whether specific immunoprofiles present in aTTP patients would allow to identify prognostic factors to predict death and disease recurrence in these patients.

PB 695 | The in vitro and in vivo Effects of Streptokinase in a Papio *ursinus* Baboon Model of Acquired Thrombotic Thrombocytopenic Purpura (TTP) - A Pilot Study

J. Joubert[1,2], W.J. Janse van Rensburg[1], S.M. Meiring[1,2], C. Tersteeg[3], K. Vanhoorelbeke[3]

[1]University of the Free State, Department of Haematology and Cell Biology, Bloemfontein, South Africa, [2]National Health Laboratory Service, Universitas Academic Laboratories, Haematology and Cell Biology, Bloemfontein, South Africa, [3]IRF Life Sciences, KU Leuven Campus Kulak Kortrijk, Laboratory for Thrombosis Research, Kortrijk, Belgium

Background: The accumulation of large VWF multimers due to absence/inhibition of ADAMTS13, is central to the pathogenesis of TTP. Recently, plasmin has been identified as a back-up for ADAMTS13, suggesting utility of streptokinase in the treatment of acquired TTP, possibly at lower doses than used for fibrinolysis. A *Papio ursinus* baboon model of acquired TTP has previously been used for the preclinical study of novel therapies in TTP.

Aims: To determine the in vitro and in vivo effects of streptokinase in a *Papio ursinus* baboon model of acquired TTP.

Methods: VWF activities & multimer patterns, and thromboelastograms, were assessed (amongst other parameters) after spiking citrated baboon blood specimens with increasing concentrations of streptokinase. After induction of TTP with an anti-ADAMTS13 mAb, escalating doses of streptokinase (ranging from 50 000 to 900 000 IU) were administered intravenously to a 13 kg baboon, and the effects of streptokinase assessed on (amongst others) peripheral blood counts, fibrinolysis, VWF activities & multimer patterns, and thromboelastograms.

Results: After spiking, fibrinolysis with loss of large VWF multimers, was observed at a concentration of 2200 IU/mL - roughly equivalent to a dose of 1 500 000 IU in a 10 kg baboon. Escalating intravenous streptokinase doses (maximum: 900 000 IU) had no effect on platelet counts, or VWF activities & multimer patterns. Doses above 700 000 IU did however lead to activation of fibrinolysis as evidenced by increasing plasmin-antiplasmin complexes and fibrin(ogen) degradation products, and declining plasminogen levels.

Conclusions: Although intermediate dose streptokinase does activate the fibrinolytic system in a *Papio ursinus* baboon model of acquired TTP, it has no effect on the TTP phenotype. As suggested by in vitro data, further in vivo studies in this model would require higher streptokinase doses to confirm proof-of-concept, before it can be considered a therapeutic option in acquired TTP.

PB 696 | mRNA Identification of a Novel Isoform (ISF) and ISF3 from ADAMTS13 in Different Types of Cells

J. Paiva[1], A.C. Kempfer[2], M.F. Alberto[1], A.I. Woods[2], C. Dos Santos[1], A. Sánchez-Luceros[1,2], M.A. Lazzari[2]

[1]*Hematologic Research Institute Mariano R. Castex - National Academy of Medicine of Buenos Aires, C.A.B.A, Argentina,* [2]*IMEX-CONICET-National Academy of Medicine of Buenos Aires, C.A.B.A, Argentina*

Background: ADAMTS13 is a plasma metalloprotease that cleaves von Willebrand factor (VWF).

Alternative splicing (AS) is a common feature of ADAMTS gene expression, in ADAMTS13 this process could product cleave the genomic sequence in different positions and causes several potential variants. Shonrom (2009) described mRNA of ISF1 in cancer lines and ISF1, ISF2 and ISF3 of Hep3B. We described previously (ISTH 2013) mRNA of ISF1 and ISF2 in Plts, HUVEC and ISF2 in two breast cancer lines (MDA-MB231, MCF7).

Aims: Determine the presence of ISF3 in Plts, HUVEC and cancer cell lines, characterize and identify a potential ADAMTS13 ISF.

Methods: Total RNA was isolated by TRIZOL method. The integrity was verified by 260/280 optical density ratio. mRNA was reverse transcribed using special primers. We designed primers to amplify the sequence of ADAMTS13 to differentiate Iso1 (421bp) and Iso3 (334bp). β-actin was used as control. Hep3B ISFs were used as control. The PCR products were analyzed on agarose gel containing SYBR Safe. IQTL software was used to quantitative analysis (Pixel intensity values=PIV).

Results: All PCR performed, except the negative controls, were positive for β-actin and negative control did not present bands.

A particular novel ISF (ED7-8) and ISF3 were observed in all cells studied: Plts, HUVEC, Hep3B, MDA-MB231 and MCF7 (Figure 1).

The evaluation of PIV was made respect to ISF1 of each cell. The mean and standard deviation (SD) of three assays showed in Table I.

The PIV results of ISF3 and ED7-8 respect to Hep3B were not statistically significant for all the samples except for HUVEC. A large number of Plts PIV measurements would be necessary to decrease the high standard deviation obtained.

TABLE I ISFs1 and ED7-8 PIV results respect to Hep3B in studied cells

	ISF 3			ED7-8 ISF		
	Mean (%)	SD	p-value	Mean (%)	SD	p-value
Hep3B	11.8	6.2	1.000	30.0	5.5	1.000
Plts	2.8	0.5	0.061	116.0	82.6	0.148
HUVEC	1.8	0.4	0.043	8.6	7.6	0.017
MDA-MB231	8.1	8.8	0.557	54.0	30.0	0.246
MCF7	12.6	11.0	0.897	56.5	23.2	0.121

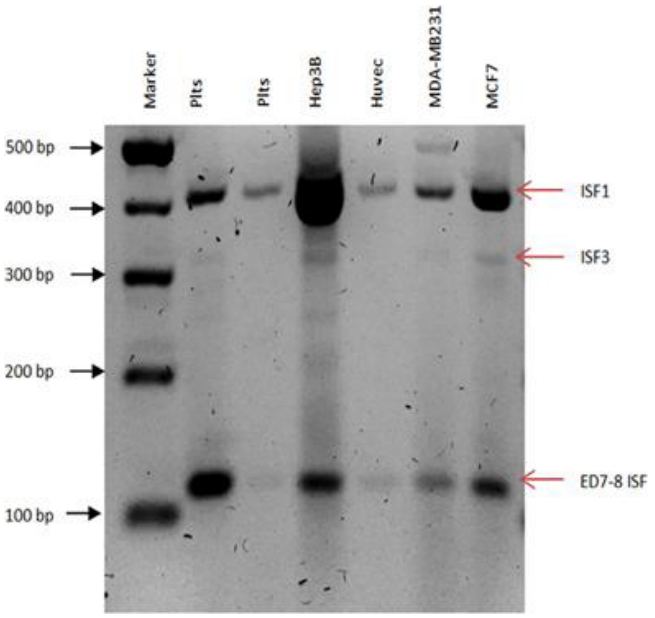

FIGURE 1 Differentiation of ISFs 1, 3 and novel ED7-8 on agarose 2%

Conclusions: The ISF 1, 3 and ED7-8 were identified by sequence analysis and quantified in relative form.

Additional studies are also required to elucidate the relationship between the presence of the ADAMTS13 ISFs, translational regulation, protease activity and cells proliferation.

PB 698 | Splenic Anti-ADAMTS13 Response in Relapsing Thrombotic Thrombocytopenic Purpura (iTTP) Patients Mirrors the Acute Immune Response in Plasma

M. Skowronska[1,2], J.A. Kremer Hovinga[1,2], M. Schaller[1,2]

[1]*Bern University Hospital, Department of Hematology, Central Hematology Laboratory, Bern, Switzerland,* [2]*University of Bern, Department of Clinical Research, Bern, Switzerland*

Background: Anti ADAMTS13 autoantibodies (ATS13-Abs) are a hallmark of iTTP. Long-lasting clinical remission in 90% of relapsing iTTP patients can be achieved by splenectomy (S).

Aims: To confirm the high number of pathogenic, ATS13-Abs producing B-cells in the spleen in relapsing iTTP found previously (Schaller et al. Blood, 2014) by a new approach.

Methods: ATS13$^+$ splenic mononuclear cells of 4 relapsing iTTP patients (A, C, E, F) were single cell sorted. RNA of individual ATS13$^+$ B-cells was reverse transcribed and Abs amplified by nested PCR. Selected Abs of pat E (relapsing iTTP with non-inhibitory ATS13-Abs, relapse 4 months after S, in remission after rituximab) and pat F (severe, relapsing iTTP with persistence of ADAMTS13 < 5% and a strong inhibitor, in remission after concomitant S and rituximab) were cloned into plasmids containing constant IgG4 regions and transfected into

HEK293T cells. Abs in the supernatant were screened for binding to ATS13 by ELISA and their inhibitory potential in a Bethesda-like assay.
Results: Sequencing revealed 80 ATS13-Abs clones with enrichment of IGHV1-69 encoded Abs (15% versus 1% among all splenic B-cells). ATS13 Abs were encoded by gene families IGHV3 (43,6% and 29.2%), IGHV4 (33.3% and 16.7%), IGHV clan I (IGHV1, 5 or 7; 23% and 54.2%) in pat E (n=39 Abs) and F (24 Abs), respectively, and among clan I Abs 2.6% and 16.7% employed IGHV1-69. Cloning of ATS13-Abs sequences resulted in 7 (pat E) and 2 (Pat F) IgG, of which 6 and 1 were ATS13 binding. In line with the plasma-phenotype of acute TTP episodes all ATS13-Abs of pat E were non-inhibitory, and a strong functional ATS13 inhibitor in pat F.
Conclusions: The spleen is an important reservoir of pathogenic B-cells in relapsing iTTP, and mirrors the ATS13-Abs response in plasma during acute TTP episodes. Different mechanisms may elicit distinct tolerance breaks, as inhibitory and non-inhibitory ATS13-Abs show different gene usage preferences.

PB 699 | The Incidence of Thrombotic Thrombocytopenic Purpura in Israel, as Determined by ADAMTS-13 Activity and Anti-ADAMTS-13 Antibody Levels

A. Keren-Politansky[1], E.J. Dann[2,3], G. Tennenbaum[1], B. Brenner[2,3], G. Sarig[1,3]

[1]Rambam Health Care Campus, Hematology Laboratory, Haifa, Israel, [2]Rambam Health Care Campus, Hematology and Bone Marrow Transplantation, Haifa, Israel, [3]The Bruce Rappaport Faculty of Medicine, Technion, Israel Institute of Technology, Haifa, Israel

Background: Thrombotic thrombocytopenic purpura (TTP) is a rare, life-threatening disease. Measurement of ADAMTS-13 activity and anti-ADAMTS-13 antibody (antibody) levels may advance the TTP diagnosis and therapy efficacy monitoring.
During 2005-2013, the Hematology Laboratory at Rambam was the central and sole facility in Israel to perform ADAMTS-13 assessment.
Aims: To estimate the incidence of TTP in Israel based on the measurement of ADAMTS-13 levels.
Methods: During 2005-2013, 393 patient blood samples were received for TTP diagnosis. ADAMTS-13 activity and antibody levels were measured using the TECHNOZYM ADAMTS-13 ELISA kits. Acquired TTP was defined by the presence of anti ADAMTS-13 antibodies and low activity during the acute episode. Congenital TTP was defined as ADAMTS-13 activity < 10% without the presence of antibodies.
Results: Out of the 393 samples, 117 (30%) were diagnosed as acquired TTP, with average levels of ADAMTS-13 activity 11±18 % and antibodies 56±34 U/ml. Nine patients (2.3%) had an ADAMTS-13 activity level between 1-10% and 10 patients (2.5%) < 1%; in none of them anti-ADAMTS-13 antibodies were found.
Female patients accounted for 64% of acquired and 80% of congenital TTP; in 8% of them the acute episode occurred during pregnancy.
Median age of patients at first episode of acquired TTP was significantly higher than congenital TTP (41 vs. 27 years, P=0.04).
No increased frequency of TTP diagnosis across the four seasons was observed.
The annual incidence of newly diagnosed acquired and congenital TTP in Israel was found to be 2.0 and 0.3 patients, respectively, per million population.
Therapy response monitoring by ADAMTS-13 levels was performed in 44% of acquired and 37% of congenital TTP patients.
Conclusions: The incidence and characterization of TTP patients in Israel is comparable to other worldwide TTP registries.
Measurement of ADAMTS-13 activity and antibody levels can advance TTP diagnosis and treatment efficacy monitoring.

PB 700 | A Rapid and Simple Assay for the Determination of ADAMTS-13 Activity

M. Griffiths, H. Vetr, N. Binder

Technoclone Herstellung von Diagnostika und Arzneimitteln GmbH, Vienna, Austria

Background: The standard laboratory test for ADAMTS-13 Activity is an ELISA, which requires at least 4 h to process. It tends to be performed by specialized laboratories only. Therefore, for a physician to receive a patient's ADAMTS-13 activity result can range from 24 h to as much as one week. This delay in reporting could have a negative impact on patient care.
Aims: We have developed a rapid and simple assay which would allow the physician to have an initial reportable result for ADAMTS-13 Activity within 1 hour from the blood draw.
Methods: The assay is based on flow through technology, which allows for simple, rapid processing. Plasma samples are pre-incubated with a substrate which is cleaved by ADAMTS-13 present in the plasma. This pre-treated sample is applied to the test unit which contains a membrane with immobilized antibodies specific for the cleaved substrate. As the sample flows through the membrane into an absorbent pad the cleaved substrate binds to capture antibody. A secondary antibody is used to detect the membrane bound complex. Using a gold conjugate a red colour is produced. The colour intensity is proportional to the level of ADAMTS-13 activity in the plasma sample and compared with a colour standard card, allowing semi-quantitative analysis of the patient sample. The assay can be performed at room temperature without specialized laboratory equipment. The assay processing time is under 30 minutes. The test is designed for evaluation of a single patient sample, with a positive control run in parallel.
Results: The designed assay cut-off value of 10% ADAMTS-13 Activity is clinically relevant for differentiation of TTP patients. A 100% correlation was observed when TTP patient samples (n=20) were run in the TECHNOZYM ADATMS-13 ELISA and this assay.
Conclusions: This rapid and simple assay is versatile and suitable as a cost effective screening assay enabling quick turnaround for ADAMTS-13 activity reporting.

PB 701 | Retrospective Analysis of the Relapse Rate in Patients Surviving Acute Acquired Thrombotic Thrombocytopenic Purpura (TTP) Treated with or without Rituximab

S. Herold[1], T. Falter[1,2], V. Schmitt[1], V. Weyer[3], H. Roßmann[1], C. von Auer[4], K. Lackner[1], B. Lämmle[2], P. Wild[2], I. Scharrer[4]

[1]University Medical Center Mainz, Institute of Clinical Chemistry and Laboratory Medicine, Mainz, Germany, [2]University Medical Center Mainz, Center for Thrombosis and Haemostasis, Mainz, Germany, [3]University Medical Center Mainz, Institute of Medical Biostatistics, Epidemiology and Informatics (IMBEI), Mainz, Germany, [4]University Medical Center Mainz, Department of Hematology, Oncology and Pneumology, Mainz, Germany

Background: Acquired TTP is caused by autoantibody mediated severe ADAMTS13 deficiency leading to microangiopathic hemolytic anemia (MAHA) and thrombocytopenia with or without ischemic organ involvement. 80-90% of patients survive with plasma exchange (PEX), fresh frozen plasma replacement and corticosteroid (CS) treatment; survivors are at high risk for relapse. The anti-CD20 monoclonal antibody rituximab is increasingly added to conventional PEX and CS in plasma-resistant and/or relapsing patients.

Aims: We analysed the relapse rate in survivors of acute TTP treated with or without rituximab added to PEX and CS.

Methods: 88 patients treated at or referred for consultation to our center between disease onset and November 2014 were evaluated. Number, duration, clinical manifestations, laboratory data and treatment of each bout were documented. Diagnostic criteria of acute TTP were thrombocytopenia, MAHA, increased LDH and (since 2004) severe ADAMTS13 deficiency (< 10%).

Results: 88 (female n=70; male n=18) patients had a total of 253 acute episodes (median 2, range 1-21/patient) over a median observation period of 8.1 years (range 0.03-32 years). Median duration of the acute episodes was 29 days. The relapse rate of the whole group was 2.6% per month. Women had a relapse rate of 2.3% per month and men of 3.7% (p=0.001). Information on therapy was evaluable in 232 acute TTP episodes. Rituximab was administered in 76 of those in 46 patients. Relapse rate after episodes not treated with rituximab (n=156) was not significantly higher (p=0.874) than after episodes where rituximab was added.

Conclusions: This retrospective analysis does not show a significant reduction of acute TTP relapses by rituximab given during an acute bout. A selection bias favouring the application of rituximab in plasma-refractory or recurring disease may exist. Therefore, only prospective evaluation of rituximab, ideally by a randomized controlled trial, will better define its role in acquired TTP.

PB 702 | Epidemiology of Thrombotic Microangiopathy in Malaysia

Y.Y. Yap, P.A. Zulkarnain, K.B. Law, S. Carlo, J. Sathar, K.M. Chang

Ministry of Health of Malaysia, Ampang Hospital, Haematology Department, Ampang, Malaysia

Background: Thrombotic thrombocytopenic purpura (TTP) is rare and severe form of thrombotic microangiopathy (TMA) with severe deficiency in ADAMTS-13 protein. In Malaysia, there has not been a study addressing the epidemiology of TMA as yet.

Aims: To study the epidemiology of TMA and the overall survival in relation to ADAMTS-13 activity.

Methods: The cases (year 2012-2016) are traced through the Ampang hospital electronic hospital information system (ehis) and the haemostasis laboratory archived records. The records are matched with the National Registration Department for outcome. The retrospective data is analyzed using SAS (Statistical Analysis System) version 9.4.

Results: There are a total of 227 cases with the mean age of 35 years and female predominance (61%). The young adulthood is the most prevalent group (36%), followed by 25% of middle adulthood, 20% of adolescent, 13% of children and 6% of elderly adulthood. The three main ethnic distribution namely the Malay-57%, Chinese-21%, Indian-9% and also the others-13%. There is 25% of ADAMTS-13 activity < 10% and the ADAMTS-13 activity < 5% is only 16% if more stringent cut-off point used for TTP. For the ADAMTS-13 inhibitor (n=163), 36% of the cases are positive while 7% of cases are borderline positive and 57% of cases are negative. The ADAMTS-13 Inhibitor is positive for 74% cases and 81% cases for patients with ADAMTS-13 activity < 10% and < 5% respectively, indicating acquired TTP (p< 0.0001). The hereditary TTP is possibly present in 18% of ADAMTS-13 activity < 10% and 11% of ADAMTS-13 activity < 5% with negative inhibitor testing. There is 19% mortality cases. The overall survival is lower in the ADAMTS-13 activity ≥ 5 % (OR: 10.14, *p*=0.0287, 95% CI: 1.34 - 76.21).

Conclusions: Most of the cases are not related to primary TTP. The secondary TTP has a significant lower OS than primary TTP. Therefore, secondary causes of TMA must be sought in order to prevent mortality. Further prospective study will be needed to verify this observation.

PB 703 | Highly Sensitive Fully Automated Chemiluminescent Immunoassay for Rapid Quantification of ADAMTS13 Activity

M. Mirabet, S. Blanch, J. Puig, J. Serra

Biokit R&D, Chemiluminescent Immunoassays, Lliçà d'Amunt, Spain

Background: Thrombotic Thrombocytopenic Purpura (TTP) is a rare disease associated with a severe deficiency of the activity of the VWF-cleaving protease ADAMTS13 (a disintegrin and metalloproteinase with a thrombospondin type 1 motif, member 13). ADAMTS13 activity assays have been shown to be useful for diagnosis, management, and prognosis in individuals with TTP. However, the utility of ADAMTS13 activity assays for initial diagnosis of TTP is currently limited by long turnaround times.

Aims: To evaluate the analytical performance of a chemiluminescent ADAMTS13 activity assay (Instrumentation Laboratory, Bedford, MA, USA) currently in development.

Methods: The ADAMTS13 activity assay is a fully automated 2-step immunoassay with a time to first result of 33 minutes. Reagents are standardized against the WHO 1st International Standard for determination of ADAMTS13 in plasma. Magnetic particles are coated with the VWF73 peptide substrate containing the ADAMTS13 cleavage site, and chemiluminescent detection is based on an isoluminol-labeled monoclonal antibody that reacts specifically with the cleaved peptide. A method comparison study was performed using 72 plasma samples compared against a commercial fluorescence resonance energy transfer (FRET) method.

Results: The method comparison study revealed comparable results with the FRET assay (r=0.94, slope 0.94 by Weighted Deming). The chemiluminescent ADAMTS13 activity assay demonstrated a linearity of 0.3%-150% with good within-laboratory precision (< 5.2 % CV) across the measuring range.

Conclusions: The chemiluminescent ADAMTS13 activity assay shows comparable results to a commercial FRET assay. The assay is automated, has a very low limit of quantification, and rapid time to first result allowing for reliable assessment of ADAMTS13 activity for levels < 10%.

PB 704 | Clinical Characteristics and Outcome of Patients with Thrombotic Thrombocytopenic Purpura at Siriraj Hospital

Y. Chinthammitr, W. Wangchinda

Faculty of Medicine Siriraj Hospital, Mahidol University, Department of Medicine, Bangkok, Thailand

Background: Thrombotic thrombocytopenic purpura (TTP) is a life-threatening disease characterized by microvascular platelet thrombi resulting in microangiopathic hemolytic anemia (MAHA) and thrombocytopenia. Therapeutic plasma exchange (TPE), the current standard of treatment, significantly improves the prognosis. However, the mortality rate remains over 10%.

Aims: To study the clinical features, laboratory characteristics, outcome, and mortality rate and determine factors associated with the mortality in TTP patients at Siriraj hospital.

Methods: The data of TTP patients at Siriraj hospital from 1999 to 2013 were retrospectively reviewed.

Results: Forty five patients (34 women) had a median age of 40.6 years (range 16.0-76.0). All patients presented with MAHA and thrombocytopenia, 88.9% had neurological symptoms, 46.7% had fever, and 33.3% had renal impairment. There were 5 patients with the classical pentad of TTP. 30 patients (66.7%) were identified as idiopathic TTP. Secondary causes of TTP included 9 SLE, 2 cancer, 2 HIV infection, one psoriasis, and one renal transplantation. Plasma ADAMTS13 activity was determined in 17 patients in which 12 patients had severe ADAMTS13 deficiency (< 10%). 41 patients underwent TPE, 29 patients (71.1%) achieved response outcome with an average of 5 cycles of TPE (range 1-21). Response rate in idiopathic TTP was 80%. Adjunctive therapies included fresh frozen plasma transfusion prior to initiation of TPE, glucocorticoid therapy, and cytotoxic agents. Overall mortality rate was 24.4%. In multivariate analysis, male sex (odds ratio [OR] 48.0; 95% confidence interval [CI] 2.3-1024.7) and fever (OR 36.4; 95% CI 1.2-1145.7) were associated with increased mortality rate. Four patients had TTP relapse, however, there was no mortality in TTP relapse group.

Conclusions: Mortality rate of TTP at Siriraj hospital was 24.4%. Factors associated with increased mortality rate were male sex and fever.

PB 705 | Characteristic of ADAMTS13 in Patients with Acute Phase of Kawasaki Disease

N. Tsujii[1], K. Nogami[1], M. Matsumoto[2], H. Yoshizawa[1], T. Takase[3], I. Tanaka[3], T. Sakai[4], A. Isonishi[2], K. Matsuura[2], Y. Fujimura[2], M. Shima[1]

[1]Nara Medical University, Pediatrics, Nara, Japan, [2]Nara Medical University, Blood Tranfusion Medicine, Nara, Japan, [3]Yao Municipal Hospital, Pediatrics, Osaka, Japan, [4]Kokuho Central Hospital, Pediatrics, Nara, Japan

Background: Kawasaki Disease(KD) is an acute febrile vasculitis with vascular endothelial cell (VEC) injury occurs to small and medium arteries, most commonly coronary arteries. ADAMTS13 is known as a VWF-cleaving protease. Inflammatory cytokines and VEC injury stimulate the release of unusually large VWF multimers(UL-VWFM). The accumulation of high plasma UL-VWFM results in low enzyme-to-substrate ratio and leads to the needless formation of platelet thrombi, termed TTP. In addition, ADAMTS13 is reported to be available to modulate the shear-induced inflammation by VWF.

Aims: To know the characteristics of ADAMTS13 in acute phase of KD.

Methods: ADAMTS13 activity and VWF antigen(VWF:Ag) of 38 patients with KD(21 males, 17 females) were measured before, 1 week, and 1 month after treatment. Univariate and multiple linear regression analyses were performed to determine the relationship with clinical and biochemical variables.

Results: ADAMTS13 activity was 79.5±27.5%, 123.2 ±52.4%(p 0.001), and 121.7±37.1%(p 0.001), respectively. VWF:Ag was 169.3±49.3%, 150.7±54.3%(p=0.129), and 110.1±32.5%(p 0.001), respectively. The ratio of VWF:Ag to ADAMTS13 activity was 2.51±1.43, 1.64±1.40(p=0.011), and 1.02±0.55(p 0.001), respectively. Before treatment, in univariate linear regression analysis, ADAMTS13 activity was correlated with the white blood cell counts(WBC), platelet count, and albumin(Alb), VWF:Ag with sodium(Na), and potassium,C-reactive protein(CRP), and the ratio of VWF:Ag to ADAMTS13 with WBC, Alb, Na, and CRP, respectively. In multivariate linear regression analysis, Alb was for ADAMTS13 activity, CRP was for VWF:Ag, and Alb and Na were predictors for the ratio of VWF:Ag to ADAMTS13 before treatment.

Conclusions: In acute phase, the low ADAMTS13 activity and the high ratio of VWF:Ag to ADAMTS13 were revealed. These were independently associated with parameters of VEC injuly and got normalized with treatment. Subclinical platelet thrombi formation and shear-induced inflammation should be cared.

PB 706 | Acquired TTP in Prague: More than 20 Years Single Centre Experience

P. Salaj, J. Louzil, V. Pohlreichova, V. Geierova, I. Capova, I. Hrachovinova

Institute of Hematology and Blood Transfusion, Centre of Hemostasis and Thrombosis, Prague, Czech Republic

Background: Acquired thrombotic thrombocytopenic purpura (TTP) is a rare but life threatening condition caused by production of autoantibodies against metaloproteinase ADAMTS13 and its severe deficiency results in microangiopathic haemolytic anemia (MAHA) and thrombocytopenia, neurological symptoms, renal impairment and fever.
Aims: Evaluation of our patients with diagnose of TTP including demographic, clinical and laboratory data.
Methods: From 1993 to 2016 we have treated 34 patients: 26 women (76%) and 8 men (24%). Median age was 40 years (16-63) in female and 45 years (25-57) in male patients. At diagnosis: all of patients presented with MAHA and thrombocytopenia, 90% had neurological symptoms, 55% fever and 26% renal impairment. The complete „pentade syndrome" occurred in only 7% of patients. Bleeding was present in 65% of patients.
Results: Diagnostic testing revealed mean initial ADAMTS13 activity of 3% (0-8%) and inhibitor value was 94IU/ml (44-164) without previous treatment (two patients received FFP before established diagnose).
The standard first line treatment comprised of therapeutic plasma exchange (TPE) and corticosteroids. This treatment led to TTP remmission in 18 ptn. (58%). The need for extending immunosuppressive therapy with prolonged TPE was in 16 ptn. (42%) with single or combination of rituximab, vincristine, immunoglobulins or cyclophosphamide. Median number of TPEs in one single episode was 28 (3-95).
The remission of TTP was achieved in all our patients. The median duration of the first remission was 56 months (2.5-200). Twelve patients have relapsed (5 repeatingly). In the whole cohort only 4 patients have died: 2 because of TTP relapse, and 2 of non-TTP cause.
Conclusions: Early diagnose with an aggressive and adequate treatment leads to an excellent outcomes and durable responses in our center. These results are comparable and consistent with literature and treatment results in other hematology centers.

PB 707 | Complements are Activated to a Similar Level in both Thrombotic Thrombocytopenic Purpura and Atypical Hemolytic Uremic Syndrome

D. Oh[1], S.J. Lee[1], J.O. Kim[2], N.K. Kim[2], S.Y. Chong[1], J.Y. Huh[3], R.I. Baker[4]

[1]CHA University, Internal Medicine, Seongnam, Korea, Republic of, [2]CHA University, Institute for Clinical Research, Seongnam, Korea, Republic of, [3]CHA University, Laboratory Medicine, Seongnam, Korea, Republic of, [4]Murdoch University, Western Australian Centre for Thrombosis and Haemostasis, Perth, Australia

Background: Uncontrolled complement activation has a major role in the pathogenesis of atypical hemolytic uremic syndrome (aHUS) and the restraint of this process by eculizumab is life saving. However, the evidence of complement dysregulation in the pathogenesis of thrombotic thrombocytopenic purpura (TTP) is still unclear.
Aims: In this study we examined the presence of complement activation biomarkers in patients with aHUS and TTP and the levels were compared to normal healthy controls.
Methods: Patients with thrombotic microangiopathic thrombocytopenia diagnosed either as TTP or aHUS were chosen from the Korean TTP registry. Prospective plasma and serum samples prior to intervention were collected from newly diagnosed patients with TTP (n=48), aHUS (n=50), and 40 healthy controls and frozen at -70^{0}C. Complement activation products were measured by ELISA.
Results: The level of alternate (C3a, C5a and factor Bb) and terminal markers (C5b-9) were significantly increased in patients with aHUS or TTP compared with controls. There were no significant differences in complement activation product levels between the patients with TTP and aHUS except that the level of factor Bb was higher in aHUS patients than those with TTP.
Conclusions: Complement biomarkers are activated to a similar level in both newly diagnosed cases of TTP and aHUS.

PB 708 | aPreliminary Report on the Genetic Background and Clinical Course of Upshaw-Schulman Syndrome in Polish Patients

J. Windyga[1,2], M. Gorska-Kosicka[1], K. Bykowska[2], E. Odnoczko[2], B. Baran[2], M. Letowska[3], E. Stefanska-Windyga[4], J.A. Kremer Hovinga Strebel[5]

[1]Institute of Hematology and Transfusion Medicine, Disorders of Hemostasis and Internal Medicine, Warsaw, Poland, [2]Institute of Hematology and Transfusion Medicine, Laboratory of Hemostasis and Metabolic Diseases, Warsaw, Poland, [3]Institute of Hematology and Transfusion Medicine, Transfusion Medicine, Warsaw, Poland, [4]Institute of Hematology and Transfusion Medicine, Outpatient Clinic for People with Disorders of Blood Coagulation, Warsaw, Poland, [5]Bern University Hospital and Department of Clinical Research, Hematology and Central Hematology Laboratory, Bern, Switzerland

Background: USS is a form of congenital thrombotic thrombocytopenic purpura characterized by hemolytic anemia with red cell fragmentation, thrombocytopenia and organ ischemia due to thrombosis in microcirculation. The underlying cause of USS is an inherited deficiency of von Willebrand factor cleavage protease - ADAMTS13.
Aims: To characterize the causative mutations in the *ADAMTS13* gene and the clinical course of USS in Polish patients treated in the reference Centre in Warsaw.
Methods: We measured ADAMTS13 activity, antigen and inhibitor using chromogenic, enzyme-linked immunosorbent assay (Technoclone, Vienna) and performed Sanger sequencing of all 29 exons and flanking intronic regions of the *ADAMTS13* gene.
Results: The study comprised 10 symptomatic patients (7 families) with undetectable baseline ADAMTS13 activity and antigen. ADAMTS13 inhibitor test was negative. Molecular analysis of *ADAMTS13* gene showed 7/10 patients (4 families) to be homozygous

for the well-known frameshift mutation c.4143dupA in exon 29. Three patients were compound heterozygous for the following mutations:
1) c.[4143dupA(;)2455delG];
2) c.[2272T>C(;)3178C>T];
3) c.[3178C>T(;)4143dupA].
In the study patients the first symptoms of USS occurred at the median age of 4 whereas the diagnosis was made much later at the median age of 21. A specific case is the patient with c.[2272T>C(;)3178C>T] genotype who presented USS at the age of 52 (ischemic stroke). Five experienced at least one ischemic stroke, 7 had at least one episode of renal failure. In two patients the disease was triggered by pregnancy. Five patients required regular FFP infusions to control the hemostatic balance through ADAMTS13 supply. USS-related deaths were reported in two families.
Conclusions: The mutation spectrum in Polish USS patients does not differ from those of the populations already characterized. The clinical course of USS in our study group was severe. The significant time interval between onset of the first symptoms and the definitive diagnosis is of special concern.

PB 709 | A Murine Anti-ADAMTS13 Monoclonal Antibody against the Disintegrin-like Domain Inhibit the Enzyme Activity

Z. Ma[1,2], F. Shen[1,2], J. Su[1,2], J. Ling[3], J. Yin[1], C. Ruan[1,2]

[1]MOH Key Lab of Thrombosis and Hemostasis, Jiangsu Institute of Hematology, the First Affiliated Hospital of Soochow University, Suzhou, China, [2]Collaborative Innovation Center of Hematology, Soochow University, Suzhou, China, [3]Children's Hospital of Soochow University, Department of Hematology and Oncology, Suzhou, China

Background: ADAMTS13 (adisintegrin and metalloprotease with a thromboSpondin type 1 motifs 13) is a plasma metalloprotease that proteolytically regulates von Willebrand factor (VWF), a critical mediator of platelet tethering and primary haemostasis. The physiological importance of the ADAMTS13-VWF axis is highlighted by cases of either inherited or acquired ADAMTS13 deficiency, which is associated with life-threatening thrombotic thrombocytopenic purpura (TTP). Preparation of murine monoclonal antibody against human ADAMTS13 is crucial for further study for the function of ADAMTS13.
Aims: Preparation of murine monoclonal antibody against human ADAMTS13 is crucial for further study for the function of ADAMTS13.
Methods: Balb/c mice were immunized by purified recombinant ADAMTS13 truncated eukaryotic protein (ADAMTS13-T7) without TSP-1 8 and CUB domain. Murine anti-human ADAMTS13 monoclonal antibody (McAb) was developed by standard hybridoma technology and identified by ELISA. The recognition of McAb with full-length recombinant ADAMTS13 protein was identified by Western blotting. In function assay, the influence of McAb on the proteolysis of VWF by ADAMTS13 was observed. Moreover, a series of small fragment of ADAMTS13 were prokaryotically expressed and purified, which were to confirm the domain McAb recognized.
Results: A murine anti-ADAMTS13 McAb SZ-169 (1G11) was obtained. In ELISA, SZ-169 (1G11) showed the higher affinity to ADAMTS13-T7 compared with full-length ADAMTS13. The results of Western blotting demonstrated that SZ-169 (1G11) could both recognize full-length ADAMTS13 and the disintegrin-like domain. In addition, under static (denatured) conditions, SZ-169 (1G11) could inhibit the cleavage of VWF by ADAMTS13 dramatically in increasing concentrations of the McAb.
Conclusions: Our results further indicated that the disintegrin-like domain of ADAMTS13 is critical to efficient substrate cleavage. McAbs SZ-169 (1G11) could be provided as the useful tool for further study of mechanism of ADAMTS13.

PB 710 | Relationship between ADAMTS13 Antigen (Ag) and Free IgG Anti-ADAMTS13 Antibody (Free IgG ab), Functional ADAMTS13 Inhibitor (FI) and Circulating Immune Complexes (CIC) Using two ELISA Techniques, in Patients (P) with Acquired Thrombotic Thrombocytopenic Purpura (aTTP)

A.C. Kempfer[1], J. Paiva[2], A. Sanchez-Luceros[1], A. Woods[1], M.M. Casinelli[2], M.A. Lazzari[1]

[1]IMEX-CONICET-National Academy of Medicine of Buenos Aires, Hemostasis and Thrombosis, Ciudad Autónoma de Buenos Aires, Argentina, [2]Hematological Research Institute M:R:CAstex. National Academy of Medicine, Hemostasis and Thrombosis, Buenos Aires, Argentina

Background: TTP is caused by the absence of functional ADAMTS13. The deficiency may be congenital or acquired. Thomas (2015) suggests that enhanced ab-mediated clearance provides a major pathogenic mechanism in aTTP, corroborated by the reduced levels of circulating Ag in P with non-inhibitory ab.
Aims: The aim of this study was to evaluate the relationship of ADAMTS13-measurements in 64 P, [(55 in the acute phase of their first episode (ap) and 9 in non-acute phase (nap)] at first consultation.
Methods: Activity (Ac), Ag, FI and free IgG ab were evaluated by ELISA. CIC by ELISA using ab: clone 20A5 (A) or monoclonal from Ag kit (B).
Results: The P were 46 female/ 18 male. The median age was 37±19 (SD).
Inter-assay and intra-assay variation were acceptable for CIC in A and B. The cut off for normal levels of ADAMTS13-specific CIC was 0.501, n=28 in A and 0.503, n =25 in B. The medians of A and B were not significantly different p=0.1069 ($p < 0.05$). A is the elected ELISA. CIC median of all P was 0.42, n=60 and CIC median of P with higher levels was 0.55, n=16.
All ADAMTS13-related measurements were in Table I.
In ap P, there was a very weak correlation found between Ag and CIC (Spearman's coefficient r= -0.017, n=51), and between Ag and FI (r=-0.061, n=40). There was a moderate correlation (r=-0.477, n=55) between Ag and free IgG ab (including two P with high titre ≥850 U/

TABLE I ADAMTS13-related parameters

ADAMTS13-related parameters	ap P (% of total)	nap P (% of total)
Ac (U/mL)	49 (94%)	-
severely reduced (<10%)	3 (6%)	3 (25%)
reduced (10%-40%)		5 (50%)
normal (>40%)		1 (25%)
Ag (μg/mL)	-	-
undetectable (0.010 μg/mL)	5 (9%)	-
severely reduced (<0.100 μg/mL)	16 (29%)	1 (8%)
reduced (0.100-<0.600 μg/mL)	28 (51%)	6 (50%)
normal (0.600-1.600 μg/mL)	6 (11%)	2 (42%)-
FI (negative<30%)	-	-
detectable	37 (86%)	8 (83%)
undetectable	3 (14%)	1 (17%)
Free IgG ab (U/L)		-
detectable(>12 U/mL)	47 (85%)	8 (83%)
undetectable (≤12 U/mL)	8 (15%)	1 (17%)
CIC	-	-
detectable	14 (27%)	2 (22%)
undetectable	37 (73%)	7 (78%)

mL). The 95th percentile said that the free IgG ab was below 318 U/mL, then there was a strong correlation (r =-0.643, n=53).

Conclusions: The prevalence (pr) of ap P with aTTP who had CIC pr=27% was lower than that found by Lotta (2014) and Mancini (2016), pr=47% and pr=39% respectively, although we substituted the ab and doubling the number of ap P of our previous report (pr=33%). Thomas (2015) said that not all anti-ADAMTS13 ab promote clearance, as free IgG ab did not correlate with Ag, exemplified by two P in remission with high-titre ab. In our study, only 95% of free IgG ab (without high titres) might be a variable with prognostic relevance.

PB 711 | 'Predisposed' Hemophagocytosis in a Patient with Thrombotic Thrombocytopenic Purpura

T. Shimomura[1], T. Takafuta[2], H. Niimi[1], S. Munemasa[1], M. Kadono[1], Y. Tachiyama[3]

[1]*National Hospital Organization Hiroshima-Nishi Medical Center, Internal Medicine, Otake, Japan*, [2]*National Hospital Organization Hiroshima-Nishi Medical Center, Clinical Research, Otake, Japan*, [3]*National Hospital Organization Hiroshima-Nishi Medical Center, Clinical Laboratory, Otake, Japan*

Background: Although the diagnosis of thrombotic thrombocytopenic purpura (TTP) may not be established before the determination of disintegrin and metalloproteinase with thrombospondin motif 13 (ADAMTS13) activity, therapeutic plasma exchange must be started immediately. Hemophagocytic lymphohistiocytosis (HLH) is a condition in which immune dysregulation causes hemophagocytosis and disseminated intravascular coagulation (DIC), thereby presenting or mimicking thrombotic microangiopathy, and compromising the distinction from TTP.

TABLE 1 Laboratory Data

Variable	Reference Range	On the First Admission	On the Second Admission
Peripheral Blood Smear		minimal	3+ schistocytosis
Lactate Dehydrogenase (U/liter)	119 - 229	1950	6090
Ferritin (ng/ml)	10 - 260	> 40000	72878
Triglycerides (mg/dl)	30-149	233	405
Fibrinogen/Fibrin Degradation Product (ug/ml)	0 - 5	33.9	96.2
EBV DNA (copy/10*6 White Blood Cells)	< 20	94	Not detected
ADAMTS13 (%)		25.8	< 0.5
Inhibitor (Bethesda Unit/ml)	< 0.5	<0.5	1.2

Aims: We present a case of TTP with previous HLH that demonstrated typical bone marrow hemophagocytosis at the time of diagnosis.

Methods: Case presentation. A Japanese woman in her thirties was admitted to our hospital because of fever and severe thrombocytopenia. Generalized lymphadenopathy, hepatosplenomegaly, and bone marrow hemophagocytosis were present. Other test results are shown in the table. Anemia had progressed. Epstein-Barr virus (EBV)-encoded RNA 1 positivity in the biopsied cervical lymph node and elevated viral load supported the diagnosis of EBV-HLH. Dexamethasone administration induced clinical remission. After more than a year, she was re-admitted for abdominal pain with acute oliguric renal failure. Although similar thrombocytopenia with DIC and hemophagocytosis were observed, marked schistocytosis of more than 20% and extremely high levels of lactate dehydrogenase, as shown in the table, prompted us to perform therapeutic plasma exchange, which brought quick clinical improvements.

Results: We evaluated the plasma ADAMTS13 activity and the inhibitor for the enzyme at the time on both admissions, and confirmed the loss of the proteinase activity by the inhibitor only in the second admission as shown in the table.

Conclusions: Recurrent bone marrow hemophagocytosis after the definitive HLH does not preclude a diagnosis of TTP. This further emphasizes the importance of plasma exchange therapy at the time of presumptive diagnosis of thrombotic microangiopathy.

PB 712 | Technozym® ADAMTS-13 Activity Assay for Determination of Inhibitory Antibodies against ADAMTS-13

L. Wagner, M. Kafka, F. Nasufi, N. Binder

Technoclone Herstellung von Diagnostika und Arzneimitteln GmbH, Vienna, Austria

Background: Acquired TTP is frequently caused by inhibitory autoantibodies against ADAMTS-13. Determination of ADAMTS-13

inhibitors therefore provides a valuable tool for diagnosis and patient follow-up in TTP. ADAMTS-13 antibodies can be detected in vitro either as IgG by ELISA, or functionally in a Bethesda based assay due to their inhibitory effect on ADAMTS-13 activity.

Aims: Aim of this study was to evaluate the usability of TECHNOZYM® ADAMTS-13 activity ELISA in combination with a Bethesda based assay for detection of inhibitory antibodies against ADAMTS-13.

Methods: We determined ADAMTS-13 activity in plasma samples from patients clinically diagnosed with TTP and in normal plasma as negative control. The inhibitory antibodies against ADAMTS-13 were determined by a Bethesda-type method similar to the one used to analyze inhibitory FVIII antibodies. Patient plasma was heat-treated at 56°C for 30 min to eliminate endogenous ADAMTS-13 activity. A serial dilution was made before mixing 1+1 with normal human plasma (NHP). ADAMTS-13 activity of all dilutions was determined with TECHNOZYM® ADAMTS-13 activity ELISA.

Results: Residual activity in % was calculated from the results obtained in IU/mL for all patient plasma dilutions and the control mixture. The residual activity of patient plasma between 25% and 75% was used to further calculate the Bethesda Units (BU).

The results for inhibitory auto-antibodies were considered to be positive if the result of patient plasma was found to be >0.5BU.

All normal plasma samples were found to be below the 0.5BU limit. The inhibitor titer in TTP samples ranged from 0.64 BU/mL to 8.24 BU/mL.

Conclusions: In this study we demonstrate that combining TECHNOZYM® ADAMTS-13 activity ELSIA with a Bethesda based assay setting provides a good method for measurement of functional inhibitors. That allows differentiation of different forms of TTP and may enable close monitoring of inhibitor titer changes in the course of the disease and in response to treatment.

PB 713 | Evolution of ADAMTS13 Activity in Patients with Relapsing Acquired Thrombotic Thrombocytopenic Purpura

F. García-Candel[1], J.J. Cerezo[1], A. Moret[2], D. Iyú[3], A. Martinez[1], E. Fernandez Poveda[1], M. Moya Armao[1], E. Salido Fierrez[1], V. Cabañas Perianes[1], R. Pérez López[1], M. Berenguer Piqueras[1], N. Marin[3], J.M. Moraleda[1]

[1]Hospital Clinico Universitario Virgen de la Arrixaca, Hematology, El Palmar (Murcia), Spain, [2]Hospital La Fé, Hematology, Valencia, Spain, [3]Murcia University, Human Physiology, Murcia, Spain

Background: The diagnosis of acquired Thrombotic thrombocytopenic purpura.

(TTP) is based on the study of ADAMTS13 (activity and antibody), acquiring special importance in establishing the risk of relapse.

Aims: To record the levels of ADAMTS13 in patients with relapsing episodes.

Methods: 13 patients diagnosed with PTT in our center, 5 patients (38%) were followed up, 4 women and 1 male from 2002 to the present with recurrent episodes. They presented an average of 3 episodes.

We studied the activity of ADAMTS13 and anti-ADAMTS13 IgG by ELISA technique.

The treatment of these cases was followed by the common protocol: plasma exchange, prednisone and rituximab in cases of more severe or relapsing / refractoriness.

ADAMTS13 activity was measured at diagnosis, three months after the complete response and one year after diagnosis.

Results: Patient 1 presented three episodes with persistence of severe deficiency of ADAMTS13 and anti-ADAMTS13 despite treatment. Patient 2 presented five episodes, but only was recorded ADAMTS 13 activity in both fourth and fifth episodes, with severe deficiency but achieving antibodies negativization.

Patient 3 presented two episodes with persistent presence of antibodies anti-ADAMTS13 and severe deficiency despite treatment . Is currently in folow-up after third episode.

Patients 4 and 5 had two episodes and they achieving antibodies negativization after second episode with rituximab, plasma exchange and prednisone treatment.

Conclusions: Patients with severe deficiency at presentation and persistence of anti-ADAMTS13 developed relapsing disease, whereas patients without severe deficiency and anti-ADAMTS13 disappearance rarely relapse . Measuring the activity of ADAMTS13 is critical to define the long-term prognosis and follow-up of patients with acquired TTP. More prospective studies should be done to establish the relationship between risk of relapse or recurrence and activity of ADAMTS13 and anti-ADAMTS13.

PB 714 | Evaluation of Sample Interferences on ADAMTS-13 Activity Measurement

L. Wagner, M. Griffiths, H. Vetr, S. Geiter, N. Binder

Technoclone Herstellung von Diagnostika und Arzneimitteln GmbH, Vienna, Austria

Background: Beside it's ability to directly inhibit plasma ADAMTS13 activity, unconjugated bilirubin interferes with certain fluorogenic assays with major impact on clinical diagnosis of TTP and treatment monitoring.

Aims: Aim of this study was to evaluate the possible interference of unconjugated bilirubin and other potential interfering substances with TECHNOZYM® ADAMTS-13 activity ELISA.

Methods: To investigate the assay performance in the presence of interfering substances plasma samples were spiked with increasing amounts of this substances and ADAMTS-13 activity was determined. 3 samples with different ADAMTS-13 activity levels have been analysed. A deviation of up to 15% from the un-spiked sample was regarded as acceptable.

Results: For hemolysis no interference was observed with samples containing up to 200 mg/dL haemoglobin. For lipemia, samples containing at least 500 mg/dL Intralipid or samples containing up to 20 mg/dL unconjugated Bilirubin no interference was observed.

A possible interference of rheumatoid factor was evaluated and no interference was detected up to 40 U/mL.

Within the spectrum of therapeutic intervention of TTP CD20 antibodies, like rituximab, were described to be successful especially within refractory patients. Thus, we also tested for interfering potential of CD20 antibodies in ADAMTS-13 activity assay. No interference was observed up to a level of 200 µg/mL of CD20 blocking antibodies, which corresponds to the upper level of serum concentrations found after Rituximab administration.

Conclusions: In this study, we demonstrate that with TECHNOZYM® ADAMTS-13 activity ELSIA no significant interferences could be detected for all tested interfering substances, allowing an accurate clinical diagnosis of TTP and treatment monitoring.

PB 715 | Early Detection of Refractoriness and Silent Relapse in Acquired Thrombotic Thrombocytopenic Purpura

P. Manresa Manresa, F. López Castaño, H. Sarmiento Palao, I. Molina Pomares, L. Hernández Mateo, P. Marco Vera

Hospital General Universitario de Alicante, Servicio de Hematología, Alicante, Spain

Background: Acquired thrombotic thrombocytopenic purpura (PTT) is a primary thrombotic microangiopathy. The diagnosis is based on a decreased activity of ADAMTS 13 due to autoantibodies. The standard therapy for this disorder is the combination of corticosteroids and plasma exchange until clinical and biological response. After dischard, there is no protocol for monitoring these patients.

Aims: To develop a protocol in order to detect risky situations.

Methods: After clinical response our patients are monitored by measuring the activity levels of ADAMTS 13 (normal> 40%) and autoantibodies (normal < 10 IU / mL).

If these parameters are pathological, the determination is repeated weekly. Patelet count and clinical monitoring are done. If the parametrs remain pathological, even with normal patelet count, we consider it as a refractory patient and we proceed with second line treatment (Rituximab).

All patients are also monitored biannually. In case of detecting pathological values, we make a close follow up. If relapse is confirmed, we proceed to the second line treatment.

Results: We have follow up fifteen patients since January of 2015 to date. Four silent or subclinical relapses were detected. Three of them recieved Rituximab and they maintain an optimal biological response. One patient refused the treatment and now she is been closely monitored. One early detection of refractoriness was detected and treated successfully.

Conclusions: Early monitoring of ADAMTS 13 after clinical response allows the detection of refractory patients and subclinical relapses.

Biannual monitoritation also allows the detection of risky or silent relapses.

With our protocol four patients have been benefited from biannual monitoring and one from early monitoring.

PB 716 | Upshaw-Schulman Syndrome: The Importance of the Modulating Effect of the Different Genetic Variations

P. Manresa Manresa, H. Sarmiento Palao, F. López Castaño, I. Molina Pomares, L. Hernández Mateo, P. Marco Vera

Hospital General Universitario de Alicante, Servicio de Hematología, Alicante, Spain

Background: Congenital Thrombotic thrombocytopenic purpura, also known as Upshaw-Schulman syndrome (USS), is a rare disorder classified as a type of primary thrombotic microangiopathy. It is caused by an inherited deficiency of ADAMTS-13 without an inhibitor. Low ADAMTS13 levels result in increased ultra-large von Willebrand factor multimers which induce platelet adhesion and thrombosis. We describe a late-onset USS in a healthy man patient with three single nucleotide polymorphism (SNP), previously reported *in vitro*.

Aims: To demonstrate the genetic origin of the disorder and the effect of the interaction between the SNPs.

Methods: ADAMTS-13 activity was analyzed by a chromogenic test measured with ELISA. Quantification of antibodies IgG against ADAMTS-13 was obtained by ELISA with IMUBIND. PCR of ADAMTS13 coding sequence was performed. *In silico* prediction of functional effects were performed using Polyphen-2.

Results: We present a case of a 58 years old male who presented in 2009 a platelet count of 5 x10^9 /L, hemolytic anemia, neurogical symptoms and schistocytes. He has suffered from six unspecified acute episodes to date with late-onset, mild symptomatology and good response to therapy.

He had a very low ADAMTS13 activity (< 10%) and no evidence of inhibitor measured in several occasions both in relapse and remission conditions.

Genetic sequence of ADAMTS13 gene showed three variants. Heterozygous c.1852C>G p. (Pro618Ala) has a negative effect on ADAMTS13 function and secretion levels, which is weakened by the association of two more variants: heterozygous c.19C>T p. (Arg7Trp) and homozygous c.1342C>G p.(Gln448Glu).

Conclusions: In our patient the phenotype is correlated with his genotype: late onset, mild symptomatology, relapses with moderate thrombopenia and a quick response to plasma infusion.

SUS is a rare disease with great genetic and clinical polymorphism. It is important to emphasize the modulating effect of the different genetic variations. In our case the variations have caused an attenuating effect.

PB 717 | Characterization of a Hereditary Thrombotic Thrombocytopenic Purpura (TTP) Misdiagnosed as HELLP Syndrome

X. Bai, J. Su, L. Cao, Z. Yu, C. Ruan

Jiangsu Institute of Hematology, The First Affiliated Hospital of Soochow University, Suzhou, China

Background: Hereditary thrombotic thrombocytopenic purpura (TTP) is characterized by abnormally disseminated thrombus due to the

mutations of ADAMTS13, which cleaves its substrate von Willebrand factor(VWF) in normal conditions.

Aims: To characterize the clinical and genetic molecular features of a pregnant patient with congenital TTP.

Methods: ADAMTS13 activities were analyzed by residual collagen binding assay (R-CBA) plus FRET-VWF substrate. And the inhibitors of ADAMTS13 were analyzed by 1:1 mixture of patient and pooled normal plasma followed by R-CBA. And all exons of the ADAMTS13 gene, including the intron-exon boundaries, were PCR-amplified with the corresponding primers, and the PCR products were directly sequenced.

Results: The patient with the second trimester of pregnancy, was admitted to hospital intensive care unit due to the high TBILL (33, normal range:5-21), high LDH(420, normal range:0-248), high ALT(48, normal range 0-35) and the low platelet count number(20×10^9) although all her coagulation indexes were normal. She was discharged from hospital after abortion. However, the following routine blood test demonstrated that her platelets had cyclical fluctuation almost every two weeks, and the congenital TTP was suspected because her ADAMTS13 activities were less than 5% (both R-CBA and FRET-VWF substrate) and had absence of ADAMTS13 inhibitors. The corresponding heterozygous mutations were found in this patient, including R594W and IVS3+1G>A.

Conclusions: The clinical HELLP syndrome in the patients with pregnancy sometimes resembles the features of TTP, and it is difficulty to differentiate these two distinct diseases clinically. ADAMTS13 activity and corresponding inhibitor assay are helpful to dissolve this problem in clinic.

PB 718 | The Next Case Report of Thrombotic Thrombocytopenic Purpura (TTP) after Influenza Vaccination

D. Kaspřák[1], Z. Kořístek[1,2], M. Navrátil[1], P. Richterová[1], J. Gumulec[1,2]

[1]University Hospital Ostrava, Department of Haematooncology, Ostrava, Czech Republic, [2]University of Ostrava, Faculty of Medicine, Ostrava, Czech Republic

Background: Thrombotic thrombocytopenic purpura (TTP) is a very rare disease belongs to the group of thrombotic microangiopathy (TMA). TTP is characterized by microangiopathic haemolytic anaemia, consumptive thrombocytopenia, and significantly reduced activity of metalloprotease ADAMTS13 (< 10%) and leads to significant damage of vital organs and death. Secondary TMA can be induced also after using some drugs.

Aims: Description of TTP case induced most likely after influenza vaccination.

Methods: -

Results: Case report. A 38-year-old woman was admitted from an external hospital due to breathlessness, faintness, fevers, dark urine, severe non-immune haemolytic anaemia (HGB 66 g/l) and thrombocytopenia (PLT $4x10^9$/l). Suspected TTP was confirmed by undetectable low ADAMTS13 activity and extremely high titre of inhibitor of ADAMTS13 (> 100 U/ml). The cause of this secondary TTP was most likely influenza vaccination 10 days before the development of the first symptoms. No other cause has not been detected by detailed testing. Immediately was started a series of exchange plasmapheresis and immunosuppressive corticotherapy. The platelet count rose very slowly in the following days (PLT $75x10^9$/l), there was still elevated schistocytes count and activity of lactate dehydrogenase (7.7 ukat/l). Because of the persisting symptoms weekly rituximab therapy was indicated (375 mg/m^2) for four weeks. After the second dose of rituximab application the platelets has normalized with continuing mild anaemia, and normal level of lactate dehydrogenase. There was a remission of the disease after rituximab therapy.

Conclusions: This case report highlights another rare case of a few published cases of TTP after administration of influenza vaccine, and presents ADAMTS13 deficiency with extremely high inhibitor. The patient will be monitored for recurrence or relapse of this rare disorder.

PB 719 | Thrombotic Thrombocytopenic Purpura as an Initial Presentation of Systemic Lupus Erythematosus in a Thai Child: A Case Report

R. Natesirinilkul, W. Padungmaneesub, P. Charoenkwan, S. Reungrongrat, W. Chartapisak

Faculty of Medicine, Chiang Mai University, Pediatrics, Chiang Mai, Thailand

Background: Distinguishing between systemic lupus erythematosus (SLE) and thrombotic thrombocytopenic purpura (TTP) is challenging as both diseases share the same clinical features. The delayed diagnosis of TTP is associated high mortality, especially in SLE-associated TTP. The presentation of TTP as the first manifestations of SLE was mainly reported in adults.

Aims: To report a case presented with fever, acute renal failure and alteration of consciousness and was diagnosed with TTP before the diagnosis of SLE.

Methods: A girl was investigated for the cause of rapidly progressive glomerulonephritis (RPGN). All clinical data were recorded.

Results: A 15-year-old previously healthy girl manifested with fever for 3 weeks and developed petechiae with facial swelling for 1 day. On admission, she had marked pallor, tachycardia and right pleural effusion without skin lesion. Later, she developed alteration of consciousness. The computed tomography (CT) of brain showed diffuse brain edema. Blood tests showed Hb 4 g/dL, platelet count 15,000/mm^3, creatinine 1.5 mg/dL and observed hemoglobinuria, but normal coagulogram and fibrinogen level and negative Coombs' tests. She was diagnosed with RPGN and treated with methylprednisolone but no improvement. The blood smear showed microangiopathic hemolytic anemia (MAHA), then TTP was suspected. The ADAMTS-13 was < 3% and inhibitor was 3.3 units/mL. She was treated by fresh frozen plasma (FFP) transfusion and plasmapheresis for two episodes, then was gradually improved. The rest of tests later showed positive

antinuclear antibody (ANA), low serum C3 and C4 levels at 247 and 31.5 mg/dL, respectively, but negative anti-double stranded DNA antibody. She was diagnosed with SLE and received steroid and cyclophosphamide to maintain her in remission.

Conclusions: The clinical suspicious and blood smear are the key for the early diagnosis of TTP. The further tests should be performed to determine the definite diagnosis and treatment. TTP can be the initial symptom of SLE.

PB 720 | A Case of SLE with Different Types of Thrombotic Microangiopathy during the Course

E. Tatsumi[1], M. Miyamoto[1], F. Kamitani[1], S. Oono[1], N. Yada[1], K. Yoshimoto[1], M. Hayakawa[2], M. Matsumoto[2], Y. Akai[1], K. Nishio[1]

[1]Nara Medical University, General Internal Medicinne, Kasihara, Japan, [2]Nara Medical University, Blood Transfusion, Kasihara, Japan

Background: Thrombotic microangiopathy (TMA) is a pathologic condition leading to microangiopathic hemolytic anemia (MAHA) and thrombocytopenia. There are many underlying causes for a TMA, including thrombotic thrombocytopenic purpura (TTP). Since the diagnosis and management of TMA is very challenging, it is very important to understand the mechanisms for TMA. We present a case of SLE with two types of TMA during the course.

Aims: To understand the various underlying mechanism that lead to TMA for appropriate treatment.

Methods: We measured plasma levels of ADAMTS13 (A13) activity, inhibitor titers to A13, and non-neutralizing biding antibody to A13 (NNAb) by ELISA.

Results: A 26-year-old female was admitted to the N hospital with systemic edema for 1 month and fever. They diagnosed her as TTP (first TMA) with thrombocytopenia (platelet count: $8X10^6$/L), severely reduced levels of A13 (< 0.5%), and renal dysfunction. After 4 times PE, the platelet count and A13 activity was improved to $80X10^6$/L and 80%, respectively. But one week later, her platelet count dropped again and showed exacerbation of MAHA despite enough levels of A13, that is second TMA, then she was referred to our hospital for further investigation of TMA. On admission, we diagnosed her as SLE with nephrotic syndrome and TMA, and started methylprednisolone pulse therapy. To investigate the cause of first TMA, we examined her plasma on admission to the N hospital. We found no inhibitors to A13 but increased levels of NNAb, indicating that first TMA may be caused by NNAb. Several methylprednisolone pulse therapies were given, each time her second TMA (MAHA, thrombocytopenia and increased percentage of schizocyte) responded only for a few days, suggesting that steroid after pulse therapy cannot suppress SLE vasculitis mediating second TMA. Then we started giving her 6 times cyclophosphamide pulse therapy, leading complete remission of SLE and TMA.

Conclusions: It was very important to understand the underlying mechanisms for appropriate TMA treatment.

PB 721 | Congenital Thrombotic Thrombocytopenic Purpura without Nephropathy and Neuropathy

C. Albayrak[1], D. Albayrak[2]

[1]Ondokuz Mayis University, Pediatric Hematology, Samsun, Turkey, [2]Samsun Medicalpark Hospital, Pediatric Hematology, Samsun, Turkey

Background: Congenital TTP is due to an inherited deficiency of ADAMTS13, but acquired immune TTP is due to the reductionof ADAMTS13 by autoantibodies directed against ADAMTS13. Other clinical forms of thrombotic microangiopathy (TMA) occur in the absence of severe deficiency.

Aims: We present a patient with TTP without without nephropathy and neuropathy.

Methods: A 5-day-old girl was admitted to our hospital with fatigue. Physical examination revealed pallor and hepatomegaly. A blood smear showed hemolysis with 10% schistocytes and polychromasia. He had anemia with 5.5 g/dL hemoglobin level and 14.6% reticulocyte level. He had also thrombocytopenia (18,000/mm3) and elevated lactate dehydrogenase (LDH) as 856 U/L. A direct Coombs test was negative. The other blood parameters of the patient were as follows: haptoglobin < 5 mg/dL, C3 122 mg/dL, creatinine level 0.5 mg/dL, blood urea nitrogen 12 mg/dL, and indirect bilirubin 7 mg/dL. Urine analysis was normal. On the second day of admission, the patient's thrombocyte count dropped to 38,000/mm3, his LDH level remained elevated, and schistocytes were still present on his peripheral blood smear.

Results: Her gene analysis was performed to confirm whether the patient had aHUS or not.

Conclusions: We present a patient with TTP without without nephropathy and neuropathy.

PB 722 | Thrombotic Microangiopathies (TMA): First Report of 250 Cases from a Single Institution Experience in Latin America

C. Dos Santos[1], M. Agazzoni[1], M. Barrenechea[1], J. Paiva[1], M.M. Casinelli[1], A.C. Kempfer[2], M.L. Romero[1], M.A. Lazzari[2], A. Sánchez-Luceros[1,2]

[1]Hematologic Research Institute Mariano R. Castex - National Academy of Medicine of Buenos Aires, Hemostasis and Thrombosis, Buenos Aires, Argentina, [2]IMEX-CONICET-National Academy of Medicine of Buenos Aires, Hemostasis and Thrombosis, Buenos Aires, Argentina

Background: TMA are characterized by microangiopathic hemolytic anemia (MAHA), thrombocytopenia and organ failure. Worldwide, patients' cohort studies have been of great interest to understand pathological mechanisms and develop methods to differentiate entities, specifically between atypical Hemolytic Uremic Syndrome (aHUS) and adquired or congenital Thrombotic Thrombocytopenic Purpura (aTTP/cTTP).

Aims: For the first time, we described laboratory and clinical features of consecutive TMA patients studied in our department.

Methods: A prospective study (n=250) from January 2013 until June 2016, requiring patients' informed consent, was approved by the institutional Ethical Committee. Laboratory (Technozyme® ADAMTS13 activity and IgG anti-ADAMTS13, platelets, creatinine, LDH) and clinical parameters were recorded. Mann-Whitney U-test was used to compare parameters across groups ($p< 0.05$).

Results: The two major TMA groups were aHUS (n=94) and TTP (n=57). In both groups, women were more frequently affected than men (% aHUS: 38♂ vs 62♀ ; % TTP: 25♂ vs 75♀), particularly in the non-pediatric population (% aHUS: 17♂ vs 40♀ ; % TTP: 15♂ vs 65♀). Cases of aHUS (n=26) and aTTP (n=17) studied during remission or treatment were excluded from the analysis. Mean of ADAMTS13 activity was significantly lower in TTP than in aHUS patients. The presence of IgG anti-ADAMTS13 confirmed aTTP diagnostic. Patients with deficient ADAMTS13 activity presented a more severe thrombocytopenia than patients with normal activity. While LDH level was slightly higher in aHUS than in TTP groups, creatinine was significantly increased in aHUS compared to aTTP subjects. Rates of MAHA observed in all 3 entities were superior to 70%. In aHUS, 29% (n=27) of cases were associated with chronic kidney disease compared to only 12% (n=7) in TTP, a disorder more frequently related to neurological alterations (51% vs 28%).

Conclusions: The first description of a TMA cohort in Argentina confirmed the importance of ADAMTS13 analysis to differentiate TTP from aHUS.

TABLE 1 TMA disorders divided into subgroups and characterized by patients' sex distribution

SUBGROUPS	Number of males (%)	Number of females (%)	Total number n=250 (%)
aHUS	36 (38)	58 (62)	94 (38)
- aHUS acute phase (ap)	28 (77)	40 (69)	68 (72)
TTP	14 (25)	43 (75)	57 (23)
- aTTP acute phase (ap)	6 (43)	23 (53)	29 (51)

Background: An ADAMTS13 level of < 10% in patients with microangiopathic thrombocytopenia (MAT) confirms the diagnosis of thrombotic thrombocytopenic purpura (TTP) and differentiates TTP from aHUS and other MAT causes. However, routine ADAMTS13 laboratory testing is challenging due to differences in the methodology of ADAMTS13 assays, poor turnaround-time and little standardisation of results between laboratories. The APMAT Network recently implemented standardised ADAMTS13 testing in select Asia Pacific laboratories in Australia, New Zealand, China, Korea, Japan, Taiwan, Hong Kong, Malaysia, Thailand,

India and Singapore and sought to conduct an external quality assessment study of assays performed at these centres. The results were compared to an established ECAT survey on the same samples.

Aims: To establish and assess standardised ADAMTS13 testing in the APMAT Network.

Methods: Two surveys were conducted 6 months apart at 23 laboratories across 11 countries. Each survey utilised two blinded plasma samples of known activity. Laboratories performed ADAMTS13 activity and inhibitor titre assays using the same chromogenic ELISA (Technoclone GmbH); the results were compared to the ECAT analysis from the same samples.

Results: The APMAT survey samples mean and standard deviation were slightly higher when compared to the ECAT cohort, but still within the expected variation (< 20%). Similarly, inter-laboratory variations were within an acceptable range; samples with low intrinsic ADAMTS13 activity exhibited higher variation (CV=30% to 47%) than samples with high activity (CV=18%). ADAMTS13 inhibitor survey results produced smaller CVs (18% to 34%) but had a wider range and contained more outliers (5-10%). 100% of laboratories achieved a passing Z Score (-3< Z-Score< 3) for the activity assay, and 90-95% achieved a passing Z-score for the inhibitor assay.

Conclusions: ADAMTS13 assay standardisation is feasible in a international multicentre setting and has potential to expedite correct MAT diagnosis.

PB 724 | Treatment of Thrombotic Thrombocytopenic Purpura and Hemolytic Uremic Syndrome in Pediatric Patients - A Single Center Experience

O. Serbic[1], B. Andric[1], Z. Radonjic[1], N. Stajic[2,3], D. Jevtic[4], D. Djokic[4], M. Kuzmanovic[3,4]

[1]Mother and Child Health Care Institute of Serbia ‚Dr Vukan Cupic', Belgrade, Department of Blood Transfusion, Belgrade, Serbia, [2]Mother and Child Health Care Institute of Serbia ‚Dr Vukan Cupic', Belgrade, Department of Nephrology, Belgrade, Serbia, [3]University of Belgrade, School of Medicine, Belgrade, Serbia, [4]Mother and Child Health Care Institute of Serbia ‚Dr Vukan Cupic', Department of Hematooncology, Belgrade, Serbia

Background: Thrombotic thrombocytopenic purpura and hemolytic uremic syndrome (TTP/HUS) are rare entities in children. Therapeutic plasma exchange (TPE) is recommended treatment.

Aims: To report ten-year experience in the treatment of TTP/HUS in children with TPE from pediatric tertiray care center.

Methods: We treated two patients with TTP (median age of 17 y) and three with HUS (5±3.6 y) from 01.01.2007 to 31.12.2016. Efficacy of TPE was estimated measuring the platelet (PLT) count, reticulocytes, LDH, haptoglobin in patients with TTP and diuresis, serum creatinine in patients with HUS.

Results: Patients with TTP had the mean PLT count 28.4±17.1x10^9/l, Hb 81.3±2.4 g/l. Boy with TTP suffered CVI. Patients with HUS had oliguria, proteinuria, Hb 85.5±3.53 g/l and one patient of them had diarrhea and convulsions. We done 82 TPE, 62 in patients with TTP and 20 TPE at HUS. The frequency of TPE was daily, with 1.5 total plasma volumes (TPV). The plasma cryoprecipitate removed and fresh frozen plasma (FFP) were used as replacement fluids. The apheresis system was filled with allogeneic blood in one patient with low body weight (10 kg). For TTP patients TPE is performed until the platelet count was > 150x10^9/l for three consecutive days, for patients with HUS to the establishment of diuresis. Average of quantity replaced plasma was 3754.5 ml (835.6 to 6286), the blood flow was 32.3 ml/min (9.8 to 44) and the duration of the procedure was 215 min (157.8 to 289.5). One patient with TTP had two exacerbations, another patient two relapses. We continued TPE daily with a good final response. Steroids, folic acid, vincristine and LMWH or aspirin also included in the treatment in our patients. Patients with TTP had mild allergic reactions to plasma proteins (FFP without cryoprecipitate).

Conclusions: Four our patients were successfully treated with TPE. Immediate initiation of TPE, with additional forms of treatment was crucial for favourable outcome.

PB 725 | Successful Treatment of Renal Infiltration Complicated by Atypical Hemolytic Uremic Syndrome in a Child with Acute Leukemia

Z. Kaya[1], E.Ö. Özmen[2], M. Akgül[2], B. Topuz[2], E. Akkuzu[3], N. Alıcı[2], N. Buyan[4]

[1]Gazi University Medical Faculty, Pediatric Hematology, Çankaya, Turkey, [2]Gazi University Medical Faculty, Pediatric Hematology, Ankara, Turkey, [3]Gazi University Medical Faculty, Pediatric Intensive Care, Ankara, Turkey, [4]Gazi University Medical Faculty, Pediatric Nephrology, Ankara, Turkey

Background: Renal infiltration occurs in 7% to 42% of children with leukemia; however, it has rarely been described in association with atypical hemolytic uremic syndrome (HUS). A literature search revealed only one case of simultaneous occurrence of atypical HUS and ALL to date.

Aims: We report successful treatment of a child with ALL who had renal infiltration complicated by atypical HUS.

Methods: A 9-year-old boy presented with oliguria, hypertension, and periorbital edema. He was diagnosed with t(8;14)(q24;q32) positive pre-B ALL with meningeal involvement and tumor lysis syndrome (TLS). Anemia, thrombocytopenia, elevated uric acid and lactate dehydrogenase were identified. Steroid treatment was initiated. The patient's electrolyte imbalance resolved but his urine output remained inadequate despite effective hydration and hemodialysis for TLS. Radiological imaging and urinalysis suggested renal infiltration secondary to leukemia. While on steroid therapy, the patient's LDH and creatinine levels increased markedly again and his anemia and thrombocytopenia worsened. His ADAMST13 activity was normal. He developed atypical HUS in the first week after diagnosis.

Results: Renal failure did not respond to plasma infusion and steroid administration. Therapeutic plasma exchange was administered for 2 consecutive days, after which clinical and laboratory assessments revealed a dramatic response. Induction chemotherapy was continued.

At the time of writing, the patient was in remission and had experienced no signs of recurrence.

Conclusions: Atypical HUS is a rare but serious life-threatening complication in patients with malignancy. Although anemia, thrombocytopenia, and elevated LDH are common abnormalities in patients with leukemia, coexistence of second unexplained LDH elevation with anemia, thrombocytopenia, and renal dysfunction should alert the physician to the likelihood of atypical HUS development. Plasma exchange seems to be a better treatment for renal infiltration complicated by atypical HUS in leukemia.

PB 726 | Transplant/Imunosupressor Related Thrombotic Microangiopathy

F. Mousinho[1], A.P. Azevedo[2], C. Pimenta da Silva[2], C. Jorge[3], E. Cacheira[3], P. Sousa e Santos[1], A.M. Batalha Reis[2], J. Viana[4]

[1]Centro Hospitalar Lisboa Ocidental, Hospital São Francisco Xavier, Hematology, Lisbon, Portugal, [2]Centro Hospitalar Lisboa Ocidental, Hospital São Francisco Xavier, Clinical Pathology-Hematology Laboratory, Lisbon, Portugal, [3]Centro Hospitalar Lisboa Ocidental, Hospital Santa Cruz, Nephrology, Lisbon, Portugal, [4]Centro Hospitalar Lisboa Ocidental, Head of Clinical Pathology, Lisbon, Portugal

Background: De novo HUS (Haemolytic Uremic Syndrome) can affect 3 to 14 percent of kidney transplant recipients. Calcineurin Inhibitors, namely Cyclosporine or Tacrolimus and Mammalian target of rapamycin (mTOR) inhibitors (sirolimus, everolimus) seem to be related with cases of HUS culminating in loss of kidney transplant. However antibody-mediated rejection may also play a role in kidney transplant failure, leading to difficulties in understanding which process was standing first when renal function started to deteriorate.

Aims: The author describes a case of thrombotic microangiopathy in a patient with renal transplant on Tacrolimus therapy.

Methods: Case report: Woman, 48 years old, with history of chronic renal insufficiency due to Membranous Glomerulonephritis diagnosed in 1986, who undergone kidney transplantation in 2009. This patient was admitted to the nephrology ward because of sudden renal graft function deterioration (creatinine 4.9mg/dL) in December of 2016.

Results: Blood tests showed signs of haemolytic anaemia (haemoglobin 7,7g/dL with rare schizocytes, associated with very low level of haptoglobin and high unconjugated bilirubinaemia) with thrombocytopenia. Immediately the hypothesis of HUS had to be taken into account.

Conclusions: The Laboratory has an important role in the prompt detection and diagnosis of these disorders, as analytical data, including blood smear observation, is a key sign for suspicion. Secondary thrombotic microangiopathy should be assumed when blood signs are present and therapeutic approach managed, in order to save the transplanted organ. Even though, the most likely etiology of HUS was related to the transplant and imunosuppressor therapy, it is known that some patients seem to have a genetic or acquired predisposition to this event, which under the right stimulus, can trigger a thrombotic microangiopathic event. HUS associated with transplant is a potential life threatening situation that, if not recognized soon, can lead to loss of the transplanted organ or even death.

PB 727 | A Heterozygous Mutation of G-protein-Coupled Receptor 25 in a Family with inherited Thrombocytopenia and Thrombosis

J. Yamanouchi[1], T. Hato[1], Y. Ikeda[1], H. Takeda[2], M. Yasukawa[1]

[1]Ehime University, Department of Hematology, Toon, Japan, [2]Ehime University, Proteo-Science Center, Matsuyama, Japan

Background: Inherited thrombocytopenia is associated with bleeding tendency and no association with thrombotic tendency has been reported. We found a family with autosomal dominant form of thrombocytopenia associated with arterial and venous thrombosis.

Aims: To identify a causative gene for hereditary thrombocytopenia with thrombosis.

Methods: A propositus was a 42-year-old Japanese woman with thrombocytopenia and deep vein thrombosis (DVT). She had normal activities of antithrombin, protein C, and protein S, and negative results for lupus anticoagulant and anti-cardiolipin antibodies. She has suffered from thrombocytopenia (20 - 50 x 10^9/L) for at least 20 years. Six members among her family pedigree had thrombocytopenia, and also suffered from thrombosis including mesenteric artery thrombosis, young-onset myocardial infarction, femoral artery thrombosis, repeated cerebral infarction, DVT, and pulmonary embolism. Importantly, the family members with these thrombotic disorders had exclusively thrombocytopenia. Whole exome sequencing was performed with venous blood from the 6 affected and 6 non-affected family members to identify a causative gene for thrombocytopenia.

Results: We identified a heterozygous change (c.764G>T:p.G255V) in *GPR25* gene, an uncharacterized G protein-coupled receptor. The mutation was completely linked with thrombocytopenia. The mutated residue was located at the transmembrane domain of GPR25. We generated anti-GPR25 monoclonal antibodies and confirmed that GPR25 was expressed on the platelet surface. The patient's platelets showed the same level of PAC1 (a monoclonal antibody recognizing the active conformation of integrin αIIbβ3) binding and P-selectin expression as platelets from healthy subjects. ADP-induced aggregation of patient's washed platelets was enhanced as compared with normal washed platelets.

Conclusions: We identified a novel gene mutation responsible for inherited thrombocytopenia and thrombosis that may induce platelet hyper-reactivity.

PB 728 | Seven Years' Experience of Healthcare Cards Delivery from the French Reference Center on Inherited Platelet Disorders (CRPP)

Background: A French Plan for rare diseases allowed to structure healthcare for patients with inherited platelet disorders (IPD) through a territory network referred as the Reference Center on inherited Platelet disorders (CRPP).

Aims: To estimate the distribution of IPD based on healthcare cards delivery since October 2009.

Methods: Requests for cards are subjected to the coordinating center for a review process. It issues a numbered card after checking the diagnosis and eliminating duplicates.

Results: 352 healthcare cards (249 families (F)) for thrombocytopenia (T) and 283 (197 F) for platelet dysfunction (PD) have been delivered. Among T, 134 are explained by MYH9 (median age [range]: 34 [0.7-82] yrs) and 56 by GPIBA/GPIBB/GP9 variants (10 pseudoWillebrand, 31 Jean Bernard-Soulier Syndrome (JBS), 2 di-george syndrome and 13 mono-allelic JBS). The remaining corresponds to TUBB1(8), FLNA(4), ACTN1(5), ITGB3(2), PRKACG(1), TRPM7(1) variants. Nineteen are gray platelet syndrome of which 14 correspond to NBEAL2 variants (29 [16-71] yrs). Three are due to FLI1 mutation and 3 correspond to TAR, Paris-Trousseau and Lowe syndromes. Forty-four are forms prone to leukemia: ANKRD26(22), ETV6(14) and RUNX1(8). Nine X-linked T (4 Wiskott Aldrich Syndrome, 3 XLT and 2 GATA1 variants) have been evidenced. For 63 T (18%; 54 F) genetic diagnosis remains unknown. Among PD, 159 patients (101 F) carry Glanzmann Thrombasthenia (28 [1.9-89] yrs) and 70 suffer a dense granule defect (55 F) (43 [3.9-75] yrs), including 3 Hermansky-Pudlack syndrome. Six patients (4 F) display inside out signaling defect (1 FERMT3 and 5 RASGRP2 variants). Five patients (4 F) carry P2RY12, 2 GP6 variants or defect in collagen response, 1 suffers a Scott syndrome. For 41 patients (14%; 27 F) etiology remains unknown.

Conclusions: This is the first effort to estimate the distribution of IPD in France. Data collected are being used to describe the prevalence and epidemiology.

PB 729 | Novel RUNX1 Mutations in Families with Inherited Thrombocytopenia

P. Noris[1], D. De Rocco[2], F. Melazzini[1], C. Marconi[3], A. Pecci[1], R. Bottega[4], C. Gnan[2], F. Palombo[3], P. Giordano[5], M.S. Coccioli[6], A.C. Glembotsky[7], E. Cigalini[8], P. Heller[7], M. Seri[3], A. Savoia[2,4]

Trambusti', University of Bari, Department of Biomedical Science and Human Oncology, Bari, Italy,* [6]*U.O.C of Pediatrics, Hospital ,D. Camberlingo', Francavilla Fontana, Brindisi, Italy,* [7]*Instituto de Investigaciones Médicas Alfredo Lanari, Universidad de Buenos Aires, IDIM-CONICET, Buenos Aires, Argentina,* [8]*IRCCS Policlinico San Matteo Foundation, Department of Internal Medicine, Pavia, Italy*

Background: Familial platelet disorder with propensity to acute myeloid leukemia (FPD/AML) is a rare autosomal dominant inherited thrombocytopenia (IT) caused by mutations in the hematopoietic transcription factor RUNX1 and associated with an increased risk of developing myeloid neoplasms, such as AML and myelodysplastic syndromes (MDS). It is characterized by impaired megakaryopoiesis and moderate thrombocytopenia, with normal-sized and dysfunctional platelets.

Aims: To unravel the molecular basis of ITs and to improve our knowledge on the molecular basis and clinical-laboratory picture of FPD/AML.

Methods: Whole exome sequencing (WES) was performed in 86 propositi with an unknown IT after the diagnostic workup based on the must updated diagnostic algorithm for ITs (Clin Genet 2016;89:141). *RUNX1* variants detected by WES were confirmed by Sanger sequencing in the propositi and all available family members, which also undergo clinical and laboratory characterization.

Results: We identified 3 pedigrees with different *RUNX1* heterozygous mutations: the novel variants c.578T>A and c.967+2_5del, and the known c.351+1G>A. The 13 affected subjects had mildly reduced platelet count, normal platelet size, variable expression of other morphological/functional platelet defects of alpha-granules content, glycoprotein expression and *in vitro* platelet aggregation. Three patients from 2 families developed AML, with a prevalence lower than reported in literature, probably because of a different criteria of enrolment (*RUNX1* is usually analyzed in ITs associated with AML).

Conclusions: FPD/AML lacks of pathognomonic criteria and is characterized by normal platelet size as the other ITs predisposing to hematological malignancies (*ANKRD26* and *ETV6*-related thrombocytopenias). Given the importance of recognizing these diseases for patients´ counseling, follow-up, and therapeutic approach, we recommend a systematic screening for *RUNX1*, *ANKRD26*, and *ETV6* mutations in all patients with an autosomal dominant IT and normal platelet size.

PB 730 | A Novel Mutation in *TBXA2R* Impairs the Expression of the TPβ Isoform of the Platelet Thromboxane Receptor and Associates with Bleeding Diathesis

L. Bury, E. Falcinelli, A.M. Mezzasoma, G. Manni, E. Cesari, P. Gresele

University of Perugia, Department of Medicine, Perugia, Italy

Background: The platelet thromboxane A_2 receptor (TP) is a G protein-coupled receptor playing an essential role in hemostasis by binding thromboxane A_2 (TxA_2). Two isoforms of TP, TPα and TPβ, are generated by alternative splicing from the TBXA2R gene. While the expression and function of TPα in platelets is well established, that of TPβ is still a matter of debate. The TP defect is a very rare autosomal dominant bleeding disorder characterized by mild mucocutaneous bleeding caused by mutations in *TBXA2R*, with 5 mutations, all affecting TPα, in a few families described.

We have studied a woman with a lifelong bleeding diathesis and platelet dysfunction in response to TP agonists, characteristics that oriented towards a TP defect.

Aims: To characterize the platelet dysfunction, to confirm TP defect by molecular genetic analysis, to investigate the impact of the mutation on the TP protein.

Methods: Platelet function was studies by light transmission aggregometry (LTA), flow cytometry and lumiaggregometry, TBXA2R gene was analyzed by PCR and direct sequencing. TP isoform expression was assessed by real time PCR and Western blotting (WB) using antibodies selective for the two TP isoforms.

Results: Platelet LTA was defective in response to arachidonic acid, U46619, U44069 and secondary wave to ADP and epinephrine. Sequencing of *TBXA2R* revealed a novel heterozygous A>T substitution at g.A11765T, not present in healthy controls, corresponding to the alternative splice site of TPβ. We confirmed the expression of the TPβ isoform in ultrapurified platelets by real time PCR and WB. Real time PCR showed a 50% reduction of the mRNA coding for TPβ accompanied by a reduction of the TPβ protein by WB in patient platelets.

Conclusions: We describe a novel g.11765A>T variation in *TBXA2R* associated with a mucocutaneous bleeding diathesis hitting the splice site that regulates the expression of the TPβ isoform. These findings suggest that TPβ has role in platelet function.

PB 731 | Spontaneous Loss of Mitochondrial Potential and Phosphatidylserine Exposure in Fibrinogen-bound Platelets of Patients with Wiskott-Aldrich Syndrome

S. Obydennyi[1,2], D. Pershin[2], A. Maschan[2], A. Shcherbina[2], M. Panteleev[1,2,3]

[1]*Center for Theoretical Problems of Physicochemical Pharmacology, Russian Academy of Sciences, Moscow, Russian Federation,* [2]*Dmitry Rogachev National Research Center of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation,* [3]*Moscow State University, Physical Faculty, Moscow, Russian Federation*

Background: Bleeding in Wiskott-Aldrich syndrome (WAS) is due to thrombocytopenia of unclear origin. Our previous studies suggested that WAS platelets are more likely to expose phosphatidylserine (PS) possibly leading to their destruction by macrophages.

Aims: To investigate PS exposure of fibrinogen-immobilized WAS platelets.

Methods: Whole blood was collected into sodium citrate. All patients (n=8) and healthy donors gave their written informed consent, and the study was approved by the institutional ethics committee. Platelets were loaded with Fura Red, immobilized and incubated on a fibrinogen surface for 50 min, followed by real-time confocal microscopy. Annexin V was used for PS detection, while tetramethylrhodamine was added in some cases to detect mitochondrial potential.

Results: Fibrinogen-immobilized WAS platelets had a high tendency to undergo spontaneous activation with PS exposure in comparison with normal platelets(25% versus 6%, P< 0.05). Signaling events preceding PS exposure were similar to those previously reported for procoagulant platelet formation in normal subjects upon stimulation: a series of cytosolic calcium spikes followed by membrane potential loss in all mitochondria, sustained cytosolic calcium increase and PS externalization. Cyclosporin A (CsA), an inhibitor of mitochondrial permeability transition pore opening, decreased the PS-positive platelet fraction several-fold.

Conclusions: WAS platelets spontaneously expose PS via a mitochondria-dependent necrotic mechanism, which may contribute to their clearance and thrombocytopenia.

PB 732 | ACTN1 Macrothrombocytopenia: Deleterious Effects of Rod-domain ACTN1 Variants

A. Vincenot[1,2], M. Poggi[3], N. Schlegel[1,2], O. René[1,2], S. Binard[1,2], P. Saultier[3], S. Kunishima[4], M.C. Alessi[3,5]

[1]*CHU Robert Debré, National Reference Center on Inherited Platelet Disorders, Paris, France,* [2]*CHU Robert Debré, Biological Hematology, Paris, France,* [3]*Faculté de Médecine de la Timone, Lab N.O.R.T - UMR Inserm_1062/INRA_1260/AMU, Marseille, France,* [4]*National Hospital Organization Nagoya Medical Center, Department of Advanced Diagnosis, Clinical Research Center, Nagoya, Japan,* [5]*Hôpital de la Timone, National Reference Center on Inherited Platelet Disorders, Marseille, France*

Background: Mutations of *ACTN1*, the gene coding for alpha-actinin isoform 1, have recently been identified as responsible for a mild form

of inherited macrothrombocytopenia (IMT). All the mutations already described except one are located in the two important functional domains (Calmodulin-like domain and Actin-Binding Domain) involved in its dimerization and binding to actin.

Aims: Molecular and functional characterization of newly *ACTN1* identified mutations.

Methods: *ACTN1* variants were identified by Sanger sequencing in patients with IMT after having excluded *MYH9* defects. Organization of actin filaments was examined by immunofluorescence staining in two cell-lines (CHO and HeLa cells) transfected with *ACTN1* variants. Phenotype data of the affected patients are reported.

Results: In 6 patients of 5 unrelated families, we identified five different variants in the 4 Spectrin Repeats (SR) of the rod-domain of ACTN1 affecting highly conserved amino-acid residues and predicted to be deleterious by Sift® and Polyphen2®*in silico* programs.

Compared to wild-type *ACTN1*, cells transfected with each *ACTN1* variant presented actin filament disruption, change of actin network with shorter and thicker actin fibers, and coarse distribution of unbound actinin in the cytoplasm especially in CHO cells.

Phenotype analysis showed a moderate thrombocytopenia (platelet count mean: 91 G/L), the presence of few giant platelets (defined as platelet size over than red cell one - mean: 6%) and numerous macroplatelets (defined as platelet size under red cell size and over ½ red cell one - mean ± SD:41±18 %). No bleeding tendency was reported.

Conclusions: We identified five novel *ACTN1* variants located in the SR domain causing actin network disorganization, indicating that the rod domain plays also a key molecular role, probably by modulating its dimerization or its binding to others proteins.

PB 733 | Complete Failure of Integrin αIIbβ3 Activation in Kinetic Assay Associates with Severe Bleeding Problems in a Patient with Kindlin-3 Deficiency

H. Kato[1], Y. Ito[2], H. Kashiwagi[1], Y. Morikawa[1], K. Akuta[1], N. Nishiura[1], S. Honda[3], K. Kokame[3], T. Miyata[3], Y. Kanakura[1], Y. Tomiyama[4]

[1]*Osaka Universtity Graduate School of Medicine, Hematology and Oncology, Osaka, Japan,* [2]*Nagoya University Graduate School of Medicine, Neonatology and Pediatrics, Nagoya, Japan,* [3]*National Cerebral and Cardiovascular Center, Molecular Pathogenesis, Suita, Japan,* [4]*Osaka Universtity Hospital, Blood Transfusion, Osaka, Japan*

Background: Activation of platelet fibrinogen receptor integrin αIIbβ3 by inside-out signaling is essential for platelet aggregate formation. Although it has been established that the direct interaction of talin and Kindlin-3 with β3 is critical for conformational change and activation of αIIbβ3, the details of inside-out αIIbβ3 activation is still obscure. Recently, we reported the patient with CalDAG-GFEI deficiency and the importance of CalDAG-GEFI for immediate αIIbβ3 activation kinetics associated with severe bleeding problems (Kato et al. Blood 2016).

Aims: To elucidate the role of Kindlin-3 in inside-out signaling, we analyzied platelets of a newly diagnosed Kindlin-3 deficient patient and compared with those of CalDAG-GEFI or P2Y12 receptor deficiency.

Methods: We analyzed platelets from a 8-month-old baby who showed easy bruising and prolonged bleeding time (>20min) by flow cytometry, western blotting, sequencing, and shear-induced thrombus formation after obtaining written informed consent.

Results: Peripheral blood platelet count and the expression levels of platelet surface glycoproteins in platelets of the patient were comparable to those of control. αIIbβ3 activation determined by activated αIIbβ3 specific antibody PAC-1 was strongly impaired in all agonist stimulation including PMA. Western blotting analysis found deficiency of Kindlin-3 in patient's platelets and the sequencing results revealed homozygous nonsense mutation W277X in Kindlin-3. In contrast to the delayed αIIbβ3 activation kinetics in CalDAG-GEFI deficient platelets and transient activation in P2Y12 deficient platelets, no αIIbβ3 activation was observed by "initial velocity assay" at any time points after PAR1-TRAP stimulation. In addition, shear induced thrombus formation on collagen was severely impaired than that of CalDAG-GEFI deficiency.

Conclusions: Unlike CalDAG-GEI or P2Y12 deficiency, Kindlin-3 deficiency resulted in the complete failure of αIIbβ3 activation in kinetic assay and associated with severe bleeding symptoms.

PB 734 | Identification of Two New *P2RY12* Heterozygous Mutations Responsible for Hemorrhagic Diathesis in Two Unrelated Families

A. Dupuis[1], V. Heim[1], D. Desprez[2], P. Ohlmann[1], A. Lorenzo[3], C. Gachet[1]

[1]*Université de Strasbourg, INSERM, EFS Grand Est, BPPS UMR-S 949, FMTS, Strasbourg, France,* [2]*Hopitaux Universitaires de Strasbourg, Strasbourg, France,* [3]*Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland*

Background: Since 2001, eleven mutation of *P2RY12* gene have been described with, in almost all cases, a hemorrhagic diathesis related to the presence of either a biallelic mutation of the *P2RY12* gene or of a heterozygous mutation associated with another primary hemostasis anomaly.

Aims: Here, we report two new heterozygous mutations of *P2RY12* found in *propositi* from unrelated families in the absence of any other detectable primary hemostasis defect.

Methods: Blood platelet exploration were performed in two patients (KC and CJP) with a bleeding history with normal platelet count and without any coagulation or Willebrand disorders. We examined platelet aggregation by light transmission and granular content by HPLC and ELISA. $P2Y_{12}$ quantification was performed by radioligand binding studies using intact platelets and downstream signaling was assessed by cAMPc measurement using a radio-immunoassay (CJP only) and the VASP test. *P2RY12* gene was sequenced using in-house primers.

Results: Platelet aggregations performed in citrated PRP and washed platelets showed a severe defect of ADP-induced aggregation in both patients while nucleotides and serotonin granular content were normal. $P2Y_{12}$ expression was reduced in both patients (282 sites per

platelet in CJP, 218 in KC, vs 573 in the control). The ADP receptor reactivity assessed through the VASP assay was normal (> 70%) in both cases but a moderate decrease in inhibition of cAMP formation was found after stimulation of CJP platelets by low concentrations of ADP (1 to 5 μM). *P2RY12* sequencing revealed the presence of one unknown heterozygous mutation in each patient: p.Phe95Ser in KC and p.Tyr259Cys in CJP.

Conclusions: We identified two new $P2Y_{12}$ variants affecting two essential amino acids as predicted by recent crystal structure studies. These mutations seem to be sufficient to induce a bleeding tendency even if the mutation is heterozygous. Reproduction of each variant is ongoing in 1321N1 cells using HA-tag plasmid vectors.

PB 735 | Glanzmann's Thrombasthenia in China: New Insights into its Pathogenesis

Z. Lu[1], M. Jiang[1], Z. Yu[1], Z. Wang[1], L. Xia[1,2], C. Ruan[1]

[1]*Jiangsu Institute of Hematology, Key Laboratory of Thrombosis & Hemostasis of Ministry of Health, The First Affiliated Hospital of Soochow University, Suzhou, China,* [2]*Cardiovascular Biology Research Program, Oklahoma Medical Research Foundation, Oklahoma City, United States*

Background: Glanzmann's thrombasthenia (GT) is a rare genetic bleeding disorder characterized by defects of the integrin aIIβ3 on the platelet membrane. Most patients with GT were found in areas where consanguineous marriages are common. There has yet been no large clinical and genetic study of GT in China, however.

Aims: To determine the molecular basis of GT in patients from China and extend knowledge of its pathogenesis.

Methods: Clinical features of 89 patients with GT were evaluated. Mutations in 30 patients were detected by Sanger sequencing, while 15 patients were analyzed using a panel of 89 genes related to hemostasis by next-generation sequencing.

Results: Consanguinity of these patients is much lower (16.8%) than in GT-prone countries. Mortality was relatively high (7.4%). Fifty mutations were identified, among which 36 were new. Most patients were compound heterozygotes. In variant types of GT patients, three mutations were identified on ITGA2B, which are different from previous reports. p.R584X, p.Q891X, p.Q778P on ITGA2B and p.C400Y on ITGB3 were hot spot mutations. Among 36 novel mutations, there were 18 missense mutations, five nonsense mutations, seven splicing mutations, one insertion mutation and five deletion mutations. Molecular modeling revealed these novel mutations induced changes in aIIβ3 domain structures, thereby interfering with integrin activation and function. In 15 patients who underwent next-generation sequencing, one patient revealed no molecular genetic anomalies and three patients were only identified with one heterozygous mutation in ITGA2B or ITGB3, which could not explain the diagnosis of GT. However, mutations in other genes related to hemostasis were found in these patients. These data suggest that, besides ITGA2B and ITGB3, mutations in other genes involved in coagulation may contribute to the pathogenesis of GT.

Conclusions: Our results show unique clinical and genetic features of GT patients in China and highlight the necessity of next-generation sequencing in GT patients.

PB 736 | A New Form of Inherited Thrombocytopenia (IT) Due to Monoallelic Loss-of-function Mutation in the Thrombopoietin (THPO) Gene

P. Noris[1], C. Marconi[2], D. De Rocco[3], F. Melazzini[1], T. Pippucci[2], G. Loffredo[4], T. Giangregorio[3], A. Pecci[1], E. Cigalini[5], M. Seri[2], A. Savoia[3,6]

[1]*IRCCS Policlinico San Matteo Foundation and University of Pavia, Department of Internal Medicine, Pavia, Italy,* [2]*Policlinico Sant'Orsola Malpighi and University of Bologna, Department of Medical and Surgical Science, Bologna, Italy,* [3]*Institute for Maternal and Child Health, IRCCS Burlo Garofolo, Trieste, Italy,* [4]*Azienda Ospedaliera ,Santobono-Pusilipon', Dipartimento di Oncologia, Ospedale Pausilipon, Napoli, Italy,* [5]*IRCCS Policlinico San Matteo Foundation, Department of Internal Medicine, Pavia, Italy,* [6]*University of Trieste, Department of Medical Sciences, Trieste, Italy*

Background: The THPO-MPL axis plays a central role in platelet biogenesis: it activates the signaling cascade inducing megakaryocytes (MKs) differentiation from progenitor cells and regulates MK maturation, proplatelet extension, and nascent platelet release into the bloodstream.

Patients with inherited defects of MPL interfering with THPO binding present with severe congenital amegakaryocytic thrombocytopenia, evolving into trilineage bone marrow aplasia; similarly, a homozygous loss-of-function variant in the *THPO* gene was responsible for recessive aplastic anemia in a Micronesian family. At the opposite, gain of function mutations in *MPL* and *THPO* cause congenital thrombocytosis.

Aims: To unravel the molecular basis of ITs and to improve the clinical and laboratory characterization of the new ITs identified.

Methods: Whole exome sequencing was performed in 86 propositi with an unknown IT, part of our case series of 274 consecutive families, 151 of which without a definite diagnosis after the diagnostic workup based on the must updated diagnostic algorithm (Clin Genet 2016;89:141).

Results: The molecular analysis identified 2 unrelated individuals carrying the heterozygous variant c.91C>T (p. Arg31*), which is expected to result in mutant protein degradation and THPO haploinsufficiency. In each family the segregation with the disorder was confirmed analyzing one affected relative. Thrombocytopenia was mild, bleeding tendency absent in all cases. Platelet size was normal or slightly enlarged. *In vitro* platelet aggregation and major surface glycoproteins were normal. Serum THPO levels were at the extreme lower limit of the normal range, confirming that *THPO* mutation was responsible for haploinsufficiency.

Conclusions: The p. Arg31* mutation in THPO causes a new autosomal dominant form of mild, non-syndromic thrombocytopenia. This innocuous disorder is relatively rare (1.3% of families of our case series) but it must be differentiated from ITs with normal-sized platelets that predispose to hematological malignancies.

PB 737 | MYH9 Variants Defined by Next-generation Sequencing: Predicting Variants Likely Causing MYH9-related Disorder

L. Bury[1], I. Simeoni[2,3,4], P. Gresele[1], on behalf of the BRIDGE-BPD and the ThromboGenomics Consortia

[1]*University of Perugia, Department of Medicine, Perugia, Italy,* [2]*Cambridge University Hospitals, Department of Haematology, Cambridge, United Kingdom,* [3]*NHS Blood and Transplant, Cambridge Biomedical Campus, Cambridge, United Kingdom,* [4]*NIHR BioResource - Rare Diseases, Cambridge University Hospitals, Cambridge Biomedical Campus, Cambridge, United Kingdom*

Background: Variants in the *MYH9* gene, coding for the heavy chain A of non-muscle myosin class II, are associated with the *MYH9*-related disorder (MYH9-RD) characterized by macrothrombocytopenia, Döhle-like inclusion bodies in neutrophils and ear, eye, kidney and liver involvement of various severity.

Aims: To screen cases with an *MYH9* variant within the Bleeding, Thrombotic and Platelet Disorders (BPD) enrolled in the BRIDGE-BPD and in the ThromboGenomics (Simeoni *et al.* Blood 2016) cohorts.

Methods: Patient DNAs were subjected to whole genome or targeted sequencing and clinical information collected using Human Phenotype Ontology (HPO) terms. Rare variants were defined after computational analysis excluding variants with minor allele frequencies >1/1000. Each variant was reviewed by a Multi Disciplinary Team and labelled with pathogenicity and contribution to the phenotype.

Results: 34 MYH9-RD cases with 22 different variants preferentially localized in 10 of the 41 exons of *MYH9* were found. We found 15 missense variations, 2 stop-gain, 3 frameshift, 1 insertion and 1 deletion. All cases had macrothrombocytopenia and 14 cases out of 34 had typical Döhle-like inclusion bodies. Variants involving the SH3/MD interface of MYH9 head, the coiled-coil and the tail domains were found in cases with a mild phenotype, confirming previous data (Pecci *et al.* Hum Mutat. 2014). Some degree of bleeding diathesis was present in 20 patients. In 10 out of 34 cases, MYH9-RD had not been suspected. Out of the 22 variants, 8 were not previously reported in the Human Gene Mutation Database (HGMD) and in the Exome Aggregation Consortium (ExAC) control datasets: 3 novel variants hit the SH3/MD interface, 4 the coiled-coil domain and 1 the non-helical tail.

Conclusions: Our results add knowledge to the characterization of MYH9-RD confirming its clinical and genetic heterogeneity and show that, in the presence of unclassified macrothrombocytopenia, MYH9-RD should be suspected.

PB 738 | Aberrant Gsalpha Signalling in Platelets from AHO Patients Linked to Impaired Platelet Function

F. Swieringa[1,2], F.A. Solari[1], M.A.H. Feijge[2], N.J.A. Mattheij[2], O. Pagel[1], F. Beck[1], C.T.R.M. Stumpel[3], J. Pohlenz[4], J. Faber[5], A. Russo[5], O. Schwab[6], B. Zieger[6], K. Jurk[7], A. Sickmann[1], P.E.J. van der Meijden[2], I.M.L.W. Körver-Keularts[3], R.P. Zahedi[1], J.W.M. Heemskerk[2]

[1]*Leibniz Institute for Analytical Sciences - ISAS-e.V., Bioanalytics, Dortmund, Germany,* [2]*Maastricht University, Biochemistry, Maastricht, The Netherlands,* [3]*Maastricht University Medical Centre, Clinical Genetics and School for Oncology & Developmental Biology, Maastricht, The Netherlands,* [4]*University Medical Center of the Johannes Gutenberg University Mainz, Pediatric Endocrinology, Mainz, Germany,* [5]*University Medical Center of the Johannes Gutenberg University Mainz, Pediatric Hematology, Oncology, Haemostaseology, Mainz, Germany,* [6]*Medical Center - University of Freiburg, Pediatrics and Adolescent Medicine, Division of Pediatric Hematology and Oncology, Freiburg, Germany,* [7]*University of Mainz, Center for Thrombosis and, Mainz, Germany*

Background: Albright hereditary osteodystrophy (AHO) patients are diagnosed with pseudohypoparathyroidism, causing impaired (parathyroid) hormone signalling when inherited maternally. The syndrome is accompanied by mutations in the *GNAS* complex gene locus for Gsα, resulting in a variable degree of cellular signalling via Gsα, adenylate cyclase (AC) and cAMP-dependent protein kinase A (PKA).

Aims: To elucidate the altered platelet Gs-AC-PKA signalling and platelet function in AHO patients.

Methods: Platelet function (activation, aggregation, thrombus formation) was studied in blood from diagnosed AHO patients and control subjects. Platelets were treated with a dose range of Gs stimulating prostaglandins. Using mass spectrometry quantitative changes in the prostaglandin-induced phosphoproteome were assessed for patient and control platelets.

Results: In platelets from diagnosed AHO patients we measured normal to impaired responsiveness to prostaglandins, in terms of suppression of platelet activation, aggregation and thrombus formation. Concerning the target protein of PKA signalling, Gs stimulation caused either no (n=2), a moderately impaired (n=3) or a greatly impaired (n=3) phosphorylation of vasodilator-stimulated phosphoprotein. We identified 3,457 phosphopeptides (for 1,170 proteins), of which 239 peptides were Gs regulated. In platelets from an AHO patient, the global proteome was in essence unchanged, but 149 protein sites were altered in phosphorylation that: *(i)* agreed with prior iloprost-induced changes, *(ii)* contained a PKA target consensus sequence, *(iii)* could be classified to Signaling & adapter proteins (20×), Protein kinases & phosphatases (18×) and Small GTPases & regulators (12×).

Conclusions: Patients diagnosed with AHO to a variable degree have platelets with aberrant PKA-dependent signalling and phosphorylation patterns, along with altered function; pointing to a different disease penetrance. Quantitative platelet phosphoproteomics is a powerful tool to detect such altered phosphorylation.

PB 739 | Pseudo-Glanzmann Thrombasthenia due to Mutation in RasGRP2 Gene Encoding for CalDAG-GEFI

N. Rosenberg[1,2], R. Dardik[1], H. Hauschner[3], S. Nakav[4], O. Barel[5], J. Luboshitz[1], J. Yacobovich[6], H. Tamary[2,6]

[1]Sheba Medical Center, Hemophilia Center, Ramat Gan, Israel, [2]Tel Aviv University, Sackler School of Medicine, Tel Aviv, Israel, [3]Sheba Medical Center, Amalia Biron Research Institute of Thrombosis and Heamostasis, Ramat Gan, Israel, [4]Rabin Medical Center, Petah Tikva, Israel, [5]Sheba Medical Center, Bioinformatic Center, Ramat Gan, Israel, [6]Schneider Children's Medical Center, Pediatric Hematology, Petah Tikva, Israel

Background: The nature of an inherited platelet disorder was investigated in three patients that exhibited massive mucocutaneous bleeding episodes, impaired platelet aggregation with ADP, epinephrine and collagen but normal aggregation with ristocetin, and normal platelet count and size, and were therefore misdiagnosed as Glanzmann Thrombasthenia.

Aims: To detect the basis for the bleeding disorder.

Methods: Flow cytometry and molecular sequencing.

Results: Using flow cytometry we observed normal surface expression of the integrins αIIbβ3 and αvβ3, as well as normal integrin αIIbβ3 activation following incubation with the activating antibody LIBS6. In contrast, platelet activation following ADP or epinephrine was impaired as measured by anti P-selectin or PAC1 antibodies. Direct sequencing of the exons encoding for the cytoplasmic tails of integrin αIIbβ3 did not detect any candidate mutation, therefore we performed whole exome sequencing (WES) followed by bioinformatic analysis of platelet expressed genes. WES detected a mutation in RasGRP2 gene in two patients:

1 - A 9 month old boy of Kavkazi Jewish origin was found to be homozygous for deletion G1279 in exon 11; his parents were found to be heterozygous for this deletion despite absence of consanguinity;

2 - A 20 year old girl of Christian-Arab origin was found to be homozygous for a single nucleotide insertion, 1480-7C in a CCCCCCC sequence in exon 13. Interestingly, the third patient, a 22 year old girl of Kavkazi Jewish origin was also homozygous for the deletion G1279 in exon 11, suggesting that this mutation might be common in the Kavkazi Jewish community.

Conclusions: RasGRP2 encodes the CalDAG-GEFI protein, a major signaling molecule functioning as Rap1 GTPase activator regulating integrin-mediated aggregation and granule secretion. Only 7 patients carrying 5 different mutations in RasGRP2 gene were previously published. All of them suffered from severe bleeding without any impact on leukocyte function, in contrast to the observations reported in mice.

PB 740 | GATA1 T296P Mutation Causes a Severe Bleeding Disorder due to Platelet A-Granule and Partial δ-Storage Pool Deficiency

K. Jurk[1], S. Sollfrank[2], O. Pagel[3], K. Groß[1], A. Czwalinna[4], J. Erkel[5], K.J. Lackner[2], U. Walter[1], H. Rossmann[2], R.P. Zahedi[3], F. Bergmann[4]

[1]University Medical Center of the Johannes Gutenberg University Mainz, Center for Thrombosis and Hemostasis (CTH), Mainz, Germany, [2]Institute of Clinical Chemistry and Laboratory Medicine, University Medical Center Mainz, Mainz, Germany, [3]Leibniz-Institut für Analytische Wisschenschaften - ISAS - e.V., Dortmund, Germany, [4]Coagulation Laboratory, MVZ Wagnerstibbe, Amedes-Group, Hanover, Germany, [5]St. Marienhospital, Pediatric Department, Vechta, Germany

Background: The transcription factor GATA1 regulates megakaryopoiesis including megakaryocyte relevant genes, e.g. *GPIBA*, *NBEAL* and *SYK*. *GATA1* mutations in humans are predominantly located within the N-terminal zinc finger domain leading to complex disorders such as X-linked thrombocytopenia associated with gray-platelet like syndrome.

Aims: To elucidate the platelet phenotype and genetic diagnosis of a 35-year-old patient and his 4-year-old daughter who suffer from severe bleeding, e.g. frequent epistaxis and hematoma since infancy not caused by von Willebrand disease or subhemphilia.

Methods: Platelet phenotype and function was analyzed by aggregometry, flow cytometry, immunoblotting, ELISA and electron microscopy. Whole exome sequencing and pyrosequencing was used for genetic analyses.

Results: Agonist-induced aggregation of patients' platelets with increased mean volume was impaired but normal in response to high concentration of collagen or arachidonic acid which was associated with an ATP-secretion defect. Western analysis and electron microscopy revealed paucity of α- and δ-granules accompanied by big vacuoles containing granule/membrane fragments. Patients' platelets did not take up mepacrine and serotonin levels were reduced but still in the normal range. A not yet described *GATA1* mutation (c.886A>C, p.T296P) close to the C-terminal zinc finger domain was identified in the index patient (hemizygous), in his symptomatic daughter (heterozygous) and his asymptomatic mother (heterozygous).

Conclusions: We describe for the first time a *GATA1* T296P mutation as cause of severe platelet dysfunction due to paucity of α-granules and dense bodies which lack adenosine nucleotides but contain normal levels of serotonin. Recent platelet proteome analysis is expected to help the identification of downregulated proteins that explain the granule defects. Imbalanced X-chromosome inactivation might explain the different phenotypes of the *GATA1* mutation carriers.

PB 741 | Detection and Analysis of Gene Mutations in Patients with Glanzmann Thrombasthenia by Next Generation Sequencing

D. Zhang, Y. Jia, L. Zhang, L. Qin, Y. Lin, F. Xue, R. Yang, K. Ru

Chinese Academy of Medical Sciences & Peking Union Medical College, Institute of Hematology & Hospital of Blood Diseas, Tianjin, China

Background: Glanzmann thrombasthenia (GT) is an inherited genetic disorder affecting platelets, which is characterized by spontaneous mucocutaneous bleeding and abnormally prolonged bleeding. The underlying defect is failure of platelet aggregation due to qualitative and/or quantitative deficiency of platelet integrin αIIbβ3 resulting from molecular genetic defects in either *ITGA2B* or *ITGB3*. When striving for applicability in routine clinical practice, it soon becomes clear that population Sanger sequencing is too labor-intensive and time-consuming.
Aims: In this study, we aimed to assess *ITGA2B* or *ITGB3* gene mutations through next generation sequencing (NGS) in diagnosed GT patients.
Methods: A cohort of 5 patients with clinical symptoms of GT were enrolled for molecular genetic analysis by NGS. Sample DNA was amplified using Ampliseq primer panel, and libraries were prepared following the manufacturer´s Ion Ampliseq Library Preparation protocol. Individual samples were barcoded, pooled, templated, and sequenced on the Ion Torrent Proton Sequencer.Raw sequencing reads were quality and adaptor trimmed by Ion Torrent Suite and then aligned to the hg19 reference sequence.
Results: We identified pathogenic mutations from all the 5 patients, including homozygous mutations in ITGA2B gene in 2 patients (p.Q778P; p.L1020L). Compound heterozygous mutations were identified in 3 patients, 2 patients with ITGA2B:p.Q778P and ITGA2B:p.R584X, and 1 patient with ITGA2B:p.R584X and ITGB3:p.R662H. The Q778P, R584X and L1020L mutations of ITGA2B gene were missense, nonsense and splicing mutation, respectively. Mutations in *ITGB3* p.R662H was novel missense mutation that had never been reported.
Conclusions: NGS technology may be an useful method to detect the missense, nonsense and splicing mutations in GT patients. NGS technology is systematic and efficient, and can provide a convenient method for clinical diagnosis and scientific research. Novel mutation of *ITGB3* gene found in GT patients need to be further studied.

PB 743 | Refined Detection and Characterization of Delta Storage Pool Disorders: A Cohort Study on Pediatric Patients

G. Manukjan[1], J. Eilenberger[1,2], O. Andres[3], C. Schambeck[4], S. Eber[2], H. Schulze[1]

[1]*University Hospital Würzburg, Experimental Biomedicine, Würzburg, Germany,* [2]*Pediatrics Practice, Munich, Germany,* [3]*University Hospital Würzburg, Pediatric Clinic, Würzburg, Germany,* [4]*Haemostasikum, Munich, Germany*

Background: Delta storage pool disorders (SPD) remain frequently undetected due to moderate bleeding symptoms and insensitive detection methods. Since the cause of acquired and inherited delta-SPDs can be either a dense granule uptake or release defect it is of high interest to readily discriminate subgroups for precise diagnosis and therapy.
Aims: We aimed to classify a cohort of pediatric patients with unspecified bleeding disorder by delta-SPD characteristics and to prove reliability of our kinetic mepacrine assay.
Methods: We included 51 patients with defective ADP/ATP release as well as aggregation and a mild to moderate bleeding diathesis according to the ISTH-BAT bleeding score without differential diagnosis and prior to drug treatment. 46 patients declared a positive bleeding family history, indicating an inherited cause. We developed a whole-blood-based flow cytometric kinetic assay, measuring mepacrine uptake in platelet dense granules and agonist-induced mepacrine release over 5 minutes.
Results: We found a positive correlation between mepacrine release and ADP/ATP release, which was overall significantly lower in the patient cohort compared to healthy controls. 12 patients showed a significantly reduced CD63 exposure after stimulation, measured by flow cytometry. However, this could not be correlated to mepacrine release defects, excluding CD63 as a reliable dense granule marker. Patients could be classified into following groups: inconspicuous (16), uptake defect (7), release defect (10), or a combined defect (11). Noticeably, patients with a selective release defect showed a higher ISTH-BAT bleeding score compared to other subgroups.
Conclusions: Our data demonstrate that implementation of a kinetic mepacrine assay as sensitive and cost-effective diagnostic tool helps to detect unclassified SPD and allows discrimination of relevant subgroups. Since platelet activation measured by flow cytometry correlated well with aggregometry, the underlying defect can be confirmed as granule-based.

PB 744 | Multiplex PCR and Cycle Sequencing for Detection of Mutations in *ACTN1*, *TUBB1* and *ANKRD 26*

L. Dai[1], J. Cutler[2], M. Mitchell[2]

[1]*St Thomas' Hospital, London, United Kingdom,* [2]*Viapath Analytics at Guy's & St. Thomas' Hospitals, London, United Kingdom*

Background: Genetic investigation of patients with inherited thrombocytopenia involves screening for mutations in multiple (>20) genes including *ACTN1*, *TUBB1* and *ANKRD 26*. This list of genes is likely to become even longer as the causative mutation remains unaccounted for in ~ 50% of patients. Conventional methods to screen for mutations in multiple genes are tedious and time-consuming.
Aims: To improve efficiency of analysis, we have developed a multiple gene screening method using multiplex PCR and universal primer tags coupled with cycle sequencing.
Methods: In an assay system for screening of three genes *ACTN1*, *TUBB1* and *ANKRD 26*, 18 amplicons were designed to cover 21 exons of *ACTN1*. These amplicons were divided into 2 sets of multiplex PCR, each containing 9 primer pairs. All the primers were tagged with a series of 9 pairs of different universal primers. To analyze *TUBB1* and *ANKRD 26*, the third set of multiplex PCR was designed to contain 3 amplicons for 4 exons of *TUBB1* and 1 amplicon for the 5' UTR of *ANKRD 26*, and these primers were also tagged with the universal primers used in the sets 1 and 2. Following multiplex PCR, cycle sequencing was performed using the universal primer tags to acquire DNA sequences.
Results: The developed method was evaluated in screening 8 unrelated patients with thrombocytopenia. 8 mutations were identified,

including 2 novel mutations in *ACTN1* (p.Ala135Ser and p.Gln533Leu), 2 novel mutations in *TUBB1* (p.Leu253Val and p.Gly235Alafs*2), and 4 mutation in the regulatory region of *ANKRD 26* (c.-128G>C in one patient, c.-134G>A in one patient, and c.-140 C >G in two patients).

Conclusions: Multiplex PCR simplifies the template preparation for DNA sequencing, and incorporation of universal primer tags to the specific primers further speeds up subsequent cycle sequencing processes. The developed method can easily be expanded to include more genes, and provides an efficient approach to analysis of the multiple genes involving in inherited thrombocytopenia.

PB 745 | Delta Storage Pool Deficiency in a Patient with a R216Q Mutation of GATA1

M. Blaauwgeers[1], I. van Asten[2], A. Huisman[2], S. Korporaal[2], E. Beckers[3], M. Coppens[4], J. Eikenboom[5], M. Kruip[6], M. Nijziel[7], R. Tamminga[8], R. Urbanus[2], R. Schutgens[1]

[1]University Medical Center Utrecht, Van Creveldkliniek, Utrecht, The Netherlands, [2]University Medical Center Utrecht, Utrecht, The Netherlands, [3]Maastricht University Medical Center, Maastricht, The Netherlands, [4]Academic Medical Center, University of Amsterdam, Amsterdam, The Netherlands, [5]Leiden University Medical Center, Leiden, The Netherlands, [6]Erasmus Medical Center, Rotterdam, The Netherlands, [7]Radboud University Medical Center, Nijmegen, The Netherlands, [8]University Medical Center Groningen, Groningen, The Netherlands

Background: The transcription factor GATA1 is fundamental in the differentiation of hematopoietic progenitor cells to platelets and red blood cells. Several GATA1 mutations have been linked to human diseases , including X-linked thrombocytopenia with thalassemia (XLTT). XLTT is caused by a missense mutation (R216Q) and is characterized by thrombocytopenia, abnormal platelet structure and hemolytic anemia resembling beta-thalassemia. Delta storage pool deficiency (δ-SPD) has been reported in one of eight patients with XLTT, but it remains uncertain whether δ-SPD is a pathological feature of this specific GATA1 mutation.

Aims: To study dense granules in platelets of a patient with the R216Q mutation of GATA1.

Methods: -

Results: The patient is a 46 year old male with a lifelong history of bleeding (ISTH-BAT score 16), but normal aggregation tests. Informed consent was obtained for blood collection to perform several diagnostic tests to screen for δ-SPD. Platelet ADP content was measured in platelet lysates using bioluminescence and revealed a platelet ADP content of 0,8 µmol/10^{11} platelets (ref range 1,7-3,8 µmol/10^{11} platelets) on repeated measurements. Mepacrine, an acridine derivative that binds to adenine nucleotides in dense granules and emits green fluorescence, was used to determine dense granule content, by measuring mepacrine uptake in the FITC spectrum of the flow cytometer. Mepacrine uptake was decreased (< 2.5th percentile of normal) compared with healthy platelets. Whole mount electron microscopy (EM) was performed to visualize and quantify dense granule numbers and showed near absence of dense granules.

Conclusions: The decreased platelet ADP content, lowered mepacrine uptake and the virtual absence of dense granules on EM are consistent with the diagnosis of δ-SPD. Hence, this study confirms the presence of δ-SPD in another patient with the R216Q mutation of GATA1. Further studies are required to determine the precise role of the R216Q mutation in the defective formation of dense granules.

PB 746 | Genetic Heterogeneity in Familiar Macrothrombocytopenia with Decreased Expression of GpIIbIIIa

C. Lau[1,2], J. Oliveira[2,3], M. Sampaio[2,4], A. Gonçalves[2,3], M. Pereira[2,4], M. Gonçalves[1,2], E. Cruz[2,4], R. Santos[2,3], M. Lima[1,2], S. Morais[2,4]

[1]Centro Hospitalar do Porto (CHP), Laboratório de Citometria, Serviço de Hematologia Clínica, Porto, Portugal, [2]Unidade Multidisciplinar de Investigação Biomédica, Instituto de Ciências Biomédicas Abel Salazar (UMIB/ICBAS/UP), Porto, Portugal, [3]Centro Hospitalar do Porto (CHP), Unidade de Genética Molecular, Centro de Genética Médica Dr. Jacinto Magalhães (CGMJM), Porto, Portugal, [4]Centro Hospitalar do Porto (CHP), Setor de Trombose e Hemostase, Serviço de Hematologia Clínica, Porto, Portugal

Background: Congenital autosomal dominant macrothrombocytopenia (AD-MT) associated with decreased expression of GpIIbIIIa, although rare, represents the main congenital macrothrombocytopenia in our centre. Gain of function mutations in ITGA2B or ITGB3 with constitutive GpIIbIIIa activation and impaired platelet (PLT) maturation have been described in these cases.

Aims: Characterization of eight Portuguese families with macrothrombocytopenia and decreased expression of GpIIbIIIa.

Methods: Clinical and laboratory evaluation of 27 individuals from eight unrelated families with AD-MT and decreased GpIIbIIIa expression. Laboratory studies: PLT counts (impedance/flow cytometry), mean PLT volume (MPV) and morphology, PLT occlusion time, PLT aggregation and ATP release studies, antiPLT antibodies, PLT glycoprotein expression (CD41a/GpIIbIIIa, CD42b/GpIb and CD61) by flow cytometry, PLT electron microscopy and genetic analysis of ITGA2B and ITGB3 genes.

Results: AD inheritance pattern. Absent to moderate bleeding. Moderate thrombocytopenia with increased MPV. Normal to slightly increased PLT occlusion times. Decreased ADP and collagen-induced PLT aggregation, normal ristocetin-induced PLT agglutination. Decreased levels of CD41a/GpIIbIIIa (41-65%) and CD61/GpIIIa (48-77%) and increased CD42b/GpIb (113-225%) expression. Heterozygous variants in ITGA2B (n=3) and ITGB3 (n=2) were identified in six families. Two variants were previously reported in association with AD-MT. Three are novel and classified as pathogenic based on their absence in variant databases, bioinformatic and segregation analysis. The genetic study of two families is still being carried-out.

Conclusions: Macrothrombocytopenia with decreased expression of GpIIbIIIa presents with wide clinical spectrum and needs to be identified in order to avoid misdiagnosis. Our results reveal high genetic heterogeneity in our cohort and expand the mutational profile of AD-MT.

PB 747 | Pseudodominance in a Family with Bernard-Soulier Syndrome due to a Homozygous Variant in the Platelet Glycoprotein IX (GP9) Gene

C. Lau[1,2], J. Oliveira[2,3], A. Gonçalves[2,3], M. Gonçalves[1,2], M. Pereira[2,4], E. Cruz[2,4], R. Santos[2,3], M. Lima[1,2], S. Morais[2,4]

[1]Centro Hospitalar do Porto (CHP), Laboratório de Citometria, Serviço de Hematologia Clínica, Porto, Portugal, [2]Unidade Multidisciplinar de Investigação Biomédica, Instituto de Ciências Biomédicas Abel Salazar (UMIB/ICBAS/UP), Porto, Portugal, [3]Centro Hospitalar do Porto (CHP), Unidade de Genética Molecular, Centro de Genética Médica Dr. Jacinto Magalhães (CGMJM), Porto, Portugal, [4]Centro Hospitalar do Porto (CHP), Setor de Trombose e Hemostase, Serviço de Hematologia Clínica, Porto, Portugal

Background: Bernard-Soulier syndrome (BSS) is a rare platelet (PLT) disorder due to a defect of the GPIb/IX/V (which binds to von Willebrand factor), characterized by mucocutaneous bleeding, thrombocytopenia, giant platelets and impaired ristocetin-induced agglutination. Mutations in the GP1BA, GP1BB and GP9 genes have been described.

Aims: To describe the clinical and laboratory features of a family with BSS, with an apparent autosomal dominant (AD) pattern (Figure 1).

Methods: Platelet counts (impedance/flow cytometry), mean PLT volume (MPV), morphology, occlusion time, aggregometry (ADP/collagen/ristocetin) and flow cytometry (CD42a/GpIX, CD42b/GPIb, CD41a/GPIIbIIIa). Genetic study was done in patient I.2 using a panel for massive parallel sequencing (394 loci). Variant filtering was restricted to exonic regions and splice-sites and with minor allelic frequency below 1%. Confirmation and screening of the disease-causing variant was done by Sanger sequencing.

Results: Moderate bleeding, thrombocytopenia, giant PLT, increased MPV (>20fL) and PLT occlusion time, impaired ristocetin-induced agglutination, normal ADP/collagen-induced aggregation, and reduced expression of CD42b/GPIb (6.1-9.6%) and CD42a/GPIX (6.8-8.5%). Among the filtered-in variants a homozygous single nucleotide change (NM_000174.4:c.182A>G) was identified in exon 3 of GP9, in patient I.2. This variant causes a missense substitution (p.Asn61Ser) previously reported as pathogenic (Wright,1993 - PMID:8481514; ClinVar), associated with BSS type C. It was also found in homozygosity in the patient's affected daughters, whereas asymptomatic individuals I.1, III.1 and III.2 were found to be heterozygous for this variant.

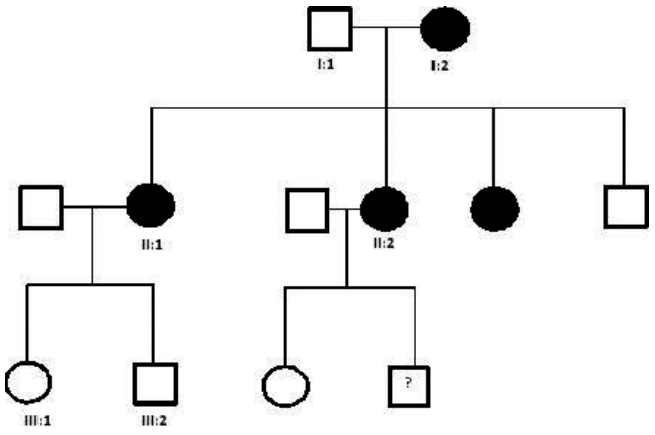

FIGURE 1

Conclusions: This is the first report of pseudodominant BSS in a family where transmission of a recessive disease mimics an AD inheritance. BSS is a rare entity (estimated prevalence of 1/1000000 live births), making this pedigree all the more interesting for lack of declared consanguinity.

PB 748 | Highly Significant Bleeding Diathesis in Patients with Platelet Dysfunction due to a Novel Mutation in *RASGRP2*, Encoding CalDAG-GEFI (p.Gly305Asp)

E. Bermejo[1], M.F. Alberto[1], P. David S.[2], P. Nurden[3], A. Sanchez Luceros[1], A.T. Nurden[3], W. Bergmeier[2]

[1]Hematological Research Institute of the National Academy of Medicine of Buenos Aires, Hemostasis and Thrombosis Department, Ciudad Autónoma de Buenos Aires, Argentina, [2]University of North Carolina at Chapel Hill, Department of Biochemistry and Biophysics & McAllister Heart Institute, Chapel Hill, NC, United States, [3]Institut Hospitalo -Universitaire (IHU) LIRYC PTIB Hôpital Xavier Arnozan, Pessac, France

Background: Mutations affecting RASGRP2, the gene encoding the Rap GTPase activator, CalDAG-GEFI, give rise to a novel, and rare, group of platelet signal transduction abnormalities. We here report platelet studies of a novel variant, CalDAG-GEFI(p.Gly305Asp), previously identified in an Argentinian pedigree.

Aims: To fully characterize the platelet function defect and to describe the therapeutic approach for the treatment of hemorrhage in the two siblings (P1, P2) affected in this consanguineous family.

Methods: Flow cytometry was used to quantify platelet adhesion receptor expression, and to measure integrin activation (fibrinogen binding) and granule secretion (surface expression of CD62P and CD63) in the patients' and control platelets activated or not with classic agonists and PMA. Platelet aggregation was measured by lumi-aggregometry. Thromboelastometry (ROTEM®) and Thromboelastogram [TEG®] were used to measure platelet procoagulant activity. Western blotting procedures were used to detect CalDAG-GEFI.

Results: Two brothers (P1 and P2) have a lifelong history of bleeding with severe epistaxis successfully treated with rFVIIa. Other bleedings include hemorrhage from minor wounds. Platelet counts were normal, as was αIIbβ3 and GPIb expression. Fibrinogen binding, granule release, and the platelet aggregation response were significantly impaired with ADP or collagen but not PMA-activated platelets. ROTEM and TEG were normal, suggesting intact plasma coagulation, residual αIIbβ3 outside-in signaling and platelet pro-coagulant activity. CalDAG-GEFI protein expression was markedly reduced but not absent. Homology modeling places the Gly305Asp substitution at the GEF-Rap1 interface, suggesting that the mutant protein has very limited catalytic activity.

Conclusions: We characterize a new loss-of-function mutation in RASGRP2 causing impaired platelet adhesive function and highly significant bleeding in humans.

PB 749 | Positive Impact of Social Media as a Support Group for Females with Glanzmann Thrombasthenia in Saudi Arabia - A Mother's Initiative

M. Saleh[1], T. Owaidah[2], A. Aljefri[3], H. Alzahrani[4], S. Parween[3], R. Barmada[3], M. Zulfiqar[3], S. Jose[5], V. Mohammed[3]

[1]King Faisal Specialist Hospital & Research Centre, Pediatric Hematology / Oncology, Riyadh, Saudi Arabia, [2]King Faisal Specialist Hospital & Research Centre, Pathology and Laboratory Medicine, Riyadh, Saudi Arabia, [3]King Faisal Specialist Hospital & Research Centre, Pediatric Hematology & Oncology, Riyadh, Saudi Arabia, [4]King Faisal Specialist Hospital & Research Centre, Oncology Cancer Department, Riyadh, Saudi Arabia, [5]King Faisal Specialist Hospital & Research Centre, Pediatric Nursing Department, Riyadh, Saudi Arabia

Background: Glanzmann Thrombasthenia (GT) is a rare inherited platelet disorder with limited information available. Most common presentation of the disease is mucous membrane bleeding and menorrhagia a major bleeding manifestation in females, Hematology service at King Faisal Specialist Hospital and Research Centre, Riyadh, deals with several such female patients and their mother´s.

Aims: To assess use of social media as a support group providing medical and psychosocial support to families affected with GT.

Methods: WhatsApp group titled "Female GT Support Group" was created in January 2016 by a mother, with an intention to provide a portal for mothers like her to be able to discuss challenges unique to females with GT; for medical validation purposes a female hematologist was added. Mothers and patients learnt of the group from one another and started referring.

Results: Thirty participants comprising of patients and mothers were added within a year. Majority of discussions involved, heavy periods, nose and gingival bleeding, hormonal, oral contraception and iron supplement therapy, feasibility of transfusion. Mothers discussed post-marital concerns experienced particularly by women involving bleeding during antenatal period, pregnancy and methods of delivery. Women who bore children shared their experiences and information on how PGD can help in family planning. Information on Iron Nutrition, Dental care and first aid to stop bleeding was shared. Other concerns on how to cope with school absence were addressed.

Conclusions: They were psychologically relieved to learn that they are not alone and felt comfortable sharing their stories resulting in better understanding of disease spectrum from mild to severe; helping them remain calm avoiding immediate emergency room visits and had a positive perspective towards family planning. In our experience social media proved to be an effective support model, however, addition of a Gynecologist, Dentist and Geneticist will result in comprehensive information to families.

PB 750 | Five New Cases of Hermansky-Pudlak Syndrome: Identification of Novel Genetic Variants in *HPS4* and *HPS3* Associated to Relevant Clinical Complications

J.M. Bastida[1], J.R. Gonzalez-Porras[1], M.L. Lozano[2,3], M. del Rey[4], R. Benito[4], N. Bermejo[5], M. Karkukak[6], M. Trapero[7], K. Janusz[4], Y. Yucel[6], J.M. Hernandez-Sanchez[4], V. Palma-Barqueros[2], V. Vicente[2,3], J.M. Hernandez-Rivas[1,4], J. Rivera[2,3]

[1]Hospital Universitario Salamanca - IBSAL, Hematologia, Salamanca, Spain, [2]Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, IMIB-Arrixaca,, Murcia, Spain, [3]CB15/00055-CIBERER, Murcia, Spain, [4]IBSAL, IBMCC, CIC, Universidad de Salamanca-CSIC, Salamanca, Spain, [5]Hospital San Pedro de Alcantara, Hematologia, Cáceres, Spain, [6]Sakarya University Training and Research Hospital, Medical Genetic, Sakarya, Turkey, [7]Hospital Universitario Puerta de Hierro - IDIPHIM, Hepatology, Majadahonda, Spain

Background: Hermansky-Pudlak syndrome (HPS) is an inherited platelet disorder characterized by bleeding diathesis, oculocutaneous (OC) albinism and sometimes serious clinical complications. Heterogeneous clinical symptoms and a large numbers of possible genetic culprits (9 *HPS* genes, >118 exons) complicate unequivocal HPS diagnosis.

Aims: To assess the clinical and platelet phenotype in 5 patients with HPS suspicion and to identify their genetic defect by high-throughput sequencing (HTS).

Methods: We studied 5 patients from 3 families (2 Spanish, 1 Turkish) presenting with OC albinism. Clinical records were reviewed and bleeding scored with ISTH-BAT. Platelet phenotyping (only Spanish patients) included: platelet aggregation, GPs expression and granule secretion,^{14}C-serotonin uptake and whole mount electron microscopy. Patients DNAs were analyzed by HTS using a 71 gene panel (Lozano ML et al 2016).

Results: Clinical and laboratory findings in these patients are shown in Table 1. The Spanish patients (P1,P2,P5) showed impaired platelet aggregation to mild agonists and reduced platelet dense granules. In family 1 (F1), HTS identified a homozygous, potentially harmful, c.2054delC (p.Pro685Leu fs*17) variant in *HPS4*. One sister (P1) had Crohn´s disease and severe gastrointestinal (GI) bleeding. This variant had been reported in a 46yr Asian patient with pulmonary fibrosis. *A* novel missense homozygous *HPS4* variant, c.272T>C (p.Leu91Pro), was found in two Turkish siblings (F2). One had severe GI bleeding requiring colectomy (P4) and the other developed pulmonary fibrosis. Patient 5, suffering from mild GI bleeding, bears a heterozygous novel variant in *HPS3* (c.2464C>T, p.Arg822X) and, most likely, an additional unrevealed mutation.

Conclusions: HTS facilitates genetic confirmation of HPS diagnosis, and may help investigating phenotype-genotype relationships in HPS. The novel p.Leu91Pro variant in *HPS4* associates with severe clinical phenotype.

Funding: GRS 1370/A/16; ISCIII & Feder (PI14/01956), CIberer CB15/00055, SETH

PB 751 | Quality of Life Is Reduced in Patients with (Suspected) Congenital Platelet Function Disorders

M. Blaauwgeers[1], K. Fischer[1], I. van Asten[2], S. Korporaal[2], A. Huisman[2], M. Kruip[3], M. Coppens[4], M. Nijziel[5], J. Eikenboom[6], R. Tamminga[7], E. Beckers[8], R. Urbanus[2], R. Schutgens[1]

[1]University Medical Center Utrecht, Van Creveldkliniek, Utrecht, The Netherlands, [2]University Medical Center Utrecht, Utrecht, The Netherlands, [3]Erasmus Medical Center, Rotterdam, The Netherlands, [4]Academic Medical Center, University of Amsterdam, Amsterdam, The Netherlands, [5]Radboud University Medical Center, Nijmegen, The Netherlands, [6]Leiden University Medical Center, Leiden, The Netherlands, [7]University Medical Center Groningen, Groningen, The Netherlands, [8]Maastricht University Medical Center, Maastricht, The Netherlands

Background: Platelet function disorders (PFDs) are rare bleeding disorders, characterized by mucocutaneous bleeding and prolonged bleeding after surgery or childbirth. Repeated bleeds throughout life can have a significant effect on health related quality of life (HR-QoL).

Aims: To assess how HR-QoL is affected by PFDs as compared to healthy controls.

Methods: HR-QoL is determined within a nationwide cross-sectional study in the Netherlands (‚Thrombocytopathy in the Netherlands' (TiN)), where adult patients with an increased bleeding tendency, suspected for having a PFD, are prospectively included. HR-QoL is assessed using the Short Form (SF)-36 survey, including 8 domain scores ranging from 0 to 100 (optimal). Bleeding severity is evaluated using the ISTH Bleeding Assessment Tool (BAT), resulting in a bleeding score (BS, range 0-48 for men, 0-56 for women; 0 optimal). For this interim analysis we used data of all patients included in the TiN-study in 2016. T-tests are used to compare SF36 domain scores to the general Dutch population scores and univariable linear regression analysis to assess the association between BS and HR-QoL.

Results: In this interim analysis, 83 patients were included, of whom 23% male, median age 43 (range 18-76) years. The median BS was 11 (IQR 7-15). Compared to the general population, patients with a (suspected) PFD showed significantly lower (p < 0,001) scores in the domains of role limitations due to physical functioning, bodily pain, general health perception, vitality and social functioning.

Patients with more severe bleedings had a lower HR-QoL in several domains as compared to patients with less severe bleedings.

TABLE 1 Univariable regression analysis for the association between bleeding score and SF36 domains. * p-value < 0,05]

	β	95% CI	p-value
Physical functioning (PF)	-1,852	-2,636 to -1,068	<0,001 *
Role limitations due to physical functioning (RP)	-2,456	-4,130 to -0,782	0,005 *
Bodily pain (BP)	-1,465	-2,465 to -0,466	0,005 *
General health perception (GH)	-1,243	-2,224 to -0,261	0,014 *
Vitality (VT)	0,064	-0,782 to 0,910	0,880
Social functioning (SF)	-2,322	-2,322 to -0,316	0,010 *
Role limitations due to emotional problems (RE)	-1,893	-1,893 to 0,855	0,454
Mental health (MH)	-0,307	-1,009 to 0,396	0,387

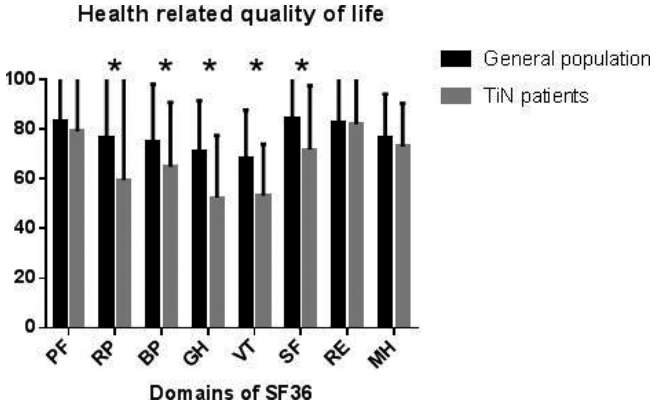

FIGURE 1 Health related quality of life for the domains of SF36. *: p-value < 0,001

Conclusions: We demonstrate a lower HR-QoL in patients with a (suspected) PFD compared with the general population and an inversed association between HR-QoL and bleeding phenotype, mainly in the physical domains. Final analyses will be performed in the full TiN study population (estimated 150 patients), including multivariable analyses adjusted for other determinants of HR-QoL.

PB 752 | The Diagnostic Performance of Impedance Aggregometry and Platelet Function Analyzer Regarding Platelet Function Disorders as Detected by Light Transmission Aggregometry

F. Moenen[1], M. Vries[2], H. ten Cate[2], P. Verhezen[3], R. Wetzels[3], E. Beckers[1], Y. Henskens[3]

[1]Maastricht University Medical Centre+, Department of Hematology, Maastricht, The Netherlands, [2]Maastricht University Medical Centre+, Department of Biochemistry, Maastricht, The Netherlands, [3]Maastricht University Medical Centre+, Central Diagnostic Laboratory, Maastricht, The Netherlands

Background: Light transmission aggregation (LTA) is the gold standard for the diagnosis of platelet function disorders (PFDs). Due to its time-consuming and variable (pre)analytical methods, the LTA is subjected to specialized laboratories. Whole blood impedance aggregometry (Multiplate) and platelet function analyzer (PFA) may be used as rapid screening tools to exclude PFDs.

Aims: To assess the diagnostic performance of Multiplate and PFA regarding the detection of PFDs, using the LTA as reference test.

Methods: Adults from three observational studies investigating bleeding symptoms were included in this analysis: preoperative patients with and without bleeding symptoms; patients referred to the hematologist for bleeding evaluation and patients with a known bleeding disorder of any kind. Patients using medication interfering with hemostasis, with platelet count < $100x10^9$/L and hematocrit < 0.25 L/L were excluded. A PFD was defined as ≥2 abnormal LTA curves. Abnormal test results on Multiplate and PFA were compared to the gold standard LTA for platelet function disorder. Informed consent was obtained and the medical ethical committee approved the studies.

Results: A total of 415 patients were included. In preoperative patients with and without bleeding symptoms and in patients referred to the hematologist for bleeding evaluation, the sensitivity for the detection of a PFD was low (0-36%) and specificity was high (84-98%) for both PFA and Multiplate. In patients with a known bleeding disorder, sensitivity for the detection of a platelet function disorder was 100%, with a specificity of 73-100% (see table 1 and 2).

Conclusions: In preoperative patients with and without bleeding symptoms, and in patients referred for bleeding disorders, the Multiplate and PFA cannot be used as a screening test to exclude PFDs. However, in patients with a known bleeding disorder, the Multiplate and PFA performed reasonably well, which might indicate that in more severe bleeders these assays could be used to screen for PFDs.

TABLE 1 Diagnostic performance of the Multiplate (AA, TRAP, ADP, COL) for the detection of PFDs diagnosed by the LTA (AA, TRAP, ADP, COL, EPI, RIST)

Patient population	Multiplate ≥1 agonists abnormal	LTA ≥2 agonists abnormal	Sensitivity % (95%CI)	Specificity % (95%CI)	PPV % (95%CI)	NPV % (95%CI)
preoperative patients without bleeding symptoms n = 91	2	6	0 (0-26)	98 (98-99.5)	0 (0-79)	93 (93-95)

PB 753 | Evaluation of the Platelet Function in Different Inherited Thrombocytopenias. Correlation of Platelet Response Measured by Flow Cytometry with Bleeding Scores and Clinical Phenotypes

M.A. Alberelli[1], A. Savoia[2], E. De Candia[3]

[1]*Fondazione Policlinico Universitario A. Gemelli, Catholic University of Rome, Area of Haematology/Oncology, Rome, Italy,* [2]*Università Degli Studi di Triest-IRCCS Burlo Garofolo, Dipartimento di Scienze Mediche, Chirurgiche e della Salute, Trieste, Italy,* [3]*Fondazione Policlinico Universitario A. Gemelli, Catholic University School of Medicine, Area of Haematology/Oncology, Rome, Italy*

Background: Inherited thrombocytopenias (IT) are a heterogeneous group of exceedingly rare conditions characterized by low platelet counts. IT patients differ in their tendency to bleed despite similarly low platelet counts, therefore abnormal platelet function is likely to contribute to the bleeding. Whether platelet dysfunction coexists in ITs, worsening the bleeding risk, is unknown in most of them.

Aims: Our aim was to investigate platelet function in patients with different ITs using the flow cytometry, i.e. the sole platelet function assay that can distinguish between the effects of thrombocytopenia and the effects of abnormal platelet function. The platelet function was correlated with platelet count and a bleeding score.

Methods: Flow cytometric analysis of platelet activation was performed using the PE-conjugated P-selectin antibody and the FITC-conjugated PAC-1 antibody recognizing the activated integrin αIIbβ3 complex, together with Pe-Cy5-conjugated anti-CD42b to identify platelet population in whole blood samples. Platelets were stimulated with ADP 4-10 mM or PAR1-AP 10-25 mM and the binding of antibodies was analyzed by flow cytometry. ISTH-BAT and WHO bleeding scores were used to assess the bleeding risk of the patients.

Results: Thirteen patients with different inherited thrombocytopenias, having both great/giant platelets (Gray Platelet Syndrome, MYH9-RD disorders, Bernard-Soulier biallelic and mono allelic) and small platelets (Wiskott Aldrich syndrome) and different degrees of thrombocytopenia were studied in our center (Fig.1). Interestingly, those patients with higher bleeding scores had also a worse platelet activation pattern, independently of platelet count.

ID PATIENT	DIAGNOSIS	PLT count (x 10^3/ µL)/ MPV (fl)	WHO/ISTH-BAT Score	P-Selectin (MFI % ctrls)		PAC-1 (MFI % ctrls)

FIGURE 1 Clinical and laboratory characteristics of IT patients

Conclusions: ITs are very rare diseases and studies on platelet function have scantly been performed. Although preliminary results are shown here, the correlation between the clinical phenotype and the platelet activation pattern suggests interesting application of this method for the identification of patients at higher risk of bleeding.

PB 754 | Management of a Patient with Glanzmann Thrombasthenia during a Coronary Artery Bypass Graft Surgery: A Case Study

M. Kurdi[1], A. Ankri[1], J. Amour[2], C. Brumpt[3], J. Delort[4], G. Lebreton[5], L. Croisille[6], R. D'orion[7], I. Martin-Toutain[8]

[1]*University Hospital Pitié Salpêtrière, Paris, France,* [2]*University Hospital Pitié Salpêtrière, Anesthesie, Paris, France,* [3]*University Hospital Lariboisière, Laboratory of Hematology, Paris, France,* [4]*University Hospital Pitié Salpêtrière, EFS, Paris, France,* [5]*University Hospital Pitié Salpêtrière, Cardiac Surgery, Paris, France,* [6]*University Hospital Henry Mondor, EFS, Créteil, France,* [7]*University Hospital Le Kremlin Bicêtre, Hemophilia Refernce Center, Le Kremlin Bicêtre, France,* [8]*University Hospital Pitié Salpêtrière, Laboratory of Hematology, Paris, France*

Background: Glanzmann thrombasthenia (GT) due to mutations that affect the αIIbβ3 integrin. Platelets (PLT) have been suggested to play a role in the early development of atherosclerosis. As one test of this hypothesis that GT may have a protective effect from atherothrombosis.

Aims: We report a Coronary Artery Bypass Graft Surgery (CABG) and right Carotid endarterectomy (CEA) in a 57-year-old Tunisian man with GT type I disease (no platelet αIIbβ3 expression).

Methods: The patient showed typical signs of GT with no PLT aggregation in response to physiological agonists. He presented a low PLT count (80 G/l). GT was diagnosed at 5 years old; He suffered from repeated epistaxis and gingivorrhagia but never required transfusion. He received blood transfusions only for his circumcision at 11 years old. He presented recently unstable angina, atrial fibrillation and right carotid atherosclerosis which first treated by Aspirin. These lesions were deemed inaccessible to percutaneous therapy. Therefore, CABG and CEA were recommended.

Results: A multidisciplinary team was established to optimize perioperative management. The research of anti-HLA and anti-integrin αIIbβ3 allo-antibodies was negative.

Prophylactic HLA-matched PLT administration was continued before and through the immediate postoperative period and no bleeding complications occurred. PLT transfusion recovery was confirmed by the percentage of αIIbβ3 expression on PLT surface (expression of αIIbβ3 increased from 0 to 55%). The PLT function analysis by aggregation and function tests was not normalized.

The patient was discharged under a treatment of VKA in the reason of his atrial fibrillation chads2.

His screening tests for risk factors for thrombosis revealed presence of FII G20210A mutation.

Conclusions: This observation suggests that atherosclerosis can develop despite the lack of αIIbβ3 integrin and that cautious administration of aspirin or VKA is possible in patients with congenital hemostatic disorder in event of severe thrombotic complication.

PB 755 | Compound Heterozygosity for Mutations in ITGA2B Including a Novel p.Cys198Ser in Glanzmann Thrombasthenia

E. Hashimoto[1], S. Kunishima[2], Y. Takagi[1,3], S. Suzuki[1], N. Kawamura[1], A. Makiyama[1], H. Sakane[1], A. Fujioka[1], T. Uehara[4], S. Tamura[1], A. Takagi[1], T. Kojima[1]

[1]Nagoya University Graduate School of Medicine, Nagoya, Japan, [2]Clinical Research Center of Nagoya Medical Center, Nagoya, Japan, [3]Japan Society for the Promotion of Science, Tokyo, Japan, [4]Kameda Medical Center, Kamogawa, Japan

Background: Glanzmann thrombasthenia (GT) is a rare autosomal recessive disorder of platelet aggregation caused by quantitative or qualitative deficiencies of the αIIbβ3. The proband was a 2-year-old Japanese boy, whose platelet count was 380,000/μL and Ivy bleeding time was prolonged for more than 20 min. The expression level of αIIbβ3 on his platelets was 5.2% of normal.

Aims: To elucidate the genetic basis of the type II GT, we analyzed *ITGA2B* and *ITGB3* for genomic DNAs from the patient and his parents.

Methods: We obtained genomic DNAs from peripheral blood leukocytes and analyzed *ITGA2B* and *ITGB3* by PCR-based direct sequencing for all exons including exon/intron boundaries. Transient expression of *ITGA2B* and *ITGB3* constructs in 293T cells followed by flow cytometry and Western blotting (WB) were also performed. The research was approved by the Institutional Review Boards.

Results: We identified a novel missense mutation in *ITGA2B* exon 5 (c.593G>C; p.C198S) and a previously reported mutation in exon 23 (c.2333A>C; p.Q778P). Since his farther had the former mutation and his mother had the latter one, the patient was expected to be a compound heterozygote for both mutations. No mutation was found in his *ITGB3*. In the expression experiment using 293T cells, the surface αIIbβ3 expression determined by flow cytometry was greatly reduced in the p.C198S compared to the wild type, and moderately reduced in the p.Q778P. This suggested that the p.C198S was a type I mutation, while the p.Q778P was a type II mutation. On the other hand, WB analysis showed that both β3s were reduced as compared with the wild type, and αIIb of the p.Q778P was reduced, but not of the p.C198S. Both *ITGA2B* mutants may affect assembly and stability of αIIbβ3 and lead to decreased surface expression, but further study is needed to clarify the precise molecular mechanisms disturbed surface expression of type II GT.

Conclusions: Genetic analysis of a type II GT patient revealed compound heterozygosity for novel and previously reported *ITGA2B* mutations.

PB 756 | Quantitative Evaluation of Bleeding due to Platelet Disorders Associated with Dense Granule Deficiency and/or Impaired Aggregation Responses

J. Iyer[1], M. Badin[1], J. Brunet[1], L. Graf[2], G. Pare[1], A.D. Paterson[3], G.E. Rivard[4], C.P.M. Hayward[1,5,6]

[1]McMaster University, Pathology and Molecular Medicine, Hamilton, Canada, [2]Centre for Laboratory Medicine and Hemophilia and Hemostasis Centre, St. Gallen, Switzerland, [3]The Hospital for Sick Children, Toronto, Canada, [4]Centre Hospitalier Universitaire Sainte Justine, Montreal, Canada, [5]McMaster University, Department of Medicine, Hamilton, Canada, [6]McMaster University, Hamilton Regional Laboratory Medicine Program, Hamilton, Canada

Background: Inherited platelet disorders (IPD) that cause dense granule deficiency (DGD) and/or impaired platelet aggregation (IPA) responses are a heterogenous group of uncharacterized bleeding disorders whose bleeding problems have rarely been quantified, except by bleeding scores.

Aims: Our goal was to quantify bleeding risks for these IPD.

Methods: Bleeding histories were evaluated for subjects recruited to a study on IPD (n=32 with IPD from 8 families and 10 sporadic cases; 17 unaffected relatives from IPD families; 60 general population controls) using: (i) the International Society for Thrombosis and Haemostasis bleeding assessment tool (ISTH-BAT) to determine bleeding scores; and (ii) CHAT-P, a clinical history assessment tool (Haemophilia, in press) to gather information on bleeding and treatment responses and to estimate bleeding risks as odds ratio (OR) with 95% confidence intervals (CI) for IPD and control subjects.

Results: Subjects with IPD (n=28 IPA; n=6 DGD) had higher ISTH-BAT scores (median: 9, range: 0-18) than unaffected relatives (median: 1,

range: 0-6) and controls (median: 0, range: 0-6) (p< 0.01). Subjects with IPD had increased risks (OR, 95% CI, p value) for experiencing bleeding including: abnormal bruising (63, 16-241, p< 0.0001); prolonged nosebleeds (27, 7-108, p< 0.0001); excessive bleeding from injuries (14, 3-57, p< 0.0001) or surgery (17, 4-72, p< 0.0001); and menorrhagia (12, 3-53, p=0.0004). Subjects with IPD that had exposures to hemostatic challenges such as operations (27/32, 84.3%) had significantly higher bleeding scores (median: 11.5, range: 4-18) than those without (median: 8, range: 0-15) (p= 0.01) and a number of patients with IPD (6/14, 42%) had received treatments after diagnosis that were successful in preventing bleeding with surgeries and dental procedures.

Conclusions: IPD associated with DGD and/or IPA responses are mild bleeding disorders that significantly increase bleeding risks. ISTH-BAT scores for IPD are influenced by exposures to hemostatic challenges.

PB 757 | MYH9 Disorders Are the Most Common Cause of Macrothrombocytopenia in Australia: Importance of Mean Platelet Diameter Measurement and Döhle Body Detection for Improved Diagnosis

M.-C. Morel-Kopp[1,2], D. Rabbollini[1,2], Y. Chun[1], K. Fixter[1], S. Kunishima[3], S. Gabrielli[1,2], Q. Chen[1,2], W. Stevenson[1,2], P. Tan[4], K. Radhakrishnan[5], R. Bird[6], P. Ockleford[7], L.P. Chew[8], C. Ward[1,2]

[1]The University of Sydney, Northern Blood Research Centre - Kolling Institute, Sydney, Australia, [2]Royal North Shore Hospital, Department of Haematology and Transfusion Medicine, Sydney, Australia, [3]Nagoya Medical Center, Department of Advanced Diagnosis, Clinical Research Center, Nagoya, Japan, [4]Royal Perth Hospital, Haematology Department, Perth, Australia, [5]Monash Children's Hospital, Children's Cancer Centre, Melbourne, Australia, [6]Princess Alexandra Hospital, Haematology Department, Brisbane, Australia, [7]Auckland City Hospital, Haematology Department, Auckland, New Zealand, [8]Sarawak General Hospital, Clinical Research Malaysia, Sarawak, Malaysia

Background: Inherited macrothrombocytopenias (IMT) are rare and often misdiagnosed as immune thrombocytopenia (ITP) leading to unnecessary treatments including splenectomy. Giant platelets are suggestive of IMT rather than ITP, but are not detected by automated cell counters, which can underestimate mean platelet volume (MPV).

Aims: MYH9 disorders are characterised by macrothrombocytopenia and leukocyte inclusions which are often missed on blood films. They may also cause nephropathy, sensorineural hearing loss or cataract, with a strong correlation between genotype and phenotype, hence the importance of correct diagnosis.

Methods: We used Next-Generation Sequencing (NGS) to investigate a large cohort (N=121) of patients with lifelong thrombocytopenia not previously diagnosed with IMT.

Results: Variants of the *MYH9* gene, which encodes the non-muscle myosin heavy chain IIA (NMMIIA) were by far the most common with 10 rare benign variants (N=14), 3 variants of uncertain significance (VUS) (N=4) and 7 pathogenic variants (N=15) identified. NMMIIA immunofluorescent (IF) staining on blood film is the current diagnostic gold standard but not widely available. MPV values for subjects with MYH9 variants were not consistently elevated. In contrast, mean platelet diameter (MPD) derived from scanned blood films was clearly increased in IMT compared to ITP. When available, the blood films of patients with pathogenic mutations were evaluated. All demonstrated macrothrombocytopenia; however, inclusion bodies were not easily appreciated. NMMIIA-IF was performed in 4 cases; all demonstrated abnormal NMMIIA clustering, including 2 cases with a VUS.

Conclusions: From our cohort, MYH9 disorders are the commonest cause of IMT. MPDs are markedly and consistently increased in MYH9 disorders and useful for differential diagnosis. As neutrophil inclusions are often missed on stained blood films, NMMIIA-IF is critical for diagnosis which may also include MYH9 genotyping.

PB 758 | Hemorrhagic Diathesis in Four Patients with the Heterozygous Pro258Thr Mutation of the P2RY12 Gene

M. Blaauwgeers[1], I. van Asten[2], A. Huisman[2], S. Korporaal[2], E. Beckers[3], M. Coppens[4], J. Eikenboom[5], M. Kruip[6], M. Nijziel[7], R. Tamminga[8], R. Urbanus[2], R. Schutgens[1]

[1]University Medical Center Utrecht, Van Creveldkliniek, Utrecht, The Netherlands, [2]University Medical Center Utrecht, Utrecht, The Netherlands, [3]Maastricht University Medical Center, Maastricht, The Netherlands, [4]Academic Medical Center, University of Amsterdam, Amsterdam, The Netherlands, [5]Leiden University Medical Center, Leiden, The Netherlands, [6]Erasmus Medical Center, Rotterdam, The Netherlands, [7]Radboud University Medical Center, Nijmegen, The Netherlands, [8]University Medical Center Groningen, Groningen, The Netherlands

Background: The platelet ADP-receptor P2Y12 plays a crucial role in platelet activation and aggregation. Inherited defects of this receptor, caused by mutations in the P2RY12 gene, are classified as autosomal recessive disorders, implying that only homozygous mutations will affect the function of the P2Y12 receptor. However, a few patients with bleeding symptoms and defective aggregation in response to ADP have been reported to have heterozygous mutations.

Aims: To describe the phenotype and functional assays in four additional patients with a heterozygous mutation of P2RY12.

Methods: -

Results: Patients 1 and 2 are unrelated women, 22 and 32 years of age. Patients 3 and 4 are a father and daughter, age 62 and 30. Bleeding symptoms mainly include epistaxis, menorrhagia and prolonged bleeding after minor wounds. The platelet count and standard coagulation tests showed no abnormalities. All patients had an abnormal aggregation in response to ADP; patients 1,2 and 3 with light transmission aggregometry and patient 4 with flow cytometry. Platelet aggregation in response to collagen and arachidonic acid was normal. Genetic analysis identified a heterozygous missense mutation (Pro258Thr) in the P2RY12 gene in all patients.

Conclusions: The heterozygous Pro258Thr mutation in the P2RY12 gene results in bleeding symptoms and defects in ADP-activating signaling pathway by affecting the function of the ADP-receptor. It is

suggested that the Pro258 region of the P2Y12 molecule is important for receptor function and that the Pro258Thr mutation results in a dysfunctional variant of P2Y12 by altering the protein hydrophobicity, size and rotational mobility.

PB 759 | Nine-year Effective Management of an LAD III Patient with Conventional Pro-hemostatic and Immunological Treatment

P. Saultier[1,2], S. Szepetowski[1], C. Falaise[1,3], L. Vidal[2], M. Canault[2], V. Barlogis[1], M.-C. Alessi[2,3], H. Chambost[1,2]

[1]Department of Pediatric Hematology and Oncology, Timone Enfants Hospital, APHM and Aix Marseille Univ, Marseille, France, [2]Aix Marseille Univ, INSERM, INRA, NORT, Marseille, France, [3]APHM, CHU Timone, French Reference Center on Inherited Platelet Disorders, Marseille, France

Background: Leukocyte adhesion deficiency type III (LAD III) is a severe recessive autosomal condition characterized by a leukocyte adhesion deficiency and a Glanzmann-like bleeding tendency caused by *FERMT3* variants. The outcome is typically poor, due to life threatening infections and bleedings. Hematopoietic stem cell transplantation (HSCT) is a pivotal treatment, albeit associated with high treatment-related mortality. In 2011, our team reported a 33-month-old LAD III boy carrying a novel c.310-2A>C *FERMT3* variant.

Aims: The purpose of the study was to discuss the therapeutic management in LAD III.

Methods: A retrospective analysis of the patient's medical record was performed (follow-up time 9 years). A systematic analysis of all other reported cases of LAD III was performed, focusing on complications and treatments.

Results: Regarding infections, the patient had probable Pneumocystis jiroveci pneumonia at 5 months of age, treated with wide-spectrum antibiotic therapy and cotrimoxazole. An immunoglobulin (Ig) G deficiency was diagnosed and supplemented every 3 weeks. He has received prophylactic cotrimoxazole and itraconazole until 3.5 years of age and then cotrimoxazole only. Several major bleedings including hematuria and post-traumatic tongue bleed, were treated with a combination of recombinant factor VIIa (off-label use), tranexamic acid and platelet transfusion. In the literature, platelet transfusion was the main reported treatment. Overall, the patient was treated with conventional pro-hemostatic and immunological treatment and has not undergone HSCT, which was performed in 59% of LAD III patients reported in the literature.

Conclusions: The therapeutic management of this LAD III patient, excluding HSCT, led to favorable outcome at 9 years of age. Such discrepancy with the literature as regards therapeutic and prognosis issues highlights the need for international registries and cohort studies to identify prognostic factors that could guide the therapeutic strategy.

PB 760 | Assessment of the Severity of the Epistaxis by Epistaxis Severity Score in the Inherited Platelet Disorders

R. Messaoudi[1], M. Lahmer[2], D. Saidi[1], Z. Zouaoui[3], H. Touhami[1], M.A. Bekkadja[4], A. Arabi[4], N. Sidi-Mansour[5]

[1]University Hospital Oran, Department of Hematology, Oran, Algeria, [2]University Hospital Sidi-Bel-Abbès, Department of Epidemiology, Sidi, Algeria, [3]University Hospital Sidi-Bel-Abbès, Sidi, Algeria, [4]University Establishment Oran, Oran, Algeria, [5]University Hospital Constantine, Constantine, Algeria

Background: A nosebleed is bleeding from the nasal cavity, it can be the revealing symptom of inherited platelet disorders.

Aims: We found during our clinical practice difficulties in the assessment and quantification of an episode of epistaxis, in order to adapt the therapeutic strategy.

Methods: We applied the ESS score validated for patients with hereditary hemorrhagic telangiectasia to the inherited platelet disorders.

Results: 60 patients with inherited platelet disorders (TG 34, 18JBS, 8MH).The average age of our population is (21, 33 ± 12,61) years, the youngest had 11 months old and the oldest was 52 years. The results of the .The average severity score of epistaxis is in the moderate zone for the GT (5,34 ± 2,33) and Jean Bernard Soulier disease (4,93 ± 2,58) and in the minor area for May-Hégglin disease (3,22 ± 3,27).15 patients or 44,1% in the GT have moderate epistaxis and 11 patients or 32,3% have severe epistaxis. In JBS disease 7 patients or 38,8% have minor epistaxis and 7 patients 38,8% had severe epistaxis. In May-Hegglin disease 3 (37,50%) patients did not have epistaxis, 2 (25%) patients had a minor epistaxis and 2 patients with moderate epistaxis. The comparison test did not find any significant differences in the 3 platelet disorders on the ESS score (p = 0,540).

Conclusions: The ESS score is a clinical tool that quantifies epistaxis during the inherited platelet defects and thus makes the objective medical information. We await further studies of inherited platelet disorders with the introduction of ESS score in order to better assess the severity of the disease.

PB 762 | A Study of Comparison of Platelet Aggregation Response Obtained on Sysmex CS-2000i with Chrono-log Light Transmission Aggregometer

A. Abraham[1], S.C. Nair[2], T. Geevar[2], P. Tavkar[3], S. Singh[2], H.F. Margaret[2], R. V[2]

[1]Christian Medical College & Hospital, Department of Transfusion Medicine & Immunohematology, Vellore, India, [2]Christian Medical College& Hospital, Department of Transfusion Medicine & Immunohematology, Vellore, India, [3]Sysmex Corporation, Kobe, Japan

Background: Light transmission aggregometry (LTA) is considered as the gold standard for testing platelet function. However LTA is time consuming, technically challenging and affected by many pre analytical variables related to sample preparation and performed usually in

specialized laboratories only by experienced personnel who needs to be present till the end of testing. These challenges can be overcome by performing platelet aggregometry in an automated coagulometer that detects photo optical changes as the endpoint. We performed platelet aggregometry studies on carefully prepared platelet rich plasma (PRP).

Aims: To compare and correlate results of aggregometry obtained on automated coagulation analyser Sysmex CS-2000i (wavelength: 660 nm) with the current reference instrument Chrono-log light transmission aggregometer (wavelength: Infrared)

Methods: We performed platelet aggregometry studies on platelet rich plasma (PRP) of 5 patients which included 2 Glanzmann thrombasthenia (GT), 1 Glanzmann Thrombasthenia variant, 1 Bernard Soulier syndrome (BSS) and 1 patient with platelet function defect alongside 6 normal controls on both CS 2000i (Sysmex Corporation, Japan) and on chrono-log (Chrono-Log Corporation, USA). Concentrations of various agonists used in both platforms is shown (Table 1). Stirrer speed was 1200 rpm for Chrono-log and 800 rpm for Sysmex CS-2000i.

TABLE 1 Concentrations of various agonists on Sysmex and chrono-log

Agonist	Concentration in sysmex	Concentration in chrono-log
Ristocetin	1.2 mg/ml	1.5 mg/ml
ADP	4 µmol/L	10 µmol/ml
Epinephrine	5 µmol/L	10 µ mol/ml
Collagen	2 µgram/ml	2 µ gram/ml
Arachidonic acid	1 mmol/L	10 µ mol/ml

Results: The reference range for various agonists on Sysmex were as follows: Ristocetin (66.7% - 87.5), ADP (58.2%- 86.03%), Epinephrine (59.96%-86.04%), Collagen (67.3%-93.73%) and AA (62.86-93.46%). Platelet aggregometry results done on both platforms shown in Table 2.

Conclusions: This data suggests that automated platelet aggregometry in CS 2000i is reproducible and offers the advantage of walkaway automation saving on personnel.

PB 763 | Minor Dental Surgery in Patients with Glanzmann Thrombasthenia Patients

A.J. Sikorska[1], B. Ceglarek[1], K. Bykowska[2], K. Maślanka[3], B. Baran[2], J.M. Teliga Czajkowska[4], J. Windyga[1,2]

[1]Institute of Hematology and Transfusion Medicine, Department of Disorders of Hemostasis and Internal Medicine, Warsaw, Poland, [2]Institute of Hematology and Transfusion Medicine, Department of Hemostasis and Metabolic Disorders, Warsaw, Poland, [3]Institute of Hematology and Transfusion Medicine, Department of Immunohematology and Immunology for Transfusion Medicine, Warsaw, Poland, [4]Medical University of Warsaw, Department for Didactics of Gynaecology and Obstetrics, Warsaw, Poland

Background: Glanzmann's Thrombasthenia (GT) is a rare inherited autosomal recessive disorder where bleeds are variable and can be treated with platelets transfusion, rVIIa and antifibrinolytics,

Aims: Report on efficacy of rVIIa use in three GT patients undergoing invasive dental procedures.

Methods: Platelet aggregation was measured by light transmission aggregometry (LTA). Platelet GP expression level was detected by flow cytometry using monoclonal antibodies anti GP IIb/IIIa (Beckman Counter); antiGPIb/IX/V (Alexis BioBiochemicals); anti GP IIIa (Dako).

Results: Case 1: A patient (44yrs) with GT recognized in childhood following prolonged bleeding. Tooth 36 extraction under cover of rFVIIa at 90µg/kg every 3 hrs, . 4 days bleeding was continuing despite of rFVIIa, acidum tranexamicum (At) and Spongostan anal seams (Sa). Teeth extraction within 2 yrs : rFVIIa was administered 2 h before procedure and then at two doses every 2 hrs, followed by 2 doses every 6 h. and 3 doses every 8 hrs. Complete hemostasis was restored. Case Case 2:GT patient (29yrs) with recurrent vitreous hemorrage, epistaxis and menorrhagia required RBC and PC transfusions. Seven multi-stage teeth extractions were performed. Before extraction (teeth 36 and 37) 2 units of PC were transfused and Sa applied. Bleeding subsided on day 2 after transfusion of 1 unit of PC. Before extraction of teeth 14 and 16 rFVIIa, At and Sa were administered. Two units of PC, 1 unit of RBC and rFVIIa were administered every 12 hours for 2 days because of following night bleeding from the socket. Before removal of teeth 46, 47 and 21 rFVIIa (every 12hrs,3 days), At and 2 units of PC were given. Bleeding subsided on the 3rd day.Case report 3: GT patient (40yrs) with bleeding history. Tooth 36 and 18

TABLE 2 Platelet aggregometry results on Sysmex and chrono-log (AA- Arachidonic acid, PFD- Platelet function defect)

Patients	Ristocetin (%)	ADP (%)	Epinephrine (%)	Collagen (%)	Arachidonic acid (%)
GT (Average of 2 patients)	Sysmex: 36 Chrono-log: 89	Sysmex: -19.8 Chrono-log: 1	Sysmex: -12 Chrono-log: 8	Sysmex: -13 Chrono-log: 5	Sysmex: -23 Chrono-log:5.5
BSS	Sysmex: 0.7 Chrono-log: 14	Sysmex: 24.2 Chrono-log: 20	Sysmex: 28.5 Chrono-log: 20	Sysmex: 31.8 Chrono-log: 15	Sysmex: 30.5 Chrono-log: 16
GT variant	Sysmex: 0.9 Chrono-log: 73	Sysmex: -11.2 Chrono-log:1	Sysmex: -3.8 Chrono-log: 3	Sysmex: 1.3 Chrono-log: 1	Sysmex: 1.4 Chrono-log: 37
PFD	Sysmex: 42.6 Chrono-log:115	Sysmex: 9.1 Chrono-log: 39	Sysmex: 9.2 Chrono-log: 18	Sysmex: 34.3 Chrono-log: 73	Sysmex: 62.5 Chrono-log: 76

extractions were made under cover of rFVIIa and Sa. rFVIIa was given 8-11 times every 2-3 hours and then every 4-6 hrs. for 3 days.

Conclusions: rFVIIa is an effective drug in the management of bleedings in patients with GT following teeth extractions.

PB 764 | Flow Cytometric Mepacrine Uptake Related to Platelet Size in Patients with Moderate Macrothrombocytopenia

S.J. Rodriguez Moreno, M.F. Alberto, E. Bermejo, M.L. Romero, S. Meschengieser, A. Sachez Luceros

IIHEMA. Academia Nacional de Medicina, Hemostasia y Trombosis, Buenos Aires, Argentina

Background: Flow cytometric mepacrine uptake (MU) is used in diagnosis of dense granule (DG) disorders. MU has disadvantages as variable background due to retention of excess of mepacrine in platelet cytoplasm which will also depend on mean platelet volume (MPV). This makes it difficult to apply MU to measure DG content in macrothrombocytopenias (MTP).

Aims: To evaluate MU in patients with moderate MTP compared to a normal range related to platelet size.

Fig.1

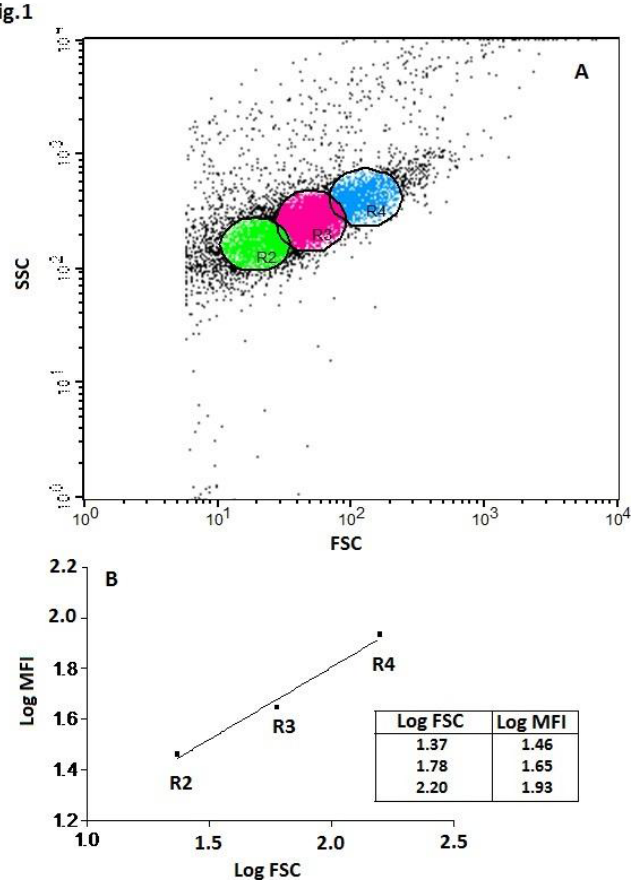

FIGURE 1 A: Dot plot SSC vs FSC and regions to obtain pairs of values MFI-FSH. B: linear regression MFI (FL1) vs FSH in one N.

Fig.2

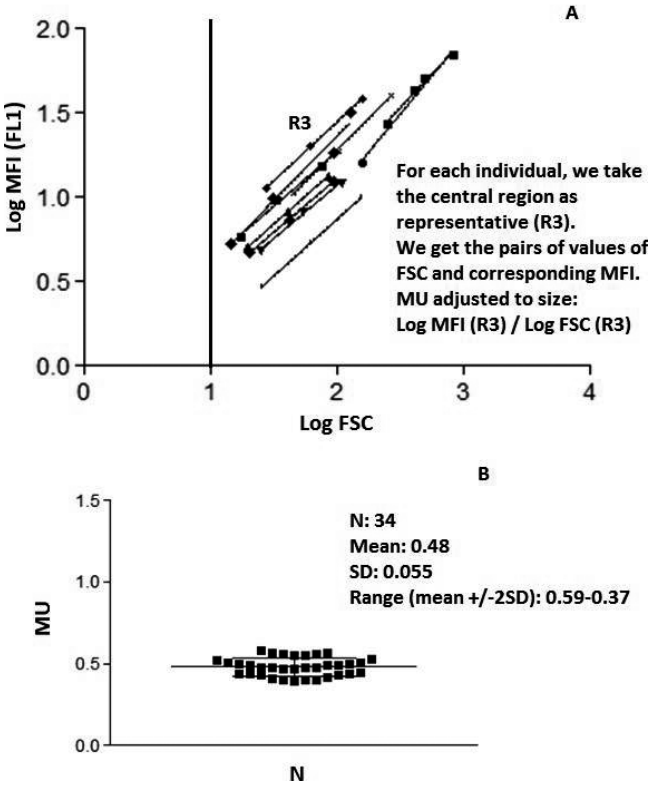

FIGURE 2 A: linear regressions . B: normal range

Methods: We evaluated three groups: subjects with normal ATP release (N,n=34) patients with decreased ATP release (SPD,n=4) and patients with MTP (n=5).Platelet-rich plasma (PRP) was adjusted to $300x10^9$ / L. The PRP range of the MTP patients was: $88\text{-}137x10^9$ /L. MPV was measured in all PRPs. ATP release with collagen 8.0 ug/uL by lumiaggregometry was taken as complete release(3.9-8.0 uM ATP). For MU, 25uL of PRP were incubated with 500uL of 5uM mepacrine in Tyrodes' buffer or Tyrodes' buffer as negative control,30 minutes at 37°C and diluted 1/80 in Isoflow.Means of frontal dispersion (FSC) and fluorescence intensity (MFI) were obtained and analyzed as shown in Fig.1-2.

Results: MPV of MTP vs N was significantly higher (13.5+/-0.41fL vs 8.6+/-1.5fL p=0.0027). Analyzed together the three groups data,VPM vs FSC correlated positively (r = 0.89 p < 0.0001). Each group member presented a positive linear relationship between MFI vs FSC on a logarithmic scale with similar slopes (Fig.2A).The normal range of MU was calculated dividing the logarithm of MFI with the logarithm of FSC in the N group (Fig.2B) (mean+/-2SD =0.48+/- 0.11). All SPD and only one MTP had decreased values (range 0.25-0.28 and 0.32 respectively).

Conclusions: MU in N, SPD and MTP showed a positive relationship between size and DG content with a similar rate of increased. This allowed us to calculate a normal range fitted to platelet size. This range was validated with SPD group. One of MTP had a decreased MU suggesting a concomitant reduction of DG content. More studies are necessary to confirm our results.

PB 765 | Circumcision in Children with Inherited Bleeding Disorders - A Tertiary Care Centre Experience in Saudi Arabia

M. Saleh[1], Z. Habib[2], A. Aljefri[3], H. Musallam[4], L. Tuleimat[4], S. Jose[5], M. Zulfiqar[3], V. Mohammed[3], N. Alshaikh[6]

[1]King Faisal Specialist Hospital & Research Centre, Pediatric Hematology / Oncology, Riyadh, Saudi Arabia, [2]King Faisal Specialist Hospital & Research Centre, Surgery Department, Riyadh, Saudi Arabia, [3]King Faisal Specialist Hospital & Research Centre, Pediatric Hematology & Oncology, Riyadh, Saudi Arabia, [4]King Faisal Specialist Hospital & Research Centre, Medical Student, Academic and Training Affairs, Riyadh, Saudi Arabia, [5]King Faisal Specialist Hospital & Research Centre, Pediatric Nursing Department, Riyadh, Saudi Arabia, [6]King Faisal Specialist Hospital & Research Centre, Fellow, Academic and Training Affairs, Riyadh, Saudi Arabia

Background: Circumcision is one of the most common surgical procedure performed amongst male neonates. Apart from religious obligations, it is considered a vital ritual for a young adult to become a member of the society. It could pose serious hemorrhagic side effects amongst bleeders, which could be controlled with appropriate coagulation factor infusion, blood products, and antifibrinolytic agents ;pre and post circumcision.

Aims: To analyze outcomes of circumcision amongst children with inherited bleeding disorders , to determine extent of complications and provide guidelines for circumcision management.

Methods: We retrospectively reviewed medical records of pediatric patients (< 14 years) with inherited bleeding disorders, who underwent circumcision at our institute. IRB approved case report form was used to collect data and SPSS Version 20.0 was used for statistical analysis.

Results: A total of 33 patients with inherited bleeding disorders were identified, 49% (16) with Hemophilia, 30% (10) Glanzman Thrombasthenia,15% (5) Von Wille Brand disease and 6% (2) rare bleeding disorder, with a median age of 1 year (1.99 - 13.0 yrs) at the time of procedure. Twenty-two (67%) out of the 33 patients received appropriate factor replacement therapy (FRT) before and after the procedure,3 of whom had bleeding complications and of the eleven (33%) patients who did not receive FRT, 2 experienced bleeding. Overall incidence of bleeding complication was 15% (5/33).

Conclusions: Post-circumcision complication rate of 15% in our patients is comparable to published rates of 0.1 to 35% ,in patients without a bleeding disorder. In our experience circumcision for bleeders could be practiced under supervision of hematologist with adequate FRT, blood product support and local control by fibrin glue. However, parents and patients must be informed of bleeding risks despite taking adequate measures. National guidelines on use of haemostatic agents amongst bleeders for circumcision is required.

PB 766 | Patient Experiences with Hereditary Thrombotic Thrombocytopenic Purpura (hTTP): A Conceptual Framework of Patient-reported Outcomes (PROs)

A. Oladapo[1], D. Ito[1], C. Hibbard[2], S.E. Bean[3], R.N. Krupnick[4], B.M. Ewenstein[1]

[1]Shire, Cambridge, United States, [2]Shire, R&D, Cambridge, United States, [3]QuintilesIMS, New York, United States, [4]QuintilesIMS, Cambridge, United States

Background: Hereditary thrombotic thrombocytopenic purpura (hTTP) (severe ADAMTS13 deficiency) is characterized by microangiopathic hemolytic anemia, thrombocytopenia, and diverse clinical signs and symptoms. Existing patient-reported outcome (PRO) tools are limited in assessing the burden of hTTP. A better understanding of hTTP symptoms and impacts will help identify outcomes meaningful to patients for the purpose of developing a disease-specific tool.

Aims: The purpose of this study was to gain an in-depth understanding of the most salient symptoms and impacts of hTTP experienced by patients, in order to formulate a conceptual model of the burden of illness.

Methods: A literature review was conducted to construct a preliminary conceptual model of symptoms and impacts of hTTP. Interviews were conducted with 5 hematologists treating hTTP in the United States, United Kingdom, and Austria to revise the model. Concept elicitation interviews were then conducted with 11 patients in the United States (mean age, 38.2 years; range, 21-52 years). The clinician and patient interviews were used to refine the preliminary model, resulting in a final conceptual model of the most relevant symptoms and impacts that reflect the patient experience with hTTP.

Results: The most salient hTTP symptoms in the model were fatigue, pain (muscular and joints), cognitive impairment (forgetfulness, difficulty communicating), vision problems (temporary blindness, blind spots, blurred vision, worsening vision), headache, and bruising. The most salient effects of the disease on patients' lives were identified as ability to work/study, and emotional consequences (depression, anxiety, mood swings).

Conclusions: The final conceptual model indicates high disease burden and highlights areas of need within the current treatment paradigm. This conceptual model will inform the development of a PRO instrument that can be used to assess the outcomes of current and future therapies.

PB 767 | Application of ISTH - Bleeding Assessment Tools to Inherited Platelet Disorders

R. Messaoudi[1], M. Lahmer[2], L. Zatla[1], Z. Zouaoui[3], H. Touhami[1]

[1]Univesity Hospital Oran, Department of Hematology, Oran, Algeria, [2]University Hospital Sidi-Bel-Abbès, Department of Epidemiology, Sidi, Algeria, [3]University Hospital Sidi-Bel-Abbès, Department of Hematology, Sidi, Algeria

Background: The inherited platelet disorders are a heterogeneous group of diseases responsible for bleeding manifestations at widely

TABLE 1 Comparison of bleeding ISTH -Bleeding Assessment Tools score (BAT), severity class

	T.G(34)	J.B.S.S(18)	M.H(8)	Total(60)	P
Average score	11,70±3,98	12,11±5,96	6,75±4,30		0,02
< 5	1 (2,9%)	0 (0,0%)	2 (25,0%)	3 (5,0%)	0,001
5-10	15 (44,1%)	8 (44,4%)	5 (62,5%)	28 (46,7%)	0,19
> 10	18 (52,9%)	10 (55,5%)	1 (12,5%)	29 (48,3%)	0,09

varying degrees. Despite the development of diagnostics means, we observed during our clinical practice deficiencies in assessment tools bleeding risk and quantification of bleeding symptoms.

Aims: Our goal is to provide a clinical scoring at targeted screening and prognosis.

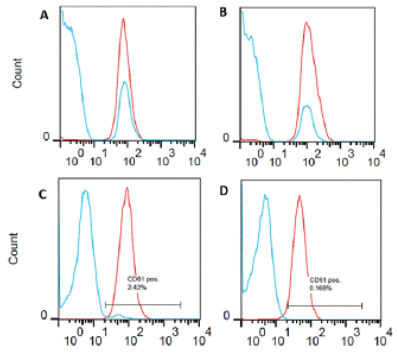
Methods: Application of clinical score ISTH-BAT for all adult patients and children with inherited platelet disorders (34 thrombasthenia glanzmann, 18 Jean Bernard Soulier diseases, 8 diseases of May-Hégglin).

Results: 60 patients with inherited platelet disorders (TG 34, 18JBS, 8MH), the average age of our population is (21,33 ± 12,61) years, the youngest was 11 months old and the oldest was 52 years.

In the TG, the average ISTH-BAT 11,70 ± 3,98, 12,11 ± 5,96 in the JBS, higher against the disease MH 6 , 75 ± 4.30, the comparison test found a significant difference (p = 0,02).

The sensitivity of the ISTH-BAT in the detection of thrombopathy is 97% in the Glanzmann thrombasthenia and 100% in the Jean-Bernard Soulier disease.

Conclusions: The ISTH-BAT bleeding score is tool for the screening of new patients and prognosis for patients with severe hemorrhagic symptoms, were expected to generalize in the coming years for all patients of the Algerian territory for its validation for inherited platelet disorders.



Flow cytometry post platelet transfusion, using antibodies directed against CD61-APC. Blue – patient. Red - normal control. A. Day of transfusion B. Two days post transfusion C. four days post transfusion D. A week post transfusion

FIGURE 1 Consecutive post transfusion flow cytometry

Results: A total of 3 female GT patients (ages 1, 19, 39 years) undergoing 4 surgeries were included. Surgical procedures were: diaphragmatic hernia repair with CVL insertion and extraction, cholecystectomy and salphingo-oophorectomy. Consecutive blood counts and FC analysis following platelet transfusions showed gradual decrease of donor platelets from 21%, 15%, 1%, correlating with 82,740, 49,200, 3,280 X 10^9/L active platelets respectively in one of the patients (figure 1), whereas in another patient one hour post transfusion FC demonstrated 3% donor platelets equivalent to 6,060 active platelets, both patients did not experience any bleeding. The third patient experienced post-surgical bleeding at day 8 after salphingo-oophorectomy, when FC demonstrated 1% of donor platelets correlating with 2600 active platelets.

Conclusions: Results suggest that very low number of active donor platelets (as revealed by FC) may suffice to achieve proper hemostasis. Our study points to the potential role of consecutive FC examinations to demonstrate the number of active platelets as an ancillary tool for decision making in GT patients undergoing surgery.

PB 768 | Post Platelet Transfusion Flow Cytometry Analysis as an Ancillary Test Guiding Treatment of Glanzmann Thrombastenia Patients Undergoing Surgical Procedures

A. Barg, H. Hauschner, A. Lubetsky, S. Levy Mendelovich, M. Misgav, N. Rosenberg, G. Kenet

Tel Hashomer and the Sackler Medical School, Thrombosis and Hemostasis Institute, Tel Aviv, Israel

Background: Glanzmann thrombasthenia (GT) is a disorder of platelet function caused by mutations in the αIIbβ3 genes. Standard therapy includes platelet transfusions, yet GT patients may form antibodies against αIIbβ3 antigen or against MHC-class I, hampering efficacy of treatment.

Aims: We aimed to assess potential correlation between bleeding and number of active platelets in GT patients undergoing surgical procedures.

Methods: GT patients undergoing surgery interventions during study period were included. Sequential blood counts and flow cytometry analysis (FC) were performed as an ancillary test to estimate the effectiveness of platelet transfusions, given at investigator discretion.

PB 769 | Successful Management of Severe Bleeding with Combined Platelet Transfusion, rFVIIa and Tranexamic Acid Therapy in Glanzmann Thrombasthenia Patient

B. Ceglarek[1], A.J. Sikorska[1], K. Bykowska[2], K. Maślanka[3], A. Misiak[4], A. Szczepanik[4], J.M. Teliga Czajkowska[5], J. Windyga[2,6]

[1]Institute of Hematology and Transfusion Medicine, Department of Disorders of Hemostasis and Internal Medicine, Warsaw, Poland, [2]Institute of Hematology and Transfusion Medicine, Department of Hemostasis and Metabolic Disorders, Warsaw, Poland, [3]Institute of Hematology and Blood Transfusion, Department of Hemostasis and Metabolic Disorders, Warsaw, Poland, [4]Institute of Hematology and Transfusion Medicine, Department of General, Oncological and Metabology Surgery1, Warsaw, Poland, [5]Medical University of Warsaw, Department for Didactics in Obstetrics and Gynecology, Warsaw, Poland, [6]Institute of Hematology and Transfusion Medicine, Department of Hemostasis and Metabolic Disorders Department of Hemostasis and Metabolic Disorders, Warsaw, Poland

Background: Glanzmann Thrombasthenia (GT) is a rare autosomal recessive bleeding disorder .The bleeding tendency in GT is variable. Standard treatments for GT comprise platelet concentrate transfusions (PCT), rFVIIa and antifibrinolytic agents.

Aims: Report of successful therapy with rVIIa in a 48 year old female with GT diagnosed at the age of 2.

Methods: Case report: The patient experienced 10 severe bleeding episodes (menorrhoea, epistaxis, gingivorrhoea, gastrorrhagia) and was treated with PCT and rVIIa. She was admitted to IHTM in a severe condition with abdominal pain, nausea, vomiting blood and stomach contents. Lab tests revealed anaemia and hyperbilirubinaemia. No alloimmunization to human leukocyte antigens (HLA) and/or platelet membrane GPIIb/IIIa was determined. Gastroduodenoscopy and laparoscopic cholangiography by duodenal route were performed under haemostatic cover of platelet transfusions. The diagnosis: reflux oesophagitis, haemorrhagic gastritis, severe gastric ulcer and Vater's papilla bleeding, major duodenal papillis and cholecystolithiasis.

Results: Treatment consisted in platelet (6 units) and RBC (18 units) transfusions as well as rFVIIa (total dose of 42mg) and tranexamic acid administrations and several gastric coagulations. Applied therapy allowed to control the bleeding. The patient recovered and cholecystectomy was successfully performed 10 months later. Isoantibodies against GP IIb-IIIa were then detected and 9 severe bleeding episodes followed at 2-3 month intervals (gastrorrhagia and Vater's papilla bleeding, Vater's papilla bleeding, transverse colon hemorrhage). Successful therapy was administered with argon coagulation-9 procedures, HLA compatible platelet transfusions (47units), transfusions of RBC (38 units) and tranexemic acid.

Conclusions: Management of severe bleeding in GT proved successful in our case owing to combined use of rFVIIa, tranexamic acid and HLA-compatible platelet transfusion as well as and RBC transfusions supported by argon coagulations and cholecystectomy.

PB 770 | Immature Platelets Fraction and its Application in the Differential Diagnosis of Congenital and Acquired Trombocytopenia

J. Neves[1], C. Faria Coelho[2], C. Teixeira[2], E. Cruz[2], C. Lau[2], S. Morais[2], I. Freitas[2]

[1]Centro Hospitalar do Porto (CHP), Clinical Pathology, Porto, Portugal, [2]Centro Hospitalar do Porto (CHP), Porto, Portugal

Background: The immature platelets fraction (IPF) quantifies the platelet population with higher RNA contente, reflecting medullary response.

Congenital thrombocytopenia is a heterogeneous group of entities that are difficult to recognize. Late recognition and absence of family history may lead to misdiagnosis of acquired thrombocytopenia, in particular immune thrombocytopenic purpura (ITP). Differential diagnosis between this condition (ITP) and congenital trombocytopenia may be clinically difficult, requiring experience in the evaluation of platelet morphology and further studies with specific tests, such as aggregometry, flow cytometry and genetic studies. These tests are unavailable in most clinical laboratories. In this context, determination of IPF may offer an advantageous and reproducible alternative.

Aims: IPF clinical application in differencial diagnosis of thrombocytopenia

Methods: Prospective study included 27 patients diagnosed with ITP, 11 patients with MYH9-associated macrothrombocytopenia (MYH9MT), 5 patients with Bernard Soulier´s syndrome, 22 patients with other congenital macrotrombocytopenia, and 50 healthy individuals. Whole-blood automated platelet parameters were measured on the Sysmex XE-5000 hematological analyzer.

Results: IPF was significantly increased in all groups compared to the control group. The highest values were observed in the MYH9MT group, followed by Bernard Soulier syndrome, other congenital macrotrombocytopenias, and ITP groups, respectively. All differences observed among groups were statistically significant ($p < 0.001$).

Conclusions: The fact that pacientes with congenital trombocytopenia had higher IPF values than patients with ITP may provide the evidence to pursue further evaluation for congenital thrombocytopenia. However IPF parameter is not completely discriminative of this condition.

In conclusion, our results support IPF as an automated, fast-performing and low cost parameter, useful for the differential diagnosis of congenital and acquired thrombocytopenia.

PB 771 | A Case of Acquired, Transient Bleeding Diathesis Associated with Platelet Dysfunction

E.A. Femia, G.M. Podda, V. Caroppo, C. Cheng, M. Cattaneo

Unità di Medicina III, ASST Santi Paolo e Carlo - Dipartimento di Scienze della Salute, Università degli Studi di Milano, Milano, Italy

Background: Delta-storage pool deficiency (dSPD) is a congenital platelet function disorder that is associated with decreased number and/or contents of platelet delta-granules. Cases of acquired dSPD have been described in association with some conditions.

Aims: We report a case of a 14-year old girl, referred to us in October 2014 for moderate mucocutaneous bleedings, which manifested for the first time 6 months before, in the absence of any clinically overt disorders. At the time of her referral, her bleeding score (ISTH/SSC) was 6 and physical inspection revealed no abnormalities. Two weeks before the appearance of bleeding manifestations, a mycoplasma pneumonia infection was diagnosed, which was successfully treated with Clarithromycin.

Methods: We measured: platelet aggregation and secretion (lumiaggregometry); the platelet content of serotonin (spectrofluorometry), ATP and ADP (luminometry); platelet membrane glycoproteins (GP) and phosphorylation of vasodilator-stimulated phosphoprotein (VASP-P) (flow cytometry); serum thromboxane B2 (TXB2) (ELISA).

Results: Blood cells count and morphology, von Willebrand factor antigen and ristocetin cofactor activity, GP and VASP-P were normal. Platelet aggregation and ATP release induced by ADP, epinephrine, thrombin receptor activating peptide, and collagen were impaired. Serotonin and ADP content, and serum TxB2 were reduced. Similar results were obtained 4 months later (February 2015). On February 2016 the bleeding manifestations had disappeared spontaneously, and platelet function were normal.

	Oct 2014	Feb 2015	Feb 2016	normal range
Platelet 5HT (nmol/10^8plts)	0,14	0,15	0,68	0,21-0,67
Platelet ADP (nmol/10^8plts)	1,1	1,76	3,29	1,99-4,67
Platelet ATP (nmol/10^8plts)	6,5	7,62	8,02	5,29-11,34
ATP/ADP	6	4,32	2,43	1,30-3,29
serum TXB2 (pmol/10^8plts)	38	38	127	63-472

FIGURE

Conclusions: To the best of our knowledge, this is the first case of acquired, transient platelet dysfunction associated with delta-granules defect and defective thromboxane production, with apparently spontaneous onset and offset. Whether the mycoplasma pneumonia infection of the patient at the time of first bleeding manifestations had any pathogenic role is uncertain, and deserves further investigation.

PB 1557 | Twice-daily Low-dose Aspirin Improves Platelet Inhibition in Patients with Essential Thrombocytosis

M.L. Larsen[1,2], O.H. Pedersen[1,2], A.M. Hvas[2], P.B.v.K. Niekerk[3], S. Bønløkke[3], S.D. Kristensen[1], E.L. Grove[1]

[1]Aarhus University Hospital, Cardiology, Aarhus N, Denmark, [2]Aarhus University Hospital, Clinical Biochemistry, Aarhus N, Denmark, [3]Aarhus University Hospital, Department of Hematology, Aarhus, Denmark

Background: Insufficient platelet inhibition has been reported in up to 40% of aspirin-treated patients, including patients with essential thrombocytosis. In order to maintain sufficient platelet inhibition, a shorter dosing interval with aspirin has been suggested.

Aims: To investigate the antiplatelet effect of low-dose aspirin given twice-daily compared to standard once-daily dosing in patients with essential thrombocytosis.

Methods: We included 22 patients with essential thrombocytosis. Patients were treated for 7 days with standard once-daily aspirin (75 mg once-daily) followed by 7 days treatment of twice-daily aspirin (37.5 mg twice-daily). The two regimens were separated by 14 days aspirin washout. Blood samples were obtained 1h and 24h after the last pill intake in each regimen. The effect of aspirin was evaluated by platelet aggregation and serum thromboxane B_2 levels. Platelet aggregation was measured by whole blood impedance aggregometry (Multiplate® analyzer, agonist: arachidonic acid (ASPItest 0.5 mM)). Serum thromboxane B_2 levels were determined using an enzyme-linked immunosorbent assay.

Written informed consent was obtained from all participants. The Dansih Ethics Committee and Medical Agency approved the study.

Results: Platelet aggregation at the end of the dosing interval (24h) was significantly higher than at 1h during both regimens. The difference in platelet aggregation from 1h to 24h was used to compare the two regimens. We demonstrated a significantly lower difference in platelet aggregation in the twice-daily regimen compared to the once-daily: mean of difference = 227 AU*min (95% CI: 92 to 363, p< 0.01).

In addition, a significantly lower difference in thromboxane B_2 was demonstrated in the twice-daily regimen compared to the once-daily regimen: mean of difference = 10.3 ng/mL (95% CI: 6.3 to 14.3, p< 0.01).

Conclusions: Twice-daily dosing with low-dose aspirin provides a more consistent platelet inhibition compared with standard once-daily dosing in patients with essential thrombocytosis.

PB 1558 | Long-term Aspirin (ASA) Use Significantly Attenuates Platelet Interactions with von Willebrand Factor (VWF) in Acute Coronary Syndromes (ACS)

D. Kenny[1,2], R. Walsh[1], D. Foley[3], A.J. Ricco[4], E. Dunne[1,2]

[1]Royal College of Surgeons in Ireland, Dublin, Ireland, [2]Irish Centre for Vascular Biology, Dublin, Ireland, [3]Beaumont Hospital, Dublin, Ireland, [4]Biomedical Diagnostics Institute, Dublin, Ireland

Background: In ACS platelets tether to VWF via the glycoprotein (GP)Ib receptor and initiate a complex signalling cascade, ultimately activating the integrin $\alpha_{IIb}\beta_3$ receptor that crosslinks fibrinogen and causes platelet arrest. Platelet adhesion via the GPIb receptor is rapidly reversible, shear dependent, and includes characteristic start-stop translocation of platelets. Long-term ASA use (≥ 5 years) is associated with a reduction in the incidence of cancer and cardiovascular events.

Aims: It is not clear if prior use of ASA is beneficial in patients with ACS. We hypothesise that platelet function will differ in ACS patients on prior long-term aspirin compared to those recently started on ASA.

Methods: We have developed a microfluidic assay utilizing video microscopy to accurately measure dynamic platelet behaviour in microliters of blood perfused across VWF at arterial shear rates (1500 s^{-1}), termed the DPFA. Tracking multiple individual platelets from frame to frame with unique motion-analysis software, the assay measures the total number of platelets 1) interacting with VWF, 2) translocating across VWF, and 3) stably adhering to the surface, as well as 4) the speed and distance platelets travel across VWF.

Results: We recruited 67 patients with ACS. Standard light transmission aggregometry demonstrated that all patients had a uniform response to aspirin. The duration of ASA therapy ranged from 1 day to 395 months. Platelets from patients on ASA therapy for greater than 5 years travelled a greater distance at higher velocities (P≤0.04 and 0.03 respectively, 1-way ANOVA) compared to those of patients newly prescribed ASA therapy. Quintile analysis based on length of treatment with ASA demonstrated that long-term ASA use reduced the number of platelets adhered to the surface, with a significant decrease in platelets that translocate and then form stable bonds to VWF (ANOVA, p≤0.01).

Conclusions: We demonstrate for the first time that prior long-term use of ASA significantly attenuates platelet interaction with VWF.

PB 1559 | Patients with Coronary Artery Disease Have a Pathological P2Y12 Platelet Response with Heightened Procoagulant Platelet Potential

L. Pasalic[1,2,3], J. Lau[4,5], G. Pennings[4], H. Campbell[3,6], E. Wing-Lun[7], E. Lau[2,8], D. Connor[9], D. Muller[7], L. Kritharides[4,5], V. Chen[6,10,11]

[1]*Westmead Hospital, Haematology, Sydney, Australia,* [2]*ICPMR, Westmead Hospital, Haematology, Sydney, Australia,* [3]*University of New South Wales, Prince of Wales Clinical School, Sydney, Australia,* [4]*ANZAC Research Institute, Sydney, Australia,* [5]*Concord Hospital, Cardiology, Sydney, Australia,* [6]*ANZAC Research Institute, Platelet and Thrombosis Research Laboratory, Sydney, Australia,* [7]*St Vincent's Hospital, Cardiology, Sydney, Australia,* [8]*Sydney Centres for Thrombosis and Haemostasis, Westmead, Australia,* [9]*St Vincent's Centre for Applied Medical Research, Blood, Stem Cell and Cancer Research Unit, Sydney, Australia,* [10]*Concord Hospital, Haematology, Sydney, Australia,* [11]*University of Sydney, Sydney, Australia*

Background: Procoagulant platelets (PP) play a critical role in thrombin generation. We previously demonstrated that patients with coronary artery disease (CAD) have a heightened PP response to thrombin and thrombin/collagen, the mechanism of which is unknown.

Aims: To determine if the $P2Y_{12}$ pathway is involved in the heightened PP response to thrombin in patients with CAD.

Methods: We adapted a flow cytometry assay based on cell death marker, GSAO (PMID 26474813), to assay PP formation ex vivo in whole blood. Blood from healthy controls and patients undergoing elective coronary angiography was treated with thrombin ± collagen and assayed by FACS. PP subset was defined as GSAO+/CD62P+, and expressed as % all platelets.

Results: The enhanced PP response associated with CAD was not correlated with changes in platelet aggregation, dense granule release and activation of α2bβ3 integrin, suggesting independence of activation and procoagulant function. CAD patients demonstrated a significantly increased PP response to 5μM ADP compared with healthy controls (7.5±1.0% vs 2.7± 0.9%, P< 0.05), which was attenuated in patients on DAPT (7.5 ± 1.0% vs 4.1 ± 0.5%, P < 0.01) (Fig. 1). The heightened response to thrombin or combination of thrombin + collagen was not supressed by aspirin but showed partial attenuation in patients on DAPT. Patients on the weaker $P2Y_{12}$ inhibitor clopidogrel, showed no difference in response to thrombin + collagen, compared with patients on no $P2Y_{12}$ inhibitors ($P = 0.99$). In contrast, patients on prasugrel or ticagrelor demonstrated marked reduction in thrombin + collagen response relative to clopidogrel treated patients (27.2 ± 4.5% vs 12.0 ± 1.8%, n = 8-22, $P < 0.05$) or those on no $P2Y_{12}$ inhibitors (27.6 ± 3.1 vs 12.0 ± 1.8%, $P < 0.01$) (Fig. 2).

Conclusions: Our data suggests activation of the $P2Y_{12}$ pathway leads to pathological PP response in patients with CAD in response to either ADP, or thrombin + collagen, with a suppression of the thrombin + collagen response seen with strong $P2Y_{12}$ antagonists.

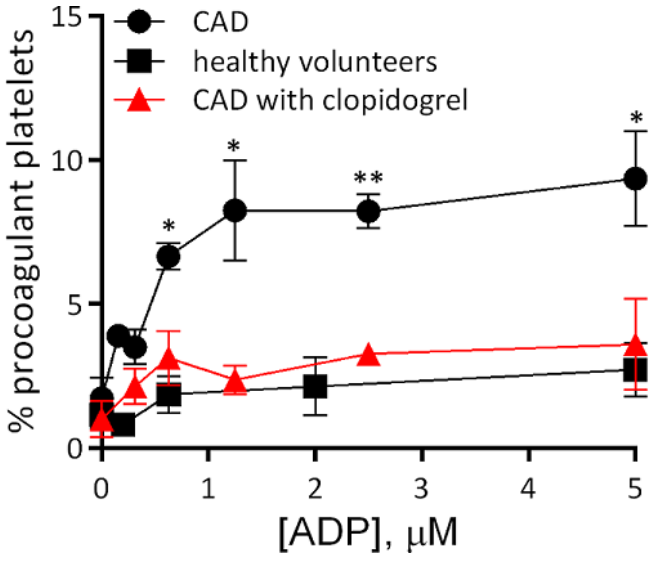


FIGURE 1 Clopidogrel partially attenuates a heightened procoagulant platelet response to ADP observed in CAD

PB 1560 | Platelet Inhibition with Ticagrelor Versus Clopidogrel in Patients with Peripheral Artery Disease: The EUCLID Platelet Substudy

J. Berger[1], B. Katona[2], Y. Guo[3], L. Karotkin[4], M. Abu-Fadel[5], I. Arif[6], J. Badimon[7], R. Becker[6], A. Hirsch[8], H. Gornik[9], J. Mills[10], J. Olin[7], C. Rockman[11], C. Staniloe[1], U. Zafar[7], N. Zantek[8], D. Angiolillo[12], W. Hiatt[13], on behalf of the EUCLID Executive Committee and the EUCLID Platelet Study Investigators

[1]*New York University School of Medicine, Cardiology, New York, United States,* [2]*Astra Zeneca, New York, United States,* [3]*NYU Langone Medical Center, Population Health, New York, United States,* [4]*New York University, New York, United States,* [5]*University of Oklahoma Health Science Center, Norman, United States,* [6]*University of Cincinnati, Cincinnati, United States,* [7]*Mount Sinai School of Medicine, New York, United States,* [8]*University of Minnesota, Minneapolis, United States,* [9]*Cleveland Clinic, Cleveland, United States,* [10]*Duke University, Durham, United States,* [11]*New York University School of Medicine, Vascular & Endovascular Surgery, New York, United States,* [12]*University of Florida, College of Medicine, Jacksonville, United States,* [13]*University of Colorado School of Medicine, Aurora, United States*

Background: Patients with peripheral artery disease (PAD) are at increased risk of atherothrombotic events and benefit from platelet inhibiting therapies. The EUCLID trial demonstrated no significant benefit from ticagrelor versus clopidogrel for the reduction of cardiovascular or limb events in patients with PAD.

Aims: The EUCLID platelet substudy aimed to compare the antiplatelet effects of ticagrelor and clopidogrel in patients with PAD.

Methods: Patients were randomized to receive either clopidogrel (75 mg daily) or ticagrelor (90 mg twice daily). The effect of study drug was studied in 75 patients during maintenance therapy (≥6-weeks post randomization). In 42 patients, platelet inhibition was measured at baseline and after 2- and 6-weeks of study drug (≈12 hrs after last dose). In all patients, pharmacodynamic assessments were made using light transmission aggregometry (in response to ADP 5 and 20uM, collagen 1ug/ml and arachidonic acid [AA] 150uM), VerifyNow P2Y12, and VASP phosphorylation.

Results: During maintenance therapy, ticagrelor achieved lower platelet activity of ADP-induced platelet aggregation than clopidogrel (maximum platelet aggregation to ADP 5uM, 39% vs. 60.5%, P< 0.001; ADP 20uM 51% vs. 67.5%, P=0.004; VerifyNow, 74 vs. 165 PRU, P< 0.001; VASP 16.9 vs. 45.8 PRI, P< 0.001). High on-treatment platelet reactivity was observed more frequently in the clopidogrel treated group (P< 0.05 for each ADP-mediated assay). The effect at 14-days and 6-weeks was consistent with a greater platelet inhibition with ticagrelor compared with clopidogrel. The inhibition of collagen- or AA-induced platelet aggregation was not different between groups.

Conclusions: In patients with PAD, ticagrelor achieved greater inhibition of ADP mediated platelet activity versus clopidogrel. The inhibition of non-ADP mediated platelet activity was not different between groups. Despite greater platelet inhibition, ticagrelor was not superior to clopidogrel for the reduction of cardiovascular events in patients with PAD.

PB 1561 | Antiplatelet Agents are the Key Drugs for the Prevention of Recurrent Arterial Thrombosis in Patients with Antiphospholipid Syndrome

N. Ohnishi, Y. Fujieda, Y. Ogata, S. Abe, M. Kono, S. Tanimura, R. Hisada, E. Sugawara, H. Nakamura, K. Ohmura, S. Shimamura, M. Doi, M. Kato, K. Oku, T. Bohgaki, O. Amengual, S. Yasuda, T. Atsumi

Division of Rheumatology, Endocrinology and Nephrology, Hokkaido University Graduate School of Medicine, Sapporo, Japan

Background: Antiphospholipid syndrome (APS), one of the most common acquired thrombophilia, is a systemic autoimmune disease characterized by the presence of arterial and/or venous thrombosis. However, the optimal prophylaxis of recurrent arterial thrombosis for APS patients is controversial.

Aims: The objective of this study is to evaluate the efficacy of several prophylactic treatments for recurrent arterial thrombosis in patients with APS.

Methods: This study involved a cohort of 206 patients with APS who visited Hokkaido University Hospital rheumatology clinic from April 1990 to March 2016. Patients who were followed-up for less than 2 years and those without arterial thrombosis were excluded. A total of 90 APS patients (female 73, age 43 years (9-79)) were subsequently analysed. We retrospectively assessed the efficacy of warfarin monotherapy (wf, n=13), antiplatelet monotherapy (AP, n=41), combination therapy of warfarin and antiplatelet agent (wf+AP, n=21), and dual antiplatelet therapy (DAPT, n=15) in the secondary prevention of arterial thrombosis in patients with APS.

Results: The median follow-up period was 12 years (2-27). Thrombotic events recurred in 40 (44.4%), patients (wf, AP, wf+AP, DAPT: 11, 18, 8, 3). A total of 14 (15.6%) patients died, (wf, AP, wf+AP, DAPT: 1, 5, 4, 4), and 9 (10.0%) patients had serious bleeding events, (wf, AP, wf+AP, DAPT: 0, 5, 2, 2). In Kaplan-Meier analysis, 10-years recurrence-free survival rate was 62%, and the treatment with warfarin monotherapy was less effective than other treatment options (Log-rank p=0.001). There were no statistically significant differences in bleeding events and mortality among the groups.

Conclusions: Antiplatelet agents are the key drugs for the prevention of recurrent arterial thrombosis in patients with APS.

PB 1562 | Cyclic Nucleotide Modulators and P2Y12 Antagonists as Novel Anti-platelet Combination Therapy

P.C. Armstrong[1], P. Ferreira[1,2], M.V. Chan[1], C.-C. Shih[1,3], M.H. Lundberg Slingsby[1], T.D. Warner[1]

[1]*Queen Mary University of London, William Harvey Research Institute, London, United Kingdom,* [2]*University of São Paulo, Departamento de Farmacologia, São Paulo, Brazil,* [3]*National Defense Medical Center, Department of Pharmacology, Taipei, Taiwan, Republic of China*

Background: Cyclic nucleotides are intrinsic to maintaining platelet quiescence and a synergistic relationship exists between cyclic nucleotides and $P2Y_{12}$ inhibition. Drugs that modulate soluble guanylate cyclase or those that inhibit phosphodiesterase (PDE), targeting cyclic nucleotide generation and degradation respectively, are approved treatments for pulmonary hypertension.

Aims: Determine anti-thrombotic efficacy of cyclic nucleotide modulators in combination with $P2Y_{12}$ inhibitors.

Methods: Mice were administered (i.v) sub-optimal doses of prasugrel (0.3mg/kg), cinaciguat (0.3mg/kg) + dipyridamole (2.0mg/kg), or a combination of all three (PCD). Whole blood aggregometery was performed using as agonists arachidonic acid, collagen, PAR-4 amide, or thromboxane mimetic U46619. Alternatively mice underwent FeCl-induced thrombosis and carotid artery blood flow was monitored.

Results: Blood from mice treated with PCD demonstrated the lowest aggregation response to each agonist. *In vivo* thrombotic response was not altered in mice treated with either prasugrel or cinaciguat+dipyridamole. Complete and stable occlusion occurred within 8 minutes in all groups, including vehicle. In contrast, PCD strongly inhibited the thrombotic response with time to occlusion >24 minutes.

Conclusions: Our studies demonstrate that cinaciguat and dipyridamole when combined with prasugrel produce strong anti-platelet effects. We therefore provide proof of concept that modulation of cyclic nucleotides in combination with $P2Y_{12}$ inhibition powerfully combine as a potentially novel therapeutic regimen. This combination, achievable using approved drugs, should allow for timely translation to clinical investigation. Moreover, by taking advantage of intrinsic physiological synergism, such an approach may be effective using lower doses of individual drugs than are currently prescribed.

PB 1563 | Prasugrel vs. Ticagrelor after STEMI: Results from the Düsseldorf STEMI Registry

M. Golabkesh, D. Dimitroulis, A. Mohring, L. Dannenberg, A. Fürnkranz, H. Makimoto, T. Zeus, M. Kelm, A. Polzin

Heinrich Heine University Medical Center Düsseldorf, Division of Cardiology, Pulmonology, and Vascular Medicine, Düsseldorf, Germany

Background: P2Y12 inhibition is indispensable after coronary intervention. By now prasugrel and ticagrelor are recommended in patients with ST-elevation myocardial infarction (STEMI) in secondary prevention of ischemic events. Prasugrel is a thienopyridine. It is more potent in platelet inhibition than clopidogrel, as its metabolization to the active substance is less complex. Ticagrelor is a cyclopentyltriazolpyrimidine. As active metabolite, it does not require metabolization. In contrast to thienopyridines, it inhibits the P2Y12 receptor reversibly. Both agents are superior to clopidogrel in secondary prevention.

Aims: In this registry analysis we compared ticagrelor with prasugrel P2Y12 inhibition in STEMI patients.

Methods: We included 318 patients during hospitalization and in a 12 months follow-up during ambulatory care at our department. Patients received dual antiplatelet therapy with aspirin and ticagrelor (Ti) or prasugrel (Pr) during follow-up period. Major adverse cardiac and cerebrovascular events (MACCE) (death, myocardial infarction, stroke, unplanned reintervention) and thrombolysis in myocardial infarction (TIMI) bleeding events (major/minor) were registered.

Results: Ti 35 vs. Pr: 24 MACCE (Hazard Ratio 1.24, 95% confidence interval [CI] 0.79-2.09; log-rank p-value = 0.41). TIMI major bleedings: Ti-group: 6 vs. Pr-group: 1 (HR 3.87, 95%CI 0.87-17.3). TIMI minor bleedings: Ti: 6 vs. Pr: 1 (HR 3.75, 95%CI 0.85-16.7). Weight (Ti: 84±17 kg vs. Pr: 84±20; p=0.8), peak-troponin (Ti: 4383±6191 ng/l vs. Pr: 5615±10748; p=0.2), peak-creatine kinase (Ti: 1740±2317 U/l vs. Pr: 1928±2251; p=0.5), Age: (Ti: 63±12 vs. Pr: 57±10 years; p< 0.0001).

Conclusions: In this register analysis no difference in 12 months follow-up existed between ticagrelor and prasugrel treated patients. Interestingly, prasugrel treated patients were significantly younger. Meta-analysis and larger registry analyses are needed to assess the optimal P2Y12 inhibition in STEMI patients.

PB 1564 | Acetazolamide and Methazolamide Suppress Platelet Procoagulant Responses and Thrombosis in vivo

E.O. Agbani, C.M. Williams, R. Aungraheeta, A.W. Poole

University of Bristol, School of Physiology, Pharmacology and Neuroscience, Bristol, United Kingdom

Background: The carbonic anhydrase (CA) inhibitors acetazolamide (ACZ) and methazolamide (MTZ) have been used extensively clinically as weak diuretic agents, with applications in the treatment of glaucoma and altitude sickness in particular. Recently, we showed acetazolamide to be potently antithrombotic in a mouse model of arterial thrombosis.

Aims: To investigate the effects of ACZ and MTZ on *in vitro* and *in vivo* procoagulant responses of activated human platelets.

Methods: Biochemical assays and immunocytochemistry, super-resolution microscopy and 4D live-platelet imaging, thromboelastometry and $FeCl_3$ model of arterial thrombosis.

Results: We confirmed the expression of CA1, 2 and 13 isoenzymes in human platelets and determined that while CA1 and 13 were essentially cytosolic, CA2 co-localised significantly with P-selectin expressing granules. Furthermore, CA activity was blocked by 100 μM ACZ or MTZ. However, ATP secretion or aggregation in response to thrombin 0.2 U/ml or collagen related peptide 5 μg/ml were comparable in ACZ- or MTZ-treated to untreated platelets. In contrast, pre-incubation of platelets with 100 μM ACZ or MTZ attenuated intracellular chloride ion entry and membrane phosphatidylserine exposure. This was associated with diminished membrane ballooning, procoagulant-spreading and microvesiculation in platelets adherent to fibrillar collagen. Bolus pre-treatment of whole human blood with 50 μM ACZ or MTZ, in the presence of 30 μM aspirin, significantly attenuated clot formation, as assessed by thromboelastometry. Finally, *in vivo* thrombus formation

was suppressed after $FeCl_3$ injury in mice administered 7 or 10mg/kg single dose ACZ or MTZ, respectively.

Conclusions: Acetazolamide and methazolamide suppress platelet procoagulant responses and *in vivo* thrombosis. These CA inhibitors may now be evaluated for a new indication as antiprocoagulant antithrombotics in translational research.

PB 1565 | Effect of Aspirin Therapy on Abacavir-associated Platelet Hyperreactivity in HIV-infected Patients: A Randomized, Double-blind, Placebo-controlled, Cross-over Study

D. Francisci[1], E. Falcinelli[2], E. Schiaroli[1], P. Minuz[3], S. Orsini[2], L. Malincarne[1], M. Sebastiano[2], A.M. Mezzasoma[2], M.B. Pasticci[2], G. Guglielmini[2], F. Baldelli[1], P. Gresele[2]

[1]University of Perugia, Department of Experimental Medicine, Division of Infectious Diseases, Perugia, Italy, [2]University of Perugia, Department of Medicine, Section of Internal and Cardiovascular Medicine, Perugia, Italy, [3]University of Verona, Department of Medicine, Section of Internal Medicine, Verona, Italy

Background: Ischemic cardiovascular events are a relevant cause of morbidity and mortality in HIV-infected patients. Use of abacavir (ABC), a nucleoside analog reverse transcriptase inhibitor, has been associated with increased risk of myocardial infarction (MI). ABC induces platelet hyperreactivity that may contribute to enhance MI risk.

Aims: To explore whether low-dose aspirin reduces in vivo platelet activation and platelet hyperreactivity associated with ABC use in HIV-infected subjects.

Methods: In a randomized, placebo-controlled, double-blind cross-over study forty ABC-treated HIV-infected patients with platelet hyperreactivity were randomized to aspirin 100 mg daily for 15 days with subsequent cross-over to placebo for additional 15 days or placebo for 15 days with subsequent cross-over to aspirin for further 15 days. In vivo platelet activation and ex vivo platelet hyperreactivity were measured at day 15 and 30. One group of healthy subjects was studied concomitantly.

Platelet hyperreactivity was defined by a score based on laboratory variables reflecting in vivo platelet activation and ex vivo platelet hyperresponsiveness.

Results: Aspirin therapy reduced significantly platelet hyperreactivity (from 9.3±0.3 to 7.5±0.2, $p< 0.05$), however without bringing it back to the levels of healthy controls (4.2±0.4). Circulating platelet microparticles were reduced by aspirin treatment, although they remained higher than in healthy subjects while s-Pselectin and sCD40L remained elevated, showing persistence of in vivo platelet activation. Suppression of serum TxB_2 and urinary 11-dehydro-TxB_2 excretion confirmed compliance to therapy.

Conclusions: Aspirin reduces in vivo platelet activation and platelet hyperreactivity associated with ABC-treatment in HIV-infected patients, however without normalizing them. Whether the observed reduction of platelet activation is sufficient to prevent cardiovascular events requires a prospective large scale trial.

PB 1566 | Investigation of the Physiological Mechanisms Leading to the Release of BDNF by Platelets and their Susceptibility to Antiplatelet Agents

R. Boulahya[1,2], L. Ledoux-Hutchinson[3], A. Béliveau[3], J.-N. Vallée-Trudeau[3], S. Landry[3], Y. Merhi[1,2], J.-F. Tanguay[1,2], M. Lordkipanidzé[1,3]

[1]Montreal Heart Institute, Montreal, Canada, [2]Université de Montréal, Faculty of Medicine, Montreal, Canada, [3]Université de Montréal, Faculty of Pharmacy, Montreal, Canada

Background: A large extra-cerebral pool of Brain-derived neurotrophic factor (BDNF) is found in platelets. With concentrations reaching 100-1000 fold those of neurons, platelet-stored BDNF is hypothesized to play an important role in the vasculature.

Aims: To investigate the platelet mechanisms that regulate circulating levels of BDNF in healthy volunteers and patients suffering from coronary artery disease (CAD) on dual antiplatelet therapy.

Methods: Platelet aggregation was studied in response to arachidonic acid, ADP, collagen, epinephrine and TRAP. Antiplatelet agents were added in vitro for samples obtained from healthy volunteers (aspirin, P2Y12 inhibitor AR-C66096, and GPIIbIIIa inhibitor abciximab) and in vivo for samples obtained from CAD patients.

Results: BDNF was abundant in platelets within cytoplasmic granules. Exogenous BDNF did not induce platelet aggregation, either on its own or in synergy with other agonists. All agonists induced the release of platelet BDNF. The ADP signalling pathway was an important regulator as in vitro inhibition of the P2Y12 receptor systematically reduced the release of BDNF. Inhibition of the GPIIbIIIa receptor abolished the release of platelet BDNF, thereby confirming the role of platelet aggregation in the regulation of peripheral BDNF. Baseline BDNF levels in CAD patients on dual antiplatelet therapy were similar to that of healthy volunteers. The increase in the release of platelet BDNF in response to all agonists was less important in CAD patients in comparison with healthy volunteers (Fig).

Conclusions: Platelet aggregation is required for BDNF release by platelets. The use of antiplatelet drugs, especially a P2Y12 receptor inhibitor, decreases the quantity of BDNF released by platelets. Further studies are needed to assess the clinical importance of modulating BDNF release in CAD patients, especially on cognitive function in this high-risk population for vascular cognitive impairment.

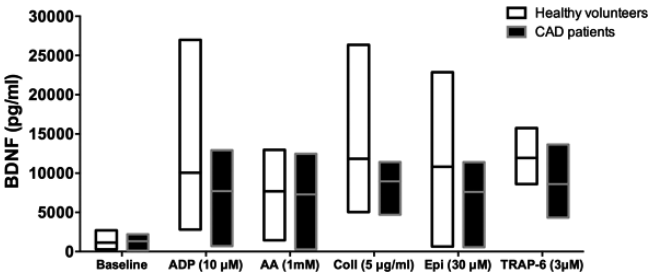

FIGURE 1 BDNF release in response to agonists in healthy volunteers and patients suffering from coronary artery disease (CAD)

PB 1567 | Clopidogrel Efficiency in Cerebral Aneurysm Stenting: Are Biological Tests Useful?

N. Ajzenberg[1,2], R. Abbas[3], F. Tubach[3], D. Faille[1,2], M.-G. Huisse[1,2], L. Ikka[4], J. Moret[4], L. Spelle[4]

[1]APHP, Hematology Bichat Hospital, Paris, France, [2]INSERM U 1148, Paris, France, [3]APHP, Epidémiologie et Recherche Clinique, Paris, France, [4]APHP, Service de Neuroradiologie Interventionnelle, Hopital Bicêtre, Kremlin Bicêtre, France

Background: Pretreatment by clopidogrel and aspirin is accepted as a standard step in cerebral aneurysm stenting in order to decrease thrombotic complications. Current pre-procedure anti-aggregant therapy protocols have been adopted from interventional cardiology. However no guidelines are clearly defined in this setting. Correlation between clopidogrel biological resistance and thrombotic risk in intracranial stent implantation is not clearly established.

Aims: To determine if the threshold of different tests evaluating biological pre-procedure clopidogrel resistance used in cardiology could be applied to cerebral aneurysm stenting to detect thrombotic risk.

Methods: We prospectively studied 111 patients scheduled for aneurysm stenting by flow diverter because of lateral aneurysm (n=78) or bifurcation (n=33). All of them were treated by clopidogrel 75 mg/day at least 5 days before the procedure. Clopidogrel resistance was evaluated by ADP (5 mM)-induced light transmitted aggregation (maximal aggregation >50% and late aggregation after 6 min >14%), VASP-Phosphorylation by flow cytometry (VASP-P >50%), VerifyNow^{å} P2Y12 (PRU>240) and shear-induced platelet aggregation (SIPA) at 4000 sec-1 >40%.

Results: A thrombotic event was reported in 12 patients (10.8%). 2 of them occurred during the procedure and the other 10 post-procedure. Biological resistance to at least one the 5 parameters tested was observed in 59.8% of the patients. Performance of the tests was evaluated. Poor sensitivity was observed: 8.3% for ADP late aggregation and SIPA and 66.7% for VASP-P. Specificity of the tests varied between 48% for VASP-P and 86.7% for VerifyNowP2Y12.

Conclusions: Biological tests evaluating pre-procedure clopidogrel efficiency in intracranial flow-diverting stent implantation are not able to predict thrombotic complications. The location and the size of the aneurysm together with procedure complexity are probably more relevant to predict thrombotic complications.

PB 1568 | Comparison of Platelet Function Tests in a Trial of Different Aspirin Dose Regimens in Type 2 Diabetes

P. Harrison[1], M.A. Bethel[2,3], I. Kennedy[2,3], S. White[2,3], R.L. Coleman[2,3], R.R. Holman[2,3]

[1]University of Birmingham, Institute of Inflammation and Ageing, Birmingham, United Kingdom, [2]University of Oxford, Diabetes Trial Unit, Oxford, United Kingdom, [3]Oxford National Institute for Health Research, Biomedical Research Centre, Oxford, United Kingdom

Background: Aspirin (ASA) efficacy is reduced in type 2 diabetes (T2D) but the best method of assessment is uncertain.

Aims: We compared six platelet function tests for the assessment of ASA responsiveness.

Methods: We examined 3 ASA dosing regimens in 24 T2D patients randomized to 2-week treatment periods in a crossover design with ASA 100mg/day, 200mg/day or 100mg twice daily. Platelet function after each regimen was compared using kappa statistics when measured with: Light transmission aggregometry (LTA-0.5mg/ml of arachidonic acid (AA) and 10µM ADP); Multiplate whole blood aggregometry (WBA-0.5mM AA and 6.5µM ADP); PFA-100-CADP and CEPI; VerifyNow ASA; Urinary 11-dehydro-thromboxane B_2 (TxB_2); Serum TxB_2. All COX-1 dependent tests and some COX-1 independent tests (PFA-CEPI, LTA-ADP) demonstrated significant reductions in platelet reactivity with all ASA doses. Two COX-1 independent tests (WBA-ADP and PFA-CADP) showed no overall reduction in platelet reactivity.

Results: Overall classifications for detecting all ASA doses, compared to baseline, were: Very good-LTA-AA (k=0.95) & VerifyNow ASA (k=0.85); Good-Serum TxB_2 (k=0.79); Moderate-LTA-ADP (k=0.59), PFA-100-CEPI (k=0.56), Urinary TxB_2 (k=0.55), WBA-AA (k=0.47); Poor-PFA-100-CADP (k=-0.02) and WBA-ADP (k=-0.07). No significant kappa statistic differences were seen for each test for each ASA dose. Correlations for each test with serum TxB_2 measurements were: Very good-VerifyNow ASA (k=0.81, R^2=0.56), LTA-AA (k=0.85, R^2=0.65); Good-PFA-100 CEPI (k=0.62, R^2=0.30); Moderate-Urinary TxB_2 (k=0.57, R^2=0.51), LTA-ADP (k=0.47, R^2=0.56); Fair-WBA-AA (k=0.31,R^2=0.31); Poor-PFA-100-CADP (k=0.04,R^2=0.003), WBA-ADP (k=-0.04, R^2=0.0005).

Conclusions: Platelet function tests are not equally effective in measuring the antiplatelet effect of ASA and correlate poorly amongst themselves. The clinical usefulness of the different assays to measure ASA responsiveness remains undetermined.

PB 1569 | The Offset of Ticagrelor Prior to Coronary Artery Bypass Graft (CABG) Surgery

K.W. Ow, M. Thomas, W. Parker, H. Judge, R. Storey

University of Sheffield, Sheffield, United Kingdom

Background: The optimal timing of discontinuation of ticagrelor prior to coronary artery bypass graft (CABG) surgery is unknown. In the ONSET/OFFSET study of patients with stable coronary artery disease, ticagrelor´s effects dissipated within 48-120 hours of discontinuation. However, there is evidence that the pharmacodynamics of antiplatelet therapy are altered during an acute coronary syndrome (ACS). Regulatory authorities recommend that ticagrelor be discontinued 5 days prior to CABG. The PLATO study showed that ticagrelor was associated with fewer deaths following pulmonary adverse events and sepsis compared to clopidogrel. It is unknown if ticagrelor‘s effect of inhibiting cellular adenosine uptake might underlie this observation.

Aims: To characterise the effect of discontinuation of ticagrelor on platelet activity and adenosine uptake inhibition.

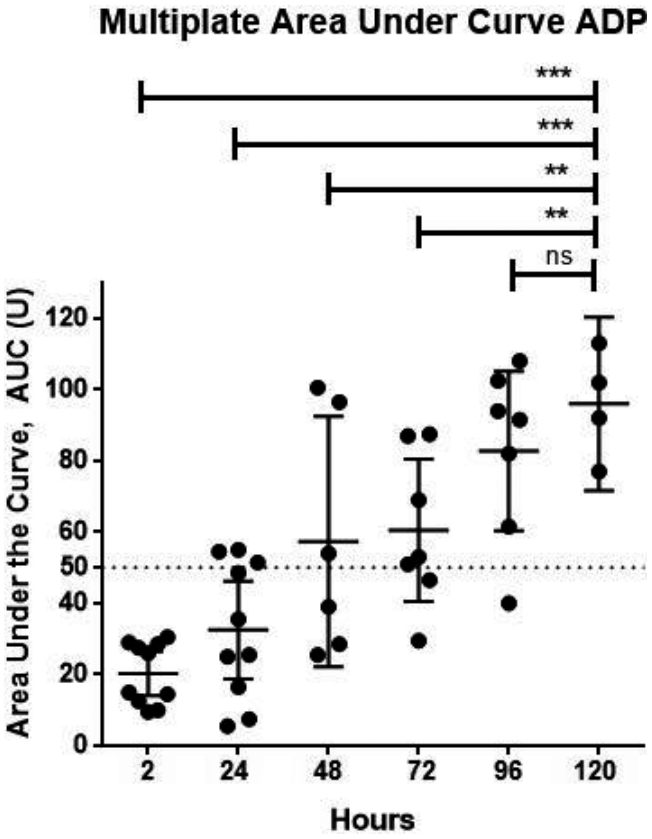

FIGURE 1 Whole-blood aggregometry data points of each patient, obtained from the Multiplate analyser and also the mean of each respective timepoint

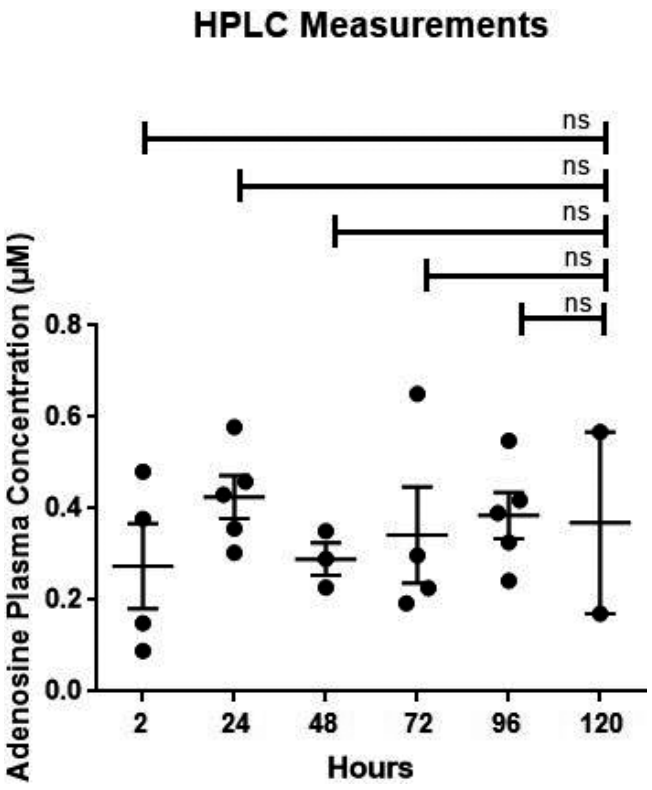

FIGURE 2 Adenosine plasma concentration data points of each patient, measured using HPLC and also the mean values of each respective timepoint

Methods: ACS patients, treated with ticagrelor and referred for CABG were recruited. Venous blood was drawn at 6 timepoints:2 hours(h), 24h, 48h, 72h, 96h, and 120h after the last dose of ticagrelor. Whole-blood aggregometry was carried out using the Multiplate analyser and the value of area under the curve (AUC)(units, U) was recorded. A protocol was referred to, where AUC of >50U supports safe progression to surgery, while values ≤50U indicate re-testing 24h later. Inhibition of adenosine uptake was determined by measuring the adenosine plasma concentration (APC).

Results: 13 patients recruited, received ticagrelor prior to CABG. At 96h post ticagrelor, the mean AUC was 82.8U, (95% confidence interval, CI, 60.4, 105.2). Only at 96h was the lower limit of the CI >50U. The comparison between 72h and 120h showed a significant difference (P=0.007) while 96h and 120h showed no significant difference. APC was measured in 7 patients and showed no significant difference across all timepoints.

Conclusions: ACS patients might be safe to undergo CABG surgery 96h after the cessation of ticagrelor. Ticagrelor might have no measurable effect on adenosine transport in ACS patients.

PB 1570 | Nanoparticle Inhibition of Shear Induced Platelet Aggregation

D.N. Ku, C. Aidun, M. Griffin, Y. Zhu, Z. Liu

Georgia Institute of Technology, Mechanical Engineering, Atlanta, United States

Background: Thrombosis in stenoses requires vWF unfolding under pathologically high shear rates with binding of platelets through A-1 (SIPA).

Aims: We hypothesize that vWF refolding and/or separation of A-1 from GPIb on platelets will prevent SIPA.

Methods: We test for SIPA in a microfluidics chamber with a stenosis shape of an atherosclerotic plaque. Whole blood is mixed with charged nP, ~ 60 nm. Occlusion time (OT) is measured in normal controls, then with + and - charged nP.

We then studied vWF -platelet interaction under high shear rates through a simulation using Lattice-Boltzman computational fluid dynamics. This multiscale study simulates the interaction of vWF polymers with nanoparticles (nP) under high shear conditions and vary the charge density.

Results: Experimental SIPA was rapid under high shear for normal controls and positively-charged nP (OT=200 +/- 10 s). Negatively-charged nP exhibited a significant lengthening of OT (1100 +/- 300 s, n=4, p< 0.05). The effect was dose-dependent and charge-dependent. Computational modeling showed that negatively-charged nP can cause shear-elongated vWF molecules to roll back to a globular form provided the charge is high enough. This configuration change was dependent on nP charge and charge density.

Figure 1. nP (red) and vWF (blue) in shear flow (6500 1/s) with arrows showing flow direction. vWF fully elongates in shear flow; then - nP adhere to positive A1 patch to create a fold (middle) and roll up the elongated vWF back into globular state (bottom).

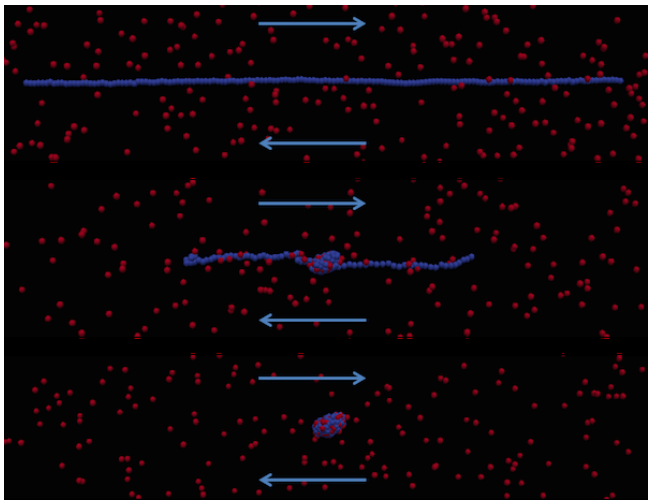

FIGURE 1 nP (red) and vWF (blue) in shear flow (6500 1/s). vWF elongates in shear; then - nP adhere to + A1 to fold and roll vWF into globular state

Conclusions: Negative nP can significantly inhibit the formation of arterial-type thrombus under pathologically high shear rates. The particles alter the shear threshold of vWF unfolding by physical interactions between domains under hemodynamic conditions. The particles may further inhibit vWF-platelet binding by physical steric separation. The demonstration of reduction in SIPA by nanoparticles opens up a new class of possible anti-platelet therapeutics based on physics instead of chemical mechanisms.

PB 1571 | Plasma Fibrinogen Level is an Important Determinant of Platelet Reactivity in the VerifyNow Assay

A. Dobrovolsky[1], P. Laguta[1], E. Titaeva[1], E. Guskova[1], E. Yarovaya[2], E. Panchenko[1]

[1]Russian Cardiology Research and Production Complex, Moscow, Russian Federation, [2]Lomonosov Moscow State University, Faculty of Mechanics and Mathematics, Moscow, Russian Federation

Background: The VerifyNow assay is based upon the ability of activated platelets to cross-link beads coated with fibrinogen (Fg). However, Fg is abundant protein of blood, and therefore it may affect test results by competing with Fg of beads for binding to activated platelets.

Aims: The objective of this study was to assess the influence of artificial alteration of Fg level in blood on platelet reactivity measured by the VerifyNow $P2Y_{12}$ assay.

Methods: A 10 ml samples of citrate blood were obtained from donors (n=9) and patients on clopidogrel therapy (n=8), who provided informed consent to participate in the study. Then each blood sample was divided into 3 portions: baseline and two aliquots in which Fg level was altered by adding either 1/10 volume of purified Fg solution (10.6 g/l, clotting ≥95%) or corresponding buffer. In these samples we measured indices of platelet reactivity (Base and PRU) using the VerifyNow $P2Y_{12}$ cartridges and concentration of Fg by the clotting assay of Clauss. For each studied individual we then calculated magnitudes of change in platelet reactivity values (dBase and dPRU) and Fg concentration (dFg) by subtracting from baseline value those, which were measured after addition of Fg or buffer.

Results: Relative to baseline, addition of buffer significantly increased platelet reactivity, whereas addition of fibrinogen decreased it. Analysis of the relationship between change of platelet reactivity values and change in fibrinogen concentration revealed strong negative correlations: dBase = -63.3xdFg-27.1 (r=-0.924, p< 0.0005) and dPRU= -54.4xdFg-21.8 (r= -0.764, p< 0.0005).

Conclusions: Thus, our experiments demonstrated that: (1) the VerifyNow $P2Y_{12}$ assay is significantly influenced by Fg level in analyzing samples; (2) this effect of Fg is an *in vitro* phenomenon; (3) correcting for fibrinogen effect may be needed to improve the accuracy of the test in the measuring of antiplatelet effect of clopidogrel therapy.

PB 1572 | Effects of Clopidogrel with or without Aspirin on the Generation of Extracellular Vesicles in the Microcirculation and in Venous Blood in Healthy Young Males

L. Traby[1], A. Kaider[2], M. Kollars[1], S. Eichinger[1], M. Wolzt[3], P.A. Kyrle[1]

[1]Medical University of Vienna, Department of Medicine I, Division of Hematology and Hemostasis, Vienna, Austria, [2]Medical University of Vienna, Center for Medical Statistics, Informatics and Intelligent Systems, Institute of Clinical Biometrics, Vienna, Austria, [3]Medical University of Vienna, Clinical Pharmacology, Vienna, Austria

Background: Dual anti-platelet therapy with clopidogrel (C) and aspirin (A) protects from arterial thrombosis but confers a considerable bleeding risk. Extracellular vesicles (EV) are prothrombotic. We tested the hypothesis that C+A has a stronger effect on EV generation than C alone.

Aims: To compare the effects of C+A and C alone on EV generation in blood obtained from the microvasculature and in venous blood.

Methods: In a prospective, randomized, double-blind, placebo-controlled trial 44 healthy males (mean age: 26 years) received either C (600mg loading dose, 150mg maintenance dose daily) + A (100mg daily) or C alone over 7 days. Blood was obtained from a microvascular injury (bleeding time incision) and by venipuncture at baseline (BL), 2h, 24h and 8 days. The number of EV was assessed by FACS (FACSCalibur®, Becton Dickinson). EV were defined by size (forward scatter, < 1 µm) and annexin V binding and labeled using antibodies (anti-CD41a: platelet positive EV [PLT+EV]; anti-CD142: TF positive EV [TF+EV]). Data are given as median (quartiles). The Wilcoxon signed rank test was used for short-term treatment effect (BL vs 2h), the Wilcoxon rank sum test for differences between groups (A vs placebo). AUC was used to discriminate the difference in effects over time (Wilcoxon rank sum test).

Results: EV generation was similar in subjects treated with C+A or C (both in shed blood and in venous blood) when levels at BL and

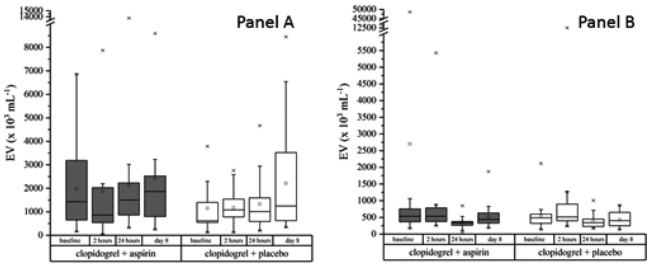

FIGURE 1 Effects of clopidogrel (C) + aspirin (A) and of C on the generation of microvascular EV (Panel A) and on venous EV (Panel B).

2h were compared [shed blood: C+A: 1433 (653; 3184) vs 862 (545; 2026), p=0.4; C: 614 (552; 1402) vs 1079 (781; 1538), p=0.7; venous blood: C+A: 532 (369; 754) vs 534 (375; 782), p=0.91; C: 486 (322; 597) vs 514 (399; 897), p=0.17]. There was also no difference in the effects of C+A and C alone on EV generation in shed- or venous blood over 24 hours and 8 days (Fig. 1).

Conclusions: Neither C+A, nor C alone affected EV generation in the microvasculature or in venous blood.

PB 1573 | Assessment of Low Platelet Reactivity (LPR) with Multiple Electrode Impedance Aggregometry (MEA) and Risk of Bleeding in Patients Receiving P2Y12 Receptor Inhibitors

D. Dineva, I. Paskaleva, B. Baycheva, N. Gocheva, G. Georgiev, E. Trendafilova

National Heart Hospital, Clinical Laboratory, Sofia, Bulgaria

Background: Antiplatelet therapy with P2Y12 inhibitors recommended in patients undergoing percutaneous coronary intervention (PCI) is associated with an increased risk for bleeding. Patients with LPR show a 1,7-fold higher risk for major bleeding complications.

Aims: To evaluate the proportion of patients with LPR and bleeding receiving P2Y12 receptor inhibitors - clopidogrel, prasugrel and ticagrelor and to determine the cut-off value of LPR for risk of bleeding.

Methods: The platelet function was assessed with MEA on Multiplate analyzer by ADP-test in 3760 patients who underwent PCI with stent implantation in for period of 4 years. Patients were treated with 75 mg/d clopidogrel, or 10 mg/d prasugrel, or 2 x 90 mg/d ticagrelor.

Results: We found TIMI minor bleeding complications like cutaneos haematoma, epistaxis, haemoroidal bleeding and hemoptoe in 0.6% of patients as maintenance therapy per year. The mean value of ADP-induced platelet aggregation in the subgroup of patients on clopidogrel therapy with bleeding was 12 ± 6,9 U vs. 22 ±10 U in the group of patients with good response without bleeding. In the subgroups of patients on prasugrel and ticagrelor therapy with bleeding ADP -induced platelet aggregation was 9,3 ± 6,4 U and 10,7 ± 6,4 U, respectively. Antiplatelet therapy in patients with bleeding was adjusted with decreasing of the daily dose of P2Y12 inhibitors or switched to another P2Y12 inhibitor. Tailored treatment leads to optimal level of ADP inhibition and decreasing of the bleeding.

Conclusions: ADP-test < 15 U has been associated with increasing risk of minor bleeding; LPR predicts a higher risk for bleeding complications. There were no differences in MEA values in patients with bleeding complications between used P2Y12 inhibitors. Tailored antiplatelet therapy into the optimal range of platelet reactivity, based on standardized platelet functional assay reduces the risk of secondary bleeding events.

PB 1574 | Concomitant Use of Antiplatelet and Direct Oral Anticogulants Increase but Not Significantly the Bleeding Risk in Patients with Atrial Fibrilation

J.J. Cerezo-Manchado, B. Navarro-Almenzar, A. Maritnez-Marin, F. García-Candel, V. Cabañas, D. Iyu, N. Marin, M. Blanquer, A.B. Martinez-Garcia, S. Eduardo, J.M. Moraleda

University Hospital Virgen de la Arrixaca, IMIB-Arrixaca, Murcia University, Murcia, Spain

Background: Direct oral anticoagulants (DOACs) are a very useful drugs in prevention of thromboembolic events for patients with atrial fibrillation due to the excellent safety profile has presented in clinical trials and real life studies. However these patients sometimes need to take antiplatelet in combination with these drugs increasing the bleeding risk.

Aims: The objective of this study was analyze if the antiplatelet use in combination with DOACs is associated with a significantly elevation of the bleeding risk.

Methods: A retrospective study was conducted of patients who were treated with DOACS in our unit from 2011-2016. Data were obtained from our hospital register that has local committee approval. Patients were followed until discontinuation drug or to the last follow. Dose of DOACS was chosen to clinical judgment. The main variable investigated were the percentage of mayor bleedings. Major bleeding was defined according to the criteria of the ISTH 2005. Statistical analyzes were performed using SPSS 21.0 (SPSS Inc.,Chicago, IL). All the confidence interval was at 95%.

Results: A total of 514 patients were finally included with 74(73-75) years old. Gender was female in 301(58.6%) patients. Mean of CHA2DS2-VASc and HAS-BLED was 3,9(3.8-4.1) and 2.5(2.4-2.6) points respectively. Patients used antiplatelets and DOACs were 59(11,5%). Mean follow-up was 1,2(1.0-1.3) years. The number of patients with a mayor bleeding in the concomitant group was 6(10%) compare with control group 22(4.9%). In univariate analyze this different was not significant, p value equal to 0.101, despite the concomitant group had an odds ratio 2.1(0.8-5.6) times superior to suffer a mayor bleeding.

Conclusions: The use of antiplatelet therapy with DOACs has been described like a factor to increase bleedings in some studies. In our case we showed a double risk of bleeding in this kind of patients

however without a significant outcome, may be due to we need more patients in the case group.

PB 1575 | Arginine-containing Oligopeptides as Antiplatelet Agents Under Experimental Type-2 Diabetes Mellitus

M. Grigorjeva, L. Luapina

Lomonosov Moscow State University, Biology, Lab. Blood Coagulation, Moscow, Russian Federation

Background: The correlation between high blood glucose level and dysfunction of the anticoagulation system has been identified. In addition to hyperglycemia, increase in platelet aggregation (PA) was observed under diabetes mellitus. It has previously been shown that oligopeptides have anticoagulant and antiplatelet effects in organism. Also it is known that arginine improves rheological properties of blood and inhibits platelet aggregation. Special attention is drawn to regulatory oligopeptides with the addition of arginine to their molecules.

Aims: The study of arginine-containing oligopeptides Arg-Pro-Gly (RPG), Pro-Arg-Gly (PRG) and Pro-Gly-Pro-Arg (PGPR) influence on ADP-induced PA (ADP-PA) under development of experimental type-2 diabetes mellitus (T2DM) in rats.

Methods: All experiments were carried out on male Wistar rats and were conformed with the Declaration of Helsinki. Experimental T2DM was induced by intragastrically administration of 40% glucose solution (2g/kg) for 10 days. After that the rats intranasally administrated the peptides (1000 μg/kg) for 6 days with continued glucose administration. Control T2DM rats was administrated saline. Blood for measuring of ADP-PA was collected 1h after the last peptides injection and 7 days after peptides withdrawal.

Results: The studied peptides decreased ADP-PA during all time of experiments. PRG, RPG and PGPR lead to ADP-PA decrease 1h after the last peptide injection on 55, 38, 30% accordingly. These effects were observed after peptides withdrawal: ADP-PA decreased on 57, 42, 44% vs. control. PRG had maximal antiplatelet effect.

Conclusions: Thus arginine-containing oligopeptides have protective antiplatelet effects against enhanced rat PA induced by a continuous glucose load. These effects were preserved after peptides withdrawal, that indicate prolonged effects of peptides. We conclude that arginine-containing oligopeptides RPG, PRG and PGPR could potentially used as antiplatalet agents against hypercoagulation due to the development of experimental T2DM.

PB 1576 | Combined Effect of *CYP2C19* G681A Polymorphism and Plateletcrit on Clopidogrel Low-responsiveness in Thai Patients with Acute Coronary Syndrome

S. Jirungda[1,2], N. Komanasin[2,3], V. Senthong[2,4], B. Pussadhamma[4], P. Makarawate[2,4], K. Anutarapongpan[5], D. Kaewkes[5]

[1]*Khon Kaen University, Biomedical Sciences, Graduate School, Khon Kaen, Thailand,* [2]*Khon Kaen University, Cardiovascular Research Group, Khon Kaen, Thailand,* [3]*Khon Kaen University, Faculty of Associated Medical Sciences, Department of Clinical Microscopy, Khon Kaen, Thailand,* [4]*Khon Kaen University, Faculty of Medicine, Department of Medicine, Khon Kaen, Thailand,* [5]*Queen Sirikit Heart Center of the Northeast Hospital, Khon Kaen, Thailand*

Background: The *CYP2C19* G681A (rs4244285) polymorphism, platelet indices, high platelet reactivity, and clopidogrel low-responsiveness have been shown to predict the major adverse cardiovascular events (MACEs) in patients with acute coronary syndrome (ACS). However, the relationship between platelet indices and clopidogrel responsiveness is unclear.

Aims: To investigate the combined effect of *CYP2C19* G681A polymorphism and platelet indices on clopidogrel responsiveness in Thai ACS subjects.

Methods: A total of 56 ACS subjects treated with clopidogrel were recruited. Polymorphism of *CYP2C19* G681A was determined by polymerase chain reaction-restriction fragment length polymorphism techniques. Platelet reactivity in term of closure time (CT) was measured by using platelet function analyzer-200 (PFA-200). The CT ≤ 106 and exceeding 106 seconds were classified as clopidogrel low-responder and responder, respectively. Platelet indices were examined by automated analyzer XE-2100 (Sysmex, Japan).

Results: Individual with 681AA revealed significantly lower CT compared to 681GA and 681GG (p=0.002 and 0.001, respectively). However, no significant influence of the carrier of G681A on clopidogrel low-responder when compared to 681GG (p=0.051). Among platelet indices, only plateletcrit (PCT) revealed a significant increase in clopidogrel low-responder compared to clopidogrel responder group (p=0.034). Based on ROC analysis, PCT at the cutoff point of 0.2 could predict clopidogrel low-responder with a sensitivity of 57.5% and a specificity of 66%. However, no significant influence of PCT > 0.2 on clopidogrel low-responder when compared to PCT ≤ 0.2 (p=0.080). Interestingly, when combined 681GA or AA with PCT > 0.2, the result revealed an increased risk of clopidogrel low-responsiveness compared to the group with 681GG + PCT ≤ 0.2 [OR (95% CI) = 4.3 (1.1, 16.5)].

Conclusions: These findings suggested that the combination of *CYP2C19* G681A polymorphism with PCT enhance risk of clopidogrel low-responsiveness in Thai ACS subjects.

PB 1577 | Inhibition of Platelet Aggregation by Fibrinogenase from the Antarctic Scallop *Adamussium colbecki*

N. Raksha, D. Gladun, L. Ostapchenko

Educational and Scientific Center ‚Institute of Biology and Medicine' Taras Shevchenko National University of Kyiv, Kyiv, Ukraine

Background: Thrombolytics have been extensively used in the therapeutic treatment of thrombosis. Fibrinogenases because of their role

in dissolving of blood clots as well as prevention their formation have attracted special medical and scientific attention. Enzymes that affect hemostasis have been isolated from different sources. Now special attention is paid to the hydrobionts from the Antarctic region which are poorly explored and potentially can be a valuable source of new bioactive compounds.

Aims: We test the effect of fibrinogenase from *A. colbecki* on platelet aggregation.

Methods: For estimating fibrinogenolytic activity fibrinogen was incubated with enzyme at 100:1 ratio at different time intervals. The fibrinogen digestion was analyzed by polyacrylamide gel electrophoresis (SDS-PAGE) under reducing conditions. Platelet aggregation was determined using aggregometer.

Results: Fibrinogenase was isolated using affinity and size exclusion chromatography which provided a high level of homogeneity as confirmed by SDS-PAGE. Purified fibrinogenase directly degraded fibrinogen. Susceptibility of fibrinogen chains to proteolysis was different - the enzyme cleaved preferentially Aα-chain and more slowly Bβ-chain. Furthermore, fibrinogen hydrolysis occurred in a concentration-dependent manner. Taking into account that fibrinogen is an essential for platelet aggregation we tested whether fibrinogenase from *A. colbecki* could affect platelet aggregation. According to our result investigated enzyme inhibited ADP-induced platelet aggregation and the inhibition increased with increasing concentration of the enzyme. Data analysis revealed inhibition of platelet aggregation by 80% for 12.5 µg/mL fibrinogenase and by 31% for 6.25 µg/mL fibrinogenase.

Conclusions: We hypothesized that fibrinogenase may inhibit platelet aggregation by hydrolyzing the Aα-chain of fibrinogen to prevent fibrinogen from combining with fibrinogen receptor on platelet membrane.

PB 1578 | Platelet (plt) reactivity in patients with essential thrombocythemia (ET) receiving antiplatelets therapy with aspirin (ASA)

S. Gamba[1], M. Marchetti[1], A. Vignoli[1], L. Russo[1], C.J. Tartari[1], C. Giaccherini[1], C. Verzeroli[1], F. Marchesi[1], G. Finazzi[2], A. Rambaldi[2], A. Falanga[1]

[1]*ASST Papa Giovanni XXIII, Immunohematology and Transfusion Medicine, Bergamo, Italy,* [2]*ASST Papa Giovanni XXIII, Hematology, Bergamo, Italy*

Background: Antithrombotic prophylaxis with ASA (100 mg/o.d.), alone or in combination with hydroxyurea (HU) cytoreductive therapy, is widely used in ET to prevent thrombosis and control microcirculatory symptoms. A recent study suggested that in these patients twice-daily 50 mg ASA may be more effective than 100 mg/o.d.. The effect of daily versus twice-daily ASA on platelet reactivity is unknown in ET.

Aims: To evaluate by multiple electrode aggregometry (MEA) the influence of ASA therapy ±HU on platelet aggregation in ET patients.

Methods: We compared platelet response to Arachidonic acid (ASPI test) and thrombin receptor activating peptide (TRAP test) in 65 ET patients. Control groups were: 72 non-ET patients on chronic ASA prophylaxis, and 111 healthy subjects (CTR). A cutoff value of < 30U in ASPI test was used to identify the response or not to the antiplatelet effect of ASA. A normalized AA-induced aggregation (r-AA-agg), defined as ASPI/TRAP ratio, was calculated to reflect individual variation to ASA.

Results: In ET patient group TRAP values, but not ASPI values, were significantly higher ($p < 0.001$) compared to CTR. Analysis of ET patients according to treatment, showed that ASPI values in ASA±HU-treated ET patients (n=45) were significantly lower ($p < 0.001$) compared to non-ASA-treated ET patients (n=20), while were significantly higher ($p < 0.001$) compared to ASA-treated non-ET patients. Only 11 (5 on ASA alone and 6 on ASA+HU) out of 45 ET patients (24.4%) responded to ASA treatment, showing ASPI values < 30U. Differently, 94 % of non ET-patients on ASA responded (i.e. ASPI values < 30U). Same results were obtained with the r-AA-agg, with ASA±HU-treated ET patients being less responsive than non-ET ASA-treated group.

Conclusions: MEA is a rapid method to evaluate the response to antiaggregating treatment. The results show a greater sensitivity of ET platelet to aggregating stimuli compared to non-ET patients on ASA. This may account for failure of the antithrombotic prophylaxis observed in these patients.

PB 1579 | The Influence of Prostaglandin E1 on the Correlation between the Multiple Electrode Aggregometry ADP and the VerifyNow P2Y12 Test in Patients Using P2Y12 Inhibitors

P.W.M. Verhezen[1], M.J.A. Vries[2], M.J.J. Haartmans[2], R.J.H. Wetzels[3], C.G.M. van Oerle[2,3], Y.M.C. Henskens[2,3]

[1]*Maastricht University Medical Centre+, Central Diagnostic Laboratory, Maastricht, The Netherlands,* [2]*Maastricht University, Biochemistry, Maastricht, The Netherlands,* [3]*Maastricht University Medical Centre +, Central Diagnostic Laboratory, Maastricht, The Netherlands*

Background: Platelet function tests, such as the Multiplate (MADP) and the VerifyNow P2Y12 (VNP2Y12), can be used to determine platelet reactivity in patients on P2Y12-inhibitors, which has been shown to be related to the risk of adverse events. However, correlation and agreement between therapeutic windows of these tests are poor. Both assays stimulate platelets with ADP. However, in the VNP2Y12, prostaglandin E1 (PGE1) is added to block the activation of the P2Y1 receptor by ADP, but PGE1 is not present in MADP.

Aims: We assessed if addition of PGE1 to MADP could improve the correlation between MADP and VNP2Y12.

Methods: Sixty patients with coronary artery disease on dual antiplatelet therapy (P2Y12-inhibitor, ascal) were included. Platelet function testing was performed 30-60 days after percutaneous intervention to help guide antiplatelet therapy. Forty patients used clopidogrel, 16 prasugrel and 4 ticagrelor. The MADP (6.5 µM ADP) and the VNP2Y12 (20 µM ADP/22 nM PGE1) were performed for clinical care purposes, addition of the PGE1 (9.4 nM) to the MADP was performed for research purpose only, in accordance with local medical ethical guidelines.

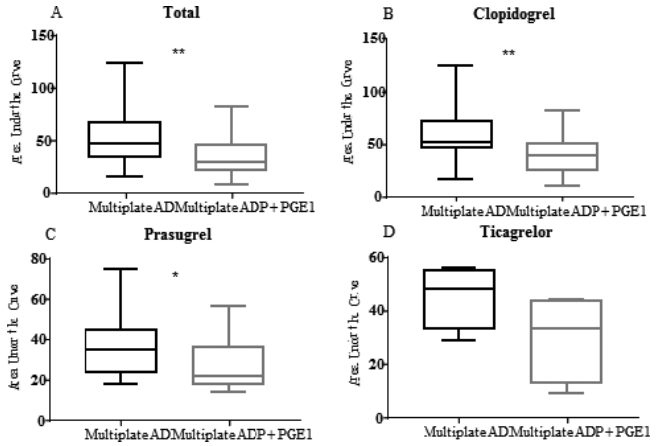

FIGURE 1 (A-D): Comparison of median area under the curve (AUC) MADP without PGE1 versus median AUC MADP with addition of PGE1

Results: In the total-, the clopidogrel-, and prasugrel group, the median of MADP with addition of PGE1 was significantly lower than the median of MADP without PGE1 (29.5 vs 47.0; 38.0 vs 51.0; and 22.0 vs 35.0 ($P < 0.05$), respectively. (Figure 1 A-C). The ticagrelor group showed the same trend (with PGE1 (33.5), without PGE1 (48.0)), however this was not significantly different (P=0.125) (Figure 1 D). Addition of PGE1 to MADP did not increase the correlation between MADP and VNP2Y12 (Table 1).

TABLE 1 Spearman correlation of MADP (without and with PGE1) versus VNP2Y12.

	Total Group (n=60)	Clopidogrel group (n=40)	Prasugrel group (n=16)
Correlation (r) MADP without PGE1 vs VNP2Y12	0.646	0.579	0.642
Correlation (r) MADP with PGE1 vs VNP2Y12	0.530	0.558	0.200

Conclusions: In patients on P2Y12-inhibitors, addition of PGE1 to MADP lowered the platelet reactivity, but did not improve the correlation between MADP and VNP2Y12. Therefore, the presence of PGE1 in the VNP2Y12, but not in the usual MADP assay, cannot explain the poor correlation and agreement between therapeutic windows of these tests.

PB 1580 | Could Aspirin Play a Role in Diminishing ADP Induced Platelet Aggregation in Clopidogrel Naïve Patients?

S. Georgantis, G. Soufla, M. Katafygioti, T. Kanellopoulou, T. Kostelidou

Onassis Cardiac Surgery Center, Laboratory of Coagulation and Haemostasis, Athens, Greece

Background: Platelet aggregation by ADP, collagen, l-epinephrine, and thrombin suggests a physiological process in blood coagulation. Excessive platelet aggregation is acknowledged to be responsible for the formation of thrombus on the coronary artery wall leading to acute coronary syndrome (ACS) or acute myocardial infarction. Antiplatelet treatment with aspirin and/or clopidogrel inhibits platelet aggregation protecting from possible thrombotic events. Aspirin blocks cyclooxygenase 1 (COX-1) and therefore thromboxane A2 (TXA2) generation while clopidogrel blocks the ADP-P2Y12-dependent platelet activation pathway.

Aims: To evaluate the platelet function of high risk patients for an acute coronary syndrome, or patients undergoing percutaneous coronary interventions (PTCI), that receive anti-platelet treatment at the Onassis Cardiac Surgery Center over a six-month period.

Methods: Laboratory assessment of platelet function was based on platelet aggregation tests performed by the in vitro addition of ADP, Collagen, Ristocetin and Arachidonic acid as aggregating agents on a BIODATA platelet aggregometer.

Results: A total of 500 platelet aggregation assays were performed at the Laboratory of Coagulation and Haemostasis of the Onassis Cardiac Surgery Center over a six-month period. In 35 cases of aspirin-only treated patients, we observed a diminished ADP-induced platelet aggregation ranging from 33% to 50% of normal aggregation for each patient.It has been reported that blocking of lectin-like oxidized low-density lipoprotein (LDL) receptor-1 (LOX-1) inhibits ADP-induced aggregation. Platelet treatment with aspirin has been shown to reduce LOX-1 expression and to inhibit ADP-induced aggregation.

Conclusions: We can only speculate that antiplatelet treatment with aspirin in our patients may have affected ADP-induced aggregation through down regulation of LOX-1 expression; however further in depth studies are required to elucidate the possible role of aspirin in the diminished ADP-induced aggregation observed.

PB 1581 | Obesity Is Associated with Reduced Platelets SERCA3 Isoform Expression and Subsequent Platelet Inhibition, Reversible after Weight Loss

R. Bobe[1], Z. Elaïb[1], M. Coupaye[2], J.J. Lopez[1], C. Repererant[1], A. Kondriateff[1], Y. Becker[1], M. Pépin[3], F. Teillet[4], D. de Prost[4], A. Stepanian[5,6]

[1]INSERM, U1176, Le Kremlin-Bicêtre, France, [2]Hôpital Louis Mourier (AP-HP) - Université Paris Diderot, Explorations Fonctionnelles, Colombes, France, [3]Hôpital Ambroise Paré (AP-HP), Court Séjour Gériatrique, Boulogne-Billancourt, France, [4]Hôpital Louis Mourier (AP-HP) - Université Paris Diderot, Hématologie et Transfusion, Colombes, France, [5]APHP - Hôpital Lariboisière, Hematology, Paris, France, [6]Institut Universitaire d'Hématologie, EA3518, Paris, France

Background: In obese subjects, platelet activity is described as increased and their sensitivity to antiplatelet agents as reduced. We previously observed that platelet Sarco/Endoplasmic Reticulum Ca2+ ATPase (SERCA3) expression was decreased in patients with morbid obesity when compared to non-obese subjects, in conjunction with reduced sensitivity to agonists and lower calcium response of platelets.

Aims: To explore these dysfunctions after weight loss.

Methods: Monocentric case/control study (2011-2014). Cases (women with body mass index (BMI) ≥35 kg/m^2, without hypertension, diabetes, dyslipidemia, cancer, sepsis or inflammation) and Controls (women with BMI >18.5 and < 25 kg/m^2, without same exclusion criteria) were matched for age ± 3 years. Each pair of subjects

Time	1 Controls n=40	1 Cases n=40	p	2 Controls n=40	2 Cases n=40	p
Age (years)	39.3 ± 9.6	36.4 ± 9.5	0.9			
BMI (kg/m²)	21.4 ± 1.9	44.1 ± 6.5	<10⁻³	21.4 ± 2.1	30.7 ± 7.0	<10⁻³
Platelets (Giga/L)	243 ± 49	284 ± 42	0.002	244 ± 56	269 ± 69	0.1
Fibrinogen (g/L)	2.8 ± 0.4	4.0 ± 0.9	<10⁻³	2.8 ± 0.6	3.3 ± 0.9	0.01
CRP (mg/L)	2.2 ± 1.3	13.2 ± 8.7	<10⁻³	2.4 ± 1.4	5.1 ± 10.7	0.2

FIGURE 1 Clinical and laboratory data of study population at inclusion (time 1) and one year after bariatric surgery in cases (time 2). p with Studen

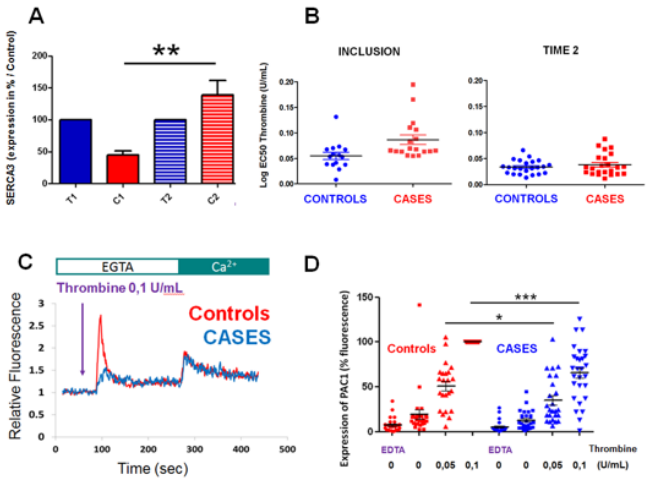

FIGURE 2 (A) SERCA3 expression in cases at inclusion (C1) is decreased when compared to controls (T1) and is increased after weight loss (C2). (B) At

has been seen twice: at inclusion and 1 year after gastric bypass surgery in case. SERCA levels were measured by immunoblotting. Aggregation was examined under magnetic agitation conditions in washed platelets stimulated with various agonists. Activity of thrombin-stimulated platelet was measured by flow cytometry using PAC-1. BAPTA Oregon-green (calcium fluorescent marker) loaded platelets were analyzed for calcium mobilization and influx in response to different agonists by flow cytometry and video microscopy.

Results: We included 40 cases and 40 controls, with one-year follow-up after bariatric surgery in cases (Figure 1).

After weight loss, platelet SERCA3 expression, calcium mobilization in response to agonists (Thrombin, collagen, PAR4-AP) and platelet aggregation was normalized when compared to control subjects (Figure 2).

Conclusions: This is the first report of a human pathophysiological condition, associated with a platelet SERCA3 deficiency. In obese subjects, these dysfunctions are reversible and normalized after weight loss. We suggest that SERCA3 decrease might be a physiological response to reduce the rate of spontaneous activation of platelets.

PB 1582 | Patterns and Levels of Platelet Glycosylation in Patients with Coronary Heart Disease and Type 2 Diabetes Mellitus

L. Li, C. Qu, X. Wu, J. Dai, Y. Lu, Y. Gong, R. You, Y. Liu

Peking University First Hospital, Clinical Laboratory, Beijing, China

Background: Coronary heart disease(CHD) and diabetes mellitus(DM) have high reactivity of platelets and an increased risk of thrombosis. Platelets play an important role in the pathogenesis of the underlying atherosclerotic process. Platelet glycosylation is closely related to platelet function and survival. However, the alteration of platelet glycosylation in CHD and T2DM still remains unknown.

Aims: The aim is to evaluate the patterns and levels of platelet glycosylation in patients with CHD or T2DM and to investigate the relationship between them.

Methods: Platelet samples were obtained from 55 healthy controls and 102 patients (including 33 CHD, 30 T2DM, 39 CHD complicated with T2DM (CHD+T2DM). Platelet glycosylation was detected using eight-lectin based assay by flow cytometry. Platelet activation (CD62P and PAC-1) was measured on resting and stimulated conditions by flow cytometry. Platelet aggregation was measured by light transmission aggregometry.

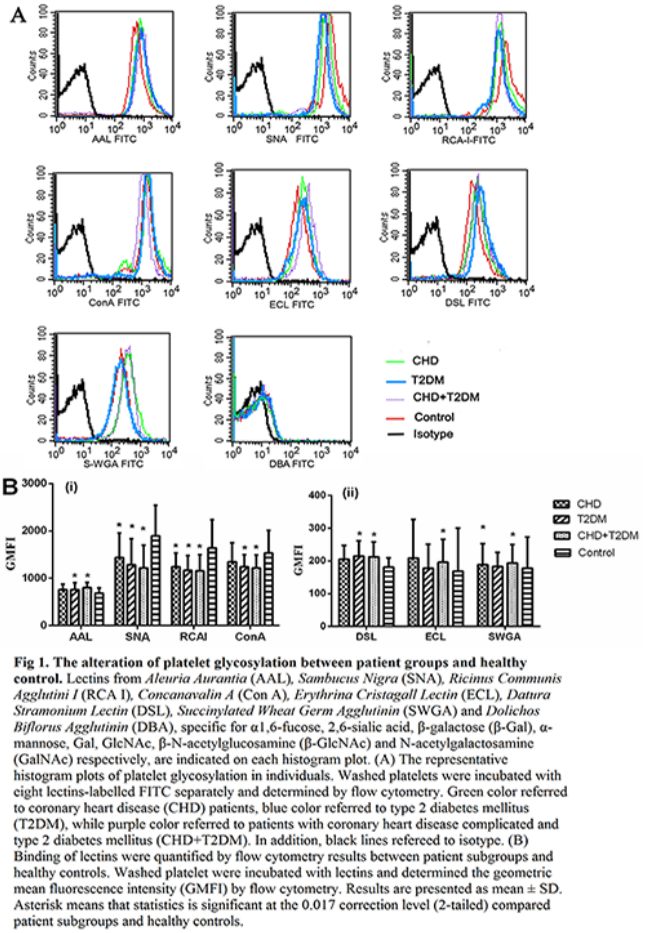

Fig 1. The alteration of platelet glycosylation between patient groups and healthy control. Lectins from *Aleuria Aurantia* (AAL), *Sambucus Nigra* (SNA), *Ricinus Communis Agglutini I* (RCA I), *Concanavalin A* (Con A), *Erythrina Cristagall Lectin* (ECL), *Datura Stramonium Lectin* (DSL), *Succinylated Wheat Germ Agglutinin* (SWGA) and *Dolichos Biflorus Agglutinin* (DBA), specific for α1,6-fucose, 2,6-sialic acid, β-galactose (β-Gal), α-mannose, Gal, GlcNAc, β-N-acetylglucosamine (β-GlcNAc) and N-acetylgalactosamine (GalNAc) respectively, are indicated on each histogram plot. (A) The representative histogram plots of platelet glycosylation in individuals. Washed platelets were incubated with eight lectins-labelled FITC separately and determined by flow cytometry. Green color referred to coronary heart disease (CHD) patients, blue color referred to type 2 diabetes mellitus (T2DM), while purple color referred to patients with coronary heart disease complicated and type 2 diabetes mellitus (CHD+T2DM). In addition, black lines refereed to isotype. (B) Binding of lectins were quantified by flow cytometry results between patient subgroups and healthy controls. Washed platelet were incubated with lectins and determined the geometric mean fluorescence intensity (GMFI) by flow cytometry. Results are presented as mean ± SD. Asterisk means that statistics is significant at the 0.017 correction level (2-tailed) compared patient subgroups and healthy controls.

FIGURE 1 The alteration of platelet glycosylation between patient groups and healthy control

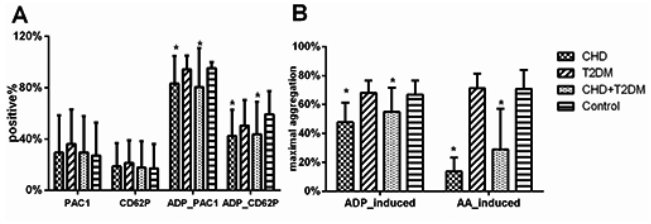

Fig 2. Platelet activation and aggregation between patient groups and healthy controls. (A) The activation was detected in resting and ADP-stimulated platelets. The levels of platelets activation analyzed on flow cytometry and were expressed as the percentage of CD62P or PAC-1 positive platelets. Activation of platelet on resting and stimulated in vitro by flow cytometry. (B) ADP- and AA-induced platelet aggregation by LAT. The maximal amplitude (%) was as equal as maximal aggregation. Results are presented as mean ± SD. Asterisk means that statistics is significant at the 0.017 correction level (2-tailed) compared patient subgroups and healthy controls.

FIGURE 2 Platelet activation and aggregation between patient groups and healthy controls

Results: In CHD group, platelet surface weakly expressed β-Gal and 2,6-sialic acid and strongly expressed β-GlcNAc. In T2DM group, lectins binding to platelet of β-Gal, 2,6-sialic acid and α-mannose were decreased, while α1,6-fucose and GlcNAc were increased. There was positive correlation between ConA (specific for α-mannose) and PAC-1 in T2DM patients, while negative correlation in healthy controls. Patterns and levels of platelet glycosylation in CHD + T2DM group are a combination of CHD group and T2DM group, in addition to the level of ECL highly elevated (specific for β-Gal). The level of ConA was significantly correlated with glucose in T2DM group, also correlated with HbA1c in CHD+T2DM group.

Conclusions: Our findings suggested that platelets decreased in sialylation, galactosylation and mannosylation, and increased in fucosylation and GlcNAcylation in CHD and T2DM patients. The changes of platelet glycosylation may be associated with high platelet reactivity, leading to the increased risk of thrombosis in CHD and T2DM.

PB 1583 | Hemostatic Abnormalities in Patients with Ehlers-Danlos Syndrome

M. Abbattista[1], A. Artoni[1], B. Marinelli[2], A. Lecchi[1], S. Lamarca[1], A. Bassotti[2], I. Martinelli[1]

[1]Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, U.O.C. Ematologia non Tumorale e Coagulopatie, Milan, Italy, [2]U.O.C. Medicina del Lavoro, Fondazione IRCCS Ca' Granda - Ospedale Maggiore Policlinico, Medicina Preventiva, Milan, Italy

Background: The Ehlers-Danlos Syndrome (EDS) represents a heterogeneous group of disorders of the connective tissue. EDS is often associated with an increased bleeding risk, but a comprehensive study of hemostasis in patients with EDS is lacking.

Aims: To evaluate the bleeding severity in a cohort of patients with Ehlers-Danlos syndrome and to correlate the results of coagulation tests with a quantitative method to assess bleeding tendency.

Methods: 100 EDS patients (M/F:23/77, median age:34y) were included in the study. ISTH Bleeding Assessment Tool (ISTH-BAT) was used to evaluate the bleeding history of patients. Primary and secondary hemostasis tests were performed: whole blood count, PT ratio, aPTT ratio, fibrinogen, von Willebrand factor ristocetin co-factor (RICOF), endogenous thrombin potential (ETP), platelet aggregation and platelet secretion (studied by lumi-aggregometry). If PT or aPTT were prolonged, coagulation factors were tested.

Results: ISTH-BAT, ranged from 0 to 14, was above 5 in 49 patients (49%). PT and/or aPTT were slightly prolonged in 10 patients (10%), due to mild coagulation factors deficiencies. RICOF was above 45% in all patients. ETP was normal in all patients. Among patients with ISTH-BAT>5, 60% had a reduction of platelet aggregation and 40% had a secretion defect in response to ADP as aggregating agent. At least one platelet function abnormality is present in 74% of patients with a ISTH-BAT>5 and also in 67% of patients with a ISTH-BAT≤5. The impairment of platelet aggregation was correlated with ISTH-BAT. The risk of an abnormal response to ADP was 2-fold increase in patients with ISTH-BAT>5, for an odds ratio of 2.4 (95% CI 1.0-5.5).

Conclusions: In our cohort half patients with EDS had an ISTH-BAT>5 and platelet function abnormalities.

PB 1584 | Acquired Glanzmann Thrombasthenia due to Marked Reduction of Surface αIIbβ3 Expression with Non-function Blocking Anti-αIIbβ3 Antibodies

K. Akuta[1], H. Kashiwagi[1], T. Yujiri[2], N. Nishiura[1], Y. Morikawa[1], H. Kato[1], S. Honda[3], Y. Kanakura[1], Y. Tomiyama[1,4]

[1]Osaka University Graduate School of Medicine, Department of Hematology and Oncology, Suita, Japan, [2]Yamaguchi University School of Medicine, Third Department of Internal Medicine, Ube, Japan, [3]National Cerebral and Cardiovascular Center, Department of Molecular Pathogenesis, Suita, Japan, [4]Osaka University Hospital, Department of Blood Transfusion, Suita, Japan

Background: Acquired Glanzmann thrombasthenia (aGT) is a bleeding disorder generally caused by function-blocking autoantibodies against integrin αIIbβ3.

Aims: We analyzed an unusual case of aGT caused by marked reduction of surface αIIbβ3 expression with non-function blocking anti-αIIbβ3 antibodies (Abs).

Methods: A 72 year-old Japanese man suffering from ITP since his 50's showed exacerbation of bleeding symptom despite of mild thrombocytopenia (80-90 x 10^9/L). His bleeding time was prolonged and platelet aggregation was absent with all agonists but ristocetin. Analysis of αIIbβ3 expression in platelets and genetic analysis of *ITGA2B* and *ITGB3* was performed. We also analyzed effects of anti-αIIbβ3 Abs of this patient on platelet function and αIIbβ3 expression.

Results: Surface αIIbβ3 expression was markedly reduced to around 5% of normal. By sharp contrast, Western blotting of platelet lysates showed that the patient's platelets contain 40-95% of normal-sized αIIbβ3. Substantial amount of fibrinogen was also detected in his platelets. These results suggest that low surface expression of αIIbβ3 by internalization may cause GT-like phenotype of this patient. There were no abnormalities in whole coding region of *ITGA2B* and *ITGB3* cDNA. Anti-αIIbβ3 IgG Abs were detected in platelet eluates and plasma, and epitopes of these Abs are located in β-propeller domain of αIIb. However, these Abs did not interfere with aggregation and

PAC1 binding of normal platelets, indicating that the Abs were non-function blocking. Surface αIIbβ3 and GPIb expression of megakaryocytes (MgK) derived from cord blood cells was impaired by incubation with IgG purified from the patient's plasma, as observed by ITP autoantibodies. After 2 years of aGT diagnosis, his bleeding symptom has improved and surface αIIbβ3 expression was recovered to 20% of normal with reduction of anti-αIIbβ3 Abs.

Conclusions: Anti-αIIbβ3 Abs of this patient may cause internalization of αIIbβ3 leading to severe platelet dysfunction and impairment of MgK maturation.

PB 1585 | Platelet Function and Ibrutinib Treatment in Chronic Lymphocytic Leukaemia and Mantle Cell Lymphoma: Effects of Drug and of Disease Itself

A. Ignatova[1], E. Nikitin[2], A. Tharmakulanathan[3], S. Ramström[3,4], A. Poletaev[1], D. Polokhov[1], A. Fedotov[1], E. Seregina[1], A. Pshonkin[1], V. Vorobiev[2], V. Ptushkin[2], M. Panteleev[1]

[1]Dmitry Rogachev National Research Center of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation, [2]Botkin City Clinical Hospital, Moscow, Russian Federation, [3]Linköping University, Department of Clinical Chemistry and Department of Clinical and Experimental Medicine, Linköping, Sweden, [4]Örebro University, Department of Clinical Medicine, School of Medical Sciences, Örebro, Sweden

Background: Ibrutinib treatment in chronic lymphoblastic leukemia (CLL) and mantle cell lymphoma (MCL) is associated with bleeding. It can be due to a combination of inhibition of platelet glycoprotein VI signalling by ibrutinib and ADP degradation by CD39 on lymphocytes.

Aims: To investigate platelet function in CLL/MCL patients before and on ibrutinib treatment.

Methods: A total of 14 MCL patients and 20 CLL patients were included; controls were 70 healthy donors. All gave their written informed consent, and the study was approved by the hospital´s ethics committee. Blood was collected before ibrutinib treatment (point 0), then at 2, 4, 8 weeks (points 1-3) and 3-6 months (point 4) on treatment. Cell count, light transmission and whole blood aggregometry, APTT, and PT assays were performed. Platelets were phenotyped by flow cytometry before and after activation. Levels of CD42b, CD61, CD62P, PAC1, annexin V binding, and mepacrine release were determined. Thrombin generation in platelet-rich plasma of healthy donors supplemented with ibrutinib (with or without collagen-related peptide) was monitored using the calibrated automated thrombogram method.

Results: Granule release, integrin activation and procoagulant activity in patients before treatment were significantly impaired in CLL versus MCL versus healthy controls. Further profound decrease of PAC1 binding and procoagulant PLT formation were observed on ibrutinib therapy. Aggregation in points 1 and 2, but not in points 0, 3, 4 was impaired in patients with bleeding. Platelet count was decreased in most patients before and on therapy; clotting assays remained within the normal range. Thrombin generation was dose-dependently inhibited by ibrutinib *in vitro*.

Conclusions: Platelet function is initially impaired in CLL and MCL patients, additionally inhibited by ibrutinib, and then restored on treatment. However, our data suggest that initial impairment involves other mechanisms than CD39, and that effect of ibrutinib is not only glycoprotein VI-dependent.

PB 1586 | Chronic Immune Thrombocytopenic Purpura (ITP) in Egyptian Children: A 10 Year Single Center Retrospective Study

M. Abdelwahab[1], M. Aydeen[2], D. Ezzat[3]

[1]Cairo University Pediatric Hospital, Pediatric Hematology, Cairo, Egypt, [2]Bani Swaf General Hospital, Pediatrics, Bani Swaf, Egypt, [3]Bani Swaf University, Pediatric Hematology, Bani Swaf, Egypt

Background: 20 -25% of children with newly diagnosed ITP will develop chronic disease. Treatment guidelines are determined by many factors; bleeding risk, likelihood of response, impact on quality of life, side effects of drug(s) given, patient/parent anxiety and resource constraint.

Aims: To study the demographic and clinical data as well as response to treatment of chronic ITP in Egyptian children.

Methods: After the ethical committee approved the study, all records of children diagnosed with chronic ITP and following in the Paediatric haematology outpatient clinic in the past 10 years were reviewed. First line treatments included steroid therapy, intravenous immunoglobulin, anti-D and azathioprine. Second line treatments included splenectomy, triple therapy (0.8 mg/kg/d prednisolone, 2mg/kg/d, Azathioprine and 2.5mg/kg/d Cyclosporine), other as Mycophenolate Mofetil and Rituximab. Demographic, clinical, and treatment data was collected and analysed with descriptive statistics.

Results: 222/854 (30%) of our studied ITP cohort developed a chronic course. Their mean current age is 9.4±4.1 with equal gender prevalence, 24.8% are of consanguineous marriage and 5.4% have a similarly affected sibling .Patients' mean initial platelet count is 18x109/L. 46.4% developed epistaxis, 9.9%hematuria and menorrhagia was reported in 25/34 (73.5%) of teenage girls whilst 1.8% developed intracranial hemorrhage. 45.5% of the Egyptian cohort received short pulse methylprednisolone, 12.2% intravenous immunoglobulin, 7.7% anti-D, 24.3% Azathioprine,8.6% triple therapy, 14% underwent splenectomy and 3.6% received other treatment regimens. 39% achieved complete remission, 49% partial remission and 12% no response.

Conclusions: Our studied Paediatric cohort is more liable to develop a chronic course, require second line treatments due to the frequency and / or severity of mucous membrane bleeds and they are more prone to develop intracranial haemorrhage.

PB 1587 | Acute Episodes of Atrial Fibrillation Cause Altered Platelet Function and Procoagulant Microparticle Consumption

L. Pourtau[1], J.M. Sellal[2,3], R. Lacroix[4,5], P. Poncelet[6], O. Bernus[1], G. Clofent-Sanchez[7], J.-C. Bordet[8], M. Hocini[1,2], M. Haïssaguerre[1,2], F. Dignat-George[4,5], F. Sacher[1,2], P. Nurden[1]

[1]IHU Liryc, Electrophysiology and Heart Modeling Institute, Pessac, France, [2]Bordeaux University Hospital, Electrophysiology and Ablation Unit, Pessac, France, [3]Centre Hospitalier Régional Universitaire, Département de Cardiologie, Nancy, France, [4]INSERM, VRCM, UMR-S 1076, Marseille, France, [5]CHU Conception, Department of Haematology and Vascular Biology, Marseille, France, [6]BioCytex, Research & Technology Department, Marseille, France, [7]CNRS, Centre de Résonance Magnétique des Systèmes Biologiques, U 5536, Bordeaux, France, [8]Hôpital Edouard Herriot, Laboratoire d'Hématologie, Lyon, France

Background: Increased coagulation activity has been described during atrial fibrillation (AF) requiring antithrombotic treatment. Platelets and microparticles (MP) have been shown to be involved this process.
Aims: To determine the consequences of induced-AF on platelet function and MP levels in the left atrium of patients with non-valvular AF.
Methods: Paroxysmal and persistent AF patients (n=51) referred for catheter ablation were recruited. Patients in sinus rhythm (n=12) were induced in AF and left atrium blood samples were taken before and after acute episode of AF (20min). Measures of platelet aggregation, P-selectin, αIIbβ3, GPIb, PAR-1, receptor expression by flow cytometry and platelet morphology by transmission electron microscopy were performed. Levels of procoagulant and fibrinolytic MP were determined by functional assays.
Results: A significant reduction in platelet aggregation to TRAP (66.0±2.9% vs 84.9±3.0%) was found under basal conditions in AF patients, but improved after acute induced-AF suggesting a process of desensitization partially reversed by the acute AF episode. Platelet morphology revealed the presence of pseudopods and an increased number of vacuoles indicating some platelet reactivity. No differences in surface platelet receptor levels of P-selectin, αIIbβ3, GPIb, or PAR1 were found by flow cytometry. Finally, while the left atrium levels of fibrinolytic MP remained stable, a significant decrease of tissue factor-dependent procoagulant activity of MP was observed after acute induced-AF (15.9±3.7fM vs 5.3±2.0fM) suggesting that the MP were captured either by the surrounding tissues and/or incorporated into micro-clots.
Conclusions: During acute AF episodes an increased platelet response to thrombin receptor through PAR1 and associated with tissue factor-dependent procoagulant MP consumption is in favor of local increased thrombotic events. Therefore, AF pathophysiology involves in addition to plasma coagulation, a cellular participation which acts in synergy to promote thrombus formation.

PB 1588 | Impaired Platelet Responsiveness in Thrombocytopenic Cancer Patients after Chemotherapy as a Consequence of Mitochondrial Dysfunction

C.C.F.M.J. Baaten[1], F.C.J.I. Moenen[2], Y.M.C. Henskens[3], F. Swieringa[1,4], R. Wetzels[3], R. van Oerle[3,5], H.F.G. Heijnen[6], H. ten Cate[5], G.P. Holloway[7], E.A.M. Beckers[2], J.W.M. Heemskerk[1], P.E.J. van der Meijden[1]

[1]Maastricht University / Cardiovascular Research Institute Maastricht (CARIM), Department of Biochemistry, Maastricht, The Netherlands, [2]Maastricht University Medical Center, Department of Hematology, Maastricht, The Netherlands, [3]Maastricht University Medical Center, Central Diagnostic Laboratory, Maastricht, The Netherlands, [4]Leibniz Institute for Analytical Sciences - ISAS-e.V., Department of Bioanalytics, Dortmund, Germany, [5]Maastricht University / Cardiovascular Research Institute Maastricht (CARIM), Laboratory for Clinical Thrombosis and Hemostasis, Department of Internal Medicine, Maastricht, The Netherlands, [6]University Medical Center Utrecht, Cell Microscopy Center, Department of Cell Biology, Department of Clinical Chemistry and Haematology, Utrecht, The Netherlands, [7]University of Guelph, Department of Human Health and Nutritional Sciences, Guelph, Canada

Background: Severe thrombocytopenia (≤50x10^9 platelets/L) in hematological malignancies after intensive chemotherapy is associated with an increased risk of bleeding. However, platelet count only weakly correlates with bleeding risk, suggesting involvement of other hemostatic factors.
Aims: To investigate possible changes in platelet and coagulation activities accompanying thrombocytopenia in cancer patients receiving chemotherapy.
Methods: After ethical approval and written informed consent, blood was obtained from 89 patients with hematological malignancies before and after (1h) platelet transfusion. Coagulation factors were determined. Platelet functions were assessed by flow cytometry. Mitochondrial morphology and activity were determined by electron microscopy and high-resolution respirometry. Thrombus and fibrin formation were assessed on a collagen-tissue factor surface under flow.
Results: Patients showed normal coagulation factor activity levels, except for high VWF and fibrinogen and low FVII levels. The patients´ platelets were reduced in Ca^{2+} responses, integrin $\alpha_{IIb}\beta_3$ activation and secretion upon agonist stimulation, compared to control platelets ($p< 0.01$). Patients´ platelets showed a time-dependent increase in phosphatidylserine exposure independent of agonist stimulation or caspase activity, which was enhanced by the mitochondrial apoptosis inducer ABT-737. Mitochondrial function in patients´ platelets was markedly impaired, as evidenced by a reduced mitochondrial membrane potential
($p< 0.001$) and lower maximal O_2 consumption ($p< 0.05$), in spite of normal mitochondrial content. After platelet transfusion, the diminished thrombus and fibrin formation normalized, underscoring the loss-of-function of autologous patients´ platelets.
Conclusions: Impaired platelet responsiveness in chemotherapy treated patients is the consequence of mitochondrial dysfunction. Transfusion partly recovers platelet functionality, improving thrombus and fibrin formation.

PB 1589 | Coated-platelet Formation is a Sensitive Indicator of Dasatinib Elicited Side-effects

J. Kappelmayer[1], I. Beke Debreceni[1], A. Kerényi[1], V. Treszkai[1], G. Mezei[2], P. Batár[2]

[1]*University of Debrecen, Faculty of Medicine, Department of Laboratory Medicine, Debrecen, Hungary,* [2]*University of Debrecen, Faculty of Medicine, Institute of Internal Medicine, Debrecen, Hungary*

Background: Tyrosine kinase inhibitors (TKI) are a very effective group of drugs that considerably prolong survival in patients with chronic myeloid leukemia. Several lines of evidence suggest that dasatinib (Sprycel) may induce bleeding due to its effect on platelets.
Aims: We hypothesized that dual agonist activated platelet formation (coated platelets) may be a useful marker to monitor TKI side-effects in addition to classical platelet function tests.
Methods: Citrate-anticoagulated blood samples from healthy volunteers were used in PFA-100 assay, lumi-aggregometry and during coated platelet formation. This latter test was executed by dual activation of gel-filtered platelets by the snake venom convulxin and thrombin to simultaneously activate collagen and thrombin receptors.
Results: We could confirm that dasatinib at 400 nM prolongs PFA-100 closure times by the collagen/epinephrine cartridge but not by collagen/ADP cartridge. This supra-therapeutic dasatinib concentration also prevented platelet aggregation and ATP release after 1 µg/ml collagen and 500 µg/ml arachidonic acid challange and similar inhibitory effect could be observed down to 150 nM dasatinib concentration. Coated-platelet formation was significantly inhibited by preincubation with 400 nM dasatinib (p=0.001) resulting in 9±8.5% of coated platelet formation versus controls with no TKI (41±10%). The effect of dasatinib was dose-dependent and the inhibitory effect could be observed already at 10 nM dasatinib that is the low therapeutic concentration of the drug (coated platelet = 34±4.2%, p=0.02), however this low dasatnib concentration had no inhibitory effect on platelet aggregation and release results. Contrary to dasatinib, another second generation TKI, nilotinib (Tasigna) did not exert any effect on coated platelets.
Conclusions: We suggest that the measurement of coated platelets is a more sensitive marker than lumi-aggregometry to detect TKI associated side-effects in platelets.

PB 1590 | Thrombocytopenia and Altered Coagulation as Independent Predictors of the Etiology of "Tropical Jaundice" in Adults Presenting to Emergency in a Tertiary Care Hospital in North India

A. Bhalla[1], V. Suri[1], M. Singh[1], M. Biswla[2], R. Ratho[3], M.P. Singh[3], A. Duseja[4], P. Malhotra[1]

[1]*PGIMER, Medicine, Chandigarh, India,* [2]*PGIMER, Microbiology, Chandigarh, India,* [3]*PGIMER, Virology, Chandigarh, India,* [4]*PGIMER, Hepatology, Chandigarh, India*

Background: Fever with jaundice or tropical jaundice is common presenting feature of the patients visiting for emergency.The knowledge of region specific prevalence is needed to improve the management of such patients.
Aims: To study the region specific aetiology of Fever and Jaundice in patients presenting to medical emergency.
Methods: 106 adult patients with a diagnosis of "Tropical Jaundice" with fever(body temperature > 101°F) of 14 days without any localisation but causing jaundice (hyperbilirubinemia ≥ 1.5 mg/dl or elevated AST/ALT more than three times) were enrolled.All these patients were evaluated for malaria(peripheral smears/rapid diagnostic kits), scrub typhus(PCR /IgM ELISA),leptospirosis(IgM ELISA), enteric fever by blood cultures,dengue(NS1 antigen/IgM ELISA),Hepatitis(IgM ELISA of EBV/HSV, IgM ELISA of HAV/HEV and HBsAg with IgM HBc ELISA if HBsAg positive).
Results: 63 were males and 43 were females. The mean duration of fever before presentation was 7.75 ± 3.58 days. 7 patients (6.6%) died. 92 patients (86.8%) improved with treatment,7 patients (6.6%) left treatment against medical advice. The various etiologies included scrub typhus24 (22.6%), Hepatitis E 14 (13.2%),malaria 9 (8.5%),dengue fever, enteric fever, hepatitis A and leptospirosis in 4 (3.8%), 2 (1.9%), 2 (1.9%) patients and 1 (0.9%).Probable sepsis accounted for 31 patients. Conjunctival suffusion (OR=22.17), severe anemia (OR=5.5), respiratory crepitations (OR=5.27), thrombocytopenia (OR=1.14), hepatomegaly (OR=1.04), normal INR (OR=0.29) and altered mentation (OR=0.25) were significant predictors of a diagnosis of scrub typhus. Severe anemia(Hb< 8),Hypoalbuminemia,severe thrombocytopenia (Platelet count < 50,000)and a near normal INR at admission were predictors of a malarial vs a viral etiology of Tropical jaundice.
Conclusions: Scrub infection has emerged as common etiology of tropical jaundice in recent times. Simple tests like a baseline platelet count and coagulogram(INR/PTTK) can help in early diagnosis and thus treatment.

PB 1591 | Plasma microRNAs Characterizingpatients with Immune Thrombocytopenia

Y. He, B. Zou, C. Ruan

The First Affiliated Hospital of Soochow University, Jiangsu Institute of Hematology, Suzhou, China

Background: Dysregulation of microRNA (miRNA) expression is associated with many diseases. The expression profile of miRNAs in plasma of immune thrombocytopenia (ITP) patients have not been fully understood.
Aims: The aims of this study were to determine whether plasma from ITP exhibit an altered miRNAs expression profile and evaluate their diagnostic value for ITP prediction.
Methods: Plasma samples were obtained and allocated into a discovery set composed of 10 ITP patients and 6 healthy controls, a validation set with 52 ITP patients and 52 healthy controls. miRNA

microarray assay and quantitative real time PCR (qPCR) verification were performed in the discovery set and validation set, respectively. Receiver operator characteristic (ROC) curves were constructed to evaluate their diagnostic value for ITP prediction.

Results: Microarray data showed a alteredplasma miRNA profile and a total of 23 plasma miRNAs were identified in ITP patients compared to healthy controls(fold change>1.5, $P< 0.01$). The qPCR results verified eight upregulated miRNAs (miR-320c,miR-642b-3p, miR-1275, miR-3141, miR-4270, miR-4499, miR-4739 and miR-6126) and three downregulated miRNAs (miR-144-3p, miR-1281 and miR-3162-3p) in ITP patients. The plasma levels of miRNAs varied in different phases of ITP disease. ROCanalysis showed a good diagnostic value could be achieved by a panel of four miRNAs (miR-144-3p, miR-1275, miR-3141 and miR-3162-3p).A significant positive correlation was found between platelet count and plasma levels of miR-3162-3p(r=0.338, P=0.01). Bioinformatic analysis indicated that the highest scoring functional pathways associated with ITP wereproteoglycans, thyroid hormone signaling pathwayand estrogen signaling pathway.

Conclusions: Our results indicate a differential plasma miRNA profile exists in patients with ITP disease. The plasma miRNA signature could be served as an independent biomarker in the diagnosis of ITP.

PB 1592 | Evaluation of in vitro Effects of Tyrosine-kinase Inhibitors on Primary Haemostasis

F. Eckart[1], M. Suttorp[1], R. Ursula[2], R. Knoefler[3]

[1]Medical Faculty, Technical University of Dresden, Department of Pediatric Haematology and Oncology, Dresden, Germany, [2]Institute of Medical Informatics and Biometry, Dresden, Germany, [3]Department of Pediatric Haemostaseology, Dresden, Germany

Background: Tyrosine-kinase inhibitors (TKIs) are established for the treatment of chronic myeloid leukaemia (CML). An increased bleeding risk in some patients on dasatinib is described but the underlying mechanism is not yet clear.

Aims: We investigated platelet function and haemostasis screening testing in TKI-incubated blood samples collected from healthy young adult volunteers.

Methods: Each specimen (n=15) of citrated whole blood (WB) was incubated for 30 min with TKI at different final concentrations (imatinib 1.5 µmol/l, dasatinib 0.4 and 0.2 µmol/l, bosutinib 0.4 µmol/l, nilotinib 4 µmol/l). Platelet function (aggregation and ATP release) was investigated by the Chronolog lumi-aggregometer type 560 using collagen (1 µg/ml), arachidonic acid (0.5 mmol/l) and thrombin (0.5 U/ml). Function of primary haemostasis was screened by the PFA-100® test using buffered citrated WB.

Results: Dasatinib at 0.4 µmol/l almost completly inhibited collagen-induced aggregation and ATP-release and caused a marked prolongation of the PFA-100® closure times (CT) with the collagen/epinephrine cartridge. Contrastingly, platelet activation by the other agonists and the CT with the collagen/ADP cartridge was not influenced. The concentration dependency of this effect was demonstrated using dasatinib at 0.2 µmol/l.

In imatinib-incubated samples the collagen-induced aggregation was significantly increased compared to controls while for the other parameters no significant differences were found. The PFA-100® CT was not influenced by imatinib. Comparable results were obtained for bosutinib and nilotinib.

Conclusions: Our data clearly demonstrate that dasatinib but not imatinib, bosutinib and nilotinib impairs primary haemostasis by influencing the collagen-mediated platelet activation.

As CML is mostly diagnosed in elderly people, clinical relevance of these findings must be judged on in the context of underlying vascular endothelial diseases.

PB 1593 | What Do we Know about Post Transfusion Purpura? A Novel Insight into the Correlation between HPA Antibodies and Clinical Picture

I. Farkash[1,2], T. Rashal[2,3], S. Chen[4], M. Hareuveni[3], L. Bonstein[5], D. Stavi[1], Y. Bar-on[2,3], I. Avivi[2,3], I. Kirgner[2,3]

[1]Ichilov Hospital, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [2]Tel Aviv University, Tel Aviv, Israel, [3]Ichilov Hospital, Tel Aviv Sourasky Medical Center, Hematology, Tel Aviv, Israel, [4]Military, Tel Aviv, Israel, [5]Rambam Medical Center, Haifa, Israel

Background: A 72 year old patient was admitted with purpura and severe thrombocytopenia (PLT 6000/mm3), 10 days after receiving a red blood cell transfusion. Laboratory investigations showed Human Platelet Antigen (HPA) HPA-1aa and HPA-3bb genotype, in the presence of anti HPA-3a, HPA-1b and HLA antibodies. Post Transfusion Purpura (PTP) was diagnosed, and the patient was treated with intravenous immunoglobulin (IVIG), achieving a full PLT recovery within 14 days. This abstract is the first systemic review summarizing the current literature on this rare phenomenon, focusing on the correlation between HPA antibodies and PTP.

Aims: The primary outcome was to examine the differences in anti HPA distribution before and after the employment of the Monoclonal Antibody Immobilization of Platelet (MAIPA) test since 1995, and correlate the results with the demographic and clinical characteristics.

Methods: A review of PubMed and Medline was performed, looking for all articles since 1965 , that included the keywords ´´PTP" and anti HPA.

Results: A total of 69 articles were examined . 173 cases were reviewed ; 157 in women and 15 (including our case) in men. Data are summarized in the table below.

TABLE 1 Anti HPA distribution by gender

Population (n)	HPA 1a	HPA 1b	HPA others	Combination*
All Women (157)	131(83%)	6(4%)	23(15%)	3(2%)
**Women 1995 (28)	21(75%)	1(3.5%)	6(21%)	0(0%)
All Men (16) combination(4)	8 3(42%)	3 ***1(14%)	9 4(43%)	4(25%)
**Men 1995 (12) combination(4)	7 3(44%)	1 1(6.25%)	8 4(50%)	4(33%)

* combination - at least 2 antibodies not included HLA

**sub analysis after MAIPA standardization

*** we add our patients to analysis

Patients with HPA -1a had a lower platelet nadir(1-26,000, median 6), with only 6 out of 38 patients had a platelet count > 10,000/mm3. In patients expressing other anti HPA groups, 6/13 had platelet counts > 10,000/mm3 (2 -26,000, median 11.6). There was no correlation between the incidence of bleeding events and PLT level.

Conclusions: Despite the small number of cases and the bias associated with retrospective analysis the current data suggest that in women, HPA-1a antibody is the predominant culprit for PTP, whereas in men, the distribution is wider. Furthermore, a combination of anti HPA is more common in men than in women.

PB 1594 | Further Characterization of Platelets Bearing Mutations in Calreticulin or JAK2 Genes in Essential Thrombocythemia Patients

H. Hauschner[1,2], N. Rosenberg[1,2], U. Seligsohn[1,2], M. Koren-Michowitz[2,3]

[1]*Chaim Sheba Medical Center, Amalia Biron Research Institute of Thrombosis and Hemostasis, Ramat-Gan, Israel,* [2]*Tel Aviv University, Sackler School of Medicine, Tel Aviv, Israel,* [3]*Asaf Harofeh Medical Center, Hematology, Zerifin, Israel*

Background: Essential Thrombocythemia (ET) is a chronic blood disorder characterized by overproduction of platelets by megakaryocytes and is associated with an increased risk of thrombo-hemorrhagic complications. Acquired mutations in the genes of *JAK2* or calreticulin (*CALR*) are associated with the disorder in the majority of the cases. CALR-mutant patients have a very high platelet count but relatively low risk of thrombosis compared to JAK2-mutant patients.

Aims: To examine whether CALR mutations have a different effect on platelets activation and intracellular Ca^{+2} concentration compare to JAK2 mutation and wild type.

Methods: Two platelet activation markers, CD62P and PAC1, were measured following ADP activation of patients' platelets carrying the JAK2 mutation (JAK-mt) (11 patients), the *CALR* mutation (CALR-mt) (8) and normal subjects (13). In addition, immature platelets fraction (IPF) and absolute number of immature platelets were counted. Intracellular calcium concentration was measured using a fluorescent indicator by flow cytometry. CALR was stained along with actin in adherent platelets, using confocal microscopy.

Results: Expression of activation markers following ADP stimulation decreased significantly in CALR-mt patients compare to JAK-mt patients or normal subjects. Interestingly, intracellular calcium concentration was significantly higher in resting platelets of CALR-mt patients. CALR in adherent platelets was dispersed in the cytoplasm in ET patients of both mutations compare to normal subjects, where it seemed in the center of the platelet. No significant difference between the three groups was detected in the IPF. However, since the CALR-mt patients had higher platelet count compare to JAK-mt patient, and by far more than normal subjects, the absolute number of immature platelets was significantly higher in those patients.

Conclusions: Platelets of CALR-mt patients are less reactive compared to JAK2 patients and this compensates the higher platelet count and hence they are less prone to thrombosis.

PB 1595 | Clinical Evaluation of the Revised International Prognostic Score of Thrombosis for Essential Thrombocythemia (IPSET-Thrombosis) in a Cohort of 746 Chinese Adult Patients

R. Fu, H. Li, F. Xue, X. Liu, L. Zhang, R. Yang

Institute of Hematology and Blood Disease Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin, China

Background: For predicting thrombotic events in patients with essential thrombocythemia (ET), the revised International Prognostic Score of Thrombosis model (IPSET-thrombosis) was reported to be better than the original IPSET-thrombosis.

Aims: The study aimed at evaluating Whether the revised IPSET-thrombosis model was applicable to Chinese patients ET.

Methods: Medical records of 746 patients with a diagnosis of ET were retrospectively analyzed.

Results: According to the revised IPSET-thrombosis model, the number of very low-, low-, intermediate-, and high-risk patients were 271 (36.3%), 223 (29.9%), 63 (8.4%) and 189 (25.3%), respectively. The four groups exhibited significantly different thrombosis-free survival ($P< 0.001$). Thirty-six patients were reclassified as intermediate-risk according to the revised IPSET-thrombosis instead of low-risk per the original IPSET-thrombosis. Nineteen intermediate-risk patients per the original IPSET-thrombosis were upgraded to high-risk according to the revised IPSET-thrombosis. Fifty-one high-risk patients per the original IPSET-thrombosis were reclassified as low-risk in the revised IPSET-thrombosis. It suggests that the revised IPSET-thrombosis potentially avoids over- or under-treatment. In low-risk patients per the revised IPSET-thrombosis, the rate of thrombosis in patients with cardiovascular risk factors (CVF) was higher than in those without (16.3% *vs.* 5.2%, $P=0.022$), and comparable with intermediate-risk patients per the revised IPSET-thrombosis (16.3% *vs.* 14.3%, $P=0.765$). As

a result, a new revised IPSET-thrombosis model more applicable to Chinese ET patients was developed in which patients with CVF in the low-risk group per the revised IPSET-thrombosis were reclassified as intermediate-risk group.

Conclusions: For predicting thrombotic events, the revised IPSET-thrombosis model was better than the original IPSET-thrombosis model. The revised IPSET-thrombosis was optimized and a new revised IPSET-thrombosis model more applicable to Chinese ET patients was developed.

PB 1596 | Variations of Mean Platelet Volume with Time Since Blood Sampling in Different Anticoagulants

G.M. Podda[1], P. Soru[1], G. Casazza[2], E.A. Femia[1], G. Carpani[3], M. Cattaneo[1]

[1]Unità di Medicina III, ASST Santi Paolo e Carlo - Dipartimento di Scienze della Salute, Università degli Studi di Milano, Milano, Italy, [2]Università degli Studi di Milano, Dipartimento di Scienze Biomediche e Cliniche ‚L. Sacco', Milano, Italy, [3]S.I.M.T., ASST Santi Paolo e Carlo, Milano, Italy

Background: The mean platelet volume (MPV) is useful for the classification of congenital thrombocytopenias and to distinguish between congenital and acquired thrombocytopenias. It has also been suggested that high MPV is associated with increased risk for cardiovascular events. It is known that MPV increases in EDTA samples with time. Anticoagulants different from EDTA have been tested and proposed as potentially useful for assessing platelet indices.

Aims: Aim of our study was to identify the ideal pre-analytical variables for measuring MPV.

Methods: MPV was measured in blood samples from of 100 thrombocytopenic patients and 100 healthy blood donors collected in K2EDTA, Citrate-Theophylline-Adenosine-Dipyridamole (CTAD), Citrate-Tris-Pyridossalphosphate (CPT) and magnesium-anticoagulant (Mg-AC). Blood cell count was performed (COULTER® LH 750 Hematology Analyzer) in each sample immediately after sampling (t0) and at 20 (t20), 40 (t40), 60 (t60), 120 (t120) and 180 (t180) minutes.

Results: MPV steadily increased with time both in blood donors and thrombocytopenic patients, in all anticoagulants, with the exception of CTAD, and stabilized at t120 (Figure 1 and 2). As a consequence, the percentage of subjects with high MPV, defined as greater than the 95th percentile of values obtained in blood donors at t0, increased with time both in blood donors and thrombocytopenic patients: for instance the prevalence of thrombocytopenic patients with high MPV in K2EDTA blood samples increased from 49% at t0 to 82% at t180.

Conclusions: Our study shows that: 1) MPV varies with time of measurement after blood sampling and with the anticoagulant used to collect blood samples; 2) the increase in MPV remained stable between 120 and t180. Thus, MPV should be measured either immediately after blood sampling or between 120 and 180 min. Variations of MPV with time were lowest in CTAD anticoagulant.

Figure 1. Variation over time of MPV in blood samples in different anticoagulants from 100 **blood donors.**

	Anticoagulant			
Time	K2EDTA	CTAD	CPT	Mg-AC
t 0	7.9 (7.2-8.6)	7.5 (6.9-8.3)°	7.3 (6.6-7.9)°	7.0 (6.4-7.4°
t20	8.6 (7.8-9.3)*#	7.7 (7.0-8.4)*#	7.6 (6.9-8.3)*#	7.2 (6.5-7.9)
t40	8.8 (8.0-9.5)*#	7.7 (6.9-8.3)*#	7.7 (7.1-8.5)*#	7.4 (6.7-8.1)*#
t60	8.9 (8.1-9.8)*#	7.7 (6.9-8.4)*	7.9 (7.1-8.5)*	7.4 (6.8-8.1)*#
t120	9.2 (8.4-9.9)*#	7.7 (6.9-8.4)*	7.7 (7.0-8.6)*	7.6 (6.8-8.3)*#

FIGURE 2

PB 1597 | Cytosolic Calcium Concentrations in Platelets from Patients with Pulmonary Embolism and Implications for Therapy

J. Pike, N. Alves, J. Kline

Indiana University School of Medicine, Emergency Medicine, Indianapolis, United States

Background: Prior work has shown platelet hyperactivity with evidence of apoptosis in acute pulmonary embolism (PE). Cytosolic [Ca++] is a key mediator in platelet activation and apoptosis.

Aims: Link cytosolic [Ca++] to morphological and functional changes associated with hypercoagulability in PE.

Methods: Patients had image-proven submassive PE within 24 h of diagnosis with blood analyzed within 60 min. Patient informed consent was obtained in this IRB-approved study. Thromboelastography (TEG, Haemoscope 5000) was performed on whole blood, and cytosolic [Ca++] was measured in Fluo-8 loaded platelets using spectrofluorometry and fluorescence microscopy with agonist stimulation or antagonist inhibition (PAF and PAR receptor antagonists WEB 2086 and SCH79797) or soluble guanylate cyclase activation with cinaciguat. Comparisons (2-way ANOVA, Dunnett's) were made to platelets from healthy controls.

Results: On TEG, PE platelets had shorter R time, higher angle and MA, both without or with platelet agonists (arachidonic acid and ADP), indicating global hypercoagulability. On fluorescence microscopy, unstimulated PE platelets were hypoactive with lower basal [Ca++] (90±45 nM vs controls 177±95 nM, P< 0.001). With agonists (arachidonic acid, ADP and thrombin), PE platelets had more fragmentation,

pseudopod formation, and disintegration, with a similar relative increase in [Ca++]: 324±250, 148±88*, and 118±78*, respectively, vs 499±332, 309±155, and 224±75 in controls (*P< 0.001). WEB 2086, SCH79797, and cinaciguat reduced thrombin-stimulated [Ca++] to 95±46, 124±77, and 122±35, respectively, vs 381±419, 166±45, and 190±95 in controls.

Conclusions: Patients with PE have a globally hypercoagulable TEG profile with platelets that show an apoptotic morphology, lower basal [Ca++], and preserved [Ca++] increase with thrombin that was effectively blocked by multiple antagonists. These data suggest a large proportion of apoptotic but not necrotic platelets in PE and emphasize the need and options for early platelet protection.

PB 1598 | Probable Risks and Benefits of Second Line Therapy Splenctomy versus TPO Mimetics in Chronic Idiopathic Thrombocytopenic Purpura an Experience of a Third World Country, Pakistan

T. Imran[1], H.N. Altaf[2], F. Bakhtiar[3], T. Butt[4], R. Akbar[5]

[1]*Jamila Sultana Thalessemia Center, Pathology, Rawalpindi, Pakistan,* [2]*Shifa College of Medicine, Shifa Tameer e' Millat University, General Surgery, Islamabad, Pakistan,* [3]*Pakistan Council Science and Technology, Pakistan Council Science and Technology, Islamabad, Pakistan,* [4]*Fauji Foundation Hospital, Pathology, Rawalpindi, Pakistan,* [5]*Rawal Institute of Health Sciences, pathology, Islamabad, Pakistan*

Background: Immune Thrombocytopenia (ITP) is an autoimmune disease of low platelet count and a tendency to bleed. Difference between splenectomy and TPO receptor agonists is that the first prolongs platelets' lifespan by eliminating platelets destruction, second stimulates platelet production. Our study compares changing standards of care from surgical to non surgical approach of treatment.

Aims: To evaluate the usefulness of splenectomy in patients of chronic ITP in the era of new treatment modalities in a developing country.

Methods: It was a descriptive Cross Sectional Study. In this study we analyzed data of 32 cases of chronic ITP for complete response (CR), partial response (PR) and no response (NR) to therapy. Three approaches were used i.e splenctomy, combination therapy (non-approved medical BCSH) and TPO agonist as group one, two and three respectively. The data was analyzed using SPSS 20.

Results: There were 71% females and 28% males. In group one (21 patients) 66% had CR, 24% showed PR and NR was noted in 9.5 % patients. While in group two (7 patients) 28% had CR, PR was 57% and NR was 14%. In group three (4 patients) 75% had CR and 25% had PR.

Conclusions: Our study predicts splenectomy to be cost effective and safe second-line treatment for chronic ITP. TPO agonists have become the standard in developed world but further research is required in developing countries for their cost effectiveness and long term safety.

PB 1599 | Sonoclot Signature Analysis In Thrombocytopenic Patients

K. Mishra[1], P. Malhotra[1], D. Lad[1], N. Varma[2], R.K. Dhiman[3], Y. Uday[1], A. Khadwal[1], G. Prakash[1], J. Ahluwalia[2], S. Varma[1]

[1]*PGIMER, Internal Medicine, Chandigarh, India,* [2]*PGIMER, Hematology, Chandigarh, India,* [3]*PGIMER, Hepatology, Chandigarh, India*

Background: Patients of thrombocytopenia behave differently when it comes to risk of bleeding. The biggest puzzle remains how to predict the risk of bleeding. Though there is a correlation of platelet count with the bleeding risk, a study which can determine platelet function can help stratify these patients. Platelet function studies usually require normal platelet counts. A global test of coagulation like sonoclot can be handy for the clinician if it can show differences between bleeders and non bleeders amongst thrombocytopenic patients.

Aims: To look for utility of sonoclot signature in predicting risk of bleeding in thrombocytopenic patients.

Methods: In this prospective observational study, a total of 50 patients with thrombocytopenia with or without a history of bleeding were included. All patients included had platelet counts lower than 20000/μL. Thirty of them had no history of any recent (last 7days) bleeding (Non-Bleeders) while 20 of them had history of (WHO grade ≥2) bleeding (Bleeders). They were evaluated as per unit protocol for the etiology of thrombocytopenia. The diagnoses included both non-malignant and malignant conditions. All these patient samples were evaluated by Sonoclot. Sonoclot measures activated clotting time (ACT), clot rate (R1) and platelet function (PF).

Results: Both the groups were matched in terms of patient age, diagnoses, platelet count, prothrombin time and activated partial thromboplastin time. The ACT was significantly longer in the bleeders compared to non-bleeders. The platelet function was significantly lower in the bleeders than the non-bleeders. The clot rate was non-significantly lower in the bleeders. (Table 1 and Figure 1)

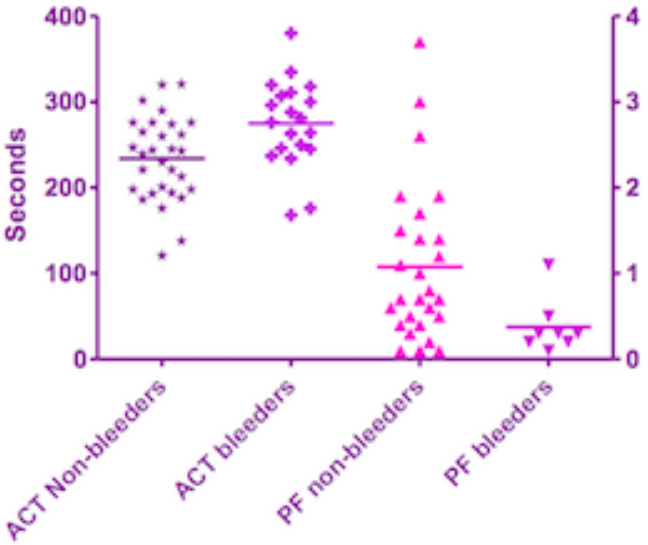

FIGURE 1 Sonoclot Analysis

TABLE 1 Comparison of non-bleeders with bleeders

		Non-bleeders (n=30)	Bleeders (n=20)		
S No	Parameters	Median±SD	Median±SD	P value	Normal value
1	Age (years)	39.5±18.91	40.5±14.76	NS	
2	Platelet(/µL)	11500±4735	7000±4593	NS	150-450 x103
3	Prothombin time (seonds)	14±1.921	14±2.294	NS	11-14
4	Activated partial thromboplastin time (seconds)	29±2.141	28±2.447	NS	25-35
5	ACT (seconds)	241±49.15	278±50.83	0.009	100-155
6	CR (R1) (unit)	18.5±6.042	16.5±4.041	0.06	9-35
7	Platelet function (unit)	0.7±0.916	0.3±0.351	0.01	>1.5

Conclusions: This is the first study to the best of our knowledge demonstrating the use of sonoclot in severe thrombocytopenic patients. Sonoclot offers ease of use as compared to other global tests of coagulation (TEG/ ROTEM). Sonoclot is a handy outpatient or bed side tool to predict risk of bleeding in thrombocytopenic patients.

PB 1600 | High Incidence of Platelet Dysfunction is unmasked in Newly-diagnosed Multiple Myeloma

T. Ruchutrakool, B. Buasatit, P. Plurksathaporn, W. Owattanapanich

Faculty of Medicine Siriraj Hospital, Mahidol University, Department of Medicine, Bangkok, Thailand

Background: Multiple myeloma (MM) is a plasma cell disorder that causes monoclonal protein (M-protein). M-protein can affect coagulation factors and platelets leading to coagulopathy and platelet dysfunction.

Aims: We aimed to study the incidence of bleeding symptoms in newly-diagnosed MM patients as an initial presentation and the effect of M-protein on platelet function.

Methods: The newly-diagnosed MM patients who did not receive antiplatelets had been prospectively enrolled. Baseline characteristics and laboratory results were collected. Platelet aggregation was determined by changes of optical density. Platelet activation assessed by P-selectin expression at resting and activating state was measured by flow cytometry. Impaired platelet aggregation to ^{3} 2 agonists was classified as abnormal platelet function group (group 1) whereas patients with normal platelet aggregation test were classified as group 2.

Results: During September to December 2016, eighteen patients were enrolled. The median age was 65 years (range 42-90). The M-protein consisted of IgG kappa (4), IgG lambda (4), IgM kappa (1), IgA lambda (1), IgA kappa (2) and free light chain (kappa 5, lambda 1). Only one patient (5.5%) presented with abnormal uterine bleeding. Six patients (33.3%) had abnormal platelet aggregation test (group 1). Compared between two groups, there was no significant difference of baseline characteristics including age, sex, and comorbidities. Likewise, there was slightly lower the mean value of P-selectin expression in group 1 than in group 2 (21.7 vs. 28.3%; p=0.6). In contrast, the mean value of M-protein in group 1 was significantly higher than in group 2 (6.35 vs. 2.69 g/dL; p=0.01).

Conclusions: Although bleeding manifestations in MM patients are uncommon, high incidence of platelet dysfunction is seen in this study. The high level of M-protein significantly predicts acquired platelet dysfunction.

PB 1601 | Effects of Time and Different Anticoagulants on Platelet Count in Blood Donors and in Thrombocytopenic Patients

G.M. Podda[1], P. Soru[1], G. Casazza[2], E.A. Femia[1], G. Carpani[3], M. Cattaneo[1]

[1]*Unità di Medicina III, ASST Santi Paolo e Carlo - Dipartimento di Scienze della Salute, Università degli Studi di Milano, Milano, Italy,* [2]*Università degli Studi di Milano, Dipartimento di Scienze Biomediche e Cliniche ‚L. Sacco', Milano, Italy,* [3]*S.I.M.T., ASST Santi Paolo e Carlo, Milano, Italy*

Background: The accuracy of platelet count (PC) measurement is pivotal for the diagnosis and management of patients with thrombocytopenia. We showed that some degree of time-dependent formation of platelet agglutinates in EDTA-blood occurs in some patients with thrombocytopenia, leading to underestimation of their platelet count.

Aims: Aim of the study was to assess the variation of PC over time in different anticoagulants, in blood donors (BD) and thrombocytopenic patients (TP).

Methods: PC was measured in blood samples from of 100 TP and 100 BD, collected in different anticoagulants: EDTA, Citrate-Theophylline-Adenosine-Dipyridamole (CTAD), Citrate-Tris-Pyridossalphosphate (CPT) and magnesium-anticoagulant (Mg-AC). Blood cell count was performed (COULTER® LH 750 Hematology Analyzer) in each sample within 10 min after sampling (t0), and at 20 (t20), 40 (t40), 60 (t60), 120 (t120) and 180 (t180) min. PC was also measured by flow cytometry (FC), the gold-standard technique for PC measurement, in non-anticoagulated blood immediately after sampling.

Results: At t0, there were no differences between PC measured by FC and by cell counter in antico agulated samples, except for CTAD-anticoagulated samples from TP (figure 1 and Figure 2). In TP, PC decreased significantly at t20 in EDTA-anticoagulated samples, and only at t120 in samples with the other anticoagulants (Figure 2). A similar

FIGURE 2

pattern was observed with BD, although the exetnt of PC decrease was lower than in TP (figure 1).

Conclusions: PC decreased over time in blood samples from TP, independently of the anticoagulant used, although the effect was more remarkable with EDTA. PC was more stable in BD. When EDTA is used to collected blood samples for cell counts, measurement of PC should be performed with 20 min from sampling to obtain accurate results.

PB 1602 | In vitro Ibrutinib Effect (Inhibitor of Bruton´S Tyrosine Kinase) on Platelets Function. A Single Centre Study

S. Gkotsi[1], M. Dimou[2], A. Chanos[1], O. Katsarou[1], P. Panayiotidis[2], P. Kotsi[1]

[1]*Laiko General Hospital, Hemostasis Department Hempophilia Centre Blood Bank, Athens, Greece,* [2]*Laiko General Hospital, 1st Propaideutic Internal Medicine Department, Athens, Greece*

Background: Ibrutinib is a Bruton´s tyrosine kinase (BTK) inhibitor , in use for the treatment of B- cell malignancies and shown to increase the risk of hemorraghic complications in this patient setting. BTK is expressed in platelets and plays an important role in platelet signaling pathways.

Aims: To sttudy the effect of ibrutinib on platelets function in vitro, in patients (pts) with B cell malignancies receiving treatment with the drug.

Methods: 14 patients under Ibrutinib were included. Platelets function was examined before and at least one month after treatment. Impedance Aggregometry (Multiplate analyzer-IA) in whole blood was performed using ADP, collagen, ristocetin arachidonic acid (AA) and thrombin (TRAP-6) as agonists. Light Transmission Aggregometry (LTA) was also performed in platelet rich plasma (PRP) and washed patient platelets with ADP and colllagen (two different concentrations) epinephrine, ristocetin and AA. TxB2 (thromboxane B2) was measured by elisa (ENZO) in washed patient platelets after aggregation using AA for 6 min and the addition of EDTA as stop solution.

Results: Collagen aggregation was reduced i) In pts whole blood IA (mean before treatment (A) 26U, mean after treatment (B) 25U and controls mean (C) 63U.

ii) LTA in washed pts platelets with concentration 20 µg/ml B:32% vs C:81% (p< 0.0001) and with 10 µg/ml B:18% vs C:73% (p< 0.0001).

Ristocetin in whole blood (IA) in pts with platelets >10^9/L (n=8) showed A: 34U, B:21U vs C: 109U.

LTA with washed platelets using AA as agonist showed reduced aggregation B:49% vs C:59% p=0.014. TXB2 was found reduced in pts vs controls (B:750ng/ml vs C:1112ng/ml).

Conclusions: Ibrutinib has a more pronounced effect on platelets aggregation with collagen and ristocetin and a mild effect on AA aggregation. Patients in our cohort didn´t show a bleeding phenotype. IA is simple and fast and could be used to advice pts programmed to undergone hemostasis challenges.

PB 1603 | The Platelet Function Analyzed by Flow Cytometry in Psoriatic Patients on Reference Therapy

T. Vavilova[1], A. Ermakov[2], L. Gaikovaya[2], L. Karyakina[2], R. Pavlova[2]

[1]*Federal Almazov North-West Medical Research Centre, Saint Petersburg, Russian Federation,* [2]*North-Western State Medical University named after I.I. Mechnikov, Saint Petersburg, Russian Federation*

Background: Platelets have an important role in hemostasis and thrombosis as well as in increasing inflammation. The pathogenesis of psoriasis may involve platelet activation.

Aims: Aim of the study was to identify platelet function activity in patients with a psoriasis on reference therapy by flow cytometry accurate measurement method.

Methods: The study included 13 psoriatic patients at the age of 44±9 years and 25 healthy volunteers at comparable age. All patients received the reference therapy and the selection phototherapy. The amount of receptor GPIIb-IIIa and P-selectin on the platelet surface were assessed in whole blood and platelet-rich plasma before and after activation of 10 uM ADP by flow cytometer Cytomics FC500 (Beckman Coulter). The fluorescence-labeled monoclonal antibodies to CD61 (GPIIb-IIIa) and CD62 (P-selectin) were used.

Results: The pool of platelets expressed P-selectin after 20 uM ADP activation was significantly lower in psoriatic patients prior to treatment in comparison to healthy volunteers (4,4±1,9% vs 26,7±2,0%; p<0.05). The expression of P-selectin on the activated platelets membrane increase up to 7,9±4,4% (p<0.05) to Day 10 of reference therapy but has not reached the level of healthy individuals. The same results were obtained for GPIIb-IIIa: before ADP-activation 5,9±0,7 MFI, after ADP-activation 18,2±1,9 MFI; in healthy volunteers - 9,6±0,4 MFI and 25,1±1,4 MFI, respectively; p<0.05.

Conclusions: The decrease in the number of ADP-activated platelets may reflect their exhaustion as a result of long circulation and involving in inflammatory processes in skin. Against the background of the carried-out therapy the P-selectin expression on platelets surface increase significantly, caused by emergence of functionally full-fledged platelets replenished from bone marrow.

Thus, system reference therapy of psoriasis in combination with phototherapy, leads to platelets function normalization trend according to decrease in inflammatory presentation of skin.

PB 1604 | PANDA, a Biomarker for Diagnostic of Leaky Gut Syndrome

M. Lopez[1,2], G. Nowak[3]

[1]Justus Liebig University Giessen, Giessen, Germany, [2]Instituto Venezolano de Investigaciones Científicas, Caracas, Venezuela, [3]University Hospital Jena, Jena, Germany

Background: Platelets are anucleate cells that play a crucial role in primary hemostasis. In addition, they also play a role in inflammation and immunity by expressing Toll-like receptors (TLRs) to sense and bind microbial products, such as LPS. In patients with leaky gut syndrome (LGS), a condition also referred to as „increased intestinal permeability", LPS leaks into the intestinal microcirculation and binds to platelet´s surfaces. Heparins also interact with platelets via the GP IIIa, that is a part of the fibrinogen receptor (GPIIb/IIIa). After binding of heparin molecules on GPIIIa, platelets are partially activated and started platelet-platelet interactions with adhesive proteins. The activation threshold of LPS-bound platelets by heparin is lower than that of LPS-free platelets. For this reason, we propose that the **P**latelet **A**nalyzed **N**umber in **D**ifferent **A**nticoagulants (or PANDA) could be an indicator (biomarker) for LGS.

Aims: The aim of this work was to investigate whether differential platelet aggregation in heparin and EDTA blood could be a biomarker for diagnostic of LGS.

Methods: Platelet count was determined in EDTA- and heparin-blood from 40 patients with LGS-associated gastrointestinal diseases using an automatized hematological counter. Platelet count was also determined in healthy adult volunteers (control group).

Results: A highly significant difference ($p < 0.0001$) in platelet count in heparin and EDTA blood was seen in patients with gastrointestinal diseases. In contrast, in healthy volunteers the platelet number in both blood samples was very similar.

Conclusions: Our results indicate that the PANDA test can be used as Biomarker for LGS-associated gastrointestinal diseases.

PB 2357 | Knock down the CD70 Expression in DCs Could Inhibit the CD4+ T Cells Differentiating to Tregs in ITP

Z. Zhou[1], Y. Wang[1], H. Li[2], R. Yang[2]

[1]The Second Affiliated Hospital of Kunming Medical University, Department of Hematology, Kunming, China, [2]State Key Laboratory of Experimental Hematology, Institute of Hematology and Hospital of Blood Disease, Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin, China

Background: CD70 expressed on T cells causes a decrease in T-cell response, an impairment of autoreactive T-cell immune tolerance.

Aims: This study aims to assess the biological properties and functions of CD70 costimulatory molecule on dendritic cells(DCs) from patients with chronic immune thrombocytopenia (ITP).

Methods: DCs were generated from monocytes isolated from peripheral blood. Chemically synthesized siRNA was then transferred into the cells to block CD70 expression. The CD4+ T cells were co-cultured with DCs to assess the suppression capacity of DCs in the proliferation of CD4+ T cells and the production of IL-10 and IFN-γ by CD4+ T cells. The CD4+ T cells were co-cultured with DCs to assess the ability of DCs in the induction of Regulatory T cells (Tregs).

Results: Dendritic cells were transfected with FITC-labelled scrambled siRNA for 4-6h. The transfection efficiency was average 60%. After transfection (48 h), the results of real-time RT-PCR analysis showed strong and specific downregulation of CD70 mRNA. DCs from transfected group could inhibit the proliferation of PHA-activated CD4+ T cells than the negative control in ITP patients($p=0.008$), but showed no difference in group of normal control ($p=0.08$). In chronic ITP patients and normal controls, the DCs from transfected group could inhibit the expression of IFN-γ compared with the group of negative control ($p=0.018$, $p=0.043$) and increase the expression of IL-10 ($p=0.012$, $p=0.043$). In chronic ITP patients and normal controls, the DCs from transfected group were defective in inducing the CD4+ T cell differentiating to CD4+CD25+CD127low Tregs compared to the negative control ($p=0.012$, $p=0.043$).

Conclusions: In our study, the DCs from siRNA group could inhibit the CD4+ T cells and induce the CD4+ T cells differentiating to Tregs. This approach is a useful tool by which costimulatory molecules of DC can be studied as well as a potential therapeutic option for autoimmune disease.

PB 2358 | IL-10 Producing B Cells Induced by CD72 Ligation Suppress Th1 and Th17 Polarization in Primary Immune Thrombocytopenia

M. Lyu[1,2], Y. Hao[3], Y. Li[3], C. Lyu[3], H. Li[3], F. Xue[3], X. Liu[3], L. Zhang[3], R. Yang[3]

[1]Institute of Hematology and Blood Disease Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, State Key Laboratory of Experimental Hematology, Tianjin, China, [2]Affiliated Suzhou Hospital of Nanjing Medical University, Department of Hematology, Suzhou, China, [3]Institute of Hematology and Blood Disease Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College,, State Key Laboratory of Experimental Hematology, Tianjin, China

Background: Primary immune thrombocytopenia (ITP) is characterized by reduced platelet count secondary to immune-mediated destruction. Impaired regulatory T cell (Treg) and B cell (Breg) compartment and skewed T helper cells (Th)1 and possibly Th17 responses have been described in ITP patients. CD72, a co-receptor of B cell, is involved in the pathogenesis of ITP. The role of CD72 on defect of Breg and aberrant T-cell polarization in ITP remains unknown.

Aims: We aimed to investigate the contribution of CD72 in control of interleukin (IL)-10 producing B cells and Th development in chronic ITP.

Methods: Distribution of IL-10 producing B cells was tested in ITP patients and healthy controls. Peripheral blood mononuclear cells (PBMCs) or PBMCs depleted of $CD19^+$ B cells were activated by anti-CD40 and IL-21 in the presence or absence of anti-CD72 to elucidate the effects of CD72 on IL-10 producing B cells and $CD4^+$T cells. The potential regulatory mechanism of CD72 was also investigated in co-culture of isolated $CD4^+$T cells with $CD19^+$B cells.

Results: The frequency of IL-10 producing B cells was decreased in ITP patients and was positively correlated with platelet counts.In culture of PBMCs with anti-CD72, the frequency of IL-10 producing B cells was elevated and $CD40^+$T cell proliferation was inhibited in patients and controls. Furthermore, under this stimulatory condition, $CD4^+$ T cells from ITP patients produced less interferon-γ (IFN-γ) and IL-17 but more IL-4, whereas their conversions into Tregs and IL-10^+T cells remained unchanged. Depletion of B cells completely reversed the effect of B cells mediated by CD72 on $CD4^+$ Th cells and cytokine production. Moreover, the observed regulatory effect of B cells mediated by CD72 was partly dependent on IL-10 release and cell-to-cell contact.

Conclusions: This study showed that the ligation of CD72 might suppress effector T cells by enhancing IL-10 producing B cells in ITP. This underscores the critical role of targeting CD72 in the amelioration of ITP.

PB 2359 | Impact of Platelet Transfusion on Thromboembolic Events in Patients with Acute Heparin-induced Thrombocytopenia

S. Miyata[1], T. Maeda[2], H. Yamamoto[3], H. Okazaki[4]

[1]National Cerebral and Cardiovascular Center, Division of Transfusion Medicine, Suita, Japan, [2]National Cerebral and Cardiovascular Center, Transfusion Medicine, Suita, Japan, [3]National Cerebral and Cardiovascular Center, Center for Advancing Clinical and Translational Sciences, Suita, Japan, [4]University of Tokyo, Transfusion Medicine, Tokyo, Japan

Background: Platelet concentrate (PC) transfusion is considered to be relatively contraindicated for heparin-induced thrombocytopenia (HIT), since transfused platelets (plts) could be activated by HIT antibodies (Abs), triggering thromboembolic events (TEEs). However, it remains unclear if PC transfusion is a risk for TEEs in HIT.

Aims: To clarify the impact of PC transfusion on TEEs in HIT patients (pts) whose diagnosis was confirmed with the washed plt activation assay, considering the temporal relationship between PC transfusion and TEEs.

Methods: Sera of pts that activated plts at a therapeutic (but not high) heparin concentration were defined as positive. Of these, sera that activated plts within 30 min or in the absence of heparin were defined as strongly positive (SG+). The remaining sera were considered weakly positive (WK+).

Results: We analyzed 609 pts clinically suspected of having HIT (Table 1). Pts with stronger plt-activating Abs had a higher incidence of TEEs after heparin exposure than those who tested negative (NEG) [60% (70/116) in SG+, 48% (33/69) in WK+, and 31% (130/424) in NEG, p< 0.001). In each group, 20-29% of pts received PC transfusion for thrombocytopenia that led to HIT suspicion. Among transfused pts, the incidence of TEEs after heparin exposure was higher in pts with stronger plt-activating Abs [52% (14/27) in SG+, 43% (6/14) in WK+, and 27% (33/121) in NEG, p=0.031], but the incidence of TEEs after PC transfusion was almost similar [22% (6/27) in SG+, 21% (3/14) in WK+, and 15% (18/121) in NEG, p=0.51]. In HIT pts, 89% (8/9) of TEEs after PC transfusion occurred before starting non-heparin anticoagulants.

Conclusions: Among pts who received PC transfusion for thrombocytopenia that led to HIT suspicion, the overall incidence of TEEs was

TABLE 1 Association of platelet transfusion with thromboembolic events in patients clinically suspected of having HIT

Patients clinically suspected of having HIT (n = 609)	enrolled in a nationwide HIT registry	approved by the Ethics Review Committees		χ^2 or Fisher´s exact test
Washed platelet activation assay	Strongly positive	Weakly positive	Negative	
Diagnosis	HIT	HIT	non-HIT	
Number of patients	116 (19.0%)	69 (11.3%)	424 (69.6%)	609 (100%)
TEEs after heparin exposure	70/116 (60.3%)	33/69 (47.8%)	130/424 (30.7%)	p<0.001
PC transfusion for thrombocytopenia leading to HIT suspicion	27/116 (23.3%)	14/69 (20.3%)	121/424 (28.5%)	p=0.24
Among patients with PC transfusion				
TEEs after heparin exposure	14/27 (51.9%)	6/14 (42.9%)	33/121 (27.3%)	p=0.031
TEEs after PC transfusion	6/27 (22.2%)	3/14 (21.4%)	18/121 (14.9%)	p=0.51

higher in pts with HIT Abs with more robust plt-activating properties. However, PC transfusion appeared not to increase TEEs significantly in HIT pts even with stronger plt-activating Abs, especially in those undergoing non-heparin anticoagulant therapy.

PB 2360 | Isolation of a Monoclonal IgG Kappa with Functional Autoantibody Activity against Platelet Factor 4/Heparin from a Patient with a Monoclonal Gammopathy of Undetermined Significance and Clinically Overt Heparin Thrombocytopenia

D. Faille[1], M. Hurtado-Nedelec[1], A. Ouedrani[1], J. Amiral[2], M.-G. Huisse[1], M.-P. Chauveheid[1], M. Mazighi[3], N. Ajzenberg[1]

[1]*CHU Bichat, Paris, France,* [2]*Hyphen Biomed, Neuville sur Oise, France,* [3]*CHU Lariboisière, Paris, France*

Background: A 62-year-old man followed for several years for chronic thrombocytopenia (platelets 80 G/L) and monoclonal gammopathy of undetermined significance (MGUS, IgG1 kappa peak 3.8 g/l) was hospitalized for cerebral thrombophlebitis. At day 6 of treatment with unfractionated heparin, he developed extensive thrombosis of the right radial and ulnar vein, which made suspect heparin-induced thrombocytopenia (HIT). IgG antibodies against platelet factor 4 / heparin (PF4/H) were strongly positive (>3000AU, Zymutest®HIA IgG; Hyphen BioMed). Heparin-induced platelet agglutination assay (HIPA) was positive at therapeutic concentrations of heparin (0.2 and 0.5 IU/ml) and negative at 50 IU/ml, confirming the diagnosis of HIT. Platelet activation was observed in the absence of heparin. This result, combined with the presence of thrombocytopenia and thrombosis prior to treatment with heparin, suggested spontaneous HIT. We tested patient plasma collected before initiation of heparin treatment and found a high titer of anti-PF4/H that persisted beyond 100 days after the thrombotic episode.

Aims: To show that patient monoclonal IgG and anti-PF4/H antibodies are one same entity.

Methods: Anti-PF4/H antibodies were purified by affinity chromatography.

Results: Immunofixation carried out on the fraction obtained at pH 2.5 showed that it contained a monoclonal IgG kappa. This fraction tested in ELISA showed a strong affinity for PF4/H but not for PF4 alone and induced platelet activation in the presence and absence of heparin.

Conclusions: This is the first reported case of MGUS associated with a human monoclonal IgG with anti-PF4/H activity responsible for a clinically overt HIT. This human monoclonal IgG has the specificity of activating platelets even in the absence of heparin, which distinguishes it from other monoclonal anti PF4/H such as KKO. We therefore aim to further characterize the reactivity of this monoclonal IgG in order to identify its precise endogenous antigenic target.

PB 2361 | Anticoagulation Stewardship Program for Heparin Induced Thrombocytopenia: A Cooperative Effort between a Community Hospital System Pharmacy Anticoagulation Service and an Associated Reference Laboratory

C. Mahan[1], L. Kelly[2], A. Pierce[3], A. Burnett[4], A. Haghamad[5]

[1]*University of New Mexico, Presbyterian Healthcare Services, College of Pharmacy, Albuquerque, United States,* [2]*University of New Mexico, Presbyterian Healthcare Services, Albuquerque, United States,* [3]*Presbyterian Healthcare Services, Tricore Labs, Albuquerque, United States,* [4]*University of New Mexico, College of Pharmacy, UNM Hospitals, Albuquerque, United States,* [5]*Tricore Labs, Albuquerque, United States*

Background: Heparin induced thrombocytopenia(HIT) is a rare and potentially life- or limb-threatening complication. HIT misdiagnosis may cause exposure to high-cost, unindicated anticoagulants with high bleeding risk. Anticoagulation treatment is typically initiated when a heparin induced platelet antibody(HIPAB) is ordered. Prior studies including a pharmacy/lab intervention have demonstrated a reduction in inappropriate ordering of HIT labs by utilizing the 4T score and contacting the physician for low risk patients.

Aims: We hypothesized that a pharmacy-led, multidisciplinary team-based intervention with 4T pre-test probability would reduce inappropriate HIPAB tests, reduce costs, and decrease exposure to high-risk anticoagulants. A previous retrospective study of our system revealed that 81% (47/58) of patients tested in a 3 month period were low risk and unindicated.

Methods: In March 2016, the laboratory began notifying the pharmacy when HIPAB tests were ordered. A pharmacist would calculate a 4T score, contact the ordering provider and suggest test cancellation if low (≤3) risk. Special coagulation pathologists provided clinical support to the pharmacist if needed.

Results: After eight months, only 14.8% (16/108) of HIPAB tests were unindicated. The intervention resulted in a decrease of inappropriate HIT testing by 66.2% and estimated cost savings of $45,000. Average monthly tests decreased from 23 ordered and 23 processed to 14.5 and 7.1 per month, respectively in the same time frame, with an 86% acceptance of cancelling HIPAB for recommended patients. Overall ordered HIT labs decreased from 219 in 2015 down to 50 in 2016 increasing HIPAB yield from 10% to 44%.

Conclusions: A joint multidisciplinary team based intervention with Pharmacists, Pathologists, and special coagulation technicians can result in improved patient care and cost savings. This study provides validation that a pharmacist intervention and multidisciplinary approach in multiple hospitals systems can improve patient care as related to HIT.

PB 2362 | IP-10 and MCP-1 Gene Polymorphisms in Chinese Patients with Chronic Immune Thrombocytopenia

X. Zhang[1,2], D. Zhang[2], R. Yang[2]

[1]*Zhongnan Hospital of Wuhan University, Hematology, Wuhan, China,* [2]*Institute of Hematology & Hospital of Blood Diseases, Chinese Academy of Medical Sciences & Peking Union Medical College (CAMS & PUMC), Thrombosis and Hemostasis, Tianjin, China*

Background: Aberrant Th1/Th2 polarization is considered to play a crucial role in the abnormal immune state of primary immune thrombocytopenia (ITP). IFN-γ-inducible protein of 10 kilodaltons (IP-10) and Monocyte chemoattractant protein-1(MCP-1) gene are involved in enhancing the Th1 and Th2 immune response, respectively. The serum levels and biological activity of the IP-10 and MCP-1 proteins may be regulated by a single nucleotide polymorphism occurring at position -201 and position -2518 of the IP-10 and MCP-1 gene promoters.

Aims: We designed our study on investigating the relationship between the distribution of IP-10 (-201G/A) and MCP-1(−2518A/G) polymorphisms and the susceptibility of ITP.

Methods: A total of 235 ITP patients and 162 healthy donors were enrolled in this study, and the distributions of polymorphisms were investigated mainly by polymerase chain reaction-restriction fragment length polymorphism. Stratified analyses were conducted based on gender and onset age.

Results: The percentage of AA + AG genotype and the frequency of A allele of IP-10 in the ITP group was significantly elevated compared to the control group, while no differences were revealed in the genotype and allele distributions of MCP-1 between the two groups. Additionally, a comparable association between the AA + AG genotype and the ITP disease was observed in the adult cohort in IP-10. In the female cohort, a more evident discrepancy with regard to allelic and genotypic frequency distributions was observed in the IP-10 gene.However, there was no significant difference in either genotypes or allelic distribution of IP-10 in the male cohort.

Conclusions: In this study we demonstrated that the A allele and AA+AG genotype of IP-10 were associated with an increased risk of chronic ITP in Chinese people, indicating that individuals with A allele on IP-10 might have a higher risk of chronic ITP. This genetic change may be partly associated with the Th1 dominant immune response and female prone of the development of adult chronic ITP.

PB 2363 | Decreased TLR4 Expression on Monocytes May Cause Regulatory T Cells Abnormality in Patients with Primary Immune Thrombocytopenia

Y. Hao[1], B. Sun[2], H. Li[1], Y. Li[1], M. Lyu[1], R. Fu[1], L. Zhang[1], R. Yang[1]

[1]Institute of Hematology and Blood Diseases Hospital, Chinese Academy of Medical Sciences, Tianjin, China, [2]Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin, China

Background: TLR4, a key member of the TLRs, has been reported to be implicated in autoimmune diseases. An increasing number of studies have indicated that the TLR4 signaling pathway might interact with Tregs. However, the effect of TLR4 on Treg differentiation in chronic ITP remains unclarified.

Aims: The aim of the study was to explore the effect of TLR4 on Treg differentiation in chronic ITP.

Methods: Expression of TLR4 on monocytes in ITP patients and healthy controls was determined by flow cytometry. PBMCs were cultured in complete RPMI 1640 medium with or without anti-TLR4 and meanwhile stimulated with lipopolysaccharide (LPS). Tregs and Th17 cells were detected by flow cytometry. Levels of IL-10, IL-17A and TGFB1 in cell culture supernatants were measured by ELISA.

Results: Expression of TLR4 on monocytes was significantly decreased in patients with ITP than that in healthy controls and it had positive correlation with platelet count. The result of further experiments *in vitro* showed that activation of TLR4 with LPS could promote differentiation of Treg cells and anti-TLR4 attenuated this effect. There was no significant difference about Th17 cells among three subgroups. However, the Th17/Treg cell ratio was decreased after stimulation with LPS and increased with anti-TLR4. Moreover, activation of TLR4 with LPS could significantly promote the secretion of IL-10 and TGFB1, while anti-TLR4 significantly suppressed the secretion of them. Nevertheless, the secretion of IL-17A did not reach the statistical difference among three subgroups.

Conclusions: Decreased TLR4 appears to cause Tregs abnormality in ITP by modulating Tregs differentiation and immunoregulatory cytokines.

PB 2364 | The Abnormal Expression of Rap1 in Various Cells of Patients with Immune Thrombocytopenia

W. Liu[1,2], H. Li[2], R. Yang[2]

[1]People Hospital of Jiangsu Province, The First Affiliated Hospital of Nanjing Medical University, Nanjing, China, [2]Institute of Hematology and Blood Disease Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin, China

Background: Primary immune thrombocytopenia (ITP) is an autoimmune disease involved in the abnormal immunity and megakaryopoiesis. Rap1 plays a dominant role in the regulation of cell-cell interactions and MAP kinase (MAPK) activity in lymphocytes and megakaryocytes, which are important pathogenesis of ITP.

Aims: This study aimed to investigate the role of Rap1 played in ITP.

Methods: Megakaryocytes were induced from bone marrow $CD34^+$ cells of ITP patients and healthy controls (HC) in vitro. The expression of Rap1 in lymphocytes and megakaryocytes were measured by flow cytometry. The expression and subcellular localization of the Rap1 in immature and mature megakaryocytes were analyzed by confocal microscopy.

Results: The results showed that the expression of Rap1 in $CD4^+$ T, $CD8^+$ T, and $CD19^+$ B lymphocytes of ITP patients were significantly lower than that of healthy controls ($P = 0.004$, $P = 0.005$, $P = 0.009$, respectively). And the expression levels of Rap1 were increased obviously of ITP patients in remission

($P = 0.022$, $P = 0.019$, $P = 0.019$, respectively). Rap1 was predominantly detected on internal α-granule and the plasma membrane. High levels of Rap1 were detected in the majority of immature

megakaryocytes (ITP versus HC, $P > 0.05$), while the expression levels were decreased with the maturation of megakaryocytes (ITP versus HC, $P < 0.05$).

Conclusions: This is the first study indicates that abnormal expression of Rap1 in lymphocytes and megakaryocytes might participate in the pathogenesis of ITP. These findings suggest Rap1 as a therapeutic agent for ITP to be assessed in the future.

PB 2365 | Resequencing of GWAS Loci Identifies New Candidate Genes on Chromosome 5 for Heparin-induced Thrombocytopenia

A. Witten[1], J. Bolbrinker[2], A. Barysenka[1], F. Rühle[1], E. Garbe[3], R. Kreutz[2], M. Stoll[1]

[1]Institute of Human Genetics, University Clinic Muenster, Genetic Epidemiology, Münster, Germany, [2]Institute of Clinical Pharmacology and Toxicology, Charité - Universitätsmedizin Berlin, Berlin, Germany, [3]BIPS - Institute for Epidemiology and Prevention Research, Department of Clinical Epidemiology, Bremen, Germany

Background: Treatment with unfractionated (UFH) or low molecular weight (LMWH) heparins is an important strategy in the prevention and treatment of thrombotic diseases. Heparin-induced thrombocytopenia (HIT) is the most important specific adverse drug reaction (ADR) in response to heparin therapy resulting in a paradoxical prothrombotic state.

Aims: We conducted a pharmacogenetic genome-wide association study (GWAS) to explore whether a genetic predisposition contributes to the individual risk for HIT.

Methods: Within a surveillance case-control study program at a single pharmacovigilance center in Berlin, Germany, we selected 182 suspected HIT cases and 182 controls (matched for age, sex and exposure to the same class of heparin) for the pharmacogenetic study consisting of a GWAS (96 cases and 96 controls) and a replication in additional 86 cases, followed by imputing and overall fine mapping analysis. In order to find variants not detected in our GWAS but contributing to the detected association signals, we applied next generation sequencing (NGS)-based targeted resequencing approach in a subgroup of 73 HIT patients and 23 controls.

Results: One single nucleotide polymorphism (SNP, rs1433265) from initially 16 identified SNPs in our GWAS was successfully replicated ($P=1.5\times10^{-4}$) and remained the most strongly associated SNP ($P=3.5\times10^{-5}$) after imputing genotypes on chromosome 5. Fine mapping revealed two significantly associated haplotypes with an odds ratio of 0.63 (95% CI, 0.46-0.88; $P=5.6\times10^{-3}$) and 2.41 (95% CI, 1.64-3.55; $P=4.9\times10^{-6}$). We applied targeted resequencing for the regions with the 16 most strongly HIT-associated SNPs. A C-alpha test was applied to perform a gene-based test for the impact of rare variants in our targeted region and we were able to detect two candidate genes, *ICE1* (P = 0.010) and *ADAMTS16* (P= 0.005) containing 17 and 23 rare variants, respectively.

Conclusions: These results provide a basis for further studies that aim to characterize the genetic predisposition to HIT.

PB 2366 | Elevated Plasma sCXCL16 Correlated with Th1 Polarization in Patients with Primary Immune Thrombocytopenia

Y. Hao[1], X. Dou[2], Y. Li[1], H. Li[1], M. Lyu[1], R. Fu[1], L. Zhang[1], R. Yang[1]

[1]Institute of Hematology and Blood Diseases Hospital, Chinese Academy of Medical Sciences, Tianjin, China, [2]Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin, China

Background: CXCL16, a CXC subtype member of the chemokine superfamily, exists in two forms, the membrane-bound CXCL16 and the soluble CXCL16 (sCXCL16). CXCL16 is the sole ligand for the receptor CXCR6. sCXCL16 functions as a chemotactic factor for functional-CXCR6-expressing Th1 and Tc1 cells. Moreover, sCXCL16 has been showed to be modulated by Th1 type cytokines, such as IFN-γ and TNF-α and implicated in immune response of autoimmune diseases. However, the role of sCXCL16 in ITP has not been clarified yet.

Aims: The aim of the study was to explore the role of plasma sCXCL16 in ITP.

Methods: Plasma sCXCL16, IFN-γ and IL-4 were measured by ELISA. Expression of CXCR6 on lymphocyte subsets were determined by flow cytometry. The mRNA expression of CXCL16 and CXCR6 were detected based on real-time PCR. In addition, plasma sCXCL16, CXCL16 and CXCR6 mRNA levels of 8 patients were monitored before and after treatment.

Results: Plasma sCXCL16 levels were significantly increased in active ITP patients compared to remission patients and healthy controls. And elevated plasma sCXCL16 levels positively correlated with IFN-γ, IFN-γ/IL-4 ratio and negatively correlated with IL-4, platelet counts in ITP patients. Besides, expression of CXCR6 on lymphocyte subsets and mRNA levels of CXCL16 and CXCR6 in PBMCs were higher in active ITP patients compared to remission patients and healthy controls. Additionally, plasma sCXCL16 and IFN-γ levels were reduced while CXCR6 mRNA expression were down-regulation after effective treatment compared with those before treatment.

Conclusions: Elevated plasma sCXCL16 might be implicated in the pathogenesis of ITP by correlated with Th1 polarization and disease activity.

PB 2367 | Time to Disappearance of Platelet-activating Antibodies Depends on the Strength of Their Platelet Activating Properties in Patients with Heparin-induced Thrombocytopenia

T. Maeda[1], H. Okazaki[2], S. Miyata[1]

[1]National Cerebral and Cardiovascular Center, Division of Transfusion Medicine, Suita, Japan, [2]University of Tokyo, Department of Transfusion Medicine, Tokyo, Japan

Background: Heparin-induced thrombocytopenia (HIT) is caused by platelet-activating antibodies (HIT Abs), which decline to an

Fig

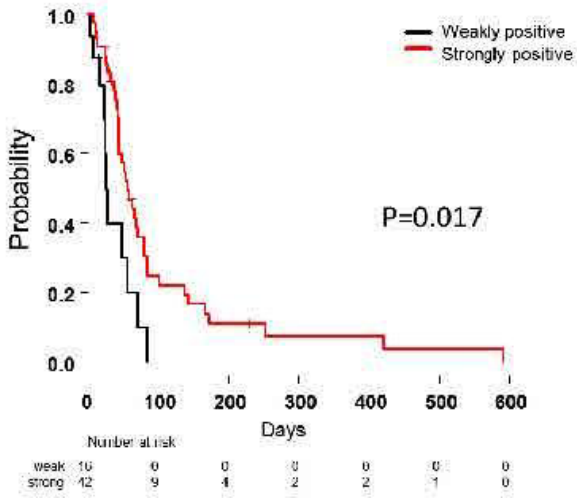

FIGURE 1

undetectable level within a couple of months. Since evidence for an anamnestic response on heparin re-exposure is lacking in patients (pts) with a history of HIT, heparin can be re-administered during cardiovascular surgery (CVS) when HIT Abs are no longer detectable. Therefore, predicting the time to the disappearance of HIT Abs is crucial in acute HIT patients who require CVS.

Aims: To clarify the time to the disappearance of HIT Abs with the washed platelet activation assay.

Methods: In a nationwide registry of pts clinically suspected of having HIT, 196 pts whose sera activated platelets at a therapeutic (but not high) heparin concentration were diagnosed with HIT. The current analysis included 58 pts in whom subsequent sera were available to study changes in levels of HIT Abs at least twice over time. Sera that activated platelets within 30 min or in the absence of added heparin were defined as strongly positive (pos). The remaining positive sera were considered weakly pos.

Results: Among the 58 pts, 42 and 16 tested as strongly and weakly pos, respectively, when HIT was diagnosed. Figure 1 shows the proportion of pts over time in whom HIT Abs remained detectable. The time to disappearance of HIT Abs was significantly longer in pts who initially tested strongly pos than those who tested weakly pos (p=0.017, log-rank test). The median time to a negative test according to Kaplan-Meier analysis was 55 and 26 days in pts who tested strongly vs weakly pos, respectively.

Conclusions: Higher strength platelet-activating properties of HIT Abs were significantly associated with longer time to Ab disappearance. Based on these results, we recommend that if acute HIT patients require CVS, those who are weakly pos should wait for a couple weeks while those who are strongly pos should undergo plasma exchange or use an alternative anticoagulant.

PB 2368 | Predictive Factors for Successful Splenectomy in Immune Thrombocytopenic Purpura

M. Mitrovic[1,2], S. Matic[2,3], J. Bodrozic[1], M. Smiljanic[1], D. Antic[1,2], I. Djunic[1,2], M. Virijevic[1,2], P. Miljic[1,2], D. Tomin[1,2], N. Suvajdzic[1,2]

[1]Clinic of Hematology, Clinical Center of Serbia, Belgrade, Serbia, [2]Faculty of Medicine, University of Belgrade, Belgrade, Serbia, [3]The First Surgical Clinic, Clinical Center of Serbia, Belgrade, Serbia

Background: In the era of new drugs a proper patient's selection for splenectomy is particularly necessary. However, it is not clear whether there are pre or post-operative parameters able to predict splenectomy response.

Aims: To determine the pre and postoperative factors with potential to predict successful splenectomy outcome.

Methods: We retrospectively analyzed the data on 123 ITP patients (median age 43 years, range 19-74; 84/39 female/male; median follow-up from splenectomy 112 months (range: 2-364)) who underwent splenectomy between 1986 and 2015.

Results: The median pre-operative platelet count (PC) was 99×10^9/L (range 20-320×10^9/L). Complete remission (CR) was achievedin in 95/120 (79%), partial remission (PR) in 10/120 (7.5%) and 15/120 (112.5%) patients were refractory. Thirteen of the 110 (11.8%) responsive patients relapsed.

By univariate analysis younger age (41 vs 48, p= 0.025), lower number of pre-splenectomy therapies

(1 vs 2, p=0.028), response to steroids (69.5% vs 22.7%, p=0.021), higher PC at the time of splenectomy (90×10^9/L vs. 37×10^9/L, p=0.021), higher PC on the first and seventh days after splenectomy (387×25^9/L vs. 25×10^9/L, p=0.0035) and platelet destruction in spleen (86% vs 0%, p=0.0003) were predictive for good response. By multivariate analysis younger age (p=0.003), and the PC on the first (p=0.043) and seventh days (p=0.0013) after splenectomy were predictive of a favorable response.

Relapsed patients had significantly lower CR rate (53% vs. 93%, p=0.002), PC three weeks (150×10^9/L vs. 340×10^9/L, p=0.048) and three months (130×10^9/L vs. 278×10^9/L, p=0.007) after splenectomy. Only CR rate retained statistical significance (p=0.0023) by multivariate analysis.

Conclusions: Splenectomy is effective in approximately two thirds of patients with ITP. Our study have been identified some potential predictive factor for successful splenectomy. However, large population based studies for testing a predictive cut-off of age, pre and post-splenectomy PC values are needed.

PB 2369 | The Th17/Treg Imbalance and Fatigue in Primary Chronic Immune Thrombocytopenia

Y. Li, Y. Hao, M. Lyu, H. Li, R. Yang

State Key Laboratory of Experimental Hematology, Institute of Hematology and Blood Disease Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin, China

Background: Fatigue is an important symptom for patients with primary chronic immune thrombocytopenia (ITP). However, the biological mechanisms underlying ITP related-fatigue are unknown.

Aims: This study aimed to determine the relationship between ITP related-fatigue and Th17/Treg imbalance.

Methods: We assessed fatigue in patients with chronic ITP using the Functional Assessment of Chronic Illness Therapy-Fatigue scale (FACIT-Fatigue). Peripheral blood was collected to assess Th1, Th2, Th17 and Treg cell populations by Flow cytometry and to measure the levels of interleukin-10 (IL-10), IL-6, IFN-γ, IL-4, IL-17A, and IL-1β by ELISA.

Results: Thirty-seven patients were recruited including fifteen men and twenty-two women aged between 18 and 65 years (mean age 45.6 ± 12.6 years). Participants were dichotomized into severe fatigue (n = 12) and low-moderate fatigue (n = 25) groups. There were no differences between the two groups stratified by fatigue severity with regard to age, gender, disease duration, platelet counts, comorbidities, and previous treatment regimens. The ratio of Th17 to Treg was significantly higher in the severe fatigue group compared to the low to moderate fatigue group (0.30±0.25 versus 0.42±0.21, p=0.038). Plasma IL10 level was significantly higher in low to moderate fatigue patients than in severe fatigue patients (1.48±0.51 versus 0.91±0.47, p=0.002). Furthermore, plasma IL-6 level in severe fatigue group was significantly higher in low to moderate fatigue group (2.08±1.28 versus 1.49±0.51, p=0.019). In contrast, there was no significant difference between IFN-γ, IL-4, IL-17A, and IL-1β cytokine concentration between the two groups. Th17/Treg ratio correlates with plasma IL-6 levels (r=0.407, p= 0.013). Higher IL-10 levels were associated with a lower Th17/Treg ratio (r = −0.408, p = 0.025).

Conclusions: Our preliminary findings suggest that an imbalance in the Th17/Treg ratio is associated with the fatigue severity of chronic ITP.

PB 2370 | Predictors of Fatigue among Individuals with Primary Immune Thrombocytopenia in China

Y. Li, M. Lyu, Y. Hao, R. Yang

State Key Laboratory of Experimental Hematology, Institute of Hematology and Blood Disease Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin, China

Background: Fatigue is an aspect of primary immune thrombocytopenia (ITP), which is important to patients.

Aims: This cross-sectional study was conducted to examine a range of variables potentially associated with fatigue among individuals with ITP and to determine which variables best predict subjective fatigue.

Methods: Two hundred and seven patients with ITP and 213 matched healthy controls (MHCs) were assessed for patient-reported fatigue with the Chinese version of the Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue scale. In addition, to further investigate other factors potentially predicting fatigue; sleep quality (the Pittsburgh sleep quality index (PSQI)), physiological conditions (the Hospital Anxiety and Depression scale (HADS)) and bleeding score(the ITP-specific Bleeding Assessment Tool (ITP-BAT)) were also evaluated. Correlations between fatigue and other variables were examined, and the predictors of fatigue were determined with multiple regression analyses.

Results: The mean age was 42.1±10.9 years and 40.5±11.1 years in ITP patients and healthy controls, respectively (p=0.864). The FACIT-F score was significantly lower in ITP patients (37.5±9.05) compared to 217 MHCs (45.8±6.02) (p=0.001).

The FACIT-F score in ITP patients was negatively correlated with the PSQI (r=-0.654, p 0.001), HADS-depression (r=-0.598, p 0.001), HADS-anxiety (r=-0.616, p 0.001) and bleeding severity (r=-0.276, p 0.001). Platelet count was positively correlated with the FACIT-F score (r=0.307, p 0.001). A multiple linear regression analysis revealed that ITP-related fatigue could be explained by sleep quality, platelet count, depression, and bleeding severity.

Conclusions: Fatigue severity was mainly associated with disease-related factors but also patient-related variables, indicating that the etiology of fatigue in ITP is multifactorial. Interventions addressing depressive symptoms, sleep quality, bleeding symptoms and platelet count could be potential avenues for treatment of fatigue in patients with ITP.

PB 2371 | Elevated Plasmacytoid DCs Proportion and Plasma IFNα Concentration in Active ITP Patients

H. Li, Y. Hao, R. Yang

Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin, China

Background: Dendritic cells (DCs) are key factors in linking innate and adaptive immunity. Among them, Myeloid DCs (mDCs) are highly potent in antigen capture, presentation and therefore can effectively stimulate T-cells. plasmacytoid DCs (pDCs) release copious amounts of type I IFNs following activation and induce differentiation of plasma cells. DCs abnormalities are involved in many autoimmunities. However, whether the distribution of DCs is abnormal in ITP was still unknown.

Aims: To detect the distribution of DCs and associated cytokines expressions in ITP patients.

Methods: A total of 23 untreated active ITP patients, 25 ITP patients in remission and 28 healthy donors (HCs) were enrolled in this study. Our research was approved by the hospital-based ethics committee and comply with the declaration of Helsinki. In addition, the proportion of mDCs (lin-HLA-DR+CD11c+CD123-) and pDCs (lin-HLA-DR+CD11c-CD123+) were detected by FACS. The plasma IFNα, IL-6 and TNFα levels were analyzed by ELISA. And the mRNA expressions of Interferon regulatory factor (IRF) 5, IRF7, Toll like receptor (TLR)7 and TLR9 in peripheral blood mononuclear cells were detected by real-time PCR.

Results:

(1) The percent of pDCs in peripheral blood from active ITP patients (16.64±3.04) was higher than those of patients in remission (10.24±1.39) and HCs (9.56±1.43), and no difference were found between patients in remission and HCs. However, although mDCs proportion seems decreased in active ITP compared with HCs, there was no difference was found.

(2) the plasma IFNα concentration in active ITP patients (40.15±8.42 pg/mL) was elevated compared with this in patients in remission (15.15±3.75 pg/mL) and HCs (8.78±2.67 pg/mL), and no difference was found between patients in remission and HCs .Nevertheless, the concentrations of IL-6 and TNFα were not different among these three subsets.

(3) No difference of IRF5, IRF7, TLR7 and TLR9 mRNA expressions were found.

Conclusions: elevated proportion of pDCs may be involved in ITP by promoting IFNα secretion.

PB 2372 | A Prospective, Double-blind, Multicenter Study on FCM-based Measurement of Circulating Reticulated Platelets as a Diagnostic Assay for Immune Thrombocytopenia

Y. Hou[1], R. Xu[2], D. Li[3], K. Bi[4], X. Wang[5], C. Zheng[6], M. Hou[1], J. Peng[1]

[1]*Qilu Hospital, Shandong University, Department of Hematology, Jinan, China,* [2]*Affiliated Hospital, Shandong University of Traditional Chinese Medicine, Department of Hematology, Jinan, China,* [3]*Jinan Central Hospital, Department of Hematology, Jinan, China,* [4]*QianFoShan Hospital Affiliated to Shandong University, Department of Hematology, Jinan, China,* [5]*Shandong Provincial Hospital Affiliated to Shandong University, Department of Hematology, Jinan, China,* [6]*Shandong University Second Hospital, Department of Hematology, Jinan, China*

Background: Reticulated platelets (RP) are immature platelets that contain residual RNA and represent the youngest platelets in the circulation. Based on differential diagnosis, immune thrombocytopenia (ITP) still lacks a definitive test to support the identification of active patients.

Aims: To distinguish ITP from isolated thrombocytopenia due to aplastic thrombocytopenic disorders or chemotherapy-induced thrombocytopenia.

Methods: We performed a 6-month, prospective, multicenter validation study (NCT02967328) involving 6 clinical sites and 524 patients each with a platelet count less than 60×10^9/L. Informed consent was obtained from all participants and the study was approved by the medical ethics committee of Qilu Hospital. The percentages of reticulated platelets (RP%) were analyzed by flow cytometry using thiazole orange that binds cytosolic RNA. Results of a central, blinded clinical review of the entire cohort served as the reference standard. The differences between mean values were evaluated using Student *t* test.

Results: Of the 524 tested patients, 39 were classified as ITP by the review board. The FCM-based measurement of RP% identified 34 out of 39, and RP% above 8.6% (mean + 3SD of controls) had a negative predictive value of 98.8% (95% confidence interval [CI], 97.2 to 99.6) with a sensitivity of 87.2% (95% CI, 71.8 to 95.2) and a specificity of 88.0% (95% CI, 84.7 to 90.7). ITP patients with RP% above 8.6% demonstrated significantly higher levels of immature platelets (Fig. 1), lower concentrations of serum thrombopoietin (Fig. 2) and big platelet morphology showing brilliant cresyl blue-stained granules, compared to other thrombocytopenic patients. Bone marrow cytologic analysis of the 5 patients with false negative results revealed 4 with insufficient numbers of megakaryocytes.

Conclusions: These data suggested that FCM-based measurement of RP% might be valuable in identifying thrombocytopenic disorders due to early platelet destruction such as ITP.

PB 2373 | Comparison Head-to Head of Two Functional Assays in the Assessment of Heparin-induced Thrombocytopenia

M.-C. Gonthier[1], D. Faille[1], M. Alhenc-Gelas[2], C. Pouplard[3], N. Hezard[4], M.-G. Huisse[1], M.-C. Bourrienne[1], N. Ajzenberg[1]

[1]*Bichat-Claude Bernard University Hospital, Haematology-Hemostasis, Paris, France,* [2]*Georges Pompidou European Hospital, APHP, Haematology-Hemostasis, Paris, France,* [3]*University Hospital of Tours, Haematology-Hemostasis, Tours, France,* [4]*University Hospital of Reims, Haematology-Hemostasis, Paris, France*

Background: Diagnosis of Heparin-induced thrombocytopenia (HIT) is difficult to achieve especially in cardiac surgery and requires laboratory confirmation using functional tests.

Aims: To compare the performance of 2 functional assays: serotonin release assay (SRA) and heparin-induced platelet activation test (HIPA) in patients suspected of HIT in cardiac surgery and medical setting.

Methods: 115 patients suspected of HIT (78 after cardiac surgery and 37 in medical setting) were included between 2010 and 2015. Criteria of inclusion were: anti-PF4/heparin IgG (OD>0.5 Zymutest®HIA IgG; Hyphen BioMed), HIPA and SRA results. Two senior hematologists established final clinical diagnosis according to kinetics of platelet count, existence of any other cause of thrombocytopenia, +/- thrombotic event, anti-PF4/H levels, HIPA and SRA results (HIPA was positive if patient's plasma activated at least 2 donor washed platelets in the presence of 0.2 or 0.5 IU/ml of heparin but not at 0 and 50 IU/ml of heparin, SRA was positive if the release was ≥20% at 0.1 or 0.5 IU/ml of heparin with no release at 0 and 10 IU/ml heparin from washed platelets of at least one donor).

Results: Among the 115 patients, 51 (44%) had a diagnosis of HIT based on HIPA and/or SRA positive results. Sensibility and specificity for SRA were 0,92, and for HIPA 0.84 and 1, respectively. Positive and negative predictive value of HIPA and SRA were very similar (table1). In 11 patients with HIT diagnosis, discordant results were observed: SRA was the only positive test in 7 out of the 11 and HIPA in 4 others. In 3 patients without HIT confirmed, SRA was the only positive functional test. No patient had only HIPA positive test in this group.

TABLE 1 Tests performances for diagnosis of Heparin-induced thrombocytopenia (HIT) of HIPA and SRA in all patients

	HIPA	SRA
Sensitivity, % (95% CI)	84,4 (70,5-93,5)	92,2 (81,1-97,8)
Specificity, % (95% CI)	100 (93,0-100)	92,3 (81,5-97,9)
Positive predictive value, % (95% CI)	100 (90,8-100)	92,2 (81,1-97,8)
Negative predictive value, % (95% CI)	87,9 (76,7-95,0)	92,3 (81,5-97,9)

Conclusions: We observed good and similar performance of HIPA and SRA. Interestingly, sensibility and specificity seem better in cardiac surgery than medical setting (table2). Comparison head-to-head of HIPA and SRA demonstrates that HIPA could be used to confirm the HIT diagnostic in all clinical settings.

TABLE 2 Tests performances for diagnosis of HIT of HIPA and SRA in patients in cardiac surgery and medical setting

	Cardiac surgery		Medical setting	
	HIPA	SRA	HIPA	SRA
Sensitivity, % (95% CI)	90,6 (75,0-98,0)	94,3 (80,8-99,3)	69,2 (38,6-90,9)	87,5 (61,7-98,5)
Specificity, % (95% CI)	100 (89,4-100)	97,0 (84,2-99,9)	100 (81,5-100)	84,2 (60,4-96,6)
Positive predictive value, % (95% CI)	100 (88,1-100)	97,1 (84,7-99,9)	100 (66,4-100)	82,4 (56,6-96,2)
Negative predictive value, % (95% CI)	91,7 (77,5-98,3)	94,1 (80,3-99,3)	81,8 (59,7-94,8)	88,9 (65,3-98,6)

PB 2374 | Regulation of FcγRIIA-mediated Platelet Activation by a Cytochalasin-sensitive Cytoskeletal Rearrangement: its Clinical Application to the Detection of Functional HIT Antibody

A. Yasumoto, Y. Yatomi

University of Tokyo, Department of Clinical Laboratory Medicine, Tokyo, Japan

Background: The signaling pathway resulting from FcγRIIA is essential in platelet activation induced by heparin-induced thrombocytopenia (HIT) antibody (Ab), i.e. anti-platelet factor 4/heparin.

Aims: We examined the effect of cytochalasin on the activation of FcγRIIA on the assumption that a unique cytoskeletal rearrangement may be employed in this signaling pathway.

Methods: A mouse monoclonal HIT Ab (mouse HIT MoAb) used in this study was derived from clone 5A1, and the aggregation of washed platelets, which were collected from healthy donors, was observed by using PA-200 (Kowa). This study was approved by the Institutional Research Ethics Committee of the Faculty of Medicine, the University of Tokyo.

Results: A long lag time before the onset of platelet aggregation was observed for that induced by a mouse HIT MoAb. Platelet aggregation induced by the mouse HIT MoAb was dependent on the concentrations of this antibody and heparin and the platelet count, and was completely inhibited by high concentrations of heparin and anti-human CD32 antibody (clone IV.3). When high concentrations of the mouse HIT MoAb were added, platelet aggregation occurred in the absence of heparin, which may be analogous to spontaneous HIT syndrome. When platelets were preincubated with suitable concentrations

(around 0.5 μg/mL) of cytochalasin B (CB), the lag time was markedly shortened before the onset of platelet aggregation induced by the mouse HIT MoAb; even heparin-independency was induced by the CB treatment. Finally, the effects of the mouse HIT MoAb was mimicked by HIT Ab from the patients with HIT. Our present results indicate that platelet activation via FcγRIIA, including that by the mouse HIT Ab, involves a cytochalasin-sensitive cytoskeletal rearrangement and that CB enhances platelet activation induced by HIT Ab.

Conclusions: In a practical viewpoint, the use of CB may be useful for the improvement of sensitivity in the detection of functional HIT Ab.

PB 2375 | Vitamin D Receptor Gene Polymorphisms in Adult Primary Immune Thrombocytopenia

M. Sakr

Menoufia University, Internal Medicine - Hematology, Shibin-Elkom, Egypt

Background: Recently, several studies have demonstrated the role of vitamin D receptor (VDR) polymorphisms in the development of autoimmune diseases. Vitamin D affect both innate and adaptive immune responses that have been blamed in immune thrombocytopenia (ITP) pathogenesis.

Aims: The aim of this study is to assess the association of vitamin D receptor gene polymorphism BsmI in cases of adult primary immune thrombocytopenia.

Methods: Vitamin D receptor polymorphism *BsmI* (rs1544410) was detected by Polymerase Chain Reaction followed by Restriction Fragment Length Polymorphism (PCR-RFLP). Deoxyribonucleic acid (DNA) samples were extracted from peripheral blood of 40 ITP patients and 60 geographically and ethnically matched healthy controls.

Results: Statistically significant difference was found in the BsmI polymorphism between ITP patients and controls ($\chi 2 = 8.77$, P value=0.01). The BsmI polymorphism B allele was higher in ITP group than that in controls but in statistically insignificant difference ($\chi 2 = 2.125$, P = 0.145). bb genotype played a protective role in ITP incidence.

Conclusions: This is the first published report on VDR gene polymorphisms in adult primary ITP patients. The BsmI genotype was associated with increased risk for ITP incidence with no obvious effect on bleeding severity, platelet count nor site of bleeding.

PB 2376 | Anti-PF4/Heparin Antibodies and Platelet Derived PF4 Bearing Microparticles in Acute Sepsis

M.T. Sartori, C. Zurlo, E. Campello, M. Bon, E. Duner, C.M. Radu, R. Bendo, P. Simioni, F. Fabris

University of Padua, Department of Medicine, Padua, Italy

Background: Heparin induced thrombocytopenia (HIT) is due to antibodies (ab) against platelet factor 4 (PF4) bound to heparin. A possible pre-immunization by bacterial antigens mimicking PF4/heparin complexes (PF4/H) has been suggested with anti-PF4/H ab generation during infection. Platelet derived microparticles (MPs) were shown both in HIT and in sepsis, as markers of platelets activation.

Aims: To evaluate the development of anti-PF4/H ab and the levels of total MPs and platelet derived PF4 bearing MPs (PF4-MPs) in acute septic patients.

Methods: Thirty-four patients admitted for sepsis (cases) confirmed by clinical and laboratory exams, 28 inpatients treated with heparin without infection (C1) and 65 healthy subjects (C2) were studied. Anti-PF4/H ab, either IgG-IgM-IgA or specific IgG, expressed by optical density (OD), were assayed by ELISA methods; MPs were measured using flow cytometry. In septic patients anti-H/PF4 ab and MPs were measured at admission (T0) and 7 days later (T1).

Results: Anti-PF4/H IgG-IgA-IgM levels were significantly higher in cases (T0 0.341 OD, T1 0.367 OD) compared to both C1 (0.224 OD, $p < 0.05$) and C2 (0.303 OD, $p < 0.05$), whereas anti-PF4/H IgG levels in cases showed a non significant increase at T1, and were slightly higher respect to both control groups. Total MPs median levels in cases were significantly increased as compared to C2 (cases T0 3251 MP/μL and T1 2044 MP/μL vs C2 1728 MP/μL, $p < 0.001$), but not to C1 (2388 MP/μL). PF4-MPs levels were significantly higher only in cases at T0 (391 MPs/uL) than in both C1 (94 MPs/uL, $p < 0.001$) and C2 (93 MPs/uL, $p < 0.001$). No correlation was seen between anti-PF4/H ab and MPs, clinical and biochemical parameters.

Conclusions: In sepsis we showed a modest but significant development of anti-PF4/H ab, likely IgM type suggesting an immunization. In addition, we found for the first time the generation of PF4-MPs as a result of platelets activation, and the role of these MPs in sepsis needs to be clarified.

PB 2377 | Monocyte Subsets and Platelet Apoptosis in Patients with Primary Immune Thrombocytopaenia

R. Justo Sanz[1], I. Fernandez Bello[1], D. Hernandez-Florez[2], E. Monzón Manzano[1], M. Álvarez Román[1], M. Martín Salces[1], L. Valor[2], M. Rivas Pollmar[1], V. Jiménez Yuste[1], J. Lopez-Longo[2], N. Butta[1,3]

[1]Hospital Universitario La Paz-IdiPaz, Hematology, Madrid, Spain, [2]Hospital Universitario Gregorio Marañón, Rheumatology, Madrid, Spain, [3]Grant from FIS-FEDER PI15/01457, NVB holds a Miguel Servet II (FIS-FEDER CP14/00024), Madrid, Spain

Background: Immune thrombocytopenia (ITP) is an autoimmune disorder. In its pathophysiology, autoantibodies against platelet glycoproteins and abnormalities in T lymphocytes-mediated immunity are involved. Platelet-monocyte cross-talk participates in many immune-inflammatory diseases and their interaction might regulate life span of they both (Pawelski et al, Front Biosci, 2014,6:75-91).

Aims: We aimed to study monocyte subsets distribution in ITP patients and their correlation with platelet apoptosis.

Methods: Blood samples of 29 patients with primary chronic ITP and 32 healthy controls sex and gender matched were included.

A multi-parametric flow cytometry panel (BD Biosciences) were used for the characterization of monocyte subsets. Platelet-surface exposure of phosphatidylserine (PS) and active caspase-3, -8 or -9 were assessed by flow cytometry (FITC-labelled Annexin V, BD Pharmingen and Millipore respectively).

E-selectin and plasminogen activator inhibitor-1 (PAI-1) were determined by ELISA.

Results: Intermediate (IM, CD14++CD16+), but not non-classical (NCM, CD14+CD16++) and classical (CM, CD14++CD16-) monocytes were increased in ITP patients (Table 1). The lower the platelet count the higher increase in IM count (Spearman r = -0.6, p < 0.001).

Platelets from ITP patients significantly exposed more PS than controls and activity of their caspases -3, -8 and -9 were increased (Table 1).

TABLE 1 Results are expressed as Mean±SD or Median (range). *P<0.05; **P<0.001

	CONTROL	ITP
CLASSICAL MONOCYTES/µL	67 (57-111)	75 (42-110)
INTERMEDIATE MONOCYTES/µL	98 (64-141)	596 (394-824)**
NON CLASSICAL MONOCYTES/µL	501 (410-631)	513 (352-757)
ANNEXIN V BINDING (%)	59.3±8.4	69.0±14.6*
CASPASE-3 (%)	47.4±8.9	60.8±10.0*
CASPASE-8 (%)	47.8±9.7	63.4±13.0*
CASPASE-9 (%)	47.5±8.3	58.0±13.1*
PAI-1 (ng/ml)	10.4 (6.6-23.4)	27.01 (16.2-43.8)**
E-Selectin (ng/ml)	10.69 (6.57-14.47)	30.49 (17.53-45.33)**

These apoptosis markers significantly correlated to IM and NCM counts (Table 2).

TABLE 2 Correlation calculated with Spearman test. "R" values are shown. All of them are significant with P<0.001

	ANNEXIN V (%)	CASPASE 3 (%)	CASPASE 8 (%)	CASPASE 9 (%)
INTERMEDIATE MONOCYTES/µL	0.425	0.608	0.721	0.663
NON CLASSICAL MONOCYTES/µL	0.422	0.633	0.759	0.705

Since monocyte-platelet interaction might be involved in endothelial damage, E-selectin and PAI-1, markers of endothelial injury, were measured and increased plasma levels of they both were found (Table 1).

Conclusions: Our results showed that IM subset was expanded and correlated with thrombocytopaenia and platelet apoptosis signs in ITP patients. Moreover, their interaction might react against vascular endothelium in ITP patients as reported for other autoimmune diseases.

PB 2378 | BAFF-TACI Signaling Promotes the Differentiation of Terminal Effector T Cells in Primary Immune Thrombocytopenia (ITP)

Y. Min[1,2,3], X. Li[1], M. Nie[1], C. Wang[4], P. Jun[1], M. Hou[1], N. Li[2], Y. Shi[1]

[1]Qilu Hospital, Shandong University, Haematology Oncology Centre, Jinan, China, [2]Karolinska Institutet, Department of Medicine-Solna, Clinical Pharmacology Group,, Stockholm, Sweden, [3]Affiliated Hospital of Jining Medical University, Department of Haematology, Jining, China, [4]Second Hospital affiliated to Shandong University, Department of General Medicine, Jinan, China

Background: Primary immune thrombocytopenia (ITP) is an autoimmune disease. Its pathogenesis involves complex immune dysfunctions. Besides autoantibody-secreting B cells, $CD4^+$ T helper cells, $CD8^+$ cytotoxic T cells and aberrant cytokine profiles also play important roles. Our previous study has shown that B cell activating factor (BAFF), via binding to TACI (transmembrane activator and CAML interactor), is involved in ITP by influencing the homeostasis and polarization of $CD4^+$ T cells.

Aims: To explore how BAFF-TACI signaling influences T cell memory and migration.

Methods: Peripheral blood mononuclear cells form ITP patients and healthy controls (HCs) were co-cultured with allogeneic dendritic cells under stimulation of IL-2 and BAFF with/without BAFF-receptor blocking antibodies.

Results:

1. BAFF -TACI interaction did not change the differentiation profiles of central memory T cells (T_{CM}) and effector memory T cells (T_{EM}) among $CD4^+$ cells.
2. The proportion of $CCR7^-$ cells, whose migrating ability toward draining lymphoid nodes is tampered owing to lost of CCR7, was significantly increased in $CD8^+$ T cells in both patients and HCs under BAFF-TACI signaling.
3. The increase of $CD8^+CCR7^-$ cells was not accompanied by changes of the activation status of $CD8^+$ T cells, but rather by transformational biases towards different $CD8^+$ T-cell subsets. Specifically, BAFF-TACI interaction caused a preferential differentiation of terminal effector cells ($T_{TermEff}$, $CD45RA^+CCR7^-CD27^-$) in ITP; whereas a $CD8^+$ T_{EM} ($CD45RA^-CCR7^-CD27^-$) transformation dominated in $CD8^+$ cells of HCs.

Conclusions:

1. BAFF-TACI signaling has no influence on $CD4^+$ memory cell profiles.
2. BAFF-TACI interaction weakens the homing ability of $CD8^+$ T cells in both HCs and ITP by promoting the transformation of $CCR7^-$ cells.
3. BAFF-TACI signaling increases the cytotoxicity of $CD8^+$ T cells in ITP by interfering with their differentiating direction, which leads to an aberrant over-transformation of terminal effector cells.

PB 2379 | Delayed Clearance of Argatroban in Patients with Heparin Induced Thrombocytopenia

E. Groarke, A.M. Sweeney, N. O'Connell

St. James's Hospital, National Coagulation Centre, Dublin, Ireland

Background: Argatroban is a direct thrombin inhibitor used in the treatment of Heparin Induced Thrombocytopenia (HIT). Argatroban has advantages including a short half-life (45 minutes), ease of monitoring with the activated partial thromboplastin time (APTT) and limited renal clearance. However, patients with HIT typically have significant co-morbidities including hepatic dysfunction or multi-organ failure which have been associated with a lower dose requirement for Argatroban.

Aims: To quantify the risk of drug accumulation in patients treated with Argatroban.

Methods: Patients were identified from laboratory records of Heparin Induced Platelet Aggregation (HIPA) results. Data collected included: age, gender, clinical diagnoses, dose and duration of Argatroban, presence of significant organ dysfunction, evidence of drug accumulation during treatment and thrombotic or bleeding complications.

Results: Eight patients were identified with a positive HIPA who were treated with Argatroban between 2013-2016. Starting doses of Argatroban were: 2mcg/kg/min (n=1, 14.5%), 1mcg/kg/min (n=5, 71%), 0.5mcg/kg (n=1, 14.5%), missing data n=1. During treatment with Argatroban, four patients required dose adjustments; increased in two and decreased in two (by 10% and 90%). Two patients showed evidence of clinically important delayed clearance of Argatroban with therapeutic levels of Argatroban at more than 16 hours after cessation of the infusion. In one patient, delayed clearance occurred without the presence of hepatic dysfunction or multi-organ failure. Delayed clearance resulted in postponement of a planned procedure but no bleeding.

Conclusions: Two of eight patients treated with Argatroban showed evidence of drug accumulation, in one case without typical risk factors. Clinical management of patients with HIT in a critical care setting may be complicated by delayed clearance.

PB 2380 | Sleep Quality in Chinese Patients with Primary Immune Thrombocytopenia: Contributing Factors and Effects on Health-related Quality of Life

Y. Li, B. Sun, Y. Hao, M. Lyu, H. Li, R. Yang

State Key Laboratory of Experimental Hematology, Institute of Hematology and Blood Disease Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin, China

Background: Normal sleep is paramount for a healthy lifestyle and high quality of life. Sleep modulates the immune system and thus affects the course of several chronic inflammatory conditions.

Aims: The objective of this study was to examine the prevalence of sleep disturbance, contributors of sleep disturbance and the association between sleep quality and health related quality of life (HRQoL) in patients with ITP independent of known predictors of HRQoL.

Methods: We enrolled 249 patients with ITP in the cross-sectional study. Self-report sleep quality (Pittsburgh Sleep Quality Index [PSQI]), and HRQoL (36-item Short Form [SF-36]) were evaluated for all patients. Independent samples t-tests, Chi square analysis, logistic regression modeling and linear regression were used to analyze these data.

Results: Our study found that one hundred and thirty-eight (71%) patients with ITP were ‚poor sleepers' (global PSQI≥7). There was a significant positive correlation of global PSQI score with fear of bleeding among ITP patients (r=0.670, p 0.001). Meanwhile, logistic regression models identified fear of bleeding (odds ratio 4.383 [95% confidence interval 2.941; 6.533]) as predictor of poor sleep quality. Poor sleepers in ITP had a significantly lower Physical Component Scale (PCS) scores, Mental Component Scale (MCS) scores and total SF-36 scores than good sleepers. The global PSQI score was a significant independent predictor of the MCS (β= -0.549, p 0.001) and PCS (β= -0.634, p 0.001) after controlling for age, gender, fear of bleeding, platelet count at diagnosis and current treatment measures in multivariate analysis.

Conclusions: Sleep disturbance is common for patients with ITP in China, which significantly impaired their HRQoL. The findings suggest that fear of bleeding contributed significantly to sleep disturbances in ITP and the importance of objective interventions to improve their sleep quality and finally to improve their HRQoL.

PB 2381 | Immune Thrombocytopenia in Patients with Chronic Hepatitis C Virus Infection and Non-alcoholic Fatty Liver Disease

T. Saralidze[1], F. Gabunia[2], I. Mamatsashvili[3], N. Gogokhia[4], T. Svanidze[1], T. Saralidze[5]

[1]Tbilisi State Medical University, Department of Internal Medicine N1, Tbilisi, Georgia, [2]Infectious Diseases, AIDS and Clinical Immunology Research Center, AIDS Inpatient Department, Tbilisi, Georgia, [3]Tbilisi State Medical University, Department of internal Medicine N1, Tbilisi, Georgia, [4]Tbilisi State Medical University, Department of Clinical Laboratory, Tbilisi, Georgia, [5]David Tvildiani Medical University, Faculty of Medicine, Tbilisi, Georgia

Background: Thrombocytopenia(TP) is a challenging clinical problem in patients with chronic hepatitis C virus infection(HCV) and nonalcoholic fatty liver disease(NAFLD). Development of TP in these patients is multifactorial but one of the main cause is immune genesis. Previous studies showed that amount of macrophage-lymphocyte rosettes (MLR) formation in vein blood leukocyte culture correlates with immune reactivity of organism(in norm it equals 37,4±2,2%, while in patients with immune hemolytic anemia or immune thrombocytopenia(ITP) it increases up to 60-85%).

Aims: Our aim was to reveal immune genesis of TP in patients with chronic HCV and NAFLD.

Methods: Fibroscan and Fibrotest were used for assessment METAVIR stages of fibrosis. We studied 15 patients with NAFLD(9 with cirrhosis(F4), 6 with F2-F3) and 25 with chronic HCV(15 with cirrhosis(F4), 10 with F2-F3). All patients had moderate(50-75×10^3/μL) or severe(< 50×10^3/μL) TP. In all was studied MLR formation in vitro.

Results: Among patients with NAFLD in 5(3 cirrhosis, 2-F3) MLR was in the range of 20-25%, pointing to nonimmune genesis of TP,

whereas in the rest(6 cirrhosis, 4 with F2-F3) MLR reached 69-78% revealing ITP. In chronic HCV patients low MLR was revealed in 2 with cirrhosis and 3 with F2, while in all the rest (13 with cirrhosis, 7 with F2-F3) was revealed high indices of MLR(62-83%) pointing to ITP. It is notable that in all cases of nonimmune TP, TP was moderate, while in ITP cases it was severe or moderate. In chronic HCV patients treated with Sofosbuvir or Ledipasvir/Sofosbuvir amount of platelets increased in all cases. Platelet count reached low level of norm in non-immune TP, while in patients with ITP mild thrombocytopenia was remained.

Conclusions: In conclusion, MLR formation in vitro can be used successfully for the revealing ITP in patients with chronic liver disease to tailor more precise treatment for each patient, especially in cases of severe TP, when platelet transfusions can cause platelet refractoriness due to HLA alloimmunization.

PB 2382 | Epidemiology and Management of Immune Thrombocytopenia: A Nationwide Population-based Study in Korea

S.-M. Bang, J.Y. Lee, J.-H. Lee, H. Lee, B. Kang, J.-W. Kim, S.H. Kim, J.-O. Lee, J.W. Kim, Y.J. Kim, K.-W. Lee, J.H. Kim, H.S. Choi, J.S. Lee

Seoul National University Bundang Hospital, Gyeonggi-Do, Korea, Republic of

Background: The epidemiology of immune thrombocytopenia (ITP) is not well characterized in an Asian population.

Aims: We aim to investigate the nationwide incidence and practice patterns of ITP.

Methods: From 2010 to 2014, ITP patients were identified using the Korean Health Insurance Review and Assessment Service database.

Results: The overall incidence rate of ITP was 5.3 per 100,000 person-years (95% CI: 5.1-5.5). The overall incidence rate ratios of children under 15 years old to adults and females to males were 3.9 (95% CI: 3.7-3.9) and 1.3 (95% CI: 1.2-1.4), respectively. Of the total 10,814 patients, 3,388 patients (31%) needed treatment for ITP. Among treated patients, 1,821 patients (54%) continued treatment for more than three months. First-line therapy consisted of corticosteroids (CS) in 42%, immunoglobulin (IVIg) in 35%, CS with IVIg in 19%, and other immunosuppressive agents (ISA) in 4%. Among treated patients, 75% of adults and 33% of children continued treatment for more than three months. After three months, the most frequently used drug was CS in 63% of patients, followed by CS with IVIg in 17%, ISA in 15%, and IVIg in 5%. Only 104 patients underwent splenectomy; of these, 51% received salvage treatment after a median of one month after surgery (range: 0-27). Platelet transfusions were performed in 1,082 patients. The proportion of patients who received platelet transfusions of 12 units or more per month for at least two consecutive months was significantly higher among patients treated for more than three months compared with patients who completed treatment within three months.

Conclusions: This population-based study is the first to describe the incidence of ITP and its treatment reality for patients in Korea.

PB 2383 | Laboratory Identification of Heparin Induced Thrombocytopenia: A Re-evaluation

E.J. Favaloro[1,2], G. McCaughan[1], K.K.E. Lau[1], S. Mohammed[1], L. Pasalic[1,2]

[1]ICPMR, Westmead Hospital, Westmead, Australia, [2]Sydney Centres for Thrombosis and Haemostasis, Westmead, Australia

Background: Heparin induced thrombocytopenia (HIT) is a feared complication of heparin therapy, assessed clinically and facilitated by laboratory testing, which comprises both immunological and functional assays. Clinical evaluation is aided by pre-test probability assessment, for example by 4Ts score. Neither 4Ts nor lab testing has 100% sensitivity or specificity for HIT, and combining both in a sequential process offers the highest likelihood of appropriate diagnosis or exclusion of HIT.

Aims: To (re)evaluate HIT diagnosis/exclusion using contemporary laboratory methods combined with 4Ts.

Methods: Prospective study combining 4Ts with a battery of contemporary methods, including ELISA, chemiluminescence (AcuSTar), later flow (STiC), serotonin release assay (SRA), light transmission aggregometry (LTA) and whole-blood aggregometry (Multiplate).

Results: 80 patients referred for HIT testing were evaluated. Immunological methods (ELISA, AcuSTar, and STiC) showed limited agreement with one another (r^2 values < 0.5), despite yielding similar proportions of negativity/positivity (Table 1). Overall, STiC yielded many equivocal findings, and ELISA higher levels of positives. Three functional methods also showed limited agreement, although Multiplate showed better correlation with SRA than LTA. Using SRA as gold standard, all immunological methods showed reasonable sensitivity but poor specificity to HIT. Multiplate showed higher sensitivity than LTA to HIT. Stronger reactivity in all immunological methods showed better sensitivity to HIT than lower reactivity. Overall, a combination of immunological methods, taking into consideration reactivity strength, plus 4Ts showed highest likelihood of appropriate diagnosis or exclusion of HIT.

TABLE 1 Differential test patterns in HIT investigation

Grade, rank	Means	STIC (%)	AcuStar (%)	ELISA (%)	SRA (%)	Multiplate (%)
-, 0	negative	44.7	73.0	59.4	64.4	69.7
+/-, 1	equivocal	28.9	NA	NA	NA	NA
+, 2	positive	15.4	9.0	12.9	5.9	11.8
++, 3	strong positive	11.1	18.0	27.7	29.7	18.4
0 or 1	neg or equiv	73.5	73.0	59.4	64.4	69.7
1 or 2	all positive	26.5	27.0	40.6	35.6	30.3

Conclusions: Laboratories should be aware of the strengths and limitations of individual methods for detecting HIT. A composite and sequential approach provides the best opportunity for effective diagnosis/exclusion of HIT.

PB 2384 | Experience in Diagnostic Assays for Heparin-induced Thrombocytopenia

A. Keren Politansky[1], R. Hoffman[2,3], Y. Nadir[2,3], B. Brenner[2,3], G. Sarig[3,4]

[1]Rambam Health Care Campus, Hematology Laboratory, Haifa, Israel, [2]Rambam Health Care Campus, Thrombosis and Hemostasis Unit, Haifa, Israel, [3]Bruce Rappaport Faculty of Medicine, Technion, Israel Institute of Technology, Haifa, Israel, [4]Rambam Health Care Campus, Hematology laboratory, Haifa, Israel

Background: The diagnosis of heparin-induced thrombocytopenia (HIT) requires clinical data and laboratory detection of platelet activating factor 4/heparin (PF4/H) antibodies by immunological or functional assays. Although antigen screening assays are widely used, the functional assays are performed only by several expert labs.

Aims: To analyze the experience of a tertiary medical center in clinical and laboratory diagnosis of suspected HIT.

Methods: A retrospective review of the Hematology Laboratory database on patients evaluated between 2008-2016 at Rambam, identified 412 individuals with clinical suspicion of HIT. Till 2011, 135 cases were screened using particle gel PaGIA (Biorad) and between 2012-2016, 277 cases were screened by lateral flow Milenia (Biotec GmbH). All patients diagnosed with HIT were treated with Fondaparinux (Arixtra). Functional assay with heparin/LMWH induced platelet aggregation was performed using light transmission aggregometry (Helena AggRAM) to validate borderline or positive results in indistinct cases.

Results: From the tested samples, 63% vs. 75% were negative in PaGIA and Milenia, respectively (P=0.03), and were considered negative for HIT. During 2008-2011, only 38% of cases with non-negative immunoassay results underwent functional aggregation, whereas, in 2012-2016, 83% of such cases were further evaluated. None of the borderline PaGIA samples was positive in the functional assay compared to 13.3% borderline Milenia results. 10.5% of positive PaGIA and 51.7% of positive Milenia were confirmed by a positive functional HIT assay (P=N.S.). The survival rate among 14 patients with a positive functional assay was 42.7 % (6 patients).

Conclusions: The Milenia assay introduced at our lab in 2012, has improved the screening process. The functional assay provides a more accurate HIT diagnosis. Combined approach of an optimal laboratory and clinical investigation is crucial to obtain a precise HIT diagnosis.

PB 2385 | Prevalence of Heparin Induced Thrombocytopenia among Iranian Patients with Cardiac Surgery

M. Ahmadinejad[1], M. Shahbazi[1], A. Chegini[1], R. Shamriz[1], Z. Ahmadinejad[2]

[1]Blood Transfusion Research Center, High Institute for Research and Education in Transfusion Medicine, Tehran, Iran, Islamic Republic of, [2]NIOC Hospital, Tehran, Iran, Islamic Republic of

Background: Heparin-induced thrombocytopenia (HIT) is a life-threatening, pro-thrombotic syndrome caused by anti-PF4/ heparin IgG antibodies(PF4 Ab). It's incidence is different among patients population with higher incidence of PF4 Ab in post-cardiac surgery. HIT diagnosis in Iran is almost always based on clinical criteria and rarely with considering the results of immunological assays (very limited centers performing first-line HIT diagnostic tests but no functional assays). This approach may lead to over-diagnosis of HIT and inappropriate use of alternative anticoagulants.

Aims: To determine the prevalence of HIT among patients undergo CPB, along with planning for setting up heparin induced platelet aggregation (HIPA) functional assay to establish a national referral HIT diagnostic lab for the first time in Iran.

Methods: We followed 92 patients that had been undergone CPB from 9/2015 to 5/2016.The signs and symptoms of HIT were evaluated by 4Tscoring system as a probability testing. From all cases with 4Tscore ≥ 4, an anticoagulant free blood sample was obtained and sent to the referral coagulation lab of IBTO for detection of Anti/Heparin PF4 IgG Ab (ELISA) and antibodies with ability of platelet activation (HIPA). Subjected patients were considered as HIT if they showed all three criteria: 4TScore≥4, Positive PF4 Ab (OD≥0.2) and Positive HIPA. All laboratory tests were rechecked in Hospital of Greifswald University, Germany (kindly supported by Professor A. Greinacher).

Results: 14 patients had 4TScore≥4 (15 %). 8 of 14 patients (8.6%) = PF4 Ab positive. 5 of all cases fulfil all criteria
(5.4 % incidence of HIT in our study).

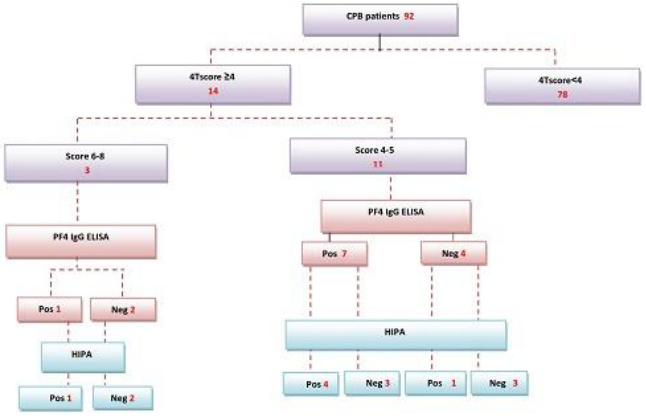

FIGURE 1 Flowchart of clinical and laboratory results of patients

TABLE 1 clinical and laboratory data of 5 patients with definite HIT

Patient no.	Age (years)	4T,s-score	Anti-PF4 / heparin (OD units)	HIPA test	Thrombosis event
1	64	5	0.617	Positive	No
2	63	5	0.470	positive	No
3	66	5	0.286	Positive	No
4	61	5	1.028	Positive	Aortic valve thrombosis
5	72	6	1.088	Positive	Recurrent stroke

Conclusions: Our study indicated that for accurate diagnosis of HIT, considering clinical criteria along with complete laboratory diagnostic panel (including immunological as well as functional assays) are necessary to prevent over-diagnosis of HIT and for this purpose establishment of at least one national referral lab is needed in our country with about 80 million population.

PB 2386 | HIT or Miss: Improving the Quality of Diagnosing Heparin-induced Thrombocytopenia at an Academic Medical Center

M. Schaffner[1], I. Bogdanich[2], M. Zimmerman[3], J. Smelser[2], R. Hobbs[2], U. Perepu[1,3]

[1]University of Iowa Carver College of Medicine, Iowa City, United States, [2]University of Iowa, Department of Pharmaceutical Care, Iowa City, United States, [3]University of Iowa Hospitals and Clinics, Department of Internal Medicine, Iowa City, United States

Background: Heparin-induced thrombocytopenia (HIT) is a rare but serious complication seen in hospitalized patients. The 4T score is a validated tool to assess the pretest probability of HIT. Although a low 4T score has been shown to have a high negative predictive value, previous studies suggest that the 4T scoring system is often underutilized prior to ordering heparin-platelet factor 4 (PF4) antibodies or the platelet serotonin release assay.

Aims: To assess the efficiency of calculating the 4T score prior to heparin-PF4 antibody testing when HIT is suspected.

Methods: We performed a retrospective chart review of patients over the age of 18 who had heparin-PF4 antibody testing ordered between January and August 2016. 4T scores were calculated retrospectively from data in the electronic medical record (EMR).

Results: 181 heparin-PF4 antibody tests were performed, of which 146 (81%) were negative (low dose optical density < 0.40), 31 (17%) positive and 4 (2%) equivocal. The 4T score was significantly higher in patients with positive or equivocal heparin-PF4 antibody values compared to those with negative values (p< 0.0001) when analyzed either as dichotomous or continuous variables [Figure 1]. ROC curves demonstrated that the 4T score was highly predictive of a positive or equivocal heparin-PF4 antibody value [Figure 2: AUC 0.804, 95% CI, 0.736 to 0.884]. A 4T score of ≤2 and ≤3 had negative predictive values of 96% and 92%, respectively. 123/181 (68%) of heparin-PF4 antibody tests were ordered in patients with 4T scores ≤3, amounting to a cost of $45,387 (estimated annual cost: $68,081), excluding the additional costs of managing HIT. Subsequently, a data-driven algorithm utilizing a 4T calculator prior to heparin-PF4 antibody testing was implemented within the EMR. We plan to reevaluate utilization in 6 months.

Conclusions: Incorporating routine 4T scoring prior to heparin-PF4 antibody testing for HIT has the potential to be an efficient and cost-effective management tool at large medical centers.

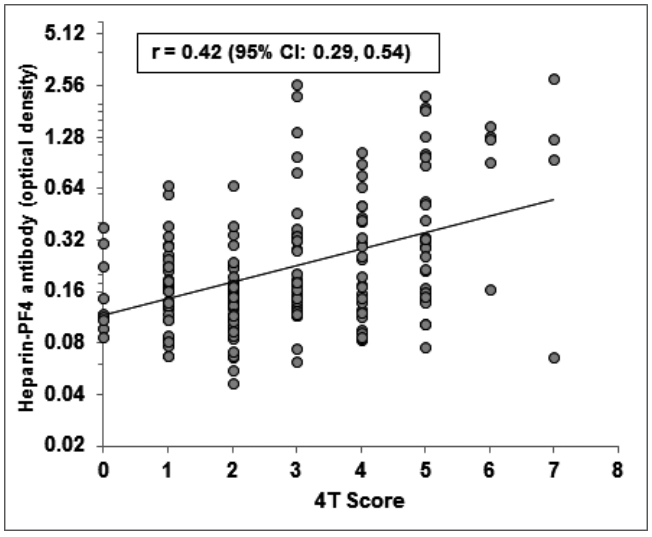

FIGURE 1 Correlation of 4T score with heparin-PF4 antibody (measured by optical density).

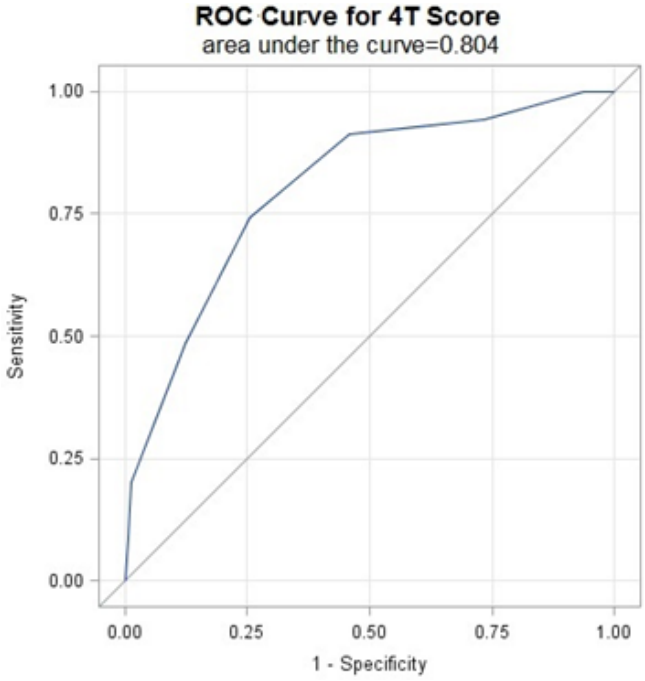

FIGURE 2 ROC curve of 4T score as a predictor of equivocal/positive heparin-PF4 antibody test.

PB 2387 | Practical Limitations of Diagnostic Algorithms in the Management of Heparin Induced Thrombocytopenia: Clinical Case Report

S. Nowak-Harnau[1], S. Enkel[2], M. Jurisic[1], C. Reiß[1], B. Zimmermann[1], R. Jouni[1], T. Bakchoul[2]

[1]Zentrum für Klinische Transfusionsmedizin gGmbH, Tübingen, Germany, [2]University Hospital Tübingen, Transfusion Medicine, Tübingen, Germany

Background: Heparin-induced thrombocytopenia (HIT) can be associated with devastating complications such as life-threatening

thrombosis making it one of the most serious adverse drug reactions.

Aims: The diagnosis of HIT is challenging due to a number of practical issues and methodological limitations.

Methods: We report on a clinical case of HIT which demonstrates the limited sensitivity of a rapid assay and the 4Ts score, respectively, emphasising the need for a clear diagnostic algorithm in the clinical practice.

Results: A 61 year old woman with a spinal cord tumour was admitted to our hospital with pain and tenderness in the right leg. Clinical examination and laboratory markers were suggestive for thrombosis. Despite treatment using low molecular weight heparin (LMWH) the patient developed a progressive thrombosis involving calf, popliteal, femoral, and vena cava. The diagnosis of HIT was suspected. First evaluation of the patient by the treating physician revealed a 4Ts score of 3. The rapid immunoassay (Lateral Flow Immunoassay) was negative. Although these results were suggestive against HIT, we initiated further laboratory investigation and decided to switch heparin to argatroban due to the progressive thrombosis. Strong anti-PF4/heparin IgG antibodies were detected using ELISA (OD 2.458) and the Heparin induced platelet activation (HIPA, platelet activation 4/4 cells). Critical review of the medical records and direct patient´s interview revealed that the 4Ts score was miscalculated on day 7 because of

(1) previous treatment with LMWH heparin (initially reported as s.c. insulin) was not recognized and rapid-onset HIT was not considered, and

(2) chemotherapy was considered to be a sufficient reason for thrombocytopenia. The 4Ts score was re-calculated revealing 6/8 points (high risk).

Conclusions: In clinical practice, we recommend an integrated diagnostic approach combining clinical assessment (the 4Ts score), immunoassays and functional assays as well.

PB 2388 | Low Serum Vitamin D Levels in Egyptian Adults with Chronic Primary Immune Thrombocytopenia: A Single Center Study

A.R. Soliman[1], W. Elsalakawy[2], A. Saeed[2], S. Mohammed[3]

[1]Ain Shams University, Hematology Unit, Internal Medicine Department, Cairo, Egypt, [2]Ain Shams University, Hematology Department, Cairo, Egypt, [3]Faculty of Medicine - Misurata University, Misurata, Libyan Arab Jamahiriya

Background: Immune thrombocytopenia (ITP) is a disorder characterized by immune-mediated accelerated platelet destruction and suppressed platelet production. Low vitamin D levels have been found in several autoimmune diseases, such as rheumatoid arthritis, SLE. The mechanisms underlying the link between vitamin D with autoimmunity are not completely understood. No currently available studies about vitamin D status in primary ITP patients.

Aims: To evaluate vitamin D levels in patients with primary chronic ITP and compare these levels with normal control subjects and thrombocytopenia due to other non immune causes.

Methods: The study included 80 adult subjects, 40 ITP patients (They were segregated into 20 responders and 20 non-responders), 20 cases of thrombocytopenia due to non ITP causes and 20 healthy control subjects. Measurement of serum 25vitamin D was done with ELISA.

Results: Vitamin D levels were significantly lower in patients with ITP (range=2-40ng/ml; mean±SD=17.29±10.96 ng/ml) and thrombocytopenia due to non-ITP causes (range=10-40ng/ml; mean±SD=21.05±8.31 ng/ml) in comparison to normal healthy controls (range = 10-65 ng/ml; mean±SD=36.70±16.30 ng/ml) (P=0.000), but there was no statistically significant difference between levels in ITP versus non- ITP thrombocytopenia (P=0.225). There was no statistical significant difference between responders & non-responders.

Conclusions: Vitamin D levels are lower among ITP patients in relation to healthy control subjects which might point out to a role in aetiopathogenesis of ITP attributable to the sunshine vitamin deficiency.

PB 2389 | Efficacy and Safety of a New 10% Intravenous Immunoglobulin Product in Patients with Primary Immune Thrombocytopenic Purpura

J. Hong[1], S.-M. Bang[2], Y.-C. Mun[3], H.-Y. Yhim[4], J.H. Lee[5], D. Oh[6]

[1]Gachon University Gil Medical Center, Internal Medicine, Incheon, Korea, Republic of, [2]Seoul National University Bundang Hospital, Internal Medicine, Seongnam, Korea, Republic of, [3]Ewha Womans University School of Medicine, Internal Medicine, Seoul, Korea, Republic of, [4]Chonbuk National University Medical School, Internal Medicine, Jeonju, Korea, Republic of, [5]Green Cross Corp., Yongin, Korea, Republic of, [6]CHA University, Internal Medicine, Seongnam, Korea, Republic of

Background: Intravenous immunoglobulin (IVIg) is a key drug in the treatment of primary immune thrombocytopenia (ITP). We recently developed IVIG-SN 10%, a 10% intravenous immunoglobulin formulation.

Aims: This study aimed to investigate the efficacy and safety of IVIG-SN 10% in adult patients with primary ITP.

Methods: It was a non-randomized, open-label, single arm, multicenter prospective study (ClinicalTrials.gov identifier: NCT02063789). Patients received 10% IV-Globulin SN formulation with a dose of 1g/kg/day for two consecutive days; infusion rate was initially 0.01mg/kg/minute and then doubled every 30 minutes to a maximum of 0.08 ml/kg/minute. The primary endpoint was the response after treatment with 10% IV-Globulin SN formulation.

Results: One hundred five patients with severe ITP were enrolled. Among 81 eligible patients, 31 patients were newly diagnosed, 7 patients had a persistent ITP, and 43 patients had a chronic ITP. Their median time to response was 2 days and the mean duration of platelet count ≥ 50 x 10^9/L was 8.80 ± 7.90 days. Response rates were not significantly different when compared according to the phase of ITP or previous treatment for ITP. The drug was well tolerated and the frequency of mucocutaneous bleeding was decreased during the study period.

Conclusions: 10% IV-Globulin SN formulation was efficacious in adult prmary ITP patients regardless of their disease status as well as safe given that the resolution of bleeding and manageable adverse events.

PB 2390 | Quantification of Specific T and B Cells Immunological Markers in Children with Chronic and Transient ITP

S. Levy Mendelovich[1], A. Lev[1], S. Aviner[2], N. Rosenberg[3], H. Kaplinsky[4], S. Nechama[5], H. Miskin[6], A. Dvir[3], G. Kenet[3], I. Shoshan Eizen[7], R. Somech[1]

[1]Immunology Services, Pediatric Department A, Ramat Gan, Israel, [2]Barzilai University Medical Center, Department of Pediatrics, Ashkelon, Israel, [3]Amalia Biron Research Institute of Thrombosis and Hemostasis, Chaim Sheba Medical Center, Ramat Gan, Israel, [4]Pediatric Hemato-Oncology Department, Ramat Gan, Israel, [5]Laniado Hospital, Pediatric Hemato-Oncology Department, Netanya, Israel, [6]Pediatric Hematoloy Unit, Shaare Zedek Medical Center, Jerusalem, Jerusalem, Israel, [7]'Edmond and Lily Safra' Children's Hospital, Sheba Medical Center, Tel Hashomer affiliated to Sackler School of Medicine Tel Aviv University, Neonatology Department, Ramat Gan, Israel

Background: : Immune Thrombocytopenia (ITP) is characterized by a transient (non-chronic) or permanent (chronic) decline in the number of platelets. Predicting the course of ITP, at the time of diagnosis, is of importance. Here we studied at diagnosis, clinical and immunological parameters in order to distinguish between different courses. The latter included the measure of new B and T cells using quantification of kappa-deleting recombination excision circles (KRECs) and T-cell receptor excision circles (TRECs), respectively.

Aims: The purpose of this study was to look at clinical and immunological parameters which at the time of diagnosis will enable one to distinguish between patients with chronic and non-chronic courses of ITP. Another goal was to evaluate the immune function in patients by measuring neogenesis of B and T cells using quantification of KREC and TREC, respectively.

Methods: Blood samples were collected from 44 children with a clinical diagnosis of ITP. Real Time PCR was performed in order to quantify the number of copies of TREC and KREC followed by collection of clinical data from medical files. The children were retrospectively divided into two groups: chronic and non-chronic.

Results: 24 patients (54%) were classified as non-chronic ITP and 20 patients (46%) were classified as chronic ITP. We confirmed some clinical parameters (e.g. gender, age) but not others (e.g. preceding infection, level of thrombocytopenia) that distinguish patients with chronic and non-chronic course. While KREC quantification was similar in patients regardless the outcome of their disease, it was significantly higher than the level of controls ($p<0.05$). TREC quantification was not different between patients and controls.

Conclusions: KREC but not TREC levels are different in patients comparing to controls, pointing to an overreaction of B cell development as a role in the pathogenesis of ITP. These results may shed more lights on the immune mechanism of ITP.

PB 2391 | Risk of Cancer Occurrence and Survival in Patients with Primary Immune Thrombocytopenia

J.-D. Wang, Y.-T. Tsan, W.-C. Chan, K.-M. Tong, C.-H. Lin

Taichung Veterans General Hospital, Center for Rare Disease and Hemophilia, Taichung, Taiwan, Republic of China

Background: It has been shown that platelet-derived serotonin supports hepatocellular carcinoma development in mice chronically exposed to carbon tetrachloride. Mouse models of acute viral hepatitis in which hepatocellular damage is resolved in a few days to show that platelets are present at sites of organ damage; their depletion reduces the number of virus-specific CD8 T cells ameliorating disease severity; and this positive outcome is reversed by reconstituting thrombocytopenic animals with normal but not dysfunctional platelets.

Aims: The aim of our study is to investigate whether the number of platelet is associated with cancer development and progression.

Methods: We analyzed data of 968 patients with primary immune thrombocytopenia (ITP) retrieved from Taiwan's National Health Insurance Research Database between 1997 and 2013, by comparing variables to 9680 age- and gender-matched healthy individuals from the general population.

Results: There were 103 ITP patients and 866 individuals of general population with newly diagnosed cancer (Hazard ratio 0.871, 95 % CI 0.659-1.151). The cumulative incidences of cancer in ITP and the general population were 10.6 % and 9.0 %, respectively. The survival time after acquiring cancer is shorter in ITP cohort (HR 1.955, 95 % CI 1.377 - 2.777). After excluding patients who died of bleeding and infection, no difference of survival time after acquiring cancer was found between the two cohorts (HR 1.507, 95 % CI 0.700 - 3.245).

Conclusions: The study suggests that platelet count may not be associated with cancer occurrence and prognosis. However, a prospective, large scale, and controlled study is needed to elucidate this issue.

PB 2392 | Bleeding Outcome during Pregnancy in Patients Diagnosed with Immune Thrombocytopenia

B. Suwanawiboon, O. Amornariyakool

Faculty of Medicine Siriraj Hosptial, Mahidol University, Bangkok, Thailand

Background: Immune thrombocytopenia (ITP) is a common cause of thrombocytopenia in women of reproductive age. Prior studies investigated the natural history of ITP and birth outcome. However, the data regarding maternal bleeding complications is limited.

Aims: To investigate the prevalence and predictive factors of bleeding complications during pregnancy in ITP patients.

Methods: A retrospective study of pregnant women diagnosed with ITP was performed.

Results: A total of 99 women with 106 pregnancies was included. The mean age was 29±6.1 years. Forty-three pregnancies (40.6%) were primigravida and 27 (25.5%) were newly diagnosed ITP. Primary ITP was diagnosed in 93 pregnancies (87.7%). The median time of ITP diagnosis before pregnancy was 36 months (range 8-96 months). The median platelet (plt) count during the 1st, 2nd and 3rd trimesters was 73.3 x10^9/L (range 45.0-158.0 x10^9/L), 86.7 x10^9/L (range 55.0-142.0 x10^9/L) and 74.5 x10^9/L (range 42.0-122.0 x10^9/L), respectively. ITP treatment was given in 52 pregnancies (49%). The median plt count prior to the delivery was 72.0 x10^9/L (range 34.3-141.5 x10^9/L). Severe thrombocytopenia (plt count < 30,000 x10^9/L) was found in 20 out of 100 pregnancies (20%). Bleeding occurred in 25 pregnancies (23.6%), of which 72% happened in prenatal period and 4.7% was major bleeding. The prevalence of obstetric (OB) and non-OB bleeding was 13.2% and 11.3%, respectively. Mucocutaneous bleeding was the most common type of non-OB bleeding. Pregnancies with prenatal bleeding had significantly lower levels of platelet count in 3rd trimesters compared to those without bleeding (p=.021). However, there was no association between plt count at delivery and PPH. In addition, prenatal bleeding was significantly correlated with bleeding manifestations at the diagnosis of ITP (OR 4.8, 95% CI 1.02 - 22.29, p=.047).

Conclusions: Severe bleeding was uncommon during pregnancy in ITP patients. Bleeding manifestations at the diagnosis of ITP was the predictive factor for prenatal bleeding.

PB 2393 | Development of PF4/Heparin Dependent Antibodies in Patients Undergoing Extracorporeal Membrane Oxygenation and Clinical Impact

C. Vayne[1,2], M.A. May[3], E. Lemoine[3], E.A. Guery[1], J. Rollin[1,2], Y. Gruel[1,2], C. Pouplard[1,2]

[1]University Hospital of Tours, Haemostasis, Tours, France, [2]UMR CNRS 7292, Tours, France, [3]University Hospital of Tours, Anesthesiology, Tours, France

Background: Extracorporeal membrane oxygenation (ECMO) provides circulatory support in patients with severe cardiac failure and anticoagulation with unfractionated heparin (UFH) is necessary in these patients with a high risk for heparin-induced thrombocytopenia (HIT).

Aims: The aim of this study was to prospectively evaluate the incidence of "pathogenic" anti-platelet factor 4/heparin (PF4/H) antibodies in patients with ECMO and their impact on platelet count (PC) and clinical evolution.

Methods: From July 2014 to August 2016, 27 patients treated longer than 5 days by UFH for ECMO were studied. Plasma samples collected after initiation of ECMO were systematically analysed for the presence of antibodies (Abs) to PF4/H by ELISA (HAT 45®, GTI, cut off value: 0.4). Serotonin release assay (SRA) was performed with samples positive in ELISA.

Results: Demographic data and clinical characteristics of patients are presented in table 1.

TABLE 1 Demographic and clinical results of patients with ECMO according to the presence of anti- PF4/H Abs.

	ECMO n = 27	Patients without anti-PF4/H Abs n = 9	Patients with anti-PF4/H Abs n = 18
Age median years [range]	56 [17-76]	53 [17-76]	57 [36-69]
Sex ratio (M/F)	20/7	6/3	14/4
Setting of ECMO medical/surgical	17/10	7/2	10/8
ECMO duration (median days) [range]	14 [6-28]	17 [8-28]	12 [6-26]
SOFA score (median)	11 [7-14]	11 [7-14]	11 [8-13]
Issue : Favourable/ death/Bridge by heart turbine	8/11/8	2/4/3	6/7/5
Thrombotic complications	5	3	2
Sepsis	18	8	10

Significant levels of Abs to PF4/H were present in 2/27 patients before ECMO. Sixteen of 25 additional patients (64%) then developed Abs to PF4/H three to ten days after initiation of ECMO, with optical densities in ELISA higher than 1.0 in 7 cases. Serotonin release assay was positive in only one patient, therefore considered as having HIT. PC decreased (< 100 G/L) early, from day 1 to day 4 in 25 patients despite Abs to PF4/H were absent in most cases. PC recovered in 20 cases although Abs to PF4/H were present in 12 of them including the patient with HIT in whom UFH was replaced by argatroban. Thrombosis and death were not more frequent in patients with Abs to PF4/H.

Conclusions: Development of anti-PF4/H Abs is frequent in patients receiving heparin for ECMO, but these antibodies are rarely pathogenic and not associated with less favourable outcome.

PB 2394 | Platelet Survival in Treatment of ITP

M. Kostal, P. Dulicek, E. Ivanova, P. Sadilek

4th Department of Internal Medicine, University Hospital Hradec Kralove Charles University, Faculty of Medicine, Hematology, Hradec Kralove, Czech Republic

Background: Splenectomy is used as a 2nd line therapy of immune thrombocytopenia. Even though it is the most effective therapeutical option, approximately one third will eventually relapse. There are some important undesired side effects such as increased risk of thrombosis and risk of overwhelming postsplenectomy infection.

Aims: Predictive factors are needed to maximize probability of ITP remission after the splenectomy.

Methods: We searched in ITP registry for platelets survival and turnover before the splenectomy and compare the data with remisions after the procedure.

Results: We found 27 splenctomized patients during years 2003-2015 with complete pre-splnenectomy platelet examination. Mean age of patients was 41 years. Median of survival time was 5 hours, spleen/liver destruction ratio was 4,8. Complete remission was observed in 92% of patients. Long-term remission without need of any other therapy was 76%. Patients with relaps were older (mean age 38 vs. 51, p=0,18). There was no statistical difference in platelet survival times or place of platelet destruction between the groups.

Conclusions: Splenectomy is still used in treatment of ITP. Predictive factors are missing and platelet survival may be helpful for patient's and physician's decision. More data are needed before statistical significance can be reached.

PB 2395 | When Cancer Patients are HIT: A Literature Review of Heparin-induced Thrombocytopenia (HIT) and Clinical Outcomes in Cancer Patients

T.H. Oo, C.M. Rojas-Hernandez

University of Texas MD Anderson Cancer Center, Benign Hematology, Houston, United States

Background: Thrombosis is the second leading cause of death in cancer patients. Cancer patients are at 4-7 times higher risk of thrombosis compared to the general population. HIT poses a thrombosis risk of 30-50% in the first month after diagnosis in the general population. The thrombosis risk in cancer patients affected by HIT is not known.

Aims: We conducted a literature review to determine the thrombosis outcomes in cancer patients affected by HIT.

Methods: We performed a literature search through January 2, 2017 with search terms "heparin-induced thrombocytopenia AND cancer" in PUBMED and EMBASE databases. Manuscripts with details unavailable, remote history of cancer, remote history of HIT, other thrombophilia, and in other languages were excluded. The primary endpoint was the thrombosis rate in the first month of HIT diagnosis. Secondary endpoints were recurrent thrombosis rate after 1 month, anticoagulant-associated bleeding rate and overall survival (OS).

Results: Of 509 citations screened, 44 manuscripts/abstracts (55 patients) were eligible for analysis. M:F, 1.0:2.6; solid cancers vs hematologic cancers, 2:1; median 4T scores of 6. HIT diagnosis by antibody-based tests vs functional assays vs both, 7.5:1.0: 5.0. Unfractionated heparin caused HIT in 67% of cases.Thrombosis rate in the first month was 80% with a recurrent thrombosis rate of 6.8% at months 2 to 6. The overall clinically relevant, major and nonmajor, bleeding rate was 5.7%. Median OS for available cases was 4 months with 95% CI [2.6-5.4].

Conclusions: The thrombosis risk appears very high in cancer patients affected by HIT. The recurrent thrombosis rate beyond 1 month is comparable to that of cancer patients without HIT. Likely due to high thrombogenicity from both cancer *per se* and HIT, the anticoagulant-associated bleeding risk in this population appears to be acceptable. Larger studies are required to confirm our findings.

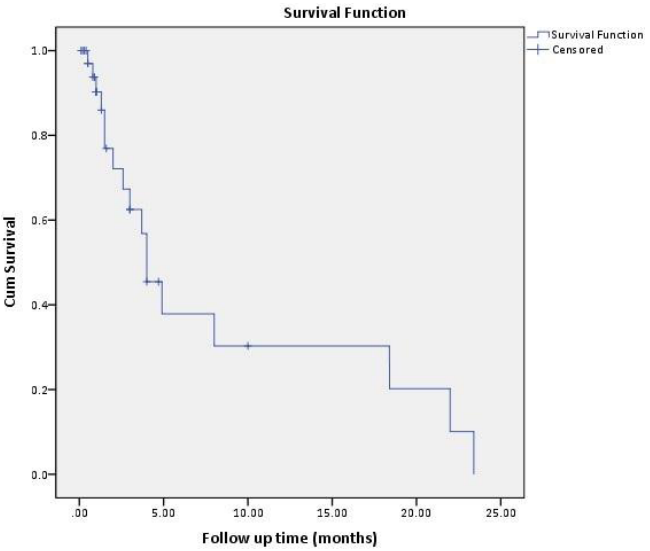

FIGURE 1 Overall Survival

TABLE 1 Patient Characteristics and Clinical Outcomes

Total number of cases	55
Age (years), Median [IQR]; Female, N (%)	63[53-67]; 40 (72.7%)
Solid malignancy, N (%); Hematologic, N (%); Solid + hematologic, N (%)	36 (65.5%); 18 (32.7%); 1 (1.8%)
4T score: Median [IQR]	6 [5-7]
Diagnostic testing: Antibody-based screening only, N (%); Functional assay only, N (%); Both screening and functional assays, N (%)	30 (54.5%); 4 (7.3%); 21 (38.2%)
Culprit medications: Heparin, N (%); Low molecular weight heparin, N (%); Heparin/LWMH, N (%)	37 (67.3%); 14 (25.4%); 4 (7.3%)
All thrombotic events within 4 weeks from HIT, N(%)	44 (80.0%)
Recurrent thrombotic events after 4 weeks from HIT,N(%)	3 (6.8%)
Alternative anticoagulation treatment: Anticoagulation during the first 4 weeks since HIT, N(%); Long term anticoagulation (>4 weeks since HIT), N(%)	53 (96.4%); 34 (61.8%)
Bleeding complications during alternative Anticoagulation, N(%); Clinical relevant non-major bleeding, N; Major bleeding, N	3 (5.7%); 1; 2

PB 2396 | Evaluation of Increased Incidence of Heparin Induced Thrombocytopenia at a Large Academic Teaching Hospital

J. Rimsans[1], M. Barra[1], H. Badreldin[1], J. Lauffenburger[1], J.M. Connors[2]

[1]*Brigham and Women's Hospital, Department of Pharmacy, Boston, United States,* [2]*Brigham and Women's Hospital, Division of Hematology, Department of Medicine, Boston, United States*

TABLE 1 PF4 and SRA Results in Patients with Heparin Induced Thrombocytopenia

Year	PF4 Positive	PF4 Optical Density 0.40 - 0.99	PF4 Optical Density 1.0 - 1.99	PF4 Optical Density ≥ 2.0	SRA Positive	SRA Negative	SRA Not Sent
2015 - n(%)	19	9 (47.4%)	7 (36.8%)	3 (15.8%)	6 (31.5%)**	12 (63.2%)	1 (5.2%)
2016 - n(%)	22	9 (41.0%)	6 (22.7%)	7(31.8%)	13(59.1%)*	6 (27.2%)	4(18.2%)***

*Two patients from 2016 had an initial negative PF4 and then SRA was positive within 10 days ** Two patients from 2015 had an initial negative PF4 then SRA was positive within 7 days ***Of the four in 2016 who did not have an SRA sent, had OD 2.42, 1.97, 0.5, and 0.733.

Background: An increase from 2% to 3.7% in PF4 positive heparin induced thrombocytopenia (HIT), defined as OD >0.4, from calendar year 2015 to 2016, was observed by our hemostatic and antithrombotic stewardship (HAT) service.

Aims: To identify patient factors associated with the observed increase in the number of HIT cases.

Methods: A retrospective chart review of patients with suspected HIT treated with a direct thrombin inhibitor (DTI) was performed comparing 2015 to 2016. Patients' baseline characteristics, history and type of heparin product exposure, calculated 4-T score, PF4 and SRA results, and additional risk factors were compared between groups. A bivariate logistic regression analysis was used to identify risk factors in PF4 and SRA positive HIT cases.

Results: A total of 118 patients were treated with a DTI for suspected HIT prior to PF4 result: 54 in 2015 and 64 in 2016. The number of PF4s sent per year was significantly decreased by 37.4%. In 2015, there were 19/54 (35.2%) PF4 positive patients' versus 22/64 (34.4%) in 2016. There was a 1.7% increase in the number of positive PF4s in 2016 compared to 2015. Of those who were PF4 positive, 6 (31.6%) were SRA positive versus 13 (59.1%). A multivariate analysis showed sepsis and previous heparin exposure within the past 100 days had the highest incidence of HIT, whereas those receiving renal replacement therapy or cardiopulmonary bypass were lower.

Conclusions: Screening completed by the HAT service decreased the number of PF4 tests sent without affecting the yield of a positive PF4 test. Though the sample size was small, we were not able to detect statistical differences in patient characteristics related to incidence, though higher rates noted in those with sepsis and previous heparin exposure within the past 100 days. Additional analysis is anticipated.

PB 2398 | rhTPO is Conductive to Remission from Acute Hemorrhage Phase of Children Severe ITP

M. Jingyao[1], C. Zhenping[2], W. Runhui[2]

[1]*Beijing Children's Hospital Capital Medical University, Hematology Oncology Center, Beijing, China,* [2]*Beijing Children's Hospital Capital Medical University, Beijing, China*

Background: Severe bleeding is always a concern in treatment of children SITP. rhTPO, which can stimulate thrombopoiesis, is applied to children ITP in their acute hemorrhage phase.

Aims: To discuss the effect of rhTPO in acute hemorrhagic phase of children SITP.

Methods: We collected 22 cases of children SITP, who received rhTPO or combination of rhTPO and immunosuppressor with the IBLS of score 2. After observation for 2 weeks, we examined the PLT and IBLS regularly to accessed the effect of rhTPO in hemorrhagic phase of children SITP.

Results: ①Evaluation of therapeutic effect: OR was 68.2% and the median time for PLT rising to more than 30×10^9/L was 6 days. Rate of patients whose IBLS declined to score 1 was 18.2%, those down to 0 was 77.3%. ②Adverse events: One C-SITP evaluated as no response died eventually with IBLS remained to be score 2, others had no serious hemorrhagic event and drug-related adverse events. ③Correlation between combination with immunosupressor therapy and effect of rhTPO: OR of those received rhTPO alone was 25.0%, that of those received combination therapy was 72.2%, effect of the latter was better than the former (P=0.014). Rate of those received rhTPO alone with IBLS declined to score 0 and 1 was 25.0% and 75.0% respectively, those received combination therapy with IBLS declined to score 0 and 1 was 88.9% and 5.6% respectively, the latter was better than the former in controlling hemorrhage (P=0.013).

Conclusions: As for children SITP in acute hemorragic phase, rhTPO could rise PLT and control hemorrhage in short period effectively, getting children SITP through hemorragic phase safely, without any serious hemorrhagic event and drug-related adverse events. Combination with immunosupressor could be more effective in rising PLT and controlling hemorrhage, though it need further verification from large prospective data in future.

PB 2399 | Neuropilin-1 Expression on Regulatory T Cell Can Affect its Immunosuppressive Function in ITP

H. Zhou[1,2], L. Su[1], L. Liu[3], Y. Song[1]

[1]*Affiliated Tumor Hospital of Zhengzhou University, Zhenghzhou, China,* [2]*Henan Tumor Hospital, Zhenghzhou, China,* [3]*The First Affiliated Hospital of Zhengzhou University, Zhenghzhou, China*

Background: Primary immune thrombocytopenia (ITP) is an acquired autoimmune disorder characterized by lots of immune dysfunctions . Abnormalities of regulatory T cells (Treg) have been proved in the

pathologic process of ITP. Neuropilin-1 (NRP-1) plays an vital role in the immunoregulation and expresses on Treg in ITP patients.

Aims: However it's unclear whether NRP-1 is related to the dysfunctions of Treg in ITP.

Methods: We found that anti-NRP-1 only inhibit the proliferation of $CD4^+$T cell instead of $CD8^+$T cell, and it also increased the apoptosis of Treg rather than $CD4^+$T cell, $CD8^+$T cell and platelet.

Results: Our results indicated that NRP-1 have no functions on Th1/Th2 polarization with no unchanged interleukin-10(IL-10) level, and mRNA level of T-bet and GATA-3,except decrease of interferon-γlevel. Also, we confirmed that dexamethasone (DXM) could promoted the expression of NRP-1 on Treg, but higher expression of NRP-1 have no effect on Foxp3 expression.

Conclusions: NRP-1 might play an important role in ITP by influence immunosuppressive function of Treg which mediate the interaction between dendritic cell(DC) and T cell.

PB 2400 | Thrombotic Events in Patients Treated with Eltrombag

T. Arias Fernández, J. Zanabili Al-Sibai, S. Gonzalez Muñiz, P. Palomo Moraleda, L.R. Morais Bras, L.F. Avila Idrovo, C. Castañon Fernandez, A. Sole Magdalena, A. Fernandez Rodriguez

Hospital Central de Asturias, Oviedo, Spain

Background: Immune thrombocytopenia (ITP) is an autoimmune disease (AID). The diagnosis is by exclusion and a major concern is determining whether the ITP is primary or secondary to an underlying condition that might benefit from treatment.

Eltrombopag is an agonist of thrombopoietin and is an option to patients who have failed to corticoids, splenectomy or Rituximab. Five percent of thrombotic events during treatment are described.

Aims: We submit 2 cases of thrombosis.

Methods:

CASE 1: A 15-year-old girl was diagnosed of ITP. She had Antinuclear Antibodies (1/640) but AID was ruled out. She had several relapses treated with corticoids and immune globulin (IG). Presented Cushing syndrome so she asked for a therapeutic alternative. She responded to 50mg/24h dose of Eltrombopag. After 4 weeks, she developed an acute pulmonary thromboembolism (fig.1). Eltrombopag was stopped and platelet levels were monitored. During the hospitalization presented nefrotic syndrome and anti-phospholipid antibodies were found. She was treated with corticoids and LMWH. The final diagnosis of AID is still pending.

CASE 2: A 51-year-old woman was diagnosed of primary ITP. She developed steroid dependence, so started Eltrombopag as bridge to splenectomy, which was chosen as second line of treatment. Prophylactic LMWH were suspended 4 weeks later. She relapsed 2 months after surgery and was treated with Eltrombopag and prednisone. A month later, she developed portal and superior mesenteric vein thrombosis (fig.2). She received corticoids and IG in order to maintain therapeutic doses of LMWH. Nowadays, she has normal platelet levels without specific treatment.

Results: Thrombosis is an unfrequent complication described with Eltrombopag, but we should not forget ITP by itself has increased thrombotic risk. Both cases had thrombotic risk factors: splenectomy and anti-phospholipid antibodies.

Conclusions: We should not underestimate the prothrombotic effect of ITP.

We must take into account other risk factors, not only the side effects of the drugs.

PB 2401 | Familial Thrombocytopenia - Course of 3 Subsequent Pregnancies in an Idiopathic Thrombocytopenic Purpura (ITP) Patient; Case Report

J.M. Teliga-Czajkowska[1], A. Sikorska[2], B. Ceglarek[2], K. Bykowska[3], E. Dmoch-Gajzlerska[1], K. Czajkowski[4]

[1]Medical University of Warsaw, Department of Obstetrics and Gynecology Didactics, Warsaw, Poland, [2]Institute of Hematology and Transfusion Medicine, Department of Hemostatic Disorders and Internal Medicine, Warsaw, Poland, [3]Institute of Hematology and Transfusion Medicine, Department of Hemostasis and Metabolic Disorders, Warsaw, Poland, [4]Medical University of Warsaw, 2nd Dept. Clinic of Obstetrics and Gynecology, Warsaw, Poland

Background: Idiopathic thrombocytopenic purpura (ITP), a relatively common platelet disorder when sensitization with autoantibodies leads to premature removal of platelets from circulation. Patients present easy bruising, petechiae, manorrhagia or hemorrhage. In pregnacy and particularily during peripartum period it is essential to prevent and control acute bleeding.

Aims: To highlight the need for sources of complications during pregnancy, delivery and puerperium.

Methods: A case report.

Results: A 34 year old patient with familial ITP. Her three pregnancies were all complicated with extremely low platelet counts - (below $10x10^3$μL). The patient responded poorly to high-dose corticosteroids. As result of repeat high-dose intravenous immunoglobulin administration the platelet count increased to over $20x10^3$μL. This may have been caused either by blockage of Fc receptors on macrophages or inhibition of antiplatelet antibody biosynthesis. Before each of her C-sections performed due to hazards of fetal thrombocytopenia, platelet transfusion was ordered. Despite sharp decline in platelet count (< $10x10^3$μL) 4 hours after the procedure - no major bleeding episode occurred in the puerperium. In the otherwise healthy offspring thrombocytopenia was the only complication of an early neonatal period. Each of the infants had platelets nadir in the first day of life: - 12 ,27 ,$110x10^3$μL respectively.

Conclusions: It is recommended to refer to a multidisciplinary approach in severe cases of familial ITP during pregnancy and puerperium. Delivery should be planned in special perinatal care units and careful surveillance in the neonatal period is highly advisable.

PB 2402 | Treatment Options and their Outcomes in Pediatric Immune Thrombocytopenic Purpura Patients

K. Perveen, S. Ansari, S. Parveen, S. Munzir, T. Shamsi

National Institute of Blood Disease and Bone Marrow Transplantation, Karachi, Pakistan

Background: There are several therapeutic options available in immune thrombocytopenic purpura (ITP). Its efficacy varies significantly.
Aims: The aim of this study was to determine the treatment options and their outcome in pediatrics ITP patients.
Methods: A case series conducted at NIBD from 2008-2016**.** Total 67 ITP patients of either gender having isolated thrombocytopenia were included. ITP was classified into acute (remission occur within 3 months), persistent (spontaneous remission or patients not maintaining complete response from 3-12 months) and chronic (platelets < $150X10^9$/L persisting >12 months after diagnosis). Prednisone or IVIG were first-line and Azathioprine, Rituximab were second-line treatment. Splenectomy was done in chronic ITP patients with significant bleeding or if the first-line treatment failed. Outcome was evaluated as Complete Response (CR), Partial Response (PR) and No Response (NR).
Results: Out of total 67 patients, 29.85% patients achieved complete remission in acute ITP phase, 36.17% achieved complete remission in persistent ITP phase while chronic ITP was noticed in 30 children. Overall 47.45% children showed CR with Prednisone, 44.44% with Azathioprine and 43.75% with Anti-D. Splenectomy was done in 7 patients, among them response was observed in 71.42% children.
Conclusions: ITP was found safe disease with lower rate of morbidity and no mortality. Most of the pediatric ITP (55.22%) resolved before chronic stage. Future work on pathophysiology and in mechanism of ITP is required to identify patient tailored therapy.

PB 2404 | Childhood Immune Thrombocytopenic Purpura (ITP) in Gorgan Taleghani Hospital

N. Mirbehbahani[1], Z. Payab[2]

[1]Golestan University of Medical Science, Hematology, Gorgan, Iran, Islamic Republic of, [2]Hamta, Hematology, Gorgan, Iran, Islamic Republic of

Background: ITP is the main reason of Thrombocytopenia in children which is most prevalent in 1 to 4 years old children And it´s incident is not gender dependent. Initial treatments are applied to patients with platlet count lower than 20000/mm3 or symptomatic cases. The initial treatments include Prednisolone and IVIG. In 20 % of cases disease manifestation becomes chronic (longer than 12 months).
Aims: We decided to investigate finding in our ITP patients in Gorgan Taleghani Hospital and compared them with references.
Methods: we investigated in-patients files from December2014 to March2016 in Hematology department of Taleghani Hospital and recorded demographic data and patients contact information. Then these patients files were followed up in out-patients files.
Results: 49 patients with ITP diagnosis were recorded between 2014-2016 .patients were from 22days to 15years with mean age of 8.3 years. male to female ratio was 1.33/1. platlet counts had minimum and maximum of 1000 /^{mm3}and 55000/^{mm3} respectively with mean value of 18820/^{mm3}. Initial treatment of patients found out to be only Prednisolone in 0 patients (0%), IVIG in 7patients (14.3%), and both Prednisolone & IVIG in 42patients (85.7%). in 1 patients (2.04%), disease took a chronic form (lasted longer than 12 month). in 1 patients (2.04%) with ITP initial presentation, definite diagnosis turned out to be AML M_7.
Conclusions: our derived data had good correspondence with global findings except chronicity.Taking into account the fact that in 1 patient with ITP initial presentation, definite diagnosis turned out to be AML M_7 , we recommend to pay enough attention to differential diagnosis in ITP cases.

PB 2405 | Pharmacokinetic Variations, Fc Receptor Polymorphisms and their Impact on Response to IVIG in Pediatric Immune Thrombocytopenia

D.E. Schmidt[1,2], K.M.J. Heitink-Polle[3,4], A.G. Laarhoven[1], B. Veldhuisen[1], M.C.A. Bruin[3,5], L. Porcelijn[6], E. van der Schoot[1], G. Vidarsson[1], M. de Haas[1,6,7]

[1]Department of Experimental Immunohematology, Sanquin Research and Landsteiner Laboratory, Academic Medical Center, University of Amsterdam, Amsterdam, The Netherlands, [2]Department of Immunohematology and Blood Transfusion, Leiden University Medical Center, Leiden, The Netherlands, [3]Department of Pediatric Hematology, University Medical Center Utrecht, Utrecht, The Netherlands, [4]Department of Pediatrics, Flevoziekenhuis, Almere, The Netherlands, [5]Princess Maxima Center for Pediatric Oncology, Utrecht, The Netherlands, [6]Department of Immunohaematology Diagnostics, Sanquin Diagnostic Services, Amsterdam, The Netherlands, [7]Center for Clinical Transfusion Research, Sanquin Research and Department of Immunohematology and Blood Transfusion, Leiden University Medical Center, Leiden, The Netherlands

Background: 30-40% of pediatric patients with immune thrombocytopenia (ITP) are non-responders to intravenous immunoglobulin (IVIG), but it remains unclear which factors determine a patient´s responsiveness. IVIG clearance varies significantly between individuals and has been shown to affect the clinical outcome in Guillain-Barre syndrome. This variation may depend on variable levels of saturation of the neonatal Fc receptor (FcRn) for immunoglobulin G (IgG) and polymorphism affecting its expression. In addition, it is possible that polymorphisms of myeloid Fc-receptors (FcγR) may be involved.
Aims: To investigate whether variations in IVIG pharmacokinetics and Fc receptor polymorphisms could explain clinical outcome in newly diagnosed childhood ITP.
Methods: Blood samples were analyzed from 134 children with newly diagnosed ITP allocated to careful observation or administration of 0.8g/kg IVIG in a multicenter randomized controlled trial. Increases in serum IgG levels (ΔIgG) were measured by nephelometry 1 week and 12 weeks after trial inclusion. Polymorphisms in the neonatal Fc

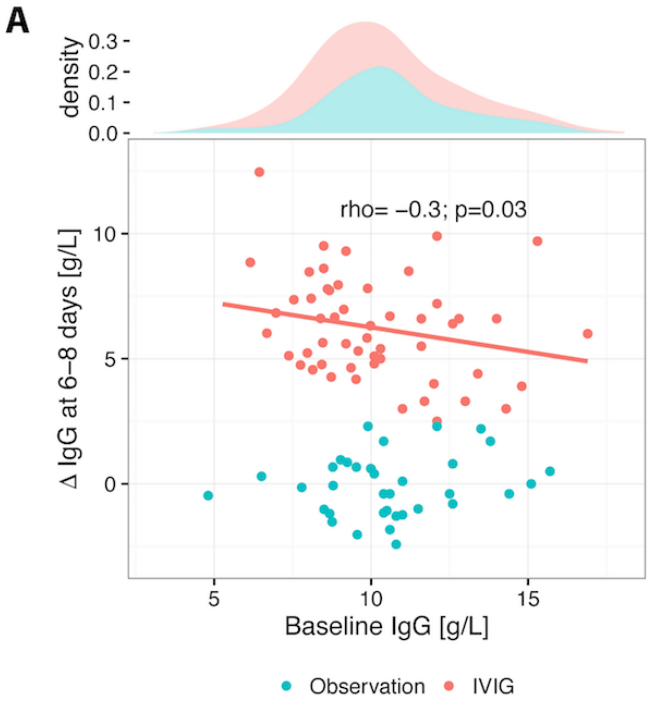

FIGURE 1 Changes in IgG after 1 week vs baseline IgG levels in children with newly diagnosed ITP.

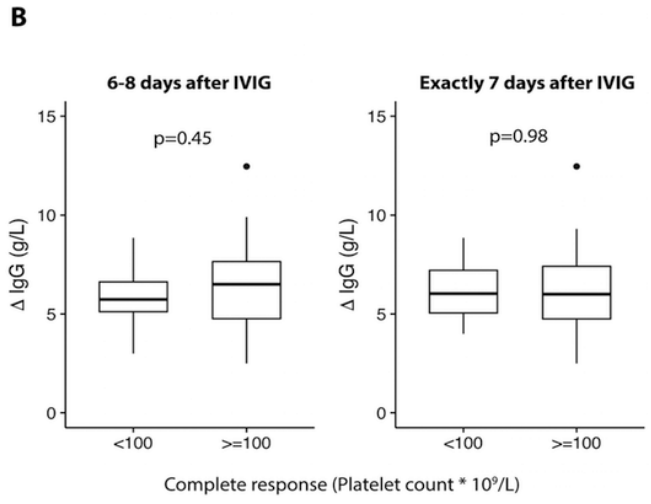

FIGURE 2 Increases in serum IgG 1 week after IVIG and resolution of thrombocytopenia (platelet count > 100 * 10^9/L).

receptor (FcRn) promoter and a panel of FcγR polymorphisms were determined.

Results: Pediatric patients with ITP showed a high interindividual variation in ΔIgG.

Lower ΔIgG levels may partly be explained by high pre-treatment serum IgG and saturation of FcRn-dependent IgG recycling. No association between affinity- and expression-determining polymorphisms in FcRn or FcγR and ΔIgG was detected. Our data indicate that ΔIgG between responders and non-responders were similar (Bayesian t-test; BF_{10} = 0.3, BF_{01} = 2.8).

There was no association between ΔIgG and increased Buchanan bleeding scores.

Conclusions: Post-IVIG increases in IgG did not explain heterogeneity in the clinical response in childhood ITP. We were unable to confirm that polymorphisms in FcRn or FcγR affected IVIG responsiveness. Therefore, from our data, neither dose adjustment nor genotyping of Fc receptors are tangible strategies to decrease the number of non-responders.

PB 2406 | Fetal/Neonatal Alloimmune Thrombocytopenia - An Underestimated Life-threatening Clinical Condition

L. Bonstein[1], R. Lauterbach[2], N. Atweh[2], A. Abu-rumi[2], N. Haddad[3]

[1]Rambam Health Care Campus, Blood Bank and Platelet Immunology Laboratories, Haifa, Israel, [2]Rambam Health Care Campus, Platelet Immunology Laboratory, Haifa, Israel, [3]Rambam Health Care Campus, Hematology and BMT, Haifa, Israel

Background: In fetal/neonatal alloimmune thrombocytopenia (FNAIT), platelets (PLT) are destroyed by maternal antibodies directed against fetal antigens. Thrombocytopenia may be severe and lead to intracranial hemorrhage in about 10% of cases. FNAIT is estimated to be markedly underdiagnosed, partly due to the fact that complete blood count (CBC) is not routinely done in all neonates.

Aims: To evaluate the degree of awareness of FNAIT in an attempt to decrease the risk of this devastating condition.

Methods: A retrospective analysis.

Results: A retrospective analysis of 322 suspected FNAIT cases sent over the past 4 years to our reference laboratory from the majority of medical centers in the country revealed a low referral rate of 39%. In addition, 50% of the families with a thrombocytopenic newborn were referred for evaluation weeks after discharge, when the antibody titer could already be below the detection level and 27% of the mothers with a previously suspected FNAIT pregnancy were referred for such evaluation only during a subsequent pregnancy. A supplementary retrospective analysis performed at our center between 2010-2015 showed that a CBC test was done for various clinical reasons only in 7370 (23.1%) of 31952 newborns. Thrombocytopenia (< $150x10^9$ PLT/L) was found in 2505 (34%) of these babies, being severe (< $50x10^9$ PLT/L) in 220 (2.98%) of them. Extended evaluation of the latter subgroup demonstrated that 45 newborns were term and had no other possible causes for the low PLT count. Yet, only 7 babies were referred for FNAIT assessment: 4 of them were found positive for PLT antibodies. Thus, in the current analysis, 84% of the newborns with severe thrombocytopenia were not assessed for FNAIT.

Conclusions: Awareness of physicians and cooperation of the multidisciplinary team (neonatologists, pediatric hematologists and gynecologists) involved are crucial for FNAIT diagnosis. Development of uniform guidelines for the evaluation of this life-threatening clinical condition is warranted.

PB 2407 | Variable Impairment of Platelet Function in Patients with Severe, Genetically Linked Immune Deficiencies

M. Nagy[1], T.G. Mastenbroek[1], N.J.A. Mattheij[1], S. de Witt[1], K.J. Clemetson[2], J. Kirschner[3], A.S. Schulz[4], J.M.E.M. Cosemans[1], B. Zieger[5], J.W.M. Heemskerk[1]

[1]*Maastricht University / Cardiovascular Research Institute Maastricht (CARIM), Department of Biochemistry, Maastricht, The Netherlands,* [2]*Inselspital, University of Bern, Department of Haematology, Bern, Switzerland,* [3]*Medical Center - University of Freiburg, Department of Neuropediatrics and Muscle Disorders, Freiburg, Germany,* [4]*University Medical Center Ulm, Department of Pediatrics and Adolescent Medicine, Ulm, Germany,* [5]*Medical Center - University of Freiburg, Faculty of Medicine, Department of Pediatrics and Adolescent Medicine, Division of Pediatric Hematology and Oncology, Freiburg, Germany*

Background: Based on studies with mice, in young patients with severe immune deficiency linked to mutations in *STIM1* (calcium-regulating protein), *ORAI1* (Ca^{2+} channel) or *FERMT3* (integrin-regulating protein kindlin-3), platelet dysfunction is expected.

Aims: Assessment of the consequences of homozygous or heterozygous mutations in these 3 genes on overall platelet hemostatic functionality.

Methods: Platelet function analysis of patients (3 children, 1 adult, 5 parents) with mutations in *ORAI1*, *STIM1* or *FERMT3*. Measurement of platelet calcium signaling. Multi-parameter assessment of whole blood thrombus formation (arterial or venous shear rate) on microspots, activated via GPVI (collagen), CLEC2 (rhodocytin) or GPIb/$\alpha_{IIb}\beta_3$ (von Willebrand factor/fibrinogen). Comparison with data from healthy donors.

Results: In platelets from 4 out of 6 immune-compromised patients (including parents) with a mutation in *ORAI1* or *STIM1*, store-operated Ca^{2+} entry (SOCE) was substantially or completely reduced in comparison to control platelets. Platelets from patient with heterozygous mutation in *STIM1* showed normal thrombus formation, in spite of reduced SOCE. Platelets from 5 patients with mutations in *ORAI1* were reduced in thrombus formation, most discriminative for surfaces acting via CLEC2 and GPIb/$\alpha_{IIb}\beta_3$. Phosphatidylserine exposure was consistently low, irrespective of surface and shear rate. Platelets from family members with mutation in *FERMT3* scored lowest in thrombus formation at all surfaces. Bone marrow transplantation of patients (n=2) resulted in an overall improvement of platelets function and thrombus parameters.

Conclusions: Cumulative parameters of thrombus formation were more severely reduced in blood from patients plus relatives in the order of $STIM1^M$<$ORAI1^M$<$FERMT3^M$. The reduced hemostatic potential is primarily (n=7) linked to signaling dysfunctions and secondarily (n=1) to a low platelet count.

PB 2408 | Whole Blood Aggregometry to Assess Platelet Function in Children on Cardiopulmonary Bypass

R. Bercovitz[1,2], C. Drew[1], S. Jobe[1,3], D. Newman[4]

[1]*BloodCenter of Wisconsin, Medical Sciences Institute, Milwaukee, United States,* [2]*Medical College of Wisconsin, Pathology and Pediatrics, Milwaukee, United States,* [3]*Medical College of Wisconsin, Pediatrics, Milwaukee, United States,* [4]*BloodCenter of Wisconsin, Blood Research Institute, Milwaukee, United States*

Background: Cardiopulmonary bypass (CPB) causes platelet destruction and dysfunction; therefore, platelets are often transfused empirically to pediatric patients to reduce bleeding risk. Whole blood aggregometry (WBA) is a rapid test of platelet function and has safely reduced transfusions without increased bleeding in adults, but is not routinely used in children.

Aims: Use WBA to measure change in platelet function in children on CPB.

Methods: This IRB-approved study consented children 1-60 months old undergoing surgery with CPB at Children's Hospital of Wisconsin 2015-2016. WBA uses electrical impedance to measure platelet aggregation after agonist activation. Agonists used were thrombin receptor activating peptide (TRAP) and ADP. WBA was performed pre-CPB, on CPB after surgical repair completed, and post-CPB (after platelet transfusion). ANOVA used for >2 groups (Dunn's test for multiple comparisons), Wilcoxon rank sum test was used for 2-group comparisons.

Results: 63% of patients (27/43) received a platelet transfusion. Platelet count decreased in most subjects (median: -176x10^9/L in transfused, -96x10^9/L in non-transfused patients). Patients had a post-transfusion increase (median, 82x10^9 platelets/L), whereas

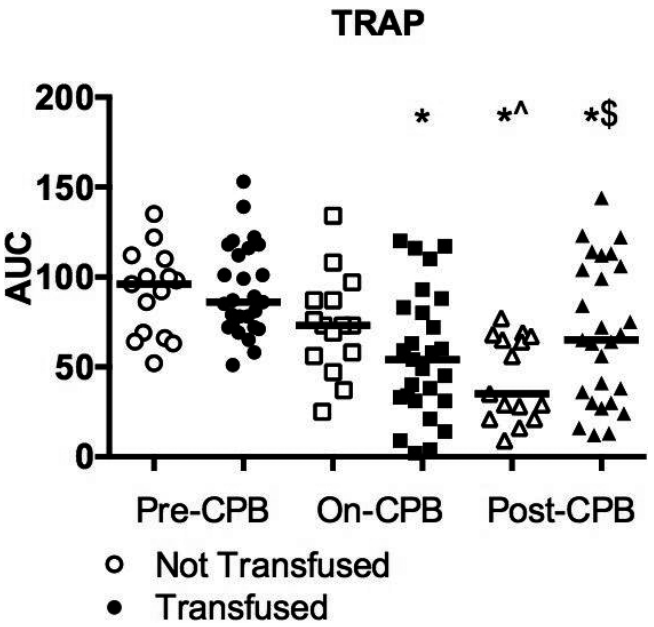

FIGURE 1 Change in TRAP response due to CPB. Significant difference compared to *pre-CPB, ^on-CPB, and $ non-transfused patients at the same time point.

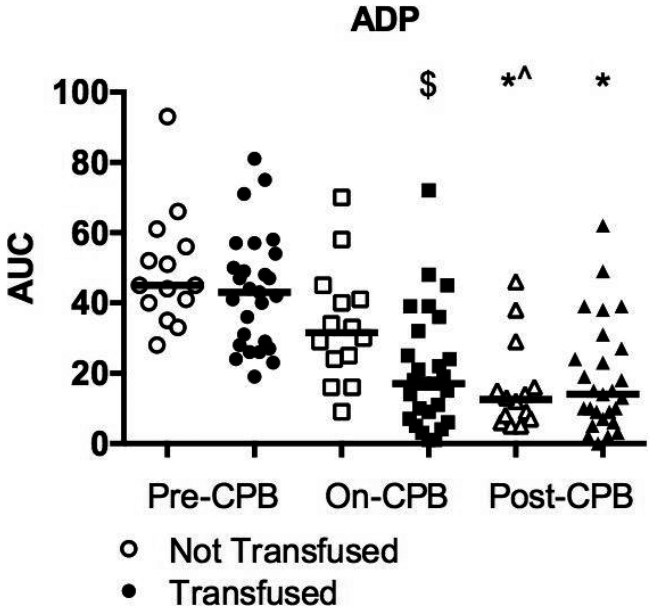

FIGURE 2 Change in ADP response due to CPB. Significant difference compared to *pre-CPB, ^on-CPB, and $ non-transfused patients at the same time point.

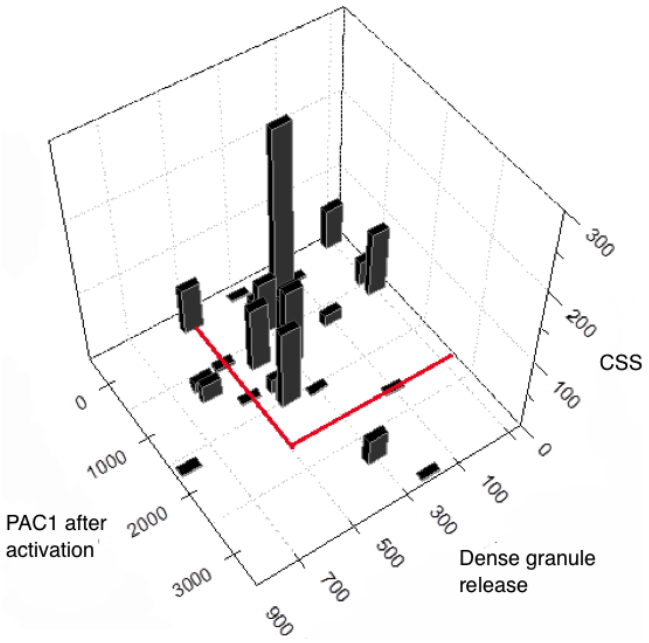

FIGURE 1 Correlation between CSS, PAC1 after activation and dense granule release

non-transfused patients had a further decrease in platelets post-CPB (median: -27x10^9/L). WBA in response to TRAP mirrored changes in platelet count (Fig 1), whereas response to ADP was not improved despite platelet transfusion (Fig 2). Two of three subjects that had a very poor response to TRAP (AUC < 20) pre- and post-transfusion had excessive postoperative bleeding.

Conclusions: CPB decreased platelet count and response to TRAP and ADP. Platelet count and TRAP response improved after platelet transfusion. ADP response remained poor even in transfused patients, suggesting that stored platelets have decreased reactivity to ADP. Poor response to TRAP despite transfusion was associated with bleeding. Future studies are needed to evaluate using WBA to guide platelet transfusions and hemostatic management.

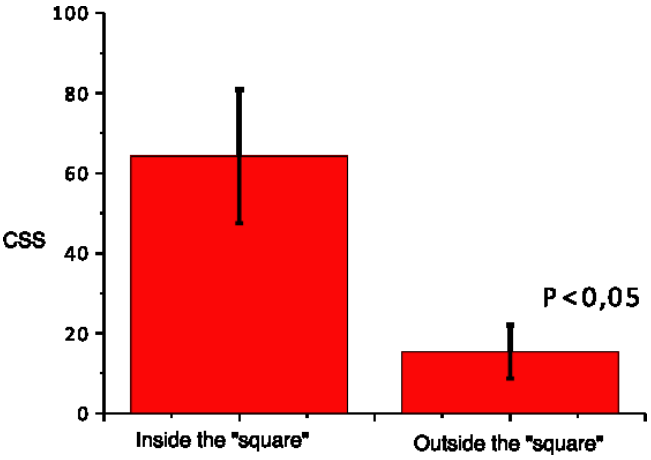

FIGURE 2 Comparison of patients inside and outside the

PB 2409 | Platelet PAC1 expression and dense granules function reflects bleeding severity in children

P. Zharkov, I. Demina, D. Fedorova, M. Panteleev

Federal Research Clinical Centre of Pediatric Hematology Oncology and Immunology N.A. D. Rogachev, Moscow, Russian Federation

Background: There is no clear data on the correlation between the degree of in vitro platelet function failure (PFF) and bleeding severity (BS) in children with suspected IPD7.

Aims: To analyze the correlation between PFF degree determined using flow cytometry (FC) and BS in children.

Methods: 32 patients (1-17 yo) with bleeding without Willebrand disease, factor XIII deficiency, or other coagulopathy were included. PF was evaluated with FC before and after stimulation with CRP plus TRAP. Fluorescencently labeled antibodies against CD42b, CD61, CD62P and PAC-1 were used; dense granule release (DGR) was studied using loading with mepacrine; procoagulant activity was evaluated using annexin V. To standardize BS a clinical score (CS) system was developed and calculated with formula: i*[∑(SLa*SSa)+ …+ (SLx*SSx)], where i is a systemic index which equals 5 when three or more bleeding localizations persist, and equals 1 when two or less bleeding localizations persist. The term (SL*SS) reflects the score for each localization (SL, 1 to 10 points) and severity (SS, 1 to 10 points). All comparisons were performed with OriginPro 8.0 (OriginLab, MA, USA) software using Mann-Whitney U-test.

Results: Out of the 32, three patients were excluded because of normal results or preanalytical issues. Among the remaining 29 patients, four children were diagnosed with CD61 deficiency, and 25 had different combined defects. We used a two-parameter statistical model to analyze the relationship between PFF and CSS (fig. 1).

The majority of platelets with CSS≥ 10 were situated in the square 0< PAC1< 2000, 0< DGR< 500 (all units are arbitrary).

A comparison between CSS among those patients in this ´´square´´ with those who were outside the the region, revealed a statistically significant difference (fig 2).

We did not find any statistically significant correlation between CSS and other studied parameters.

Conclusions: PFF degree determined as a combination of integrin activation and DGR in vitro correlates with BS in children.

PB 2411 | Utility of Small Volume Whole Blood Platelet Function Assays in Adolescent Women with Heavy Menstrual Bleeding

A. Rocheleau[1], A. Khader[1], A. Ngo[1], M. Recht[2], O. McCarty[1], K. Haley[2]

[1]*Oregon Health & Science University, Biomedical Engineering, Portland, United States,* [2]*Oregon Health & Science University, The Hemophilia Center, Portland, United States*

Background: Qualitative platelet disorders (QPDs) have been reported in up to 40% of young women with heavy menstrual bleeding (HMB). Diagnosing QPDs remains challenging due to the limitations of currently available clinical platelet function assays. Herein we applied a panel of small-volume whole blood assays to a population of adolescent women with HMB.

Aims: To determine the utility of the platelet function assays in evaluating HMB in adolescent women.

Methods: The study was approved by the Institutional Review Board. Written informed consent and/or assent was obtained. Citrated venous whole blood from each participant was used in a panel of assays: activation of GPIIbIIIa integrin as measured by PAC-1 mAb; platelet granule secretion as measured by P-selectin expression; platelet aggregation; platelet static adhesion on collagen or von Willebrand Factor (vWF); and platelet adhesion to collagen or vWF under low or high shear flow. The activation, aggregation, and static adhesion assays were assessed in response to the following agonists: ristocetin, TRAP-6, U46619, ADP, calcium ionophore, collagen-related peptide, and epinephrine. In addition, participants underwent evaluation for HMB per the clinical standard at the treating institution.

Results: Twelve participants with clinical bleeding symptoms were included in the study of which 7 were diagnosed with a clinically-identifiable bleeding disorder (BD). Participants diagnosed with a BD exhibited lower GPIIbIIIa activation and P-selectin expression in response to calcium ionophore compared to subjects without a BD diagnosis. A dramatic reduction in platelet adhesion was observed in flow assays for the participant diagnosed with thrombocytopenia.

Conclusions: Our assays detected differences among participants with and without clinically-identifiable BDs. These results demonstrate the potential clinical utility of our small volume whole blood platelet function panel.

PB 2412 | Novel Mutations in Thai Patients with Glanzmann Thrombasthenia

D. Sosothikul, P. Suchartlikitwong, Y. Kittikalayawong, R. Hirunsatit, C. Ittiwut, V. Shotelersuk, K. Suphapeetiporn

Chulalongkorn University, Department of Pediatrics, Bangkok, Thailand

Background: Glanzmann thrombasthenia (GT) is an autosomal recessive platelet disorder, caused by defects of the platelet integrin αIIbβ3 (GPIIb/IIIa) resulting from pathogenic mutations in either *ITGA2B* or *ITGB3*. It is characterized by spontaneous mucocutaneous bleeding. Molecular features of GT in Thailand have not been identified.

Aims: This study aimed to determine the clinical and molecular features of unrelated Thai patients with GT.

Methods: Four patients with clinically suspected GT were recruited at the Division of Pediatric Hematology/Oncology, King Chulalongkorn Memorial Hospital. The diagnosis was based on clinical and hematological parameters as well as molecular genetic analysis. Whole exome sequencing (WES) was performed in all cases.

Results: Of the four patients studied, the median age at first suspicion of GT was 2.5 years. All presented with severe bleeding symptoms (WHO bleeding scale 3). Flow cytometry to assess the surface GPIIb/IIIa complex showed reduced expression with the value being less than 5% in all cases, thus categorized into GT type 1. By WES, we successfully identified seven mutant alleles in *ITGA2B*. One alteration, the c.2911_2912insC was detected in two unrelated families. One patient was found to be homozygous for the c.617T>A. Of five different causative variants identified, four have never been previously described. These include missense and frameshift (c.617T>A, c.1522_1531del, c.2911_2912insC, and c.2377C>T). The novel missense variants were absent in an in-house database of 200 Thai exomes.

Conclusions: This study identified seven causative variants in *ITGA2B* in four unrelated patients with GT (87.5%). Four novel pathogenic variants were identified, expanding the genotypic spectrum of *ITGA2B* causing GT.

PB 2413 | Chemotherapy Induced Thrombocytopenia and Bleeding in Children and Young Adults with Cancer

S. Mkhitaryan, S. Danielyan, A. Avagyan, D. Zohrabyan, L. Sargsyan, L. Safaryan, L. Harutyunyan, L. Hakobyan, S. Iskanyan, S. Bardakchyan, R. Papyan, M. Asatryan, G. Tamamyan

Muratsan University Hospital, Yerevan State Medical University, Clinic of Chemotherapy, Yerevan, Armenia

Background: Chemotherapy induced thrombocytopenia (CIT) has long been recognized as a significant complication of cancer therapy,but there is still lack of consensus about the optimal approach to prophylaxis and/or treatment of this important morbidity.

Aims: The aim of the study is to estimate the frequency and features of CITand associated clinically significant bleeding in children and young adults.

Methods: For this retrospective, hospital-based study, children (0-18y) and young adults (19-40y) with differenttypes of solid tumors and hematologic malignancies who received chemotherapy at the Clinic of Chemotherapy of Muratsan Hospital Complex of Yerevan State Medical Universitywere identified from the patients' database and included in the study (overall 122 patients). Thrombocytopenia was defined as a decrease of platelet count below < $100x10^9$/L. For assessing bleeding WHO scale (0 = no bleeding, 1 = no petechiae, 2 = mild blood loss, 3 = gross blood loss, 4 = debilitating blood loss) was used.

Results: Overall the whole group of patients received 430 chemotherapy cycles.During 131 (31.6%) chemotherapy cycles patients developed CIT. The study revealed statistically significant negative correlation between the age of the patient and the severity of CIT. Another important finding of the study was that the patients, who previously were exposed to radiation therapy, were more likely to develop CIT,than those, who haven't received radiation therapy. From 430 cycles of chemotherapy only 31 (7.2%) cycles reported to have a bleeding incidence.

Conclusions: As a result of the study we concluded, that although CIT is a common complication of cancer therapy, clinically significant thrombocytopenia and bleeding are quite rare.

PB 2414 | Pregnancy Management of Fetal Alloimmune Thrombocytopenia (NAIT): A Case Report

O. Paoletti[1], L. Pecoroni[2], P. Cavalli[3], M. Crotti[2], M. Franchini[4], G. Marchitelli[5], R. Morandini[1], C. Paccapelo[6], C. Poggiani[7], A. Riccardi[5], A. Zimmermann[1], S. Testa[1]

[1]Cremona Hospital, Haemostasis and Thrombosis Center, Department of Laboratory Medicine, Cremona, Italy, [2]Cremona Hospital, Department of Transfusion Medicine and Hematology, Cremona, Italy, [3]Cremona Hospital, Medical Genetics, Cremona, Italy, [4]Mantova Hospital, Department of Transfusion Medicine and Hematology, Mantova, Italy, [5]Cremona Hospital, Department of Obstetrics and Gynaecology, Cremona, Italy, [6]IRCCS Ca' Granda Foundation, Ospedale Maggiore Policlinico, Department of Transfusion Medicine and Haematology, Milan, Italy, [7]Cremona Hospital, Department of Pediatrics, Cremona, Italy

Background: NAIT is caused by maternal immunization against platelet antigens (HPAs) and represents the most frequent cause of isolated fetal/neonatal thrombocytopenia. Clinical neonatal manifestations ranges from mild asymptomatic to severe thrombocytopenia that can lead to spontaneous intracranial hemorrage (20-25% of cases).

Aims: We describe a case of this rare underdiagnosed condition.

Methods: Clinical, laboratory and radiological informations were collected on medical record

Results: *A 35*-year-old pregnant woman with a previous miscarriage and 1 pregnancy complicated by NAIT with severe thrombocytopenia and minor bleeding symptoms referred to our clinic Serological tests confirmed maternal anti-HPA-1b, anti-HPA-5a, anti-HLA-class1 antibodies. Amniotic liquid showed HPA-1a/1a and HPA-5a/5b antigenic profile. Maternal antibodies were monitored every two weeks, an increase of anti-HPA-1b antibodies was observed from week 16. At week 18 she started prednisone 0.5 mg/Kg/die and IVIG 1gr/Kg/iv per week.

Maternal anti-HPA-1b was performed from the beginning of IVIG therapy to delivery every 2 weeks, showing a progressive reduction in titre. From week 32, IVIG dose was increased to 2gr/Kg/iv per week until delivery. A cesarean section was performed at week 38. The newborn, actively clinically monitored during the first week, didn't developed major or minor bleeding manifestations and always showed normal platelet count and negative Ab anti HPA-1b.

Conclusions: This case showed a successfully management of NAIT during a second pregnancy and the necessity of increase general knowledge on this condition. At present, no screening test on platelet antigen profile on both parents is indicated before a first pregnancy but they are required after a first NAIT to plan the following pregnancies. Since this syndrome shows high risk of recurrence and greater severity in subsequent pregnancies there is a general consensus on antenatal management with maternal first-line therapy using intravenous immunoglobulins (IVIG) and steroids.

TRANSFUSION & BIOTHERAPEUTICS

PB 307 | Plasma Derived FVIII Concentrates Induce Neutrophil Extracellular Trap (NET) Formation

M.F. Brodde[1,2], A. Bertling[1], B.E. Kehrel[1]

[1]University Hospital Muenster, Anaesthesiology, Intensive Care and Pain Medicine, Muenster, Germany, [2]OxProtect GmbH, Muenster, Germany

Background: Previously we showed pdFVIII induced platelet and neutrophil activation.

Aims: Here we studied whether pdFVIII may boost inflammation by the formation of NETs.

Methods: Three pdFVIII products and two rFVIII products were studied. Neutrophils were gently isolated from fresh human blood. Whether FVIII concentrates induced generation of reactive oxygen species from non-activated neutrophils was determined as the linear rate of superoxide dismutase-inhabitable reduction of cytochrome C. Activation of CD11b was analysed by flow cytometry using an activation specific antibody against CD11b labelled with PE. Associate formation in whole blood between platelets and neutrophils was measured by flow cytometry. Effect of factor VIII products on DNA release from isolated human neutrophils was measured by three methods, fluorescent dye Syto13 binding to nucleic acids, a sandwich ELISA against histone-DNA complexes and microscopy.

Results: Significant activation of CD11b was only observed on neutrophils treated with (0.1-1 U/ml) pdFVIII, but not on neutrophils treated with rFVIII. pdFVIII induced neutrophil ROS production as well as the

release of extracellular DNA, which was not observed with rFVIII. Fluorescence microscopy showed the pdFVIII induced NETs present alpha defensins (HNP1-3) and myeloperoxidase. In addition to experiments with isolated neutrophils, we studied the effect of FVIII on neutrophils in melagatran anticoagulated whole blood. Two of three tested pdFVIII clearly and significantly induced the formation of associates between neutrophils and platelets. In contrast, rFVIII had no effect. The activation effects of pFVIII on neutrophils were more pronounced in the presence of platelets.

Conclusions: Based on these in vitro results pdFVIII products in contrast to rFVIII products seem to be proinflammatory by activating neutrophils. Further research aims to investigate the effect of factor VIII products ex vivo.

This work was supported by a grant of Bayer Vital GmbH, 51368 Leverkusen, Germany

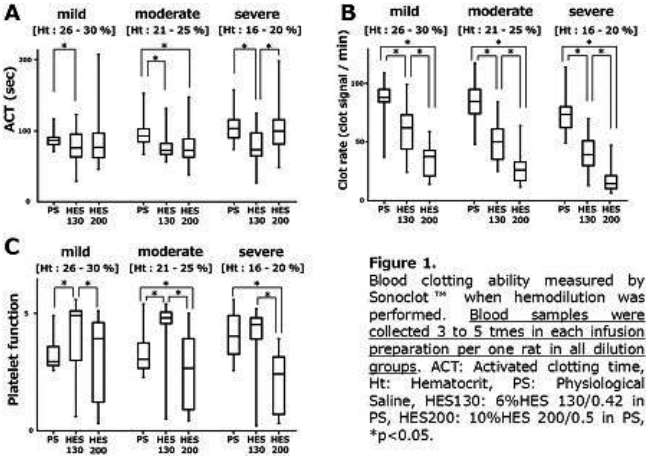

Figure 1.
Blood clotting ability measured by Sonoclot™ when hemodilution was performed. Blood samples were collected 3 to 5 tmes in each infusion preparation per one rat in all dilution groups. ACT: Activated clotting time, Ht: Hematocrit, PS: Physiological Saline, HES130: 6%HES 130/0.42 in PS, HES200: 10%HES 200/0.5 in PS, *p<0.05.

PB 308 | Vlidation of Hemostatic Impairment Induced by Hydroxyethyl Starch *in vivo*

R. Azumaguchi, Y. Tokinaga, M. Kimizuka, S. Kazuma, S. Hayashi, M. Yamakage

Sapporo Medical University, Department of Anesthesiology, Sapporo, Japan

Background: Precedent studies suggest that hemodilution using hydroxyethyl starch (HES) may inhibit blood coagulation. However, **resolution by α-amylase or the possibility of ´effective´ dilution was not considered** because most of the studies were *in vitro* or retrospective clinical studies in which the dilution level was not standardized.

Aims: We compared the blood clotting ability using Sonoclot™ when hemodilution was performed with physiological saline, 6% HES 130/0.42 and 10% HES 200/0.5 in order to clarify the influence of HES on coagulation ***in vivo* when diluted equally**.

Methods: Thirty male Wistar rats were divided into 3 groups of 10 rats. After tracheotomization, continuous monitoring of blood pressure were performed under artificial respiration. Each infusion preparation was given at 0.5 ml/h, and additional intravenous administration was permitted without limit in order to maintain blood pressure. Blood samples of 1.5 ml were taken for blood gas analysis and Sonoclot™ every 30 minutes. Hemodilution was continued until the hematocrit level was reduced to 16-20% without 20% decrease of mean blood pressure. Activated clotting time, clot rate (CR) and value of platelet function (PF), were recorded in each hematocrit and were considered to indicate the degree of hemodilution, divided into 3 groups (mild:26-30%, moderate:21-25%, severe:16-20%). Factor Ⅹ and soluble GPⅡb/Ⅲa were assayed by ELISA. Statistical analysis was performed using the Kruskal-Wallis H-test followed by the Newman-Keuls-type test for multiple comparisons. P values < 0.05 were considered statistically significant.

Results: CR was significantly reduced by the larger molecular weight HES despite equal dilution (Fig. 1B). PF was rather high in HES 130/0.42(Fig. 1C). Factor X tended to be reduced in HES 200/0.5 (Fig. 2A).There was no significant difference in GPⅡb/Ⅲa (Fig. 2B) .

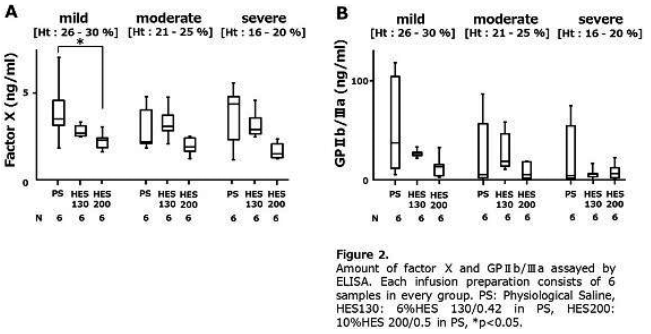

Figure 2.
Amount of factor X and GPⅡb/Ⅲa assayed by ELISA. Each infusion preparation consists of 6 samples in every group. PS: Physiological Saline, HES130: 6%HES 130/0.42 in PS, HES200: 10%HES 200/0.5 in PS, *p<0.05.

FIGURE 2

Conclusions: Hydroxyethyl starch impairs coagulation but all of HES do not inhibit platelet function necessarily. This cannot be explained by amount of factor X or GPⅡb/Ⅲa.

PB 309 | Ex Vivo Haemostatic Capacity of Thawed Plasma Beyond 24 Hours: Comparison between FFP and RTFP24

A.L. Ang[1,2], W.H. Wong[1], W.C. Tan[2], S. Lam[2], P. Kuperan[2,3], H.J. Ng[1,2], J. Chay[2], H.H. Tan[2], C.W. Tan[1], S.S. Chua[2]

[1]Singapore General Hospital, Haematology, Singapore, Singapore, [2]Health Sciences Authority, Blood Services Group, Singapore, Singapore, [3]Tan Tock Seng Hospital, Haematology, Singapore, Singapore

Background: Extending shelf-life of thawed plasma (TP) stored at 1-6°C to >24 hours (h) allows rapid plasma availability in massive transfusion protocol with less wastage. Most studies involved FFP (plasma frozen within 8h) or frozen plasma (FP) prepared from whole blood (WB) stored at 1-6°C up to 24h, which supported TP's storage up to 5 days in USA. Data on RTFP24 (FP prepared after ambient storage of WB up to 24h) is limited. We recently switched from FFP to RTFP24 for its operational benefits after validating its comparability to FFP at time of thaw.

Peak of thrombin generation (nM)	182.3 (107.1-251.0)	124.7 (68.8-189.5)*	34.3 (23.6 to 45.6)%	154.7 (102.6-331.4)	103.3 (62.5-303.6)*	35.5 (-0.6 to 53.5)%

Aims: Study RTFP24's ex vivo haemostatic capacity >24h post-thaw and compare to FFP.

Methods: 20 units (U) each of RTFP24 and FFP (blood group O:8U, A:5U, B:5U, AB:2U) were thawed ≥3 weeks after preparation, stored at 1-6°C till 4 days post-thaw (D4) and measured for FII, FV, FVII-XI; FXIII (chromogenic); fibrinogen; vWF:Ag; protein C (PC), ATIII; protein S (coagulometric); thrombin generation (calibrated automated thrombogram without PC activator) at time of thaw (D0) and D4. Labile factors (FV, FVII, FVIII) were also measured on D1-D3. Data was analysed for significant differences from corresponding baselines within each TP type and between both TP types at D4 using non-parametric tests.

Results: FV, FVII and FVIII declined from D1 (p< 0.001) except that FV declined from D2 in FFP (p< 0.01). ≥95% of FFP and RTFP24 U maintained clotting factors within reference ranges at D4 (except FV and FVIII) with no significant decline in proportion of such U from D0 (except FVIII). However, proportion with abnormal thrombin generation (using our reference ranges) increased at D4 for both TP types (p< 0.05). At D4, RTFP24 was comparable to FFP except for lower ETP (p=0.03) and higher FXIII (p=0.01). Of these, only FXIII was different between RTFP24 and FFP at baseline (p=0.03). See tables for other results.

Conclusions: While comparable to FFP, RTFP24 may have less efficacy at D4 from lower ETP. We do not recommend universally extending RTFP24's shelf-life to >24h post-thaw.

PB 310 | Effect of Handling on the Functional Utility of Stored Platelet Units

J. Zilberman-Rudenko[1], F.Z. Zhao[2], S.E. Reitsma[1], J. Pang[1], C. Tyrrell[3], W. Hasan[3], M.A. Schreiber[2], O.J.T. McCarty[1], OHSU

[1]*Oregon Health & Science University, Biomedical Engineering, Portland, United States,* [2]*Oregon Health & Science University, Division of Trauma, Critical Care and Acute Care Surgery, Department of General Surgery, Portland, United States,* [3]*Oregon Health & Science University, Knight Cardiovascular Institute, Portland, United States*

Background: 7000 units of stored platelets are infused daily into patients with significant bleeding all over the United States. The platelet units commonly need to be urgently delivered to the critical care team with the requirement that platelets remain functional in order to immediately improve hemostasis. A pneumatic tubing transport system is frequently used to facilitate a rapid and controlled delivery of reagents including platelet units within a hospital. However, the potential detrimental effect of shear forces due to gravitational effects platelets may experience during this delivery method is not well understood, leasing many hospitals to not permit platelet transportation using pneumatic systems.

Aims: Determine whether pneumatic tubing transport has a functional effect on stored platelet units.

Methods: Stored platelet units were divided into 3 groups: pre-transport, pneumatic tubing and ambulatory transport. Platelet activation (P-selectin expression) and microaggregation (CD41+/CD31+ events) and glycoprotein (GP) Ib receptor expression levels were quantified using FACS in the presence of select agonists. The hemostatic function of platelets was assessed by quantifying platelet adhesion and aggregation following perfusion of whole blood over collagen under shear. VWF multimer levels were assessed via western blot.

Results: While the mode of transport did not affect platelet GPIb receptor or VWF multimer levels, our results show that transport of stored platelet units through pneumatic tubing led to a decrease in platelet adhesion on collagen and vWF as compared to platelet units transported by ambulatory transport.

Conclusions: Our results suggest that subjecting platelets to high velocities within pneumatic tubing may diminish the ability of stored platelets to form a hemostatic plug on exposed extracellular matrix proteins and thus reduce their efficiency at staunching blood loss at an injury site.

PB 311 | Coagulations Parameters and Need for Transfusion in Patients with Veno-arterial Extracorporeal Membrane Oxygenation in Clinical Hospital Center Rijeka

N. Vukelic-Damijani[1], N. Katalinic[1], A. Starcevic[1], J. Sokolic[2], Z. Zupan[2], S. Balen[1]

[1]Clinical Hospital Center Rijeka, Clinical Institute for Transfusion Medicine, Rijeka, Croatia, [2]Clinical Hospital Center Rijeka, Department of Anesthesiology and Intensive Care Medicine, Rijeka, Croatia

Background: Adult patients supported by veno-arterial extracorporeal membrane oxygenation (V-A ECMO) have high blood products requirements. The main indication are severe cardiac failure and cardiopulmonary resuscitation.

Aims: Analysis of coagulation parameters and need for transfusion in ECMO patients during three years period.

Methods: Retrospective analysis and statistics elaboration of medical and laboratory data regarding adult patients during V-A ECMO treatment.

Results: In our hospital 38 adult patients were treated by V-A ECMO from 2014 to 2016; 9 women and 29 men. Mean ECMO time was 6 days (1 to 19). Surviving patients were 22 and 16 died. The mean values of coagulation parameters in first day were: prothrombin time (PT) 68%, International Normalized Ratio (INR) 1.36, activated partial thromboplastin time (aPTT) 76s, fibrinogen 3.4 g/L, antithrombin III (ATIII) 63%.The highest transfusion requirements patients had during the first day. Red blood cells (RBCs) were transfused to 36 patients (mean units in died 11 vs. 6 in survivors). Eighteen patients received 185 units of fresh frozen plasma (FFP), mean units in died were 8 vs. 6 in survivors. The same number of patients received transfusion of 122 units of platelets (mean units in died were 4 vs. 3 in survivors). Antithrombin III was the most frequently used blood derivate during the first ECMO day in 9 patients (mean units in died 469 vs. 227 in survivors). During monitoring of coagulation parameters normalization of all values is obvious, except of ATIII which is under lower limits all the time.

Conclusions: The values of PT/INR and antithrombin III are the most subjected to the changes during the initial period of ECMO treatment. Transfusion requirements of blood components and derivates were the mostly intense in the first day. The difference between patients who died and survivors was clinically significant although statistically can not be determined due to small sample.

PB 312 | Blood Loss and Transfusion of Blood Products in Children Undergoing Craniofacial Surgery

A.L. d'Amore[1,2], N. Juul[2], C. Fenger-Eriksen[2], M. Rasmussen[2], L. Krogh[2], G. von Oetting[3], A.-M. Hvas[1]

[1]Aarhus University Hospital, Clinical Biochemistry, Center for Haemophilia and Thrombosis, Aarhus, Denmark, [2]Aarhus University Hospital, Anesthesiology and Intensive Care, Section of Neuroanaesthesia, Aarhus, Denmark, [3]Aarhus University Hospital, Neurosurgery, Aarhus, Denmark

Background: Craniosynostosis (CS) is a condition where the cranial sutures ossify prematurely. To avoid brain damage, CS needs to be corrected surgically within the first years of life. This intervention is associated with substantial blood loss, which can exceed the child´s total blood volume. Reviewing international literature, the reported amount of blood loss during these operations differs significantly.

Aims: The overall aim was to investigate whether the amount of blood loss and transfusion of blood products have changed during a 15-year period. This was done by comparing two cohorts of children (2000-2006 vs 2013-2014) operated for CS at our institution.

Methods: All medical records of children who underwent craniofacial reconstruction during the periods 2000-2006 (n=123) and 2013-2014(n=52) were reviewed. Demographic parameters and clinical information was obtained. The intraoperative blood loss was registered as evaluated by the attending anesthesiologist, while the postoperative blood loss was reported as the total output in surgical drains

during ICU-stay. Information on the amount of transfused blood products was obtained from the anesthesia and ICU records.

Results: Per February 1st, 2017, the data of the first 111 patients (2000-2006: n=85; 2013-2014: n=24) were analyzed. These preliminary results show no difference has yet been detected in terms of intraoperative (25 ml/kg vs 26 ml/kg p=0.94) or postoperative blood loss (26 ml/kg vs 27 ml/kg p=0.27) while a numerically, though not significantly, reduced amount of transfused blood products during surgery (median 19 ml/kg vs 15 ml/kg p=0.25 for red blood cells; median 18 ml/kg vs 13 ml/kg p=0.27) for fresh frozen plasma.

Conclusions: The present preliminary results suggest that the amount of transfused blood products has dropped, though not significantly, between the analyzed time periods.

PB 313 | Inappropriate Fresh Frozen Plasma Transfusion in Children

Y. Guzin[1], Y. Oymak[2], T.H. Karapınar[2], S. Gözmen[3], Y. Ay[2], C. Vergin[2]

[1]Dr. Behcet Uz Children's Hospital, Pediatric, Izmir, Turkey, [2]Dr. Behcet Uz Children's Hospital, Pediatric Hematology, Izmir, Turkey, [3]Dr. Behcet Uz Children's Hospital, Izmir, Turkey

Background: Fresh frozen plasma (FFP) is a product extracted from whole blood. Blood products should be used according to transfusion guidelines to reduce the transfusion related complications.

Aims: In this study our aim is to evaluate inappropriate FFP transfusion in children.

Methods: Data were obtained from FFP transfusion records between April -December 2016. We based on National Blood Products Guideline for FFP transfusion indications. Thus inappropriate FFP transfusion ratio according to clinical department was determined.

Results: Ninety male (61.6%) and 56 (38.4%) female patients with a mean age of 3.5±5.1 years were enrolled in this the study. Totaly 286 units of FFP in 146 transfusion episods were used. Forty-one (28.1%) and 105 (71.9%) of products were used in surgical and pediatric services respectively. Twenty nine (19.8%) of 146 transfusion episods were inappropriate . The ratio of inappropriate transfusions according to services were seen in table 1. The reason for inappropriate FFP transfusion were as follows: 16 (%39,3) patients for operation, seven (24.1%) patients for burn, five (17.3%) patients for alongation of coagulation parameters and one (3.5%) patients for gastrointestinal bleeding with normal coagulation parameter. There were no transfusion related complication during FFP transfusion periods.

Conclusions: Collection of blood and blood products based on voluntary donation and the cost is high. Transfusion of blood products has troublesome side-effects. In this study inappropriate FFP transfusion rate was found 19.8% . This ratio could increase up to 60% in adult groups. Different educational programs based on needs may raise awareness among clinicians for appropriate FFP transfusion.

TABLE 1 The ratio of inappropriate fresh frozen plasma transfusions according to services

	Pediatric services	Surgical services	Total
Appropriate	98 (67.1%)	19 (13.1%)	117 (80.2%)
İnappropriate	7 (4.8%)	22 (15.0%)	29 (19.8%)
Total	105 (71.9%)	41 (28.1%)	146 (100%)

PB 314 | Knowledge, Attitude and Practice Regarding the Voluntary Blood Donation among the Young Student Population of Karachi

B. Nepal

Dow University of Health Sciences, Deaprtment of Transfusion Service, Karachi, Pakistan

Background: Safe blood is a crucial and irreplaceable component in the medical management of many diseases. The Voluntary non-remunerated blood donation is the ideal sources of quality blood, which forms less than 15 % of the demand of the blood in Pakistan.

Aims: To assess the knowledge, attitude and practice regarding the voluntary blood donation among the young student population of Karachi.

Methods: A cross sectional prospective study was conducted among 600 students from different universities and colleges of Karachi. A well-structured and pre-tested questionnaire, in English, was used to access the knowledge, attitudes and practices about voluntary blood donation. A scoring mechanism was used to understand overall knowledge level. Obtained data was analyzed.

Results: The sample population consisted of 54% male and 46% female students in the age group of 18-28 years. Only 65 % of the students have heard about voluntary blood donation and 28 % of the students have given blood once in their lifetime and among them 19 % are blood donors at the moment. 42 % of the participants believed that there is a specific reason why they don´t donate blood and 59 % believed that there is a risk involved for the donors, when donating blood. 80 % students wanted to promote voluntary blood donation. Fear and lack of awareness on blood donation are the reasons for not donating blood. Students gather information about voluntary blood donation from several sources mostly schools, colleges, family and friends.

Conclusions: This study showed that myths and misconceptions are leading the youngsters not to donate blood. Study also showed how increasing awareness and marketing through different ways can boost the culture of voluntary blood donation in society. Student population can be motivated to participate in different ways. There is a dire need to mobilize the electronic media for educating our youth about voluntary blood donation due to its access to masses.

PB 315 | Burden of Hemoglobinopathies on the Blood Bank of a Tertiary Care Setting

R. Akbar[1], L. Zafar[2]

[1]Foundation University Medical College Rawalpindi, Rawalpindi Cantt, Pakistan, [2]Foundation University Medical College, Rawalpindi, Pakistan

Background: Hemoglobinopathies are an emerging global health burden. The true magnitude of the hemoglobinopathies is still unknown in our region because of lack of facilities for the diagnosis and management. Besides that, haemoglobinopathies impose additional burden to the blood transfusion services because of lack of availability of rare blood groups and blood components.Additionally they are also at high risk of transfusion transmissible diseases.

Aims: The aim of this study was to assess the burden of hemoglobinopathies on the blood bank of a tertiary care hospital.

Methods: In our study, the transfusion requirements of all the patients having various hemoglobinopathies were studied from Jan 2015-Jan 2016.The data of all the patients who were issued red cell concentrates during this period was recorded.Particulars of those patients who needed washed red cells were also recorded in the proforma Forward and reverse ABO grouping and Rh grouping was done on all samples along with cross match and all the findings were recorded in the proforma.

Results: A total of 4684 red cell concentrates were issued during the study period. Out of these,452 (9.64%) red cell concentrates were issued to the patients having various hemoglobinopathies.95% of these red cells were issued without replacement donations. Of these donations, the frequencies of A^+, B^+, $AB^{+,}$ and O^+blood groups were 22.44%, 33.61%, 6.58%, and 35.07%, respectively.

Conclusions: Extensive screening of the population for identification of carriers of hemoglobinopathies is essential and further it will be of assistance in taking adequate therapeutic and preventive measures.

PB 316 | Major Blood Groups and A2 Subgroup in Mixed Pakistani Population of Karachi

B. Nepal[1], N. Nusrat[2]

[1]Grande International Hospital, Deaprtment of Transfusion Service, Maijubahal, Nepal, [2]Dow University of Health Sciences, Deaprtment of Transfusion Service, Karachi, Pakistan

Background: The Major blood groups are distributed in varying frequencies in different parts of world and in different ethnic groups. Information is scant in this aspect in mixed Pakistani population especially the frequency of weak subgroup A2 of blood group A.

Aims: To observe the frequency of major blood groups and sub-group A2 in a mixed Pakistani population in the catchment area of Dow international medical college, Karachi.

Methods: 536 healthy unrelated donors and their patients for whom they donated blood, of both sexes were selected for four months. Venous samples were taken and forward and reverse grouping were done by tube method in the blood bank of DDRRL affiliated with Dow international medical college and its affiliated Ojha hospital.

Results: The dominant group was "O" n 111(40 %) and B group was the second largest n 149 (39 %). The third largest was A group n 72 (20 %) and least was n 13 (4%). From A group, 20 were A2 group. This constituted 3 % of all samples and 18 % of A group individuals.

Conclusions: The blood group frequency of a mixed Pakistani population had differences with the studies done in other countries and for the first time, the frequency of A2 sub-group was estimated in mixed Pakistani population.

PB 317 | New Tools for the Delivery of RNA to Platelets

S. Novakowski, S. Romani, G. Prakash, C. Kastrup

University of British Columbia, Michael Smith Laboratories, Vancouver, Canada

Background: Platelets are an integral part of hemostasis and commonly used in the clinic to reduce bleeding. The ability to directly genetically manipulate platelets would be a useful tool for modifying and studying platelet function, and potentially for modifying and improving platelets which are used for transfusion. While a number of technologies have been used to deliver genetic material to cells throughout the body, few are well suited for use with platelets, which are anucleate and prone to activation.

Aims: Previous work has shown that platelets can be transfected with synthetic miRNA using Lipofectamine, however it is unknown whether lipid- based nanotechnologies suited for in vivo applications could also be used with platelets. Using these technologies, this project aims to develop a method that would allow for direct delivery of RNA to transfusable platelets with high efficiency, without inducing significant platelet activation.

Methods: Here, we developed a way to directly introduce mRNA to platelets, using lipid nanoparticles (LNPs) to deliver *in vitro* transcribed mRNA to platelets *ex vivo*. Flow cytometry, immunofluorescence confocal microscopy, and quantitative PCR were used to measure the endocytosis of LNPs and encapsulated mRNA into platelets. Platelet activation was determined by P-selectin expression and the extent of platelet aggregation.

Results: Using this approach, we have shown that exogenous mRNA encapsulated within LNPs is rapidly endocytosed by platelets while causing minimal platelet activation and aggregation. Components of the LNPs required to prevent platelet activation and promote uptake have been identified. Delivered mRNA can be detected in platelets for several hours following uptake, however regulation of protein expression has not yet been detected.

Conclusions: This is one step toward developing new tools for transfecting platelets. In the long term, these tools may lead to modified platelet products with a longer shelf-life or improved hemostatic ability.

PB 318 | Effects of Activated Human Platelet Releasates on Wound Healing of Immunodeficient Mice: Comparison with Basic FGF

K. Tozawa[1], Y. Ono-Uruga[2,3], T. Mori[4,5], N. Takizawa[2,3], M. Murata[6], S. Okamoto[1], Y. Ikeda[1,7], Y. Matsubara[2,3,6], M. Yazawa[8]

[1]*Keio University School of Medicine, Division of Hematology, Tokyo, Japan,* [2]*Keio University School of Medicine, Center for Clinical Research, Tokyo, Japan,* [3]*Kanagawa Academy of Science and Technology, Kawasaki, Japan,* [4]*National Cancer Center Hospital, Department of Pathology, Tokyo, Japan,* [5]*Keio University School of Medicine, Department of Pathology, Tokyo, Japan,* [6]*Keio University School of Medicine, Department of Laboratory Medicine, Tokyo, Japan,* [7]*Waseda University, Faculty of Science and Engineering, Tokyo, Japan,* [8]*Keio University School of Medicine, Department of Plastic and Reconstructive Surgery, Tokyo, Japan*

Background: Activated platelets release cytokines and growth factors, which are involved in tissue repair. Recent evidence supports the clinical application of platelets to accelerate wound healing. Recombinant basic fibroblast growth factor (rbFGF) is also in clinical use for this purpose.

Aims: The present study compared the effect of human platelets with that of rbFGF on wound healing of immunodeficient NOD.Cg-Prkdc^{scid}Il2rg^{tm1Wjl}/SzJ (NSG) mice.

Methods: Human platelets were washed and stimulated with 10 mM calcium/PBS for 15 min, and the sample was prepared as 4x10^7 platelets/20 µL (PLT). The cytokine and growth factor levels in the supernatants of PLT were measured by ELISA. Full-thickness excisional wound (0.5 cm^2) were treated with either PLT or 6 µg/20 µL rbFGF. These dosages were determined based on the therapeutic dose currently used in the clinical settings. The wound size was measured chronologically, and the histological examinations of wounded skin were performed with hematoxylin-eosin staining. This study was approved by the ethics review committee for the use of human samples and animal experiments of Keio University.

Results: PLT released 32±1 pg/mL of bFGF, 59±6 pg/mL of platelet derived growth factor, 78±4 pg/mL of vascular endothelial growth factor, 4±0.4 µg/mL of transforming growth factor beta 1, and 8±1 pg/mL of epidermal growth factor. The wound area (% of Day 0) on Day 5 was 87±6% in PLT group and 122±0% in rbFGF group, indicating that the healing process was faster in the PLT group. The histological examination indicated that there were differences in the patterns of wound healing. The wounds treated with PLT showed increased newly organized collagen, and relatively advanced growth of the epithelium and layer construction as compared to those treated with rbFGF.

Conclusions: While bFGF concentration in supernatant of activated platelets was low, they released various cytokines and growth factors related tissue repair and showed more beneficial effects on wound healing than rbFGF.

PB 320 | SAG Mediated Therapy Leads to a Predominant Th1 during Visceral Leishmaniasis on Triggering CD2 Epitope

S. Sinha[1,2], S. Sundaram[1]

[1]*University of Allahabad, Centre of Biotechnology, Allahabad, India,* [2]*Rajendra Memorial Institute of Medical Sciences, Division of Immunology, Patna, India*

Background: Visceral Leishmaniasis is a macrophage associated disorder for the treatment of which antimony based drugs like SAG and SSG were the first choice in the recent past. The clinical value of antimony therapy is now declined against VL because increasing cases of Sodium Antimony Gluconate (SAG) resistance have reached outstanding proportion in Bihar, India.

Aims: We have evaluated the effect of combining CD2 with conventional antimonial (sb) therapy in protection in BALB/c mice infected with either drug sensitive or resistant strain of Leishmania donovani with 3 million parasites via-intra-cardiac route.

Methods: Mice were treated with anti CD2 adjunct SAG subcutaneously twice a week for 4 weeks. Assessment for measurement of weight, spleen size, anti-Leishmania antibody titer, T cell and anti-leishmanial macrophage function was carried out day 0, 10, 22 and 34 post treatments.

Results: The combination therapy was shown boosting significant proportion of T cells to express CD25 compared to SAG monotherapy. Although, the level of IFN-γ was not statistically different between combination vs monotherapy ($p = 0.298$) but CD2 treatment even alone significantly influenced IFN- γ production than either SAG treatment ($p = 0.045$) or with CD2 adjunct SAG treatment ($p = 0.005$) in Ld-S strain as well as in Ld-R strain. The influence of CD2 adjunct treatment was also documented in anti-leishmanial functions in macrophages. As shown, the super-oxide generation began enhancing very early on day 10 after SAG treatment with CD2 during which SAG action was at minimum. Interestingly, the super-oxide generation ability remained intact in macrophage after treatment with immunochemotherapy even in mice infected with Leishmania resistant strain.

Conclusions: Our results indicate that CD2, which can boost up a protective Th1 response, might also be beneficial to enable SAG to induce macrophages to produce Leishmanicidal molecules and hence control the infection in clinical situation like Kala-azar.

PB 321 | Characterization of a Universal Reversal Agent for Anticoagulants

K. Bakhtiari[1], S.L.M. Peters[2], D.M. Monroe[3], J.C.M. Meijers[1]

[1]*Sanquin Research, Department of Plasma Proteins, Amsterdam, The Netherlands,* [2]*Okklo Life Sciences, Nijmegen, The Netherlands,* [3]*University of North Carolina, Department of Medicine, Chapel Hill, United States*

Background: Anticoagulant medicines are widely used. Until now, there are no universal reversal agents for all anticoagulants. Cyclodextrins are macromolecular cyclic sugars. In this study, we describe the discovery of a novel class of prohemostatic cyclodextrins.

Aims: To explore in vitro and in vivo prohemostatic effects of cyclodextrins.

Methods: Fibrin polymerization assay, calibrated automated thrombography and rotation thromboelastometry in normal plasma and whole blood were used to assess the effect of cyclodextrins on coagulation in the absence or presence of various anticoagulants. In vivo hemostatic effects of a potent prohemostatic cyclodextrin was tested in mice treated with rivaroxaban using a vena saphena bleeding model.

Results: A number of potent prohemostatic cyclodextrins were discovered that concentration-dependently increased thrombin generation in normal plasma. In addition, thrombin generation was markedly enhanced in plasma of patients treated with vitamin K antagonists, and normal plasma spiked with dabigatran, rivaroxaban, apixaban, edoxaban, unfractionated and low molecular weight heparin, pentasaccharide and hirudin. Also, the procoagulant cyclodextrins shortened the clotting time in rivaroxaban-spiked whole blood. One of the procoagulant cyclodextrins fully restored the bleeding tendency in rivaroxaban-treated mice.

Conclusions: A novel class of procoagulant molecules was identified. Prohemostatic cyclodextrins act as broad spectrum anticoagulant reversal agents.

PB 322 | Antiaggregant Effect of Rubia tinctorum Butanolic Extract on Human Platelets

F. Marhoume[1,2], Y. Zaid[3], H. Bouffous[4], A. Lamrani Hanchi[5], K. Haouach[6], A. Chait[7], A. Bagri[4]

[1]Faculty of Sciences and Technology, Hassan I University, Settat, Integrative and Computational Neuroscience Team, Laboratory of Biochemistry and Neuroscience, Marrakech, Morocco, [2]Faculty of Sciences Semlalia, University Cadi Ayyad, Laboratory of Pharmacology, Neurobiology and Behavior, Department of Biology, Marrakech, Morocco, [3]University of Health Sciences MED VI, Laboratory of Thrombosis Hemostasis, Research Center, casablanca, Morocco, [4]Integrative and Computational Neuroscience Team, Laboratory of Biochemistry and Neuroscience, Faculty of Sciences and Technology, Hassan I University, Settat, Morocco, [5]Laboratory of hematology mohamed VI university hospital centre, marrakech Morocco, marrakech, Morocco, [6]Laboratory of Hematology Mohamed VI University Hospital Centre, Marrakech, Morocco, [7]Laboratory of Pharmacology, Neurobiology and Behavior, Department of Biology, Faculty of Sciences Semlalia, University Cadi Ayyad, Marrakech, Morocco

Background: *Rubia Tinctorum* is a plant belonging to Rubiaceae family that historically originated from Caucasus and Near East. This plant is widely distributed in southern and southeastern Europe, in central Asia, and in the Mediterranean including the north of Africa. It is commonly known as "El foua" in Morocco. Extracts from *Rubia Tinctorum*'s root have been used as a traditional medicine to cure various ailments. For example, studies have shown that the dried roots are useful in alleviating dropsy, paralysis, jaundice, amenorrhea and visceral obstructions. Platelets aggregation is an important reaction to stop bleeding but it is considered that excessive platelets aggregation causes thrombosis and ateriosclerosis. Recently, the antiaggregant activies of some spices were investigated.

Aims: The present investigation was undertaken to study the antiaggregatory effect of *Rubia Tinctorum* extracts on human platelets.

Methods: Ethanol extract and its n-hexane, ethyl acetate, butanol and aqueous fractions of *Rubia Tinctorum* (Rubiacea) were tested *in vitro* for their aggregant activitiy. Platelet aggregation was evaluated in platelet rich plasma (PRP) obtained from blood of healthy human volunteers. Human platelets were subjected to stimulation with collagen (0.2µg/mL) in the presence and/or absence of each extract at the concentrations 250, 500 and 1000 mg/ml respectively.

Results: A significant inhibition was observed only with the butanolic extract at 500 and 1000 mg/mL with 8% of inhibition.

Conclusions: Our findings suggest that the butanolic extract of *Rubia Tinctorum* may have component(s), which prevent platelet aggregation.

PB 1032 | Intraoperative Patient Blood Management: A Role for Very-low-Dose Recombinant Activated Factor VII

T. Hoffmann[1], S. Sixt[2], A. Albert[3], A. Dierksen[3], E. Roussel[1], A. Lichtenberg[3], A. Assmann[3]

[1]University Hospital, Transfusion Medicine - Clinical Hemostaseology, Duesseldorf, Germany, [2]University Hospital, Anaesthesiology, Duesseldorf, Germany, [3]University Hospital, Cardiovascular Surgery, Duesseldorf, Germany

Background: Recombinant activated factor VII (rFVIIa) is widely used for treatment of major bleeding beyond its labelled indications. However, conflicting data have been presented with respect to efficacy.

Aims: To evaluate the efficacy of single shot very-low-dose rFVIIa (vld-rFVIIa) in cardio-surgical patients with unabated bleeding.

Methods: Real-time monitoring of hemostatic parameters was conducted in a prospective cohort study of cardiac-surgery patients (n=281). Informed consent was obtained from all patients. The study was approved by the local medical ethical committee.

First-step bleeding therapy was carried out by goal-directed substitution of hemostatic compounds. In case of unabated bleeding single shot vld-rFVIIa (14 ± 3 micrograms/kg) was administered (n=167). Hemostatic efficacy in the vld-rFVIIa group was compared to patients without rFVIIa administration (n=114). The efficacy of vld-rFVIIa as compared to substitution therapy was assessed using prothrombin times and extrinsic clotting times by thromboelastometry as well as platelet function by impedance aggregometry.

Results: Hemostatis was achieved by single shot vld-rFVIIa in 61.3%-88.6% of patients without need for further hemostatic treatment. Clinical efficacy could be objectified by specific laboratory testing in a subgroup of 27 patients: clotting times of the extrinsic pathway were significantly shortened by vld-rFVIIa administration (prothrombin time (Quick test) +58.7 ± 13.8%, p< 0.0001; extrinsic clotting time by thrombelastometry -12.7 ± 11.9 sec, p< 0.0001). An increase of TRAP-induced platelet aggregation was observed in 18/27 patients after vld-rFVIIa administration however did not reach significance.

Conclusions: vld-rFVIIa is effective for the treatment of unabated bleeding in cardiosurgical patients. Substitutional restoration of the hemostatic potential with subsequent vld-rFVIIa-triggering of a momentary thrombin burst may represent a novel paradigm in major bleeding therapy.

PB 1033 | Preoperative Assessment of Bleeding Risk - Implementing Strategies in the Pursuit of Effective Patient Blood Management

J. Joseph[1,2], D. Behan[1], G. Mills[1], G. Lepar[3], E. Bean[3]

[1]St Vincent's Hospital, Haematology, Sydney, Australia, [2]University of New South Wales, Sydney, Australia, [3]St Vincent's Hospital, Anaesthetics, Sydney, Australia

Background: Guidelines advise that a bleeding history should be taken and that routine coagulation screening is inappropriate in patients having surgery.

Aims: A project to optimise bleeding risk assessment in patients undergoing elective surgery at a single hospital was undertaken. This underpins effective patient blood management.

Methods: 121 medical records of patients attending surgical pre-admission clinic (PAC) in a single month were audited. Demographic and clinical data were recorded including number of days between PAC attendance and surgery, patient self-completion of health questionnaire, documentation of bleeding history, record of anti-platelet and anti-coagulant therapy, and coagulation test results. Following dissemination of initial audit results, a standardized preoperative bleeding risk questionnaire was developed and introduced into routine practice in PAC and a post-intervention audit was performed.

Results: Initial audit found that 54% patients were seen in PAC less than 1 week prior to surgery and that 19% patients did not self-complete their health questionnaire, No patients had a standardised bleeding risk assessment performed and 11% patients had limited documentation of bleeding history. Coagulation testing was requested in 67% patients and 41% patients were taking anti-platelet and/or anti-coagulant therapy. Audit results were disseminated and a structured bleeding questionnaire was introduced into PAC. No change to practice of ordering coagulation tests was made at the request of anaesthetists. Post-intervention audit of 109 medical records found that 62% patients had a structured bleeding history performed. Coagulation testing was ordered in only 49% patients, a significant reduction, even though a change in this practice had not been advocated.

Conclusions: Current practice indicates that there is an over-reliance on coagulation screening in lieu of appropriate history taking in assessing bleeding risk, however introduction of structured bleeding risk questionnaires can overcome this.

PB 1034 | Indications for the Use of Fresh Frozen Plasma in Neonatal Intensive Care Unit in a Tertiary Care Hospital

R. Akbar[1], A. Khan[2]

[1]Foundation University Medical College Rawalpindi, Pathology, Rawalpindi, Pakistan, [2]Armed Forces Institute of Pathology, Rawalpindi, Pakistan

Background: Utilization of fresh frozen plasma(FFP) is high in neonatal intensive care unit and the indications for the use of FFP in neonates are limited.

Aims: To evaluate the indications for the use of fresh frozen plasma (FFP) in a tertiary care neonatal intensive care unit (NICU), specifically to examine compliance with guidelines for the use of fresh frozen plasma in neonates.

Methods: It was a prospective observational study conducted over a period of 12 months from March 2015 to March 2016 at Fauji Foundation Hospital Rawalpindi Pakistan.Data of all the neonates who received FFP transfusion was recorded taking into account the indications, pretransfusion and post-transfusion laboratory test of haemostasis, and detailed history of any bleeding episodes.

Results: A total of 192 FFP units were issued to the neonatal intensive care unit over the peroid of 12 months.Of these, 21% FFP were issued because of active bleeding and 79% neonates received FFP prophylactically with the intention of preventing haemorrhage,generally in the setting of neonatal sepsis and necrotizing enterocolitis (NEC).The most common determining factor for FFP transfusion were an abnormal activated partial thromboplastin time or prothrombin time.Using the guidelines for FFP usage in neonatal setting,it was analysed that 60% of the 192 FFP transfusions were not compliant with the standard guidelines. Using linear regression analysis, abnormalities in the prothrombin time, activated partial thromboplastin time, were not independently associated with the hemorrhagic episodes.

Conclusions: FFP transfusions are frequently used in the NICU. In the present study, a remarkably high proportion of FFP transfusions were given to non-bleeding neonates for indications not compliant with guidelines for FFP usage in neonates. Coagulation studies e.g prothrombin time and activated partial thromboplastin time were poor predictors of clinical bleeding.

PB 1035 | Intermittent Intravenous Deferoxamine for the Treatment of Transfusional Iron Overload

M. Varma

Mount Sinai St. Luke's-Roosevelt, New York, United States

Background: Transfusional iron overload (TIO) is associated with reduced survival in thalassemia and in myelodysplasia. Deferoxamine (DFO), an iron chelator, improves survival in thalassemia and TIO. It is administered as a continuous subcutaneous or intravenous infusion over 8-12 hours, 5-7 days per week. Compliance is poor (59-78%). Deferasirox is an oral iron chelator. Gastrointestinal toxicities arise in 15% of patients. Effect on survival has not been studied. We have treated seven patients with TIO, who were poorly responsive to, had contraindications to, had toxicities with, or declined continuous subcutaneous DFO and/or deferasirox, with intermittent intravenous DFO (IID).

Aims: To determine in this cohort:

1. If IID led to a significant reduction in serum ferritin concentration
2. The percentage of patients who achieved serum ferritin < 1000 ng/mL, the goal of chelation.

Methods: Institutional review board approval was obtained. The charts of this cohort followed between 07/01/03 and 12/31/15 were reviewed.

Results: Seven patients (2 thalassemia, 1 myelodysplasia, 1 aplastic anemia, 1 HIV hypoplasia, and 2 sickle cell anemia) were studied. Median age was 37 years, range 24-61 years; M:F ratio was 1:6. DFO dosing regimens ranged from 2 to 5 grams over 4 to 7 hours weekly to monthly. Median duration of therapy was 61 weeks, range 17-213 weeks. Median pre-treatment ferritin was 2364.4 ng/mL, range 1106-3299.5 ng/mL. Median post-treatment ferritin was 1435.2 ng/mL, range 803.7-2012.5 ng/mL. Paired student´s t-test showed a median reduction in ferritin of 715 ng/mL, range 181-1736 ng/mL, p=0.009. The patients with thalassemia received higher maximal doses (4.5 to 5 grams over 7 hours weekly) than did those with other disorders (2 to 3 grams over 4 hours weekly). Two patients (1 myelodysplasia, 1 sickle cell anemia) achieved ferritin < 1000 ng/mL.

Conclusions: IID in TIO is associated with a significant reduction in serum ferritin levels, and may decrease the ferritin to < 1000 ng/mL in non-thalassemic TIO.

PB 1036 | Reasons for Blood Donor Deferral among Voluntary Blood Donors in a Tertiary Care Hospital in Kathmandu, Nepal

B. Nepal, B. Gautam

Grande International Hospital, Deaprtment of Transfusion Service, Maijubahal, Nepal

Background: Ensuring the wellness of the voluntary blood donor is the main purpose of the donor deferral. It also minimizes the unwanted symptoms that may appear among blood donor recipient.

Aims: To find **Reasons For Blood Donor Deferral Among Voluntary Blood Donors In A Tertiary Care Hospital.**

Methods: This is the retrospective study carried out among voluntary blood donors at Grande International Hospital, a tertiary care hospital in Kathmandu, Nepal from January 2013 to January 2015.

Results: The data were collected from previous records of the blood donor history forms. From a total of 8,550 blood donations, 302(3.53%) blood donor were deferred due to various reasons. Among all the deferred blood donors 189(62.58%) were female where as 113(37.42%) were male. Furthermore, 289(95.69%) were temporarily deferred and 13(4.31%) were permanently deferred. The mean age of deferred blood donor was 35 years.

Out of total blood donor deferral; 101(33.48%) donor were rejected because of bed side hypertension

(i.e. blood pressure- systolic > 140 and diastolic >90 mm hg) which was followed by anaemia

(i.e. haemoglobin < 12 gm/dl) 94(31.12%), vaccinations history 43(14.23%), hypotension (i.e. Systolic < 90mm hg and diastolic < 60 mm hg) 35(11.58%), dental examination 10(3.32%) and medication history 6(1.98%). Permanent deferral namely, risk factor involving transfusion transmitted infections and chronic disease were 5(1.65%) and 8(2.64%) respectively. The prime cause of permanent deferral was risk factor involving transfusion transmitted infections while the temporary deferral was bed side hypertension. Gender wise, the leading cause of donor deferral in male was bed side hypertension and anaemia was the major cause in female.

Conclusions: The findings of the survey aid to evaluate the significant causes of blood donor deferral. This study suggests that the restrictive criteria can be used for blood donor selection. This will in turn increase the blood supply of tertiary care hospital.

PB 1037 | Haemovigilance Reports of Adverse Blood Donor Reaction among Voluntary Blood Donors in Tertiary Care Hospital in Kathmandu, Nepal

B. Nepal[1], B. Gautam[2]

[1]*Grande International Hospital, Deaprtment of Transfusion Service, Maijubahal, Nepal,* [2]*Grande International Hospital, Deaprtment of Transfusion Service, Kathmandu, Nepal*

Background: Voluntary blood donation is widely considered to be safe with very minimum chance of adverse reaction, which may occur during or after the end of phlebotomy procedure.

Aims: To access the **adverse Blood Donor Reaction Among Voluntary Blood Donors In Tertiary Care Hospital.**

Methods: This is a prospective study done among voluntary blood donors at Grande International Hospital, Kathmandu, Nepal from February 2013 to March 2015. The outlines of reported and communicated adverse donor reaction were also collected after the blood donation from voluntary blood donors in different locations including outdoor and in-house blood donation drive.

Results: In the present study 6,955 whole blood donors were included, during the period of 2 years, 105 (1.50%) adverse donor reactions were reported. Majority 89(84.76%) of adverse donor reactions were mild in nature such as, sweating; 27(25.72%), Light headedness; 19(18.09%), nausea and vomiting; 15(14.28), allergy and bruises;11(10.47%), sore arm; 9(8.58%) and hematoma; 8(7.62%) while 16 (15.24%) were severe adverse reactions similarly, anaphylaxis;11(10.49%), loss of consciousness; 3(2.85%) and convulsive syncope;2(1.90%). Markers of the adverse donor reaction were age, sex, pulse, weight, blood pressure and donation status. Age and first time status were related with significantly higher risk of adverse reaction with 18-23 years old at higher risk compared to 24-55 years old. First time donors were at higher risk compared to repeated volunteer donors.

Conclusions: The results of the study are helpful to identify and understand the complication of adverse donor reactions though the incidence of reactions in the blood donors is lower than in other studies. Donor age and donation status were strong possibilities of complications.

PB 1038 | Re-infusion of Heparinized Shed Blood in Aortic Surgery to Maintain Hemostatic Levels of Fibrinogen

M. Reyes[1], O. Preventza[2], C. Letheridge[3], J. Coselli[4], J. Anton[5], A. Bracey[1]

[1]Baylor College of Medicine, Pathology and Immunology, Houston, United States, [2]Baylor College of Medicine, Division of Cardiothoracic Surgery, Houston, United States, [3]CHI Baylor St. Luke's Medical Center, Perfusion/Thoracic Surgery, Houston, United States, [4]Baylor College of Medicine, Cardiothoracic Surgery, Houston, United States, [5]Baylor College of Medicine, Anesthesiology, Houston, United States

Background: Aortic surgery is associated with large volume blood loss. Blood salvage strategies primarily focus on red blood cell salvage and replacement withput plasma contributes to hemodilution. Fibrinogen is a critical procoagulant that must be maintained at adequate levels to preserve hemostasis.

Aims: We report early data on the impact of whole blood salvage and re-infusion in aortic surgery with a focus on impact to fibrinogen levels during whole blood salvage.

Methods: Patients (n - 9) undergoing thoraco-abdominal aortic aneurysm repair had heparinized salvaged blood collected and reinfused using a filtered cardiotomy reservoir and modular roller pump. Filtered blood was returned directly to a Belmont FMS rapid infuser with rate of return controlled by the anesthesiologist. Average volume of salvaged blood processed in this manner was 7600 ml (range 3155 ml - 13939 ml.) Fibrinogen concentration was measured by Clauss and viscoelastic methods at the following time points: pre-bypass, post-proximal anastamosis, post distal anastamosis, and post-bypass.

Results: Heparin used for bypass did not interfere with either fibrinogen assay. Fibrinogen concentration was preserved at adequate hemostatic levels in all but 1 patient. Early availability of data allowed treatment to restore adequate hemostatic activity at the post-CPB time point.

Conclusions: Salvage and re-infusion of heparinized shed blood during aortic surgery preserves hemostatic content despite large volume blood loss. Measurement of fibrinogen concentration early in the operative procedure allows for prompt restoration of fibrinogen to levels critical for hemostasis.

PB 1039 | Use of Molecular Biology to Reveal the Mechanism of Non-hemolytic Febrile Transfusion Reaction to Enhance the Transfusion Safety

D.-P. Chen[1,2], Y.-H. Wen[1], C.-P. Tseng[2]

[1]Chang Gung Memorial Hospital, Laboratory Medicine, Taoyuan, Taiwan, Republic of China, [2]Chang Gung University, Taoyuan, Taiwan, Republic of China

Background: Blood transfusion reactions occur frequently even after performing complete pre-transfusion tests. Among these reactions, febrile non-hemolytic transfusion reaction (FNHTR) is the most common type of reaction. Leukocyte-poor blood (LPR) can reduce the number of FNHTR, but FNHTR still occur in certain patients who are transfused with leukocyte-poor blood (LPR).

Aims: Hence, we proposed that the human platelet antigen (HPA), in particular HPA-3, is a potential membrane antigen that plays a role in ineffective transfusion in addition to the human leukocyte antigen (HLA) and human neutrophil antigen (HNA). In this study, we investigated whether the difference of HPA-3 genotype between the donors and recipients of blood transfusion contributes to the occurrence of FNHTR.

Methods: A total of 87 transfused LPR patients with (n=43) or without (n=44) FNHTR were collected to determine the HPA-3 gene genotype of the donors and recipients by PCR using sequence-specific primers.

Results: Our data indicated that the HPA-3 genotype was different between donors and recipients in 80.0% and 52.3% of the transfused patients with and without FNHTR, respectively (P=0.0412). The donors with heterozygous HPA-3a/3b genotype caused FNHTR more frequently than the donors with homozygous HPA-3a/3a or HPA-3b/3b genotype ($\chi 2$ = 7.86, P-value = 0.0197).

Conclusions: In conclusion, HPA-3 is a contributing factor for the occurrence of FNHTR after blood transfusion. Avoiding the use of blood from the donor with heterozygous HPA-3a/3b genotype is likely to enhance the safety of transfusion in the clinical setting.

PB 1041 | Pseudomyxoma Peritonei Surgery: Potential for Predicting Fibrinogen Use using Thromboelastometry

C. Rea[1], S. Stanford[1], J. Needham[1], A. Roy[2], N. Sargant[2], S. Rangarajan[1]

[1]Hampshire Hospitals NHS Foundation Trust, Haemophilia Haemostasis and Thrombosis Centre, Basingstoke, United Kingdom, [2]Hampshire Hospitals NHS Foundation Trust, Haematology Department, Basingstoke, United Kingdom

Background: Pseudomyxoma peritonei is a rare malignancy treated using peritonectomy and hyperthermic intra-peritoneal chemotherapy which is associated with bleeding characterised by low fibrinogen. A subgroup of patients who required extensive diathermy from an early stage in surgery due to bulk and distribution of disease have been noted to receive more fibrinogen replacement therapy.

Aims: This is a retrospective pilot study to:

1. Assess correlation of fibrinogen concentration between thromboelastometry using ROTEMâ Sigma A20 FIBTEM (clot firmness (mm) at 20 minutes post clot time), EXTEM CT (clot time from start of test to 2mm amplitude) and Clauss fibrinogen measurements.
2. Assess potential of thromboelastometry to characterise a subgroup of "high risk" bleeding patients.

Methods: Coagulation screens (Prothrombin Time (PT), Activated partial thromboplastin time (APTT), Clauss fibrinogen (FIB),) thromboelastometry (ROTEMâ Sigma analyser and reagent cartridges) were performed during surgery at multiple time points on 6 patients according to standard care.

Results: Study identified significant correlation between Clauss FIB and FIBTEM A20 results at 14 time points (r^2=0.90) using the

Mann-Whitney U test. FIBTEM A20 mean = 18.9mm (normal range 6 - 21) and Clauss FIB mean = 3.21 (normal range 1.6 - 4.2g/L).

With respect to extensive diathermy sub-group significantly lower FIBTEM A20 (p= 0.028) and Clauss FIB (=0.026) was detected. Mean volume of cryoprecipitate in the diathermy sub-group was 4 units versus 2 units for other patients.

Conclusions: Pilot study has demonstrated utility of FIBTEM A20 measurement in assessing fibrinogen status in patients as risk of developing hypofibrinogenaemia. There also appears to be a difference in the haemostatic profile for patients requiring early and extensive diathermy. Further investigation to identify patients at high risk of bleeding, underlying mechanisms and application of FIBTEM A20 measurement to optimize fibrinogen replacement therapy are planned.

PB 1042 | Comparison of Arterial and Venous Coagulation Parameters Measured with the QuantraTM System in Cardiac Surgery

F. Viola[1], D. Winegar[1], L. Fernandez[2], D. Groves[2], J. Huffmyer[2]

[1]HemoSonics LLC, Charlottesville, United States, [2]University of Virginia, Anesthesiology, Charlottesville, United States

Background: Coagulation testing is often performed in cardiac surgery and other major procedures to aid in the management of perioperative bleeding. Although reference ranges are obtained in venous samples, perioperative testing is often performed with arterial samples. Limited studies have been published on the effects of sampling site on coagulation testing.

Aims: To compare coagulation parameters determined by the Quantra System (HemoSonics LLC) for venous and arterial blood samples.

Methods: The Quantra is a novel cartridge-based viscoelastic analyzer that measures changes in clot stiffness during coagulation using ultrasound detection of resonance. A cohort of 25 patients undergoing cardiopulmonary bypass surgery were enrolled in this study. For each patient, arterial and venous samples were obtained in citrated tubes in close temporal sequence. Sampling was randomized at two of the following three time points: baseline, during bypass, or after protamine administration. Measurements were performed on a research use only (RUO) version of the Quantra and included Clot Time (CT), Heparinase Clot Time (CTH), Clot Stiffness (CS), Fibrinogen (FCS) and Platelet (PCS) Contributions to clot stiffness.

Results: Paired t-tests were performed on matched arterial vs venous samples. Data is summarized in Table I. CS, FCS and PCS were similar between arterial and venous samples. CT and CTH demonstrated a statistically significant difference. Venous clot times were prolonged relative to the arterial ones with an average bias of 0.24 min and 0.21 min, respectively.

Conclusions: This pilot study demonstrates that Quantra clot stiffness based parameters (CS, FCS, PCS) are unaffected by sampling site, whereas the clot time based parameters (CT and CTH) show good correlation in the presence of a small bias.

TABLE I

Output Parameter	Arterial (mean +/-1 SD)	Venous (mean +/-1 SD)	P-value
Clot Stiffness (CS)	19.9±9.2 hPa	20.2±9.7 hPa	P = 0.32
Fibrinogen Contribution (FCS)	2.94±2.4 hPa	2.87±2.14 hPa	P = 0.29
Platelet Contribution (PCS)	17.48±7.25 hPa	17.71±7.97 hPa	P = 0.43
Clot Time (CT)	2.11±0.64 min	2.35±0.49 min	P < 0.001*
Heparinase Clot Time (CTH)	2.15±0.41 min	2.36±0.31 min	P < 0.001*

PB 1043 | The Quantra Surgical Cartridge: A Novel Assay for the Rapid Assessment of Coagulation Function from Whole Blood

F. Viola, C. Lloyd, T. Higgins, A. Homyk, D. Bryant, T. Givens, P. Braun

HemoSonics LLC, Charlottesville, United States

Background: Previous studies have shown the benefit of rapid information to guide treatment of excessive bleeding, including targeted transfusion and better outcomes. The Quantra™ Hemostatic Analyzer (HemoSonics LLC) is a novel cartridge-based viscoelastic analyzer designed for rapid and comprehensive assessment of coagulation at the point-of-care (POC).

Aims: To introduce a novel and patented cartridge design for fully automated, rapid, and comprehensive measurements of the coagulation system to aid in the management of patient bleeding at the POC.

Methods: The Surgical Cartridge, shown in Figure 1 along with its output parameters, is a multi-channel consumable containing lyophilized reagents. The cartridge includes an interface for evacuated tubes so that no sample handling procedures are required. Cartridge performance was assessed using contrived samples that were spiked with heparin or with varying concentration of fibrinogen or platelets. Sample analysis was performed in a Research Use Only version of the Quantra by measuring changes in clot stiffness during coagulation using ultrasound detection of resonance.

Results: Clot Time (CT) demonstrated a linear response to heparin in the range 0-1U/ml, whereas Heparinase Clot Time (CTH) neutralized heparin up to 6U/ml. Fibrinogen Contribution (FCS) increased 23X over the range 90-1100mg/dl of fibrinogen, showing strong correlation with Clauss fibrinogen (r^2=0.94) and ROTEM FIBTEM (r^2=0.97). Clot Stiffness (CS) varied linearly (3X increase) over platelet count from 130-450K/ul. We also demonstrate that the reagents are stable at room temperature for over 6 months and that complete results are reported within 15 minutes of test initiation.

Conclusions: The Quantra Surgical Cartridge provides quantitative measures of coagulation function within 15 minutes. The cartridge was designed for automation, rapid results, and stability at room temperature to satisfy critical care requirements.

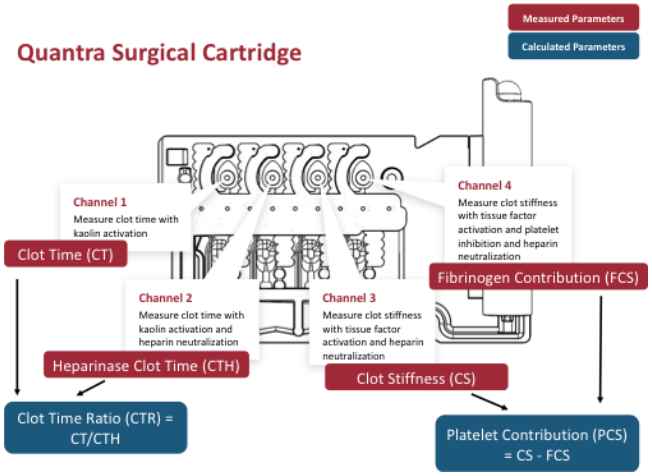

FIGURE 1 Schematic representation of Quantra Surgical Cartridge

PB 1044 | Five Years of Hemovigilance Reports of Complications of the Blood Donation Reported at a Tertiary Care Centre in Karachi

B. Nepal

Dow University of Health Sciences, Deaprtment of Transfusion Service, Karachi, Pakistan

Background: There is a minor chance of risk among blood donors. Even though blood donors are usually screened for the presence of risk factors, sometimes blood donations can put a person at panic.

Aims: The safety of the blood supply depends on the actions to protect both; blood transfusion recipient and the blood donor. Hemovigilance practice of learning of complications of blood donation and protecting them from such complications is the best way to minimize the risk to blood donor.

Methods: Comprehensive blood donor hemovigilance program was studied at Dr. Ishratul Ebad Khan Institute of blood diseases, Karachi from 2010 to 2015. Outlines of reported and communicated complications were collected after whole blood donation. Analysis was done by general logistic regression.

Results: Complications after 30,000 Whole blood donation procedures calculated1620total .(54 per 1,000 donations). The majority of the complications were faint and pre-faint reaction with light headedness (58.6 %), Sore arm (24 %), Bruises and hematoma (14.4 %). Minor complications were Agitation/sweating (2 %) and arterial puncture(1 %). Markers of the complications were age, sex, race, weight, blood pressure and donation status. All associated independently after whole blood donation. Age and first-time status were associated with a significantly higher risk of complications with 18-22 years old at higher risk compared to 23 to 50 years old. First-time donor were at higher risk compared to repeat donor.

Conclusions: The results of this study are helpful in identifying and understanding the promoter to complication of blood donation. Donor age and status were strong predictors of complications. The remedies and specific areas of care should be provided.

PB 1046 | Performance Evaluation of the Quantra Surgical Cartridge for Rapid Point-of-Care (POC) Assessment of Coagulation Function

P. Braun, C. Wang, V. Sekaran, M. Koren, C. Lloyd, F. Viola

Hemosonics LLC, Durham, United States

Background: The Quantra™ Hemostasis Analyzer and Quantra Surgical Cartridge (HemoSonics LLC) are components of a compact POC system for rapid measurement of key coagulation parameters. The system uses ultrasound to detect changes in clot stiffness for four separate assays tested in a single disposable cartridge using citrated whole blood. The four assays measure

1) kaolin clot time;

2) kaolin clot with added heparinase (to detect heparin);

3) overall clot stiffness from platelets and fibrinogen combined; and

4) clot stiffness from fibrinogen only.

Aims: Evaluate analytical performance of the Quantra Surgical Cartridge.

Methods: The Quantra Surgical Cartridge (Research Use Only version) was evaluated for precision, sample stability and sensitivity to therapeutic agents.

Results: ≤ Precision for normal whole blood samples, including variation due to instrument and cartridge lots, showed coefficients of variation (CV) of 3-6%. Precision for samples treated with 0.6 U/mL added heparin, samples containing 100-700 mg/dL fibrinogen and other abnormal samples gave CV=3-11%, except for samples with very low fibrinogen (≤ 100 mg/dL) where estimated precision was based on standard deviation. Within-device precision for quality control results was 4-11% CV. Between-lot and between-instrument variability based on QC controls were estimated as 1-4% CV. Samples were stable for ±4 hours at ambient temperature. Anticoagulants such as dabigatran and rivaroxaban prolonged kaolin clot time in presence and absence of heparinase. Heparin prolonged clot time, but prolongation was reversed by heparinase. Aspirin and tranexamic acid had little or no effect on results.

Conclusions: Results demonstrate the Quantra Surgical Cartridge provides precise assessment of four key coagulation functions with processing time of 15 min, requiring minimal operator intervention. The Quantra design is targeted to surgical settings, critical care, or other applications requiring compact size, speed and simple operation.

PB 1047 | ABO Discrepancies and Errors in a Routine Blood Bank

B. Nepal

Dow University of Health Sciences, Deaprtment of Transfusion Service, Karachi, Pakistan

Background: ABO discrepancy exist when red cell antigen grouping result do not correlate with serum grouping result.

Aims: To identify the incidence and type of ABO discrepancies and errors leading to wrong results.

Methods: All the data of ABO grouping from June 2012 till June 2013 was collected at Ishrat ul Ebad Khan institute of blood disease, Dow university of health sciences,Karachi,Pakistan.

ABO discrepancies, pre-analytical, analytical & post-analytical errors in routine blood grouping were noted and recorded on a Performa designed for the study and results were tabulated.

Results: 30 discrepancies (0.3 %), 18 (0.18 %) pre & post analytical errors were identified from a total of 10,000 blood group tests performed during the study period. The commonest of all was ABO discrepancy due to sub groups n 26 (86.6 %) followed by auto-antibodies n 4 (13.3 %).

Conclusions: ABO discrepancy is not an infrequent finding in routine blood banking while pre-analytical, analytical & post-analytical errors are also seen in routine practice and are small but very important source of mistakes which can lead to serious hazards of transfusion. Measures should be taken to identify and resolve these discrepancies while ensuring proper collection, labeling, analysis and reporting of results for safe blood transfusion.

PB 1048 | Is the Thrombin Generation Test, a Useful Research Tool, Suitable to Characterize Therapeutic Plasmas?

C. Ravanat[1], A. Dupuis[1], N. Marpaux[2], C. Naegelen[2], G. Mourey[2], H. Isola[1], M. Laforêt[1], P. Morel[2], C. Gachet[1]

[1]Université de Strasbourg, INSERM, EFS Grand Est, BPPS UMR-S 949, FMTS, Strasbourg, France, [2]Etablissement Français du Sang (EFS) Bourgogne-Franche Comté, Besançon, France

Background: The regulatory hemostatic assays required to validate therapeutic plasmas probe their FVIII activity and fibrinogen concentration but not their overall hemostatic capacity. Current coagulation assays measure only the time necessary to generate the first traces of thrombin, whereas the majority of thrombin is produced in the heart of the clot. In contrast, the thrombin generation test (TGT), which investigates the total thrombin concentration using a fluorescent substrate, is a global test of plasma coagulability integrating the entire sequence of the hemostatic process. The TGT is rarely employed in routine practice, although it is useful to detect hemophilia (deficiency in FVIII or FIX) and monitor its treatment.

Aims: The aim of this study was to determine the suitability of the TGT to assess the global hemostatic quality of therapeutic plasma derived from whole blood (WB) after pathogen inactivation and freezing.

Methods: The TGT was performed on 40 plasma units inactivated with Intercept (Cerus) and frozen within 19 h of collection. The tests were conducted 2 weeks and 6 and 12 months after Intercept treatment. Coagulation was triggered with $CaCl_2$, phospholipids and different concentrations of tissue factor (TF).

Results: The thrombin generation capacity of WB derived plasma was not markedly impaired following photochemical treatment, even in the presence of suboptimal concentrations of TF, despite a moderate decrease (30%) in FVIII. Moreover, the hemostatic properties of plasma were not degraded by storage at -25°C.

Conclusions: The TGT could represent a surrogate or additional assay to investigate the hemostatic quality of therapeutic plasma preparations. Its results enable evaluation of the impact of the different steps of plasma preparation on the hemostatic efficiency. Nevertheless, standardized inter-laboratory protocols, with normalization of the results and well defined reference values, remain to be established to ensure widespread application of the TGT in the field of therapeutic plasma.

PB 1049 | Viral Inactivation and Enrichment of Factor VIII, Factor XIII, Fibrinogen and von Willebrand Factor (VWF) Multimers from Fresh Frozen Plasma (FFP)using, "VIPS Plasma, Virus Inactivation Treatment System"

B. Nepal

Dow University of Health Sciences, Deaprtment of Transfusion Service, Karachi, Pakistan

Background: Human blood is the source of a wide range of medicinal products used for the prevention and treatment of a variety

TABLE 1 Effect of Intercept treatment and storage on thrombin generation using tissue factor at 20 pM or 1 pM (N=40)

		Average ± Standard Deviation (N=40)				Normal range (N=30)
	TF(pM)	T1	T2	T3	T4	
Lag time (min)	20	1.43 ± 0.27	1.39 ± 0.21[a]	1.43 ± 0.23	1.46 ± 0.26	1.32 - 2.33
Lag time (min)	1	4.82 ± 0.56	4.69 ± 0.60[a]	4.79 ± 0.63	4.79 ± 0.59	3.77 - 6.78

ETP - thrombin generated (nM x min)	1	1,543.6 ± 117.1	1,527.8 ± 122.8	1,557.0 ± 182.7	1,509.5 ± 118.6[c]	1170 - 2182

T1: reference value in pooled plasma before treatment - T2: after treatment and 2 weeks of frozen storage - T3: after 6 months - T4: after 12 months - Two-sided paired t-Test (alpha 0.05) a, b or c indicate a significant difference ($p<0.05$) when comparing respectively T2-T1, T3-T1 or T4-T1

of life-threatening injuries and diseases. Despite measures such as donor selection, testing of donations and of plasma pools, the transmission of blood-borne viruses by plasma and purified plasma products is at risk

Aims: To assess viral inactivation and, Factor VIII, Factor XIII, Fibrinogen and von Willebrand factor (VWF) multimers enrichment capacity of, "VIPS Plasma, Virus Inactivation Treatment System".

Methods: VIPS Plasma, Virus Inactivation Treatment System" comprise of interconnected bag system where the S/D reagents are removed by filtration and the final products subjected to bacterial (0·2 µm) filtration. Cryoprecipitate mini-pools (400 ± 20 mL) were subjected to double-stage S/D viral inactivation, followed by one oil extraction and a filtration on a S/D and phthalate [di(2-ethylhexyl) phthalate (DEHP)] adsorption device and a 0·2 µm filter. The initial and the final products were compared for visual appearance, blood cell count, factor VIII, Factor XIII, Fibrinogen and Von Willebrand factor (VWF) multimers. Initial and final products were also checked for HIV, HBV, HCV, dengue, malaria and bacterial contaminations.

Results: Our analysis showed that the treated cryoprecipitate were very clear, with negative blood count and the protein content of factor VIII, Factor XIII, Fibrinogen and von Willebrand factor (VWF) multimers were well conserved (Table 1)

TABLE 1 (Test performed at Aga Khan Labs)

Sr.No	Factor	Start%	Final%
1.	Von Willebrand factor	418%	435%
2.	Factor VIII	183%	251%
3.	Fibrinogen Level	754.1mg/dl	672 mg/dl
4.	Factor XIII (quantative)	93.9%	----

Kit ensured bacterial sterility (Table 3)

TABLE 2 (Molecular Biology: Performed at Molecular lab,DDRRL)

Sr. No	Test(By PCR)	Pre-analyasis	Post-analysia
1.	Hepatitis B Virus	Negative	Negative
2.	Hepatitis C Virus	Negative	Negative
3.	HIV Virus	Negative	Negative

TABLE 3 (Microbiology: Performed at Microbiology Lab, DDRRL)

Sr. No	Test	Pre-analysis Results	Post-analysis Results

3.	Dengue IgG (ICT)	Positive	Positive
4.	Bacterial Culture	Staph. Species Coagulase negative	No Growth

and most importantly, final product was free of HBV, HCV and HIV (Table 2).

Conclusions: further investigation is needed to characterize functional activity of the enrich component. Irrespective of that the process may offer one additional option to blood establishments for the production of virally inactivated plasma components especially in low income countries.

PB 1050 | Prolonged Platelet Storage Associated with Increased Incidence of Platelet Transfusion Adverse Events

J. Chen[1], L. Blower[1], D. Hamed[1], S. Yang[1], S. Cataland[2]

[1]*Ohio State University Wexner Medical Center, Pathology, Columbus, United States,* [2]*Ohio State University Wexner Medical Center, Hematology, Columbus, United States*

Background: Platelet (PLT) transfusion is associated with a higher incidence of adverse evens (AEs) than any other blood product. Most of PLT associated AEs are inflammatory responses. Multiple factors have been investigated for their roles in inducing PLT associated AEs. However, clinical data supporting PLT storage lesion has been largely lacking especially in the era of universal prestorage leukoreduction. Actually, recent studies failed to show the association between PLT age and PLT associated AEs.

Aims: To better understand whether prolonged storage causes PLT related AEs.

Methods: In this retrospective study, 48,212 PLT products including about 80% apheresis PLT units and 20% pooled whole blood derived (WBD) PLTs were transfused to 8726 patients with a median age of 58 years old and 1.4 to 1 male to female ratio from July 2011 to September 2016. All the PLTs were leukoreduced prior to storage. A total of 241 AEs were reported in 229 patients, 96% of whom had advanced cancer, sepsis or cirrhosis. This study was approved by the institutional review board at The Ohio State University.

Results: There was a significant increase in the incidence of transfusion related AEs with the prolongation of PLT storage ($p < 0.001$). (Fig 1) The oldest PLTs (day 5) associated with a higher incidence in most of the symptoms/signs, except for itching, hives, and rash. (Fig 2)

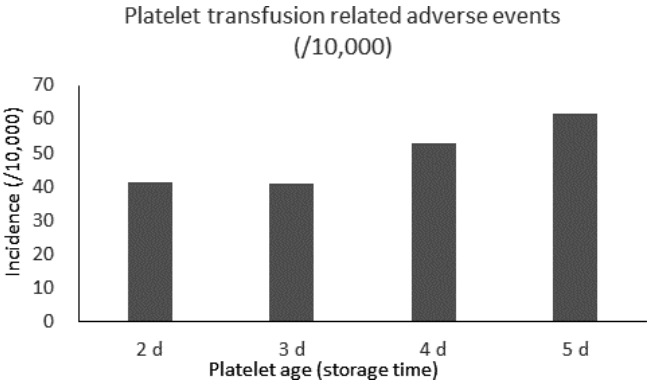

FIGURE 1 Prolonged platelet storage time associated with more transfusion related adverse events

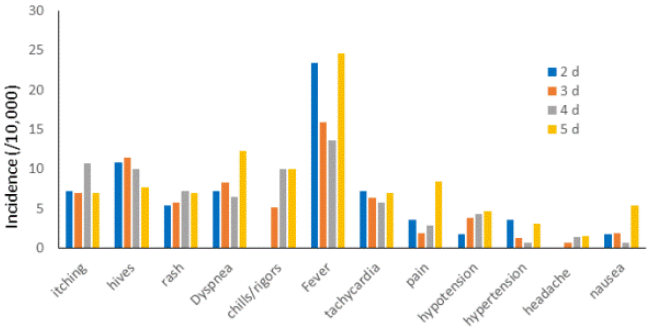

FIGURE 2 Symptoms and signs in platelet transfusion associated adverse events]

The strongest association with PLT age was seen in rigors/chills and dyspnea. Moreover, the incidences of apheresis PLT associated AEs (64.5/10,000) were significantly higher than that of pooled WBD PLTs (23.1/10,000) ($p < 0.001$).

Conclusions: Prolonged PLT storage associated with an increased incidence of transfusion AEs. Symptoms with a clear inflammation etiology had the strongest association with PLT age. Symptoms that did not appear to be associated with PLT age might be related to recipient's unstable vital signs or allergic reactions. Apheresis PLT caused more AEs than WBD platelets.

VASCULAR BIOLOGY & ANGIOGENESIS

PB 1605 | Role of the Extracellular Matrix Protein Biglycan for Platelet Adhesion and Thrombus Formation

N. Maurus[1], H. Hörmann[1], J.W. Fischer[2], M. Elvers[1]

[1]*University Clinic Düsseldorf, Research Group Molecular Hemostasis, Düsseldorf, Germany,* [2]*University Clinic Düsseldorf, Institute of Pharmacology and Clinical Pharmacology, Düsseldorf, Germany*

Background: Biglycan (BGN) is part of the small leucine-rich proteoglycans and modulates collagen fibrils to increase the stability of the collagen network. After myocardial infarction BGN is needed for tissue remodeling and deficiency of BGN leads to an increased amount of aortic aneurysms.

Aims: The aim of this project is to determine the role of BGN as an ECM protein of the vessel wall in platelet adhesion and thrombus formation.

Methods: *In vitro* and *in vivo* analysis of BGN deficient platelets and mice.

Results: ELISA and qRT-PCR data provided strong evidence that platelets are not a source of BGN. Moreover, the addition of soluble recombinant biglycan was not sufficient to activate platelets. However, we observed increased platelet adhesion under static conditions as well as increased thrombus formation on a collagen-biglycan matrix compared to collagen alone under flow *ex vivo*. In line with these results we found reduced platelet adhesion at the ligated carotid artery in *bgn*$^{-/0}$ mice *in vivo*. Furthermore *bgn*$^{-/0}$ mice displayed significantly prolonged tail bleeding times and significantly prolonged occlusion times of the carotid artery after $FeCl_3$-induced vessel injury. Accordingly, the analysis of bone marrow chimeric mice showed that loss of biglycan in the vessel wall is responsible for prolonged bleeding times, reduced platelet adhesion and prolonged occlusion times after injury of the carotid artery. Mechanistically, reduced platelet adhesion to immobilized recombinant biglycan after inhibition of the collagen receptor glycoprotein (GP)VI suggests that GPVI might serve as a receptor for biglycan.

Conclusions: This study reveals an important role of the extracellular matrix protein biglycan for platelet adhesion and thrombus formation in hemostasis and thrombosis.

PB 1606 | Platelet Inhibition Augments Rupture-induced Death in a Mouse Model of Abdominal Aortic Aneurysm

K. Saum[1], N. Robbins[1], S. Jones[1], W. Bergmeier[2], A. Wanhainen[3], N. Mackman[2], P. Owens[1]

[1]*University of Cincinnati, Internal Medicine, Cincinnati, United States,* [2]*University of North Carolina at Chapel Hill, Medicine, Chapel Hill, United States,* [3]*Uppsala University, Vascular Surgery, Uppsala, Sweden*

Background: Platelets are critical in both maintaining hemostasis and propagating thrombosis. While platelets and platelet-specific cytokines are elevated in patients with abdominal aortic aneurysm (AAA), their role in the pathogenesis of aneurysm disease remains unclear.

Aims: The purpose of this study was to determine the effects of platelet inhibition or depletion in a mouse model of angiotensin II (AngII)-induced AAA.

Methods: Accumulation of platelets and platelet-derived cytokines were quantified in low-density lipoprotein deficient (*Ldlr*$^{-/-}$) mice fed a high fat and cholesterol diet (HFD) and infused with AngII (1,000 ng/kg/min) through 28 days. The effect of a genetic deficiency of platelet receptors (protease-activated receptor 4 and $P2Y_{12}$), anti-platelet therapies (clopidogrel or aspirin), thrombin inhibition (dabigatran) and platelet depletion (anti-CD42b antibody, compared to an irrelevant IgG control) were examined in *Ldlr*$^{-/-}$ mice fed a HFD and infused with AngII for 28 days.

Results: Platelets accumulated in the abdominal aorta prior to macrophages with the platelet-derived cytokine platelet factor 4 (PF4) highly correlated to increasing abdominal diameter ($R^2 = 0.914$, $P < 0.001$). PF4 was increased in human AAA patients (n = 169) versus age and gender matched healthy controls (n = 115; $P < 0.0001$) and highly correlated with both abdominal diameter and AAA growth rate. Infusion of AngII into mice with genetic deficiency of platelet receptors or mice given anti-platelet therapies resulted in no difference in abdominal aortic diameter but augmented rupture-induced death versus littermate and placebo controls, respectively ($P < 0.01$). Platelet depleted mice died of rupture-induced death by day 12 of infusion ($P < 0.001$) in *Ldlr*$^{-/-}$, apolipoprotein E deficient, and *C57BL/6J* mouse strains infused with AngII.

Conclusions: Platelets are the first cell to accumulate in the abdominal aorta during AAA formation. Inhibition of platelet function may be detrimental in the early stages of an expanding aortic lumen.

PB 1607 | Protein Disulfide Isomerase Is Regulated by S-nitrosylation: Implications for Vascular Quiescence and Thrombus Formation

R.H. Bekendam[1,2], D. Iyu[2], F. Passam[3], K. Deceunynck[2], C. Garnier[2], L. Crescence[1], L. Panicot-Dubois[1], R. Flaumenhaft[2], C. Dubois[1]

[1]Aix-Marseille Université, INSERM UMR-S1076, Vascular Research Center of Marseille (VRCM), Marseille, France, [2]Beth Israel Deaconess Medical Center, Harvard Medical School, Division of Hemostasis and Thrombosis, Boston, United States, [3]St George Clinical School, St George Hospital, University of New South Wales, Kogarah, Australia

Background: Protein disulfide isomerase (PDI) serves an essential role in thrombus formation and PDI inhibition is being evaluated clinically as a strategy for anticoagulation management. Yet little is known about endogenous regulation of PDI in the vasculature.
Aims: To assess the effect of S-nitrosylation on the role of PDI and other thiol isomerases in the vasculature.
Methods: Platelets and endothelial cells were assessed for endogenous PDI S-nitrosylation. The effect of S-nitrosylated PDI on platelet aggregation, granule release and thrombus formation was determined.
Results: Thiols within the catalytic CGHC motif of PDI perform disulfide shuffling that is essential for its role in thrombosis. These same thiols bind nitric oxide (NO), forming S-nitrosylated PDI. We have evaluated the effect of NO on PDI function in endothelial cells and platelets. Incubation of endothelium with NO donors resulted in S-nitrosylated PDI and inhibition of its function. Elevation of endogenous NO levels by induction of endothelial NO synthase also resulted in increased S-nitrosylated PDI and decreased thiol isomerase activity at the endothelial cell surface. Inhibition of PDI by NO blocked LPS-induced thrombin generation on endothelium, which we show to be PDI-dependent. Platelet PDI is also S-nitrosylated and S-nitrosylation inhibits the reductase activity of PDI on platelets. Furthermore, PDI mediates the transfer of NO into platelets. S-nitrosylated PDI inhibited both platelet aggregation and granule release. Inhibition of PDI or exposure to NO also inhibited thrombin generation on platelets. Using a model of laser-induced vascular injury, infusion of S-nitrosylated PDI into mice blocks both platelet accumulation and fibrin formation at sites of vascular injury.
Conclusions: These studies identify NO as a critical regulator of vascular PDI, demonstrating that NO converts prothrombotic PDI into antithrombotic S-nitrosylated PDI. Thus, regulation of PDI functions as a new mechanism by which NO maintains vascular quiescence.

PB 1608 | Ultra-sensitive Molecular Magnetic Resonance Imaging of Blood Cells - Endothelium Interactions *In vivo*

M. Gauberti[1,2], A. Fournier[1], S. Martinez de Lizarrondo[1], D. Vivien[1,3], F. Docagne[1]

[1]INSERM UMR-S U1237, Caen, France, [2]Caen University Hospital, Department of Diagnostic Imaging and Interventional Radiology, Caen, France, [3]Caen University Hospital, Department of Cell Biology, Caen, France

Background: Endothelial activation is a key pathophysiological mechanism in a number of diseases, acting either as a cause or a consequence of organ injury. After activation, endothelial expression of adhesion molecule leads to leucocytes adhesion and subsequent diapedesis. In vivo imaging of these interactions may have significant diagnostic applications.
Aims: To develop a molecular imaging tool to detect endothelial activation in vivo, in a noninvasive manner.
Methods: Magnetic resonance imaging (MRI) enhanced by new formulations of microparticles of iron oxide (MPIO) targeted to activated endothelial cells either in the brain, kidney, heart or intestines in mice.
Results: Thanks to the use of micron-sized superparamagnetic particles targeted to activated endothelial cells and the optimizations performed, we were able to develop a new generation of contrast agent with very high sensitivity. Using MPIOs targeted to VCAM-1, P-Selectin or MAdCAM-1, we were able to detect endothelial activation at its early and late stages in clinically relevant contexts in mice. For instance, we detected cerebral transient ischemic attack using P-selectin targeted MPIOs in a noninvasive manner, a notoriously difficult diagnosis using currently available methods. Moreover, we detected intestinal inflammation in models of colitis and intestinal ischemia-reperfusion injury using MAdCAM-1 targeted MPIOs. If successfully translated to clinical use, this method could be used instead of colonoscopy for the diagnosis of these intestinal disorders.
Conclusions: This new platform of contrast agent for magnetic resonance imaging allows ultra-sensitive detection of the molecular effectors of blood cells - endothelium activation, which could have numerous applications for medical diagnostic.

PB 1609 | Contribution of the P2X1 Receptor Expressed by Lung Macrophages to Experimental TRALI

M.-B. El Mdawar, B. Maître, S. Magnenat, C. Gachet, B. Hechler, H. de la Salle

Université de Strasbourg, INSERM, EFS Grand Est, BPPS UMR-S 949, FMTS, Strasbourg, France

Background: Transfusion Related Acute Lung Injury (TRALI) is a non-cardiogenic pulmonary edema that may occur within 6 h after blood transfusion. Most often, this syndrome results from the presence of anti-HLA or anti-neutrophil allogeneic antibodies (Ab) in donor's

blood. We have shown previously that NF449, an antagonist of the ATP-gated $P2X_1$ receptor, markedly reduced mortality at 2 h in experimental immunological TRALI in mice.

Aims: Our objective is to investigate which cell type expressing $P2X_1$, i.e. platelets, neutrophils and monocytes/macrophages, is responsible for TRALI.

Methods: To induce TRALI, Balb/c mice were primed with lipopolysaccharides (0.1 mg/kg) 24 h before the injection of a cognate anti-MHC-I Ab (0.5 mg/kg). TRALI was assessed by the i) protein content in bronchoalveolar liquid, ii) partial pressure of oxygen in arterial blood, iii) histology. The role of the $P2X_1$ receptor was evaluated using its antagonist NF449 (10 mg/kg) administered intravenously before LPS and before anti-MHC-I Ab injection.

Results: Within the first 10 min following the injection of anti-MHC-I Ab, the severity of lung edema and the drop in aortic blood oxygenation were profoundly inhibited in mice treated with NF449. Since platelets are dispensable for TRALI, the role of neutrophils or inflammatory monocytes was evaluated by specific depletion with an anti-Ly6G mAb or an anti-CCR2 mAb, respectively. Both depletions did not inhibit TRALI, indicating that neither $P2X_1$ expressed by neutrophils nor by these monocytes is crucial for TRALI. In contrast, depletion of monocytes/macrophages by injection of clodronate liposomes, 6 h before anti-MHC-I Ab, abolished TRALI. This treatment led to the elimination of 50% of interstitial macrophages and dendritic cells in the lungs and most of Kupffer cells as shown by flow cytometry analysis or histology.

Conclusions: Macrophages play an important role in immunological TRALI which could be driven by $P2X_1$ receptor activation.

PB 1610 | The Role of von Willebrand Factor in Experimental Malaria-associated Acute Respiratory Distress Syndrome

S. Kraisin[1], S. Verhenne[1], T. Pham[2], N. Vandeputte[1], H. Deckmyn[1], K. Vanhoorelbeke[1], P.E. Van den Steen[2], S.F. De Meyer[1]

[1]*Laboratory for Thrombosis Research, KU Leuven Campus Kulak Kortrijk, Kortrijk, Belgium,* [2]*Laboratory of Immunobiology, Rega Institute for Medical Research, KU Leuven, Leuven, Belgium*

Background: Malaria is a global health burden resulting in 429,000 deaths in 2015. Recent clinical studies have demonstrated that severe malaria is associated with acute endothelial cell activation, accumulation of highly active von Willebrand factor (VWF) multimers, and a significant reduction in ADAMTS13 activity.

Aims: To investigate the role of VWF in malaria using a murine model of malaria-associated acute respiratory distress syndrome.

Methods: Wild-type (WT) and VWF knock out ($Vwf^{-/-}$) mice on a C57BL/6J background were inoculated with 10^4*Plasmodiumberghei* (*Pb*) NK65-infected erythrocytes. Blood samples were taken to assess platelet count as well as levels and activities of VWF and ADAMTS13. Giemsa-stained blood smears were made to determine parasitemia. Pulmonary edema was assessed by measuring protein levels in bronchoalveolar lavage fluid.

Results: Plasma VWF levels in infected WT mice significantly increased 3 days after infection (2-fold increase; p< 0.0001), but normalized afterwards. No change in VWF multimer patterns was observed until the end stage (day 8/9) at which high molecular weight VWF multimers were markedly decreased (p< 0.0001). This was accompanied by a reduction of the ADAMTS13 activity/antigen ratio (p< 0.0001). Interestingly, severe thrombocytopenia was observed in both WT and $Vwf^{-/-}$ mice, indicating a VWF-independent mechanism. $Vwf^{-/-}$ mice died more rapidly with higher parasitemia compared to WT (p=0.003). Alveolar leakage in lungs was significantly lower in $Vwf^{-/-}$ mice ($Vwf^{-/-}$: 1.8±0.4, WT: 3.6±0.5 mg/mL; p=0.02).

Conclusions: Our data demonstrate that *Pb*NK65-mediated murine malaria infection is associated with early elevated levels of plasma VWF, which is indicative for endothelial cell activation and in accordance with human malaria. Our findings also show that VWF does not contribute to malaria-associated thrombocytopenia. Furthermore, VWF might influence the development of parasitemia and lung pathology, potentially by interfering with the sequestration of infected erythrocytes.

PB 1611 | Blood Platelets Bind Aβ Peptides via Integrin αIIbβ3 and Induce Amyloid-β Aggregation in Cerebral Vessels

L. Donner[1], L. Gremer[2], G. Pagani[3], H. Gohlke[3], D. Willbold[2], M. Elvers[1]

[1]*Research Group Molecular Hemostasis, University Clinic of the Heinrich-Heine-University, Düsseldorf, Germany,* [2]*Institute of Structural Biochemistry (ICS-6), Research Centre Jülich, Jülich, Germany,* [3]*Institute for Pharmaceutical and Medicinal Chemistry, Department of Mathematics and Natural Sciences, Heinrich-Heine-University, Düsseldorf, Germany*

Background: Cerebral amyloid angiopathy (CAA) is a critical factor in the pathogenesis of Alzheimer`s disease (AD). It is characterized by the deposition of the Aβ peptide, mainly Aβ40, in the walls of cerebral vessels, which induces the degeneration of vessels wall components, reduces cerebral blood flow and aggravates cognitive decline. Moreover, Aβ was shown to activate platelets and to enhance platelet aggregation. Activated platelets contribute to more than 90% circulating Aβ. Recently, we have shown that platelets modulate soluble Aβ peptides into fibrillar Aβ structures in platelet cell culture.

Aims: Investigation of the molecular mechanisms mediated by platelets in the development of CAA and its implication for the progression of AD.

Methods: Analysis of amyloid and platelet interaction.

Results: The binding of Aβ with its RHDS sequence (N-Terminal region) to platelet integrin αIIbβ3 induces outside-in signaling and the secretion of clusterin from platelets. Chaperon protein clusterin promotes the modulation of soluble Aβ40 peptides into fibrillar Aβ aggregates. We found that not only the N-terminal region but also the C-terminal region of Aβ is important for the aggregation of Aβ peptides and the induction of signaling pathways in platelets. Moreover, the antiplatelet therapy with Clopidogrel reduces vascular Aβ plaques in cerebral vessels of APP23

transgenic mice, which develop CAA. The effects of long-term platelet inhibition for the reduction of parenchymal plaques are currently on going.
Conclusions: The interaction of platelets with Aβ peptides directly contribute to Aβ plaque formation. Thus, AD patients may benefit from anti-platelet therapy.

PB 1612 | Platelet Extracellular Vesicles Induce a Proinflammatory Smooth Muscle Cell Phenotype

T. Vajen[1], B.J. Benedikter[2,3], A.C.A. Heinzmann[1], E.M. Vasina[1], Y. Henskens[4], M. Parsons[5], P.B. Maguire[5], F. Stassen[2], J.W.M. Heemskerk[1], L.J. Schurgers[1], R.R. Koenen[1,6]

[1]Maastricht University / Cardiovascular Research Institute Maastricht (CARIM), Biochemistry, Maastricht, The Netherlands, [2]Maastricht University School of Nutrition and Translational Research in Metabolism (NUTRIM), Medical Microbiology, Maastricht, The Netherlands, [3]Maastricht University School of Nutrition and Translational Research in Metabolism (NUTRIM), Respiratory Medicine, Maastricht, The Netherlands, [4]Maastricht University Medical Center +, Central Diagnostic Laboratory, Maastricht, The Netherlands, [5]UCD Conway Institute, School of Biomolecular and Biomedical Science, University College Dublin, Dublin, Ireland, [6]Ludwig-Maximilians-University (LMU), Institute for Cardiovascular Prevention (IPEK), München, Germany

Background: Extracellular vesicles are gaining increasing attention as mediators of cell communication during health and disease. Platelets are a major source of extracellular vesicles, releasing them upon activation or during aging. Platelet extracellular vesicles (platelet EV) have been shown to exert modulatory effects on immune as well as vascular cells.
Aims: We hypothesize that platelet EV modulate the function of vascular smooth muscle cells (SMC).
Methods: In this study, platelet EV were isolated from aging platelet concentrates by differential centrifugation, quantified and characterized by flow cytometry, nanoparticle tracking analysis (NTA) and cryo-transmission electron microscopy (cryo TEM). Platelet EV were incubated with SMC for up to 96 hours in order to assess binding, proliferation, migration and pro-inflammatory phenotype of the cells.
Results: Under resting conditions, platelet EV firmly bound to SMC through the platelet integrin $\alpha_{IIb}\beta_3$, while binding also occurred upon cytokine stimulation in a CX3CL1-CX3CR1-dependent manner. In chemotaxis experiments, platelet EV increased SMC migration to a similar extent as did platelet derived growth factor (PDGF) or platelet factor 4 (CXCL4). Additionally, platelet EV induced SMC proliferation, which relied on CD40- and P-selectin-interactions. Adhesion of monocytic cells to platelet EV-treated SMC under flow conditions was significantly increased in comparison to adhesion to untreated SMC. Again, this adhesion was dependent on integrin $\alpha_{IIb}\beta_3$ and P-selectin, and to a lesser extent on CD40 and CX3CR1. Treatment of SMC with platelet EV induced the production of the cytokine interleukin 6 (IL-6). Finally, platelet EV induced a synthetic SMC morphology and decreased the expression of the contractile protein calponin.
Conclusions: These findings indicate that platelet EV exert a strong immunomodulatory activity on SMC. In particular, platelet EV induce a switch towards a pro-inflammatory phenotype, stimulating vascular remodeling.

PB 1613 | Conditional Knockout of Heme Oxygenase-1 in Lysozyme M Positive Cells Attenuates Angiotensin II Induced Vascular Inflammation

J. Lagrange[1], S. Kossmann[1,2], T. Münzel[2], P. Wenzel[1,2]

[1]Center for Thrombosis and Hemostasis (CTH), University Medical Center Mainz, Johannes Gutenberg-University, Mainz, Germany, [2]Center for Cardiology - Cardiology 1, University Medical Center Mainz, Mainz, Germany

Background: Heme oxygenase-1 (HO-1) protects vascular function in hypertension, presumably by anti-inflammatory effect on monocytes.
Aims: The purpose of this study was to explore the role of HO-1 specifically in monocytes in the development of angiotensin II (AngII) induced hypertension.
Methods: Lysozyme M ($LysM^+$) specific HO-1 knockout mice ($LysM^{Cre/wt}Hmox\text{-}1^{flox/flox}$ referred below as MHOKO) and controls ($LysM^{Cre/wt}$) were infused with AngII (1 mg× kg^{-1}× d^{-1} for 7 days using osmotic minipump) or sham-treated. Blood pressure was assessed with tail cuff plethysmography. Vascular inflammation and reactivity were explored with oxidative fluorescent microtopography and isometric tension studies. Leukocytes activation and infiltration were assessed with flow cytometry of the aortic tissue and intravital videomicroscopy Imaging.
Results: AngII infusion induced increased systolic blood pressure in both strain and aortic reactive oxygen species formation was reduced in AngII-infused MHOKO mice. AngII-infused MHOKO presented reduced vascular reactivity impairment with smooth muscle cells-dependent relaxation. Flow cytometry revealed, that vascular accumulation of $Ly6G^+$ neutrophils and both $Lys6G^-/Ly6C^{hi}$ and $Ly6G^-/Ly6C^{lo}$ monocytes was attenuated in AngII-infused MHOKO mice compared to controls. This was paralleled by reduced aortic mRNA expression of C-C chemokine receptor type 2, reduced ROS formation in circulating blood as well as attenuated leukocyte rolling in carotids of AngII-infused MHOKO mice.
Conclusions: In 1-week AngII-infusion model, conditional deletion of HO-1 in $LysM^+$ cells unexpectedly reduced vascular recruitment and protected from ROS formation in blood and infiltration of inflammatory cells, but not from arterial hypertension. Further investigations are needed to test the impact of myelomonocyte-specific deficiency of HO-1 on the phenotype and transcriptome of monocytes since very recent studies suggest a specific role of HO-1 in the maturation and trafficking of these cells.

PB 1614 | Defective Fibrin Accumulation and Thrombus Stability in Endothelial Cell-specific BAMBI Knockout-mice

I.I. Salles-Crawley, A. Zalli, J.H. Monkman, D.A. Lane, J.T.B. Crawley

Imperial College London - Hammersmith Hospital Campus, Centre for Haematology, London, United Kingdom

Background: BAMBI is a TGFβ superfamily transmembrane protein that is highly expressed in platelets and endothelial cells. *Bambi*-deficient mice exhibit decreased thrombus stability. Chimeric mice revealed that endothelial, rather than platelet BAMBI confers this phenotype.

Aims: We aimed to delineate the mechanisms by which BAMBI exerts its function on the endothelium and how it influences thrombus stability.

Methods: *Bambi*-deficient mice were subjected to the laser-induced thrombosis model. Platelets, neutrophils and fibrin(ogen) accumulation were assessed. Mouse lung endothelial cells (MLEC) were isolated from $Bambi^{+/+}$ and $Bambi^{-/-}$ mice. Expression of adhesion molecules and thrombomodulin was assessed by flow cytometry.

Results: No difference in the levels of plasma prostacyclin or nitric oxide could be observed between $Bambi^{-/-}$ and $Bambi^{+/+}$ littermates (WT). Incorporation of neutrophils in thrombi after laser injury of the endothelium was similar in $Bambi^{+/+}$ and $Bambi^{-/-}$ mice. Consistent with this, no difference in expression levels of PECAM-1, ICAM-1 or ICAM-2 was detected between $Bambi^{-/-}$ and WT MLEC. The increased number of emboli during thrombus formation present in $Bambi^{-/-}$ mice was accompanied with a defect in fibrin accumulation. Injection of hirudin prior to thrombus formation in WT mice recapitulated the $Bambi^{-/-}$ thrombus instability phenotype while it had no effect in $Bambi^{-/-}$ mice. Finally, EC *Bambi*-deficient mice ($Bambi^{EC-/-}$) exhibited normal haemostasis but defective thrombus stability with decreased fibrinogen accumulation.

Conclusions: $Bambi^{EC-/-}$ similar to $Bambi^{-/-}$ mice display increased thrombus instability accompanied by a markedly diminished ability to accumulate fibrin during thrombus formation, confirming the important role of endothelial BAMBI. Preliminary data suggest $Bambi^{-/-}$ MLEC display increased levels of thrombomodulin compared to WT MLEC. We are currently investigating how altered anticoagulant pathways may cause thrombus instability in *Bambi* deficient mice.

PB 1615 | FXI Inhibition Protects from Vascular Inflammation and Endothelial Dysfunction in Arterial Hypertension

S. Kossmann[1,2], J. Lagrange[1], S. Jäckel[1], K. Jurk[1], M. Ehlken[1], T. Schönfelder[1], Y. Weihert[1], M. Knorr[1,2], M. Brandt[1,2], A. Daiber[2], M. Oelze[2], C. Reinhardt[1], K. Lackner[3], A. Gruber[4], B. Monia[5], S. Karbach[2], U. Walter[1], Z. Ruggeri[6], T. Renné[7,8], W. Ruf[1,9], T. Münzel[1,2], P. Wenzel[1,2]

[1]University Medical Center Mainz, Center for Thrombosis and Hemostasis (CTH), Mainz, Germany, [2]University Medical Center Mainz, Center for Cardiology - Cardiology I, Mainz, Germany, [3]University Medical Center Mainz, Institute of Clinical Chemistry and Laboratory Medicine, Mainz, Germany, [4]Oregon Health and Science University, Department of Biomedical Engineering, Portland, United States, [5]Ionis Pharmaceuticals Inc., Carlsbad, United States, [6]Department of Molecular and Experimental Medicine, The Scripps Research Institute, La Jolla, United States, [7]Karolinska Institutet, Department of Molecular Medicine and Surgery, Stockholm, Sweden, [8]University Medical Center Hamburg-Eppendorf, Institute of Clinical Chemistry and Laboratory Medicine, Hamburg, Germany, [9]Department of Immunology and Microbial Science, The Scripps Research Institute, La Jolla, United States

Background: Interactions of platelets, leukocytes and the vessel wall play pivotal roles in activating coagulation and precipitating thrombosis, but how they promote vascular inflammation in arterial hypertension is unclear.

Aims: The aim of this work was to explore the roles of FXI on inflammatory driven vascular dysfunction in experimental arterial hypertension and in patients with uncontrolled hypertension.

Methods: C57BL/6 mice infused with angiotensin II (AngII) (1 $mg \times kg^{-1} \times d^{-1}$ for 7 d) and 5/6 nephrectomized (Nx) rats were used. FXI synthesis was inhibited by a FXI antisense oligonucleotide (FXI ASO). Blood pressure, endothelial function, leukocyte adhesion, vascular inflammation and thrombin generation (TG) in platelet rich plasma were measured.

Results: In mice, AngII-induced vascular dysfunction involved the activation of FXI but not of FXII. Blockade of TF or thrombin or depletion of platelets during AngII administration attenuated both endothelial dysfunction and vascular inflammation.

Inhibition of FXI synthesis was sufficient to prevent AngII-induced thrombin formation on platelets, leukocyte adhesion to the endothelium, vascular inflammation, endothelial dysfunction as well as arterial hypertension. AngII-infused mice lacking the extracellular binding domains of GP1bα were protected from AngII-induced vascular injury, identifying platelet GPIbα as a relevant platelet receptor for AngII-induced endothelial dysfunction and vascular inflammation.

FXI ASO treatment also reduced the elevated blood pressure and attenuated vascular and kidney dysfunction in Nx rats with established arterial hypertension. Further, platelet-localized TG was amplified in a platelet-dependent manner and normalized with FXI inhibition in patients with uncontrolled arterial hypertension.

Conclusions: Our results outline a new coagulation-inflammation circuit that promotes vascular dysfunction and points to the possible utility of FXI-targeted anticoagulants beyond their application as antithrombotic agents in cardiovascular disease.

PB 1616 | Function of an Endothelial-specific GPCR in Thrombosis

L. Gottlob[1,2], P. Dusart[1,2], L. Fagerberg[1], D.-A. Trégouët[3], P. Morange[4], M. Germain[3], M. Civelek[5], T. Renné[2,6], J. Odeberg[1], L. Butler[2,6]

[1]KTH Royal Institute of Technology, Science For Life Laboratory, Solna, Sweden, [2]Karolinska Institutet, Institute for Molecular Medicine, Solna, Sweden, [3]Sorbonne Universités, UPMC Univ Paris 06, Team Genomics & Pathophysiology of Cardiovascular Diseases, Paris, France, [4]Aix-Marseille University, Nutrition Obesity and Risk of Thrombosis, Marseille, France, [5]University of Virginia, Department of Biomedical Engineering, Charlottesville, United States, [6]University Medical Center Hamburg-Eppendorf, Institute for Clinical Chemistry and Laboratory Medicine, Hamburg, Germany

Background: Venous thromboembolism (VTE) affects roughly 1 in 1000 individuals annually. The role of the endothelium in VTE is not fully understood. We recently characterized the human ‚endothelial-enriched transcriptome', which contained a number of orphan g-protein coupled receptors (GPCRs). We identified an association between a single nucleotide polymorphism (SNP) in the gene locus of one of these GPCRs and the risk of VTE in the genome wide association study ‚MARTHA'. Expression quantitative trait loci analysis in human endothelial cells (EC) revealed this SNP was associated with reduced transcription of the GPCR.

Aims: The aim was to investigate the role of this endothelial-enriched orphan GPCR in VTE. Specifically, how this GPCR is regulated and its role in coagulation.

Methods: We used siRNA to deplete the GPCR (GPCR-siRNA) in EC and assessed global protein expression by quantitative mass spectrometry proteomics. Findings were confirmed by real-time pcr and protein immunoblotting. Tissue factor (TF) activity was measured using a chromogenic activity assay. The effect of GPCR-siRNA on coagulation was tested in a thrombin generation assay adapted to incorporate an EC monolayer. In addition, we developed a flow assay exposing an EC monolayer to non-coagulated human blood at venous wall shear rate and measured fibrin deposition by immunofluorescence.

Results: GPCR-siRNA significantly increased EC TF expression and activity. This effect was amplified by pre-treatment of EC with tumor necrosis factor alpha. GPCR-siRNA increased EC-induced thrombin generation in human plasma and pre-treatment with a TF inhibitory antibody abolished this effect. In addition, fibrin formation from flowing whole blood was significantly enhanced on GPCR-siRNA EC.

Conclusions: Our results suggest that this endothelial-enriched GPCR could play a role in VTE development, though the regulation of tissue factor expression.

PB 1617 | Factor VII Activating Protease (FSAP) Regulates the Expression of Inflammatory Genes through Protease Activated Receptor (PAR1) in Vascular Smooth Muscle and Endothelial Cells

K. Byskov[1], T. Boettger[2], P.F. Ruehle[3,4], N.V. Nielsen[1], M. Etscheid[5], S.M. Kanse[1,6]

[1]University of Oslo, Institute of Basic Medical Sciences, Oslo, Norway, [2]Max Planck Institute, Bad Nauheim, Germany, [3]Universitaetsklinikum Erlangen, Department of Radiation Oncology, Erlangen, Germany, [4]Friedrich Alexander University, Erlangen-Nuerenberg, Germany, [5]Paul Ehrlich Institute, Langen, Germany, [6]Oslo University Hospital, Oslo, Norway

Background: Factor VII activating protease (FSAP) knockout mice have a bigger neointima after vascular injury and a larger infarct volume after stroke. In humans, the loss of function Marburg I (MI) single nucleotide polymorphism (SNP) in the FSAP-encoding gene is associated with increased risk of stroke and carotid stenosis.

Aims: In order to understand how FSAP modifies vascular cells in man and mice, further information at a molecular level is needed.

Methods: Vascular smooth muscle cells (VSMC) and endothelial cells (EC) were stimulated with FSAP and a microarray-based expression analysis was performed. Selected genes were further analysed by qPCR and proteins by Western blotting, flow cytometry or ELISA. Phosphorylation of signal transduction proteins as well as receptor- and pathway-inhibitors were used to elucidate the mechanisms involved.

Results: Pathway analysis showed that expression levels of apoptosis/proliferation and inflammation related genes were influenced by FSAP. Following stimulation with FSAP, we identified *AREG*, *IL6* and *PTGS2* to be up-regulated in VSMC and *VCAM1*, *SELE* and *IL8* in EC. These observations were confirmed by qPCR and an elevated secretion of IL6 and IL8 was observed. These effects of FSAP were inhibited by aprotinin. Recombinant wild type protease domain of FSAP, but not the MI-isoform, could recapitulate this effect. Cellular activation by FSAP was impaired by blocking PAR1. Moreover, FSAP activated the ERK1/2 and CREB pathways, but EGFR transactivation was not detected. Besides, FSAP increased DNA synthesis and protected VSMC against serum starvation-induced apoptosis.

Conclusions: FSAP promotes an inflammation and proliferative/apoptosis-related gene expression pattern in VSMC and EC via a PAR1-dependent pathway. Also, cytokine expression, proliferation and apoptosis were altered in vascular cells. These novel cellular effects of FSAP provide a fundamental basis for understanding the role of FSAP in vascular diseases.

PB 1618 | Regulation of Platelet String Formation on Endothelial Cells in the Presence of Coagulation under Shear

T. Shirai, J. Zilberman-Rudenko, C. Puy, K.S. Garland, D.E. Sallee, S.E. Reitsma, A. Gruber, O.J.T. McCarty

Oregon Health and Science University School of Medicine, Biomedical Engineering, Portland, United States

Background: Activated vascular endothelial cells secrete von Willebrand factor (VWF), which has been shown to polymerize and capture platelets (PLT) to form PLT-VWF strings. In purified systems, the metalloprotease ADAMTS-13 has been shown to rapidly degrade VWF-strings. Coagulation factors including thrombin are known to proteolytically inactivate ADAMTS-13. Thrombin generation is promoted by feedback activation by coagulation factor XI.

Aims: Study how activation and propagation of the coagulation cascade regulates PLT-VWF string formation on endothelial cells in whole blood under shear.

Methods: Human umbilical vein endothelial cells (HUVECs) were grown to confluence in an ibidi microfluidic flow chamber. VWF secretion was induced by stimulation of HUVECs with TNFα for 4 h. Recalcified human whole blood was perfused through the chambers at a venous shear rate of 2.5 dyne/cm2 for 10 min. PLT-VWF string and fibrin formation was visualized by labeling with anti-CD41 and anti-fibrinogen antibodies, respectively, and Alexa Fluor-labeled secondary antibodies. Platelet adhesion, mean aggregate size, and fibrin deposition were quantified using ImageJ.

Results: TNFα stimulation dramatically induced ultra large (UL)-VWF secretion from HUVECs. In whole blood in the presence of coagulation, Platelets were observed to form strings on VWF. Concomitant with platelet deposition was the formation of fibrin, resulting in localized fibrin-rich platelet aggregates. The presence of a function-blocking antibody to ADAMTS13 promoted VWF-string formation, Platelet adhesion, mean aggregate size, and fibrin deposition as compared to vehicle. Interestingly, inhibition of thrombin generation either by blocking tissue factor, directly inhibiting thrombin with hirudin, or through inhibition of the intrinsic pathway of coagulation with a function-blocking FXI mAbs promoted PLT-VWF string formation.

Conclusions: Our findings suggest that activation of the coagulation cascade to generate thrombin negatively regulates PLT-VWF string formation.

PB 1619 | Recombinant Adeno-associated Virus Vector Carrying the Thrombomodulin Lectin-like Domain Suppresses the Development of Abdominal Aortic Aneurysm in Mice

H.-L. Wu, C.-H. Lai, K.-C. Wang, G.-Y. Shi

College of Medicine, National Cheng Kung University, Department of Biochemistry and Molecular Biology, Tainan, Taiwan, Republic of China

Background: The lectin-like domain (D1) of thrombomodulin (TM) suppressed the receptor for advanced glycation end product (RAGE)-mediated inflammation by sequestering proinflammatory high-mobility group box 1 (HMGB1). Our previous study showed that short-term treatment with recombinant TM containing all the extracellular domains (rTMD123) attenuates HMGB1-RAGE signaling and confers protection against $CaCl_2$-induced abdominal aortic aneurysm (AAA) formation in mice.

Aims: Herein, we attempted to investigate the potential therapeutic benefits of TM domains for AAA using the recombinant adeno-associated virus (AAV) vector.

Methods: The therapeutic effects of recombinant TMD1 (rTMD1) and recombinant AAV vectors carrying the lectin-like domain of TM (rAAV-TMD1) were evaluated in two AAA mouse models, $CaCl_2$-induced AAA model and angiotensin II-infused AAA model, respectively. One-way analysis of variance followed by post hoc Bonferroni test was used in data passing tests for Kolmogorov-Smirnov test and Bartlett´s test; otherwise, a non-parametric Kruskal-Wallis test was used.

Results: In the $CaCl_2$-induced model, treatment with rTMD1 reduced the tissue levels of HMGB1 and RAGE, macrophage accumulation, elastin destruction and AAA formation, and the effects were comparable to a mole-equivalent dosage of rTMD123. In the angiotensin II-infused model, a single intravenous injection of rAAV-TMD1 (10^{11} genome copies) effectively attenuated AAA formation, accompanied by a reduction of HMGB1 and RAGE levels and suppression of proinflammatory cytokine production, macrophage accumulation, matrix metalloproteinase activities and oxidative stress in the aortic wall.

Conclusions: These findings imply the therapeutic potential of the TM lectin-like domain in AAA. The attenuation of angiotensin II-infused AAA by single injection of rAAV-TMD1 provides a proof-of-concept validation of its application as a potential gene therapeutic agent for aneurysm development.

PB 1620 | A2 Domain of von Willebrand Factor (VWF) Mediates Human Vascular Smooth Muscle Cells (VSMCs) Proliferation and Migration

M.E. Worou[1], M. Didelot[1], P. Legendre[2], V. Muczynski[2], P.J. Lenting[2], P. Lacolley[1], C.V. Denis[2], V. Regnault[1]

[1]INSERM U 1116, Université de Lorraine, Vandoeuvre-lès-Nancy, France, [2]INSERM U 1176, Univ. Paris-Sud, Université Paris-Saclay, Le Kremlin-Bicêtre, France

Background: Vascular Smooth Muscle Cells (VSMCs) proliferation and migration are crucial events in vascular ageing and atherosclerosis. Von Willebrand factor (VWF) is a multimeric glycoprotein produced in endothelial cells and platelets, and known for its contribution to platelet-adhesion/aggregation during vascular injury. VWF deposition in the vessel wall during intimal thickening has been reported.

Aims: We hypothesized that VWF could induce human VSMCs proliferation and migration.

Methods: Human aortic VSMCs between passages 3-6 were used. After synchronization in serum free medium, cells were treated for 24h with VWF (50 - 2000 ng/mL) or PDGF (2 - 100 ng/mL) and cell proliferation was evaluated by cell counting. Cell migration was performed by wound-healing assay and evaluated at t=0,16, 24 and 48h after wounding. ERK1/2 and Akt pathways activation, and VSMCs differentiation markers were analyzed by Western blot.

Results: Our results show that VWF induces substantial VSMCs proliferation with an optimal concentration of 250 ng/ml (1.7±0.2 fold

vs. 1.8±0.2 fold for PDGF at 5 ng/mL). VWF also promotes cell migration, with a coverage up to 70% of wounded area at 48h. Moreover, VSMCs cultured with VWF showed a decrease in the protein expression of smooth muscle α-actin and serum response factor (SRF) and an increase in matrix metalloproteinase 2, indicating some degree of dedifferentiation. In search for the molecular mechanisms, we observed that VWF exposure led to an upregulation of phospho-ERK1/2 (3.1±0.1fold) and phospho-Akt (1.5±0.1 fold), suggesting that these signaling pathways contribute to VWF-mediated VSMCs proliferation. Using recombinant VWF-fragments, we next demonstrated that the proliferative and migratory effect of VWF on VSMCs was mediated by its A2 domain.

Conclusions: In conclusion, these findings provide evidence on VWF inducing VSMCs proliferation and migration. These effects involve the activation of ERK1/2 and Akt signaling pathways and are at least partially mediated by the A2 domain of VWF.

PB 1621 | Dietary Alpha-linolenic Acid Reduces Platelet Activation and *ex vivo* Thrombus Formation in Sickle Cell Disease Mice

S. Stivala[1], S. Gobbato[1], N. Bonetti[1], G. Camici[2], T. Lüscher[3], J. Beer[1,4]

[1]*University of Zurich, Center for Molecular Cardiology, Laboratory for Platelet Research, Zurich, Switzerland,* [2]*University of Zurich, Center for Molecular Cardiology, Zurich, Switzerland,* [3]*University Hospital Zurich, Cardiology, Zurich, Switzerland,* [4]*Cantonal Hospital Baden, Internal Medicine, Baden, Switzerland*

Background: Sickle cell disease (SCD) is a genetic hemoglobinopathy associated with high morbidity and mortality.

Aims: We investigated the potential therapeutic use of the plant-derived omega-3 ALA in SCD.

Methods: 8-week-old male Berkeley mice were fed for 4 weeks a low (0.03%) or a high (7.3%) ALA diet (n=14). We analysed reticulocytes and reticulated platelets, neutrophils/RBC/platelet aggregates, neutrophils PSGL-1, platelet activation (P-selectin exposure and $a_{2b}b_3$ activation), thrombus formation on collagen under flow, and aortic VCAM-1, ICAM-1 and vWF expression.

Results: Four weeks feeding with ALA significantly decreased the number of sickle cells on blood smears (3.1/100 cells low-ALA vs 2.6/100 cells high-ALA, p=0.009). Platelet/neutrophils aggregates were 28% lower in the high-ALA group (83.56% of tot neutrophils in low-ALA vs 69.03% in high-ALA, p=0.03), and neutrophil PSGL-1 was reduced by 32% by ALA feeding (mean fluorescence intensity (MFI) 2797±547 low-ALA vs 1927±373 high-ALA, p=0.05). Platelet basal activation was reduced upon high-ALA feeding, as measured by P-selectin exposure (MFI 208.42±74 low-ALA vs 59.23±79 high ALA, p=0.006, figure 1) and active $a_{2b}b_3$ integrin (MFI 233.08±29 low-ALA vs 79.4±37 high-ALA, p=0.03). Expression on aortic endothelium of ICAM-1 was reduced by 70% in the high-ALA group (positive area: 3599 mm^2 low-ALA vs 1170 mm^2 high-ALA, p=0.01), by 55% for VCAM-1 (1195 mm^2 low-ALA vs 560 mm^2 high-ALA, p=0.0006), and by 30% for vWF (5072 mm^2 low-ALA vs 3933 mm^2 high-ALA, p=0.001). Thrombus formation on collagen *ex vivo* was significantly reduced by dietary ALA (thrombus area: 43'783±2959 mm^2 low-ALA vs 10'028±724 high-ALA, p=0.04, figure 2).

Conclusions: In a mouse model of SCD, ALA reduces 1) platelet activation, 2) endothelial adhesion, 3) inflammatory responses of platelet-leucocyte interaction and vascular adhesion molecule expression. It could therefore represent a novel and cheaply available agent for the treatment of sickle cell disease.

PB 1622 | Podoplanin Overexpression on Endothelial Cells Promotes Superficial Erosive Injury and Thrombus Formation in Rat Carotid Artery

E. Furukoji[1], A. Yamashita[2], T. Hirai[1], Y. Asada[2]

[1]Faculty of Medicine, University of Miyazaki, Department of Radiology, Miyazaki, Japan, [2]Faculty of Medicine, University of Miyazaki, Department of Pathology, Miyazaki, Japan

Background: Atherosclerotic plaque erosion, a morphological pattern of plaque disruption, is characterized by a denuded plaque surface and thrombus formation. Podoplanin expression was significantly enhanced in atherosclerotic plaques. The precise mechanisms of plaque erosion and the roles of podoplanin in atherosclerotic lesions remain unclear.
Aims: To examine whether overexpression of podoplanin in arterial wall affects superficial arterial injury and thrombus formation in vivo, and factors which induce podoplanin expression in endothelial cells in vitro.
Methods: We evaluated superficial arterial injury and thrombosis formation induced by ligation in rat carotid artery. Recombinant adenoviruses expressing human podoplanin (Ad-podoplanin) or β-galactosidase (Ad-LacZ) were infected to the carotid arteries after distal ligation. We examined the effects of interleukin (IL)-3, 6, transforming growth factor (TGF)-β, and vascular endothelial growth factor (VEGF)-A (VEGF165, 500ng/mL) on podoplanin expression in cultured human aortic endothelial cells (HAOEC).
Results: Arterial endothelial cells were immunopositive for human podoplanin one day after the gene transfer. Four days after the gene transfer, occlusive thrombi were formed in all arteries (n=6) infected with Ad-Podoplanin, whereas small mural thrombi were developed in those infected with Ad-LacZ (n=6). Human podoplanin expressing cells were detached and involved in the occlusive thrombi. The administration of VEGF-A but not IL-3, 6, or TGF-β induced podoplanin mRNA expression 1.9-fold up to 24 hours, and increased the podoplanin protein level 4.0-fold at 24 hours.
Conclusions: Overexpression of podoplanin may enhance thrombus formation via detachment of endothelial cells, and VEGF-A could be a possible stimulant for podoplanin expression in endothelial cells. The results may provide novel insight into the mechanisms of plaque erosion.

PB 1623 | Evaluation a Novel Mouse Model of Abdominal Aortic Aneurysm to Study Platelet Mechanisms of the Proinflammatory Thrombus

Y. Boulaftali, S. Delbosc, M.-C. Bouton, J.-B. Michel, M. Jandrot-Perrus, B. Ho-Tin-Noé

INSERM U1148, Laboratory for Vascular Translational Science, Paris, France

Background: Abdominal Aortic Aneurysm (AAA) is defined as a permanent localized dilation in the arterial wall with a diameter >50% and characterized by thinning and weakness of the vascular wall. In humans, aneurysms are associated with intramural thrombus and are prone to rupture and often result in death. Thrombi from abdominal aortic aneurysm (AAA) patients are highly enriched in leukocytes and in bacteria, eg. Porphyromonas gingivalis (Pg). This leukocyte-rich thrombus is considered the driving force in vessel wall rupture leading to death. Beyond their role in aneurysmal thrombus formation, platelets support leukocyte recruitment and interact with bacteria. This cross-talk is an important feature in thrombo-inflammatory vascular disease.
Aims: To study the role of platelets in the aneurysmal thrombus formation.
Methods: AAA was induced by applying an elastase-soaked filter paper on the infrarenal abdominal aorta of wild-type mice. Mice were then injected or not with *Pg* once a week for 2 weeks. Platelet adhesion and leukocyte recruitment to the vessel wall were analyzed by intravital microscopy and the presence of thrombi was quantified by immunohistology at early and late time points.
Results: In elastase-treated WT mice, we observed, by intravital microscopy, an early recruitment of platelets and leukocytes to the damaged vessel wall. At 14 days, abdominal aorta aneurysm was found in all treated mice. The diameter of the aorta was increased two-fold compared to sham mice and histological analysis did not reveal thrombus formation. In contrast, to elastase-treated WT mice injected with *Pg*, the dilatation was three-fold compared to untreated mice and importantly, immunohistology showed large thrombi in the dilated vessel wall which were enriched with platelets and leukocytes.
Conclusions: Here we establish a novel mouse model of abdominal aortic aneurysm allowing us (i) to study platelet activation mechanisms in the initiation and progression of AAA and (ii) test efficient anti-platelet therapies in AAA.

PB 1624 | Increased Inflammatory Properties of Neutrophils and Endothelial Cells (ECs) in Patients with Venous Thromboembolism (VTE), Long after the Acute Disease

K.C.S. Zapponi[1], F. Orsi[2], I.R. Brito[3], J.L. Cunha[3], A.V. Romano[3], F. Santiago-Bassora[3], B.D.M. Mazetto[3], S.A. Montalvao[3], C.F. Franco Penteado[3], L.F.B. Sckayer[3], E.V. De Paula[3], J.M. Annicchino-Bizzacchi[3]

[1]University of Campinas-Unicamp/Hematology and Hemotherapy Center, Department of Clinical Pathophysiology, Campinas, Brazil, [2]University of Campinas/Faculty of Medical Sciences, Department of Clinical Pathology, Campinas, Brazil, [3]University of Campinas-Unicamp, Hematology and Hemotherapy Center, Campinas, Brazil

Background: Inflammatory cells, such as neutrophils, play a role in venous thromboembolism (VTE). Briefly, neutrophil-endothelial cell (EC) interactions consist of neutrophil chemotaxis, adhesive interactions with EC, including tethering and rolling, followed by firm attachment and migration to extravascular tissues.
Aims: Whether neutrophil-EC interactions are persistently activated after the acute phase of VTE remains a matter of debate and this is the purpose of this study.
Methods: The expression of activated adhesive molecules (CD11a/CD11b) of neutrophils was determined by flow cytometry, under basal

conditions and after TNF-α stimulus. Neutrophil chemotaxis assays were performed under basal conditions and with IL-8 stimulus. Vascular cell adhesion molecule 1 (VCAM-1), intracellular adhesion molecule (ICAM-1) and the chemokine RANTES were measured by Multiplex analysis. Serum high sensitive CRP was analyzed by nephelometry.

Results: Thirty-seven spontaneous VTE patients and 37 healthy controls, matched according to age, gender and ethnicity, were included in the study (Table1). The median period of time since VTE diagnosis was 25 months (Table1). The expression of CD11a was higher in neutrophils from VTE patient, under basal conditions and after TNF-α stimulus. Higher CD11b expression was observed in VTE patient only after TNF-α stimulus (Table2). Neutrophil chemotaxis was increased in VTE patients under basal conditions and after IL-8 stimulus (Table2). Levels of circulating VCAM-1 and ICAM-1 were also increased in VTE patients (Table2), as well as the inflammatory biomarkers hsCRP and RANTES (Table1).

TABLE 1 Demographic and clinical data and comparative analysis of inflammatory markers in VTE patients and healthy controls

	Healthy Controls (N=37)	VTE patients (N=37)	P
Female/Male	24/13	24/13	1
Age (range)	43.56 (21- 66)	44 (19 - 65)	0.48
Caucasian/Non Caucasian	28/9	28/9	1
Time after VTE (range - months)	-	25 (12-42)	-
Spontaneous VTE episode (%)	-	51.35	-
chemokine RANTES (pg/ml)	63070 ± 23930	80020 ± 29420	0.03
hs¬CRP (mg/dl)	0.17 ± 0.12	0.59 ± 0.58	0.00

TABLE 2 Comparative analysis of neutrophil and endothelial cell activation in VTE patients and healthy controls

	Healthy Controls (N=37)	VTE patients (N=37)	P
Basal CD11a (MFI)	30.84 ± 6.82	38.72 ± 22.75	0.04
TNF-α stimulated CD11a (MFI)	34.09 ± 9.64	45.65 ± 33.06	0.01
Basal CD11b (MFI)	96.22 ± 32,53	120.9 ± 71.84	0.267
TNF-α stimulated CD11b (MFI)	149.10 ± 52.74	200.0 ± 100.5	0.02
Chemotaxis (basal) (%)	12.64 ± 4.78	17.55 ± 9.79	0.02
IL-8 stimulated Chemotaxis (%)	49.88 ± 19.48	63.48 ± 29.73	0.06
VCAM-1 (ng/ml)	468.7 ± 138.4	626.8 ± 285.8	0.01
ICAM-1 (ng/ml)	44.84 ± 9.758	90.87 ± 43.74	0.00

Conclusions: In conclusion, our findings demonstrated a profile of neutrophil and ECs activation in a group of VTE patients even long after the acute event. In addition, inflammatory markers were also increased in these patients. Our data suggest that increased inflammation may persist even after a long period since the acute episode of VTE, and neutrophils and ECs, possibly, play a role in this process.

PB 1625 | Analysis of Body-wide Unfractionated Tissue Data to Identify a Core Human Endothelial Transcriptome

L. Butler[1,2], B. Hallström[3], L. Fagerberg[3], F. Pontén[4], M. Uhlén[3], T. Renné[1,2], J. Odeberg[3,5]

[1]Clinical Chemistry and Blood Coagulation, Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden, [2]Institute for Clinical Chemistry and Laboratory Medicine, University Medical Centre Hamburg-Eppendorf, Hamburg, Germany, [3]Science for Life Laboratory, School of Biotechnology, Kungliga Tekniska Högskolan (KTH) Royal Institute of Technology, Stockholm, Sweden, [4]Department of Immunology, Genetics and Pathology, Science for Life Laboratory, Uppsala University, Uppsala, Sweden, [5]Coagulation Unit, Centre for Hematology, Karolinska University Hospital, Stockholm, Sweden

Background: Endothelial cells (EC) line blood vessels and regulate haemostasis, inflammation and blood pressure. Proteins critical for endothelial function tend to be enriched or specifically expressed in EC across vascular beds. Currently, there is no definitive description of the human pan EC enriched transcriptome.

Aims: To identify a comprehensive panel of human endothelial-enriched genes using global, body-wide transcriptomics.

Methods: We performed RNA-seq tissue transcript profiling of 124 samples from 32 human organs as part of the Human Protein Atlas Project (www.proteinatlas.org). We selected 3 transcripts that encode for proteins that are known to be EC enriched across vascular beds; c-type lectin domain family 14, member A (*CLEC14A*), von Willebrand factor (*vWF*) and CD34 (*CD34*) and calculated correlation coefficient values between the FKPM values of these transcripts and those of the other >20,000 mapped protein-coding genes. A high correlation value with all 3 EC reference genes indicated tissue wide EC-enriched expression of the gene(s) in question. We used antibody-based profiling to confirm protein expression of identified transcripts across vascular beds and measured expression in cultured EC.

Results: We identified a panel of 232 human pan EC-enriched transcripts, which contained both well-described EC transcripts (e.g. *CDH5*, *ESAM*, *KDR*) and a number that encode for novel or uncharacterised EC proteins (e.g. *CXorf36*, *FAM110D*). Most identified transcripts could be detected in cultured EC from various vascular beds, and we observed maintenance of relative expression in early passage cells.

Conclusions: We describe a widely applicable method to determine cell type specific transcriptome profiles in a whole organism context, based on differential abundance across tissues. We identify potential vascular drug targets or endothelial biomarkers, and highlight candidates for functional studies to increase understanding of the endothelium in health and disease.

PB 1626 | Effects of Aspirin and Rivaroxaban on Murine Arterial Vessel Wall Remodelling after Vascular Injury

T. Mastenbroek[1], M. Kuijpers[1], M. Nagy[1], W. Chayouâ[1,2], A. Brouns-Strzelecka[3], P. Leenders[3], H. van Essen[3], S. Heitmeier[4], R. van Oerle[1], H. Spronk[1], J. Heemskerk[1], J. Cosemans[1]

[1]*Maastricht University / Cardiovascular Research Institute Maastricht (CARIM), Biochemistry, Maastricht, The Netherlands,* [2]*Synapse Research Institute, CARIM, Maastricht University, Maastricht, The Netherlands,* [3]*Maastricht University / Cardiovascular Research Institute Maastricht (CARIM), Pharmacology & Toxicology, Maastricht, The Netherlands,* [4]*Bayer Pharmaceutics, Acute Care Diseases Research, Wuppertal, Germany*

Background: Dual therapy with aspirin and rivaroxaban is increasingly being prescribed to patients with acute coronary syndrome and after coronary bypass grafting, but little is known about the effects of this treatment on the vasculature.

Aims: To study the effects of aspirin and/or rivaroxaban on vascular remodelling in mice subjected to vascular injury.

Methods: C57BL/6 mice were treated with vehicle, aspirin and/or rivaroxaban during the entire experimental period (n=12/group). Vascular injury was induced by temporary ligation of the carotid artery. Vascular stiffening was monitored for two weeks using non-invasive ultrasound imaging. Two weeks after ligation, mice were sacrificed, after which platelet-leukocyte aggregates (PLA) and vascular changes were assessed.

Results: Aspirin-treatment, calculated at 5 mg aspirin/kg/day, led to complete inhibition of arachidonic acid-induced platelet aggregation. Mean levels of plasma rivaroxaban were in the therapeutic clinical range with 344±35 and 552±101 ng/mL for the rivaroxaban and aspirin/rivaroxaban group, respectively. In all animals, temporary ligation resulted in the formation of nonocclusive thrombi. Treatment with aspirin with(out) rivaroxaban decreased the number of adhered platelets per PLA (P< 0.05) in both unstimulated and 2-MeSADP (ADP receptor) or AYPGKF (PAR4 receptor)-stimulated whole blood. Interestingly, treatment with aspirin with(out) rivaroxaban protected the arteries against ligationinduced stiffening (P< 0.05), while rivaroxaban alone showed a trend herein (P=0.08). Histological analysis indicated that ligation of the carotid artery resulted in local intima-media thickening, which was reduced with aspirin and rivaroxaban individually (P< 0.01).

Conclusions: This study provides new insight into the vasculardirected effects of aspirin and/or rivaroxaban treatment after thrombotic injury. Treatment with aspirin significantly antagonised, and rivaroxaban showed potential to inhibit, vascular stiffening, intimamedia thickening and PLA formation.

PB 1627 | Plasminogen Activator Inhibitor Type 1 in Platelets Evokes Thrombogenicity and Increases Thrombus Size by Elevating Thrombolysis Resistance under Shear Stress

K. Hosokawa[1], T. Ohnishi-Wada[1], H. Sameshima-Kaneko[1], T. Nagasato[1], H. Tanaka[2], H. Sano[2], Y. Suzuki[2], T. Urano[2]

[1]*Research Institute, Fujimori Kogyo Co., Ltd., Yokohama, Japan,* [2]*Hamamatsu University School of Medicine, Medical Physiology, Hamamatsu, Japan*

Background: Tissue plasminogen activator (t-PA) has been considered responsible for quick dissolution of unnecessary and aged thrombi.

Aims: We evaluated how tPA as well as PA inhibitor type 1 (PAI-1) affect thrombus formation under flow using a microchip-based flow chamber system equipped with a videomicroscope (Total Thrombus-formation Analysis System [T-TAS]; Fujimori Kogyo Co., Ltd., Tokyo, Japan).

Methods: t-PA-treated human whole-blood samples (n=6) were perfused over a microchip coated with collagen and tissue thromboplastin at different shear rates, and thrombus formation was quantified by measuring flow pressure changes during the perfusion experiments. The time required to reach 80 kPa was defined as complete capillary occlusion time. Rotational thromboelastometry (ROTEM) was used to evaluate fibrinolytic activity under static conditions.

Results: At a shear rate of 240 s^{-1}, t-PA (200-800 IU/mL) concentration-dependently delayed capillary occlusion, whereas at 600 s^{-1}, capillary occlusion was significantly faster and t-PA had limited effects. Thrombus formed inside the microchip after treatment by t-PA (400 and 800 IU/ml) at the shear rate of 240 s^{-1} showed reduced firmness, as observed by the frequent collapse of thrombi. The combined treatment of blood with a specific PAI-1 inhibitor (PAI-039) moderately enhanced the efficacy of t-PA, only under flow conditions. In addition, 1:1-diluted blood samples of PAI-1 deficient (-/-) mice showed a significant delay of capillary occlusion at 240 s^{-1}, compared with those from wild-type mice (1.55 fold; P< 0.001). This delayed occlusion was reproduced in samples containing platelets from PAI-1-/- and plasma from wild type, but was not observed by the opposite combination of blood components.

Conclusions: The anti-thrombotic efficacy of t-PA appeared sensitive to arterial shear flow, and that PAI-1 secreted from activated platelets plays an essential role in thrombolysis resistance.

PB 1628 | Tissue Engineered Small Vessel Conduits - The Anti-thrombotic Effect of Re-endothelialisation of Decellularised Baboon Arteries

M. Meiring[1], M. Khemisi[1], L. Laker[2], F. Smit[2]

[1]*University of the Free State, Haematology and Cell Biology, Bloemfontein, South Africa,* [2]*University of the Free State, Cardiothoracic Surgery, Bloemfontein, South Africa*

Background: The use of decellularised biological scaffolds for the reconstruction of small-diameter vascular grafts remains a challenge

in tissue engineering. Thrombogenicity is an important cause of obstruction in these vessels as a result of the decellularisation process. Seeding of the decellularised vascular constructs with endothelial cells is therefore a pre-requisite for the prevention of early thrombosis.

Aims: The aim of this study was to seed the internal surfaces of decellularised baboon arteries with endothelial cells and to compare the thrombogenicity of these conduits with that of decellularised arteries and also to that of a freshly harvested arteries in an *in vitro* circulating blood thrombotic model.

Methods: Carotid, radial and femoral arteries were harvested from two Papio ursinus baboons. Normal morphology was confirmed in the two control vessels and after decellularising the remaining arteries the effect of de-endotheliliasation were studied in the vessel scaffolds using scanning electron microscopy and transmission electron microscopy. Six of the decellularised vessel scaffolds were seeded with human umbilical vein endothelial cells. The luminal endothelialisation was established after seven days in a bioreactor and SEM confirmed confluency. Two fresh baboon arteries, four decellularised vessel scaffolds and six decellularised re-endothelialised vessel scaffolds were studied in an *in vitro* flow chamber using fresh citrated baboon blood.

Results: The decellularisation protocol resulted in a vessel scaffold with a well-preserved extracellular matrix and intact basal membrane. No thrombi could be demonstrated in the fresh control arteries and in the re-endothelialised vessel scaffolds. In the decellularised vessel scaffolds widespread platelet adhesion and activation occurred despite a relatively intact basal membrane.

Conclusions: This study supports the development of re-endothelialised tissue engineered small vessel conduits for clinical use.

PB 1629 | APAC, a Dual Antiplatelet and Anticoagulant Heparin Proteoglycan Mimetic, Integrates with Extravascular Matrix during Vascular Injury

K.A. Barreiro[1], A. Jouppila[2], R. Tulamo[3], A. Albäck[3], R. Lassila[4]

[1]*University of Helsinki, Biochemistry and Developmental Biology, Helsinki, Finland,* [2]*Helsinki University Central Hospital Research Institute, Helsinki, Finland,* [3]*University of Helsinki and Helsinki University Hospital, Vascular Surgery, Helsinki, Finland,* [4]*University of Helsinki and Helsinki University Hospital, Comprehensive Cancer Center, Department of Hematology, Coagulation Disorders Unit and HUSLAB Laboratory Services, Helsinki, Finland*

Background: APAC, a semisynthetic mimetic of mast cell-derived heparin proteoglycans inhibits both collagen-induced platelet aggregation (ED50 3-10 µg/ml) and coagulation *in vitro* and *vivo* (Lassila&Jouppila STH 2014). In two baboon arterial thrombosis models APAC locally reduced platelet thrombus and fibrin formation, maintaining vessel patency. Systemic APAC prevented ischemic kidney injury in rats (Tuuminen et al. 2016).

Aims: To assess APAC's binding and localization to denuded porcine iliac and femoral artery (IA, FA) after local exposure *in vitro* and *in vivo*. APAC co-localization with von Willebrand factor (VWF), laminin, podocalyxin, and PECAM was studied.

Methods: We used 3 models of injury: 1) *in vitro*, 2) *in vivo* repeated balloon angioplasty of IA, and 3) *in vivo* arterio-venous fistula (AVF) between FA and vein. In all models biotinylated APAC (0.5 mg/ml) reacted with vessel injury site for 2 min, prior to release of blood flow. APAC was detected using streptavidin conjugated to eFluor660, and VWF, Laminin, PECAM and podocalyxin by Immunofluorescence using a confocal microscope.

Results: APAC bound *in vitro and vivo* both to balloon-injured arteries and AVF at anastomosis and the adjacent artery and vein co-localizing with VWF, and laminin. APAC binding was limited when PECAM or podocalyxin was present. APAC-VWF and APAC-Laminin Manders' co-localization coefficients (MCC) were > 0.7 indicating strong co-localization. APAC-PECAM MCC was < 0.3 indicating weak co-localization. APAC penetrated the injured vessel wall and in AVF, leakage of APAC in the venous extravascular tissue was depicted.

Conclusions: APAC, in contrast to heparins, strongly inhibits collagen-platelet aggregation and subsequent coagulation and rapidly targets the injured vessel wall. APAC co-localized with multiple matrix components, excluding PECAM and podocalyxin. Cardiovascular interventions benefit from APAC's antithrombotic potential and local integration to vascular injury sites.

PB 1630 | Protein Kinase C-Dependent Loss of Tissue Factor by Human Pericytes Results from Altered Synthesis, Trafficking and Degradation

M. Hoffman[1], L. Sommerville[1], D. Monroe[2]

[1]*Duke University, Pathology, Durham, United States,* [2]*University of North Carolina at Chapel Hill, Medicine/Hematology, Chapel Hill, United States*

Background: Tissue factor (TF) exerts procoagulant and signaling activities that contribute to hemostasis, angiogenesis and immune responses. Conversely, increased TF expression is linked to the progression of malignancy, vascular disease and thrombosis. Many mediators of TF up-regulation have been described. However, we reported the first example of active downregulation of TF around angiogenic vessels near healing cutaneous wounds.

Aims: The aim of the current study was to characterize mechanisms that down-regulate pericyte TF, with the ultimate goal of therapeutically modulating TF expression.

Methods: Similar to dermal pericytes *in vivo*, cultured pericytes express high levels of TF. We previously reported that TF antigen is lost within 8 hours of exposure to phorbol-12 myristate 13-acetate (PMA), and remains low for at least 24 hrs. Cell surface TF activity does not decline as rapidly as total TF protein. This model recapitulates the loss of TF antigen following wounding *in vivo*. We assessed changes in TF mRNA by qRT-PCR and TF protein expression by western blotting in cultured human pericytes.

Results: TF mRNA decreased 4- and 6-fold at 8 and 12 hours after addition of PMA ($p < 0.01$) and remained low for 24 hrs. Inhibitors of

Protein Kinase C (PKC), Go6983 and GFX, inhibited PMA-induced reduction of TF mRNA ($p< 0.001$) and protein ($p< 0.001$). Since the decrease in TF mRNA did not precede the loss of protein, we also examined the role of protein degradation. PMA triggered internalization of surface TF, and shortened the half-life from 11 to 5 hours ($p< 0.001$). Inhibitors of lysosome and proteasome activity each reduced the decrease in TF in response to PMA. Confocal microscopy confirmed the pattern of TF trafficking suggested by biochemical data.

Conclusions: We propose a model in which activation of a PKC-dependent pathway triggers internalization of surface TF, which is degraded in lysosomes. Surface TF is replaced from internal stores until reduced synthesis and increased degradation deplete cellular TF protein.

PB 1631 | Design and Utility of Extracellular Matrix-embedded Microvessels to Study the Platelet-endothelium Interface

J. Zilberman-Rudenko[1], A.D. Wong[2,3], D.E. Sallee[1], S.E. Reitsma[1], C. Puy[1], T. Shirai[1], A. Mitrugno[1], P.C. Searson[2,3], O.J.T. McCarty[1,4]

[1]*Oregon Health & Science University, Biomedical Engineering, Portland, United States,* [2]*Johns Hopkins University, Department of Materials Science and Engineering, Baltimore, United States,* [3]*Johns Hopkins University, Institute for Nanobiotechnology (INBT), Baltimore, United States,* [4]*Oregon Health & Science University, Division of Hematology, Portland, United States*

Background: Under normal conditions, endothelial cells (ECs) maintain vessel patency by providing a barrier between the blood and tissue space and by pacifying platelet activation and thrombin generation in the bloodstream. The breakdown of this EC barrier function is a hallmark of vascular diseases including inflammation, atherosclerosis and cancer. In sepsis, for example, the dysfunction of vascular ECs has been correlated with poorer outcomes due to hemorrhage and multi-organ failure associated with consumption of platelets and coagulation factors into clots within the microcirculation, a condition termed disseminated intravascular coagulation (DIC).

Aims: Develop an endothelialized flow chamber to study the platelet-endothelium interface.

Methods: We developed a 3D-chamber with a perfusable cylindrical microvessel embedded in an extracellular matrix (ECM) material. This platform allows for the study of the role of thrombin generation and platelet aggregation in maintaining endothelial barrier function in healthy as compared to inflamed microvessels. Incorporation of sub-endothelial matrix proteins in these 3D-microvessel devices expands the capacity of the microfluidic studies to investigate blood cell extravasation and enables the control of physical parameters such as transmural pressure and interstitial flow through the ECM.

Results: Our initial findings show that stimulation of ECs with TNFα induced platelet deposition, VWF-string formation and increased vessel permeability and vascular leak.

Conclusions: This platform may provide insight into the pathophysiology of different disease states and serve as an expedient platform for therapy design and testing.

PB 1632 | Micropatterning Induced Alterations of Endothelial Outgrowth Cells

M. Hagen, T. Van, M. Hinds

Oregon Health & Science University, Biomedical Engineering, Portland, United States

Background: Small diameter artificial vascular grafts are a critical unmet need. *In vitro* endothelialization may be a solution, however the invasiveness of endothelial cell (EC) harvest makes this impractical. In

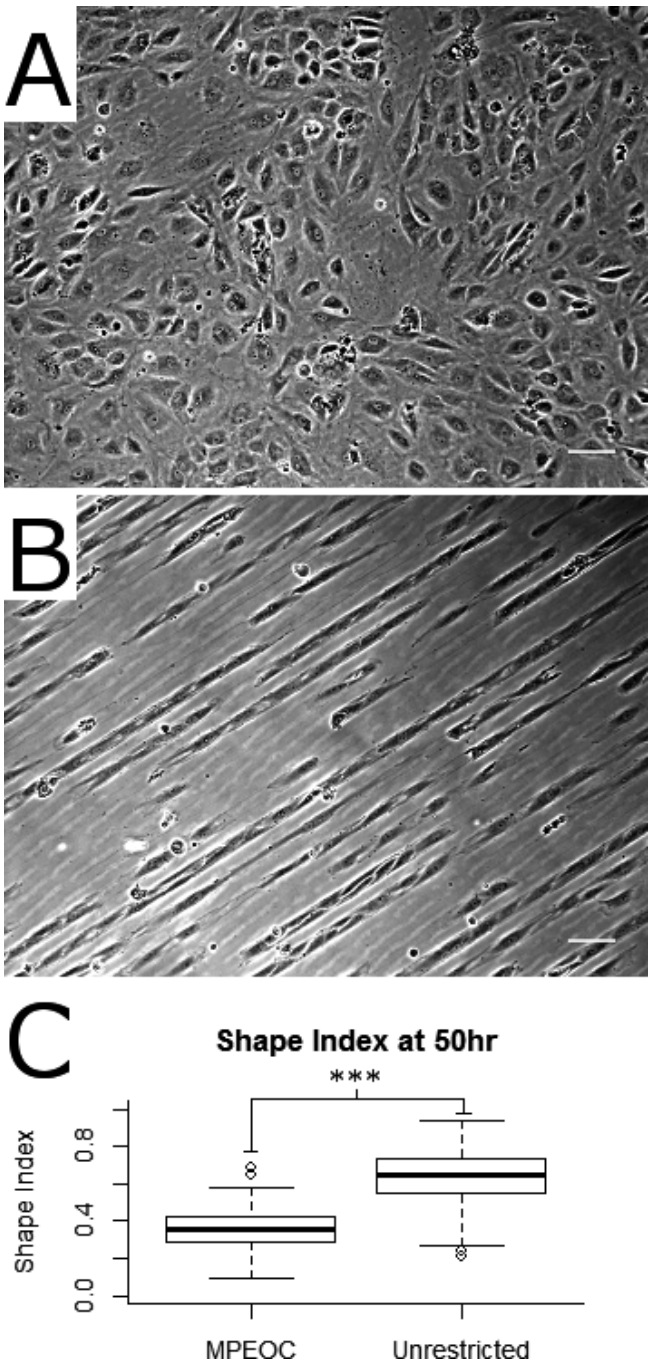

FIGURE 1 EOC patterning after 50 hrs. A) Unrestricted EOC. B) MPEOC. C) MPEOC have lower shape index than unrestricted EOC $p<.0001$. Scale bars 100μm

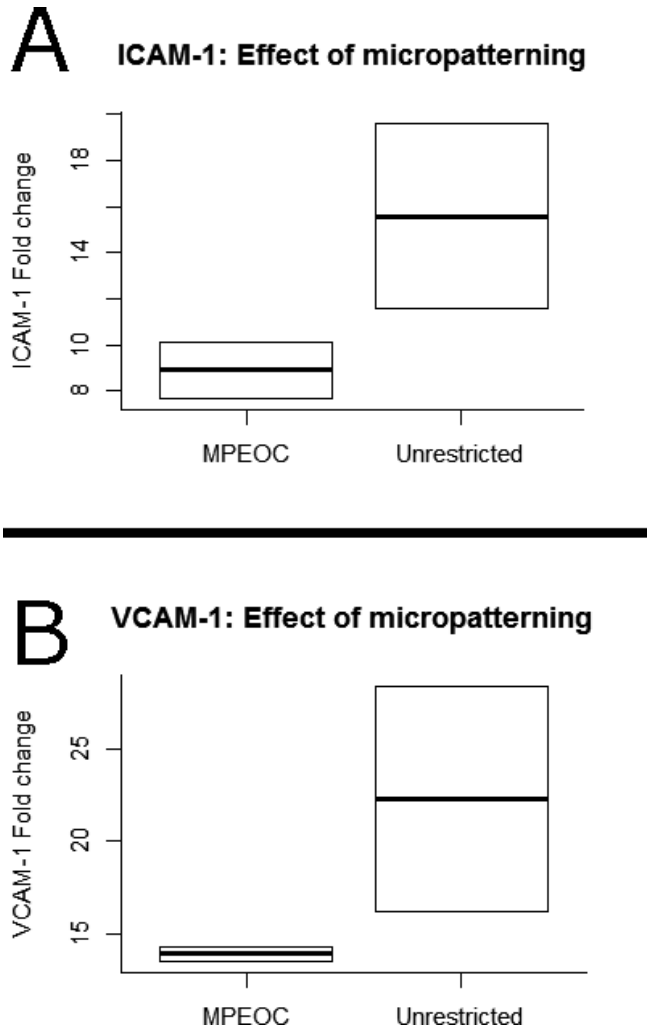

FIGURE 2 MPEOC trend toward reduced inflammatory response to TNF relative to unrestricted shown by A) ICAM-1 gene expression; B) VCAM-1 gene expression.

contrast, endothelial outgrowth cells (EOCs) are isolated with a simple venous blood draw. Like ECs, EOCs respond to flow. Static micropatterning of ECs drives elongation and immunoresistance without flow. Hence, micropatterning is considered a promising tool to alter EC phenotype. To date, attempts at EOC micropatterning have failed, thus it is unclear whether they respond similarly.

Aims:

1. Validate a novel EOC micropatterning procedure.
2. Define micropatterned EOC (MPEOC) immunogenicity to address the hypothesis that MP confers immunoresistance.

Methods: Surfaces were patterned with 25μm lanes of collagen-I and Pluronic. EOCs were seeded on patterned or unrestricted surfaces for 48 hrs. Cultures were treated with tumor necrosis factor α (TNF) for 3 hrs and collected for qPCR. EOCs were imaged at 22 and 50 hrs after seeding. A shape index (SI) quantifying cell roundness (1= circle; 0= line) was calculated. qPCR data were ΔΔ-ct calculated. SI data were analyzed using repeated measures ANOVA, while qPCR data were analyzed using two-way ANOVA.

Results: MPEOCs remained in lanes for 50 hours (Fig. 1B). SI showed significant elongation (Figure 1C, $p < .0001$), and increasing elongation over time ($p < .0001$). Preliminary qPCR showed no significant changes as a result of micropatterning, however a trend toward reduced expression of the adhesion molecules ICAM-1 and VCAM-1 was seen in TNF-treated MPEOCs relative to TNF-treated unrestricted EOCs (Figure 2).

Conclusions: EOC patterning was robust with our novel procedure. There was a trend toward decreased EOC immunogenicity with micropatterning which will be clarified in further work. EOC patterning is feasible and may be a promising tool for graft development.

PB 1633 | Endothelial Dysfunction in Idiopathic Thromboembolism Investigated through Gene Expression Profiling of Endothelial Colony Forming Cells

C. Lodigiani[1], F. Calcaterra[2], P. Ferrazzi[1], L. Libre'[1], E. Banfi[1], C. Carenza[3], D. Mavilio[2,3], S. Della Bella[2,3]

[1]Humanitas Research Institute, Thrombosis and Haemorragic Diseases Center, Rozzano, Italy, [2]Humanitas Clinical and Research Center, Laboratory of Clinical and Experimental Immunology, Rozzano, Italy, [3]University of Milan, Department of Medical Biotechnologies and Translational Medicine (BioMeTra), Milan, Italy

Background: Endothelial integrity is essential to prevent thrombosis. Endothelial colony-forming cells (ECFCs) are bone-marrow-derived cells involved in homeostasis.ECFCs isolated and cultured from peripheral blood allow an endothelial functional assessment.ECFCs from patients with idiopathic venous thrombosis (ITE) present premature cell senescence.We analyzed the gene expression profiling of ECFCs in ITE patients.

Aims: To assess if endothelial abnormalities could have a role on the pathogenesis of ITE.

Methods: ECFCs isolated and cultured from the peripheral blood of 8 patients and 5 matched controls. ECFCs were used to analyze gene expression profiling.Total RNA was isolated and reverse-transcribed cRNA was hybridized onto Illumina HumanHT-12v4 Expression BeadChip arrays.Gene Set Enrichment Analysis (GSEA) was used to interpret gene expression data.

Results: More than 4000 gene sets collected in GSEA database were analyzed: 8 gene sets resulted significantly enriched in patients, 200 gene sets resulted significantly down-regulated (false discovery rate < 10%, nominal p value < 0.01).The gene sets enriched in patients comprised the gene set composed by genes typically up-regulated by enhancer of zeste homolog 2 (Ezh2),a methyltransferase involved in the epigenetic regulation of endothelial cells functions.The gene set composed by genes typically repressed by Ezh2 resulted down-regulated in ITE patients,thus indicating an higher activity of Ezh2 in patients.The gene sets down-regulated in patients also included the Weigel oxidative stress response gene set,involved in cell response to oxidative stress.

Conclusions: Our results demonstrate ECFCs from ITE patients differ from control ECFCs in their gene expression profiling confirming that ECFC characterization can be a valid non-invasive tool to evaluate endothelial compartment.Other experiments clarifying the role of Ezh2 are needed to characterize the epigenetic dysregulation that may possibly hinder the physiologic antithrombotic function of endothelium in ITE patients.

PB 1634 | Role of Lysozyme M+ Cells in the Development of Angiotensin II-induced Vascular Inflammation

J. Lagrange[1], S. Kossmann[1,2], T. Münzel[2], W. Ruf[1,3], P. Wenzel[1,2]

[1]Center for Thrombosis and Hemostasis (CTH), University Medical Center Mainz, Johannes Gutenberg-University, Mainz, Germany, [2]Center for Cardiology - Cardiology 1, University Medical Center Mainz, Mainz, Germany, [3]The Scripps Research Institute, Department of Immunology and Microbiology, La Jolla, United States

Background: Multicellular interactions of platelets, leukocytes and the vessel wall play pivotal roles in activating coagulation and precipitating thrombosis, but also in promoting vascular dysfunction. We uncovered a coagulation-inflammation circuit through factor XI (FXI)-thrombin amplification loop that promotes vascular dysfunction highlighting the possible utility of FXI-targeted anticoagulant in treating hypertension. The role of $LysM^+$ cells (myelomonocytic cells) and their interaction with platelets during adhesion to the vascular endothelium is not completely understood.

Aims: We wanted to explore the role the interaction of $LysM^+$ cells and platelets in the development of angiotensin II (AngII)-induced vascular dysfunction.

Methods: IRG transgenic double-fluorescent mice with widespread expression of red fluorescence and GFP expression in $LysM^+$ cells were infused with AngII (1 mg× kg^{-1}× d^{-1} for 7 days using osmotic minipumps) and $LysM^+$ cells rolling in carotids were quantified using intravital videomicroscopy imaging.

Results: We were able to confirm that rolling and adhering cells were only $LysM^+$ cells with injection of acridine orange thought jugular catheter in order to mark nucleated cells, but were not able to see platelet-Leukocyte-complex formation during the time of recording. It is also interesting to note the catheter implantation increases the number of rolling and adhering $LysM^+$ cells showing here the importance of having available double transgenic mice model with expression of red fluorescence and GFP to not interfere with *in vivo* processes during experimentation.

Conclusions: We showed here for the first time that AngII-activated cells rolling and adhering to the endothelium are LysM+ cells. Further investigations are needed to explore the exact role of platelets in these processes.

PB 1635 | The Response of HUVEC to Prolonged Shear Stress for Use in in vitro Studies

B. Apta, C. Arnold, L. Huang, M. Harper

University of Cambridge, Department of Pharmacology, Cambridge, United Kingdom

Background: Endothelial cell (EC) activation and leukocyte recruitment are key events in inflammation and thrombosis. Studying EC *in vitro* has led to important insights into these processes. Many experiments have used EC cultured under static conditions. However, EC experience continuous shear stress *in vivo*. Subjecting EC to shear stress for up to 24h has been shown to modulate the expression of cell adhesion molecules involved in leukocyte adhesion and migration, including intracellular adhesion molecule-1 (ICAM-1) and vascular cell adhesion molecule-1 (VCAM-1), in response to inflammatory stimuli. The effect of more prolonged culture under shear stress has been less well characterised.

Aims: We aimed to establish the optimal time for exposure of EC to arteriolar shear stress prior to experimentation, and examine the response of these EC to TNF-α.

Methods: Human umbilical vein EC (HUVEC) were cultured under unidirectional laminar flow at a shear stress of 12dyn/cm^2 for 24h or 72h, followed by treatment with 100U/ml TNF-α for 4h. EC were stained for f-actin and vascular endothelial (VE)-cadherin, and morphology was assessed using fluorescence microscopy. ICAM-1 and VCAM-1 surface expression was measured by flow cytometry.

Results: EC cultured at 12dyn/cm^2 demonstrated cellular alignment and f-actin organisation in the direction of flow after 72h. This was not readily apparent after 24h at 12dyn/cm^2, suggesting that prolonged culture under shear stress induced further phenotypic changes. TNF-α increased ICAM-1 and VCAM-1 expression following static culture or 24h at 12dyn/cm^2. The TNF-α-induced increase in VCAM-1 expression was suppressed following 24h culture under shear, although no differences were observed in ICAM-1 expression between static and shear conditions.

Conclusions: These data suggest that prolonged exposure of EC to shear stress promotes further changes in phenotype, as despite suppressing VCAM-1 expression in response to TNF-α, 24h preconditioning was insufficient to induce complete EC alignment.

PB 1636 | Serum Sphingosine-1-phosphate is Not Associated with Age and Gender but with Blood Cell-related Parameters: Analysis of the Study of Health in Pomerania Cohort

E. Moritz[1,2], D. Wegner[3], S. Groß[2,4], M. Bahls[2,4], M. Dörr[2,4], S.B. Felix[2,4], T. Ittermann[2,4], S. Oswald[3], M. Nauck[2,4], N. Friedrich[2,4], R.H. Böger[5,6], G. Daum[5,6], E. Schwedhelm[5,6], B.H. Rauch[2,3]

[1]*University Medicine Greifswald, Institute of Pharmacology, Greifswald, Germany,* [2]*German Center for Cardiovascular Research (DZHK), Partner Site Greifswald, Greifswald, Germany,* [3]*University Medicine Greifswald, Germany, Institute of Pharmacology, Greifswald, Germany,* [4]*University Medicine Greifswald, Greifswald, Germany,* [5]*University Medical Center Hamburg-Eppendorf, Hamburg, Germany,* [6]*German Center for Cardiovascular Research (DZHK), Partner Site Hamburg/Kiel/Lübeck, Hamburg, Germany*

Background: The platelet-derived sphingosine-1-phosphate (S1P) is a bioactive signaling lipid involved in numerous biological processes such as inflammatory and immunomodulatory responses as well as vascular homeostasis. The secretion of S1P from platelets is dependent on the formation of thromboxane and the subsequent activation of the thromboxane receptor. S1P does not only play a role as mediator but also as a biomarker for cardiovascular pathologies as altered concentrations in serum are associated with coronary disease, peripheral artery disease and carotid stenosis.

Aims: To date, no reference intervals for S1P have been defined in a population-based and well characterized study cohort. The present study aimed to determine a reference range for serum S1P. We also investigated associations between individual S1P concentrations and age, gender as well as blood cell-related parameters.

Methods: We determined reference intervals for serum S1P levels according to age and gender in a sample of 1,339 healthy participants of the Study of Health in Pomerania (SHIP)-TREND cohort. Subjects with cardiovascular disease, diabetes mellitus, hypertension, metabolic syndrome, elevated liver enzymes, chronic kidney disease stadium III or IV, or body mass index > 30 kg/m^2 were excluded. S1P was measured using a liquid chromatography-tandem mass spectrometry method.

Results: The median age of the participants was 41 (25th; 75th percentile 32; 51) years and 65% were women. The median concentration of serum S1P was 0.804 (0.694; 0.920) µmol/L. No association of age and gender with S1P was observed. The overall reference interval was 0.534-1.242 µmol/L (2.5th; 97.5th percentile). S1P levels were significantly correlated with platelet numbers (R=0.28) but not with red (0.09) or white blood cell counts (0.11).

Conclusions: This study provides reference intervals for serum S1P in healthy individuals. Total serum S1P concentrations vary among healthy individuals irrespectively of age and gender but they correlate with platelet numbers.

PB 1637 | Plasma Modification of Poly(Vinyl Alcohol) for Enhanced Endothelialization and Anti-thrombogenicity

P. Jurney[1], D. Anderson[1], M. Hagen[1], E. Yim[2], M. Hinds[1]

[1]*Oregon Health and Science University, Portland, United States,* [2]*University of Waterloo, Waterloo, Canada*

Background: The interaction between a biomaterial and the constituents of blood flow are critical to the long-term patency and integrity of vascular grafts. Poly(vinyl alcohol) (PVA) is under investigation as a material for vascular grafts due to its tunable mechanical properties, non-thrombogenic surface, and amenability to luminal surface modifications. However PVA, by virtue of its inherent surface composition, discourages the migration of endothelial cells and ultimately prevents the considerable long-term benefits of endothelialization *in vivo*. Plasma treatment of the luminal surface of PVA grafts offers the opportunity to promote cell migration while maintaining or enhancing the desirable mechanical properties and non-thrombogenicity of PVA as a vascular graft.

Aims:

- Systematically evaluate plasma treatments of PVA and characterize elemental changes in surface composition in order to establish critical guidelines toward the creation of a long-term, small diameter, artificial graft.
- Determine the relationship between amide density and cell migration.

Methods: Dry PVA films were placed in a plasma chamber with either 0_2, N_2, or Ar gas to treat the films for 0.5, 1, and 5 min. The composition of the films was interrogated using x-ray photoelectron spectroscopy (XPS). Surface topography was investigated using AFM, SEM, and ESEM. Contact angle measurements were also performed to quantify the change in hydrophobicity of the films.

Results: Figure 1 shows the percent composition of PVA films without plasma treatment and with exposure to 0_2 and N_2 plasma. The results show that with this plasma treatment, nitrogen present on the surface of the film (Figure 1 insert) increases from a negligible percentage to 5.2%.

Conclusions: The increase in nitrogen content of the plasma-treated PVA surface indicates the presence of amine and amide groups critical for integrin binding. An increase in binding sites should increase cell migration and thus native endothelialization of PVA vascular grafts improving their long-term patency.

PB 2415 | Thioredoxin Interacting Protein Endothelial Deletion Protects from Alterations of Angiogenic Process in Adult Mice Submitted to Vascular Accelerated Aging

A. Domingues[1], B. Dizier[1], P. Gaussem[1,2], C. Boisson-Vidal[1], V. Nivet-Antoine[1,3]

[1]Université Paris Descartes / Sorbonne Paris Cité, UMRS 1140, Paris, France, [2]AP-HP Hôpital Européen G. Pompidou, Hématologie biologique, Paris, France, [3]AP-HP Hôpital Necker-Enfants Malades, Biochimie, Paris, France

Background: Endothelium plays a central role in angiogenesis and the ability to limit ischemic complications.Yet, aging endothelial cells become pro-oxidative, pro-inflammatory leading to endothelial dysfunction that can impair angiogenesis.

Aims: We have developed a model of vascular accelerated aging consisting in a 3 month High protein-Low carbohydrate (HP-LC) diet given to 6 month old mice. This model induced endothelial dysfunction. We also generated EC-TXNIP KO mice on the Cdh5-cre background and demonstrated that they were protected from endothelial dysfunction induced by 3-month HP-LC diet.

In this work, we hypothesized that HP-LC diet would induce a defect of angiogenesis and that endothelial TXNIP deletion might provide protection against aged-impaired angiogenesis.

Methods: EC-TXNIP KO mice and littermate controls were submitted or not to3 month HPLC diet. Angiogenic process was studied *in vivo* with the hindlimb ischemia model using near infrared Laser Doppler Imager; microCT scans and in *vitro* assays. The aortic ring assay was used for an ex *vivo* approach.

Results: After surgery, the perfusion was measured at days 0, 3, 7, 14 and 21 and showed a lower decrease of blood flow after 3 month of HP-LC diet in EC-TXNIP KO mice compared with littermate controls. Blood flow recovery was correlated with collateral formation *in vivo*. These results were associated with a protection against inflammation cells and adipocytes infiltration, myofibers necrosis. Sprouting angiogenic responses on Matrigel were assessed with the aortic ring assay. Endothelial TXNIP deletion prevents from vessel area and number of endothelial microvessel sprouts HP-LC-induced-decrease. A lowering of decreased VEGF pathway in gastrocnemius and aorta was observed in EC-TXNIP KO mice compared with littermate controls.

Conclusions: This work shows a defect in angiogenic process with ischemic damage in a vascular aging model and demonstrate the key role of TXNIP in these impairments, making TXNIP a potential therapeutic target in aging context.

PB 2416 | FHL2 is Important for Angiogenesis and Regulates TF Expression in Normal Vasculature

C. Kroone, H.H. Versteeg

Leiden University Medical Center - Department of Thrombosis and Hemostasis, Einthoven Laboratory for Experimental Vascular Medicine, Leiden, The Netherlands

Background: Four and a Half LIM domain 2 (FHL2) is a multifunctional adaptor protein with numerous binding partners. FHL2 is abundantly expressed in the cardiovascular system and has been proposed to modulate angiogenesis. Since Tissue Factor (TF) and Factor VIIa (FVIIa) also regulate angiogenesis, we hypothesized that FHL2, TF and FVIIa cooperate in the formation of new blood vessels.

Aims: To investigate the effects of FHL2 silencing on TF, FVIIa and angiogenesis.

Methods: We performed *ex vivo* angiogenesis assays with aortic explants from *Fhl2*-deficient ($Fhl2^{-/-}$) and C57BL/6 wild-type (WT) mice. Embedded in collagen, explants were fed with growth medium containing vascular endothelial growth factor (VEGF) and treated with mouse FVIIa (mFVIIa). *In vitro* angiogenesis assays were performed on stably transduced immortalized human endothelial cells (ECRFs). Levels of TF and several angiogenic markers were measured by qPCR and western blot.

Results: Sprout formation was significantly reduced in $Fhl2^{-/-}$ explants. Addition of mFVIIa increased the mean number of sprouts for both $Fhl2^{-/-}$ and WT. Knockdown of FHL2 in ECRFs reduced tube formation, cell migration and angiogenic markers *in vitro*. Paradoxically, silencing of FHL2 also upregulated expression of TF both *in vivo* and *in vitro*. Overexpression of FHL2 increased formation of tubes and angiogenic markers, while it had no impact on migration, nor did it change TF levels in ECRFs.

Conclusions: Silencing of FHL2 led to impaired angiogenesis and increased TF levels. Despite the abundance of endogenous TF in $Fhl2^{-/-}$ explants, addition of mFVIIa did not rescue the antiangiogenic phenotype.

PB 2417 | MiRNA-21 Mediates the Antiangiogenic Activity of Metformin through Targeting PTEN and SMAD7 Expression and PI3K/AKT Pathway

M. Luo, X. Tan, J. Wu

Southwest Medical University, Luzhou, China

Background: Metformin, an anti-diabetic drug commonly used for type 2 diabetes therapy, is associated with anti-angiogenic effects in conditions beyond diabetes.

Aims: miR-21 has been reported to be involved in the process of angiogenesis. However, the precise regulatory mechanisms by which the metformin-induced endothelial suppression and its effects on miR-21-dependent pathways are still unclear.

Methods: Bioinformatic analysis and identification of miR-21 and its targets and their effects on metformin-induced antiangiogenic activity were assessed using luciferase assays, quantitative real-time PCR, western blots, scratch assays, CCK-8 assays and tubule formation assays.

Results: In this study, miR-21 was strikingly downregulated by metformin in a time- and dose-dependent manner. miR-21 directly

targeted the 3'-UTR of PTEN and SMAD7, and negatively regulated their expression. Overexpression of miR-21 abrogated the metformin-mediated inhibition of endothelial cells proliferation, migration, tubule formation and the TGF-β-induced AKT, SMAD- and ERK-dependent phosphorylations, and conversely, down-regulation of miR-21 aggravated metformin's action and revealed significant promotion effects.

Conclusions: Our study broadens our understanding of the regulatory mechanism of miR-21 mediating metformin-induced anti-angiogenic effects, providing important implications regarding the design of novel miRNA-based therapeutic strategies against angiogenesis.

PB 2418 | Role of SerpinE2 (PN-1) in Diabetic Microangiopathy

L. Idir, K. Aymonnier, Y. Boulaftali, M. Jandrot-Perrus, M.-C. Bouton, V. Arocas

INSERM U 1148, Paris, France

Background: Angiogenesis deregulation is involved in many diabetic complications, in particular retinopathy and nephropathy, in which it is excessive and deleterious. Angiogenesis is highly regulated by a balance between pro- and anti- angiogenic factors, including proteases and protease inhibitors involved in vascular remodelling. SerpinE2, or protease nexin-1 (PN-1), is a protease inhibitor belonging to the serpin family, expressed by vascular and inflammatory cells. We recently demonstrated a significant anti-angiogenic effect of PN-1. In particular, data obtained in vivo using PN-1 deficient mice (PN-$1^{-/-}$) have shown that PN-1 is involved in the regulation of retinal vascular development.

Aims: We therefore hypothesize that PN-1 could modulate diabetic microangiopathies through regulation of angiogenic responses.

Methods: In this study, we used the mouse model of streptozotocin-induced type 1 diabetes to assess the role of PN-1 in the development of diabetic retinopathy and nephropathy.

Results: Neither WT, nor PN-$1^{-/-}$ diabetic mice showed any sign of retinopathy, even after 6 months of hyperglycemia. However, our results show that PN-1 may play a protective role in diabetic nephropathy. Indeed, PN-$1^{-/-}$ diabetic mice presented histological features of an aggravated nephropathy as well as an increased albuminuria, compared to WT mice. Using transgenic mice expressing beta-galactosidase under PN-1 promoter, we observed by X-Gal staining that PN-1 was essentially expressed in kidney vessels and glomeruli and that PN-1 expression was greatly increased during diabetes.

Isolectin labelling of kidney sections indicated that diabetes induced an increase of glomerular vascularisation that was greatly delayed in PN-$1^{-/-}$- compared with WT- diabetic mice, suggesting that PN-1 play a protective role in kidney.

Conclusions: In conclusion, our results indicate that PN-1 play a role in the development of diabetic nephropathy by a mechanism that remains to be established.

PB 2419 | Human Aortic Valvular Interstitial Cells: Evidence of Vasculogenic Potential during Aortic Valve Stenosis

N. Gendron[1,2], M. Rosa[3], Y. Sottejeau[3], A. Blandinieres[2], E. Rossi[2], A. Cras[2,4], E. Van Belle[3], N. Bacha[2], A. Vincentelli[3], N. Nevo[2], B. Staels[3], R. Jashari[5], A. Dupont[6], P. Gaussem[1,2], S. Susen[6], D. Smadja[1,2]

[1]Hopital Européen Georges Pompidou, Hematology, Paris, France, [2]Université Paris Descartes, Sorbonne Paris Cité, UMR_S1140, Paris, France, [3]Institut Pasteur de Lille, Inserm UMR 1011, Lille, France, [4]Hôpital Saint Louis (AP-HP), Cell Therapy Departement, Paris, France, [5]European Homograft Bank, c/o Military Hospital Queen Astrid, Cardiac Surgery, Brussels, Belgium, [6]CHU Lille, Hematology Transfusion, Lille, France

Background: Calcific Aortic valve disease (CAVD) is the most common heart valve disease in the world. Normal adult aortic valve (AV) is thin and avascular, however during CAVD a neoangiogenesis process is observed. Valvular interstitial cells (VICs) are the main cells found in AV and are responsible of valve integrity.

Aims: The purpose of this study was to examine whether VICs are progenitor cells able to modulate newly formed vessels in CAVD.

Methods: VICs were isolated from human aortic valves obtained after surgery for AVD (Pathological VICs: VICp) and normal aortic valve unsuitable for grafting and without any detected cardiac pathology (Control VICs: VICc).

Results: VIC's mesenchymal phenotype was confirmed by a $CD90^+$/$CD44^+$ expression and a multipotential differentiation potential. We injected VICp *in vivo*, in combination with endothelial progenitor cells (EPCs) in a Matrigel implant mouse model and found that VICp formed microvessels by differentiating in perivascular cells. VIC_p perivascular differentiation was confirmed *in vitro*. VIC_p are not able to undergo endothelial differentiation *in vivo* and *in vitro*. We found that conditioned media from VICp *vs* VICc were able to induce EPC proliferation. We then applied a comparative whole genomic transcriptomic approach of human VICp and VICc. Among angiogenic genes differentially expressed in VICp *vs* VICc, we observed an imbalance between ANG-2 gene (-3.51 fold VICp vs VICc) and VEGF-A (2.02 fold VICp *vs* VICc). Only VEGF-A modulation has been confirmed at the protein level in conditioned media from VICp *vs* VICc. VEGF-A blocking abolished proliferative effect of VICp.

Conclusions: In conclusion, VICs are vasculogenic progenitor cells with pericyte differentiation ability. We shown that VICp release VEGF-A and promote neovascularization during CAVD. Our findings provide evidence that blocking VEGF-A could have a pivotal role in maintaining valvular normal function by preventing angiogenesis that may lead to CAVD.

PB 2420 | Nestin Is an Endothelial Enriched Protein in the Nonproliferative Vasculature with Potential Role in Endothelial Apoptosis

P. Dusart[1,2], L. Fagerberg[1], B. Hallström[1], M. Uhlén[1], M. Civelek[3], M. Germain[4], P. Morange[5], D.-A. Tregouet[4], T. Renné[2,6], J. Odeberg[1], L. Butler[2,6]

[1]*Science for Life Laboratory, Kungliga Tekniska Högskolan (KTH), Stockholm, Sweden,* [2]*Karolinska Institutet, Clinical Chemistry, Department of Molecular Medicine and Surgery, Stockholm, Sweden,* [3]*University of Virginia, Department of Biomedical Engineering, Charlottesville, United States,* [4]*Sorbonne Universités, UPMC Univ. Paris 06, Team Genomics and Pathophysiology of Cardiovascular Diseases, Paris, France,* [5]*Aix-Marseille University, Nutrition, Obesity and Risk of Thrombosis, Marseille, France,* [6]*University Medical Centre Hamburg-Eppendorf, Institute for Clinical Chemistry and Laboratory Medicine, Hamburg, Germany*

Background:

- Known endothelial cell (EC) markers were used to seed a correlation analysis of RNAseq data from 124 individuals to search for novel endothelial genes
- One of the novel EC specific genes identified was the cytoskeletal protein nestin
- Nestin is an intermediate filament protein thought to only be expressed in proliferating cells, such as stem cells and angiogenic endothelium

Aims: To characterise nestin expression and function in nonproliferative human adult endothelial cells

Methods:

- Correlation analysis using RNAseq data from 124 healthy individuals
- Immunohistochemistry (IHC) and immunofluorescence (IF) staining alongside siRNA and qPCR to confirm gene and protein expression
- Live time lapse microscopy and annexin V/PI staining

Results:

- Nestin RNA transcripts from human tissues are positively correlated with endothelial markers such as CD34 and von Willibrand factor(VWF), and have negative correlation with proliferative markers such as PCNA and Ki-67
- IHC staining of human adult tissues shows endothelial specific nestin expression, with no concurrent endothelial staining of proliferative markers such as PCNA, indicating a nonproliferative state
- IF staining of *in vitro* cultured EC shows nestin forming a large perinuclear clump when cultured under static conditions, but spreading out to form a cell-wide filamentous network under flow conditions
- Annexin V/PI assays indicate that EC with siRNA inhibited nestin expression have increased rates of apoptosis after TNF stimulation

Conclusions:

- In contrast to previous assumptions, endothelial nestin expression is not confined solely to angiogenesis as previously thought, but is expressed in the majority of EC throughout the human adult

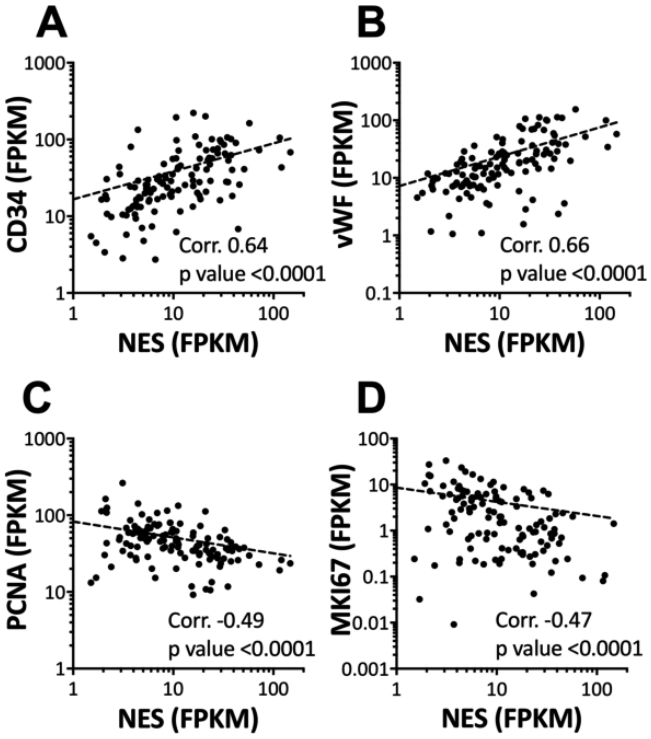

FIGURE 1 Correlation of nestin FPKM values with endothelial markers (A)CD34 and (B)VWF, and with proliferation markers (C) PCNA and (D)Ki-67

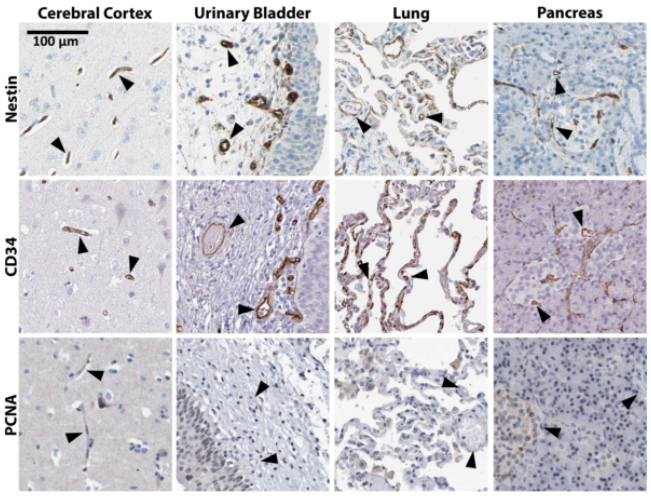

FIGURE 2 IHC stained tissue samples showing EC staining of nestin and the endothelial marker CD34, but not the proliferation marker PCNA

- Nestin expression is regulated by flow conditions, perhaps implying an important function in EC function under flow. This requires further study to elucidate the function of nestin in human EC
- EC with reduced nestin expression have increased rates of apoptosis after exposure to apoptotic stimuli

PB 2421 | Shiga Toxin Type 2, a Causal Agent of Hemolytic Uremic Syndrome, Improved Angiogenic and Repair Abilities of Late Outgrowth Endothelial Progenitor Cells

H.A. Mena[1], V.I. Landoni[2], P. Schierloh[2], N. Rodriguez Rodrigues[2], M. Schattner[1], G.C. Fernández[2], S. Negrotto[1]

[1]*Laboratory of Experimental Thrombosis, Institute of Experimental Medicine-CONICET, National Academy of Medicine, Buenos Aires, Argentina,* [2]*Laboratory of Inflammatory Process, Institute of Experimental Medicine-CONICET, National Academy of Medicine, Buenos Aires, Argentina*

Background: Hemolytic Uremic Syndrome (HUS), the main cause of pediatric acute renal failure, is caused by *E. coli* producing Shiga toxins (Stx) and characterized by massive endothelial damage, which is worsened by inflammation, especially in the presence of bacterial lipopolysaccharides (LPS). Endogenous regeneration of the vessel wall involves local and bone marrow-derived endothelial progenitor cells (EPC) as well as nearby mature endothelial cells (EC). Although Stx toxic effects on mature EC have been widely studied, its action on EPC and angiogenesis remain to be elucidated.

Aims: We aimed to analyze the effect of Stx alone or in combination with LPS on survival and angiogenic properties of EPC.

Methods: Human cord blood-derived late-outgrowth EPC and umbilical vein EC were cultured in cytokine-rich growth medium EGM2. Cells were sensitized with LPS for 18 h and then Stx type 2 was added for another 18 h.

Results: Nuclear morphology analysis revealed that Stx, at concentrations that are known to induce mature EC death, had no effect on EPC survival cultured in basic medium (EBM2+ 2% FBS), which undergo apoptosis only after LPS sensitization (Fig.1). Moreover, no Stx effect was observed when EPC were cultured on EGM2 (Fig.1). Stx receptor Gb3 was expressed on EPC surface and upregulated by LPS+Stx (180±12*% of control, n=3, *p< 0.05, ANOVA, flow cytometry). While EPC proliferation was not affected, ICAM-1 and E-selectin expression

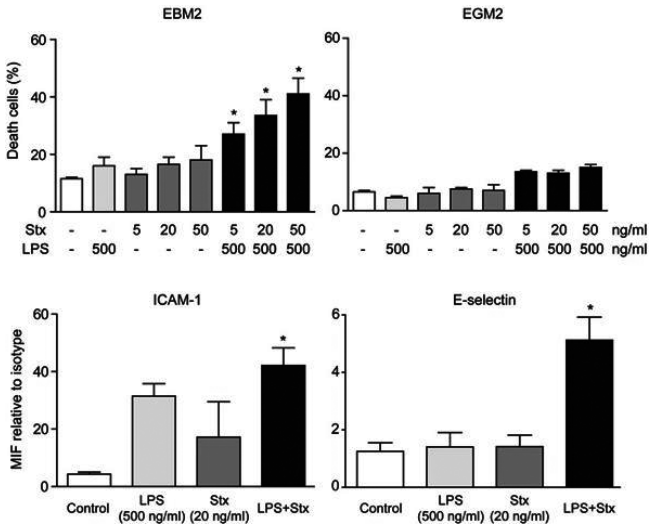

FIGURE 1 Toxicity and activation of EPC. n=3-5, *p<0.05 vs control, ANOVA

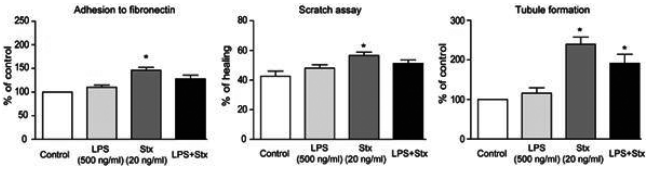

FIGURE 2 Angiogenic responses of EPC. n=4-5, *p<0.05 vs control, ANOVA

was significantly augmented by Stx on LPS-sensitized EPC (flow cytometry, Fig.1). Surprisingly and opposite to its well-known toxic effect on mature EC, Stx alone triggered EPC angiogenic functions like adhesion (pNPP assay), self-repair abilities (scratch assay) and new vessel formation (matrigel), while LPS seems to have no effect (Fig.2).

Conclusions: Our results showed that EPC not only were more resistant to Stx-mediated toxicity than mature EC, but also displayed improved angiogenic abilities, suggesting that EPC could be considered a therapeutic target to promote repair in HUS.

PB 2422 | Osteoprotegerin Promotes Tumour Development by Increasing Neovascularization

C. Boisson-Vidal[1], Z. Benslimane-Ahmim[2], A. Lokajczyk[2], B. Dizier[3], D. Heymann[4]

[1]*UMRS1140, Paris, France,* [2]*Inserm UMRS1140, Faculté de Pharmacie de Paris, Paris, France,* [3]*INSERM UMRS1140, Faculté de Pharmacie de Paris, Paris, France,* [4]*Medical School, Department of Oncology and Metabolism, Sheffield, United Kingdom*

Background: OPG is involved in ischemic tissue neovascularization through the secretion of SDF-1 by pretreated-OPG endothelial colony-forming cells (ECFCs).

Aims: As the vascularization is one of the key factor influencing the tumour growth and cancer cell dissemination, we investigated whether OPG was able to modulate the invasion of human MNNG-HOS osteosarcoma and DU145 prostate cancer cell lines *in vitro* and *in vivo*.

Methods: Cell motility was analysed *in vitro* by using Boyden chambers. Human GFP-labelled MMNG-HOS cells were inoculated in immunodeficient mice and the tumour nodules formed were then injected with OPG and/or FGF-2, AMD3100 or 0.9% NaCl (control group). Tumour growth was manually followed and angiogenesis was assessed by immunohistochemistry

Results: .*In vitro*, SDF-1 released by OPG-pretreated ECFCs markedly attracted both MNNG-HOS and DU145 cells and induced spontaneous migration of cancer cells. *In vivo*, tumour volumes were significantly increased in OPG-treated group compared to the control group and OPG potentiated the effect of FGF-2. Concomitantly, OPG alone or combined with FGF-2 increased the number of new vasculature compared to the control group. Interestingly AMD3100, an inhibitor of SDF-1, prevented the *in vivo* effects of OPG induced by SDF-1.

Conclusions: This study provides experimental evidence that OPG promotes tumour development trough SDF-1/CXCR4 axis

PB 2423 | Platelet Endothelial Aggregation Receptor-1 (PEAR1) Modulates Neoangiogenesis Via the Notch Pathway

M. Criel, K. Cludts, L. Marleen, C. Vandenbriele, L. Liesenborghs, P. Verhamme, M. Hoylaerts

KULeuven, Leuven, Belgium

Background: Tissue ischemia triggers the formation of new blood vessels from preexisting ones, a process called *sprouting angiogenesis*. This process involves endothelial cell (EC) migration, proliferation and maturation, which are tightly controlled by the Notch pathway. Recently, PEAR1 was found to modulate sprouting angiogenesis via expression regulation of PTEN, a negative regulator of EC proliferation. The molecular link between PEAR1 and PTEN is unknown, but in ECs the expression of PTEN is controlled by Notch. We hypothesized that PEAR1 indirectly influences the expression of PTEN via interaction with the Notch pathway.

Aims: This study aims to demonstrate that PEAR1 controls the expression of PTEN indirectly via the Notch pathway.

Methods: Using lentiviral vectors, PEAR1 knockdown/overexpression was introduced in human umbilical vein ECs. Next, we investigated the effect of PEAR1 knockdown/overexpression on the mRNA levels of different Notch pathway genes (HES1, HEY1, Notch1, DLL4, JAG1) and PTEN. We validated the DLL4 expression during wound healing in *Pear1*$^{-/-}$ mice with western blot.

Results: PEAR1 knockdown resulted in reduced expression of Notch1, HEY1 and mainly DLL4 (Figure 1A), genes that were less affected after PEAR1 overexpression (Figure 1B). Interestingly, the expression of PTEN followed the expression of PEAR1 both in the knockdown and overexpressing ECs (Figure 1). Moreover, during wound healing *Pear1*$^{-/-}$ mice had lower DLL4 protein levels (corrected for CD31) in the forming granuloma compared to wild type mice.

Conclusions: We identified a new link between PEAR1 and DLL4 expression in EC cultures and in a wound healing model. Further research is needed to demonstrate if expression regulation of PTEN, via the interaction of DLL4 with its receptor (Notch), is PEAR1 dependant.

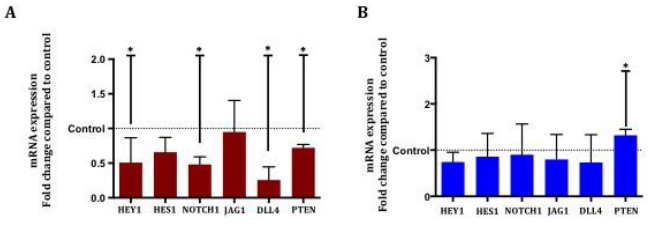

FIGURE 1 Relative mRNA expression in PEAR1 (A) knockdown and (B) overexpressing endothelial cells compared to control, for the indicated genes.

PB 2424 | Angiostatin Demonstrates Differential Hypoxic-dependent Anti-angiogenic Effects on Cardiac Endothelial Cells Derived from Non-vs Type 2 Diabetics

N. Govindasamy[1], N. Lifeso[2], P. Jurasz[1,3]

[1]*University of Alberta, Pharmacology, Edmonton, Canada,* [2]*University of Alberta, Edmonton, Canada,* [3]*University of Alberta, Faculty of Pharmacy, Edmonton, Canada*

Background: Angiostatin is a platelet-generated anti-angiogenic factor. During hypoxia, angiostatin inhibits endothelial cell (EC) matrix metalloproteinase (MMP)-2 expression and EC migration, an important early angiogenic step. Angiostatin may also impair angiogenesis by inhibiting endothelial nitric oxide synthase (eNOS) expression causing reduced NO biosynthesis and EC survival, as NO-signaling has been reported to protect ECs from apoptosis/necrosis. Angiostatin has been reported to be elevated in Type II diabetics (T2D) and NO-signaling to be reduced by T2D ECs. However, little is known about the effects of angiostatin on T2D endothelial cells during hypoxia.

Aims: To investigate the effects of angiostatin and hypoxia on cell death and the expression of angiogenic mediators by control and T2D ECs. To investigate the effects of angiostatin on angiogenesis in an *in vivo* hind limb ischemia model.

Methods: Human cardiac microvascular ECs (HMVEC-C) from non- and Type II diabetics were treated with 600nM angiostatin and incubated under hypoxic conditions. MMP-2 and eNOS levels were determined by immunoblot. HMVEC-C apoptosis/necrosis was measured via flow cytometry. Transgenic eNOS-GFP mice were injected with angiostatin (30μg) and underwent femoral artery ligation.

Results: Compared to control, angiostatin reduced MMP-2 (38±9% reduction) and eNOS (62±18% reduction) expression by hypoxic non-T2D ECs. Additionally, angiostatin induced necrosis of hypoxic T2D ECs, but not non-T2D ECs (6.98±2.1% vs non-T2D 3.03±0.3%). Administration of angiostatin reduced blood flow recovery to the ischemic limb on day 14 (30±0.08% reduction vs PBS control) along with reduced eNOS expression.

Conclusions: Our preliminary data suggests that during hypoxia angiostatin inhibits expression of angiogenesis mediating proteins by non-T2D ECs; whereas, it induces necrosis of T2D ECs. Moreover, elevated angiostatin levels reduce angiogenesis in hypoxic/ischemic tissues *in vivo*.

PB 2425 | Structural and Functional Study of Hypochlorous Acid Modified Human Antithrombin: Possible Role in Cancer

P. Ahmad, M.A. Jairajpuri

Jamia Millia Islamia, Biosciences, New Delhi, India

Background: Antithrombin (AT) is involved in many critical bio-processes like blood coagulation and inflammation. Native AT is non-antiangiogenic, however, cleaved and latent conformers of AT have been shown

to have antiangiogenic and hence, anticancer property. Any alteration in their structures and functions may cause cancer development/progression. During respiratory burst, activated phagocytes initiate the production of hypochlorous acid (HOCl) which reacts with a wide variety of bio-molecules including proteins. Excessive production of HOCl can cause tissue damage which may progress to diseases like cancer.

Aims: Effects of HOCl on structures and functions of various conformers of AT.

Methods: The purified native AT was used to make cleaved and latent forms. Various concentrations of HOCl were used to modify AT and structural/functional alterations were detected by absorbance, fluorescence and circular dichroism (CD)–spectroscopy; transmission electron microscopy (TEM), polyacrylamide gel electrophoresis (PAGE) and factor Xa inhibition assay.

Results: In PAGE, the modified native AT showed polymer formation and fragmentation, while only fragmentation took place in cleaved and latent conformers. Polymerization was further confirmed by TEM. Compared to unmodified AT, modified counterparts exhibited hyperchromicities at 278 nm. At higher concentrations of HOCl, AT showed fragmentation. A significant gradual decrease in fluorescence intensity of native AT was seen at 340 nm with increasing concentration of HOCl, while cleaved and latent conformers showed first increase and then gradual decrease in intensity. Far-UV CD results, in all the cases, showed alterations in secondary structures of AT after modification. Inhibitory activity of modified AT against protease was reduced at a concentration of HOCl that didn't initiate polymerization or fragmentation.

Conclusions: The results showed profound effects of HOCl on various conformers of AT that may have implications in cancer.

PB 2426 | Frequency of Post Thrombotic Syndrome (PTS) in Patients with Proximal Deep Venous Thrombosis (DVT) - A Prospective Observational Study from a Tertiary Care Hospital in North India

S. Varma[1], V. Suri[1], S. Kumar[1], P. Malhotra[1], N. Kalra[2], U. Gorsi[2], J. Ahluwalia[3], G. Prakash[1], A. Rani Khadwal[1], S. Kumari[1], S. Jain[1], N. Varma[3]

[1]PGIMER, Internal Medicine, Chandigarh, India, [2]PGIMER, Radiology, Chandigarh, India, [3]PGIMER, Hematology, Chandigarh, India

Background: The post thrombotic syndrome (PTS) is estimated to develop within 1 to 2 years in 20% to 50% of patients of DVT.

Aims: To investigate the frequency of PTS and the clinical indicators of PTS.

Methods: In a prospective, observational studystudy,adult adult patients with DVT of the proximal veins of lower limbs (Iliac, femoral and popliteal veins) presenting to PGIMER over 10 years (January 2005 to June 2016) who had been anticoagulated for at least six months were enrolled.Post-thrombotic syndrome (PTS) was defined in any patient with DVT with the pain and swelling of a chronic duration (occurring daily for at least 1 month) occurring 6 months or more after an episode of DVT.Patients were evaluated for symptoms and signs of PTS by using CEAP clinical scale and Villalta's scale at 0, 3 and 6 months.

Results: 210 patients (230 limbs) were enrolled in our study.198(210 limbs) and 150(162 limbs) patients were re-evaluated at 3 and 6 months.The frequency of PTS at 0, 3 and 6 months was 80.1%, 73.6% and 62.7% (CEAP clinical scale) and 51.9%, 23.5% and 25.6%(Villalta's scale).Common signs and symptoms observed among patients with PTS were pain (89.3%), cramps (35.6%), heaviness (66.8%), pruritus (22.5%), edema (80%), induration (50.4%), hyperpigmentation (35.4%), telengectesias (48.2%). Active ulceration was seen in 15 limbs (7.1%) and varicose veins were present in 35 limbs (16.6%) at enrollment. It was observed that the above signs and symptoms of PTS decreased with time with lower frequencies observed at the 3 and 6 months follow-up.Previous history of recurrent ipsilateral DVT, a BMI OF > 25 kg/m^2 ,right sided DVT at enrollment were the predisposing factors significantly associated with significantly higher frequency of PTS.

Conclusions: We observed a difference between CEAP clinical scale and Villalta's scale in diagnosing and categorizing PTS. The question is which one is better will require a gold standard against which both could be compared.

PB 2428 | Intracellular von Willebrand Factor Predominately Influences Angiogenesis

S. Selvam[1], M. Bowman[2], C. Pruss[3], P. James[1,2]

[1]Queen's University, Pathology and Molecular Medicine, Kingston, Canada, [2]Queen's University, Medicine, Kingston, Canada, [3]Queen's University, Biomedical and Molecular Sciences, Kingston, Canada

Background: Bleeding associated with angiodysplasia is a recognized complication in many patients with acquired and inherited abnormalities in von Willebrand factor (VWF). Deficiency of the largest VWF multimers has been suggested to play a role in the development of angiodysplasia but the mechanism has been unclear.

Aims: This study examines the impact of extracellular and intracellular VWF on angiogenesis using blood outgrowth endothelial cells (BOECs).

Methods: The study was approved by Queen's University REB and one healthy control gave consent for BOEC isolation. Following transfection of BOECs with Control siRNA (siCTL) or VWF siRNA (siVWF), knockdown efficiency was confirmed using confocal IF, qRT-PCR, ELISA, and western blot analysis. Recombinant VWF (rVWF; Vonvendi®) was proteolyzed by recombinant human ADAMTS13 to 75% and 50% of high molecular weight multimers (HMWM). siVWF cells were cultured in the absence or presence of 10 µg/mL of proteolyzed or unproteolyzed rVWF. Angiogenic profiles of BOECs were then characterized by migration, proliferation, and tubule formation.

Results: Relative to siCTL, siVWF inhibition of VWF gene expression (5%) and protein synthesis (0.05 ng/mg) persisted up to four days after transfection (Fig 1). Compared to siCTL BOECs, siVWF BOECs had significantly increased cell migration velocity (0.42

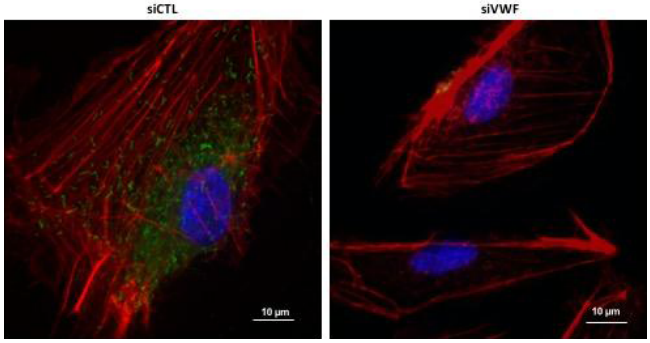

FIGURE 1 Confocal microscopy of siCTL or siVWF-treated BOECs stained for actin (red), VWF (green), and nuclei (blue)

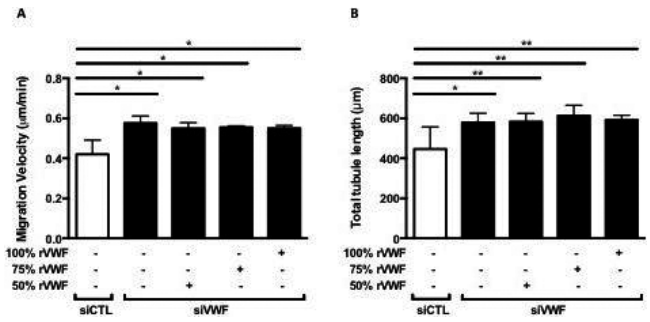

FIGURE 2 VWF-deficient BOECs display increased (A) cell migration velocity and (B) tubule formation. Error bars = mean ± SD. *P<0.05; **P<0.01

µm/min and 0.58 µm/min, respectively; P=0.04; Fig 2A), formed significantly more tubules in Matrigel (446 µm and 579 µm, respectively; P=0.04; Fig 2B), and were less proliferative (1511 cells and 1241 cells, respectively). The addition of unproteolyzed rVWF did not reverse the pro-angiogenic phenotype of siVWF BOECs. Notably, the addition of 75% and 50% HMWM rVWF to the culture media did not modify the angiogenic profile of siVWF BOECs (Fig 2).
Conclusions: Taken together, these findings highlight the importance of intracellular VWF in angiogenesis and suggest that in its absence, the multimer content of extracellular VWF does not appear to modulate the angiogenic capacity of the cell.

PB 2429 | Low Grade Inflammation Inhibits VEGF Induced HUVECs Migration in p53 Dependent Manner

M. Yamakuchi, S. Panta, T. Hashiguchi

Kagoshima University, Kagoshima, Japan

Background: In the course of studying crosstalk between inflammation and angiogenesis, high doses of pro-inflammatory factors have been reported to induce apoptosis in cells. Under normal circumstances also the pro-inflammatory cytokines are being released in low doses and are actively involved in cell signaling pathways.
Aims: Our aim is to study the effects of low grade inflammation in growth factor induced angiogenesis using tumor necrosis factor alfa (TNF*a*) and vascular endothelial growth factor A (VEGF) respectively.
Methods: Human umbilical vein endothelial cells (HUVECs) were cultured with EGM-2 media. Recombinant human TNF*a* and VEGF were used for the stimulation of HUVECs. Western blotting, ELISA assay, and immunostaining were performed as previously described. Wound healing assay and transmigration assay were used for quantifying migration of endothelial cells.
Results: We found that low dose of TNF*a* can inhibit VEGF induced angiogenesis in HUVECs. Low dose of TNF*a* induces mild upregulation and moreover nuclear localization of tumor suppressor protein 53 (P53) which causes decrease in inhibitor of DNA binding-1 (Id1) expression and shuttling to the cytoplasm. In absence of Id1, HUVECs fail to upregulate b_3-integrin and cell migration is decreased. Connecting low dose of TNF*a* induced p53 to b_3-integrin through Id1, we present additional link in cross talk between inflammation and angiogenesis.
Conclusions: Low dose TNF*a* and VEGF work in concert to upregulate P53 but the exact mechanism of how TNF*a* and VEGF together upregulate P53 has to be further studied.

PB 2430 | Oroxin A Effectively Inhibits Breast Cancer Cell-mediated Tumor Vasculogenic Mimicry

J. He, J. Wang, X. Yang, H. Qian, L. Qin

The First Affiliated Hospital of Soochow University, Suzhou, China

Background: Breast cancer is a major cause of cancer death among women. Increasing evidence has shown that breast cancer cells possess vasculogenic ability and directly form tumor blood vessel through the mechanism of vasculogenic mimicry which favors tumor growth and metastasis. Thus, vasculogenic tumor cells are sensible target for ant-tumor vasculogenic drug discovery. Although various anti-tumor angiogenic approaches have been used in the clinics to treat the disease these years, most current conventional treatment options are not well-effected and not effective to tumor cell-mediated vasculogenic mimicry.
Aims: Explored new anti-vasculogenic phytochemical derived from traditional Chinese medicinal herbs to cure breast cancer with vasculogenic ability and directly form tumor blood vessel, then figure out the mechanisms.
Methods: Using human breast cancer MDA-MB-231cells as a model, we detected the effect of Oroxin A by cell adhesion, migration, invasion, and tube-like formation in a concentration-dependent manner, followed by mRNA and protein detect to reveal the molecular mechanisms.
Results: We found that Oroxin A, an active component from the herb Oroxylum indicum, suppressed breast cancer cell-mediated vasculogenic mimicry through inhibiting breast cancer cell adhesion, migration, invasion, and tube-like formation in a concentration-dependent

manner. Mechanistic studies revealed that Oroxin A induced tumor cell mitotic catastrophe and senescence through inducing a tumor suppressive ER stress and up-regulation of P21 gene, resulting in cell cycle arrest at the G2/M transition and vasculogenic inhibition.

Conclusions: Taken together, Oroxin A effectively suppresses breast cancer cell-mediated tumor vasculogenic mimicry with low toxicity, suggesting that OA is a potential new anti-tumor neovascularization and anti-breast cancer drug candidate.

PB 2431 | Acidic preconditioning improves endothelial progenitor cell survival and angiogenesis under proinflammatory conditions and post-ischemic tissue regeneration in a murine model of type II diabetes

S. Negrotto[1], H.A. Mena[1], C. Boisson-Vidal[2], M. Schattner[1]

[1]*Institute of Experimental Medicine, CONICET-National Academy of Medicine, Laboratory of Experimental Thrombosis, Buenos Aires, Argentina,* [2]*UMR_S1140, University Paris Descartes, Paris, France*

Background: We have previously demonstrated that acidic preconditioning exacerbates angiogenic responses of human late outgrowth endothelial colony forming cells (ECFC).

Aims: We now aimed to analyze whether this strategy also improves ECFC survival and functionality in the presence of damage associated molecular patterns (DAMPs) highly augmented in ischemic milieu or in diabetes, where tissue regeneration is compromised.

Methods: Cord blood-derived ECFC in EGM2 were exposed at pH 6.6 for 6 h (preconditioned) or pH 7.4 (control) and then medium was replaced by fresh EGM2 at pH 7.4. N=4-6, *p< 0.05 vs pH 7.4, one-way ANOVA.

Results: Nuclear morphology analysis showed that several DAMPs like MSU crystals (150 mM), TNFα (50 ng/mL), histones (3 μM) or their combination induced ECFC death at pH 7.4 (30±4, 25±3, 24±3 or 52±5% of cell death), whereas a significantly lower effect was observed in preconditioned ECFC (15±3*, 5±3*, 7±2* or 18±6*%). TNFα triggered ECFC apoptosis in a concentration-dependent manner and was potentiated by high glucose, but this effect was significantly prevented by acidic preconditioning (Fig.1). When non-toxic concentrations were used, high glucose, TNFα or their combination reduced proliferation (cell count), SDF1-driven migration (transwells) and tubule formation (matrigel), whereas almost no inhibition was observed in preconditioned ECFC (Fig.1). In a murine model of type II diabetes, blood flow recovery (Doppler) after induction of hind limb ischemia was significantly improved by transplantation of preconditioned ECFC (0.79±0.04* perfusion index at 14 d post-ischemia), but not control ones (0.66±0.07), when compared with PBS-treated group (0.55±0.07).

Conclusions: Preconditioned ECFC showed improved survival and angiogenic activity in the presence of DAMPs and efficiently restored blood flow after ischemia in diabetic mice, suggesting that acidic preconditioning is an effective strategy to improve tissue regeneration despite the stressful conditions associated with inflammation and diabetes.

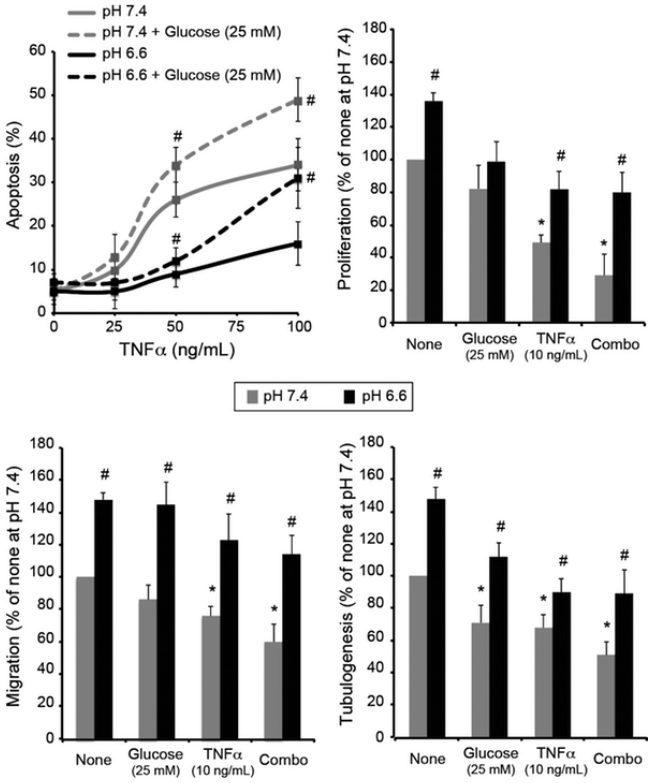

FIGURE 1 Preconditioned ECFC are more resistant to harmful effect of TNFα and high glucose. *p<0.05 vs none at pH 7.4, #p<0.05 vs same condition at 7.4

PB 2432 | Angiopoietin-2 Reduces Arteriogenesis Associated with the Suppression of the Infiltration of Macrophages in Mouse Ischemia Hindlimb Model

J. Wu, X. Tan, K. Yan

Southwest Medical University, Luzhou, China

Background: Angiopoietin-2 (Ang-2), a ligand of the Tie-2 receptor, plays an important role in maintaining endothelial cells and in destabilizing blood vessels. Collateral artery growth (arteriogenesis) is a key adaptive response to arterial occlusion.

Aims: It is unknown whether the destabilization of blood vessels by Ang-2 can affect arteriogenesis and modulate mononuclear cell function. This study aimed to investigate the effects of Ang-2 on collateral artery growth.

Methods: Hindlimb ischaemia model was produced in C57BL/6 mice by femoral artery ligation. Blood flow perfusion was measured using a Laser Doppler Perfusion Imager Quantitative RT-PCR analysis was applied to identify the level of angiogenic factors.

Results: After the induction of hindlimb ischaemia, blood flow recovery was impaired in mice treated with recombinant Ang-2 protein; this was accompanied by a reduction of peri-collateral macrophage infiltration. In addition, quantitative RT-PCR analysis revealed that Ang-2 treatment decreased monocyte chemotactic protein-1 (MCP-1), platelet-derived growth factor-BB (PDGF-BB) mRNA levels in

ischaemic adductor muscles. Ang-2 can lead to macrophage M1/M2 polarization shift inhibition in the ischaemic muscles. Furthermore, Ang-2 reduced the in vitro inflammatory response in macrophages and vascular cells involved in arteriogenesis.

Conclusions: Our results demonstrate that Ang-2 is essential for efficient arteriogenesis, which controls macrophage infiltration.

PB 2433 | Role of Circulating Endothelial Progenitor Cells at the Early-stage of Neovascularization in Post-menopausal Luminal-A-Type Breast-cancer Patients

B. Ruszkowska-Ciastek, P. Rhone, R. Wieczór, D. Rość

Faculty of Pharmacy, Nicolaus Copernicus University in Torun, Collegium Medicum, Department of Pathophysiology, Bydgoszcz, Poland

Background: Malignant diseases are the second, after heart disease, cause of morbidity and mortality worldwide.

Aims: The aim of the study has been to evaluate the number of circulating endothelial progenitor cells (CEPCs) in the blood of patients diagnosed with luminal A type breast cancer and to make an attempt at identifying associations with the number of CEPCs and selected clinicopathological factors: histological grading, hormonal status, the lump size and parity.

Methods: The study involved 74 Caucasian post-menopausal women. Forty-four women aged 48-65 (mean age of 56) with luminal A type breast cancer without distant metastasis (M0). The control group consisted of 30 healthy, non-smoking, post-menopausal women. The exclusion criteria for all the subjects were hypertension, hyperlipidaemia, hyperglycaemia, acute and chronic infection. In the whole blood samples the number of circulating endothelial progenitors was determined using flow cytometry. During the analysis the fluorescence of 100.000 cells was measured. CEPCs were identified with immunophenotype CD45-, CD31+, CD34+, CD133+.

Results: There was recorded a significantly higher number of circulating EPCs in the study group, as compared to the controls. Higher numbers of circulating endothelial progenitors were noted in the patients with luminal A-type breast cancer localised in the left breast. Additionally, there was identified a positive correlation between CEPCs and the age as well as between CEPCs and parity, as well as a negative correlation between CEPCs and the diameter of the lump as well as between CEPCs and histological breast cancer grading among luminal-A-type breast-cancer patients.

Conclusions: Based on the clinical and molecular determinants (histological grading and lump diameter), we can assume that circulating EPCs are necessary at the early-stage of breast cancer development and they can be used as a non-invasive biomarker to monitor the clinical state of patients. However, a more further study is required to confirm this thesis.

PB 2434 | Pro-Angiogenic Biomarkers are Upregulated in Patients with Advanced Osteoarthritis Undergoing Orthopedic Surgery

L. Shih[1,2], M. Rondina[1,2,3], N. Guler[4], D. Syed[4], A. Walborn[4], D. Hoppensteadt[4], J. Fareed[4]

[1]University of Utah, Molecular Medicine, Salt Lake City, United States, [2]University of Utah, Internal Medicine, Salt Lake City, United States, [3]George E. Wahlen VAMC GRECC, Salt Lake City, United States, [4]Loyola University Medical Center, Maywood, United States

Background: Angiogenesis is a central component of wound healing following surgery and may also contribute to the pathogenesis of degenerative joint disease (DJD) due to osteoarthritis (OA). OA may result in the upregulation of pro-angiogenic biomarkers from the vascular system.

Aims: We sought to examine pro- and anti-angiogenic biomarkers in patients with DJD due to OA undergoing orthopedic surgical repair.

Methods: We prospectively enrolled patients (n=25) undergoing elective total knee (TKA) or total hip (THA) arthroplasty secondary to end-stage DJD from OA. Matched healthy controls (n=48) free from DJD were included. Endogenous pro-angiogenic biomarkers (vascular endothelial growth factor (VEGF), monocyte chemoattractant protein-1 (MCP-1), and IL-8) and two anti-angiogenic factors (IFNg and IL-4) were measured using a high sensitivity biochip method.

Results: At baseline, patients with DJD had significantly higher levels of VEGF (10.5±1.2 pg/mL vs. 4.8±0.2 pg/mL, p< 0.001), MCP-1 (130.6±7.7 pg/mL vs. 88.6±3.9 pg/mL, p< 0.0001), and IL-8 (4.0±0.5 pg/mL vs. 2.6±0.1 pg/mL, p< 0.05). In patients with OA, baseline MCP-1 levels also significantly correlated with age (r^2=0.30, p=0.005). Compared to baseline values, in patients with OA, post-operative levels of VEGF (10.5±1.2 pg/mL vs. 18.8±1.5 pg/mL, p< 0.001) and MCP-1 (130.6±7.7 pg/mL vs. 153.1±11.5 pg/mL, p< 0.05) were significantly increased, with a trend towards increased IL-8 as well (4.0±0.5 pg/mL vs. 4.7±0.6 pg/mL, p=0.051). MCP-1 levels post-operatively also correlated with age in patients with OA (r^2=0.28, p=0.006).

Conclusions: In conclusion, systemic levels of the pro-angiogenic biomarkers were increased in patients with DJD at baseline compared to healthy controls and rose post-operatively while the anti-angiogenic factors IFNg and IL-4 remained unchanged. Baseline MCP-1 levels correlated positively and significantly with age, suggesting an interaction between aging and the pathophysiology of OA.

PB 2435 | VEGF-induced Angiogenesis Requires Autophagy

K. Spengler[1], N. Kryeziu[1], S. Lindenmüller[1], L.-O. Klotz[2], A.S. Mosig[3], R. Heller[1]

[1]Institute of Molecular Cell Biology, University Hospital, Jena, Germany, [2]Institute of Nutrition, Friedrich-Schiller-University, Jena, Germany, [3]Institute of Biochemistry II, University Hospital, Jena, Germany

Background: Endothelial cell functionality and integrity depends on metabolic homeostasis including the elimination of dysfunctional

organelles and proteins. Autophagy is a lysosomal degradation pathway known to regulate homeostasis in different cell types. However, its role in endothelial cells is incompletely understood.

Aims: This study was aimed at identifying the implication of autophagy in regulating endothelial functions and angiogenesis.

Methods: Experiments were performed in human umbilical vein endothelial cells with or without genetic or pharmacological impairment of autophagy (siRNA against ULK1 and Beclin1 or bafilomycin A1, respectively). Parameters of cellular stress (cytokine release, GSH levels) and function (proliferation, survival, *in vitro* angiogenesis) were monitored.

Results: Inhibition of autophagy by ULK1/Beclin1-siRNA led to cytokine release, GSH depletion and reduced basal proliferation and survival indicating the contribution of autophagy to endothelial homeostasis. Endothelial cells treated with ULK1/Beclin1-siRNA maintained sensitivity to vascular endothelial growth factor (VEGF) with respect to signalling, proliferation and survival but showed decreased angiogenic sprouting. The angiogenic response was also reduced upon a mild inhibition of autophagy with bafilomycin A1, which did not affect cell survival. These data suggest a specific role of autophagy in regulating angiogenesis in addition to its homeostatic function, which is currently being unravelled. VEGF itself was able to initiate autophagy via a pathway involving AMPKα1-mediated phosphorylation of ULK1 underlining the necessity of functional autophagy for an angiogenic response.

Conclusions: Autophagy has an important homeostatic function in endothelial cells by suppressing inflammatory and oxidative stress. It is activated by VEGF, an important angiogenic growth factor, via an AMPKα1-dependent pathway, and may promote angiogenesis by maintaining endothelial functionality and affecting angiogenic pathways.

PB 2436 | G-protein Coupled Receptor 15 Mediates Angiogenesis and Cytoprotective Function of Thrombomodulin

B. Pan[1,2], X. Wang[1,2], C. Nishioka[3], G. Honda[4], L. Zeng[2], K. Xu[2], T. Ikezoe[1]

[1]*Fukushima Medical University, Fukushima, Japan,* [2]*The Affiliated Hospital of Xuzhou Medical University, Xuzhou, China,* [3]*Kochi University, Immunology, Kochi, Japan,* [4]*Asahi Kasei Pharma, Tokyo, Japan*

Background: Thrombomodulin (TM) stimulates angiogenesis and protects vascular endothelial cells (ECs) via its fifth epidermal growth factor-like region (TME5); however, the cell surface receptor that mediates the pro-survival signaling activated by TM has remained unknown.

Aims: We aimed to identify the binding partner of TM expressed on the cell surface of ECs.

Methods: Immunoprecipitation followed by MALDI-TOF MS analysis was employed to identify the cell surface receptor for TME5. Bromodeoxyuridine incorporation and apoptosis assays with annexin V staining were used to assess the effect of TME5 on proliferation and apoptosis in vascular ECs.

Results: We identified G-protein coupled receptor 15 (GPR15) as a binding partner of TME5. TME5 rescued growth inhibition and apoptosis caused by calcineurin inhibitor FK506 in vascular ECs isolated from C57BL/6 wild type (WT) mice. On the other hand, TME5 failed to protect ECs isolated from GPR15 knockout (GPR15 KO) mice from FK506-caused vascular injury. In addition, in vivo Matrigel plug angiogenesis assay found that TME5 stimulated angiogenesis in WT mice but not in GPR15 KO mice.

Conclusions: GPR15 plays an important role in mediating cytoprotective function as well as angiogenesis of TM.

PB 2437 | CCL5 and CXCL4 Are Rapidly Internalized in Endothelial Cells

A. Dickhout, T.M. Hackeng, R.R. Koenen

Maastricht University, Cardiovascular Research Institute Maastricht (CARIM), Biochemistry, Maastricht, The Netherlands

Background: Platelet-endothelial communication is essential in the recruitment of lymphocytes to the vessel wall in thrombosis and haemostasis. Chemokines are released from the alpha granules by activated platelets and are deposited on the endothelium, facilitating subsequent leukocyte arrest. The chemokine CCL5 is essential in the recruitment of monocytes, while CXCL4 by heterophilic interactions increases the monocyte arrest-promoting properties of CCL5.

Aims: To further elucidate the role of CCL5 and CXCL4 in their leukocyte arresting properties, we investigated internalization and localization of extracellular CCL5 and CXCL4 to the endothelial cell.

Methods: HUVECs and EA.hy926 cells were incubated with recombinant human CCL5 or CXCL4 for 1 up to 120 minutes. Cells were stained against CCL5/CXCL4, DAPI and f-actin, and analysed with light-, confocal- or stimulated emission depletion (STED) microscopy. To quantify internalization cell lysates were fractionalized using ultracentrifugation and analysed by ELISA.

Results: Both CCL5 and CXCL4 are rapidly internalized in endothelial cells, whereas CXCL4 is partly presented on the cell surface, all CCL5 is internalized. The chemokines are endocytosed by a process dependent on dynamin and clathrin, as internalization was inhibited by inhibitors of these processes. Cell surface proteoglycans have a less definite role in the internalization process, as enzymatic cleavage of heparin sulphate and chondroitin sulphate did not result in a decreased internalization of CCL5 and CXCL4. Coincubation of CCL5 and CXCL4 did not influence the internalization or the localization of either of the chemokines. Localization studies by confocal and super-resolution microscopy suggested that both CCL5 and CXCL4 partly have a nuclear localization which, in some cells, seem to be confined to the nucleoli.

Conclusions: Endothelial cells rapidly internalize CCL5 and CXCL4 by clathrin and dynamin dependent endocytosis, where the chemokines seem to localize diffusely through the cytosol and nucleus.

PB 2438 | Biased Activation of PAR1: Dissecting Signal Transduction Networks that Regulate the Endothelial Barrier Function

B.L. van den Eshof[1], A.J. Hoogendijk[1], P.J. Simpson[1], F.P.J. van Alphen[2], K. Mertens[1,3], A.B. Meijer[1,2,3], M. van den Biggelaar[1]

[1]*Sanquin Research, Plasma Proteins, Amsterdam, The Netherlands,* [2]*Sanquin Research, Research Facilities, Amsterdam, The Netherlands,* [3]*Utrecht Institute for Pharmaceutical Sciences (UIPS), Utrecht, The Netherlands*

Background: The barrier integrity of endothelial cells (ECs) is tightly regulated. Two key players in this process are Protease Activated Receptor 1 (PAR1) and sphingosine-1-phosphate receptor 1 (S1PR1). Activation of S1PR1 leads to a barrier-protective response in ECs, while activation of PAR1 results in either a barrier-disruptive (thrombin) or a barrier-protective response (Activated Protein C (APC)). This so-called biased activation has been attributed to differential cleavage of the PAR1 N-terminus. It remains unknown how ECs transmit these external signals and how these translate into a coordinated response.
Aims: Dissect barrier-disruptive and barrier-protective phosphoregulation in ECs and unravel biased activation of PAR1 using quantitative phosphoproteomics.
Methods: Blood outgrowth endothelial cells were metabolically labeled using SILAC and stimulated for 2/10 min with thrombin (1U/ml), APC (20nM, in presence of 1U/ml hirudin), S1PR1 agonist SEW2871 (5μM) or TL-peptides that resemble PAR1 cleavage by Thrombin (SFLLRN-NH2), APC (NPNDKYEPF-NH2), Matrix Metalloprotease-1 (PRSFFLRN-NH2), Neutrophil Protease 3 (TLDPRSF-NH2) or Neutrophil Elastase (RNPNDKYEPF-NH2) (50μM). Phosphorylated peptides were enriched using TiO_2 precipitation, detected by Orbitrap Fusion MS and analyzed using MaxQuant software.
Results: We identified and reliably quantified >4,000 phosphosites of which ± 10% were regulated. Unlike thrombin and the canonical PAR1 TL-peptide, APC and all 4 non-canonical PAR1 TL-peptides failed to induce extensive regulation at the phosphorylation level. In contrast to barrier-disruption by thrombin, barrier-protection by SEW2871 was accompanied by limited, but distinct phosphoregulation.
Conclusions: These data indicate that only canonical PAR1 cleavage by thrombin generates a tethered ligand that potently induces signaling. In addition, in ECs barrier disruption is accompanied by extensive phosphoregulation, while this seems to play a less prominent role in protection of the endothelial barrier.

PB 2440 | Major Endothelial Cell Integrin, Alphavbeta3 as a Target in Gram-negative Sepsis Caused by Urinary Tract Infection

T. McHale[1], C. Garcierena[1], S. Smith[2], F. Fitzpatrick[3,4], S. Kerrigan[1]

[1]*Royal College of Surgeons in Ireland, Irish Centre for Vascular Biology, Dublin, Ireland,* [2]*Trinity College Dublin, Clinical Microbiology, Dublin, Ireland,* [3]*Royal College of Surgeons in Ireland, Clinical Microbiology, Dublin, Ireland,* [4]*Beaumont Hospital, Clinical Microbiology, Dublin, Ireland*

Background: Urinary tract infections caused by *Escherichia coli* are one of the most common predisposing factors for sepsis and serves as the initial manifestation of the multisystem organ failure syndrome. The vascular endothelium is a major target of sepsis-induced events and endothelial activation accounts for much of the pathology of sepsis.
Aims: The aim of this study is to identify the mechanism by which *E. coli* binds to the endothelium and exerts its injurious effects.
Methods: Human endothelial cells were sheared at physiological rates. Fluorescently labelled *E. coli* were used to assess binding. Changes in vascular permeability were measured by transwell paracellular permeation and apoptosis was assessed by flow cytometry.
Results: *E. coli* from sepsis patients attached to endothelial cells under static (P< 0.01) and hemodynamic shear (P< 0.01) conditions. *E. coli* attachment resulted in disturbances in endothelial barrier integrity, as determined by loss of tight junction protein staining (VE-cadherin), permeability changes (P< 0.01) and apoptosis (P< 0.05). Bioinformatic analysis of the *E. coli* genome identified an interesting protein called outer membrane protein A (ompA) which contains an integrin recognition motif, (R)GD. A strain deficient in expression of ompA significantly reduced binding to endothelial cells under both static (P< 0.05) and shear (P< 0.05) conditions. Complementing the deficient strain with the *ompA* gene recovered binding back to wildtype levels (P=NS). αVβ3 is a major RGD dependent integrin expressed on the surface of human endothelial cells. Low concentrations of an αVβ3 specific peptide (5nM), significantly reduced *E. coli* binding to endothelial cells (P< 0.01), apoptosis (P< 0.05) and loss of barrier integrity P< 0.05) pre- and post-infection.
Conclusions: Inhibition of *E. coli* binding to endothelial cell αVβ3 prevents endothelial dysfunction and therefore presents a first in class novel drug candidate for prevention or treatment of sepsis following a UTI.

PB 2441 | Free Heme Triggers the Disruption of the Endothelial Barrier

M.M.L. Fiusa[1], D. Garcia-Weber[2], M. Lazarini[1], J.M. Annichino-Bizzacchi[1], F. Ferreira Costa[1], J. Millán[2], E.V. de Paula[1,3]

[1]*University of Campinas, Faculty of Medical Sciences, Campinas, Brazil,* [2]*Universidad Autónoma de Madrid, Centro de Biología Molecular Severo Ochoa, Consejo Superior de Investigaciones Cientificas, Madrid, Spain,* [3]*University of Campinas, Hematology and Hemotherapy Center, Campinas, Brazil*

Background: Disruption of the endothelial barrier (EB) is observed during the inflammatory response to invading pathogens, and is thought to facilitate the access of leukocytes and phagocytes to infected or damaged tissues. Heme is an evolutionary conserved molecule present in organisms of all kingdoms, whose role as an activator of innate immunity has been recently demonstrated. Several conditions in which free heme escapes its natural scavenging systems such as sepsis and sickle cell disease are associated with increased microvascular permeability.

Aims: Here we investigated whether free heme could cause changes on EB function and morphology.

Methods: HUVEC were exposed to heme (30uM) or vehicle, and evaluated using an electric cell-substrate impedance sensing system (ECIS) that measures real-time changes in transendothelial electrical resistance (TEER), and by immunofluorescence (IF) of cell-cell junctions. The % of TEER decrease (which indicates the increase EB permeability) was monitored for at least 4 h. For IF, cells were incubated with heme for 30 minutes, and stained for VE-cadherin.

Results: Heme caused a significant increase in EB permeability that was evident as early as 30 minutes after stimulation (vehicle vs heme: at 30 minutes, 9.76±8.54 vs. 53.60±16.19, P= 0.014; at 1 hour, 8.77±6.82 vs. 38.59±6.84; P= 0.006), lasted 2 hours (at 2 hours, 9.47±10.10 vs. 33.07±3.59, P= 0.019), and was no longer significant after 4 hours (13.51±13.98 vs. 32.93±9.34, P= 0.116) and at later timepoints (Fig 1).

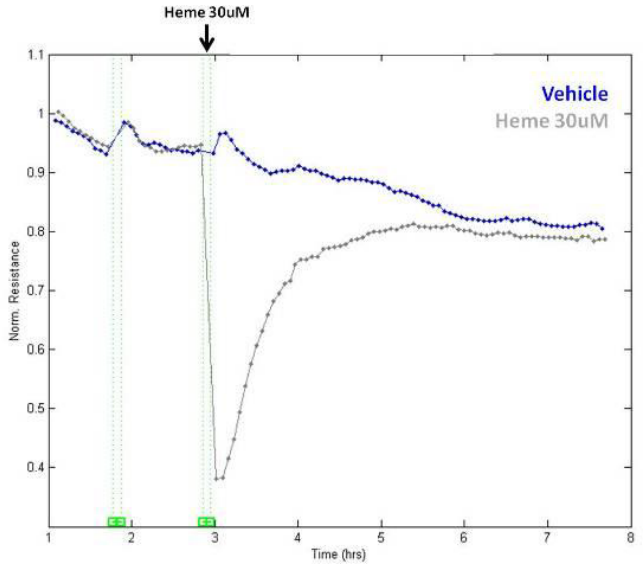

FIGURE 1 Heme stimulation decreases transendothelial electrical resistance (TEER)

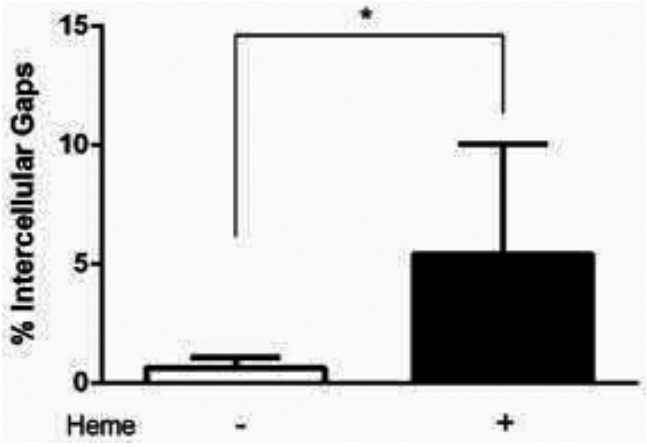

FIGURE 2 Heme induces disruption of adherens junction architecture leading an increase of Intercellular gaps (*P=0.05)

Consistent with these functional changes, the % of intercellular gaps in heme-treated cells was significantly higher (5.41%±4.639) when compared to vehicle-treated cells (0.64%±0.43; P= 0.05) (Fig 2).

Of note, higher levels of heme were observed in a cohort of patients with septic shock.

Conclusions: Heme induces a reversible increase of EB permeability which is associated with the disruption of the architecture of adherens junctions. Further studies are warranted to investigate the *in vivo* relevance of these findings.

PB 2442 | The Relevance Study of between miRNA Machinery Gene Polymorphisms (DICER rs3742330A>G, DROSHA rs10719T>C, RAN rs14035C>T, XPO5 rs11077A>C, DGCR8 rs417309G>A) and the Risk of Recurrent Implantation Failure (RIF) in Korean Women

C.S. Ryu[1], S.H. Cho[1], J.O. Kim[1], H.J. An[1], E.S. Kim[1], J.H. SaKong[1], H.A. Lee[1], H.W. Kim[1], D. Oh[2], J.H. Kim[3], W.S. Lee[3], N.K. Kim[1]

[1]CHA University, Department of Biomedical Science, College of Life Science, Seongnam, Korea, Republic of, [2]CHA University, Department of Neurology, CHA Bundang Medical Center, College of Medicine, Seongnam, Korea, Republic of, [3]CHA University, Department of Obstetrics, CHA Medical Center, Colleage of Medicine, Seongnam, Korea, Republic of

Background: Recurrent implantation failure (RIF) refers to unsuccessful implantation after recurrent transfers of morphologically good quality embryos into a normal uterus. The miRNAs are small non-coding RNA molecule containing about 22 nucleotides that found in plants, animals and some viruses. Also, the miRNAs are well known regulation of gene expression during implantation and crucial factor for successful pregnancy. In addition, the miRNA machinery gene polymorphisms were associated with implantation failure by regulation of miRNA biogenesis. So, we were selected miRNA five machinery gene polymorphisms that thought to be related implantation failure.

Aims: The aim of our study was associated with miRNA machinery gene polymorphisms (*DICER* rs3742330A>G, *DROSHA* rs10719T>C, *RAN* rs14035C>T, *XPO5* rs11077A>C, *DGCR8* rs417309G>A) in RIF risk.

Methods: We conducted a case-control study of 347 Korean women: 119 patients with at least two unexplained consecutive pregnancy losses and 228 controls with at least one live birth and no history of pregnancy loss. Genotyping was performed by polymerase chain reaction (PCR) - restriction fragment length polymorphism (RFLP) method.

Results: Consequently, the *DROSHA* rs10719TC type (AOR: 0.581, *P*=0.026) had significant association for decreasing RIF risk and dominant type (AOR: 0.641, *P*=0.051) shows tendency for decreasing RIF risk. The *RAN* rs14035CT type (AOR: 0.582, *P*=0.027) and dominant type (AOR: 0.606, *P*=0.034) had significant association for decreasing RIF risk. Also, the C-T (*DROSHA* rs10719/*RAN* rs14035; OR: 0.505, *P*=0.037) was decreased RIF risk in gene-gene interaction analysis and

the TC/CT (*DROSHA* rs10719/*RAN* rs14035; AOR: 0.326, *P*=0.004) was decreased RIF risk in combined genotype analysis.

Conclusions: In conclusion, our study demonstrated that *DROSHA* rs10719T>C and *RAN* rs14035C>T were associated with decreasing RIF risk.

PB 2443 | Plasma microRNA (miRNA) Profiling in Immune Thrombocytopenia (ITP) before and during Treatment with Thrombopoietin Receptor Agonists (TPO-RA)

L. Garabet[1,2], W. Ghanima[3,4], A. Rangberg[1], R. Teruel-Montoya[5,6], C. Martinez[5], J.B. Bussel[7], P.M. Sandset[4,8], C. Monceyron Jonassen[1]

[1]Østfold Hospital Trust, Kalnes, Center for Laboratory Medicine, Grålum, Norway, [2]Akershus University Hospital, Multidisciplinary Laboratory Medicine and Medical Biochemistry, Lørenskog, Norway, [3]Østfold Hospital Trust, Kalnes, Department of Medicine, Grålum, Norway, [4]University of Oslo, Institute of Clinical Medicine, Oslo, Norway, [5]Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, Servicio de Hematología y Oncología Médica, Murcia, Spain, [6]CB15/00055-CIBERER, Murcia, Spain, [7]New York Presbyterian Hospital, Weill Cornell Medical Center, Department of Pediatrics, Division of Hematology, New York, United States, [8]Oslo University Hospital, Department of Hematology, Oslo, Norway

Background: Dysregulated expression of miRNAs has been associated with several autoimmune diseases. ITP is an autoimmune disease characterized by thrombocytopenia and increased bleeding risk. TPO-RA stimulate megakaryocyte differentiation and platelet production and are an effective treatment for ITP. The exact role of miRNAs in the pathogenesis of ITP and in relation to TPO-RA use has not been explored.

Aims: Determine the expression profile of circulating miRNAs in ITP patients before and during treatment with TPO-RA to identify miRNAs that might be associated with pathogenesis of ITP and help understand the molecular mechanisms of effect of TPO-RA.

Methods: Exiqon Serum/plasma Focus microRNA PCR panel was used to determine the expression profile of 179 miRNAs in plasma acquired from 8 ITP patients before and 2, 6 and 12 weeks after initiation of treatment with TPO-RA and 8 matched controls. Repeated measures one-way ANOVA was used to analyze sequential samples. Pathway analysis was performed using miRPath 3.0.

Results: Comparing the expression profiling before and after the initiation of TPO showed that 14 circulating miRNAs were significantly differentially expressed; eight of these were also significantly differentially expressed in controls compared to pre-treatment patients. Among those, miR-199a-5p was up-regulated during treatment with TPO, while 423-5p and miR-590-5p were down-regulated. miR-195-5p, previously shown to be associated with thrombosis, was not among the differentially expressed in ITP compared to controls but increased after treatment. Results from pathway analysis are shown in Table 1.

Conclusions: We identified several miRNAs that were differentially expressed in ITP patients before and during treatment with TPO. Further validation of these miRNAs in a larger patient cohort with defined clinical outcomes will clarify their potential as biomarkers. The role of these miRNAs in ITP pathophysiology deserves additional study given the potential biological pathways that they may regulate.

PB 2444 | The Role of miR-143 in Collateral Vessel Growth

T. Hammerschick[1], K. Troidl[2], K.T. Preissner[1], S. Fischer[1]

[1]Justus-Liebig-University Giessen, Department of Biochemistry, Giessen, Germany, [2]Max-Planck-Institute for Heart and Lung Research, Bad Nauheim, Germany

Background: Arteriogenesis denotes the growth of collateral arteries from existing small vessels, thereby bypassing major arterial obstructions. Several microRNAs (miRs) were shown to be highly expressed in growing collaterals including miR-143. Accordingly, knockdown of miR-143 inhibited the growth of collateral arteries in mice. Furthermore, the expression of collagen type V alpha 2 chain (COLVA2), the predicted target gene of miR-143, was downregulated in growing collaterals.

Aims: We aimed to examine the role of miR-143 in vascular cell proliferation and to prove that COLVA2 is a direct target of miR-143 in arteriogenesis.

Methods: Cell proliferation was measured by using the BrdU Cell Proliferation ELISA assay.

To confirm the direct interaction between miR-143 and COLVA2 mRNA, a Dual Luciferase Reporter Assay was performed by cloning

TABLE 1 miRPath 3.0 GO analysis with subcategories of biological process and Tarbase v7.0

GO Category	p-value	#genes	#miRNAs	miRNAs
Transcription initiation from RNA polymerase II promoter	<1E-325	60	3	miR-423-5p, miR-195-5p, miR-33a-5p
Immune system process	<1E-325	350	5	miR-199a-5p,miR-423-5p, miR-195-5p, miR-221-3p, miR-141-3p
Transcription, DNA-templated	<1E-325	528	5	miR-33a-5p,miR-423-5p, miR-92b-3p, miR-221-3p, miR-141-3p
Blood coagulation	<1E-325	147	5	miR-195-5p,miR-423-5p, miR-92b-3p, miR-221-3p, miR-141-3p
Fibroblast growth factor receptor signaling pathway	<1E-325	68	5	miR-195-5p,miR-423-5p, miR-33a-5p, miR-221-3p, miR-141-3p

the COLVA2-3'UTR-sequence into the miR-specific plasmid vector psiCHECK™-2.

Results: The transfection with anti-miR-143 (but not with a scrambled anti-miRNA) in murine vascular smooth muscle cells (MVSMC) or NIH/3T3-fibroblasts, which both express high amounts of miR-143, resulted in downregulation of miR-143 expression, and decreased cell proliferation, which became significant after 72 h. The cotransfection of the plasmid carrying the COLVA2-3'UTR-sequence together with anti-miR-143 (but not with scrambled anti-miRNA) in MVSMC or NIH/3T3 cells induced the knockdown of miR143 and upregulated the luciferase expression after 48 h. These data indicate that miR-143 modulates COLVA2 expression directly by targeting the 3´UTR-region of the COLVA2 mRNA.

Conclusions: These findings identify miR-143 as a direct regulator of the COLVA2 expression. Furthermore miR-143 induces vascular cell proliferation and collateral vessel growth. Data will be helpful to develop effective strategies for the treatment of vascular diseases.

PB 2445 | Circulating miRNA-24 as a Potential Biomarker for Coronary Heart Disease in Type 2 Diabetes Mellitus Patients

X. Deng, M. Luo, J. Wu

Southwest Medical University, Luzhou, China

Background: Type 2 diabetes mellitus (DM2) is associated with cardiovascular complications and is characterized by high levels of YKL-40, an inflammatory glycoprotein involved in endothelial dysfunction.

Aims: We investigated the predictive potential of circulating miR-24 in DM2 without chronic complications, DM2 patients with coronary heart diseases (CHD), and control subjects.

Methods: Blood samples were taken from 94 subjects of both genders, and divided over three groups as follows; patients with CHD, patients with DM2 and CHD, and control subjects. Both miR-24 (using real time PCR) and routine parameters were measured.

Results: Using bioinformatic analysis, we found that miR-24 has high complementarity and a high degree of species conservation with respect to the binding sites within the 3' UTR of the YKL-40 mRNA. The expression levels of circulating miR-24, determined by quantitative real time PCR, were significantly decreased in peripheral blood of DM2-CHD and CHD patients compared with controls. Furthermore, MiR-24 strongly associated with DM2-CHD, negatively correlated with YKL-40 in DM2-CHD and DM2 patients after conducting multiple regression analysis.

Conclusions: These results provide a novel regulatory mechanism of circulating miR-24 in regulating YKL-40 levels in DM2-CHD, may serve as a biomarker for predicting patients with DM2 with CHD.

PB 2446 | Circulating Extracellular Vesicles microRNA Profile in Transfusion Dependent β-Thalassemia

C. Levin[1,2], A. Rebibo-Sabbah[3], A. Koren[1], B. Brenner[2,3], A. Aharon[2,3]

[1]Emek Medical Center, Pediatric Hematology Unit, Afula, Israel, [2]The Bruce Rappaport Faculty of Medicine, Technion, Haifa, Israel, [3]Rambam Health Care Campus, Thrombosis and Hemostasis Unit and Department of Hematology, Haifa, Israel

Background: Circulating miRNAs are small non-coding RNAs, encased in extracellular vesicles (EVs), which regulate the expression of multiple genes. Circulating miRNAs emerged as promising disease biomarkers for diagnostic and therapeutic purposes in hematological diseases. In transfusion dependent β-thalassemia (TDT) a life-threatening anemia with multi-organ complications little is known about the features of circulating miRNAs.

Aims: Evaluation of EV-miRNA profile in TDT patients according to their clinical characteristics and spleen status and in comparison with EV-miRNAs from healthy controls (HC).

Methods: 32 TDT patients and 15 HC were included in the study. The TDT patients were divided into 3 groups:
(1) non-splenectomized,
(2) splenectomized (SP) and
(3) hypersplenic (HS).
Blood samples were collected prior to blood transfusions, in EDTA tubes. Total RNA was isolated from EV pellets using miRNeasy isolation kit (Qiagen). EV-miRNA samples from the SP, HS and HC study groups were screened for the expression level of 800 miRNAs by Nanostring and validated by quantitative real-time PCR (RT-qPCR).

Results: The expression of 30 miRNA was found to be higher (>150%) in both patient groups compared to HC; the expression of 14 miRNAs was found to be lower (< 50%) in SP and HS patients compared to HC. RT-qPCR confirmed the different expression of 6 miRNAs in TDT patients compared to HC. High levels of miR-155-5p, miR-195-5p, miR-144-3p, miR-210, miR-376a-3p, and miR-378a were evident. In patients with hypersplenism the miRNAs miR-451a, miR-144-3p and miR-210 were particularly elevated. In SP patients the miR-376-c was increased.

Conclusions: Important differences in EV-miRNA profile were found between patients and HC and between different patient groups. Increased levels of miRNAs are probably involved in erythropoiesis in patients with hypersplenism. The identified alterations may represent potential peripheral biomarkers for monitoring transfusion dependent β-thalassemia patients.

PB 2447 | Plasma miR-103b as a Novel Biomarker for Screening Pre-diabetes and Newly Diagnosis of Type 2 Diabetes

M. Luo, Y. Luo, J. Wu

Southwest Medical University, Luzhou, China

Background: MicroRNAs (miRNAs) play a crucial role in the pathogenesis of type 2 diabetes (T2DM). The prevalence of pre-diabetes predisposes an individual to the development of T2DM. Recent studies suggested an association of circulating miR-103b with pre-diabetes and T2DM.

Aims: In the current study, we investigated whether plasma miR-103b plays a diagnostic role in the pathogenesis of T2DM and pre-diabetic syndrome.

Methods: Bioinformatic analysis and identification of miR-103b and its targets were assessed using quantitative real-time PCR and receiver-operating characteristic (ROC) analyses in 50 patients with pre-diabetic mellitus (pre-DM), 48 patients with non complicated diabetic group (NCDM), and 52 healthy individuals.

Results: miR-103b was especially gradually down-regulated in plasma from patients with pre-DM and NCDM. Dramatically, miR-103b level in pre-DM was decreased 10-fold comparing to healthy individuals. Further analysis found that the area under the curve (AUC) for the ROC analysis of miR-103b was 0.887 (95% CI 0.809-0.944). At a cut-off value of 1.633, the sensitivity was 89.8 % and the specificity was 73.5 % in discriminating T2D patients from healthy individuals. The bioinformatic analysis has demonstrated that miR-103b has a high degree of site conservation among different mammalian species i.e., *Homo sapiens*, *Mus musculus*, *Rattus norvegicus*, *Pongo pygmaeus*, *Sus scrofa* and etc. 53 potential targets of miR-103b were predicted; most of these putative target genes involved in MAPK, Wnt, insulin and RAS signaling pathways and enriched in various biological processes, moleculer functions, and cell component.

Conclusions: These results reveal that plasma miR-103b can be used as an objective complement to traditional diagnosis of pre-diabetes, indicating important implications regarding the distinguish of the undiagnosed cases between diabetes and pre-diabetes by circulating miRNA.

PB 2448 | Overexpression of p21Cip1 and p27Kip1 Regulates the Proliferation of Endothelial Colony Forming Cells from Patients with Deep Venous Thrombosis

J.A. Alvarado Moreno[1], D. Moreno Lorenzana[2], J.R. Hernández López[1,3], J. Ramirez-Chan[1], I. Isordia Salas[1], M.A. Chávez Gonzalez[4], A. Majluf Cruz[1]

[1]Instituto Mexicano del Seguro Social, Unidad de Investigacion Medica en Trombosis, Mexico City, Mexico, [2]Instituto Nacional de Pediatria, Mexico City, Mexico, [3]Universidad Autonoma Metropolitana, Mexico City, Mexico, [4]Instituto Mexicano del Seguro Social, Unidad de Investigación Médica en Enfermedades Oncológicas, Mexico City, Mexico

Background: The World Health Organization reported that thrombosis, particularly "venous thromboembolic disease" (VTD), is a major cause of death, and hence, is a public health problem. We recently reported that endothelial colony-forming cells (ECFCs) derived from endothelial cells (EC) (ECFC-ECs) from patients with VTD have a dysfunctional state that generates a reduction of its proliferative ability, which is also associated to senescence and reactive oxygen species (ROS).

Aims: We examine the status of cell cycle and expression of cyclin, cyclin dependent kinase (CDKs) and CDK inhibitors (CKIs) in ECFC-ECs patients with VTD.

Methods: ECFC-ECs obtained and frozen in our laboratory were analized in passage 3 to determinate by flow cytometer: status of cell cycle by KI67. We also used monoclonal antibodys to detect the expression of cyclin D3, cyclin A, cyclin B, CDK2, CDK4, $p16^{INK4}$, $p21^{CIP1}$ and $p27^{KIP1}$. The protocol was reviewed and approved by the Human Ethical Committee of the IMSS (FIS/IMSS/PROT/G09/771) and conforms to the guidelines of the 1975 Declaration of Helsinki. Informed written consent was obtained from all subjects before enrollment.

Results: Proliferation was reduced in ECFC-ECs from patients with VTD because more of 10% of cell population was arrested in S phase of cell cycle. The regulator proteins that are involved in this cell cycle status are Cyclin D3, CDK2, with a reduce expression, while $p21^{CIP1}$ and $p27^{KIP1}$ has are over expressed with respect to normal cells.

Conclusions: Our data shows that low proliferative potential in ECFC-ECs from VTD patients associated with cellular senescence is due to an anormality in the mechanisms related with the cell cycle, particulary, an increase of expression of Cip/Kip family members $p21^{CIP1}$, $p27^{KIP1}$ and arrest in S phase of cell cycle. Our results strongly suggest that patients with a history of VTD may be at risk of new thrombotic events by this cellular mechanisms.

PUBLICATION ONLY ATHEROTHROMBOSIS & STROKE

PO 01 | New Potential Marker for Analysis of the Organism State Under the Cardiovascular Disorders

Y. Tyravska[1], V. Lizogub[1], T. Katrii[2], O. Savchuk[2]

[1]Bogomolets National Medical University, Internal Medicine #4, Kyiv, Ukraine, [2]Educational and Scientific Centre 'Institute of Biology' of Taras Shevchenko National University of Kyiv, Biochemistry, Kyiv, Ukraine

Background: The directly proportional relationship exists between level of the organism disorders and accumulation of the peptides up to 5 kDa in blood plasma. However, a clear answer to the question regarding properties of these peptides is absent nowadays.

Aims: To investigate new possible markers for analysis of the organism under the cardiovascular disorders (CVD).

Methods: Blood plasma was taken from 35 healthy donors and 6 patients with acute myocardial infarction, 11 patients with new onset unstable angina, 17 patients with progressive unstable angina,
7 patients with chronic stable angina, 6 patients with silent myocardial ischemia, 22 patients without proved coronary artery disease. Patients

were hospitalized in cardiology department of the Hospital #12, Kyiv, Ukraine. Peptides were obtained by the method of Nikolaichyk V. Concentration was counted in respect of calibration chart obtained after an analogical measurement of peptide 0,26 kDa. The purity of peptides fraction was controlled by 15% SDS-PAGE.

Results: The presence of peptides up to 5 kDa in all fractions of healthy donor as well as fractions of patients with all tested CVD was shown. The SDS-PAGE image was typical of all tested pathologies. The concentration of peptides separated from the blood plasma of patients with CVD was significantly higher in comparison with healthy donors. Thus, the most concentrated peptides pool (PP) fraction was obtained from the patients with the acute myocardial infarction, which was 14 times more concentrated than fraction of healthy people. The PP fraction in patients with progressive unstable angina was 6 times more concentrated. The PP fraction of patients with the new onset unstable angina, chronic stable angina as well as patients without proved coronary artery disease were 5 times higher than that in healthy donors.

Conclusions: The results showed that all tested CVD accompanied by increased concentrations of peptides up to 5 kDa. It could be used as a tool for monitoring of the organism state under the CVD.

PO 02 | Apolipoproteins and Serum Inflammatory Markers in Young Patients with Myocardial Infarction

K. Dahal[1], P. Karki[1], R. Maskey[1], K. Sherpa[1], M. Lamsal[2]

[1]B.P. Koirala Institute of Health Sciences, Internal Medicine, Dharan, Nepal, [2]B.P. Koirala Institute of Health Sciences, Biochemistry, Dharan, Nepal

Background: CAD is gradually emerging as one of the major health challenges in Nepal and has been recognized among younger age group more frequently in recent years even in Nepal.

Aims: The present study aims to estimate the serum apolipoproteins and inflammatory biomarkers and thereby assess the risk factors prevalent in young patients of acute myocardial infarction attending the tertiary care centre of eastern Nepal.

Methods: This is a hospital-based cross- sectional study conducted from August 2015 to July 2016 in Thirty Eight patients aged 15-45 years presented with acute myocardial infarction. Eleven risk factors were studied namely: Gender, H/O Diabetes mellitus, H/O Dyslipidaemia, Family history, Smoking,Hypertension,Obesity,Alcohol, Altered Apo B/ApoA1 ratio,HsCRP leveland Serum Uric Acid Level. The study population were further divided into two groups: Group A with patients 35 years of age or less and group B with patients 36-45 years of age.

Results: The present study found that among the total study participants, 68% were Non-obese males. Majority of the population were hypertensive with the H/O Smoking and alcohol intake. Family history of acute myocardial infraction or sudden cardiac death was present in less proportion of the patients (32%). Serum Apo B was significantly raised compared to the Apo A in the patients, but their difference between the two groups was not statistically significant. Serum hsCRP and Uric acid was significantly higher in Group B compared to Group A patients.

Conclusions: The present study elaborates the use of Apo B/ Apo- A1 ratio in AMI in young adults in a tertiary care centre of eastern Nepal. The clustering of risk factors particularly three or more risk factors in an individual predispose to CAD at relatively younger age. This study depicts that Apo B/ Apo A-1 ratio is a better predictor of Myocardial Infarction in young adults compared to the other inflammatory biomarkers.

PO 03 | Particularities of Superficial Venous Thrombosis

F. Saïd[1,2], A. Hamzaoui[1,2], I. Ben Ghorbel[1,2], M. Lamloum[1,2], T. Ben Salem[1,2], M. Khanfir[1,2], M.H. Houman[1,2]

[1]University Hospital La Rabta, Internal Medicine, Tunis, Tunisia, [2]University Tunis El Manar, University of Medicine of Tunis, Tunis, Tunisia

Background: Thromboembolic events (TEE) are very variable. Their clinical presentation, etiology and outcome depend on their localisation.

Aims: To determine clinical, etiologic and outcome characteristics of superficial venous thrombosis (SVT).

Methods: A retrospective and descriptive study of records of patients hospitalized for TEE during 20 years. We selected data of patients hospitalized for SVT. We determined clinical, etiologic and outcome characteristics of these patients.

Results: Among 1055 patients hospitalized for TEE, 139 (13.2%) patients presented SVT (84 men and 55 women). The average age of patients was 49.49 years [15-86].

SVT was associated to distal deep venous thrombosis in 10 cases, proximal deep venous thrombosis in 57 cases which 9 of them were complicated by pulmonary embolism. Thrombosis of superior cava vein was associated in 2 cases.

SVT were suspected in front of collateral venous circulation in 6 cases and venous cord in 37 cases. The other cases were accidentally discovered.

The more frequent factor risk of thrombosis found were : smoking (46%), varicose veins (32.4%), obesity (25.2%) and badrest (11.5%). On the other side, venous failure was shown in 6.5% of cases.

SVT were reported to Behçet disease in 20 cases (14.4%), hyperhomocysteinemia and neoplasms in 14 cases each one (10.1%), constitutional thrombophilia in 5 cases (3.6%) and antiphospholipid syndrom in 1 case (0.7%). SVT revealed underlying pathology in 24 patients (17.3%).

Only 7 patients were treated by heparin by cutaneous route. The other patients were treated by antivitamin K. Compression stockings were prescribed in all patients. But, only 29.5% wore them.

Post thrombotic syndrom was noted in 17 patients (12.2%). TEE recurred in 17 patients.

Conclusions: In our study, about half of SVT were lone, in the most of cases asymptomatic and idiopathic. No pulmonary embolism complicated SVT in absence of deep venous thrombosis. But, post thrombotic syndrome and reccurence were noted.

PO 04 | Venous Thrombosis in Systemic Lupus Erythematosus

F. Saïd[1,2], A. Hamzaoui[1,2], I. Ben Ghorbel[1,2], M. Lamloum[1,2], T. Ben Salem[1,2], M. Khanfir[1,2], M.H. Houman[1,2]

[1]University Hospital La Rabta, Internal Medicine, Tunis, Tunisia, [2]University Tunis El Manar, University of Medicine of Tunis, Tunis, Tunisia

Background: Systemic lupus erythematosus (SLE) is auto-immun disease which affects several organs. Frequency of Venous thrombosis (VT) in this disease is estimated at 10%.

Aims: to determine characteristics of VT occuring during the SLE.

Methods: A retrospective and descriptive study of records of patients hospitatized for VT during 20 years. We selected data of patients where VT was attributed to SLE. We studied characteristics of these patients.

Results: Among 1055 patients hospitalized for VT, 14 (1.32%) patients had SLE (11 women and 3 men) with an average of age was 42.21 years [18-70]. SLE was associated to atiphospholipid syndrom in 4 cases.

VT was proximal in 8 cases associated to pulmonary embolism in 2 cases, distal in 2 cases and superficial in 1 case. Pulmonary embolism was lone in 3 cases.

As risk factors of thrombosis, smoking and varicose veins were noted in 3 patients for each one, bedrest and surgery in 1 patient for each one.

All patients were treated by antivitamin K during an average period of 31.42 months.

Post thrombotic syndrom and reccurence occured in one case each one.

Conclusions: In our series, SLE is a rare cause of VT principally proxiaml, occured in the absence of frequent risk factor. Complications were not frequent.

PO 05 | Clinical Profil of Digestive Thrombosis Patients

F. Saïd[1,2], Z. Meddeb[1,2], M. Lamloum[1,2], S. Hamrouni[1,2], I. Ben Ghorbel[1,2], T. Ben Salem[1,2], M. Smiti[1,2], M.H. Houman[1,2]

[1]University Hospital La Rabta, Department of Internal Medicine, Tunis, Tunisia, [2]University Tunis El Manar, University of Medicine of Tunis, Tunis, Tunisia

Background: Digestive thrombosis is a rare disease. Its prognosis may be severe due to the local complications it causes : portal hypertension, Budd Chiari syndrome and digestive ischemia but also because of the underlying etiology.

Aims: to describe the clinical features of patients presenting digestive thrombosis.

Methods: Retrospective single center study having compiled patients' files comprehending the period between 2010 and 2016.

Results: The study group consisted of 12 patients. The male to female ratio was 0.5. The mean age at the time of diagnosis was 33 years.

The different locations were as follow : hepatic vein (six patients), portal vein (three patients), superior mesenteric vein (three patients) and inferior mesenteric vein (two patients).

Budd Chiari syndrome was decribed in four patients.

The clinical signs of discovery were abdominal pain in five patients, vomiting and ascites in one patient each. The other patients were asymptomatic.

All patients had an abdominal computed tomography scan which showed the digestive thrombosis.

The etiologies reported were: Behcet disease in three patients, Vaquez disease, activated proteine C resistance, cirrhosis and pancreatic pseudocyst in one patient each. No etiology was identified in four patients. All patients were treated with anticoagulant therapy. Three patients were also treated with predisone at the dose of 1 mg/kg per day and with immunosuppressive drugs because of their Behcet disease. The outcome was favorable in 8 cases. The average follow-up was 52 months.

Conclusions: The predominance of the Behcet disease as a main etiology of digestive thrombosis in our study can be explained by a recruitment bias. However, it needs more cases before drawing conclusions.

PO 06 | Prevalence of Resistance to Anti-platelet Therapy among Patients with Ischemic Stroke - Preliminary Results

A. Pathare[1], O. Al Awidi[2], A. Alsiyabi[2], A. Gujjar[3]

[1]Sultan Qaboos University Hospital, Department of Haematology, Muscat, Oman, [2]College of Medicine and Health Sciences, Sultan Qaboos University, Department of Haematology, Muscat, Oman, [3]College of Medicine and Health Sciences, Sultan Qaboos University, Department of Medicine, Muscat, Oman

Background: Aspirin and Clopidogrel are currently the most prevalent antiplatelet agents used in the prevention of ischemic, non-cardioembolic strokes. However, variable response to antiplatelet therapy needs monitoring by platelet function studies.

Aims: To explore the prevalence of resistance to anti-platelet therapy with aspirin and/or clopidogrel among patients with ischemic, non-cardioembolic stroke.

Methods: Adult patients who developed ischemic stroke over the past two years and received treatment either with Aspirin or Clopidogrel or both agents were enrolled. Those with cardioembolic stroke or intracranial hemorrhage were excluded. Compliance with therapy was ensured by history and hospital records. Platelet functions were studied on blood samples from patients by platelet aggregometry and PFA-200 screen. Frequency of resistance to anti-platelet agents among patients with and without stroke recurrence over the period of anti-platelet therapy were compared.

Results: Of the 27 patients studied, 20 were on aspirin and 15 on clopidogrel. Of these, 13 were on dual antiplatelet therapy. Overall, 3 patients on aspirin and 6 patients on clopidogrel had resistance to anti-platelet effect. While the failure of aspirin effect was observed in 3 patients with monotherapy, 86% of the failures with clopidogrel occurred in patients on dual antiplatelet therapy. 15/27 patients had recurrent stroke: 6/15 among those with antiplatelet agent resistance, and 9/12 without resistance.

Conclusions: Resistance to the anti-platelet effect of clopidogrel (40%) appears to be more frequent than that due to aspirin (15%) in Omani population. No significant relation of failure of anti-platelet function with stroke recurence was observed in this small cohort(Chi square, p=0.33). Further larger studies are required to explore any possible relation of resistance to anti-platelet agents with recurrence of cardiovascular events.

PO 07 | Intracerebral Hemorrhage under Antithrombotic Medication in a Recent Year

T. Nakase[1], J. Moroi[2], T. Ishikawa[2]

[1]Research Institute for Brain & Blood Vessels, Department of Neurology & Stroke Science, Akita, Japan, [2]Research Institute for Brain & Blood Vessels, Department of Neurological Surgery, Akita, Japan

Background: Antithrombotic medication will be a risk of hemorrhagic complication. Meanwhile, direct oral anticoagulants (DOACs), which are recently introduced in the clinical use, are reported to show lower risk of intracerebral hemorrhage (ICH) compared with warfarin. However, the severity at onset and the outcome of ICH patients with DOACs are still controversial.

Aims: This study aimed to reveal the clinical features of recent ICH patients with antithrombotic medication including DOACs.

Methods: Between April 2014 and March 2015, ICH patients who admitted to our hospital were consecutively screened. Hematoma size was assessed by brain CT images on admission. Outcome was measured by modified Rankin Scale (mRS). Favorable outcome was defined as mRS< 3.

Results: Twenty-eight of 129 ICH patients (21.7%) were taken antithrombotic agents (7 warfarin, 4 rivaroxaban, 1 dabigatran, 8 aspirin, 3 thienopyridines, 1 cilostazol, 3 antiplatelet and anticoagulant and 1 dual antiplatelet agents). Mortality was 14.3% and 8.9% in patients with and without antithrombotic agents, respectively. Frequency of favorable outcome was 0%, 33.3%, 63.6% and 83.3% in patients with dual antiplatelet agents, single antiplatelet and anticoagulant, single anticoagulant and single antiplatelet, respectively. Hematoma size was not different between warfarin and DOACs (29.7ml and 31.3ml, respectively). Patients with DAOCs showed favorable outcome compared to patients with warfarin, although the difference of percentage was not significant (p=0.398: 66.7% and 43.3%, respectively).

Conclusions: Outcome of patients who were taking antithrombotic agents, especially to whom multiple antithrombotic agents were prescribed, is worse. The difference of outcome among different DOACs also needs to be investigated in the future.

PO 08 | Methylenetetrahydrofolate Reductasa (MTHFR) C 677 Mutation-risk Factor for Ischemic Stroke or Not - Case Report

D. Stambolieva[1], M. Sorova[2]

[1]Institute for Transfusion Medicine, Skopje, Strumica, Macedonia, the Former Yugoslav Republic of, [2]Institute for Transfusion Medicine, Stip, Macedonia, the Former Yugoslav Republic of

Background: Homozygosis for |MTHFR C667 T polymorphism can lead to high homocysteine levels and hyperhomocystinemia as an important risk factor for thrombotic events.

Aims: To determinate a role of MTHFR C 667 T mutation in a patient with an ischemic stroke documented by a magnetic resonance imaging.

Methods: We report a case of 42 years male patient with ischemic stroke. No traditional risk factors were found (non smoker, non hypertensive, non obesity, non diabetic, no vegetarian, no family history) to understand the reason for this thrombotic event. Because he was young and healthy person, we suspected that some genetic abnormalities should be the reason. Molecular study was very surprised for us - he was heterozygous for MTHFR C667 T mutation, but also heterozygous for MTHFR A 1298 C mutation, factor V (R2) mutation, LTA mutation and PAI 4G/5G polymorphism. Unfortunately, plasma homocysteine levels were not measured in the referent laboratory and we do not received a result who was very important for the future therapy.

Results: We reported a case of 42 years male patient with ischemic stroke.

Conclusions: In this case, we have a heterozygous for MTHFR C667 T mutation, which isolated, is not a risk factor for ischemic stroke, because those persons do not have high plasma levels of homocysteine. But without an influence of any environmental factor and family history, we suspected that the synergistic effects between all those heterozygous polymorphism were a strong risk factor for thrombotic stroke in our patient. We supported him with an anticoagulant therapy, higher doses of folic acid and B complex vitamins.

COAGULANT & ANTICOAGULANT MECHANISMS

PO 09 | Role Glycin-containing Olygopeptides in Platelet Aggregation

M. Golubeva

Moscow State University, Dep. of Biology, Moscow, Russian Federation

Background: It was found that the final organism response to stress is the influence of catecholamine's in the blood system. A significant influence on the reaction may have both neuropeptides such as vasopressin and oxytocin and their products of proteolysis. So urgent is to study the influence of catecholamine's on platelet aggregation and the effect of these olygopeptides on the reaction conditions.

Aims: The aim of this work was to study the effect of C-terminal fragments of vasopressin and oxytocin on platelet aggregation under influence of epinephrine in the physiological norm.

Methods: Was used peptides representing the C-terminal fragments of vasopressin (Pro-Arg-Gly- NH2 - I), oxytocin (Pro-Leu-Gly-NH2- II) : To test with washed platelets, peptides are added in a concentration range of 10-1 - 10-10M or an equal volume of saline and the measured change in aggregation by the action of at a final concentration epinephrine 0.02 mmol / l. Aggregation was recorded on a aggregometer. The results were treated statistically.

Results: : In the first series of experiments examined the effect of the peptide I of washed platelet aggregation by the action of epinephrine. It was established that the peptide I induced a significant enhancement of aggregation in a concentration range of 10-5 - 10-10 M (p< 001). with maximum stimulation index 68%. The following series of experiments examined the effect peptide II on the platelet aggregation by the action of epinephrine. It is shown unlike peptide I this peptide virtually no effect on platelet aggregation induced by epinephrine. Only by adding the peptide at a concentration of 10-8M it caused inhibition of platelet aggregation.

Conclusions: Therefore, small regulatory peptides, which are products of proteolysis of neuropeptides, have the opposite effect on the platelets aggregation. Explore ways peptide proteolysis may lead to the development of new drugs for correction of various disorders in the body, hemostasis e.g.

PO 10 | Bleeding Disorders in Ashkenazi Jews

H.D. Solomons[1,2]

[1]University of Arkansas for Medical Sciences Witwatersrand, Haematology, Johannesburg, South Africa, [2]Witwatersrand, Haematology, Johannesburg., South Africa

Background: Bleeding Disorders in Ashkenazi Jews.

Aims: The aim of the exercise was to demonstrate bleeding disorders in Ashkenazi Jews.FactorXI (plasma thromboplastin antecedent).

Factor XI is frequently deficient in Ashkenazi Jews and this can result in a bleeding disorder This is often seen at circumcision but may result in menorrhagia in females.

Methods: The methods involved the demonstration of Bleeding disoders; predominantly Factor XI deficiency in Ashkenazi Jews. Nosebleeds or epistaxis may be severe. Factor XI concentrate is available but is often difficult to obtain. Fresh frozen plasma may have to be used. Ashkenazi Jews are of European descen tehile Sephardi Jews are usually of Spanish descent. But non-Jews may present with the disorder, mainly due to assimilation.

Results: The result showed a definite defect in the factor XI molecule with patients haaing a propensity to bleed, especially at laparotomies. There are two predominant mutations, type II and type IIII (using an older classification system). The type III mutation is an amino acid substitution (Phe283Leu) resulting in a missence mutation. This results in impaired dimerization and secretion of the FXI molecule. The seond is the type II mutation; this causes premature chain termination and results in very low levels of circulating FXI.

Conclusions: This finding is of great clinical significance as often patients do not know that they have a bleeding defect.

This is of great significance in Ashkenazi Jews. The type II mutation has been found in Iraqi Jewish and Israeli Arabic descent. Both mutations are thought to originate from a common founder, one occurring before and one after the divergence of the Jewish people!

PO 11 | Management of a Severe Congenital Protein C Deficiency Case

N. Özdemir, H. Kızılocak, G. Dikme, T. Celkan

Istanbul University, Cerrahpasa Medical Faculty, Istanbul, Turkey

Background: Congenital Protein C (PC) deficiency is a very rare condition associated with serious clinical manifestations.

Aims: Here we present a case with PC deficiency managed by FFP, anticoagulation and PC concentrate.

Methods: -

Results: A three day infant of consanguineous parents who were found to be asymptomatic carriers of heterozygous PC deficiency. presented to the emergency department with progressive skin necrosis on legs. Protein C activity was undetectable. She was initially treated with FFP at another center. At investigation she was found to have intracranial and retinal hemorrhage. Despite FFP and anticoagulation with low-molecular heparin her skin lesions progressed. Human derived PC concentrate improved skin lesions and intracranial bleeding and she was put on prophylaxis as well.

Conclusions: PC replacement is an established method for treating PC deficiency. It can also used for long term prophylaxis. Due to small number of cases, optimal management of this devastating condition is yet to be investigated.

PO 12 | Laboratory Detection of Thrombophilic Markers Frequency

V. Neceva

Institute of Transfusion Medicine, Skopje, Macedonia, the Former Yugoslav Republic of

Background: Antithrombin III (ATIII), protein C (PC) and protein S (PS) deficiencies or inherited thrombophilic defects such activated protein C resistance (APCR), f.V Leiden (fVL) or prothrombin (II G20210A) mutation are potential markers for thrombophilia (increased tendency for venous or arterial thrombosis).

Aims: To represent association between low concentration of PC,PS, positive APCR activity and presence of mutation of f.VL or II G20210A mutation at patients with thrombosis.

Methods: 100 patients (21 to 70 years old) with a history of DVT, PE and AIM. Biological activity of AT III, PC, PS with Simens BERICHROM

ATIII ,BERICHROM PC, PROTEIN S Ac kits and resistance to activated PC (ProC® Ac R, Simens Bechring) were measured on automated coagulation analyser (BCS-XP). According to reference values ATIII, PC and PS activity below 60 % were regarded as deficiency. A ratio of activated PC below 2.1 indicated APCR. fVL and II G20210A polymorphism were detected with PCR specific polymorphism detection kits (both Applied Biosystems) on a ABI Prism 7000 equipment.

Results: 29 patients from 100 had APCR (1.64±0.25 v.s.2.24 ±0.51). 15 patients from all had decreased level of PC (43.67 %±18.53 v.s. 101.47%± 39.91) and 19 patients had decreased level of PS (45 %±15.18 vs. 89.6%± 39.68). All examined had normal ATIII (96.82%±16.96). 15 patients were heterozygotes and one was homozygote for f.VL. 9 patient were heterozygotes for II G20210A.1 patient with AIM was heterozygote for fVL and II, and 1 patient with Phlebothrombosis was homozygote for fVL and heterozygote for II. This patients were APCR(1.51±0.44). 14 patients with heterozygote fVL were at same time APCR (1.68±0.16).

Conclusions: Low concentration of ATIII, PC, PS and APCR are very useful laboratory markers for thrombophilia. Recognition of thrombophilic defects (fVL and II G20210A polymorphism) are complementary and changed the diagnostic approach for thrombophilia. They all together are potentional risk factors for predicting and developing of thrombosis.

DIAGNOSTICS AND OMICS

PO 13 | Red Blood Cells Distribution Width to Estimate Lupus Activity

S. Shoeib, M. Abdelhafez, A. Hassan, H. Sherif

Menoufia University, Internal Medicine, Menoufia, Egypt

Background: Systemic lupus Erythematous is a multifactorial systemic autoimmune disease which can affect multiple organs. The general pathogenesis of this disease still needs a better understanding. Red cell distribution width is a measure of the red blood cells (RBCS) size variation.

Aims: was to study red blood cell distribution width (RDW) in systemic lupus Erythematous (SLE) patients as a lupus activity marker.

Methods: This prospective study was carried on Internal Medicine Department, Menoufia University Hospital from the period of March 2016 till august 2016. Our study included 58 Systemic lupus Erythematous patients with activity. Activity of patients was measured by Systemic Lupus Erythematous Disease Activity Index (SLEDAI).RDW was done as one of the parameters of complete blood count (CBC).Red cell distribution width was reported on the Sysmex XT. In this study we excluded any other causes of anemia and other connective tissue diseases.

Results: The study included 58 Systemic lupus erythematous patients, 20 systemic lupus patients with high activity and 38systemic lupus patients with very high activity. RDW was higher in systemic lupus patients with very high activity than in systemic lupus patients with high activity. There was a highly significant correlation between RDW and SLEDAI. There was a highly significant correlation between RDW and erythrocyte sedimentation rate (ESR).

Conclusions: There was statistically more increasing in RDW in lupus patients with very high activity than in those with high activity so RDW can be used as a lupus activity marker. RDW was associated with the inflammatory process of SLE.

PO 14 | Levels of von Willebrand Factor Antigen in Apheresis Donors and in Mild Bleeders with Near Normal Screening Coagulogram: A Study from a Tertiary Care Teaching Hospital, South India

R. Kar[1], P.L. Ambika[1], R. Kulkarni[2], D. Basu[2], S.S. Kar[3]

[1]Jawaharlal Institute of Post Graduate Medical Education and Research, Pathology, Puducherry, India, [2]Jawaharlal Institute of Post Graduate Medical Education and Research, Transfusion Medicine and Immunohaematology, Puducherry, India, [3]Jawaharlal Institute of Post Graduate Medical Education and Research, Preventive and Social Medicine, Puducherry, India

Background: Several studies have documented the influence of ABO blood group on plasma von Willebrand factor antigen (vWF:Ag) levels with significant low levels in O group, compared to other groups. Some forms of VWD can present with mild bleeding manifestations, with a normal screening coagulogram, with or without prolonged aPTT.

Aims: Among attendees of a tertiary care hospital in Southern India, to estimate vWf:Ag levels in

o apheresis donors and

o mild bleeders with near normal screening coagulogram

Methods: For apheresis donors (n=295), ABO blood group phenotype was done by standard tube method. The patients (n=39) enrolled had mild bleeding phenotype (ISTH BAT score of < 6 for females, < 4 for males and < 3 for children) whose routine coagulation

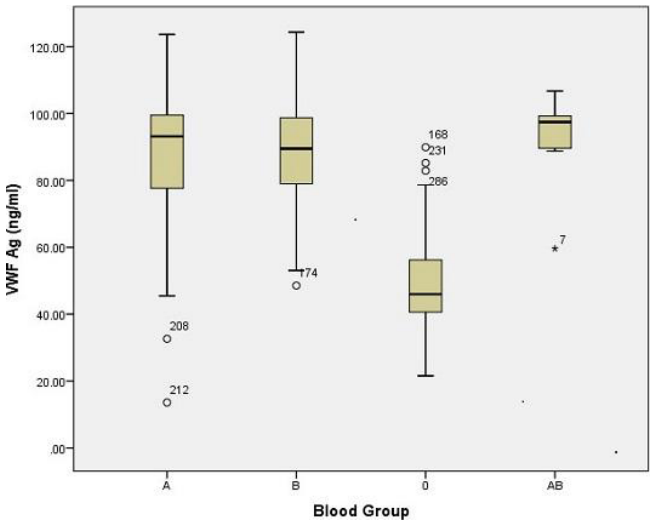

FIGURE 1 Comparision of vWF:Ag levels among various blood groups

screen (BT, PC, PT, aPTT) was either normal or showed mild aPTT prolongation. Estimation of vWF:Ag was done by ELISA method (Raybiotech, USA).

Results: All donors were males with mean age of 27.24 ± 7.25 years. The distribution of ABO blood groups was 46 (15.6 %), 135 (45.8%), 105 (35.6%) and 9 (3.1%) for A, B, O and AB respectively with mean vWF:Ag value being 87.53 ± 22.48 ng/ml, 88.84 ± 16.18 ng/ml, 48.72 ± 13.24 ng/ml and 92.04 ± 12.7ng/ml (Figure 1).

The mean vWF:Ag level was significantly higher for non-group O than group O individuals ($p< 0.05$).

Mean age of mild bleeders was 14.98 years, 74% were females, 82% had normal screening coagulogram. The average BAT score and vWF:Ag levels was 2, 3.7 and 3.2; 63.71± 20.93, 71.32± 21.59 and 68.74± 17.65 among males, females and pediatric patients respectively.

The overall mean vWF:Ag levels for donors and mild bleeders was 74.46± 25.2 ng/ml and 68.87 ± 18.93 ng/ml respectively.

Conclusions: This study emphasizes that vWF:Ag level is higher in non-group O than group O individuals.

The mild bleeders had vWF: Ag in normal range; however further work up is needed. Separate reference ranges of vWF:Ag for various ABO blood groups should be used for diagnosis of vWD.

PO 15 | Screening Test for Leiden Mutation Relevance

N. Lazic[1], Z. Pastar[1], D. Mandic[2]

[1]University Clinical Center, Department for Clinical Laboratory Diagnostics, Banjaluka, Bosnia and Herzegovina, [2]University Clinical Center, Department for Hematology, Banjaluka, Bosnia and Herzegovina

Background: Protein C in active form (APC) is important inhibit regulator of coagulation cascade. Resistance to APC (RAPC) is mainly caused by FV Leiden mutation (FVL). In persons with FVL inactivation of factor Va is much slower and the time of thrombin formation due to factor Va is prolonged resulting in hypercoagulable state.

Aims: The aim of the study: to establish incidence of RAPC in patients suspected on thrombophilia; to compare results of genetic test regarded functional coagulation test.

Methods: We examined 335 samples from patients with clinical suspicion for thrombophilia. Samples of venous blood were collected in tubes with sodium citrate, centrifuged for 10 minutes at 1500xg to separate plasma for analysis. We applied screening RAPC determination test on automated coagulation analyzer. Principle of the test is activation of the endogenous protein C and clotting time measuring. In normal person activation prolongs result 2-3 times, but in person with Leiden prolongation is minimal. Result is calculated as a ratio (ACR) between clotting time with and without activator. Cut off value for ACR ratio was 2. Patients with smaller ACR ratio were suspected to be positive for Leiden mutation and were submitted to genetic analysis.

Results: Out of 335 samples which are examined for RAPC, 20 samples or 6% were positive. All of them were confirmed to be heterozygots for Leiden mutation by DNA analysis. We did not have false positive results confirming that test specificity is high.

Conclusions: Although we put the decision limit higher then recommended by manufacturer to avoid false negative results, percent of positive was significantly lower than in literature (20-25% in patients with indications for testing). It is close to percent for general European population (3-8% according to literature data). Since the test sensitivity (cut off 1.8) is 99.2%, reason for this may be uncritical test ordering. That remains the goal for the further investigation.

PO 16 | Simultaneously Label-free Measurement of Hemoglobin Concentration and Erythrocyte Shape by Scanning Flow Cytometry

E. Iastrebova[1,2], K. Gilev[1,2], A. Chernyshev[1,2]

[1]Novosibirsk State University, Novosibirsk, Russian Federation, [2]Voevodsky Institute of Chemical Kinetics and Combustion SB RAS, Novosibirsk, Russian Federation

Background: Red blood cell (RBC) shape is not covered by modern hematology analyzers, but it has a significant correlation with pathologies. In our study we propose the simultaneously measurement of MCHC and erythrocyte shape with good accuracy combine with label-free measurement of the effective and total Band3 human erythrocyte protein.

Aims: Development of diagnostic system for screning blood cells shape to early detection of pathologies.

Methods: All experiments were carried out on the Scanning Flow Cytometer (SFC, fabricated by CytoNova Ltd., Novosibirsk, Russia, http://cyto.kinetics.nsc.ru). This instrument allows to measure light-scattering profiles (LSPs) of individual cells. Blood samples were taken by venopuncture and collected in a vacuum tube containing EDTA as anticoagulant. The sample was 1000-fold diluted in 0.9% saline and in isotonic solution of ammonium chloride.

Results: For each measured RBC we obtained the following morphological characteristics: hemoglobin concentration, sphericity index, surface area, volume, diameter, membrane spontaneous curvature, maximal and minimal thicknesses. The thickness-vs-diameter scatterplot can identify non-standard cells, such as top tail, associated with almost spherical RBCs, for example, reticulocytes. Our results confirm the possibility of precise, label-free, enhanced morphological analysis of individual intact RBCs. We determine for 15 donors the number of effective and total Band 3 protein and ration of membrane tension and elasticity for erythrocyte population. It specifies the current state of the donor anion exchange.

Conclusions: Lack of consumables and fast analysis time make the proposed method appropriate for routine clinical diagnostics, significantly increasing its descriptiveness and sensitivity to pathologies. The issued array of morphological RBC characteristics opens a new informative screening method in laboratory medicine.

FIBRINOLYSIS & PROTEOLYSIS

PO 17 | Interaction of Antithrombotic Preparation Pijavit with Proteinase Complex Longolytin and its Producer Imperfect Fungi Arthrobortys Longa

L. Podorolskaya, T. Sharkova, I. Pavlova

Moscow State University, Biolodical Faculty, Moscow, Russian Federation

Background: Imperfect fungi synthesize fibrinolytic substances and are the perspective sources of thrombolytic preparations. Longolytin - proteinase complex,- produced by imperfect fungi Arthrobotrys longa, dissolved experimental external thrombi in rabbits and inner veins thrombi in rats. Pijavit is pharmacological preparation from Hirudo medicinalis with powerfull anticoagulant and antithrombotic properties and can use instead of heparin.

Aims: The aim. To study the possibility to rise longolytin fibrinolytic (hence thrombolytic) activity by addition of new antithrombotic preparation from Hirudo medicinalis - pijavit.

Methods: In vitro pijavit 2-16 mg/ml was added to equal volume of longolytin 10-30 C.U. activity and fibrinolytic activity (F.A.) was determined on fibrin plates. In other experimental series pijavit was added to flask wih Arthrobotrys longa culture and cultural fluid F.A. was determined after 5 days of fungi culture growing and longolytin releasing.

Results: There were obtained 2 opposite results in vitro and in vital cells. In vitro longolytin F.A. was inhibited in dependence on pijavit dose and fully depressed in 16 mg/ml and more. There were depressed as plasminlike and plasminogen activator activity of longolytin general F.A. In contrast longolytin F.A. was increased by pijavit addition to Arthrobotrys longa culture. There were stimulated as F.A. on standard fibrin plates on 44% and on plates without plasminogen on 36%. Possibly this phenomenon was result of defense reaction of vital fungi's cells to appearing of great amount of proteinase's inhibitors, containing in pijavit. Pijavit created high anticoagulant activity, registered by thromboelastograpy in cultural fluid.

Conclusions: Combine using of 2 antithrombotic preparation not always results in cumulation of antithrombotic effect. It is necessary know properties of preparations Pijavit inhibited F.A. of longolytin in big doses, so its combine using must be very carefully.

HEMORRHAGIC DISORDERS, HEMOPHILIA

PO 18 | Immune Tolerance Induction in an Adult Haemophilia A Patient with a Long-standing Inhibitor

C. Feistritzer, D. Nachbaur, M. Steurer

Medical University of Innsbruck, Haematology and Oncology, Innsbruck, Austria

Background: Inhibitor development occurs in up to 36% of severe haemophilia A (HA) patients. The clinically proven strategy to eradicate FVIII antibodies is immune tolerance induction (ITI).

Aims: Predictors for ITI success include e.g. the peak historical inhibitor titre, age and the period between initial inhibitor diagnosis and start of ITI.

Methods: We present the case of a 38-year-old patient (48 kg, 174 cm) with severe HA (< 1% FVIII) without ongoing regular FVIII therapy who had a high-titre inhibitor and required urgent orthopaedic surgery. More than 20 years ago, the patient had suffered an intracranial haemorrhage, and treatment with pd-FVIII resulted in inhibitor development (max. titre 160 Bethesda units (BU).

Results: At the time of admission on the orthopaedic department, the patient's FVIII inhibitor titre was 1 BU/ml. Turoctocog alfa (NovoEight®, Novo Nordisk) was used for FVIII replacement therapy during surgery, which was considered successful. On Day 7, an increased level of inhibitors to FVIII were detected, which peaked at 12.5 BU on Day 9. The classic Bonn protocol was selected as the ITI method. The patient was treated with 5000 IU turoctocog alfa twice daily, and 5000 IU FEIBA® once daily from Day 9 to 17, after which time FEIBA® administration was stopped. The patient's inhibitor levels declined and were no longer detectable by Day 17, although PK analyses on Day 20 showed a FVIII half-life of < 6 hours and recovery at < 66%. FVIII replacement therapy was continued and within 12 months all criteria for successful ITI were achieved. During the follow up of now more than30 months, no spontaneous bleeding occurred. Quality of life improved dramatically since the successful ITI und regular FVIII treatment.

Conclusions: Here we report a rapid success of ITI in an adult patient with HA having a long-standing inhibitor. Results suggest that surgery may not prevent ITI success and that HA patients with inhibitors should be offered ITI irrespective of the time since the first inhibitor detection.

PO 19 | Evaluation of the Quality and Safety of Care in Hemophilia Self-treatment

M. Djaafri, M. Sehab, L. Zatla, R. Messaoudi, D. Saidi, H. Touhami

University Hospital Oran, Oran, Algeria

Background: Self-treatment is an irreplaceable therapeutic strategy in the treatment of this chronic disease.

Aims: We evaluate the quality and safety of care for self treatment of hemophiliacs.

Methods: We started training patients to self-treatment in 2011. To date over 107 Hemophilia A and 6 hemophilia B , 26 hemophilia A,2 hemophilia B are self treatment. The main objectives of the training: Hemophilia, a diagnosis of hemorrhage, bleeding hazardous locations, hand washing, dose calculation and preparation of the product, practical training on peripheral venous approaches on artificial arm. Training in groups or individually.

Results: The medical team should monitor the use of clotting factor concentrates and evaluate the effectiveness of self-treatment

program. After training we noticed the rapid establishment of the substitution therapy at home at the first signs of bleeding and better control of pain in the majority of hemophiliacs. There is a slight decrease in factor consumption compared to hemophiliacs who are not self treatment. There is a reduction in truancy and in Dworkin with a significant improvement in quality of life with more independence and taking responsibility.

Conclusions: The quality and safety of care are conditioned by a commitment from the neat and care givers while ensuring the implementation of safety measures and the quality of self-treatment.

PO 20 | Participation of a Group of Healthcare Professionals in the Improvement of Hemophilia Treatment in Latin America

C.A. Montano Mejia[1], M.S. Cruz[2], F.A. Espinosa Chacur[3], J.F. Lemos Garcia[4], G.F. Rojas Alba[5], A. Quiroz Astigarraga[6], C.G. Carrera Calero[7], A. Peña Hernandez[8], O.A. Avendaño[9], J.M. Cortes Bernal[10], A.M. Gaona Tottil[11]

[1]Universidad Tecnologica de Pereira, Ciencias Clínicas, Pereira, Colombia, [2]Fundacion de la Hemofilia de Salta, Salta, Argentina, [3]Hospital Clinico San Borja Arriaran, Santiago de Chile, Chile, [4]Centro Hospitalario Pereira Rossell, Medicina Transfusional, Montevideo, Uruguay, [5]Hospital de Niños, Santa Cruz de la Sierra, Bolivia, [6]Instituto de Prevision social IPS, Asuncion, Paraguay, [7]Hospital de Especialidades Eugenio Espejo, Quito, Ecuador, [8]Hospital, Servicio de Hematologia Pediatrica, Tegucigalpa, Honduras, [9]Medical Solution S. A., Guatemala, Guatemala, [10]Fundacion Hospital San Vicente de Paul, Medellin, Colombia, [11]Hospital Central, Instituto de Prevision Social, Asuncion, Paraguay

Background: Red Lapi Association started 7 years ago with a group of healthcare professionals with experience in the treatment of hemophilic patients.

Aims: The objective of the Association is to work in the education of Specialists, General Practitioners, Bacteriologists, Nurses, as well as patients and their relatives. It has also supported the development of Hemophilia programs in Latin American countries and encouraged research and publications of their experiences. RED LAPI has counted with the participation of professionals from 13 countries.

Methods: Red Lapi has held 13 meetings. A section of each meeting is always dedicated to train members. We also work in the projects that are taking place and discuss about relevant issues with governmental bodies. A part of the meetings is dedicated to provide training to doctors and paramedics of the host country and also to local patients' associations in order to create awareness around the disease and help improve Hemophilia patients' care in Latin America.

Results: This work describes the following outcomes from Red Lapi:

The impact on the improvement of patients' care from 13 Workshops. These events were held in different cities with a total attendance of 463 people.

Activities to support the diagnosis and treatment of patients.

Publications: Diagnostic and therapeutic status of haemophilia in Latin America. The Journal of Haemophilia Practice, May 2014;1(2):30-34.

Handbook of Practical Hemophilia, 1st Edition Santiago de Chile, 2nd Edition Asunción Paraguay. Distributed in 13 Latin American countries. Adopted by the Ministry of Health of Paraguay as a manual for the National Hemophilia Program.

Collaborations with governmental bodies and advice provided to implement Hemophilia programs in Ecuador, Bolivia and Paraguay. Papers presented at international congresses.

Conclusions: In developing countries it´s very important to create international work groups to achieve positive results in the growth of national programs for the diagnosis and treatment of hemophilic patients.

PO 21 | Successful Non-operative Management of Intra-abdominal Hemorrhage in Patient with Hemophilia

H.S. Yoon[1], M.J. Kim[2]

[1]Kyung Hee University Hospital, Seoul, Korea, Republic of, [2]Kyung Hee University Hospital, Department of Pediatrics, Seoul, Korea, Republic of

Background: Spontaneous intra-abdominal hemorrhages are rare bleeding episodes in hemophilia patients. That can cause many problems for severe hemophilia patients, the mortality rate increases significantly. Therefore it is very important to early diagnose and determine the treatment strategy urgently. Management of intra-abdominal hemorrhage range from conservative treatment to emergent embolization or surgery.

Aims: There is no clear guideline for managing intra-abdominal hemorrhage in patients with hemophilia. we describe two patients with intra-abdominal hemorrhage in whom bleeding was successfully controlled with non-operative management.

Methods: -

Results: One of the patients had gross hematuria and subsequent increasing abdominal pain. The other patient had significant periumbilical pain and mild fever. In our patients, we obtained an abdominal computerized tomography scan initially, in order to define the focus of bleeding, and rule out the presence of active bleeding. Intra-abdominal hematoma was observed in the both two patients, the size of the hematoma was approximately 11X4 cm, 7X5 cm, respectively. They treated successfully with coagulation factor and embolization and were discharged safely from the hospital.

Conclusions: We emphasize the role of active approach in the evaluation and non-operative management of an acute abdominal problem of this case without any surgical intervention.

PO 22 | Inhibitor Screening of Children with Hemophilia in the Diyarbakır - A Single Centre Study

M. Söker[1], H. Uzel[1], K. Öncel[1], S. Söker[2]

[1]Dicle University Medical Faculty, Pediatric Hematology and Oncology, Diyarbakır, Turkey, [2]Dicle University Medical Faculty, Histology and Embriology, Diyarbakır, Turkey

Background: Development of inhibitors in hemophilia patients is the most serious and life-threatening complication of hemophilia therapy.

Aims: The aim of this study was to determine the inhibitor prevalence in the children with hemophilia who were followed up in the Diyarbakır center at South-East Anatolia Region of Turkey.

Methods: 61 patients were included in the study (37 with hemophilia A, 8 with hemophilia B and 16 with von Willebrand disease). Ages ranged from 1 to 16 years (mean: 9.2 years). Out of 45 hemophilia A and B patients, 25 (55.5%) had severe hemophilia (factor level < 1%), 18 (40 %) had moderate hemophilia (factor level 1-5%) and two (4.5 %) had mild hemophilia (factor level >5-30%). The inhibitor positivity and titers were evaluated with Bethesda method.

Results: In this study, 7 patients were positive for inhibitors. Most of them 4 were low responders (< 5 Bethesda units), while 3 patients were high responders (>5 Bethesda units). Inhibitor was not found in any patient with hemophilia B and von Willebrand disease. Inhibitor prevalance was 18.9 % in all hemophilia A patients.

Conclusions: These results showed that the prevalence of inhibitor development was similar than the other centers of Turkey. It may be recommended that hemophilia patients should always be screened for inhibitors on regular intervals.

PO 23 | Liver Transplantation in Hemophilia Patients

A. Aires[1], M.J. Diniz[1], M. Antunes[1], A. Santos[1], T. Araújo[2], A. Mascarenhas[2], M. Rameiras[2], M. Campos[2], A. Ribeiro[2], S. Gouveia[2], E. Barroso[3], R. Perdigoto[3], A. Ferreira[3]

[1]Hospital São José, Centro Hospitalar Lisboa Central, Tranfusion Medicine Department - Hemophilia Centre, Lisbon, Portugal, [2]Hospital Curry Cabral, Centro Hospitalar Lisboa Central, Transfusion Medicine Department, Lisbon, Portugal, [3]Hospital Curry Cabral, Centro Hospitalar Lisboa Central, Liver Transplantation Centre, Lisbon, Portugal

Background: Hemophilia is a sex-linked inherited bleeding disorder resulting in the deficiency of factor VIII (hemophilia A) or factor IX (hemophilia B) and leading to lifelong bleeding complaints. The treatment consists of coagulation factor replacement. Prior to routine screening of blood products, many patients with hemophilia were infected with hepatitis C virus (HCV) and/or human immunodeficiency virus (HIV). As many of these patients are living longer now, they may develop end-stage liver disease and some will require liver transplantation.

Aims: To report our experience of liver transplantation in hemophilia patients.

Methods: A retrospective review of clinical notes and electronic case records.

Results: Between 2007 and 2016, 3 liver transplants were performed in 3 male patients with congenital hemophilia: 2 with hemophilia B and 1 with hemophilia A. The indication for transplantation was end-stage liver disease secondary to HCV infection. Two patients were co-infected with HIV and two had past alcoholic habits. A multidisciplinary team was involved in the peri-operative management and each patient had his own planning for the individualized optimization of clotting factor replacement strategy. No excess bleeding occurred in the peri or postoperative period. Overall survival patient rates at 1, 3 and 5 years, was 100% and factor VIII/IX levels became normal immediately after liver transplantation and remain within normal parameters.

Conclusions: In hemophilia patients with HCV associated end-stage liver disease, liver transplant has become an accepted treatment option. At our centre, the survival rates and peri-operative bleeding were similar to non-bleeding disorder patients, as reported by other Liver Transplantation Centres. Despite de data, concern remains about bleeding risks in the peri-procedure, however with close collaboration between the transplant team and the hemophilia treatment centre, it can be performed safely and successfully.

PO 24 | Chronic Osteolytic Lesions Secondary to Gigantic Pseudotumor of the Thigh in a Young Adult with Hemophilia B: Poor Prognosis and Outcome

R. Silva[1], J. Marun[2], D. Perez[2]

[1]Clinica General del Norte, Orthopedics, Barranquilla, Colombia, [2]Clinica General del Norte, Hemophilia, Barranquilla, Colombia

Background: Pseudotumor grows as a chronic, slowly expanding, encapsulated cystic mass as a result of recurrent hemorrhage in extraarticular musculoskeletal systems, Occasionally they cross the anatomic boundaries and could infiltratE and erodE the bones nearby. The bones usually implicated are femur, pelvis, tibia, and small bones of the hand.

Aims: To present an atypical case of hemophilic pseudotumor due to poor socioeconomic conditions and access to medical care that ended up in bad prognosis and health outcome

Methods: we present the case of a 30-year-old patient with hemophilia B with a history of irregular treatment with multiple hospitalizations during his childhood and a personal history of meningitis with epileptic syndrome, previous femur and ankle fracture, history of chronic anemic syndrome, and repetitive hematuria, consulted the emergency department with chronic ulcers of the lower limbs. Deformity of the limb, with a functional impossibility (wheelchair patient), a knee defect with a distal femur bone and proximal tibial fistula showing exposed. X-rays SHOWS osteolytic lesions of the entire femur and tibia with signs of chronic osteomyelitis secondary to a giant pseudotumor of the thigh that invaded both bones and compromised the skin as well. As a therapeutic intervention factor IX is administered, antibiotic, curettage, blood transfusion, psychological and nutritional support.

Results: This is the case of a patient with poor socioeconomic conditions who didn't consulted for medical care on time due to bad geographical access from where he lived. The patient presented rapid clinical deterioration and died after being admitted to our service.

Conclusions: Accurate knowledge of the extent and character of pseudotumors, gained through sonography, CT, and MRI, can be extremely useful in determination of proper management and follow-up

assessment . Bad prognosis and health outcome could be the result of poor access to medical care due to geographical or socioeconomical limitations in developing countries.

PO 25 | Pseudotumor ans Succeful Conservative Management in Hemophilia Patient with Inhibitors

R. Silva[1], J. Marun[2], D. C[2]

[1]Clinica General del Norte, Orthopedics, Barranquilla, Colombia, [2]Clinica General del Norte, Hemophilia, Barranquilla, Colombia

Background: Pseudotumors are a major complication in patients with hemophilia and can have a long life devastating effects, especially in the presence of inhibitors. The frequency and severity of hemophilic pseudotumours have decreased with the use of factor VIII replacement therapy. However, they may still occur in developing countries where facilities for diagnosis and treatment of hemophilia are not available. Only a few cases have been reported in the literature.
Aims: The purpose of our work is to showcase the experience in our Hemophilia Center in Barranquilla, Colombia and to highlight conservative management of hemophilia pseudotumor with long-term replacement therapy.
Methods: We report a 50 years old patient with severe haemophilia A plus low response inhibitor diagnosis with inguinal and pelvic pain, deformity in hip flexion, limp and palpable mass that was diagnosed with magnetic resonance as a pseudotumor of psoasiliac muscle with no involvement of the iliac crest. This patient underwent conservative medical treatment with rest, long term replacement of factor VIII therapy and physiotherapy with a remarkable clinical improvement; it was decided not to perform surgical treatment at the moment.
Results: Patient has developed satisfactorily and is still in periodical control observing the localized mass without increase in size or bone involvement of the iliac crest.
Conclusions: The behavior of the pseudotumour is different in children than in adults. In adults, they are usually observed at proximal bones, and do not usually respond to replacement treatment associated cost/benefit of interventional treatment versus replacement therapy, and the risk of recurrence should be taken into consideration when treating a hemophilic pseudotumor with the presence of inhibitor. **Conclusion:** The management of hemophilic pseudotumour aims at preserving function and includes conservative methods (immobilization, therapy), whenever this is feasible.

PO 27 | Unexpected Incidence of Inhibitor Development in a Hemophilic Population from the North of Spain

L.F. Avila Idrovo, A. Bernardo Gutérrez, D. Martinez Carballeira, I. Soto Ortega

University Central Hospital of Asturias, Hematology Department, Oviedo, Spain

Background: Inhibitor development is the major complication of therapy in developed world. It renders the treatment replacement ineffective and which increases both the costs of treatment and morbidity and mortality of the disease. Development of inhibitors is described in 36% and 5% of severe Hemophilia A and B patients respectively.
Aims: We describe our inhibitor population among our hemophiliac patients, as we notice we have a higher incidence and prevalence than it is described previously.
Methods: We have 54 patients diagnosed of hemophilia at the Hematology Department of the University Central Hospital of Asturias; 51 (95%) are HA (20 (37%) are severe); 3 (5%) are diagnosed of severe HB. We analyzed the variables correlated with development of inhibitor such as genetic mutation, age of diagnosis, number of exposures, type of treatment, symptoms, relapse, among others.
Results: In the period 1997- 2016, the overall incidence of inhibitor development in our severe hemophilia patient's population was 6 (26%); 4 (20%) patients having a severe HA and two (66%) patients having HB. The median age of the inhibitor detection was 11 months. The median of number of ED was 19 and one patient received continues infusion treatment of FVIII for intracranial hemorrhage in the diagnosis. The bleeding episodes included hemarthrosis, mucosal bleed, traumatic bleeding, hematuria and intracranial hemorrhage. A genetic study was performed in all of them: deletions and insertions were detected. Immunotolerance treatment was adopted in five patients (one was a transitory inhibitor); one patient with HB achieved immune tolerance, one patient with HA reached partial response, and two patients with HA and one patient with HB are refractory. In one HB patient, ITT had to be interrupted because a nephrotic syndrome development. In three refractory patients we used immunosuppressive treatment.
Conclusions: We find a higher incidence of inhibitor in our population than it is described. We have noticed a higher proportion of high risk mutations.

PO 28 | Hereditary Hypofibrinogenemia - Rare Familial Disease with Tendency to Increased Bleeding

J. Prochazkova, L. Slavík, J. Ulehlova, V. Krcova, A. Hlusi

Faculty of Medicine and Dentistry, Palacký University Olomouc; University Hospital Olomouc, Department of Hematology-Oncology, Olomouc, Czech Republic

Background: Introduction: Hereditary hypofibrinogenemia is a rare familial disease with tendency to increased bleeding. Clinical manifestation vary proportionally to the depth of the deficit from solely post-surgery or post-traumatic bleeding to spontaneous haemorrhage of various intensity. Women tend to have spontaneous abortions and increased peripartum bleeding.
Aims: Case report: 21-year old woman was sent to our department in the 27th week of her first gravidity to find the cause of slightly prolonged INR. She had a history of more intensive periods and increased bleeding after the surgery of middle ear in childhood. The assessment

of fibrinogen level was not carried out at that time. We performed laboratory examination which confirmed slightly prolonged INR together with significantly prolonged thrombin time and decreased level of fibrinogen.

Methods: -

Results: The patient was carefully observed throughout gravidity. As she had no symptoms of bleeding and stable levels of fibrinogen 0,6-1,0 g/l, she was left without substitution. At the time of delivery she obtained 7 g of fibrinogen in fractions. We continued with the substitution for 6 subsequent days with 2 g dose per day, and next twice weekly 2g until the 21st day after delivery. Then we stopped the substitution (altogether the patient obtained 29 g). From the beginning of fibrinogen substitution until the 25th day after delivery we applied prophylactic dose of low-molecular weight heparin. The delivery of a healthy new born baby with normal weight was with no complications. For the whole peripartum and postpartum period the patient was free from increased bleeding or other complications. After the subsiding of gravidity hormonal changes we could trace the decrease of fibrinogen levels to 0,35 g/l.

Conclusions: We present a successful management of gravidity and peri and postpartum period in a patient with serious hypofibrinogenemia.

PO 29 | A Case with Factor X Deficiency and Malignant Melanoma

B. Koc[1], S. Buyukkapu Bay[1], B. Zulfikar[2], F. Taş[3], R. Kebudi[2]

[1]Istanbul University, Oncology Institute, Department of Pediatric Hematology/Oncology, Istanbul, Turkey, [2]Istanbul University, Cerrahpasa Medical Faculty and Oncology Institute, Department of Pediatric Hematology/Oncology, Istanbul, Turkey, [3]Istanbul University, Oncology Institute, Department of Medical Oncology, Istanbul, Turkey

Background: Factor X (FX) deficiency is an autosomal recessive congenital rare bleeding disorder that the bleeding tendency appears at any age, although the more severely affected (< 1% activity) presents early in life with umbilical-stump bleeding, CNS or GI bleeding. Common symptoms are at all severity levels which include epistaxis and menorrhagia. Therapy usually is administration of PCC and also a new pure FX concentrate.

Aims: Here we present a boy who was diagnosed with severe FX deficiency and malignant melanoma.

Methods: -

Results: Case: A boy whose brother has severe FX deficiency was diagnosed as severe FX deficiency after birth. He has been under PCC prophylaxis because of his frequent nose bleedings. He was admitted to our centre for his congenital giant nevus on his back. On physical examination, all systems were normal, the range of motion of his joints were full and there was a giant nevus with local hairy and nodular regions from his cervical region to lumbal region. He was consultated to Dermatology Department and a biopsy was performed some regions which were suspicious and was diagnosed as malignant melanoma. Then Positron Emisyon Tomografi (PET) was performed for the evaluation of metastasis. Bilateral axillary metastasis were found. His hemostasis control was done according to the protocol of our centre and he was operated. The majority of the nevus and bilateral axillary lenf nodes were exited. All materials which existed were malignant melanoma. The patient was evaluated as stage 3 malignant melanoma and Interferon was started. The patient's theraphy is still going on and none advers event had been seen.

Conclusions: Although malignant melanoma is the most frequent skin cancer in childhood, it is a rare cancer among the solid tumors. The congenital giant nevus is a risk factor for malignant melanoma. In this report, we presented a very rare case with FX deficiency and malignant melanoma that there is no similar case in the literature.

PO 30 | Inherited Thrombocytopathy - Impact on Patient's QOL

J.M. Teliga-Czajkowska[1], A. Sikorska[2], B. Ceglarek[2], K. Bykowska[3], A. Bućko[3], E. Dmoch-Gajzlerska[1], K. Czajkowski[4]

[1]Medical University of Warsaw, Department of Obstetrics and Gynecology Didactics, Warsaw, Poland, [2]Institute of Hematology and Transfusion Medicine, Department of Hemostatic Disorders and Internal Medicine, Warsaw, Poland, [3]Institute of Hematology and Transfusion Medicine, Department of Hemostasis and Metabolic Disorders, Warsaw, Poland, [4]Medical University of Warsaw, 2nd Dept. Clinic of Obstetrics and Gynecology, Warsaw, Poland

Background: The QOL in case of women with inherited bleeding disorders is much lower due to objectively documented menorrhagia (reported to be 10% to 20%).

The gynaecological and obstetric management of these women, including appropriate anesthesia poses a lot of problems.

Aims: To highlight a difficult clinical problem

Methods: A case report and literature review.

Results: We present a case of 33 years old patient with rare bleeding disorder- thrombocytopathy due storage pool disorders. Defective platelet aggregation results from an intrinsic deficiency in numer of dense granules. Although applied treatment of menorrhagia had been individualized (III-B recommendation) there was no success.

Neither hormonal therapy (oral contraceptives [II-1 B], depot medroxyprogesterone acetate (DMPA) [II-3B], danazol [II-2B],) and non-hormonal therapy (antifibrinolytic drug tranexamic acid [II-1 B]) as well as desmopressin (II-1 B) have not increased QOL. As the patient was eager to plan pregnancy in near future, GnRH analogs [II-3B]) or local treatments (levonorgestrel-releasing IUS [II-1 B] had not be applied. Course of two pregnancies was unevenful. Before C-section performed due to orthopedic indications, transfusion of platelets was made. There was no major bleeding observed in the puerperium. In the offspring otherwise healthy, prolonged APTT with normal PLT count were noted.

Conclusions: QOL of patients with rare bleeding disorders is often low. A multidisciplinary approach is needed not only during pregnancy but in every stage of women's life.

PO 31 | Duodenal Dieulafoy´s Lesion in a Patient with Type 2 von Willebrand Disease: Case Report from Colombia

J. Restrepo-Avenia, J. Duque-Gil, J. Ramirez-Varela

Centro Médico Imbanaco, Hemophilia Treatment Centre, Cali, Colombia

Background: Recent studies have suggested that recurrent gastrointestinal bleeding (GIB) is a challenging complication in patients with von Willebrand disease (vWD).

Aims: .

Methods: We describe a 73 year-old Hispanic woman with Type 2 vWD who had recurrent GIB while on demand treatment with von Willebrand factor concentrate (Immunate®). The first episode was controlled with Immunate® *tis in die* 100 IU Kg^{-1}, but for the remaining 15 episodes, she required complementary treatments despite infusion of vWFC (blood transfusion, hypervolemic liquids, tranexamic acid, octreotide and proton bomb inhibitors infusions). We started thalidomide (50 mg *quaque die* -QD-), but GIB recurred and thalidomide was doubled; however, myelosuppression, dizziness and a superficial venous thrombosis in the left lower limb were detected; these findings disappeared spontaneously after suspension of thalidomide. We tried two more approaches:

1) Atorvastatin 10 mg PO *quaquenoctis*, but GIB recurred;

2) Prophylactic treatment with Immunate® 20 IU Kg^{-1} three times per week, then switched to Haemate-P® at the same dose of Immunate, but nonetheless, GIB recurred.

Finally in June 2016, and after two years of follow-up and multiple pharmacotherapy approaches, a new GIB occurred and Endoscopy revealed a Duodenal Dieulafoy´s lesion, managed with endoscopy injection of Adrenaline 1:10 000 + Argon plasma and hemoclips (#06). After this, our patient remained stable, without GIB manifestations during seven months, and prophylactic treatment was suspended after 6 weeks of a negative endoscopy.

Results:

Conclusions: Despite multiple treatment options and different invasive procedures, we think, as stated by Makris *et al*, that the diagnostic success of the procedure is higher in the actively-bleeding patient. We also think that identifying and controlling the lesion is an effective way to control recurrent GIB, even in the presence of other supportive care. In our case, prophylactic treatment proved to be ineffective in the prevention of recurrent GIB episodes.

PO 32 | Von Willebrand Disease Diagnosis in Algeria: A Monocentric Study

H. Boukerb[1], G. Hariti[2]

[1]*CHU Lamine Debaghine, Centre Transfusion Sanguine, Algiers, Algeria,* [2]*CHU Bab el oued, Algiers, Algeria*

Background: von Willebrand disease (VWD) is the most common inherited bleeding disorder, due to quantitative and/or qualitative defects in von Willebrand Factor (VWF). It is characterized by a high clinical, biological and molecular heterogeneity. The VWD diagnosis is difficult and requires a panel of biological tests.

Aims: We report the clinical and biological characteristics of the VWD in 43 Algerian patients diagnosed in Lamine Debaghine hospital.

Methods: The VWD diagnosis is established upon three first level tests including the VWF Ristocetin Cofactor, the VWF Antigen concentration and Factor VIII activity, the bleeding score (BS) was also calculated. Second level tests are used for the subtyping including the RIPA, VWF-Collagen Binding, Plasmatic VWF multimers analysis and FVW-FVIII binding.

Results:

- Median age of diagnosis is 12 years old.
- Sex ratio M/F is 1:2.
- BS versus age: 9,7 for adults and 6,5 for children.
- Patients classification: 62 % type 1 of VWD, 08% type 2 (03 patients with type 2A and 01 patient with type 2M) and 30% type 3.

Conclusions: Type 3 of VWD seem to be more frequent in Algeria because of the high level of consanguinity. Molecular analysis should be performed for these patients to improve the understanding of VWD pathogenesis in our country.

MANAGEMENT OF THROMBOEMBOLISM

PO 33 | The Relevance of Personalized Therapy by New Oral Anticoagulants. Current Possibilities of Laboratory Monitoring and Control in Difficult Patients

S. Safiullina[1], T. Vuimo[2], I. Tyutlina[3], L. Feiskhanova[1]

[1]*Kazan State Medical University, Kazan, Russian Federation,* [2]*Dmitry Rogachev Federal Research-and Clinical Center for Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation,* [3]*Novosibirsk TB Research Institute, Novosibirsk, Russian Federation*

Background: Nowadays, routine laboratory monitoring in patients treated by the new oral anticoagulants (NOAC) is not accepted because of the proven effectiveness of fixed doses. NOAC is designed as an alternative to vitamin K antagonists (VKA). There are reports about the possible using of laboratory control of the NOAC in routine and integral tests for evaluation of hemostasis.

Aims: To justify the personalized selection of doses of NOAC under the control of thrombodynamic test and to demonstrate the need for monitoring of preventive doses to reduce the risk of re-thrombosis and bleeding.

Methods: The research included 49 patients with episodes of arterial or venous thrombosis and patients with a thrombotic readiness condition. The 25 patients received anticoagulants: low molecular weight heparins (8), VKA (4), NOAC (13). The examination included coagulation, D-dimer and Thrombodynamic test (TD). The control group included 18 patients with atrial fibrillation, which was planned appointment of the NOAC for primary prevention of stroke.

Results: Rivaroxaban was prescribed for 20 patients and Dabigatran - for 29 patients. Before the prescription based on TD hypercoagulation shifts were identified. In patients receiving the drug in 73.7% and 51.7% cases respectively was achieved normal coagulation. In other cases required dosage increased with the subsequent control of hemostasis. Only 10% the patients of the control group had pathological hypercoagulation due to results of D-dimer and 5% according to TD. There was normal coagulation in 100% after prevention by NOAC, 3 weeks later.

Conclusions: The prevention of thrombosis needs achieving the normal coagulation with low molecular weight heparins and then switching to NOAC under hemostasis control. Rivaroxaban demonstrated a higher frequency of achieving the normal coagulation. TD is useful for the initial evaluation of the hemostasis, for monitoring of anticoagulants, sensitive to the latent hypercoagulation and allows us to choose the optimal and safe dose of drugs.

PO 34 | Long-term Anticoagulation with Direct Oral Anticoagulants (DOACs) for the Prevention of Recurrent Deep Venous Thrombosis (DVT) and Pulmonary Embolism (PE)

R. Santoro, P. Iannaccaro, S. Morgione, M.T. Paparo

Haemostasis and Thrombosis Centre, Dept Haematology, AO Pugliese-Ciaccio, Catanzaro, Italy

Background: To balance the long-term risks of recurrent venous thromboembolism (VTE) once anticoagulant therapy is stopped against the risks to continue the therapy.

Aims: To assess the benefit-risk trade off continued direct oral anticoagulant treatment in symptomatic VTE patients with at least 2 episodes of idiopathic VTE, treated for at least 6-12 months after the last episode, and in whom physicians had recognized the need to continue anticoagulation.

Methods: In the DOACs extension study in the patients that taked anticoagulants for 6-12 months a clinically important benefit was observed, but there are no data for a further continuation of therapy.

Our center has followed 34 patients on very long-term anticoagulation. Their medical history showed a median of 3 recurrent episodes of idiopathic VTE (range 2-5). Recurrent episodes were DVT in 26 patients, 2 episodes of PE in one patient, both PE and DVT in 7 patients. Patients have practiced DOACs, after the treatment of 6 months from the last thrombotic episode, for a period of 12-36 + months (median 19 months). One patient were treated with dabigatran, 10 with rivaroxaban and 23 with apixaban.

Results: There were no thromboembolic relapses, but a patient receiving rivaroxaban, with a history of two episodes of DVT and a mesenteric thrombosis presented an episode of cryptogenic stroke. There were three minor bleeding events, one with apixaban (bleeding from hemorrhoids) and two with rivaroxaban (1 epistaxis, and a patient who reported heavy periods, but not complicated by anemia). Neither major bleeding nor clinically relevant non-major bleeding was reported. There were no other adverse events related to DOACs.

Conclusions: In patients with symptomatic and recurrent VTE, in whom physicians have deemed necessary to continue the anticoagulation, a favorable benefit-risk profile of continued anticoagulation with DOACs was observed and would result in an important benefit in recurrent VTE.

PO 35 | Laboratory Tests for Management in Patient with Direct Oral Anticoagulants

L.F. Avila Idrovo, A. Bernardo Gutérrez, A. Caro Gómez, A. Fonseca Mourelle, L. Rodriguez Lorenzo, A.P. Rodriguez Gonzalez, I. Soto Ortega

University Central Hospital of Asturias, Hematology Department, Oviedo, Spain

Background: A major advantage of these agents is the lack of a requirement for monitoring; however it´s recommended monitoring the drug for Rivaroxaban Apixaban and Endoxaban use anti-Xa chromogenic studies and for Dabigatran Hemoclot thrombin inhibitor and Ecarin clotting time (DTI test).

Aims: Detection of risk of develops bleeding with monitoring the drug in patient with direct oral anticoagulants.

Methods: We conducted a retrospective study with 227 patients who received direct oral anticoagulants (DOACs) between January 2015 and December 2016. One hundred eighteen patients (52%) receive Rivaroxaban, fifty patients (22%) receive Dabigatran and fifty nine patients receive Apixaban (26%). We analyzed the variables that's increases the bleeding risk such as age, weight, prothrombin time (PT) and activated partial thromboplastin time (aPTT), therapeutic range of the drug, and measurement of serum creatinine.

Results: We found 10% of toxicity with Dabigatran, a 7% with Rivaroxaban and a 3% with Apixaban. Thirty-five patients (15%) developed bleeding of which 11% patients had a minor bleeding and a 4% of patients had a mayor bleeding, we also found that 6% of patients with Dabigatran, 2.5% with Rixaroxaban and 1.5% with Apixaban developed thrombotic episodes. Twenty percent of patient didn't have therapeutic range of the drug. For each DOACs is shown in Table 1.

When we analyzed the patients who had hemorrhage we found that all patients with Dabigatran prolonged aPTT and the PT in 80%, for other DOACs is shown in Table 2.

Conclusions: In our series, in patients with dabigatran and who suffered bleeding, we found a significant prolongation of aTTP and PT, demonstrating the importance of laboratory tests prior to the administration of these agents and in emergency situations, for these reason should be include PT and aPTT, therapeutic level of the drug and creatinine measurement, within the emergency laboratory tests in patients that receive DOACs.

TABLE 1 Results of statistic study

Variable	Apixaban	Rivaroxaban	Dabigatrán
Percentaje	25.9%	51.9%	22%
Toxicity	3.3%	6.7%	10%
Thrombotic episodes	1.6%	2.5%	6%
Percenteje out of therapeutic range	8.4%	24.5%	22%
aPTT prolonged	8.4%	2.5%	80%
PT prolonged	16.9%	21%	4%

TABLE 2 Patients with bleeding

Variable	Apixaban	Rivaroxaban	Dabigatran
percentaje	34.2%	20.8%	7.8%
aPTT prolonged	8.3%	22.2%	100%
PT prolonged	25%	33.3%	80%
median therapeutic range	177	142	154
median serum creatinine	1.02	0.9	1.35
median age	74	81	71
median weight	66	72	65

PO 36 | Effective reversal of High Dose Dabigatran Intoxication by Idarucizumab in a Bleeding Polytrauma Patient

S. Ohlenforst[1], V. Ivaskevicius[1], C. Deborre[2], N. Theuerkauf[3], C. Putensen[3], J. Oldenburg[1], H.-J. Hertfelder[1]

[1]Institute for Experimental Haematology and Transfusion Medicine, University Hospital, Bonn, Germany, [2]University Hospital, Department of Orthopedic and Trauma Surgery, Bonn, Germany, [3]University Hospital, Department of Anesthesiology and Intensive Care Medicine, Bonn, Germany

Background: The monoclonal FAB fragment antibody against the oral direct thrombin inhibitor (DTI) dabigatran ("DABI") etexilate (Pradaxa™), idarucizumab (Praxbind™, "IDARU") has recently been licenced as a specific antidote for the reversal of the anticoagulant action of DABI in emergency situations.

Aims: Evaluation of efficacy of IDARU in a 63-year-old female, who had taken DABI for the prevention of stroke due to atrial fibrillation.

Methods: The patient had a severe trauma due to defenestration from 2nd floor presumably by suicidal attempt with complex fractures of pelvis, lower spine, distal right thigh, left ankle, and foot. Impaired renal function and enteroparesis induced by trauma and deep anaesthesia probably affected DABI resorption and pharmacokinetics.

Coagulation was monitored from citrate plasma by prothrombin time (PT), APTT, thrombin time (TT), clotting factors, e.g. factor II (FII). DABI levels were measured by a commercial thrombin inhibition test.

Results: Initial laboratory findings were trauma-/bleeding-related effects (table 1). During the next 4 days (d) clotting times of PT, APTT and TT gradually prolonged despite no anticoagulant had been applied. Further analysis revealed a profile typical for a high-dose DTI treatment (PT, APTT, TT prolongations, low FII activity). After confirmation of DABI intake, a DABI level > 10-fold higher than expected median peak level of 175 ng/ml according to SmPC 2 h after intake of 150 mg BID DABI was measured. As a decline of hemoglobin (Hb) indicated pelvic hemorrhage, a rapid reversal of DABI was done by 5 g IDARU i.v.. Further Hb decline was stopped, a marked decline of DABI and shortened PT, APTT, TT and increased FII level were observed (table 1). 5 h later a rebound of DABI occurred. 3 d later DABI was below detection limit.

Conclusions: IDARU is useful to reverse DABI anticoagulant effect. However, in case of very high DABI levels the standard dose does not completely neutralize the drug, and a rebound phenomenon has to be expected.

PO 37 | Does Intra-venous Unfractionated Heparin (UFH) Have a role In the Management of Acute Peripheral Vascular Ischaemia and Surgery In 2017?

M. Creagh[1], S. Matthews[2], V. Sathish[3], X. Taylor[3]

[1]Royal Cornwall Hospitals NHS Trust, Haematology, Truro, United Kingdom, [2]Royal Cornwall Hospitals NHS Trust, Pharmacy, Truro, United Kingdom, [3]University of Exeter Medical School & Peninsula College of Medicine & Dentistry, Truro, United Kingdom

Background: Low molecular weight heparin (LMWH), at a weight adjusted dose without coagulation monitoring is commonly used in the treatment of venous thrombo-embolic events. Given its shorter half life and greater reversibility, unfractionated heparin (UFH) remains an accepted practice in peripheral arterial vascular interventions, however prescribing is demanding, monitoring is necessary with dosing revisions.
Aims: To determine the use and therapeutic efficacy of UFH in patients of a vascular surgical unit undergoing acute interventions, by analysis of prescribing, monitoring and outcomes.
Methods: A retrospective audit of an electronic prescribing system, from May 2015 to October 2016, identified 18 patients undergoing peripheral arterial vascular interventions and UFH therapy. Electronic records for peri-operative clinical details, prescribing and activated partial thromboplastin time ratio (APTT-r) testing were analysed, together with dedicated UFH dosing charts.
Results: Thirteen patients had had previous arterial events. Ten patients underwent surgical interventions, most commonly embolectomy, with eight managed conservatively for acute ischaemia. Heparin bolus therapy was documented for 17 cases, with infusions in 17, nine being continued for less than 24 hours, the longest being for six days. A therapeutic APTT-r was achieved at 12 and 24 hours in 6% and 22% of cases respectively and overall in only 50% during an infusion. There were three subsequent thrombotic events amongst the surgical cases, while two conservatively managed cases had progressive ischaemia. No excessive haemorrhage nor heparin induced thrombocytopaenia was recorded.
Conclusions: Most patients had had previous thrombotic events. UFH bolus therapy was common with infusions relatively limited in duration. Performance against a target APPT-r was poor. Whilst no excess haemorrhage was observed, the thrombotic/ischaemic outcomes suggest that the UFH schedule was of limited benefit and revision to stat bolus and, or LMWH should be assessed.

PO 38 | Oral Anticoagulants in Patients with Hereditary Protein Z Deficiency - A Case Report

J.C. Groß[1,2], B. Hummel[1], H. Lauer[1], B. Stephan[1], J. Schenk[1], H. Eichler[1]

[1]Saarland University Medical Center, Homburg, Germany, [2]Saarland University Medical Center, Clinical Hemostaseology, Homburg, Germany

Background: Protein Z (PZ) deficiency can cause clinically relevant bleeding tendency. Nevertheless, also systemic anticoagulant therapy may become necessary in some patients with this rare bleeding disorder.
Aims: We present the clinical course and laboratory findings of a 85 years old female patient with PZ deficiency, in whom anticoagulation was indicated because of intermittent atrial fibrillation.
Methods: Case Report.
Results: The patient is well known in our hemostatic care unit since many years with a PZ deficiency (680-820 µg/l; ELISA, normal range 1.000-4.000) and suffers from spontaneous hematomas and easy ulorrhoea; also a pulmonary embolism occured after hysterectomy in her 40th year of life, and she also suffered from a deep vein thrombosis of the lower leg at the age of 79 years. A PZ deficiency could also be confirmed in her daughter suggesting a hereditary disorder. Because of intermittent atrial fibrillation oral anticoagulant (OAC) therapy now became necessary and was first started with phenprocoumon at a target INR of 2,0 - 2,5. Under this regime spontaneous bleeding of the thigh occured finally requiring clinical treatment. Therefore the anticoagulant was changed to apixaban 2x 2,5 mg daily. Now the patient suffered from dramatic spontaneous hematomas and bleeding of the mouth mucosa; measuring apixaban 5,5 hours after its intake revealed a peak concentration of 253 ng/ml (chromogenic essay; therapeutic range 69-221), while PZ concentration was 680 µg/l. Anticoagulation was now changed to low-intensity - phenprocoumon with a target INR of 1,7 - 2,0.
Conclusions: OACs should be used only with special care in patients with hereditary PZ deficiency, and routine laboratory monitoring of the therapy seems to be necessary even when novel OACs are used.

PO 39 | Prevalence of Laboratory Markers of Thrombophilia in Pregnant Women with Normal Obstetric Outcomes

E. Ferreira Filho[1], V. Barros[2], F. Baptista[1], R. Francisco[1], M. Zugaib[1]

[1]Hospital das Clinicas, Universidade de Sao Paulo, Obstetrics and Gynecology, Sao Paulo, Brazil, [2]Clinics Hospital, University of Sao Paulo, Obstetrics and Gynecology, Sao Paulo, Brazil

Background: The existence of thrombophilia amplifies the state of hypercoagulability inherent to pregnancy, which can lead to obstetric and perinatal complications.
Aims: We aimed to identify the prevalence of thrombophilia in pregnant women with normal obstetric outcomes.
Methods: Cross-sectional, prevalence study, with pregnant women in prenatal follow-up at HC-FMUSP. We included patients who denied previous diseases with single and spontaneous gestation and a morphologically normal fetus. We excluded women: with personal or familial history of 1st degree thrombophilia or venous thromboembolism or thrombophlebitis; who did not collect the requested tests; who developed severe forms of preeclampsia or placental insufficiency. We searched: factor V Leiden and prothrombin gene mutation; antithrombin, protein C and protein S activities; homocysteine serum levels,

lupus anticoagulant and anticardiolipin (IgG and IgM) antibodies. We collected the following information on delivery: gestational age, delivery route, Apgar scores and birth weight.

Results: 81 patients accepted to participate in the study, 62 collected blood samples for examination; one was excluded for diagnosis of thrombophlebitis in this gestation. Data are available on 50 deliveries; four cases were excluded (two cases of fetal malformation, one case of altered Doppler velocimetry and one case of superimposed preeclampsia). The prevalence of factor V Leiden (heterozygosis) was 1.9% and mutation of the prothrombin gene (heterozygosis) was 1.8%. 20.0% presented antithrombin < 79%; 58.5% presented protein S < 55%. The concepts were born with gestational age of 39.7 ± 1.0 weeks and weight of 3242 ± 407 grams; 15.2% was small for gestational age (according to Fenton curve), 2.2% presented Apgar score < 7 in the 5th minute of life.

Conclusions: Laboratory markers for thrombophilia may undergo changes during pregnancy. Women with altered antithrombin or protein S functional dosage are being called for new blood collection at least two months postpartum.

PO 40 | Variation of Clotting Factor Levels of Pregnant Women Attending Antenatal Clinics in Irrua Specialist Teaching Hospital (ISTH), Irrua, Edo State, Nigeria

R.A. Anyanwu[1], K.C. Lele[2], I. OKOROIWU[3]

[1]Ambrose Alli University, Ekpoma, Medical Laboratory Science, Benin-City, Nigeria, [2]Imo State University, Medical Biochemisty, Owerri, Nigeria, [3]IMO STATE UNIVERSITY, IMO, MEDICAL LABORATORY SCIENCE, OWERRI, Nigeria

Background: An estimated 50,000 Nigerian women die each year from complications of pregnancy and childbirth, accounting for 10% of global estimates of pregnancy maternal death.

Aims: This cross sectional study was set out to evaluate the effects of pregnancy on some coagulation factors; FV, FVII, FVIII, FIX, plasma Fibrinogen Concentration, platelet count and PF-3 availability.

Methods: A total of 578 subjects comprising 396 pregnant women and 182 non pregnant women were recruited for the study using standard manual methods.

Results: Factor VIII (% activity) (217.24±1.95) and platelet count (X10^9/µl 339.98±4.69) of the pregnant women were significantly higher than the Factor VIII (% activity) (199.13±1.02) and platelet count (X10^9/µl) 208.54±7.09 of the non-pregnant women (p< 0.05) respectively. Thrombin was significantly reduced in pregnant group over the non-pregnant group (p< 0.05). Plasma fibrinogen concentration (% activity) (86.28±0.43) of the non-pregnant women was found to be significantly higher than the pregnant women (78.53±0.59) (p< 0.05). The PF-3(sec) and platelet count (×10^3/µl) of the 2nd trimester versus 3rd trimester were found to be statistically lower than those of the 3rd trimester (p< 0.05). The Plasma Fibrinogen concentration (% activity) of Gravida 1 (77.07±1.18) was significantly lower when compared with Gravida 2 (79.26±1.05), Gravida 3 (81.51±0.98) and Gravida 4 (78.40±1.05) (p< 0.05) respectively.

Conclusions: We observed that coagulation factors were significantly increased when measured together in pregnant women. Further investigation reveals factors VIII and fibrinogen to be significantly higher, while thrombin was significantly decrease in pregnant women respectively. Moreso, haemostatic attention should be given to pregnant women throughout the course and events of pregnancy to prevent or reduce the risk of haemorrhagic disorders and possible disseminated intravascular coagulation (DIC).

PO 41 | Catastrophic Antiphospholipid Syndrome in Obstetrics Practice (Clinical case)

A. Makatsariya, V. Bitsadze, D. Khizroeva

I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

Background: catastrophic antiphospholipid syndrome (CAPS) is an uncommon, often fatal, variant of the antiphospholipid syndrome that results in a widespread coagulopathy and high titres os antiphospholipid antibodies and affects predominantly small vessels supplying organs with the development of multiorgan failure.

Aims: To consider CAPS development and to observe the pregnancy after CAPS.

Methods: since 2001 to 2016 we discovered 17 patients with CAPS development and observed the pregnancy after CAPS.

Results: Patient Z.24 years old, was admitted to hospital at term of 27-28 weeks. Her first pregnancy was finished with spontaneous abortion. In one hour after hospitalization, eclampsia was developed and patient was delivered with cesarean section. The premature girl (weight 980 g, height 24 cm) was born. Blood loss composed 700 mL. After delivery the infusion therapy was started, including fresh frozen plasma, anti-aggregational agents, hypotensive and uterotonic drugs, corticosteroids and antibiotics. Due to polyorganic failure, plasmapheresis and anticoagulant therapy LWMH were conducted. During hemostasis research LA and APA IgG/IgM (148 GPL, MPL) were revealed.The state of patient was severe for several days, but the level of APA became lower - 87 GPL, MPL, LA was positive. On the 20th day after delivery, the woman was discharged home in satisfactory state and was recommended to continue LMWH therapy for 3 months more.

Conclusions: The diagnosis may be missed as it is well known that the antiphospholipid antibodies may be negative at the time of the thrombotic events, only to reappear later. Besides this, serological samples might be uninformative because of previous cytostatics and steroid therapy. The development of obstetric complications in patients with APS makes it necessary to suppose presence of the catastrophic variant of this syndrome. All patients with a history of previous thrombotic events or pregnancy losses, should be tested for the presence of antiphospholipid antibodies.

PO 42 | Personalized Antithrombotic Prophylaxis in Patients with Multigenie and Combined Forms of Thrombophilia and APS

V. Bitsadze, D. Khizroeva, A. Makatsariya, D. Kapanadze

I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

Background: patients with multigenic and homozygous forms of thrombophilia - this is the group of women with repeated nonspecific thromboses, unusual localization thrombosis, arterial and venous repeated thromboses repeated placenta-mediated complications. In the history of such patients - the syndrome of fetal loss, premature detachment of the normally located placenta, thrombosis during the admission of hormonal contraceptives, hormone replacement therapy. The standard approach to it is not acceptable. They require a personalized approach to the choice of therapy, the selection of the dose medications, assessment of the effectiveness and the individual definition of the duration of the treatment and prevention of complications.

Aims: to observe the pregnancy of women with multigenie and combined forms of thrombophilia and APS, to evaluate the efficiency of treatment and personalized approach to each case.

Methods: from 2001 to 2016 years we observed the pregnancy of 59 women up to the age of 37 years with multigenic and combined forms of thrombphilia.

Results: all patients with thrombosis history genetic trombophilia received LWMH. Women with APS - LWMH and antiaggregants, intravenous immunoglobulin. The presence of CAPS demanded the plasmapheresis and FFP. Itcases of ADAMTS-13 deficieny - LWMH and antiaggregants. Assessment of the effectiveness of the treatment was carried out on the basis of anti-Xa activity (theraputic level =0.5-0.8). 57 children were born from 54 women. There have been no cases of hemorrhagic and thrombotic complications.

Conclusions: Only the personalized approach to the diagnostics of thrombophilia and choice of the treatment allows you to prevent the development of obstetric complications.

PO 43 | Thrombophilia and IVF

R. Apostolovska[1], I. Nikoloska[2], V. Neceva[2], R. Dukovski[2], E. Petkovikj[2], S. Krstevska Balkanov[3], D. Trajkov[4]

[1]Institute of Transfusion Medicine, Skopje, Macedonia, the Republic of, [2]Institute of Transfusion Medicine, Skopje, Macedonia, the Former Yugoslav Republic of, [3]Deprartment of Haematology, Skopje, Macedonia, the Former Yugoslav Republic of, [4]Institute for immunobiology and Human Genetics, Faculty of Medicine, University 'Ss Kiril and Metodij', Skopje, Macedonia, the Former Yugoslav Republic of

Background: Women with thrombophilia have been shown to be at increased risk, not only of pregnancy associated thromboembolism and vascular complications of pregnancy, including pre-eclampsia and fetal loss, but also of IVF (In Vitro Fertilisation).

Aims: Whether the thrombophilia can be a cause for IVF failures.

Methods: 25 women with a single or multiple IVF failure were followed. 18 pregnant women, whose first IVF had failed (1 group), and 7 women had repeated IVF failure (3 or more-2 group), all with obstetric history of complications in pregnancy, and with individual or family history of thrombosis. Testing for thrombophilia was conducted before the pregnancy, i.e. in the period of the planning of the pregnancy.

Results: The prevalence of thrombophilia was assessed in all 25 women Genetic thrombophilia was found in all 25 women, multi genetic thrombophilia in 18 (11 in first and 7 in second group). Mutation of methylenetetrahydrofolate reductase (MTHFR-C677T) was found in 10 women in the first group, and in all of the women in the second, f.V Leiden-5, prothrombin 20210A-4 combined with deficiencies in protein S and C-1 and antithrombin III-3 and antiphospholipid antibodies (b2-glycoprotein I) thrombophilic factors were found in 9 women. Hyperhomocysteinemia was found in 8 women with MTHFR mutation (4 in each group). All women with successful pregnancy after IVF (only one woman doesn't become pregnant) failure received therapy before and during the pregnancy. One woman had a miscarriage (loss of cardiac function in the fetus). 26 healthy newborns were born from 23 women with thrombophilia and IVF failures.

Conclusions: The data stated above suggests that thrombophilia plays a role in the genesis of IVF failure, with a higher prevalence in cases of multi genetic and combined thrombophilia. Women with IVF failures should be screened for thrombophilia. Intervention with antithrombotics might improve pregnancy outcome in this women. Further research is certainly needed to shed light on this very important matter.

PO 44 | Risk Factors and Outcome of Thromboembolism in Pregnancy and Postpartum Period: A Two Years Retrospective Analysis in a Tertiary Care Hospital of Pakistan

A. Rashid, B. Moiz

Aga Khan University Hospital, Karachi, Pakistan

Background: Venous thromboembolism complicates 0.5 to 3.0 per 1,000 pregnancies and is the leading cause of maternal mortality in the most developed countries.

Aims: To evaluate the risk factors and clinical outcome of thrombosis in pregnancy and postpartum period.

Methods: A retrospective two years analysis was done from January 2015 till December 2016 at Aga Khan University Hospital. Ethical exemption was sought from institutional ethical committee. Informed consent was obtained. Files coded with thrombosis and pregnancy was reviewed for their associated risk factors and outcome. Frequencies were generated for quantitative variables.

Results: A total of 11 pregnant and postpartum females were diagnosed with thrombosis. The median age was 30 years(22-42 years). Out of 11, 8 had postpartum thrombosis. The commonest site was deep venous thrombosis(DVT) of lower limbs (55%), followed by cerebral venous sinus thrombosis (18%), inferior vena cava thrombosis, pulmonary embolism and upper limb DVT(9%) each. C-section and prolong bed rest was found to be risk factors for post-partum thrombosis. No identifiable risk factor was found for ante-partum

thrombosis. Out of 11 females, 8 (72%) were screened for heritable thrombophilia, of which two were found to have low protein S levels. Single maternal death occurred in postpartum due to pulmonary embolism following inferior vena cava thrombosis. Single induced abortion was carried out for warfarin induced embryopathy in a patient with antepartum upper limb thrombosis.

Conclusions: Thrombosis was most commonly seen in postpartum period while C-section and immobilization was found to be commonest associated risk factors. Thrombophilia screening was performed during active thrombotic episode; hence making the diagnosis of heritable thrombolphilia questionable in two females with low protein S. Maternal mortality was found to be 9%. A prospective study needs to be done to determine risk factors of thrombosis in pregnancy and postpartum period with their long term outcome and recurrence.

PO 45 | The Clinical Significance of Determining Homocysteine Levels and Functions of the Natural Anticoagulants in Women Taking Combined Oral Contraceptives and Planning Pregnancy

V. Bitsadze, N. Khamani, O. Kaplina

I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

Background: Hormonal contraception can activate hemostatic system as a side effect, deplete natural anticoagulants and promote the development of thrombotic and pre-thrombotic state.

Aims: Investigation of the basic indicators of hemostatic system in women who have been taken hormonal contraceptives during a long time (3 to 5 years).

Methods: Since 2010 have been examined 105 patients who received hormonal contraceptives (oral contraceptive, containing 30 mcg of ethinylestradiol with 2 mg of dienogest). The study included women who had no family history, and no their own thrombotic history.

Results:

1. The level of homocysteine was above normal in 63% of patients
3. Resistance to activated protein C was detected in 45% of patients.
4. Antithrombin III at the lower limit of the normal value in 68 % of patiens
5. Platelet aggregation was increased in 78% of patients.

Conclusions: Considering the undoubted influence of long-term use of hormonal contraceptives on hemostatic system with obvious signs of pro-thrombotic state, pregnancy is not recommended immediately after stopping use hormonal contraceptives. It is recommended to use B-vitamins, anticoagulants, antiplatelet agents, folic acid.

PO 46 | Case Reports of Successful Management of Pregnancy Complications and VTE in Women with Inherited Thrombophilia

L. Makhaldiani[1], N. Pirtskhelani[2,3], N. Kochiashvili[3], K. Kartvelishvili[2,3], N. Pargalava[4]

[1]K. Eristavi National Center of Experimental and Cl, Hemophilia and Thrombosis Center, Tbilisi, Georgia, [2]Tbilisi State Medical University, Tbilisi, Georgia, [3]Forensic Biology (DNA) Department, National Forensics Bureau of Georgia, Tbilisi, Georgia, [4]Georgian Center of Angiology and Vascular Surgery,, Tbilisi, Georgia

Background: Inherited thrombophilia (Factor V Leiden, Prothrombin G20210A and MTHFR C677T gene mutations) has been suggested as a possible cause of recurrent pregnancy loss (RPL) and venous thromboembolism (VTE). Inherited thrombophilia is a genetic disorder of blood coagulation resulting in a hypercoagulable state, which can result pregnancy complications. Inherited thrombophilia is a main risk factor of thrombosis during pregnancy and postpartum.

Aims: According to this fact, that management of pregnancy complications is different, the aim of analysis of case reports was to show our experience in successful management of pregnancy complications and VTE in women with inherited thrombophilia.

Methods: Under observation were 20-26 years old 2 pregnant women who had recurrent pregnancy loss and venous thromboembolism. In Patients PCR analyses were used for detection of inherited thrombophilia and duplex ultrasound for thromboembolism and pregnancy complications. In both cases, prophylaxis of thrombosis during the pregnancies was done using subcutaneous injection of enoxaparin 40 mg per day.

Results: Patient L.M. 26-year-old with a previous medical history of venous thromboembolism (DVT of the left leg) and pregnancy loss. Patient's genotype: homozygous mutation of factor V Leiden.

Patient T. A. 20 -year-old with a previous medical history of venous thromboembolism (DVT), one pregnancy loss and one episode of premature birth with infant *death*. Positive *family history* for VTE (Patient's mother and grandmother suffered with VTE). Patient's genotype: triple heterozygous form of FVL/PTH/MTHFR mutations.

In both cases pregnancy and delivery were uncomplicated for both the mother and the fetus, and a normal vaginal delivery took place.

Conclusions: Prophylaxis of thromboembolism and pregnancy complication during the pregnancy in patients with homozygous carrier of Factor V Leiden and compound thrombophilia can be safe and effective using prophylaxis dose of LMWH.

PO 47 | Control of the Anticoagulants and Antiplatelets during the Pregnancy in Women with Complicated Obstetric Medical History with Routines and Global Tests for Assessment of Hemostasis

S. Safiullina[1], T. Vuimo[2], L. Feiskhanova[1], N. Ilizarova[1]

[1]Kazan State Medical University, Kazan, Russian Federation, [2]Dmitry Rogachev Federal Research-and Clinical Center for Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation

Background: There is algorithm of initial examination and rules of treatment by low molecular weight heparins (LMWH) in women with complicated obstetric medical history.

Aims: To prove the personalized choice of dose of LMWH and acetylsalicylic acid (ASA) under control by tests for assessment of hemostasis; to show the need for individual control for improving the pregnancy.

Methods: The 78 women with complicated obstetric medical history were included in research and divided into 4 groups: infertility, early abortions, late abortions, premature birth. All patients were examined to exclude congenital and acquired thrombophilia, as well as evaluation of hemostasis by routine and global tests: thrombodynamics (TD) and thromboelastometry (NATEM). The dose selection was under the control of the TD, D-dimer and XIIa-dependent fibrinolysis. The algorithm have been developed and implemented control of the D-dimer and XIIa-dependent fibrinolysis every 2 weeks, the TD every 4-6 weeks from the date of a positive pregnancy test and up to 34 weeks, the NATEM is at 36 weeks.

Results: The patients who have not received LMWH before including to the study were found significantly more pronounced chronometric changes of hypercoagulation according to the TD, and the largest percentage of spontaneous clot formation (33%). Due to our algorithm, the dose of Enoxaparin was increased up to 0.4 ml per day in 65% of patients; to 0.6 ml in 13%; to 0.8 ml in 5.2%; to 1.0 ml in 3.4% of patients. The dose of ASA of 50 mg per day was unchanged in 77% of patients; it was increased to 100 mg in 15% and up to 150 mg in 8% of patients. In all patients the pregnancy ended well.

Conclusions: TD is useful for the evaluation of the hemostasis, for monitoring of anticoagulants, and it is hidden hypercoagulation-sensitive. The D-dimer index is useful for evaluation of pro-thrombotic readiness before prescribing the LMWH; however, it is less useful in monitoring the effectiveness during the prescribed therapy by LMWH.

PATHOGENESIS OF THROMBOEMBOLISM

PO 49 | β2GPI Titer and its Clinical Correlation with Laboratory Antiphospholipid Antibodies Syndrome Presented by Fetal Loss

N. Kassim[1], M. Ismail[1], D. Khattab[1], A. Attia[1], A. Salama[2], R. Mohie Eldine[1]

[1]Ain Shams University, Clinical Pathology, Cairo, Egypt, [2]Ain Shams University, Gynecology and Obstetrics, Cairo, Egypt

Background: Despite international efforts to standardize laboratory testing for antiphospholipid antibodies (APA), significant variation in the performance of different assays remains a critical problem.

Aims: To study the clinical utility of Beta2 glycoprotein1 (β_2GPI) and anticardiolipin (ACL) antibodies, in conjunction with the activated partial thromboplastin time-lupus anticoagulant (APTT-LA) & dilute Russell viper venom time (dRVVT) for diagnosis of APA in patients with repeated pregnancy loss.

Methods: The study was conducted on 40 Egyptian females attending Ain Shams University Hospitals with history of ≥3 consecutive early miscarriages, or one fetal loss more than 10 weeks. An informed consent is obtained from all patients. Laboratory testing was done in a two-step procedure for the coagulation-based assays; screening by APTT-LA & dRVVT screen; Positive patients were further tested by mixing study and dRVVT confirm respectively. All patients were tested for ACL IgG &β2GPI IgG. Data were analyzed statistically using SPSS version 24.

Results: Fifteen patients had prolonged APTT-LA time, only 2 were confirmed positive after applying Rosner index and these 2 patients showed positivity with ACL, while only one was positive for β2GPI. Twenty-five patients were positive for dRVVT screen, only 17 were confirmed positive by dRVVT correction ratio. Thirteen patients were positive for both APTT-LA & dRVVT screen ratio. Perfect agreement was found between Rosner Index & ACL, fair agreement was found between Rosner Index &β2GPI, slight agreement was found between dRVVT screen and APTT-LA, fair agreement was found between ACL &β2GPI (Kappa index=1.0, 0.4, 0.3, 0.4 respectively). Only Rosner index was significantly correlated with number of abortions (P=0.01).

Conclusions: dRVVT correction ratio showed high sensitivity and specificity 100% for each. APTT-LA showed low sensitivity 57.89%, mixing study improved the specificity for diagnosis of APS.

PO 50 | Antiphospholipid Syndrome in Pregnancy: A Case Report

F. Raka

Institute for Transfusion Medicine, Haemophilia Treatment Centre, Skopje, Macedonia, the Former Yugoslav Republic of

Background: Antiphospholipid syndrome (APS) is an autoimmune disorder, associated with pregnancy complications such as preeclampsia, thrombotic episodes, autoimmune thrombocytopenia, fetal growth restriction, and recurring fetal loss.

Aims: APS is one of the few treatable causes of pregnancy loss with chances of more than 70% successful pregnancy rate if adequately treated.

Methods: A 29- year old pregnant patient 8 weeks´ gestation(gw) with previous unexpected fetal death in the third trimester (35 gw) was referred to our Institute for detailed coagulation screening including Tr, PT, APTT, TT, DD, AFA, LA, AT III, PC and PS.The results were within normal range, maintaining so during the whole pregnancy. LA was twice positive. No systemic autoimmune disease was found. Low-dose aspirin and a prophylactic dose of low molecular weight heparin (LMWH) were introduced (enoxaparin a 40mg/day, s.c.). Later on, she was screened for APC-R (negative results obtained) while heterozygous mutation of MTHFR C677T gene was found. Normal homocystein levels were measured. From 27gw, weekly

cardiotocography (CTG) monitoring was performed with occasional tachycardia till the 32 gw detected. Aspirin was discontinued at the 30 gw and the prophylactic dose of LMWH was increased to 60mg /day. From 34 gw, daily CTG monitoring and ultrasonography was performed. Placenta was rapidly aging and more frequent tachycardia was registered. On 35w6d, a caesarian section was carried out . The thromboprophylaxis was continued six weeks after delivery with no side effects recorded.

Results: Rest regimen was recommended and carefull monitoring by both the gynecologist and coagulation disorder specialist with in time initiation of anticoagulation. A preterm c-section was performed which resulted in successful pregnancy outcome.

Conclusions: Attentive clinical care with regular check-ups followed by double drug regimen of combining LMWH with low-dose aspirin has proved to be a successful therapeutic management in reducing the obstetric complications.

PO 51 | One Hundred Days of Repetitive Thrombosis - Diagnostic and Therapeutic Challenge

N. Diaconu[1], D. Bejenaru[2]

[1]Institut of Cardiology, Chisina, Moldova, Republic of, [2]Municipal Hospital Nr. 3, Chisinau, Moldova, Republic of

Background: Factor V Leiden thrombophilia is characterized by a poor anticoagulant response to activated protein C(APC) and an increased risk for venous thromboembolism (VTE). Antiphospholipid antibody syndrome is an autoimmune disease characterized by the presence of thromboembolic complications. The authors therefore present the case of a 50-year-old woman with multiple thrombotic events and the presence of antiphospholipid antibodies in combination with heritable thrombophilia, which, to the best of the authors' knowledge, is the first time to be reported in Republic of Moldova.

Aims: Through this case report, the authors aim to describe the evolution of this complex pathology, probably because of its challenging diagnosis and the limited treatment.

Methods: we described the evolution of case.

Results: We present a rare case of women which during 100 days of hospitalization has developed eight thrombotic events in a row (stroke, DVP, VTE, MI, peripheral radial thrombosis, sparing artery Thrombosis), both in the venous system as well as in the artery, followed by disabling serious patient (deep paresis on the left, left leg amputation, blindness on the right and hemianopsia on the left, etc.) Thrombophilia screening tests showed patient to be a heterozygous carrier of MTHFR gene mutation (both C and A) and heterozygous FVL mutation, in presents of positive anti-beta-2-glycoprotein 1 antibodies. Because of thrombosis extension, inherited prothrombotic condition and the relatively young age of the patient, we decided to continue life-long oral anticoagulant therapy.

Conclusions: The authors conclude that clinicians need to have a high index of suspicion of trombophillia and/or APS in patients who present with a thrombotic episode - clinicians should investigate for the presence of antiphospholipid antibodies and genetic tests, as early diagnosis may influence the course of the disease. Finally, patient education on the importance of drug compliance, periodic monitoring, and prevention of thrombosis is indispensable.

PO 52 | Pulmoner Thromboembolism: A Rare Cause of Respiratory Distress in Infants with Neuroblastoma

T. Patiroglu[1], S. Kose[1], A. Ozcan[1], E. Unal[1], M. Karakukcu[1], A. Coskun[2]

[1]Erciyes University Medical Faculty, Pediatric Hematology and Oncology, Kayseri, Turkey, [2]Erciyes University Medical Faculty, Pediatric Radiology, Kayseri, Turkey

Background: Pulmoner thromboembolism (PTE) is rarely seen in children. In patients with malignancy who developed respiratory distress, PTE must be also considered in differential diagnosis.

Aims: Here, we presented a rare case with neuroblastoma who had PTE due to chemotherapy without L- asparaginase.

Methods: A 12-month old boy was admitted to the hospital with an intraabdominal mass. Abdominal ultrasounography showed a mass lesion surrounding the aorta, containing intense calcification. He had a metastatic lesion at the corpus of L1 vertebra in the whole body magnetic resonance imaging (MRI). The patient diagnosed the stage IV of neuroblastoma with a biopsy and chemotherapy consisted of cisplatin, etoposide, cyclophosphamide was started. Ten days after sixth course,he developed respiratory distress. The patient had respiratory rate of 60/min, intercostals, and suprasternal withdrawals, no cough. Lung sounds and cardiac examination were normal. O2 saturation was 76 % in room air. Blood gas analysis revealed PH:7.47, PCO2:26.3 PO2:32.6, HCO3:19.1 and O2 saturation 68.7% respectively. Radiography of chest and cardiac echocardiyography were normal. High resolution computerized tomography of thorax revealed that pulmonary parenchyma was normal and there was a thromboembolism in the pulmonary artery of the laterobasal segment of the right lower lob. The patient was diagnosed as PTE and enoxaparine was started at the dose of 1 mg/kg twice every day. Respiratory distress was improved at 13 th day of anticoagulant therapy. The appearance of tromboembolism disappeared in Thoracal CT at 15th days of anticoagulant therapy. Later, chemotherapy, according to the protocol of TPOG-2009, was continued without problems.

Results: -

Conclusions: In childhood, PTE is especially common after congenital heart diseases, nephrotic syndrome, long-lasting permanent catheterization and use of L- asparaginase. The development of pulmonary thromboembolism due to chemotherapy is a rare but important reason to be kept in mind.

PO 53 | A Challenging Deep Venous Thrombosis in a Child

A. Unuvar[1], S. Karaman[1], Z. Karakas[1], B. Bilgic[2], M. Aksoy[3]

[1]Istanbul University, School of Medicine, Department of Pediatric Hematology & Oncology, Istanbul, Turkey, [2]Istanbul University, School of Medicine, Department of Pathology, Istanbul, Turkey, [3]Liv Hospital, Department of Vascular Surgery, Istanbul, Turkey

Background: Popliteal vein thrombosis is an unusual presentation of deep venous thrombosis (DVT) in children.

Aims: We report a 10-year-old girl who presented with a 2-month history of pain and swelling of the popliteal fossa of the lower leg.

Methods: She was referred as popliteal vein thrombosis by the Division of Vascular Surgery Unit of the State Hospital, and the Department of Orthopedics of our university hospital to our unit. She was on low-molecular-weight heparin (LMWH) therapy. After the detailed clinical, laboratory, and radiological evaluation; the diagnosis was confirmed. All test results were in normal range except the mildly increased levels of homocysteine and lipoprotein(a) at the thrombosis work-up. Folic acid was added to LMWH. After, these detailed evaluations, the patient was followed by clinically and radiologically (doppler ultrasonography) in every two weeks intervals.

Results: However, two months later, USG revealed a new developed saccular aneurysm of the popliteal vein in addition to the popliteal vein thrombosis. The diagnosis was confirmed by the computed tomography angiography, also. The patient was referred for the surgical excision to the three very experienced Vascular Surgeons of different hospitals. But, they suggested the follow-up of the patient without surgery, LMWH therapy was continued, and the patient was followed-up closely, again. However, the second new aneurysm was detected in her follow-up. Wide surgical excision was done at that time, and the histopathological diagnoses were popliteal venous aneurysm and suspected angiomatoid fibrous histiocytoma (in a small area). However, molecular studies could not be done for AFH. Given the intermediate malignant potential of this tumor, the patient was evaluated again for the distance metastasis. There is no metastasis or recurrence following about four years after surgery, and she has no complaints.

Conclusions: In conclusion, the evaluation and follow-up should always be done carefully and closely in children with unprovoked DVT.

PO 54 | Use of Direct Oral Anticoagulants in Multiple Myeloma Patient with Atrial Fibrilation

A. Maritnez-Marin, J.J. Cerezo-Manchado, V. Cabañas, F. Garcia-Candel, E. Fernandez, M. Moya-Arnao, B. Navarro-Almenzar, J.M. Moraleda

University Hospital Virgen de la Arrixaca, IMIB-Arrixaca, Murcia University, Murcia, Spain

Background: The role of the direct oral anticoagulants (DOACs) in oncological patients who are receiving treatment remains unexplored for the time; irregular monitoring and drug interactions entail bleeding and thrombosis risk. There are some information in thrombosis disease and the results reported are encouraging; but there is no data in atrial fibrillation.

Aims: The main goal of this study is analyze the safety on the use of direct oral anticoagulants in patients with multiple myeloma who were receiving treatment.

Methods: A retrospective study was conducted of patients with multiple myeloma who were treated with chemotherapy and vitamin K antagonists (VKA) because of atrial fibrillation. These patients had had irregular monitoring; drug interactions, previous bleeding, and we decided to change to DOACs. The main variables investigated were minor and major bleedings, thromboembolic events, multiple myeloma chemotherapy. Patients with severe interaction between drugs were excluded. Demographics and laboratory data were collected. Statistical analyzes were performed using SPSS 21.0 (SPSS Inc.,Chicago, IL).

Results: Four patients were analyzed, all of them were men. The median age was 79.5 (73-81). Mean of CHADVASC2 and HAS-BLED was 3 and 1.25 (1-2) points respectively. Only one patient had an exitus not related with drug. Chemotherapy received was Melphalan- Dexamethasone (50%) and Bortezomib-Melphalan-Prednisone (50%). DOACs received were Apixaban 5 mg (25%), Rivaroxabán 20 mg (25 %) and Rivaroxaban 15 mg (50%). There were no thrombotic events that would have required removal drug. There were 2 patients with minor bleeding (50 %) and 1 patient with major bleeding (25%) this one had risk factor for bleeding (colon polyposis). Two of these patients discontinued the drug (50 %) for bleeding.

Conclusions: In spite of having a short serie of patients we suggest that DOACs should be safed in patients with atrial fibrilation and multiple myeloma. Further studies are needed to confirm this hypothesis.

PO 55 | Clinical Analysis of 399 Cases of Malignant Tumor Complicated with Venous Thrombosis in the Uygur and Han nationality in Xinjiang

Q. Luo

The Affiliated Tumor Hospital of XinJiang Medical University, First Department of General Medcine, Urumqi, China

Background: To investigate the characteristics of Uygur and Han patients with VTE in XinJiang,in order to improve their diagnosis and treatment and improve their prognosis.

Aims: To investigate the characteristics of Uygur and Han patients with VTE in XinJiang,in order to improve their diagnosis and treatment and improve their prognosis.

Methods: The clinical data of malignant tumor complicated with VTE were retrospectively

analyzed between 2010 to 2015 in Tumor Hospital of Xinjiang. To explore the morbidity and clinical characteristics of Uygur and Han patients with malignant tumor complicated with VTE.

Results: The mean age of onset of VTE in Xinjiang Uygur was higher than that in Han .The level of D-dimer in patients with malignant tumor was higher than that in normal group .The number of cases of gynecological system tumors, gastrointestinal tumors, lung cancer and hepatobiliary tumors were higher in Han than in Uygur patients (P< 0.01).The number of cases of pancreatic cancer and lymphoma were higher than those of Uygur, the difference was statistically significant (P < 0.01).The number of esophageal cancer in Uygur was higher than that in Han, but the difference was not significant. Tumor associated VTE more occurred in the lower limbs, the incidence of the left lower limb was 43.9%, and 25.1% of the right lower limb,and 12.8% of the bilateral lower limbs. Lower incidence of upper limb, only 1.8%. The incidence of pulmonary embolism was between the upper limbs and lower limbs, it´s 16.5%. The incidence of left lower limb, right lower limb, pulmonary embolism (P < 0.01) and bilateral lower limbs (P < 0.05) were higher in Han than in Uygur. The difference was statistically significant. There was 55.6% of PE patients showed sudden chest pain, 23% of patients showed chest tightness and shortness of breath, 11.1% of patients showed hemoptysis,and the other showed cough, sputum.

Conclusions: There are differences in the age, tumor location and thrombus location between Uygur and Han with VTE in Xinjiang Uygur and Han.

PO 56 | Circulating Neutrophil-extracellular Traps (NETs) Are Elevated in Patients with Endometriosis

D. Tàssies[1], J. Munrós[2], A. Perez[2], F. Carmona[2], J.C. Reverter[1], M.A. Martinez-Zamora[2]

[1]Hospital Clinic, IDIBAPS, University of Barcelona, Hemotherapy and Hemostasis (ICMHO), Barcelona, Spain, [2]Hospital Clinic, IDIBAPS, University of Barcelona, Gynecology (ICGON), Barcelona, Spain

Background: Neutrophil-extracellular traps (NETs) are related to the pathogenesis of inflammatory and autoimmune conditions. Endometriosis is considered a chronic inflammatory condition.

Aims: To evaluate plasma circulating NETs levels in a cohort of patients with endometriosis.

Methods: In this case-control study plasma circulating NETs levels were assessed in patients with surgically confirmed endometriosis (group E, n=82) and in patients undergoing benign adnexal surgery without surgical findings of endometriosis (group C, n=35). The median age, Body Mass Index and tobacco use were similar in both groups. Venous blood samples were obtained at the time of surgery before preanesthesic medication intake. Plasma circulating NETs levels were measured as histone-DNA complexes (i.e. nucleosomes) by a quantitative sandwich-enzyme-linked immunosorbent assay (ELISA). Results were expressed as a ratio between mU of patient/ mU of standard sample. Statistical significance was defined as a p-value < 0.05.

Results: Plasma circulating NETs levels were significantly higher in the group E compared with the group C ([median (25th; 75th percentiles)]: group E: 0.734 (0.484; 1.363); group C: 0.541 (0.411; 0.653); p =0.005)). The sub-analysis of endometriosis patients with deep infiltrating endometriosis (group DIE) or without DIE (group non-DIE) demonstrated that plasma NETs levels were higher in the DIE group (p = 0.02).

Conclusions: Patients with endometriosis have significantly higher NETs levels than controls, which seem to be mainly due to increased levels in the subgroup of DIE patients. Circulating NETs may be involved in or related with the pathophysiology of this gynecologic condition.

PO 57 | Thrombophila Associated with an Unusual Presentation of Liver Fibrosis/Cirrhosis and Splanchnic Vein Thrombosis

M.C. Shen[1,2], C.Y. Lin[1], C.W. Lee[3], C.T. Chou[3], J.S. Lin[4], S.F. Kuo[4], B.D. Lin[1], H.N. Hsieh[1]

[1]Changhua Christian Hospital, Internal Medicine, Changhua, Taiwan, Republic of China, [2]National Taiwan University Hospital, Internal Medicine and Laboratory Medicine, Taipei, Taiwan, Republic of China, [3]Changhua Christian Hospital, Medical Imaging, Changhua, Taiwan, Republic of China, [4]Changhua Christian Hospital, Laboratory Medicine, Changhua, Taiwan, Republic of China

Background: Some patients who had no common causes of liver fibrosis/cirrhosis, yet developed liver fibrosis/cirrhosis and splanchnic vein thrombosis.

Aims: To show that hypercoagulation may be another rare cause of liver fibrosis.

Methods: All laboratory tests and image studies were performed routinely. Magnetic resonance elastography (MRE) of the liver was used to evaluate the extent of liver fibrosis which were correlated with the Metavir score (F0-F4). Informed consent was obtained from patients.

Results: Patient I, a male was born in 1956. He has protein C (PC) deficiency with a functional level of 13% and heterozygous p.Gly324Ser substitution at exon 9 of the PC gene. He suffered from left proximal deep vein thrombosis (DVT) in 1998, superior mesenteric vein thrombosis (SMVT) and receiving resection of small intestine in 2003, portal vein thrombosis (PVT) with presence of collateral circulation and liver cirrhosis in 2004. Patient II, a male was born in 1950. He has familial protein S (PS) deficiency with a functional activity of 12% and heterozygous c.531-534 + 4 del at exon 6 of PS gene. SMVT occurred in 2011 and intestinal resection was done then, PVT with cavernous transformation and liver fibrosis were detected in 2012, MRE of the liver showed F2 and F3 score in patient I and II, respectively. FVIII:C/PC ratio, a good biomarker of hypercoagulation in thrombophilia, revealed a higher value, i.e. 13.25 and 2.50 in patient I and II, respectively, as compared to normal control (Mean±SD 0.85±0.28, ranges 0.35~1.56). All had no HBV (hepatitis B virus) and HCV-infections, alcoholic consumption, antiphospholipid antibodies, homocysteinemia, abnormal level of anti-mitochondrial antibody and anti- smooth muscle antibody.

Conclusions: These 2 patients had no common causes of live fibrosis/cirrhosis, yet they developed liver fibrosis and splanchnic vein thrombosis, hypercoagulation associated with thrombophilia my cause extrahepatic splanchnic vein thrombosis and intrahepatic microthrombosis leading to fibrosis.

PO 58 | Antithrombin Activity in Newly Diagnosed Diabetis Mellitus Patient seen at the University of Benin Teaching Hospital, Benin City, Nigeria

B. Nwogoh[1], K. Akaba[2]

[1]University of Benin, Department of Haematology, Benin City, Nigeria, [2]University of Calabar Teaching Hospital, Department of Haematology, Calabar, Nigeria

Background: Thromboembolic complications contribute significantly to morbidity and mortality in diabetic patients. The role of antithrombin in the pathogenesis of vascular complications in diabetics has not been investigated in our environment.

Aims: This study aims to evaluate the role of antithrombin activity (AT) in the pathogenesis of vascular complications in newly diagnosed diabetics.

Methods: This is a cross sectional study conducted at the University of Benin Teaching Hospital, Benin City. Sixty two newly diagnosed diabetics were recruited consecutively from the consultant outpatient unit between April and October 2015 and 54 non diabetic controls from the general populace. Venous blood was collected each subject into citrate and EDTA containers for determination of AT activity and haematological parameters respectively. AT activity was measured with Technoclone chromogenic AT kit (Technozyme Lot no:0551B00.02) and full blood count was analyzed using Hematology Analyzer, ERMA INC (Tokyo model FCE 2.0).

All participants gave informed consent. The study was approved by the Research and Ethics Committee of the hospital.

Result was analyzed with SPSS version 16. Student T test was used to compare difference in mean, Chi-square and Fisher´s test were used to test association of AT deficiency with vascular complications. Pearson correlation coefficient was used to correlate AT activity with BMI and haematological parameters.

Results: The mean AT activity in newly diagnosed diabetics was significantly lower than in controls (83.3 ± 30.0 vs 92.8 ± 20.0%; p = 0.050). The incidence of AT deficiency in newly diagnosed diabetics was 32.3%. AT deficiency was associated with overweight/obesity and thrombocytopenia. Microvascular complication was associated with AT deficiency.

There was a significant negative correlation between BMI and AT activity (r = --0.276; p = 0.030).

Conclusions: Low AT activity is associated with microvascular complications in newly diagnosed diabetic subjects.

TABLE 2 Correlation between AT activity, Age, BMI and Haematological Parameters in Newly Diagnosed Diabetics

		Antithrombin Activity (%)	
	units	r	p value
Age	yrs	0.076	0.556
BMI	Kg/m2	-0.276	0.030
HbA1c	%	0.112	0.565
Hgb	g/dL	-0.029	0.824
WBC	(x 109 cells/L)	0.090	0.488
Platelet	(x 109 cells/L)	0.220	0.086

TABLE 1 Association between AT deficiency with Clinical and Laboratory Parameters in Newly Diagnosed Diabetics

Variables	Sub category	Deficient AT Activity n = 20	Normal AT Activity n = 42	Statistical test	p value
Age (years)	<40 ≥40	3 (15.0) 17(85.0)	5 (11.9) 37(88.1)	Fishers	0.705
Gender	Male Female	7 (35.0) 13(65.0)	11(26.2) 31(73.8)	$\chi 2 = 0.510$	0.475

PO 59 | Portal, Mesenteric and Splenic Vein Thrombosis in a Patient with Homozygous Factor V Leiden Mutation (A1691G) Receiving Oral Contraception

A. Sikorska[1], B. Ceglarek[1], K. Bykowska[2], A. Bućko[2], A. Gwozdowska[1], J.M. Teliga-Czajkowska[3], J. Windyga[4]

[1]Institute of Hematology and Transfusion Medicine, Department of Hemostatic Disorders and Internal Medicine, Warsaw, Poland, [2]Institute of Hematology and Transfusion Medicine, Department of Hemostasis and Metabolic Disorders, Warsaw, Poland, [3]Medical University of Warsaw, Department of Obstetrics and Gynecology Didactics, Warsaw, Poland, [4]Institute of Hematology and Transfusion Medicine, Department of Hemostatic Disorders and Internal Medicine, Department of Hemostasis and Metabolic Disorders, Warsaw, Poland

Background: Women on oral contraceptives (OC) are at increased risk of venous thromboembolism (VTE). In factor V Leiden (FVL) carriers receiving OC the risk is even higher although most of FVL carriers remain asymptomatic despite long term OC use.

Aims: Report on clinical manifestations of thrombosis in homozygous carrier of factor V Leiden receiving oral contraception.

Methods: Factor Leiden mutation (G1691A) and mutation G20210A of prothrombin gene were detected using RFLP/PCR method. (EURx, Polska)

Results: Patient with no family history of venous thromboembolism, on oral contraceptives (third generation progesterone), during appendectomy at 43 was diagnosed with thrombosis of the portal, splenic and mesenteric vein. Low molecular weight heparin (LMWH) was administered followed by VKA (vitamin K antagonists). Due to unique thrombosis location and young age diagnostics for thrombophilia and myeloproliferative disorders was carried out. No bone marrow proliferative disorder was determined but factor V Leiden (homozygote) was detected. Family testing revealed that asymptomatic mother (65y) and brother (44y) are homozygotes of factor V Leiden.

Conclusions: The ethiology of splanchnic vein thrombosis is multifactorial therefore the diagnostic process of the entity should comprise searching for genetic and acquired risk factors of VTE.

PO 60 | Deep Vein Thrombosis in a Family with Leiden Mutation (FVL, G1691A), Antithrombin Deficiency (AT) and ARhD (+) Blood Type

A. Sikorska[1], B. Ceglarek[2], K. Bykowska[3], E. Odnoczko[3], B. Baran[3], J.M. Teliga-Czajkowska[4], J. Windyga[5]

[1]Institute of Hematology and Transfusion Medicine (IHTM), Department of Hemostatic Disorders and Internal Medicine, Warsaw, Poland, [2]Institute of Hematology and Transfusion Medicine (IHTM), Department of Hemostasis and Metabolic Disorders I, Warsaw, Poland, [3]Institute of Hematology and Transfusion Medicine (IHTM), Department of Hemostasis and Metabolic Disorders, Warsaw, Poland, [4]Medical University of Warsaw, Department of Obstetrics and Gynecology Didactics, Warsaw, Poland, [5]Institute of Hematology and Transfusion Medicine (IHTM), Department of Hemostatic Disorders and Internal Medicine, Department of Hemostasis and Metabolic Disorders, Warsaw, Poland

Background: In people with inherited thrombophilia the risk of deep vein thrombosis (DVT) is related to the ABO blood type. Blood type AB individuals with thrombophilic mutations are at significantly higher risk of DVT. The mechanism by which the non-O blood types contributes to thrombosis risk in FVL carriers is probably related to factor VIII levels [Morelli et al. 2005].

Aims: To establish the risk factors for familial thrombosis.

Methods: Factor V Leiden (FVL) mutation (G1691A) was identified by PCR/RFLP with restriction enzyme Mnl1 (Eurx, Poland) and the AT activity was assessed using SXa-based assay (Innovance, Antithombin, Siemens).

Results: Two cousins of sibling parents were admitted to IHTM at the same time. The younger one (son of the brother), a 31 year old white-collar worker (obesity and hypertension) was diagnosed with VTE due to prolonged immobilization. The elder one (son of the sister) a 40 year old computer programmer (no obesity, hypercholesterolemia or addictions) reported trauma-related swelling and redness of the left lower limb and was diagnosed with DVT (Doppler ultrasound). Incidents of sudden death were reported in families of both siblings; maternal grandparents of the elder cousin as well as the paternal grandparents and father of the younger one and sudden death of the paternal grandfather of the elder. Our studies revealed:· homozygous mutation in FVL and congenital AT deficiency (58%) in the elder cousin. · heterozygous FVL mutation and AT in his mother (49.46%), · heterozygous FVL mutation in his father and his two children· AT deficiency (65.92%) in his younger son. No congenital thrombophilia was determined in the brother of the elder cousin. Heterozygous FVL mutation and AT deficiency (50.13%) were determined in the younger cousin. Both were ARhD (+) blood type.

Conclusions: The thrombotic risk is significantly higher in families with AT, FVL mutation and ARhD (+) blood type. All members of both families with FVL mutation and AT were of ARhD (+) blood type.

PO 61 | Prothrombotic Mutations, Protein C Deficiency and Hyperhomocysteinemia in a Patient Presenting Recurrent Venous Thrombosis

A. Sikorska[1], B. Ceglarek[1], K. Bykowska[2], B. Baran[2], E. Odnoczko[2], E. Pleban[3], P. Szopiński[3]

[1]Institute of Hematology and Transfusion Medicine, Department of Hemostatic Disorders and Internal Medicine, Warsaw, Poland, [2]Institute of Hematology and Transfusion Medicine, Department of Hemostasis and Metabolic Disorders, Warsaw, Poland, [3]Institute of Hematology and Transfusion Medicine, Clinic of Vascular Surgery, Warsaw, Poland

Background: Patients with recurrent VTE may present complex hemostatic defects. In approximately 10% of Factor V Leiden carriers Prothrombin G20210A mutation is also detected. In Polish Factor V Leiden carriers a frequent concomitance of heterozygous protein C deficiency or prothrombin G20210A polymorphism has been confirmed (10% and 30% respectively).

Aims: Analysis of the clinical course of recurrent VTE in a patient with polygenic defect and hyperhomocysteinemia.

Methods: case report

Results: A 33 year old man -a sedentary lifestyle, 2 risk factors for VTE (exam-induced stress, long trip) presented swelling, redness and pain in the left lower limb. Doppler ultrasound revealed DVT in saphenous and popliteal veins. Anticoagulation therapy with Enoxaparin 1 mg/kg bw/7 days and warfarin-3 months was effective. The second VTE event occurred 5 years later following injury of the same limb. Doppler ultrasound confirmed proximal vein thrombosis. Six-month effective anticoagulation therapy followed. Eight months later the patient reported pain in the limb after intense exercise. Acute VTE was detected in the external iliac vein. The study confirmed heterozygous Factor V Leiden (G1691A) mutation and heterozygous prothrombin G20210A mutation, congenital protein C deficiency -0,32 IU/dl (0,70-1,40 IU/dl) and hyperhomocysteinemia - 28.5 mmol / L (n: 5.0-12.0 mmol -/- l). Family history: the grandfather had a heart attack and died of stroke later at the age of 59. The father died of heart attack, the mother had a heart attack and died of stroke. The patients' brother had DVT in both lower limbs, suffered extensive stroke and died at the age of 29.

Conclusions: Recurrent VTE was caused by several risk factors: genetic defects (Factor V Leiden and prothrombin G20210A mutations), protein C deficiency, elevated serum homocysteine, trauma, stress and sedentary lifestyle.

Co-occurrence of venous and arterial thrombosis in the family suggests the presence of complex genetic/environmental defects in other family members as well.

PO 62 | Rise and Fall of Thrombophilia Law in Argentina

B. Grand, A. Rossi

On behalf of The Women Health Issues in Thrombosis and Hemostasis Group (WHITH-CAHT) and the Argentine Thrombosis and Hemostasis Cooperative Group (CAHT), Buenos Aires, Argentina

Background: In Argentina the relationship between thrombophilia and pregnancy complications increased its popularity.Celebrities from entertainment programs made public their obstetric complications associated to thrombophilia and claimed for early detection and treatment of this "disease that attacks pregnant women". Even a law petition was presented to the Congress.

Aims: To describe how the Thrombophilia Law was voted and vetoed in Argentina.

Methods: 2015 Law projects titled "Psychophysics protection of women with thrombophilia" were presented to the Congress.

Objectives: Early detection of thrombophilia in women in fertile and prefertile age; inclusion of tests and treatments as obligatory in public/private health programs.

CAHT and WHITH-CAHT activities 2015

(1) Scientific Meeting with representatives of the city legislature and Health Ministry;2016

(2) A document signed by 35 experts in Thrombosis and Hemostasis that explained the reasons why the law was unnecessary and had serious scientific and ethical questioning;

(3) Scientific Meeting with representatives from the National Ministry of Health;

(4) Petition of a meeting with the Commission of health of the Congress.

Results: The(1)took part , but a few days after Deputies voted in favor of the law. The (2) was read in (3). In spite of our medical opinion, the Chamber of Senators voted in favor. The medical voice was ignored; the meeting with the commission of health was not done. We decided to inform through the media(newspapers, interview on the radio/TV) and social media.The president vetoed the law and argued in the Official Gazette: the tests are expressly not recommended to be routinely carried out adding that it has been criticized/questioned by medical societies Argentine Thrombosis and Hemostasis Group and Hematology in coincidence with Ministry of Health.

Conclusions: We have 2 voices regarding thrombophilia and pregnancy complications; new worldwide active medical education interventions and strategies of communication for women in reproductive age are needed.

PO 63 | Hypofibrinogenemia and Thrombosis

Y. Ouarhlent, H. Laiaidhi., F. Mezhoud, R. Chafai

CHU Batna, Hematology, Batna, Algeria

Background: Congenital hypofibrinogenemia is a blood clotting disorder characterized by a quantitative deficit that results in hemorrhage of varying magnitude. It is a rare disease with the presence of a notion of consanguinity, transmitted by the autosomal recessive mode.

Aims: Show the importance of the hemostasis assessment.

Methods: We report an observation of hypofibrinogenemie.

Results: Sir M 45 - year - old , stemming from non a consanguine marriage , married and father of 4 children followed in our department of hematology for congenital hypofibrinogenemia, admitted on 12/11/2016 for edema of the lower limb Right with necrosis of the 5th toe homolateral.

hEmogramme: WBC: 18700 ele / mm3 HB: 12: 5 g / dl, Platelets: 328000ele / mm3, TP < 14% Fg: 0.7 g / absence of PDF and the dosage of the factors of coagulations are normal IHepatic Impairment: correct, Renal assessment: correct, The dosage of the proteins c, s and antithrombin = normal,

Echo-Doppler of the lower right limb Morphological and hemodynamic study of the arteries and veins of the lower right limb.

Lymphedema of the lower right limb The main causes of thrombosis have been eliminated

The necrosis of the toes which led first to the amputation of the right 4th and 5th toes but the necrosis was not controlled twenty days later, the necrosis had spread to the 1st and 3rd toes that were necrectomy But in vain necrosis was still extended to the second toe which led to the amputation of the forefoot two days after the Doppler echo of the right lower limb showed total acute thrombosis of the right pedal artery Which alas led to the amputation of the middle third of the right leg On 25/1/2016 a good cicatrisation.

Conclusions: In this case, Hypofibrinogenemia is associated with thrombosis whereas the tendency to thrombosis is seen in dysfibrinogenemia so it is imperative in the biological assessment of thromboses to perform a TP haemostasis, TCA and fibrinogen balance which will Diagnosis of previously unrecognized fibrinogen deficiency.

PO 64 | Role of Thrombophilia Testing in Retinal Vein Occlusion: Single Center Experience from Oman

K. Al Hashmi[1], F. Al-Ghafri[1], A. Pathare[2]

[1]Sultan Qaboos University/Armed Forces Hospital, Hemato-Oncology Section, Al-Khoudh, Oman, [2]Sultan Qaboos University, Department of Hematology, Al-Khoudh, Oman

Background:

- Retinal vein occlusion (RVO) is a serious retinal vascular disorder.
- he role of thrombophilia disorder and RVO still not clear.

Aims:

- To demonstrate any relationship between studies parameters and RVO.
- To clarify any significant relationship among RVO and thrombophilia.
- To describe RVO in Omani Population.

Methods:

- A total of 11 patients referred by the ophthalmologist with RVO (central RVO, n=7; branch RVO, n=4) prospectively enrolled in this single institution study after an informed consent.
- Several routine biochemical parameters of Complete blood counts, renal liver function, serum triglycerides (mmol/L), Lipoprotien 1a (g/L) total cholesterol (mmol/L) and homocysteine (mmol/L).
- Thrombophilia screening included factor V Leiden, prothrombin geneG20210A and JAK2V612F mutation analysis; autoantibody assays like ANA, ANCA, LA, ACA, anti-beta2 glycoprotein activity and coagulation proteins estimations including protein S, protein C, antithrombin III and factor VIII levels were also performed.

Results:

- The study enrolled a total of 11 patient's, Their ages ranged between 25 to 75 years (mean ± SD; 48.8 ± 13.6) with a mild male preponderance (54.5%).
- Majority of patients developed CRVO(64%), with the remaining developing BRVO (36%).
- 27.3% and 45.5% had history of diabetes and essential hypertension, respectively.
- None of the thrombophilic factors were abnormal.except one patient each, showed positivity for anti-B2 glycoprotein antibody (11.1%), prothrombin gene G20210A heterozygosity (14.3%) and elevated serum homocysteine level (23.3 mmol/L.
- Normal Biochemical studies(S. lipoprotein 1a levels, S.triglycerides, S.total cholesterol, S.homocysteine).

Conclusions:

- 91% of patients were below the age of 60 years.
- CRVO (64%) was apparently more prevalent that BRVO (36%).
- 27.3% and 45.5% had history of diabetes and essential hypertension, respectively.
- Thrombophilia testing in RVO might not be cost effective.

PLATELETS – CLINICAL

PO 65 | Acute Severe Thrombocytopenia Induced by Abciximab: A Case Report

L. Gonçalves[1], S. Afonso[2], H. Nascimento[3], A. Leite[1], C. Koch[1]

[1]Centro Hospitalar São João, Centre of Thrombosis and Hemostasis, Porto, Portugal, [2]Centro Hospitalar São João, Department of Hematology, Porto, Portugal, [3]Centro Hospitalar São João, Department of Cardiology, Porto, Portugal

Background: Glycoprotein (GP) IIb/IIIa inhibitors are frequently used during percutaneous coronary interventions (PCI), reducing ischemic complications, improving outcomes. Severe acute thrombocytopenia is a serious adverse event of these drugs. In this setting, the balance between risk of sgnificant bleeding and thrombosis requires a careful approach.

Aims: Report a case of a patient with an acute myocardial infarction (AMI) who developed severe acute thrombocytopenia induced by abciximab.

Methods: A 69-years-old male was admitted to emergency room with a 2-hour history of chest pain radiating to the left arm. He had a previous history of AMI in 2006 treated with thrombolysis followed by coronary artery bypass grafts. The electrocardiogram showed ST elevation, cardiac biomarkers were positive, full blood counts and coagulation tests were normal. Aspirin 250 mg, ticagrelor 180 mg and morphine 2 mg iv were given. PCI was performed with incomplete thrombus aspiration. Abciximab was then given (0,25 mg/Kg iv bolus followed by a 0,125 µg/Kg/min infusion for 12 hours). Five hours after beginning abciximab, severe thrombocytopenia was detected (platelets < $10x10^9$/L), with normal hemoglobin and no signs of bleeding. Abciximab was immediately stopped. One platelet pool and methylprednisolone (500 mg pulse iv) were given. Four hours later, platelet count was $38x10^9$/L. Periodic monitoring of blood counts was performed (day 3: platelets $107x10^9$/L). Patient had hemoptoic expectoration for 4 days. On day 5 aspirin 100 mg od was started (platelets $157x10^9$/L) and clopidogrel 75 mg od was started on day 8.

Results: Platelet count completely recovered in 5 days. He did not have any major bleeding or ischemic event, his clinical situation improved and he was discharged on day 10.

Conclusions: Thrombocytopenia is a rare complication of GPIIb/IIIa inhibitors. Due to bleeding risk, it is important to monitor platelet count before and during treatmen. Management of this patient was successful.

PO 66 | Prolactin Level in Patients' Sera with Hepatitis C Virus Related Thrombocytopenia

A. Hassan, S. Shoeib, M. Abdelhafez, W. Algheriany

Menoufia University, Internal Medicine, Menoufia, Egypt

Background: PRL is involved in the activation of many immunological responses. It enhances the progression of the immune process in autoimmune diseases. Autoimmunity is a common finding in chronic hepatitis C. There was a significant association between hyperprolactinemia (HPRL) and infection with HCV genotype 3 and genotype 4.
Aims: The aim of this work was to evaluate serum levels of prolactin (PRL) in a group of patients with HCV-related thrombocytopenia compared with patients with hepatitis C virus (HCV) without thrombocytopenia and controls.
Methods: This study was carried at Internal Medicine Department, Menoufia University Hospital, from the period of Mars 2015 till December 2015. Subjects were calssified into Group (I): fourty one chronic hepatitis C patients with thrombocytopenia. Group (II): thirty five chronic hepatitis C patients without thrombocytopenia. Group (III): twenty five control healthy individuals with matched age and sex.
Results: We found hyperprolactinemia in patients with HCV-related thrombocytopenia and it was significantly higher than in patients with chronic hepatitis C patients without thrombocytopenia than controls. Also, there was association between hyperprolactinemia and low platelet count. Low platelet count was positively correlated with the degree of liver fibrosis.
Conclusions: This study shows that hyperprolactinemia is present in a subset of patients with HCV-related thrombocytopenia, so anti-prolactin may be useful in treatment of this category of patients.

PO 67 | Study of Serum Prolactin in Primary Immune Thrombocytopenic Patients

M. Abdelhafez, S. Shoeib, S. Gazareen, H. Elkholy

Menoufia University, Internal Medicine, Menoufia, Egypt

Background: ITP is a disorder characterized by immune-mediated accelerated platelet destruction and suppressed platelet production. Hyperprolactinemia (HPRL) has been described in many autoimmune diseases such as systemic lupus erythematosus.
Aims: The aims of this work were to study serum prolactin (PRL) levels in patients with primary immune thrombocytopenia (ITP) and to investigate its possible correlation with disease activity and manifestations.
Methods: The study was carried out on 40 cases of primary ITP patients (group I) and 50 healthy controls (group II). PRL was measured directly in the serum samples by VIDAS PRL kits using the ELFA technique for all patients and controls.
Results: Moderate HPRL (serum PRL 30-200 ng/ml) was present in eight (20%) of primary ITP patients, but was not present in any of the 50 controls. Among 22 patients with platelet count below 30 000/µl, eight (36.4%) patients had HPRL and 14 (63.6%) patients had normal PRL levels. HPRL was associated with lower platelet counts.
Conclusions: This study shows that HPRL is present in 20% of patients with primary ITP. Also, patients with HPRL have a lower platelet count than patients with normal PRL levels.

PO 68 | Immun Trombocytopenic Purpura in a Patient with History of Non-Hodgkin Lymphoma and Common Variable Immune Deficiency

F.N. Kalkan, S. Unal, F. Gümrük, M. Çetin

Hacettepe University Faculty of Medicine, Ihsan Dogramacı Children's Hospital, Pediatric Hematology, Ankara, Turkey

Background: Development of immune thrombocytopenic purpura (ITP) after complete remission of Non-Hodgkin lymphoma in a child is a rare entity.
Aims: Herein, we present a 9 ½ years old boy presented with thrombocytopenia who had a past medical history of Non-Hodgkin lymphoma in remission for 4 years and common variable immunodeficiency diagnosis (CVID).
Methods: While he was on intravenous immunoglobulins (IVIG) treatment on a monthly basis for the CVID, he developed petechia and hemogram showed platelet count of $7x10^9$/L. A diagnosis of ITP was established after the initial investigations including viral serology and bone marrow aspiration examination to rule out relapse of Non-Hodgkin lymphoma with bone marrow involvement. Bone marrow examination revealed increased megakaryocytes of 8-10 in number in x10 magnification. IVIG treatment at dose of 1 gr/kg was administered with a good response in platelet count $272x10^3$µ/L.
Results: Autoimmunity is a well known entity in lymphomas and CVID.
Conclusions: Although, CVID has been reported to be associated with immune cytopenias and lymphomas, the previous lymphoma diagnosis in our patient prompted a diagnostic challenge. Therefore, ITP may develop as a representation of this phenomenon.
