Results: As shown previously, HRG produces a dose-dependent inhibition (IC_{50} of 200 nM) of fXII autoactivation induced by either dextran sulphate or silica, synthetic activators of the contact pathway. Like HRG, $(HHPHG)_4$ inhibits fXII autoactivation stimulated by silica (IC_{50} of 1000 nM). Neither HRG nor $(HHPHG)_4$ affects fXIIa chromogenic activity. Clotting initiated by APTT-SP or silica is accelerated in HRG-deficient plasma, but is prolonged in a dose-dependent and saturable manner by addition of either HRG or $(HHPHG)_4$. In normal or HRG-deficient human plasma, neither HRG nor $(HHPHG)_4$ influences clotting initiated via the extrinsic pathway by addition of RecombiPlasTin.

Conclusions: A synthetic peptide analogue of the HRR of HRG recapitulates the effects of HRG on the contact system. Therefore, the HRR likely mediates the interaction of HRG with fXIIa, and may be an important probe for investigating the role of HRG in thrombosis.

PB 102 | Dabigatran and Rivaroxaban Inhibit Thrombin Generation Much Stronger than the Growth of a Fibrin Clot

N. Dashkevich[1], E. Pivovarova[2], R. Ovsepyan[1,3], Y. Kotova[1,4], D. Ayusheev[5], A. Bernakevich[5], F. Ataullakhanov[1,3,4]

[1]*HemaCore Labs LLC, Moscow, Russian Federation,* [2]*Lomonosov Moscow State University, Moscow, Russian Federation,* [3]*Federal Research Clinical Centre of Pediatric Hematology Oncology and Immunology N.A. D. Rogachev, Moscow, Russian Federation,* [4]*Center for Theoretical Problems of Physicochemical Pharmacology, Moscow, Russian Federation,* [5]*Federal Research Clinical Centre of Traumatology and Orthopedics N.N Priorov, Moscow, Russian Federation*

Background: Low amount of tissue factor (< 5pM) produces *in-vitro* ~100 nM of thrombin, which is much greater than is required to form a clot. However, tissue factor is localized to a vascular wall, and thrombin concentration can decrease with distance. It is unknown how distribution of thrombin correlates with the rate of the fibrin cloth propagation from the damage site, particularly in the presence of anticoagulants.

Aims: To investigate *in-vitro* and *ex-vivo* the effect of different anticoagulants on spatial propagation of fibrin clot and thrombin generation.

Methods: Thrombodynamics-4D is an *in-vitro* assay for simultaneous monitoring of thrombin activity and fibrin clot propagation from the immobilized tissue factor. We used plasma from healthy individuals, spiked with unfractionated heparin, dabigatran, and rivaroxaban, and samples from patients, receiving anticoagulant therapy after an orthopedic surgery.

Results: Thrombin activity propagates from the activating surface as a moving peak. Fibrin clot follows thrombin and reaches size of 2-3 mm in 60 min. Spiking of normal plasma with 0.15 IU/ml of heparin prevented moving peak formation without affecting the initiation phase. Thrombin generation persisted in 1 mm region near the activating surface. Addition of rivaroxaban and dabigatran did not have strong effect on fibrin clot growth, but the initial formation of thrombin was delayed. 0.15 μM of dabigatran decreased amount of thrombin 2-fold, while the rate of clot growth decreased 6%.

The samples from patients after orthopedic surgery showed that 3000 IU of LMWH resulted in dramatically decreased clot growth rate and absence of moving peak of thrombin. In contrast, 2-3h after 220mg of dabigatran or 10mg of rivaroxaban thrombin generation was significantly reduced, but the clot growth still persisted. Besides, the anticoagulants had distinctly different effects on the shape of the thrombin peak.

Conclusions: Amount of thrombin generated during clot formation does not fully determine clot propagation in space.

PB 103 | Factor VII Activating Protease (FSAP) and Marburg I (G534E) Polymorphism; How One Amino Acid Determines Function

N.V. Nielsen[1], D. Manna[1], E. Roedel[2], J.P. Morth[3], M. Etscheid[4], S. Kanse[1]

[1]*University of Oslo, Oslo, Norway,* [2]*Justus Liebig University Giessen, Geissen, Germany,* [3]*University of Oslo, Centre for Molecular Medicine Norway (NCMM), Nordic EMBL Partnership, Oslo, Norway,* [4]*Paul-Ehrlich-Institut, Langen, Germany*

Background: In the gene encoding FSAP (*HAPB2*) there is a single nucleotide polymorphism (SNP) called Marburg I (MI) SNP which causes the amino acid change G534E. This SNP has lower enzymatic activity and is associated with an increased risk of stroke, carotid stenosis, liver fibrosis and thyroid cancer.

Aims: To understand the mechanism behind the lower enzymatic activity of the MI-SNP of FSAP.

Methods: The catalytic domain of wild type (WT) FSAP was expressed in bacteria and characterized by an array of biochemical methods. The naturally occurring Gly residue at position 534 was mutated to Glu (MI-SNP), Ala, Asp, Leu and Gln. by site directed mutagenesis. Michaelis-Menten kinetics was performed with the different isoforms. The catalytic domain of FSAP was modelled by I-TASSER using tPA as a template.

Results: The correct expression of the catalytic domain of FSAP was confirmed by sequencing, reactivity to antibodies, activity assays against various chromogenic substrates as well as sensitivity to known FSAP inhibitors. The kinetic data indicates a very close resemblance to plasma purified FSAP. The Glu mutant (MI-SNP) showed very little activity. Asp, Leu and Gln mutants showed significantly lower activity,

whereas the Ala mutant demonstrated about 20% of the activity of WT-FSAP. The modelling data shows high overlap between the helices and sheets of FSAP and tPA as well as in the configuration of the catalytic triad. The MI mutation causes a conformational shift in two β-strands near the active site residues altering the intermolecular distances between catalytic triad residues.

Conclusions: The successful preparation of recombinant catalytic domain of FSAP opens up possibilities to perform structural and functional analysis. At the MI-SNP site only Gly or Ala were tolerated whereas other amino acid substitutions led to a loss of activity. The altered configuration of the catalytic triad in MI-SNP is responsible for the loss of its proteolytic activity.

PB 104 | Acquired Hemophilia A in Dutch Patients, a Single Center Experience

W.E.M. van Dijk[1], A. Huisman[2], K.P.M. van Galen[1], E.P. Mauser-Bunschoten[1], P.R. van der Valk[1], K. Fischer[1], R.E.G. Schutgens[1]

[1]University Medical Center Utrecht, Van Creveldkliniek, Department of Internal Medicine and Dermatology, Utrecht, The Netherlands, [2]University Medical Center Utrecht, Department Laboratory and Pharmacy, Utrecht, The Netherlands

Background: Acquired hemophilia A (AHA) is a rare autoimmune bleeding disorder that can cause life-threatening bleedings and requires immunosuppressive treatment (IST). To date, the optimal regimen for hemostatic therapy and IST is not determined.

Aims: Description of a Dutch cohort of AHA patients in order to obtain insight in the effectiveness and safety of current treatment.

Methods: A retrospective cohort study between 1999 and 2016 was performed in the Van Creveldkliniek, University Medical Center Utrecht.

Results: The cohort comprised 25 patients with AHA (60% male). The median age at diagnosis was 77 (IQR 66-80). Median FVIII level and anti-FVIII inhibitor titer at diagnosis were 5 IU/dL and 17 BU, respectively. Median follow-up was 223 days (IQR 70-500). An underlying condition was identified in 36% (*table 1*). 36 bleeding episodes occurred in 20 patients, of which 36% were severe. FVII and FVIII replacement therapies were used to treat 40% of the bleedings each. 96% of all patients were treated with IST. Outcome data after IST was available in 18 patients (*table 2*). After first line IST, 7 (39%) reached complete remission (CR). 3/3 (100%) of the patients treated with rituximab and steroids reached CR, in contrast with 3/12 (25%) of the patients treated with steroids only. Of the 11 patients with no CR after first line IST, 8 (67%) received second line IST, 2 (22%) maintenance IST and 1 (11%) died by an unknown cause. In patients with second line IST, remission data was available in 4 (50%), of whom 3 (75%) achieved CR. Remission data at final follow-up was available in 13 patients, of whom 8 (62%) reached CR. Survival data was available in 23 patients, of whom 10 (43%) were deceased. Of these, 10% died by complications of IST, no patients died by fatal bleeding.

Conclusions: This study shows first line IST fails to achieve CR in a majority of patients with AHA, although combination treatment with rituximab and steroids shows favorable results.

TABLE 1 Disease characteristics

PB 105 | Salvianolic Acids Inhibit Blood Coagulation and Platelet Aggregation: A New Class of Herb Derived Dabigatran Analogs

Y. Wang[1], M. Neves[1], D. Zhang[1], X. Xu[1], X. Lei[1], G. Zhu[1], Y. Wang[2], L. Xuan[2], J. Ding[2], H. Ni[1,3]

[1]St. Michael's Hospital, University of Toronto, Toronto, Canada, [2]Shanghai Institute of Materia Medica, Shanghai, China, [3]Canadian Blood Services, Toronto, Canada

Background: Salvianolic acids (SAs), including SAB (also called MLB) and SAC, are major components of *Salvia miltiorrhiza* root (Danshen). Danshen extracts were used to control cardiovascular disease for centuries, and its depside salt was approved in China to treat chronic angina. Although Danshen extracts are observed to inhibit thrombosis, the mechanism has not been adequately explored.

Aims: To explore the mechanism of SAs in anticoagulation.

Methods: *In vitro* coagulation assay, isothermal titration calorimetry (ITC), and molecular docking.

Results: We observed that MLB/SAC (250 μM) significantly reduced clot size and wet/dry weight. Using thromboelastography, we found that MLB/SAC markedly decreased the mechanical strength of the clot and modestly delayed initiation of coagulation in blood plasma. We further observed that MLB significantly reduced the density of the fibrin network, suggesting that SAs targets coagulation factors. Recent network pharmacology analyses predict that MLB interacts with VWF, factor XIII (FXIII), or thrombin. We found that MLB did not

inhibit VWF-dependent platelet agglutination, or significantly alter the binding of activated FXIII (FXIIIa) to fibrinogen. However, MLB significantly reduced the generation of FXIIIa from FXIII, suggesting a direct inhibition on thrombin activity/generation. We also found that MLB markedly inhibited thrombin-induced gel-filtered human and mouse platelet aggregation. These data suggest that MLB is a direct thrombin inhibitor. Indeed, ITC showed that MLB/SAC bind thrombin, with SAC possessing a 2-fold stronger affinity. MLB/SAC contain structural similarities to dabigatran, and molecular docking models docked MLB/SAC within the thrombin active site, interacting with the same residues that dabigatran contacts within the thrombin active site.

Conclusions: These data demonstrate a novel role for SAs in the inhibition of blood coagulation and platelet aggregation, likely through direct thrombin inhibition, as a new class of herb derived dabigatran analogs.

PB 106 | Fusion to Albumin Extends the Circulatory Half-life and Antithrombotic Effects of the Kunitz Protease Inhibitor Domain of Protease Nexin 2 in Mice

W. Sheffield[1,2], L. Eltringham-Smith[1], V. Bhakta[2]

[1]*McMaster University, Pathology and Molecular Medicine, Hamilton, Canada,* [2]*Canadian Blood Services, Centre for Innovation, Hamilton, Canada*

Background: Protease Nexin 2 (or Amyloid Precursor Protein) is a potent inhibitor of activated coagulation factor XI (FXIa). Its FXIa inhibitory activity is contained within a 57 amino acid (aa) Kunitz Protease Inhibitor (KPI) domain. KPI exerts antithrombotic effects in vivo but is limited by its rapid clearance.

Aims: To extend the circulatory half-life ($t_{0.5}$) of KPI via gene fusion to human serum albumin (HSA) and to characterize the pharmacokinetic and pharmacodynamic profile of KPIHSA in vivo.

Methods: KPI (63 aa), KPIHSA (598 aa), and HSA (588 aa) were expressed in *Pichia pastoris* in His-tagged form and purified from conditioned media via Ni-chelate chromatography. Clearance of ^{125}I-labelled proteins was tracked by serial blood sampling in CD1 mice following intravenous injection and $t_{0.5}$ were solved by biphasic curve fitting. ^{125}I-fibrin(ogen) deposition in the $FeCl_3$-treated vena cava and time to occlusion (TTO) of the $FeCl_3$-treated carotid artery were compared in mice treated with KPI or KPIHSA.

Results: The mean initial $t_{0.5}$ of KPI, KPIHSA, and HSA in mice were 0.048h, 0.58h, and 1.3h, and the mean terminal $t_{0.5}$ were 0.80h, 8.2h, and 17.5h, respectively. TTO was significantly lengthened in mice treated 2 min prior to $FeCl_3$ arterial injury artery with 14.3 nmoles of KPI (39 ± 17 min, mean ± SD, n=6, $p < 0.05$) or KPIHSA (49 ± 15 min, $p< 0.01$) versus saline vehicle (12.5 ± 4 min); KPI and KPIHSA did not differ. Recovery of ^{125}I-fibrin(ogen) in $FeCl_3$-induced vena cava thrombi was identically reduced from 0.267 ± 0.110% by saline vehicle to 0.114 ± 0.069% by KPI, or 0.095 ± 0.066% by KPIHSA pre-treatment 2 min pre-injury. Extending the pre-treatment interval to 60 min eliminated the KPI effect (0.282 ± 0.180%) but that of KPIHSA was unaltered (0.101 ± 0.051, $p < 0.05$ versus 60 min KPI pre-treatment).

Conclusions: Fusion to albumin slowed the clearance of KPI 10.3- to 12.3-fold without reducing its immediate antithrombotic efficacy. KPIHSA also exhibited a more durable pharmacodynamic effect than unfused KPI.

PB 107 | Immunogenicity Assessment of OBIZUR, a Recombinant B-domain Deleted Porcine- sequence FVIII, in Patients with Acquired Hemophilia A

F. Horling[1], H. Koppensteiner[1], S. Dorn[1], M. Malisauskas[1], B. Hartlieb[1], P. Allacher[2], A. Novack[3], F. Scheiflinger[1], B.M. Reipert[1]

[1]*Shire, Vienna, Austria,* [2]*IMC University of Applied Sciences, Krems, Austria,* [3]*Shire, Chicago, United States*

Background: A recombinant B-domain deleted porcine- sequence factor VIII (rpFVIII; OBIZUR) was recently approved for treatment of bleeding episodes in adults with acquired haemophilia (AHA). We previously reported results for inhibitory antibodies against rpFVIII and human FVIII (hFVIII) from a Phase 2/3 clinical trial and evaluated their impact on treatment efficacy.

Aims: The aim of this study was to extend this data by analyzing binding IgG and IgM antibodies against hFVIII and rpFVIII and evaluating their cross reactivity.

Methods: The pivotal Phase 2/3 study (NCT01178294) and the methods in principle for antibody analytics were previously reported (Whelan 2013; Kruse-Jarres 2015). 28 subjects with AHA were evaluated for inhibitory antibodies against hFVIII and rpFVIII. 26/28subjects had supplementary samples that were analyzed for total binding IgG and IgM antibodies.

Results: Consistent with AHA diagnosis all subjects evaluated (n=26) tested positive for binding IgG and inhibitory antibodies against hFVIII at screening. 20 of those subjects showed positive results for binding anti- rpFVIII IgG (10/20 had inhibitory antibodies against rpFVIII) that can be considered cross-reactive anti-hFVIII antibodies. After treatment with OBIZUR, 10 patients were tested positive for binding IgG antibodies against rpFVIII. De novo inhibitory antibodies against rpFVIII were detected in 5 subjects. Among those 2 subjects showed a concomitant decrease of anti-hFVIII IgG. This suggests that the observed anti-rpFVIII inhibitors resulted from an immunogenic response to rpFVIII.

Conclusions: An increase in cross-reactive anti-hFVIII antibodies or a specific immunogenic response to rpFVIII could contribute to the development of antibodies against rpFVIII observed during the study. All subjects had a positive response to OBIZUR treatment within 24 h after initiation. Further characterization of subclass and isotype distribution and affinities of anti-rpFVIII antibodies will provide additional insights into rpFVIII immunogenicity.

PB 108 | Affimers as a Tool to Understand Mechanistic Pathways that Control Fibrin Clot Structure and Lysis

N. Pechlivani[1], R. King[1], C. Tiede[2], K. Simmons[1], K. Kearney[1], K. Smith[1], F. Phoenix[1], R. Cheah[1], R.A.S. Ariens[1], D. Tomlinson[2], R.A. Ajjan[1]

[1]University of Leeds, Cardiovascular and Diabetes Research, Leeds, United Kingdom, [2]University of Leeds, School of Molecular and Cellular Biology, Leeds, United Kingdom

Background: Altered clot structure and impaired fibrinolysis are associated with increased thrombotic events. Elucidating mechanistic pathways for altered fibrin clot characteristics will help to develop new therapeutic targets to reduce thrombosis risk. We created a library of conformational random peptides (n=3x10^{10}) mounted on a scaffold protein, named Affimers, which we hypothesised can bind fibrinogen and alter fibrin network properties.

Aims: Study the effect of fibrinogen-binding Affimers on clot structure/lysis and identify potential interaction sites.

Methods: The library of Affimers was screened for fibrinogen binders using a phage display system. Turbidimetric assays and confocal microscopy assessed the effects of Affimers on clot structure/lysis. Mass spectrometry (MS) and molecular modelling were used to elucidate fibrinogen-Affimer binding sites.

Results: We identified one Affimer, termed G2, that decreased lag phase during plasma clot formation in turbidimetric experiments from 457±8.7 to 72±2.5 sec (mean±SEM) ($p< 0.001$), reduced clot final turbidity (FT) from 0.19±0.015 to 0.09±0.008 AU ($p< 0.001$) and completely prevented clot lysis at concentrations >23nM. In a purified system, G2 also prolonged clot lysis time in a dose-dependent manner. Confocal microscopy showed that G2 caused significant disruption to plasma and purified clots, explaining the change in FT. Despite screening against human fibrinogen, G2 had similar effects on mouse clots indicating that it interacted with conserved regions on fibrinogen. MS and molecular modelling identified 2 possible fibrinogen-G2 interaction sites, one located at fibrinopeptide B and a second close to the C-terminus of β-chain towards the D domain.

Conclusions: The fibrinogen-binding Affimer G2 modulates clot structure and inhibits fibrinolysis of human or mouse clots. The β-chain of fibrinogen represents one interaction site with G2, potentially offering a novel therapeutic target to modulate fibrin network structure/lysis.

PB 109 | The Most Significant Physiological Function of Protein S is Inhibition of Thrombin Generation

E. Goldfeld[1], W. Plautz[1], A. Dorsey[1], D. Monroe[2], R. Majumder[1]

[1]LSU Health Sciences Center, New Orleans, United States, [2]UNC Chapel Hill Department of Medicine, Chapel Hill, United States

Background: Protein S (PS) is a vitamin K-dependent anticoagulant for which several different functions have been ascribed: PS acts as a cofactor for both activated protein C and tissue factor pathway inhibitor (TFPI), and is an inhibitor of factor IXa (FIXa). This diversity of PS activity mandates establishing the relative physiological importance of each function in the different pathways of thrombin generation.

Aims: To quantitate the relative physiological importance of PS functions by measuring peak thrombin generation in the presence of PS alone, PS with protein C, and PS with TFPI.

Methods: Measurements of thrombin generation are performed in a defined assay using mixtures of the zymogen forms of factors VII, X, V, IX, VIII, and II, ± PS (Table 1), following the sub sampling method. The effect of PS is quantitated as a PS ratio; a ratio of 1 means little change in thrombin generation, whereas a ratio less than 1 signifies a decrease. The zymogen protein factors are incubated overnight with 15X the plasma concentration of antithrombin to ensure that no activated factors are present. The protein mix is then added to phospholipid vesicles (25%DOPS/75% DOPC) with an overall Ca^{2+} concentration of 3 mM and 10 pM tissue factor, and initiated with 0.2nM VIIa. Thrombin generation is then measured.

TABLE 1 Thrombin generation reaction pathways

1) VII, X, V, II, AT, lipid & TF ± PS → Thrombin (IIa)
2) VII, X, V, II, AT, lipid, TFPI & TF ± PS → IIa
3) VII, X, V, II, AT, lipid, TF, IX, VIII ± PS → IIa
4) VII, X, V, II, AT, lipid, TFPI, TF, IX, VIII ± PS → IIa
5) VII, X, V, II, AT, lipid, TF, PC, TM ± PS → IIa
6) VII, X, V, II, AT, lipid, TF, PC, TM, IX, VII ± PS → IIa
7) VII, X, V, II, AT, lipid, TF, PC, TM, IX, VII, TFPI ± PS → IIa

Results: When thrombin generation was measured in the reactions from pathway 3 (Table 1), the peak thrombin generated was twice the nanomolar amount without PS as it was with PS (Figure 1). The ratio of peak thrombin generation in the presence of PS to the absence of PS was 0.51, indicating that PS significantly inhibits thrombin generation when FIX and FVIII are both present.

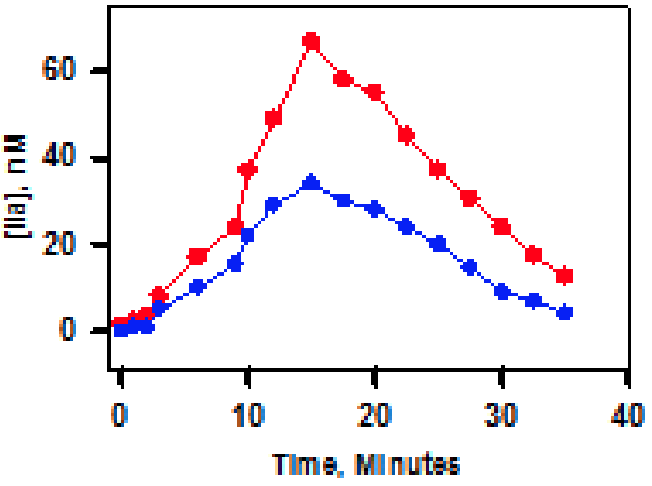

FIGURE 1 Effect of protein S on thrombin generation

Conclusions: Thrombin generation in the presence (blue curve in Figure 1) and absence (red curve in Figure 1) of PS indicates that, in a defined system, PS is a key regulator of thrombin generation. The

results of assays (pathways) 1-2 and 4-7 will further clarify the dominant role of PS with respect to its other reported functions.

PB 110 | Immunogenicity of BAX 855 in Previously Treated Patients with Congenital Severe Hemophilia A

F.M. Horling[1], P. Allacher[2], H. Koppensteiner[1], W. Engl[1], F. Scheiflinger[1], B. Abbühl[1], B.M. Reipert[1]

[1]*Shire, Vienna, Austria,* [2]*IMC University of Applied Sciences Krems, Krems, Austria*

Background: BAX 855 is an extended half-life recombinant human coagulation factor VIII modified with polyethylene glycol (PEG) (Turecek 2012). It was recently approved in the US and Japan for on-demand treatment of bleeding events and for prophylactic treatment for patients with congenital severe hemophilia A.

The efficacy and safety of BAX 855 were extensively studied during clinical development (Konkle 2015). The assessment of BAX855 immunogenicity was of particular interest because the development of neutralizing antibodies (FVIII inhibitors) is the most serious complication following replacement therapies with FVIII products.

Aims: To fully understand the potential of BAX855 to induce antibody responses, both FVIII inhibitors and total FVIII-binding antibodies as well as antibodies against PEG-FVIII and PEG were assessed

Methods: The clinical protocols (NCT02585960, NCT02210091, NCT01736475, NCT01913405, NCT01945593, NCT01599819, NCT02615691) and the methods used for antibody analytics (Whelan 2013; Lubich 2016, Konkle 2015) were previously described. Correlation analyses were done to assess any potential consequences on PK, safety and efficacy.

Results: None of the 243 subjects included in the analysis developed FVIII inhibitors (≥ 0.6 BU/mL) A total of 44 subjects tested positive for binding antibodies at single time points. 28 of these 44 subjects showed pre-existing antibodies against FVIII, PEG-FVIII, or PEG prior to first exposure to BAX 855. 13 subjects developed transient antibodies after exposure to BAX 855 (no conclusion can be drawn for 5 subjects at data cut off). There was no confirmed causal relationship between the appearance of binding antibodies and PK parameters, adverse events and hemostatic efficacy.

Conclusions: Our data indicate that BAX855 did not show an increased risk for PTPs to develop FVIII inhibitors. The data suggest that BAX855 did not induce immune responses associated with impaired treatment efficacy or with altered PK parameters.

PB 111 | Validation of a FVIII Nijmegen Bethesda Assay for the Detection of Inhibitors to Porcine FVIII

M. Robinson[1], S. Tiefenbacher[1], D.M. Adcock[1], M. Schlager[2], H. Gritsch[2]

[1]*Colorado Coagulation, Laboratory Corporation of America® Holdings, Englewood, United States,* [2]*Shire, Vienna, Austria*

Background: Neutralizing factor VIII (FVIII) antibodies may develop in patients with congenital hemophilia A following FVIII replacement therapy and may also develop spontaneously in patients without hemophilia. OBIZUR [Anti-hemophilic Factor (Recombinant), Porcine Sequence] has been shown to be effective for treatment of bleeding in patients who develop spontaneous autoantibodies to FVIII, as inhibitors directed against human FVIII frequently show lower cross reactivity to porcine rFVIII. Furthermore, porcine rFVIII is less susceptible to inactivation by inhibitory antibodies.

Aims: To validate a FVIII One Stage Nijmegen Bethesda assay (NBA) to detect inhibitors against porcine VIII.

Methods: The human FVIII NBA was modified for the detection of inhibitors to porcine FVIII by substituting the test base, buffered normal pooled plasma, with buffered porcine rFVIII (OBIZUR). Human FVIII inhibitor plasma with cross reactivity to porcine rFVIII was spiked into congenital FVIII deficient plasma to obtain validation samples at 10.0, 1.0, 0.6 (LLOQ) and 0.25 BU. Validation samples were tested in the modified NBA post heat pre-treatment at 58 ± 2°C for 90 minutes. Relative accuracy, intra- and inter-assay precision, as well as specificity and sample stabilities were assessed.

Results: Relative accuracy was demonstrated for two inhibitor positive patient plasmas. Intra- and inter-assay precision ranged between 10.0 to 14.7% and 7.5 to 10.5%, respectively. Selectivity was demonstrated in six FVIII deficient donor plasmas spiked to 1.0 BU/mL and 0.25 BU. Sample stability up to 3 hours post heat treatment and incubation, as well as 3 additional freeze thaw cycles were demonstrated. Studies to assess the stability of the buffered porcine rFVIII test base when stored at -20°C and -70°C are ongoing and will be presented.

Conclusions: The porcine FVIII NBA has been validated for the quantification of porcine FVIII inhibitors in both congenital and acquired hemophilia A plasma.

PB 112 | Single-dose Safety and Toxicological Studies of Long-acting FVIIa (MOD-5014) in Rats and Monkeys Support the Initiation of Clinical Phase 1 Subcutaneous (SC) Study in Healthy Volunteers

L. Israeli Yagev, A. Bar-Ilan, M. Hoffmann, G. Hart

OPKO Biologics, Kiryat Gat, Israel

Background: OPKO Health is a clinical-stage public company developing biobetter long-acting versions of existing therapeutic proteins utilizing a technology termed CTP. The technology involves fusion of the C terminus peptide of hCG to the target protein.

Aims: The aim of this work was to extensively characterize the pharmacokinetic (PK), pharmacodynamic (PD), and overall safety profile of FVIIa-CTP (MOD-5014) in rats and monkeys following SC administration in order to enable the initiation of a Phase 1 clinical study in healthy volunteers.

Methods: Single-dose toxicological studies of MOD-5014 were conducted in rats and monkeys at doses of 1, 3 and 9 mg/kg. Clinical pathology was evaluated during the study and followed by 14-day recovery period to assess the reversibility of toxic effects. PK and PD parameters were also assessed to confirm proper exposure margins, which were above the initial clinical dose to be tested in the SC Phase 1 study.

Results: MOD-5014 exposures based on plasma concentrations and clotting activity increased with increasing dose and confirmed a significant margin above the expected clinical doses in the SC Phase 1 study. There were no safety concerns, unexpected test article-related mortality or adverse effects. The changes noted were related to an exaggerated pharmacological activity of the drug and were reversible after the 14-day recovery period.

Conclusions: Attachment of CTP to FVIIa led to a pronounced enhancement of PK and PD exposures and elevated half-life, supported by an excellent safety profile in toxicological setting following SC injection. Our data suggest that MOD-5014 injected SC is safe and tolerable, and has the potential to significantly improve the prophylactic treatment of hemophilic patients.

PB 113 | Low Plasma FVII:C and Activated FVII as Predictive Markers for Overt Disseminated Intravascular Coagulation

S. Lertthammakiat, N. Anantasit, U. Anurathapan, N. Sirachainan, P. Kadegasem, A. Chuansumrit

Faculty of Medicine Ramathibodi Hospital, Pediatrics, Bangkok, Thailand

Background: In sepsis, binding of factor VII clotting activity (FVII:C) and activated factor VII (FVIIa) with the expressed tissue factor on monocytes is the key early step of coagulation resulting in disseminated intravascular coagulation (DIC).

Aims: To measure both FVII:C and FVIIa among pediatric patients with sepsis and DIC.

Methods: Patients aged 1 month to 20 years, who had sepsis, were enrolled. Blood samples from each patient were collected at the following periods: 0, 24 and 48 hours after the onset of sepsis.

Results: Forty-seven septic patients, aged 8 months to 18.8 years, were enrolled. They were initially divided in three groups of no DIC (n=27), non-overt DIC (n=14), and overt DIC (n=6). Positive hemoculture was reported within 24 hours among 15 patients (32%). The levels of both FVII:C and FVIIa of all patients were significantly low at onset of sepsis and gradually increased at 24 and 48 hours but were still persistently low in the overt DIC group. At 24 hours, the level of FVII:C was significantly lower in the non-overt DIC [57% (41-101)] and overt DIC groups [31% (28-49)] than that in the no DIC group [83% (70-102)] with p-values of 0.032 and 0.003, respectively. Similarly, the level of FVIIa was significantly lower in the overt DIC group [2.15% (0.86-3.96)] than the no DIC group [3.83% (2.90-5.46), p=0.031]. Using FVII:C < 65% or FVIIa < 3% at 24 hours to determine overt DIC at 24 hours, the sensitivity was both 90% and the specificity was 78.4% and 70.3%, respectively. Patients with low FVII:C and low FVIIa at 24 hours after onset of sepsis had a 16.9-fold (95%CI, 1.6-179.0, p=0.019) and 23.6-fold (95%CI, 1.9-290.7, p=0.014) chance of overt DIC at 24 hours.

Conclusions: Our study demonstrated a correlation of FVII:C and FVIIa and severity of DIC among pediatric patients with sepsis. These study results showed the role of FVII in DIC in which the low levels of FVII:C and FVIIa reflected the degree of consumption of the coagulation factor among pediatric patients with DIC.

PB 114 | imabalance of Factor VIII/ Protein C System as Major Determinant of Hypercoagulability in Cushing´s Syndrome

S. Maggiolo, E. Campello, C. Bulato, C.M. Radu, S. Gavasso, L. Spiezia, P. Simioni

Università degli Studi di Padova, Dipartimento di Medicina, Unità di Malattie Trombotiche ed Emorragiche, Padova, Italy

Background: Cushing's Syndrome (CS) is associated with an increased tendency of thromboembolic events (VTE) and hypercoagulability plays an important role in increasing cardiovascular mortality and morbidity.

Aims: To evaluate hypercoagulability by measuring thrombingeneration (TG) with and without thrombomodulin (TM) in CS patients with active disease, according to the endocrine Society Guidelines, and with disease remission.

Methods: Fifty-seven patients with CS (42 pituitary-dependent, 12 adrenal-dependent, 3 ectopic adrenocorticotropic hormone secretion) and 50 healthy controls were included. 36 patients had an active disease, 21 had the criteria for biochemical assessment of remission. Thrombophilia screening (in particular factor (F)VIII and protein C (PC) coagulometric activity) and TG endogenous thrombin potential (ETP) with and without TM were measured.

Results: CS patients showed significantly higher levels of FVIII and PC activity than healthy controls (p< 0.0001); the ratio FVIII/PC was similar between cases and controls. CS showed a significantly higher ETP in the presence of TM than controls. However, the ETP ratio (with/without TM) was not significant higher in cases compared to healthy controls. Interestingly, patients with active CS had higher levels of PC (p=0,04), a lower FVIII/PC ratio and a lower ETP ratio compared to patients with CS remission (p=0,0011). Three CS patients had VTE but their parameters did not differ compared to CS without VTE.

Conclusions: In conclusion, we confirm a prothrombotic state in CS, mainly due to a partial resistance to the anticoagulant action mediated by TM. This could be explained by the more pronounced increased of FVIII plasma levels than PC levels (similar FVIII/PC ratio). Moreover patients with disease remission showed an increased hypercoagulability tendency with higher FVIII/PC and ETP ratio, related to a more "in-balanced" ratio between FVIII and PC compare to patients with active disease.

PB 115 | Anti-Hemostatic Compounds Isolated from Coral Snake *Micrurus tener tener* VENOM

A.M. Salazar[1], B. Guerrero[1], K. Perez[1], J. Vivas[1], C. Ibarra[1], E. Salazar[1], E. Sanchez[2], A. Rodríguez-Acosta[3]

[1]Instituto Venezolano de Investigaciones Científicas, Medicina Experimental, Caracas, Venezuela, [2]University-Kingsville, Department of Chemistry and the National Natural Toxins Research Center, Texas, United States, [3]Universidad Central de Venezuela, Instituto Anatómico, Caracas, Venezuela

Background: There are anti-thrombotic and anti-fibrinolytic agents among the bioactive compounds that have been identified in snake venoms and invertebrates that have a therapeutic potential.
Aims: Isolate and characterize toxins in *Micrurus tener tener* venom *(Mtt)* with anti-hemostatic activity.
Methods: *Mtt* was initially fraccionated in a Superdex 200/HPLC column; elution was performed at 0.5 mL/min with 50 mM ammonium acetate, pH 6.9. In the obtained fractions, it was evaluated the functional activity on Factor Xa (FXa) using a coagulant assay and SBTI as positive control, and the activity on plasmin using a chromogenic assay (S-2251) and aprotinin as positive control. Fraction F10 inhibited FXa (anti-FXa) and fraction F17 inhibited plasmin (anti-plasmin). The purification of anti-FXa was followed through chromatography employing C4 and XDB-C18 columns, protein elution was performed at 1 mL/min with a 0-50% acetonitrile gradient in 0.12% TFA over 30 min. Anti-plasmin was isolated in a C-18 column protein elution was performed at 1 mL/min with a 0-50% acetonitrile gradient in 0.12% TFA over 30 min; the active fraction was re-chromatographed on the same column and the elution was performed using the same acetonitrile gradient over 60 min.
Results: Anti-FXa (1 µg/mL) inhibited 85 % of FXa activity after an incubation of 30 min at 37 °C. Anti-plasmin, Tenerplasminin-1 (1 nM), showed a molecular mass of 6542 Da; the amidolytic activity of plasmin (0.5 nM) on synthetic substrate S-2251 was inhibited by 91% as well as the fibrin(geno)lytic activity. Besides, tPA-clot lysis assay showed that Tenerplasminin-1 acted like aprotinin inducing a delay in lysis time and lysis rate. Finally, this molecule did not act on thrombin, FXa nor ADP induced platelet aggregation.
Conclusions: Both inhibitors are the first anti-FXa and anti-plasmin activities reported in *Micrurus* venoms that exhibit a high potential as anti-thrombolytic and anti-fibrinolytic agents, respectively.

PB 116 | Zinc Binds and Regulates the Activity of the Natural Anticoagulant Protein Z

T. Sengupta[1], W. Plautz[2], C.G. Subash[3], N. Manoj[3], R. Majumder[2]

[1]SSN College of Engineering, Chemistry, Chennai, India, [2]LSU Health Science Center, Biochemistry & Molecular Biology, New Orleans, United States, [3]Indian Istitute of Technology Madras, Biotechnology, Chennai, India

Background: Protein Z (PZ) is a natural anticoagulant which acts as a cofactor of protein Z dependent protease inhibitor (ZPI) in inhibiting fXa in presence of procoagulant Ca^{2+} and phospholipid membrane. PZ, bound to membrane, positions linked ZPI in close proximity of fXa, also bound to the same membrane. Presence of Ca^{2+} is required for PZ to bind to membrane and as such cofactor activity of PZ is regulated by Ca^{2+}. Multiple studies have reported the binding of bivalent metal ions other than Ca^{2+}, such as Mn^{2+}, Mg^{2+} and Zn^{2+}, to various coagulation proteins such as fVIIa, fXIa, fXa, APC, PS etc. These ions are also observed to modulate the activity of those clotting factors and anticoagulants, however, nothing is known whether those metal ions can bind to PZ and regulate its anticoagulant activity.
Aims: To study the binding of bivalent metal ions, namely Zn^{2+} and Mg^{2+}, to PZ and their effect on the anticoagulant activity of PZ.
Methods: We employed various biophysical techniques, coagulation assays and molecular modeling for the current study.
Results: Preliminary experiments revealed that both Zn^{2+} and Mg^{2+} bind to PZ but with disparate affinity. Binding K_d for Zn^{2+} was measured to be ~117 µM whereas that for Mg^{2+} was observed to be ~210 µM. Binding of Zn^{2+} was found to be pH dependent. It was interesting to notice that the affinity of Zn towards PZ was increased ($K_{d\sim}$65 µM) in presence of Ca^{2+} indicating a synergistic effect of Ca^{2+} on Zn binding. Similar effect of $Ca^{2+}$was not observed in case of Mg^{2+} binding. Zn^{2+} was also found to increase the affinity of PZ towards phospholipid in the absence of Ca^{2+}. PZ-ZPI mediated fXa inhibition was also observed to be regulated by Zn^{2+}. Finally, molecular modeling studies using the two crystal structures available for PZ suggested two putative Zn binding sites, His 206-His208-Glu226 and Cys 97-Cys 101-Cys 110 on PZ.
Conclusions: Collectively our observation suggests that Zn^{2+} binds PZ and regulates its anticoagulant activity.

PB 117 | Effects of SERPINC1, PROC, PROS1 and EPCR Polymorphisms on the Plasma Levels of Natural Anticoagulants in Healthy Individuals

G. Balla, T. Miklós, J. Kállai, S. Kovács, B. Kovács, É. Katona, É. Molnár, Z. Bereczky

University of Debrecen, Faculty of Medicine, Division of Clinical Laboratory Science, Department of Laboratory Medicine, Debrecen, Hungary

Background: Antithrombin (AT), protein C (PC) and protein S (PS) are natural anticoagulants and EPCR plays a role in PC activation. There are several polymorphisms (SNPs) that may influence their plasma levels. So far, controversial data have been published regarding their effects that is, at least in part, caused by gene-gene, gene-environment interactions in different populations.
Aims: Our aim was to investigate the effects of 12 SNPs (PROC rs1799809, rs1799808, rs1799810, rs2069928, rs1401296, PROCR rs867186, rs6088735, rs8119351, SERPINC1 rs222758, rs121909548, PROS1 rs8178649 and rs121918472) on the plasma levels of AT, PC and PS in healthy individuals.
Methods: A multiplex PCR-primer extension assay was developed to investigate the SNPs simultaneously in 366 healthy volunteers (median age 36; IQR 24; ratio of females 58.1%). AT activity was measured in heparin-cofactor (hc-AT) and progressive (p-AT) FXa-based assays, PC activity and free PS concentration were measured by chromogenic assay and latex-immunoturbidimetry, respectively.

Results: AT Cambridge (rs121909548) was not detected in our population. Mean hc-AT and p-AT activities were 97%(±8.9) és 106%(±10.5), respectively and rs2227589 was without effect on AT levels. Mean free PS concentration was 105±20.7 and as it was expected, PS Heerlen (rs121918472) decreased it markedly (105 vs 72%, p=0.045), while rs8178649 was without effect. Mean PC activity was 115%(±24.9) and among PROC promoter SNPs rs1799809 and rs1799810 decreased, while rs1799808 increased it significantly even after adjustments. PROCR rs867186 and rs8119351 significantly increased, rs6088735 decreased PC activity. Taken the combined effects of PROC and PROCR SNPs into consideration the lowest and highest PC levels showed more than 30% difference (p< 0.001).
Conclusions: PC levels are highly influenced by genetic factors. These observations may have clinical relevance from the point of view of thrombotic risk that is worthy of further investigations. (OTKA-K 116228)

PB 118 | Identification of a Novel Factor VII Activating Protease (FSAP) Zymogen-activating Peptide by Phage Display

S. Seidel[1], G. Åge Løset[1], N.V. Nielsen[1], P. Declerck[2], S. Kanse[1]
[1]*University of Oslo, Oslo, Norway,* [2]*KU Leuven, Leuven, Belgium*

Background: Factor VII activating protease (FSAP) circulates as an inactive zymogen in blood. *In vivo*, zymogen activation is mediated in an auto-catalytic manner by charged macromolecules such as histones and nucleosomes. The currently known activators are non-specific in nature and specific inhibitors for FSAP have not been designed to date.
Aims: To identify specific peptide modulators of pro-FSAP activity using phage display.
Methods: We have used a phage display approach to identify peptides that bind to pro-FSAP. The effect on peptides pro-FSAP activity was determined and the interaction was further characterized at a molecular level.
Results: Peptides that bind specifically to pro-FSAP but not to other hemostasis factors were identified. One of the, 11 amino acids long cyclic, peptides could increase the activity of pro-FSAP but none had any inhibitory potential. Neither a linear form of the peptide nor scrambled peptide or truncated forms; with up to 3 amino acids deletions at the N- and C-terminus, showed any activity. Alanine scanning suggested that the entire peptide was important for this activity. The peptide was quite specific since other zymogens such as plasminogen and pro-urokinase were not activated. Binding studies with domain deletion mutants indicated that the N-terminal region of FSAP was the key interaction site for this peptide. Upon screening of a panel of monoclonal antibodies against FSAP we identified an antibody that could block the activation of pro-FSAP by this peptide. Overlapping peptide libraries were used to map the antibody and activating-peptide binding site at the N-terminus of FSAP. However, the peptide did not activate pro-FSAP zymogen in a complex biological fluid such as plasma.
Conclusions: We have identified a pro-FSAP activating peptide. Its inability to activate pro-FSAP in plasma may be due to a low affinity, to instability or to quenching by other binding protein(s). This peptide may serve as a lead compound to develop a therapeutic concept based on pro-FSAP activation.

PB 119 | Stability of Plasma for Add-on Coagulation Tests

M. Blois, F. Fischer, A. Appert-Flory, D. Jambou, P. Toulon
Pasteur University Hospital, Hematology, Nice, France

Background: Until now, most international and national guidelines recommend to evaluate most coagulation parameters within a 4 hour-delay after blood.
Aims: This study was carried out to determine at what time point an add-on routine coagulation test can be safely honored on specimens that have been received in the laboratory earlier.
Methods: For that purpose, we evaluated citrated (3.2%) blood samples obtained from 208 patients: 60 had normal coagulation profile, 73 were on vitamin K-antagonist, 60 were on heparin therapy (unfractionated heparin, UFH, n=19, or low molecular weight, n=41), and 15 had abnormal coagulation tests for miscellaneous reasons. Prothrombin time (PT)/INR, activated partial thromboplastin time (aPTT), fibrinogen, factors (F) V, VIII, and IX, antithrombin (AT), and D-dimer were measured immediately after being received in the laboratory less than 2 h after sampling (T0), and in the same capped tubes that had been left at room temperature for 3 h, 6 h, 12 h, and 24 h. All tests were not performed in each sample. Comparison were performed using Wilcoxon test and the bias calculated according to Bland-Altman.
Results: Changes in PT/INR, fibrinogen, FV, AT and D-dimer were not statistically significant up to 24 h, or analytical comparison were significant but with mean bias below the recommended values of Ricos et al. (1999) or the GEHT (2014). The same applied for aPTT, except for patients on UFH in whom a significant and clinically relevant shortening effect was observed after a 3 h-delay. FIX level was stable for up to 12 h, whereas FVIII level significantly declined after a 6 h-storage.
Conclusions: These results suggest that within an 24 h-period and with plasma on spun-down cells kept at room temperature, add-on tests for PT, aPTT (except in patients on UFH), fibrinogen, FV, AT and D-dimer could be performed without yielding results with clinically significant differences from those obtained on the original unstored plasma. The maximum delay would be of 12 h for FIX, and 6 h for FVIII.

PB 120 | Microplate-based Method for Quantifying Polyphosphate in Biological Samples

S. Smith[1], R. Breitenfeld[2], K. Mcevoy[2], J. Morrissey[2]
[1]*University of Illinois, Urbana, United States,* [2]*University of Illinois, Biochemistry, Urbana, United States*

Background: Inorganic polyphosphate (polyP) is highly procoagulant, proinflammatory and regulates the complement cascade. We hypothesize that polyP released from platelets, inflammatory cells, and/or infectious organisms is important in the pathophysiology of conditions such as sepsis and trauma. Available methods for quantifying polyP in complex biological samples (plasma, serum or cell lysates) are difficult and extremely laborious, severely limiting their use in clinical studies.
Aims: High-throughput assay for quantifying polyP in complex biologic fluids.

Methods: We developed an ELISA-style microplate-based assay that allows quantification of polyP in plasma, free from interference from polyP-binding proteins. This assay leverages the extremely high polyP binding affinity of the cationic polymer, polyethylenimine (PE). Plasma samples are incubated in PE-coated microplate wells in the presence of EDTA and a high salt concentration. Wells are then washed with high concentrations of salt and urea, leaving the captured polyP bound to the PE-coated surface and stripping off plasma proteins. A recombinant bacterial polyP-binding protein complexed with streptavidin-peroxidase is then bound to the captured polyP, after which the bound peroxidase is detected using a chromogenic substrate.

Results: The assay readily quantifies medium-chain and long-chain polyP (≥ 130-mer and longer) in plasma with a linear working range of 10-100 nM (measured in terms of phosphate monomer).

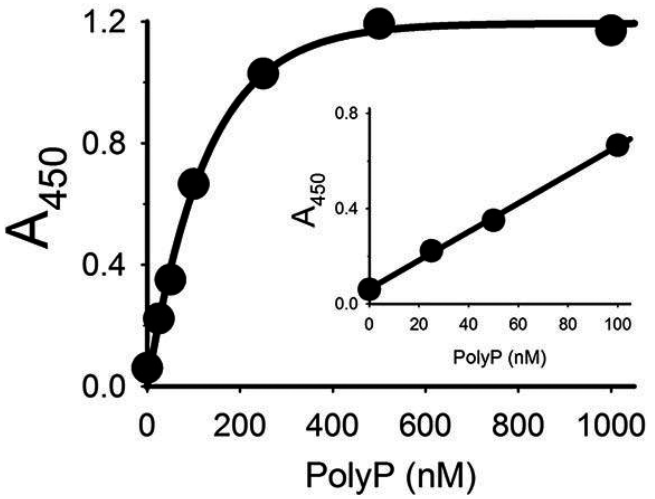

FIGURE Example of a standard curve

Conclusions: This assay may provide new insights into the roles of polyP in a variety of clinically important diseases.

PB 121 | Differential Investigation of Post-translational Modifications in Recombinant and Plasma-Derived Human Coagulation FIX

P. Soupourmas, S. Ow, M. Pelzing

CSL Behring Limited, Parkville, Australia

Background: Idelvion, a long-acting albumin fusion protein linking recombinant coagulation factor IX with recombinant albumin (rIX-FP) is produced in CHO cell line and approved for the treatment and prophylaxis of patients with hemophilia B. The post-translational modifications (PTMs) of recombinant products are strongly dependent on the cell line used for manufacture as well as on the manufacturing process itself. Alterations in PTM's can influence the biological activity and the pharmacokinetic profile of the biopharmaceutical.

Aims: To fully characterize the PTM's (with focus on N- and O-glycosylations) of Idelvion in comparison to commercially available plasma derived and rFIX.

Methods: PTM's located on the activation peptide as well as the O-glycans and the Gla domain in the light chain (LC) were characterized using a novel middle-down high resolution LC-MS method after activation by hFXIa. The released and fluorescent labeled N-Glycans were identified and quantified using in-line HPLC-FLD-MS.

Results: The degree of gamma carboxylation was confirmed, and O-linked glycans on the light chain were characterized. The PTMs on the activation peptide (AP) of rIX-FP were compared to those in plasma and recombinant FIX. The AP of the rIX-FP is highly similar to that of recombinant FIX, and similar N-Glycan structures are also found in plasma-derived FIX. The N-linked glycoforms of rIX-FP are multi-antennary complex-type glycans, including sialylated and partially sulfated forms.

Conclusions: A middle-down HPLC-MS method using high resolution mass spectrometry was developed in order to characterize the intact AP, LC, the heavy chain (HC) and the albumin domain (HSALink) of Idelvion after activation with hFXIa. The middle-down LC-MS method revealed high similarity in the PTM's of Idelvion compared with plasma derived FIX (Mononine™). The accurate mass measurement of the intact fully modified AP of Idelvion confirms a very complex N-glycosylation pattern suggesting that both N-glycosylation sites are occupied.

PB 122 | Clinical Significance of Prothrombin G20210A Mutation in Homozygous Patients

A. Shemesh[1], R. Hoffman[1], Y. Nadir[1], A. Keren-Politansky[1], M. Monreal[2], B. Brenner[1], I. Tzoran[1]

[1]Rambam Health Care Campus, Haifa, Israel, [2]University Hospetal Germans Trias i Pujol Badalona, Barcelona, Spain

Background: Prothrombin G20210A mutation (PTM) is associated with an increased risk for venous thromboembolism (VTE); however, data regarding clinical implications of this mutation are scarce, particularly in homozygous carriers.

Aims: This study aimed to assess significance of PTM as a risk factor for VTE, cardiovascular (CV) disease, obstetric complications and neuropsychiatric symptoms in patient population.

Methods: The Rambam institutional database was retrospectively searched for patients evaluated for PTM between the years 1996-2015. Clinical data of PTM carriers and non-carriers were compared.

Results: Two hundred and thirty nine patients (30 homozygous, 95 heterozygous, 114 non-carriers) were included in this analysis. VTE events were diagnosed in 50% of homozygous [odds ratio (OR) 5 (95% CI 2.1-11.92)], 27.4% of heterozygous carriers [OR 1.88 (95% CI 0.9-3.67)], and 16.7% of non-carriers. VTE rates were significantly higher in homozygous individuals than in non-carriers without severe VTE risk factors [OR 8.17 (95% CI 2.71-24.62)]. VTE recurrence rate after discontinuing anticoagulant therapy was high in carriers (20% homozygous, 11% heterozygous, 4% non-carriers; P=0.006). Of 163 women of reproductive age, 148 had obstetric complications; their prevalence was highest among homozygous women [66.7% vs. 23.7% in heterozygous, 21.9%

in non-carriers; P=0.001; OR of 7.14 (95% CI 2.27-22.45)]. Percentage of neuropsychiatric symptoms was higher in homozygous (34%) than in heterozygous (14%) individuals or non-carriers (11%; P=0.007).

Conclusions: PTM carriers, particularly homozygous individuals, are at an increased risk for VTE and its recurrence compared to non-carriers. Obstetric complications are more frequent in homozygous women. An association between PTM and neuropsychiatric symptoms is suggested.

PB 123 | Impact of Reagents on FVIII Inhibitor Titration

C. Nougier[1], C. Pouplard[2], 'Club des Biologistes' on behalf of the ‚French Study Group on Haemostasis and Thrombosis'

[1]*University Hospital of Lyon, Lyon, France,* [2]*University Hospital of Tours, Tours, France*

Background: Reliable measurement of FVIII inhibitor titre is critical in the follow up of haemophilia A patients, but a wide heterogeneity in reagents used for this procedure remains and is likely a source of variability in the results obtained.

Aims: In order to study the impact of buffers and source of FVIII used during the assay, we performed a multicentre study involving 27 laboratories.

Methods: One normal plasma sample without FVIII inhibitor (NP) and another sample containing low FVIII inhibitor titre (< 2 BU) (PP) were studied. 4 aliquots of each were sent to 27 laboratories and tested undiluted and diluted (1:1) using 4 different procedures: Pro A = ‚home made procedure' with variable reagents from one centre to another; Pro B, using Imidazol buffer (ImB) for samples dilution and the preparation of control mixture; Pro C, using ImB (as in Pro B) plus non-buffered normal pool plasma; Pro D, using ImB (as in Pro B) plus buffered normal pool plasma.

Results: Interestingly, no false positive or negative result was found when labs used "home-made" procedure (Table 1).

Moreover, lower FVIII residual activity in NP and higher FVIII inhibitor level in PP were measured when non-buffered normal pool plasma was used (Pro C, Figure 1), with more false positive results (Table 1).

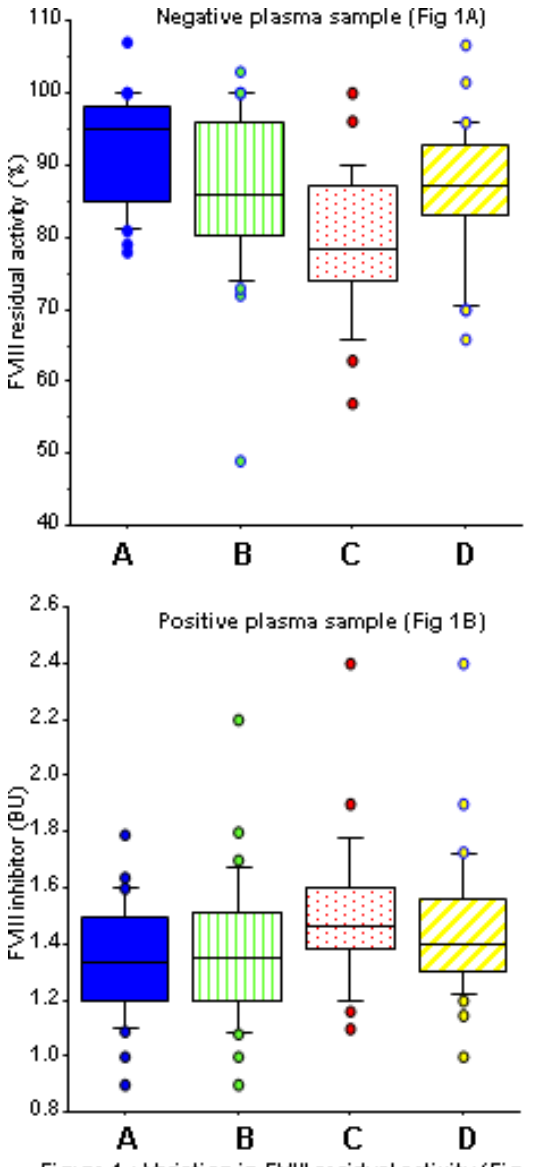

Figure 1 : Variation in FVIII residual activity (Fig 1A, negative plasma sample) and FVIII inhibitor titer (Fig 1B, positive plasma sample) according to the procedures.

FIGURE 1

TABLE 1 FVIII residual activity (%) and FVIII inhibitor (BU) in negative and positive samples

	Negative plasma sample (A)	Negative plasma sample (B)	Negative plasma sample (C)	Negative plasma sample (D)		Positive plasma sample (A)	Positive plasma sample (B)	Positive plasma sample (C)	Positive plasma sample (D)
FVIII residual activity Mean (%)	92	86	79	86	Mean FVIII inhibitor (BU)	1.34	1.37	1.50	1.46
Range (%)	[78 - 107]	[49 - 103]	[57 - 100]	[66 - 106]	Range (BU)	[0.9-1.8]	[0.9-2.2]	[1.2-2.4]	[1.0-2.4]
CV (%)	8.2	13.4	12.5	10.8	CV (%)	15.5	19.7	17.7	18.2
False positive results (> 0.6 BU)	0/27	0/27	3/27	1/27	False negative results (< 0.6 BU)	0/27	0/27	0/27	0/27
False positive results (> 0.4 BU)	0/27	2/27	8/27	4/27	False negative results (< 0.4 BU)	0/27	0/27	0/27	0/27

12 of 27 laboratories used ImB in Pro A and they measured higher FVIII residual activity in control mixture (48 %) compared to non-users of ImB (43%). Additional experiments showed that FVIII was less stable after 2 hours in control mixtures prepared with Owren Koller buffer (Stago) or Diluant factor (Werfen), than with ImB, hepes buffer or FVIII-DP (FVIII degradation < 10%). As expected, FVIII stability in test mixtures was also better with standard buffered plasma than with un-buffered or frozen-buffered plasma pools.

Conclusions: This study supports that the use of Imidazol buffer and standard buffered plasma improves the measurement of FVIII inhibitor titre.

PB 124 | Evaluation of endogenous thrombin potential among patients with antithrombin deficiency-Serbian AT deficiency study group results

M. Kovac[1], G. Mitic[2], S. Lalic-Cosic[3], V. Djordjevic[4], B. Tomic[4], Z. Bereczky[5]

[1]Blood Transfusion Institute of Serbia, Belgrade, Serbia, [2]Institute of Laboratory Medicine, Clinical Center of Vojvodina, Medical Faculty, University of Novi Sad, Novi Sad, Serbia, [3]Faculty of Pharmacy, University of Belgrade, Belgrade, Serbia, [4]Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Belgrade, Serbia, [5]Division of Clinical Laboratory Research, Department of Laboratory Medicine, Faculty of Medicine, University of Debrecen, Debrecen, Hungary

Background: Inherited antithrombin (AT) deficiency is a rare autosomal dominant disorder, caused by mutation in *SERPINC1*. It is classified into two types, where type I is a quantitative disorder characterized by both decreased antigen and activity, mostly associated with an increased risk of venous thromboembolism. While type II is a functional disorder classified into three subtypes according to the site of the causative mutation. Unlike other forms of AT deficiency Type II HBS represents a minor thrombotic risk in its heterozygous form, while homozygous type II HBS AT deficiency is characterized by early onset of arterial and venous thrombosis, as well as pregnancy related complications.

Aims: The study was conducted in order to evaluate endogenous thrombin potential (ETP) among patients with AT deficiency with regard to the type of AT deficiency.

Methods: 24 Serbian families with AT deficiency; total 65 participants were included in the study. Genotyping using Sanger fluorescent sequencing method and determination of ETP for all participants were performed. With regard to the genetic results the participants were divided in three groups: Type I deficiency (20), Type II HBS (31) and family members without mutation, as a control group (14).

Results: ETP level expressed in AUC (%) with median value of 110 (IQR 27.0) was observed in Type I; in the group with Type II HBS, the median value of 102 (IQR 18.5) was obtained; P=0.96. Among non-carriers an ETP level with median of 85 (IQ 16.5) was observed, that was significantly lower compared to the carriers of AT deficiency, P=0.001; P< 0.001.

Conclusions: The carriers of AT deficiency had significantly higher ETP in comparison with the non-carriers. With regard to the type of AT deficiency, the difference of ETP between Type I and Type II HBS was not observed.

PB 125 | Anti-FVIII IgG1 Antibody in Previously Untreated Patients with Hemophilia A Might Be Protective Against Inhibitor Development: Preliminary Results from the Hemfil Cohort Study

D. Gonçalves Chaves[1], A. Cardoso Oliveira Silveira-Cassette[2], L. Lemos Jardim[2], M. Antônio Portugal Santana[1], M. Hermida Cerqueira[3], A. Prezotti[4], C. Lorenzato[5], V. Franco[6], S. Meireles Rezende[2]

[1]Fundação Hemominas, Belo Horizonte, Brazil, [2]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, [3]Instituto de Hematologia Arthur de Siqueira Cavalcanti, Rio de Janeiro, Brazil, [4]Centro de Hematologia e Hemoterapia do Espírito Santo, Vitória, Brazil, [5]Centro de Hematologia e Hemoterapia do Paraná, Curitiba, Brazil, [6]Centro de Hematologia e Hemoterapia de Santa Catarina, Florianópolis, Brazil

Background: The development of FVIII inhibitors is the most fearful complication in patients with hemophilia A (HA). Some studies have reported that IgG1 and IgG4 are the predominant subtypes of antibodies in these patients.

Aims: To investigate the presence of anti-FVIII IgG1 antibodies in plasma samples of severe and moderately-severe (< 2%) previously untreated patients (PUPs) with HA (T0) and their relation with inhibitor development.

Methods: This cross-sectional study, derived from the HEMFIL Cohort Study, included 26 samples from PUPs with HA. An ELISA was performed to detect specific anti-FVIII IgG1. Samples were serially diluted from 1:10 to 1:640 and a numerical score was assigned based on the positivity at each sample dilution (i.e. score=1 for positive sample at 1:10; score=7 for positive sample at 1:640). A pool of five plasma samples from non-hemophilic individuals was used as negative control. Samples from HA patients were considered positive if the optical density was higher than the result of negative control plus two standard deviations. Fisher´s exact test was used for statistical analysis.

Results: A total of 13/26 (50%) and 13/26 (50%) developed inhibitor and did not after 75 exposure days (ED), respectively. At T0, 18 samples (69.2%) were considered positive for anti-FVIII IgG1 of which 5 (19.2%) were high titer (≥1:160). A total of 3/5 and 2/5 developed inhibitor and did not, respectively. A total of 7 out of 8 patients (87.5%) without anti-FVIII IgG1 at T0 developed inhibitors. Otherwise, 12/13 patients (92.3%) who reached 75 ED without inhibitors presented anti-FVIII IgG1 at T0 (p=0.01).

Conclusions: The presence of anti-FVIII IgG1 antibody in PUPs with HA before starting FVIII replacement was associated with lower incidence of inhibitor. We hypothesize that anti-FVIII IgG1 antibody might be protec for inhibitor development. Evaluation of a larger cohort with adjustment for confoundings will be required for more conclusive results. Financial support: FAPEMIG; CAPES; Fundo Nacional de Saúde.

PB 126 | Cost-effectiveness of Recombinant Porcine Factor VIII (OBIZUR) for Treatment of Hemorrhagic Events in Acquired Hemophilia A (AHA)

M. Najafzadeh[1], A.O. Oladapo[2], B.M. Ewenstein[3], T. Raj[1], R.L. Bohn[4], J. Avorn[1]

[1]Brigham and Women's Hospital and Harvard Medical School, Division of Pharmacoepidemiology, Boston, United States, [2]Shire, GHEORE, Cambridge, United States, [3]Shire, Cambridge, United States, [4]Bohn Epidemiology, Boston, United States

Background: A clinical trial showed that recombinant porcine Factor VIII (rpFVIII) is a highly effective and safe option for treating serious hemorrhage in AHA.

Aims: To estimate the cost-effectiveness of rpFVIII relative to recombinant activated FVII (rFVIIa) and Anti-Inhibitor Coagulant Complex (AICC).

Methods: We developed a patient-level simulation model to compare clinical events, and costs of the 3 treatment strategies in AHA patients. The model included medication use , hospitalizations, thrombotic events, recurrent bleeds, and product switching. Patient characteristics and model parameters were based on data from the rpFVIII trial, the EACH2 registry (rFVIIa and AICC) and input from a hemophilia expert panel. All product costs were based on US ASP prices (rpFVIII: $4.53/U; rFVIIa: $1.90/mcg and AICC: $1.92/U). We conducted one-way and probabilistic sensitivity analyses to assess model robustness.

Results: Model simulation results showed bleeds were controlled in 90% (95% CI: 79-98%), 90% (95% CI: 83-96%), and 91% (95%CI: 83-97%) of patients who initiated treatment with rpFVIII, rFVIIa, and AICC, respectively. Estimated discounted lifetime costs were $672,000, $264,000, and $134,000 and quality adjusted life years (QALYs) were 6.56 (95%CI: 5.38 - 7.63), 6.77 (95%CI: 6.07 - 7.48), and 6.69 (95%CI: 5.91 - 7.50) for rpFVIII, rFVIIa, and AICC, respectively. Expected QALYs for rpFVIII increased to 6.92 (95%CI: 5.90 - 7.75) when we assumed deaths rates equal to the rates observed for rFVIIa.

Conclusions: Given comparable efficacy, AICC showed the lowest cost per treated bleed. rpFVIII becomes comparable to rFVIIa if drug utilization and price are both reduced by 50% and 33%, respectively. However, results should be interpreted with caution as sources from which input data were drawn may not be comparable due to differences in methodology, and possible differences in AHA severity and related co-morbidities. More robust comparisons may be achievable with the availability of observational data for rpFVIII.

PB 128 | APC-Resistance Testing Based on Genetic or Functional Assays: To Be or Not to Be ?

A.C. Brisset[1], C. Stocker[1], M. Janssen[1], F. Prüller[2]

[1]DSM Nutritional Products Ltd Branch Pentapharm, Aesch, Switzerland, [2]University Hospital Graz, Clinical Institute of Medical and Chemical Laboratory Diagnostics, Graz, Austria

Background: APC-resistance (APCR) was initially detected through functional assays and subsequent identification of the Factor V Leiden (FVL, R506Q) mutation. Several conditions for acquired APCR but also other mutations in FV leading to APCR have been identified. Today, however, many laboratories perform only DNA tests for R506Q when suspecting APCR.

Aims: To investigate the impact of functional versus genetic tests considering other polymorphisms than FVL inducing APCR.

Methods: Literature search on genetic and functional assays for APCR either based on modified aPTT or snake venom. The latter does neither require Ca^{2+} nor phospholipids, tolerates an incorrect blood to citrate ratio (sample tube under-filling), shows no interference by lupus anticoagulants (Schöni, 2007) and is quite robust against the effect of other mutations than FVL which can lead to APCR (Table 1).

Results: The data confirm the widespread presence of FV mutations leading to APCR and thromboembolic (TE) sequelae, including in

TABLE 1

Name	Mutation	APCR	Clinical Consequences	Reference
FV Bonn	A512V	+	Venous thrombosis, recurrent abortions	Pezeshkpoor et al. J Thromb Haemost. 2016
FV Nara	W1920R	+	Serious DVT, Reduced levels of FV (~10%)	Nogami et al Blood. 2014
FV Cambridge	T306R	+	Venous thrombosis	Williamson et al. Blood. 1998
FV Hong Kong	D666Q	+	Venous thromboembolism	Cai et al. Thromb Res. 2010
FV Liverpool	I359T	+	Spontaneous venous thrombosis. Low APC cofactor activity for inactivation of FVIIIa	Mumford AD, et al. Br J Haematol. 2003 Steen M, et al. Blood. 2004
Not named	E666D	+	Familial history of strong venous thrombosis	Xin-Guang C, et al. Clin Appl Thromb Hemost. 2015 Sharma A, et al. Clin Appl Thromb Haemostas 2015
Not named	R485K	(+)	Thrombosis Praeeclampsia Increased risk for CAD	Hiyoshi M, et al. Thromb Haemost. 1998 Watanabe H, et al. Thromb Haemost. 2001 Faisel F et al. Eur J Hum Genet. 2004 Le W, et al. Clin Genet. 2000
HR2 haplotype FV(R2)	H1299R and other poly-morphisms	+ (mild)	HR2 haplotype FV(R2). Reduced APC cofactor activity of FV(R2). Lower levels of FV, less efficient inactivation of FVIIIa	Luddington R, et al. Thromb Haemost. 2000 Bernardi F, et al. Blood. 1997 Faioni EM, et al. Blood. 1999

ethnic groups like in indigenous populations of Africa, America, East Asia, and Australia in which FVL is virtually absent. Also constellations such as pseudo-homozygosity or the FV Graz mutation (Prüller, 2013) that may compensate for FVL and its impact on APCR should be kept in mind.

Conclusions: Genetic tests for the R506Q polymorphism may miss other causes of APCR associated with TE episodes, or on the contrary, like in the case of FV Graz constellation, may predict APCR though functional tests are normal. DNA sequencing identifies FV mutations but cannot reliably predict its impact on APCR. Functional testing with robust assays seems to be a more suitable and cost effective (Prüller et al, 2014) first line strategy to determine APCR before using DNA based methods.

PB 129 | Alteration of the Hemostatic System in Cirrothic Patients

C. Duboscq[1], J. Ceresetto[1], M. Rodriguez Grazi[2], G. Stemmelin[1], F. Villamil[2]

[1]*Hospital Británico de Buenos Aires, Servicio de Hematologia y Hemoterapia, Buenos Aires, Argentina,* [2]*Hospital Británico de Buenos Aires, Servico de Trasplante Hepático, Buenos Aires, Argentina*

Background: Cirrothic patients present a rebalance hemostatic system as a consequence of the liver synthetic capacity.

Aims: The aim of this work is to study whether procoagulant factors, physiological inhibitors and D-dimer are related to the severity of liver disease in cirrothic patients, assessed by the MELD score.

Methods: Population: 110 consecutive patients with liver cirrhosis who attend the hemostasis laboratory as part of the initial pre-liver transplant evaluation. Cirrhosis was diagnosed by a combination of clinical, laboratory and imaging findings. Severity was assessed through the MELD score.

Control group: 100 healthy individuals with equal% of blood group zero and non-zero and ages similar to the group under study.

Methodology: Factor levels by coagulable method in one stage; Antithrombin (AT), protein C (PC) and plasminogen (PLG) by chromogenic method ; free PS and DD by immunoturbidimetry. All test have been performed on ACL TOP platform with dedicated reagents (HemosiL).

Results: 110 pts were evaluated with hepatic cirrhosis (28 females, age between 19-71 years), MELD:16 (6-33),mean and rank. During the 23-month follow-up, 19 pts were transplanted and 9 presented a thromboembolic event. All parameters were significantly different from the control group (p< 0.001,see Table). Although AT and PC descend with the severity of the disease, the free PS presents a random behavior. The correlation between FVIII / PC vs MELD (r = 0.50) and FVIII / AT vs MELD (r = 0.49) is moderate but higher than the correlation between INR and MELD. Hemostatic parameters of 101 pts who didn´t have a thromboembolic events were not significantly different from the 9 patients who presented a thrombotic event during the follow up.

Conclusions: The cirrhotic patients have a hypercoagulable state, demonstrated by the elevated values of DD and the increase of the FVIII / PC and FVIII / AT ratio. These hypercoagulable parameters correlates moderately with the level of liver damage assessed through MELD score but not with DD level.

TABLE Hemostatic parameters in cirrothic patients

	Cirrothic pts median and rank	Control Group median y rank
FBG (g/L)	2.03 (6.10-5.81)	3.24 (2.01-4.15)
FV (%)	55 (14-179)	92 (86-125)
FVII (%)	44 (1-174)	98 (78-116)
FVIII (%)	193 (71-499)	89 (56-156)
AT(%); FVIII/AT ratio	42 (7-143); 4.36 (0.82-32.70)	101 (93-105); 1.02 (090-1.23)
PC (%); FVIII/PC ratio	36 (5-132); 5.35 (0.90-48.49)	105 (92-132); 0.98 (0.75-1.85)
PSfree(%); FVIII/PS ratio	78 (20-167); 2.58 (1.01-25)	84 (69-125); 1.20 (0.67-1.99)
PLG (%)	55 (38-125)	97 (85-120)
D Dimer (ngDD/ml)	1017 (42-4726)	96 (42-256)

PB 130 | In vitro Antithrombin is the Main Inhibitor of Thrombin Generation at the Surface of Endothelial Cells Acting Independently to Heparan Sulfates

B. Catieau[1], S. Chtourou[2], J.-L. Plantier[3]

[1]*LFB Biotechnologies, Loos, France,* [2]*LFB Biotechnologies, DIAS, Les Ulis, France,* [3]*LFB Biotechnologies, Laboratoire d'Hémostase et des Soins Intensifs, Loos, France*

Background: We characterized the antithrombin (AT) binding *in vitro* to living endothelial cells (HUVEC) and the potency of AT on thrombin generation assay (TGA) under supraphysiological conditions (1.0 to 2.0 U/ml; Catieau et al. Abstract 4168, ASH 2015 annual meeting).

Aims: To further depict the participation of the endothelial surface in the different anticoagulation processes and, specifically its modulation of the antithrombin potency at low doses.

Methods: HUVEC were grown in a complete EGM2 medium (Lonza) for no more than 6 passages. Cells were grown to confluence, washed with non-supplemented medium and treated or not with a mix of heparanase I, II and III (2U/ml, 2U/ml and 3U/ml respectively, Sigma) on EBM2 +/- neutralizing anti-EPCR (0.1 µg/well - Millipore). TGA, following 0.5 pM of TF/2 µM of phospholipids induction, was performed at the surface of HUVEC in AT-deficient plasma spiked with various amounts of AT (0, 0.1; 0.5 and 1 U/ml).
Results: :When the concentration of AT was increased in AT-deficient plasma, the profile of the TGA changed in function of the dose. All lag-times were similar suggesting that the Tissue Factor Pathway inhibitor inhibition was not affected in the conditions assayed. However, when no AT was spiked there was no decrease of the signal following the peak but it progressively decreases in function of the dose of AT spiked. In all conditions, the combing of heparin sulfate did not modify the efficiency of the TGA confirming our previous data. To distinguish the anticoagulation coming from AT to those from the protein C pathway, an anti-EPCR antibody was added. The addition of such antibody did not change the profile of the TGA at the different AT concentrations suggesting a minor role for the protein C pathway in comparison to AT.
Conclusions: The TGA at the surface of the HUVEC *in vitro* allowed identifying the AT as the major anticoagulant pathway working independently to heparan sulfates.

PB 131 | Pregnancy and Delivery Experiences in a Patient with Severe Factor X (FX) Deficiency Treated with a High-purity Plasma-derived Factor X (pdFX) Concentrate

G. Auerswald, M. Bührlen

Klinikum Bremen-Mitte, Prof-Hess-Kinderklinik, Bremen, Germany

Background: A female, born in 1997, was diagnosed at our center in 2001 with a basal FX:C of 3% of normal due to a homozygous missense mutation in the *F10* gene, p.Gly20Arg/c.61G>A. She had an extensive history of spontaneous and traumatic bleeds resulting in synovitis and arthrosis in her left knee and arthrosis in both ankles. She also suffered from menorrhagia (routinely treated with antifibrinolytics). The experiences of this patient with pdFX for on-demand/prophylactic treatment in a phase 3 clinical trial have been presented.
Aims: To present pregnancy and delivery experiences for this patient.
Methods: Since completing a phase 3 clinical trial in 2012, the patient has received 1500 IU pdFX (≈23 IU/kg) twice weekly under a compassionate-use program.
Results: At 17 years of age, the patient reported a spontaneous abortion at 6wk + 3d (considered by reporter as very unlikely to be pdFX related) and underwent curettage. Three subsequent spontaneous abortions were reported but unconfirmed by gynecologic examination. The patient reported another pregnancy < 2 years after the first spontaneous abortion. The frequency of pdFX treatment (1500 IU) was increased from 2 to 3 times/wk to prevent nose bleeds and protect the pregnancy. Spontaneous labor commenced at 39wk + 5d (2d following a routine pdFX dose). An additional 1500 IU pdFX dose was administered for the delivery, which required no assistance. No bleeding complications occurred during delivery of baby or placenta, placenta delivery was not delayed, and postpartum bleeding was not excessive (although lochia was increased compared with a patient without a bleeding disorder). The baby was healthy with no reported bleeding diathesis. Three weeks after delivery, the patient resumed twice-weekly routine prophylaxis.
Conclusions: These results show that pdFX was safe and effective in maintaining hemostasis during pregnancy and obstetric delivery in this patient with severe factor X deficiency.
Funding: Bio Products Laboratory

PB 132 | Impact of Thrombin (Dabigatran) and FXa Inhibitors (Rivaroxaban, Apixaban, Edoxaban) on Hemostasis Assays

J. Hammelburger[1], R. Bottenus[1], M. Triscott[2]

[1]*Instrumentation Laboratory, Reagent R & D, Orangeburg, United States,*
[2]*Instrumentation Laboratory, Vice President R & D, Bedford, United States*

Background: Direct Thrombin (Dabigatran [DAB]) and FXa (Apixaban [APIX], Rivaroxiban [RIV]), Edoxaban [EDOX]) inhibitors are direct oral anticoagulants (DOACS) for use in clinical practice as an alternative to the vitamin K antagonists (VKA) for the prevention of thrombotic events that do not require routine laboratory monitoring.
Aims: The impact of the DOACS on IL Hemostasis primary diagnostic assays on the ACL TOP was evaluated.
Methods: RIV, APIX, EDOX, and DAB, were spiked into normal pooled plasma (NPP) in the range of 0-1000 ng/mL. PTs were acquired using HemosIL RecombiPlasTin 2G (RPT 2G), ReadiPlasTin (RdPTn), PT HS Plus, and PT Fibrinogen (PT-Fib), while APTTs were determined using HemosIL SynthASil (SSL), APTT-SP, and SynthAFax (SFX). Results are in ratio for interference (1.25), peak plasma levels (C_{max}≈200 ng/mL).
Results: RIV/APIX/EDOX induced a linear, reagent concentration-dependent prolongation of the PT/APTT. DAB exhibited a similar but curvelinear response with a lag-time for PT. RIV impacted the PT with ratio ≈1.7 and APTT ≈1.4 at the C_{max}. It was sensitive at ≈74ng/mL and ≈125 ng/mL, with 2x CT (clot time) of 300-400 ng/mL and ≥ 650 ng/mL for PT and APTT, respectively. DAB impacted the APTT with ratio ≈2 at the C_{max} with sensitivity at ≈ 25 ng/mL and 2x CT at 150-200 ng/mL. It impacted the PT at > 350 ng/mL with 2x CT at ≥ 650 ng/mL. APIX was sensitive at > 200 ng/mL for PT and > 500 ng/mL for APTT, with 2x CT at ≥ 650 ng/mL PT and ≥ 1000 ng/mL APTT. EDOX impacted the PT with ratio ≈1.6 and APTT ≈1.4 at the C_{max}. It was sensitive at ≈75 ng/mL and ≈100 ng/mL, with 2x CT of ≈300 ng/mL and ≈650 ng/mL for PT and APTT, respectively.
Conclusions: The PT is more sensitive to RIV and EDOX (≈75 ng/mL) than APIX (> 200 ng/mL), and insensitive to DAB (>350 ng/mL). The APTT is more sensitive to DAB (≈25 ng/mL) than EDOX (≈100 ng/mL)

or RIV (125 ng/mL), and insensitive to APIX (> 500 ng/mL). The greatest sensitivity was seen with SFX to the DOACS; RdPTn and RPT 2G to RIV, APIX, and DAB; and PT HS Plus to EDOX.

PB 133 | Role of Factor-Xa Inhibitor Treatment on Platelet Function and Thrombus Formation

T. Petzold[1,2], M. Thienel[1,2], T. Czermak[1,2], J. Pircher[1,2], C. Schulz[1,2], S. Massberg[1,2]

[1]LMU Klinikum der Universität München, Medizinische Klinik I, Munich, Germany, [2]DZHK (German Center for Cardiovascular Research), Munich, Germany

Background: Treatment with factor Xa inhibitor (FXAI) rivaroxaban associates with a slightly decreased number of acute coronary syndromes (ACS). This is in contrast to oral thrombin inhibitor treatment, which n associates with an increased number of myocardial infarction, likely due to a pro-thrombotic effect on platelet function and thrombus formation

Aims: Our study aims to investigate whether the clinical observed reduced frequency of ACS under rivaroxaban is due to a play of chance or linked to so far undefined underlying mechanism. We therefore asked whether rivaroxaban treatment affects platelet function under static or flow conditions.

Methods: We analyzed platelet function from patients receiving either rivaroxaban (20mg once daily) or dose adapted VKA (vitamin-K antagonist) for the prevention of stroke due to atrial fibrillation. Whole blood aggregation was determined by impedance-based aggregometry after stimulation with ADP, collagen, TRAP and ristocetin. Next we determined single platelet activation and reactivity by measuring p-selectine surface expression upon stimulation with ADP, thrombin and convulxin. Further we investigated platelet adhesion and thrombus under arterial flow conditions on vWF- and collagen-coated flow chambers. Arterial thrombus formation was analyzed in a carotid injury model in FXaI and VKA treated mice.

Results: Our data did not reveal any significant differences on platelet function under static and flow conditions in FXaI or VKA treated blood. In-vivo we found a trend towards a decreased arterial thrombus formation under rivaroxaban compared to VKA treatment.

Conclusions: Within our study we did not find any evidence for an antithrombotic effect of rivaroxaban on platelet function. However future studies are required to investigate the complex interplay between platelets and the coagulation system in more detail.

PB 134 | Prolonged Targeted Temperature Management Causes an Impaired Coagulation: A Randomised Clinical Trial

A. Jeppesen[1], H. Kirkegaard[2], S. Ilkjær[1], A.-M. Hvas[3]

[1]Aarhus University Hospital, Department of Anaesthesiology and Intensive Care Medicine, Aarhus, Denmark, [2]Aarhus University Hospital, Research Centre for Emergency Medicine, Aarhus, Denmark, [3]Aarhus University Hospital, Centre for Haemostasis and Thrombosis, Department of Clinical Biochemistry, Aarhus, Denmark

Background: Mild hypothermia *per se* is presumed to impair coagulation. However, no studies have previously investigated whether hypothermia beyond 24 hours impair the coagulation even further.

Aims: Investigate whether prolonged duration of targeted temperature management (TTM) impair the clot formation compared with standard duration.

Methods: Resuscitated comatose out-of-hospital cardiac arrest patients (n=82) were randomized to standard (24 hours, n=42) or prolonged (48 hours, n=40) duration of TTM at 33±1°C. Blood samples were collected 22±2, 46±2, and 70±2 hours after obtaining target temperature and were analysed by ROTEM® using EXTEM®, INTEM® and FIBTEM® and for thrombin generation using the Calibrated Automated Thrombogram®Assay. Additionally, standard laboratory investigations were analysed. Informed content was obtained and the regional research ethic committee approved the study.

Results: At the 22-hour sample; ROTEM® and thrombin generation yielded no differences between standard and prolonged treatment except for a minor increase in time to maximum velocity (EXTEM® and INTEM®) in the prolonged group.

At the 46-hour sample; Using ROTEM® we found a 11% longer INTEM® clotting time (p=0.005) and 12% longer time to maximum velocity (p=0.007) in the prolonged group compared with the standard group. Thrombin generation analyses showed a 411 nM*minute decreased endogenous thrombin potential

(p< 0.001), a 30% longer lag time (p=0.04), a 106 nM decreased peak concentration (p< 0.001), a 36% longer time to peak (p=0.01) in the prolonged group compared with the standard group.

At the 70-hour sample; No differences were found in ROTEM® analyses between groups, however, the thrombin generation showed that there remained a longer lag time, a decreased peak and time to peak (all p-values ≤0.02) in the prolonged group compared with the standard group.

Conclusions: Clot formation and thrombin generation were impaired in prolonged TTM compared with standard treatment.

PB 135 | Features of Clinical and Laboratory Diagnostics of Disturbance of Hemostasis System in Patients with Retinal Vein Occlusion on the Background of FV Leiden Mutation and LA

S. Tatyana

The Branch of Federal State Budgetary Educational Institution of Additional Professional Education 'Russian Medical Academy of Continuing Professional Education' Russian Federation Ministry of Health, Department of Ophthalmology, Novokuznetsk, Russian Federation

Background: The number of patients with retinal venous occlusions is increasing, especially among young people. Often, they have revealed a genetic predisposition to thrombosis. Risk factors for thrombosis are

genetic resistance to activated protein C (RAPC), genetic defect in factor V (FV Leiden) and the presence of lupus anticoagulant (LA).

Aims: Explore the features of laboratory and clinical disturbances in the hemostatic system in patients with OVS on the background of FV Leiden mutation and LA.

Methods: A total of 150 patients (150 eyes) with RVO (mean age — 42 ± 10 years) were examined and divided into three groups. Group 1: patients with RVO, FV Leiden and LA (n = 12); group 2: patients with RVO and FV Leiden (n = 11) without LA; group 3: patients with RVO without FV Leiden and LA, selected from remaining 107 people for a comparable number of groups (n = 30). The control group was 50 people without RVO, but with hypertension.

Results: . It was shown that RAPC index in patients with FV Leiden mutation and the LA has the less value (0,6 ± 0,01) on comparison to patients with RVO (1,50 ±0,18) ($p < 0,05$). They also have enhanced V, VIII and von Willebrand factors and intravascular platelet activity. LA exacerbates endotheliosis in the microvasculature of the retina and in combination with FV Leiden mutation increases the thrombogenesis, participating in the pathogenesis of ischemic thrombosis of central retinal vein and its branches, which clinically manifested as retinal thrombo-hemorrhagic syndrome.

Conclusions: The hemostasis regulation genes polymorphisms detection (as well as lupus anticoagulant detection) is recommended to clarify the diagnosis and selection of adequate therapy.

PB 136 | Causes of Isolated Prolonged Activated Partial Thromboplastin Time in a Haemostasis Reference Hospital

N. Vilalta, M. Carrasco Exposito, J.A. Millón, H. Cerdà, D. Llobet, C. Vallvé, J. Fontcuberta

Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Background: The activated partial thromboplastin time (aPTT) measures the time it takes plasma to clot when exposed to substances that activate the intrinsic and common pathways of coagulation.

Some patients have unexplained prolonged aPTT. Causes of a single prolonged aPTT included: Hemophilia A or B, inherited factor deficiencies (XII, XI, X, V), acquired factor inhibitors and lupus anticoagulant inhibitors.

Aims: To determine the causes of isolated prolonged aPTT (>1.3 RATIO) in a Haemostasis reference hospital.

Methods: We performed a retrospective study of 224 consecutive patients with isolated prolonged aPTT presenting to our hospital during 2016. All patients had normal prothrombin time and thrombin time. For all patients a standard panel of tests was performed. First, we detected lupus anticoagulant (LA) using two different sensitive tests: Dilute Russell Viper Venom Time (DRVVT) and Silica Clotting time (SCT). If the result was negative, we performed an inhibitor assay. If the sample had not an inhibitor we measured coagulant factors VIII, IX, XI and XII, which are involved in the intrinsic arm of haemostasis.

Results: The most common cause of an isolated aPTT in our study was the presence of LA (81.3%). In the 182 cases of LA positivity, 108 (59.3%) samples were positive for DRVVT and SCT tests, 34 (18.7%) for DRVVT and 40 (22%) for SCT (fig.1).

Fig. 1

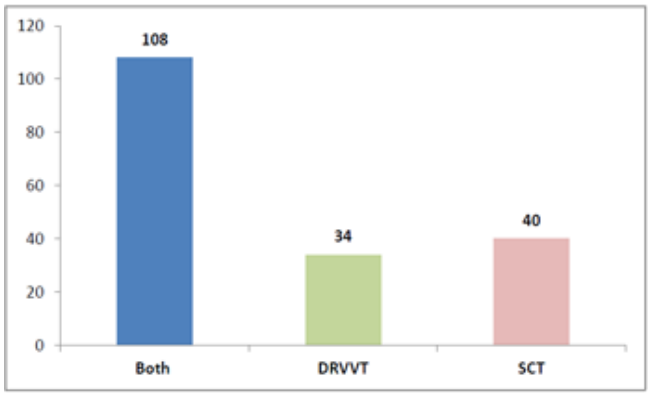

FIGURE 1

The inhibitor assay was positive in 5 cases (2.2%) due to a presence of monoclonal gammapathy in the plasma. Prolonged aPTT due to a factor deficiency was in 37 known cases (16.5%): 24 A haemophilia A, 2 haemophilia B, 6 factor XI deficiencies and 5 factor XII deficiencies (fig. 2).

Fig. 2

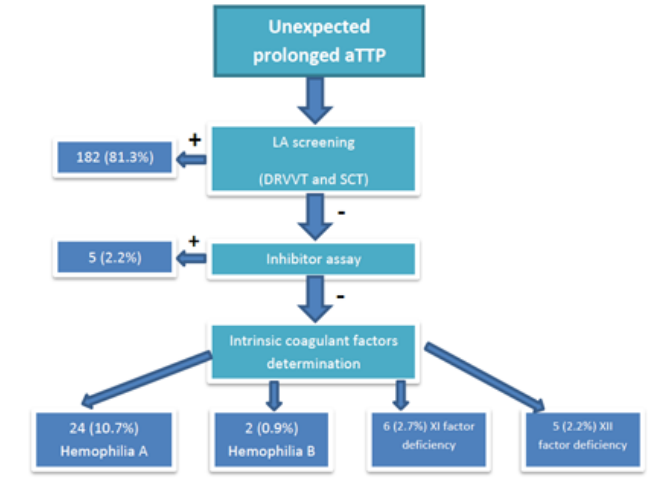

FIGURE 2

Conclusions:

- Our study suggests that most of the causes of isolated prolonged aPTT may signify an underlying thrombophilic condition.
- Our data suggest that dRVVT and SCT are sensitive tests for detecting LA.
- Using a standard test panel for screening prolonged aTTP allow for studying the patients underlying pathologic conditions and optimize the sample.

PB 137 | Evaluation of Lupus Anticoagulant and Anti Cardiolipin Antibodies in Poly Transfused Beta Thalassemia Major Patients at Hyderabad

I. Ujjan[1], A. Memon[1], A. Naz[2], M.D. harani[3], R.A. bhatti[4]

[1]Liaquat University of Medical and Health Sciences, Jamshoro, Hyderabad, Pakistan, [2]National Institute of Blood Disease & Bone Marrow Transplantation, Karachi, Pakistan, [3]liaquat university of medical and health sciences, pathology, hyderabad, Pakistan, [4]liaquat university of medical and health sciences, LUMHS university, hyderabad, Pakistan

Background: Beta thalassemia is a congenital hemolytic disease caused by defective globin synthesis resulting in decreased quantity of globin chain. The disease is widespread in the subcontinent regions. The repeated blood transfusions received by anti-Phospholipid antibody positive patients is higher than anti Phospholipid antibody negative lupus anti-coagulant was detected in 16% of patients. There is increased need of blood transfusion in beta-thalassemia major patients those develop anti-phospholipid antibodies.

Aims: Aim of this study is to determine the frequency of anti-phospholipid antibodies in transfusion dependent Beta thalassemia major patients.

Methods: This cross-sectional study was conducted at department of pathology and transfusion services, at Liaquat University of Medical & Health Sciences, Jamshoro.It was carried out from October 2012 to July 2013 after approval of IRB and signing of written consent of patients.A total of 121 patients who fulfilling the inclusion criteria at pediatric department LUMHS and thalassemia centers in Hyderabad were selected.APTT will be done on citrated plasma on CA 500 automated coagulation analyzer by sysmex anti-phospholipid antibody which include Lupus anticoagulant and Anticardiolipin antibodies will be performed by commercially available kits by EIA.

Results: Out of 121 patients 38(31.40%) patients were found to be anti-phospholipid positive and 83(68.60%) were negative. Lupus anticoagulant were present in 20 (16.53%) and Cardiolipin Antibody were present in 11(9.09%) patients.

Conclusions: Anti-phospholipid is common in patients with beta thalassemia major.APS disorder in children. In this regard, aPLs are considered as a risk factor that can shift the balance between coagulation and anticoagulation toward represents the most common acquired hypercoagulation state of autoimmune thrombosis.

PB 138 | Reference Ranges for Hemostasis Parameters in Pregnant Women from the Krasnoyarsk Area

V. Potylitsina[1], S. Lobanova[1], I. Olkhovsky[2,3], P. Toulon[4]

[1]Maternal and Child Health Care Center, Krasnoyarsk Territory, Krasnoyarsk, Russian Federation, [2]Hematology Research Center of Russian Federation Ministry of Healthcare, Krasnoyarsk Unit, Krasnoyarsk, Russian Federation, [3]Research Center of Krasnoyarsk Unit of Russian Academy of Sciences, Krasnoyarsk, Russian Federation, [4]Pasteur University Hospital, Hematology, Nice, France

Background: Pregnancy is known to be associated with significant changes in the coagulation and fibrinolytic systems. As the consequence, the reference ranges defined in healthy adult population are not optimal for ensuring proper diagnosis of both hemorrhagic and thrombotic complications in pregnant women. Moreover, no data was available, so far, for population from the Krasnoyarsk area, Siberia.

Aims: To define the reference ranges for coagulation parameters in pregnant women from Siberia.

Methods: A total 228 pregnant women, with a mean age of 29.5 years (range: 18-43), were evaluated after their informed consent was obtained. None had any complication during their pregnancy, delivery, or postpartum period. Plasma samples were obtained at different time of the pregnancy i.e. gestational weeks 1-12 (n=31), 13-21 (n=43), 22-28 (n=66), 29-34 (n=52), and 35-42 (n=36). Routine and esoteric coagulation parameters were evaluated on a fully automated analyzer ACL TOP i.e. prothrombin time, activated partial thromboplastin time, thrombin time, fibrinogen, coagulation factors (F) II, V, VII, IX, X, XI, XII, d-dimers, vWF:Ag, antithrombin, protein C, free protein S and plasminogen.

Results: Pregnancy was associated with significant shortened PT and aPTT. Moreover, significant changes were demonstrated for most specific parameters. Particularly, the plasma levels of fibrinogen, D-dimers, FVIII and vWF:Ag significantly correlated with gestational age, whereas free PS was negatively correlated.

Conclusions: The use of gestational age-specific reference ranges is critical for the accurate interpretation of haemostatic tests during pregnancy.

PB 139 | Recombinant FVIIIFc-VWF-XTEN Promotes Normal Fibrin Formation, Structure and Stability

M. Aleman, E. Kistanova, E. Seth-Chhabra, R. Peters, J. Salas

Bioverativ, Waltham, United States

Background: Coagulation culminates in the formation of a network of fibrin fibers, the density of which depends on the procoagulant activity generated at the site of injury. In hemophilia A, the lack of factor VIII (FVIII) diminishes thrombin generation resulting in fibrin clots of low density and poor stability. Factor replacement therapy aims to correct circulating FVIII levels and therefore normalize fibrin formation. Recombinant FVIIIFc-VWF-XTEN (BIVV 001) is a novel FVIII fusion protein with an extended half-life due to fusion of the D'D3 domain of von Willebrand Factor and use of Fc-fusion and XTEN technologies.

Aims: To evaluate the procoagulant activity of BIVV 001 by analyzing fibrin formation, network structure, and stability in hemophilia A plasma.

Methods: Citrated human hemophilia A plasma was spiked with increasing concentrations of BIVV 001 or recombinant FVIII (rFVIII) up

to 1 IU/mL (based on one-stage clotting assay activity). Tissue factor/$CaCl_2$-triggered fibrin formation was monitored by absorbance over time. Stability assays were performed by the addition of tissue plasminogen activator (tPA) at the start of the clotting reaction. Fibrin network structure of fluorescently-labeled clots was analyzed by confocal microscopy and an innovative high content image analysis pipeline.

Results: Both BIVV 001 and rFVIII showed similar dose-dependent increases in rate of fibrin formation compared to baseline (12±6 vs 12±4 fold change, respectively at 1 IU/mL). During tPA challenge, BIVV 001 promoted clot stability in a dose-dependent manner similar to rFVIII. Microscopic evaluation of fibrin clots formed in the presence of BIVV 001 revealed a significant improvement in fibrin network structure over baseline, to densities comparable to rFVIII.

Conclusions: In conclusion, the hemostatic potential of BIVV 001 is indistinguishable from rFVIII based on fibrin formation, network structure and stability in hemophilia A plasma.

PB 140 | Dissecting the Catalytic Enhancement of Activated Factor IX via Foot-printing Mass Spectrometry

N. Freato[1], E.H.T.M. Ebberink[1], F.P.J. van Alphen[2], C. van der Zwaan[1,2], M.G. Boon-Spijker[1], M. van den Biggelaar[1], A.B. Meijer[1,2,3], K. Mertens[1,3]

[1]Sanquin Research, Plasma Proteins, Amsterdam, The Netherlands, [2]Sanquin Research, Research Facilities, Amsterdam, The Netherlands, [3]Utrecht Institute for Pharmaceutical Sciences, Utrecht University, Utrecht, The Netherlands

Background: Like in other serine proteases, coagulation factor IX (FIX) proteolytic activation involves the generation of a novel N-terminus and intramolecular rearrangements in its catalytic machinery. However, the structural events that drive FIX activation have remained poorly understood.

Aims: We used innovative foot-printing and mass spectrometry techniques to investigate the activation of FIX in comparison with factor X (FX) and prothrombin.

Methods: Chemical foot-printing included hydrogen-deuterium exchange (HDX) and primary amine labeling by tandem-mass-tags (TMTs). FIX, FX and prothrombin were activated and trapped in their most active configuration by binding an irreversible inhibitor. For FIX, prominent changes were validated by mutagenesis in positions implicated in haemophilia B.

Results: TMT labeling revealed that FIXa was similar to FXa and thrombin in that its N-terminus became more protected once bound to a peptide substrate analogue. In all three proteins, N-terminus insertion coincided with differential Lys-exposure in one particular surface loop (the 220-loop in chymotrypsin numbering). In fact, upon activation, Lys-exposure in the 220-loop was decreased in FXa and thrombin, but increased in FIXa. Conformational changes in the 220-loop were confirmed by HDX and were most prominent after inhibition of FIXa by EGRck. Involvement of the 220-loop in FIXa activity was further addressed by E217A, E219A, K222A and K224A substitutions. All mutants displayed impaired activity towards FX. Substitutions at 217, 222 and 224 were associated with reduced N-terminus insertion, while the opposite was found for E219A. This suggests a relation between N-terminus insertion and the 220-loop.

Conclusions: We propose that substrate-driven rigidification of the 220-loop, in combination with more efficient N-terminus insertion provides an important allosteric mechanism in FIX. These data should provide the basis for exploring rate limiting events in FIXa catalytic activity in response to its cofactor FVIII.

PB 141 | Characterization of Interactive Sites of the Blood Coagulation Factor VIII and the Low-density Lipoprotein Receptor using Macromolecular Docking Prediction Algorithms

B. Fochtman, S. Shestopal, V. Simonyan, T. Lee, A. Sarafanov

U.S. Food and Drug Administration, Center for Biologics Evaluation and Research, Silver Spring, United States

Background: The low-density lipoprotein receptor (LDLR) is involved in clearance of the blood coagulation factor VIII (FVIII) from the circulation. The binding sites of the LDLR family receptors are formed by complement-type repeats (CRs), grouped in clusters. Upon ligand binding, a CR domain interacts with a surface-exposed lysine of a ligand (Fisher et al, 2006, Mol. Cell 22:277-83). Previously, we demonstrated that four adjacent CRs (2-5) of LDLR form an extended site for binding FVIII, and the interactive FVIII site is in proximity to or involves the C1-domain (Kurasawa et al, 2013, J. Biol. Chem. 288:22033-41). In the present work, we used computer modelling to predict details of this interaction.

Aims: To determine surface-exposed lysines of FVIII potentially involved in its binding to LDLR and assess mutual orientation of both molecules during the interaction.

Methods: Using atomic coordinates from the crystal structures of FVIII and LDLR exodomain (PDB 2R7E and 1N7D, respectively), each of the CRs 2-5 of LDLR was docked individually to FVIII using the molecular docking program DOT2. Promising poses, most similar to the canonical CR domain interaction, were filtered based on:

i) the distance of a FVIII lysine to the CR-coordinated Ca^{2+} ion and

ii) the ability of the lysine to interact with a conserved aromatic residue of the CR.

Finally, by modeling the linker regions between the CR domains orientations, the individual docking results were combined into a model of the FVIII-LDLR interaction.

Results: A number of surface-exposed lysines of FVIII, located on its A3, C1 and C2 domains, were determined as candidates for the interaction and aligned with particular CR domains of LDLR.

Conclusions: A model of the FVIII-LDLR interaction was built up. The data suggest that the site of FVIII for binding to LDLR is extended as involves all domains of the FVIII light chain. *Disclaimer: these contributions are an informal communication and do not bind or obligate the U.S. FDA.*

PB 142 | Comparison of Bleeding Efficacy of FIX-F_C and FIX_{WT} 7 Days Post-infusion

B. Cooley[1], F.-C. Lin[2], D. Stafford[3]

[1]McAllister Heart Institute, University of North Carolina, Pathology and Laboratory Medicine, Chapel Hill, United States, [2]University of North Carolina at Chapel Hill, Biostatistics, Chapel Hill, United States, [3]University of North Carolina Chapel Hill, Biology, Chapel Hill, United States

Background: Because hemophilia B prophylaxis is based on plasma levels of factor IX (FIX), several companies have produced FIX molecules with longer plasma residence times. But, we have previously shown that FIX with its c-terminus fused to the Fc region of IgG (FIXFc) provides no more protection from saphenous vein bleeding in hemophilia B mice than does $FIX_{WT.}$ Furthermore, FIX binds tightly to type IV collagen, which underlies the vasculature; this binding appears to explain our observation that there is ~3 times more extravascular factor IX than plasma factor IX. Here we show that FIX fused at its c-terminus with albumin (FIX_A) provides no additional benefit over FIX_{WT} in the saphenous vein bleeding model.

Aims: To compare Clotting Efficacy of FIX_{WT} and FIX_A.

Methods: Factor IX was infused into either hemophilia B mice lacking the FIX antigen or mice producing normal amounts of defective FIX. Seven days post-infusion, the saphenous vein was injured, and the number of times that clotting occurred was recorded. All mouse experiments were approved by the Institutional Animal Care and Use Committee (UNC-CH, #13-144) and followed U.S. Public Health Service guidelines for animal care and use.

Results: Fig. 1 shows no statistical difference between FIX_{WT} and FIX_A seven days post-infusion at the two different concentrations.

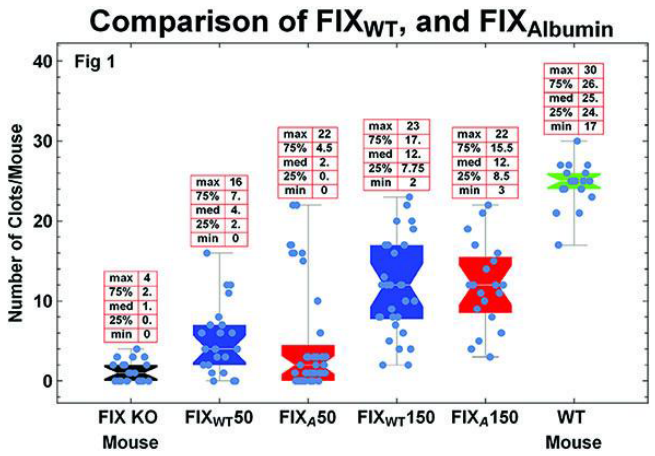

FIGURE 1 Hem B mice infused with FIXA were evaluated 7 days post infusion by saphenous vein bleeding. At neither dose was FIXA superior to FIXWT

If FIX's extracellular distribution is important for clotting efficacy, one would expect that a CRM^+ patient (a patient with defective FIX that can still bind type IV collagen) would require a higher dose of FIX for efficient prophylaxis. To test this, we utilized a knock-in mouse that expresses defective FIX_{R333Q} at normal levels. Fig 2 shows that a dose of FIX (100 IU/kg), that provides a median value of 8 clots at 7 days post-infusion in a hemophilia B mouse, provides only 5 clots in the FIX_{R333Q} mouse.

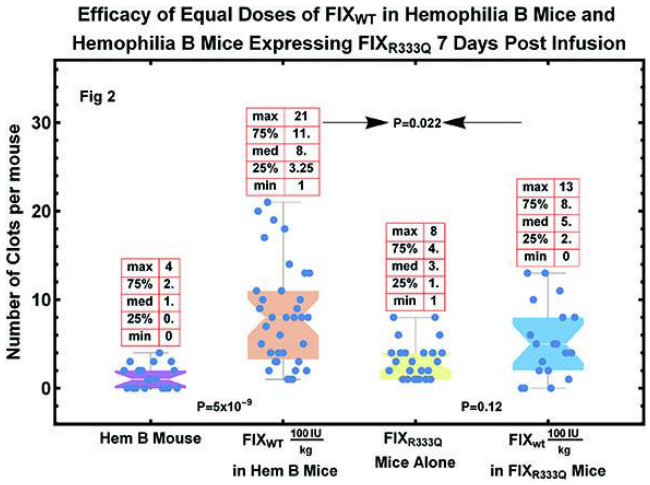

FIGURE 2 Hem B mice or mice expressing defective factor IX (FIXR333Q) showed significant differences in clotting efficacy

Conclusions: These data suggest that plasma FIX levels are not the best criterion for dosing hemophilia B. Furthermore, dosing may need to be adjusted depending upon the level of defective FIX.

PB 143 | rFVIIIFc-VWF-XTEN Demonstrates Comparable Efficacy to Recombinant Human FVIII in Mice by Acute Bleeding and Intravital Microscopy Models

M. Demers, Z. Liu, A. van der Flier, E. Seth Chhabra, T. Liu, R. Peters, J. Salas

Bioverativ, Waltham, United States

Background: Following vascular injury, the coagulation cascade activates FVIII, which leads to platelet activation and development of a stable clot. rFVIIIFc-VWF-XTEN (BIVV 001), is a novel long lasting recombinant FVIII designed to treat hemophilia A patients. BIVV 001 consists of a single chain rFVIIIFc, two XTEN linkers and the FVIII binding D'D3 domains of VWF, which prevents its association to VWF further increasing its half-life.

Aims: Compare the in vivo efficacy of BIVV 001 versus recombinant full length human FVIII (rhFVIII) in a dose-response study by clot formation in hemophilia A (HemA) mice.

Methods: HemA mice treated with BIVV 001 or rhFVIII were subjected to either tail clip or laser-induced saphenous vein injuries by intravital microscopy. For the tail clip assay, loss in blood volume was quantified for 30 minutes post injury. For the laser-injury model, the kinetics of platelet accumulation was analyzed at the site of injury for 3 minutes. The initial site was then reinjured after 5 and 10 minutes, for a total of 3 injuries induced at the same site.

Results: In the tail clip bleeding model, BIVV 001 showed comparable efficacy to rhFVIII at all tested dose levels. In the laser-injury model, the initial platelet adhesion was similar between HemA and wild-type mice but platelet deposition was decreased in HemA mice after the second and third injuries. Similarly, treatment with both FVIII molecules increased platelet deposition after the second and third injuries. Analysis of the third injuries showed similar platelet deposition profiles for BIVV 001 and rhFVIII as determined by maximal platelet accumulation, time to maximal platelet deposition, and rate of platelet accumulation.

Conclusions: BIVV 001 and rhFVIII display similar acute in vivo efficacy in HemA mice based on intravital microscopy and tail clip models when dosed based on one-stage assay activity. These results demonstrate equivalent in vivo hemostatic potential for BIVV 001 and rhFVIII.

PB 144 | How Full-length FVIII Benefits from its Heterogeneity - Insights into the Role of the B Domain

J. Anzengruber, M. Feichtinger, P. Bärnthaler, N. Haider, J. Ilas, F. Scheiflinger, B.M. Reipert, M. Malisauskas

Shire, Vienna, Austria

Background: Extensive post-translational modification of natural coagulation factor VIII (FVIII) generates various sized hetero-dimeric molecular species. This unique heterogeneity results from processing of the molecule's B domain.

Aims: We explored natural FVIII heterogeneity and its effect and that of the B domain on protein stability.

Methods: FVIII molecular species containing 70% (B70), 20% (B20) or 0% (BDDrFVIII) B domain were isolated from full-length recombinant FVIII (FL-rFVIII) produced in CHO cells; FVIII from pooled human plasma (pdFVIII) was purified. Heterogeneity and thermally induced aggregation of FVIII molecular species, FL-rFVIII and pdFVIII were analyzed by SDS-PAGE, HPLC-SEC, and DLS.

Results: FL-rFVIII and highly purified pdFVIII with similar von Willebrand factor content as rFVIII showed analogous heterogenic protein profiles. The aggregation behavior of FL-rFVIII and pdFVIII was comparable; however, clear differences to and within purified monogenic molecular species were observed. Upon exposure to elevated temperatures, aggregate size increased as B domain decreased (aggregates of BDD-rFVIII>B20-rFVIII>B70-rFVIII>FLrFVIII). Time-dependent aggregation kinetics under physical stress provided deeper insights into the different aggregation pathways of FVIII molecular species. With decreasing B domain content, oligomers formed more rapidly and triggered excessive formation of large aggregates. Furthermore, FL-rFVIII and pdFVIII showed a lower propensity for aggregation than any molecular species. The absence of a B domain was shown to facilitate formation of cross-beta sheets, a structural feature not observed in B domain containing FVIII aggregates.

Conclusions: These results demonstrate similar heterogeneity of highly purified pdFVIII and FL-rFVIII produced in CHO cells, and suggest a new role of the B domain in ensuring stability of the FVIII molecule by modulating the protein aggregation pathway.

PB 145 | Monoclonal Antibodies to FcγRIIB (CD32) Modulate FVIII-specific Recall Response *in vitro*

N. Vollack[1], J. Friese[1], S. Bergmann[1], M. Cragg[2], A. Tiede[1], S. Werwitzke[1]

[1]Hannover Medical School, Hemostaseology, Hannover, Germany, [2]University of Southampton, Southampton, United Kingdom

Background: Fc gamma receptors (FcγRs) for IgG regulate the adaptive immune response by triggering activating and inhibitory signaling pathways within immune cells. Data from a hemophilia A mouse model demonstrate that genetic deletion or blockade of inhibitory FcγRIIB (CD32) prevent the differentiation of FVIII-specific memory B cells (MBCs) into antibody secreting cells (ASCs) *in vitro*.

Aims: The mechanisms preventing the FVIII-specific recall response, however, remained unclear. Here, the potential role of CD32 inhibition was studied by modulating receptor activity with different agonistic and antagonistic anti-CD32 monoclonal antibodies (mAbs).

Methods: Splenocytes from immunized $FVIII^{-/-}$ mice were re-stimulated with FVIII in the absence or presence of anti-CD32 mAbs over 6 days. At day 6, FVIII-specific release of IFN-γ and IL-10 was quantified from cell culture supernatant and the formation of FVIII-specific ASCs was assessed. Binding of FVIII-containing immune complexes (F8-ICs) to bone marrow derived dendritic cells (BMdDCs) was also investigated.

Results: The antagonistic CD32 mAb AT128 suppressed the formation of FVIII-specific ASCs in a dose-dependent manner and reduced secretion of IFN-γ and IL-10. In contrast, the agonistic mAbs AT130-2 and AT130-5, and their $F(ab')_2$ fragments, fully supported the formation of FVIII-specific ASCs, even though the full IgG of AT130-2 reduced binding of F8-ICs to CD32.

Conclusions: These results suggest that an inhibitory signal is transmitted when F8-ICs bind to CD32 and that this is required during MBC activation to prevent apoptosis and support formation of FVIII-specific ASCs. If the inhibitory signal is lacking due to CD32 deletion or blocking with antagonistic anti-CD32 mAbs (like AT128), FVIII-specific T cell stimulation and ASC formation are suppressed whereas agonistic stimulation of CD32 with AT130-2 or AT130-5 restore T cell stimulation and ASC formation. These studies underline the central role of CD32 in regulating adaptive immune responses.

PB 146 | Factor VIII A1 Residues 346-349 is a Novel Thrombin-binding Site Responsible for cleavage at Arg372 in the Heavy Chain

H. Minami, K. Nogami, K. Sasai, S. Furukawa, M. Takeyama, M. Shima

Nara Medical University, Pediatrics, Kashihara, Japan

Background: Factor (F)VIII is activated by cleavage at Arg^{372}, Arg^{740}, and Arg^{1689} by thrombin. We demonstrated that FVIII interacts with thrombin through the A2 domain (residues 392-394 and 484-509) and C2 domain, and these interactions governed the cleavages at Arg^{740}, Arg^{372}, and Arg^{1689}, respectively (JBC 2000, 2005, BJH 2008). However, the residues 484-509 partially participated in the cleavage at Arg^{372}, supporting the presence of other thrombin-binding site responsible for this cleavage. We have recently reported that the residues 340-350 with sulfated Tyr^{346} in the acidic region in A1 contained the binding site responsible for cleavage at Arg^{372} by experiments using synthetic peptides.

Aims: To identify the crucial residues, we performed the N-terminal sequence analysis of the cross-linking product between the 340-350 peptide and thrombin bridged by the EDC reagent, and indicated that residues 344-349(EDYDDD) participated in cross-link formation. Therefore, the mutant forms of these residues converted to Ala (E344A/D345A, Y346A, D347A/D348A/D349A) were expressed in the BHK system and purified. We examined the interaction between thrombin and these mutants to identify the specific binding site.

Methods: The thrombin activation of these mutants was evaluated in a one-stage clotting assay, and the thrombin-catalyzed cleavage at Arg^{372} was by SDS-PAGE/western blotting.

Results: Initial velocity of the activation was 36.2±5.8 min^{-1} for WT, 22.1±1.4 min^{-1} for E344A/D345A, 15.0±3.2 min^{-1} for Y346A and 6.4±5.8 min^{-1} for D347A/D348A/D349A, respectively, indicative of restricted thrombin activation of Y346A and D347A/D348A/D349A compared to WT. The thrombin cleavage at Arg^{372} in Y346A and D347A/D348A/D349A were significantly delayed compared to WT. Band densitometry showed the cleavages velocity in Y346A and D347A/D348A/D349A were 56% and 24% of WT, but, that in E344A/D345A was similar to WT.

Conclusions: We demonstrated that A1 residues 346-349(YDDD) was a thrombin-binding site responsible for the cleavage at Arg^{372}.

PB 147 | Recombinant FVIIIFc-VWF-XTEN (BIVV 001) Demonstrates Equivalent Thrombin Generation and Whole Blood Clotting Profiles to Advate®

Y. Buyue, E. Seth Chhabra, J. Sommer, J. Salas, R. Peters

Bioverativ, Waltham, MA, United States

Background: Recombinant FVIIIFc-VWF-XTEN (BIVV 001) is a novel fusion protein consisting of the FVIII binding D'D3 domains of VWF, a single chain rFVIIIFc and two XTEN linkers. Appending the D'D3 domain of VWF to FVIII provides the protection and stability of endogenous VWF, while avoiding the limitation in FVIII half-life extension imposed by VWF clearance. In hemophilia A mouse models, BIVV 001 showed equivalent efficacy and >3-fold half-life extension relative to Advate.

Aims: To evaluate the hemostatic potential of BIVV 001 by thrombin generation and thromboelastometry methods.

Methods: BIVV 001 was generated, purified and characterized at Bioverativ. BIVV 001 or Advate was added to naïve whole blood from severe hemophilia A donors (FVIII chromogenic activity < 0.5%) based on one-stage clotting assay with Actin FSL or labeled potency, respectively, followed by EXTEM (1:15000 dilution of Innovin®) and INTEM (1:300 dilution of INTEM reagent) analysis on ROTEM®. For thrombin generation assay (TGA), platelet-poor plasma obtained from the same visits was spiked with BIVV 001 or Advate and the assay was performed using modified CAT® method (PPP low reagent from Stago as trigger).

Results: BIVV 001 and Advate were compared side-by-side for each visit. In EXTEM and INTEM assays, increasing FVIII levels (0-30%) resulted in shortened clot time for both FVIII molecules. Despite the inter- and intra- subject differences, at similar FVIII activity, the two FVIII molecules tested showed comparable whole blood clotting profiles. In TGA, BIVV 001 and Advate showed clear dose responses in the measured range (0-100%) and comparable thrombin generation parameters.

Conclusions: BIVV 001 demonstrated equivalent whole blood clotting and thrombin generation profiles to Advate at similar FVIII activity levels. These results, together with in vivo pre-clinical efficacy data, suggest that Actin FSL based one-stage assays can predict the hemostatic potential of BIVV 001.

PB 148 | Altering FIX Zymogenicity Extends Procoagulant Function and Improves Hemostatic Function in Murine Hemophilia B

L. Ivanciu[1,2], V.R. Arruda[1,2], R.M. Camire[1,2]

[1]The Children's Hospital of Philadelphia, Philadelphia, United States, [2]University of Pennsylvania, Philadelphia, United States

Background: Strategies to improve hemophilia B (HB) treatment include extending zymogen factor IX (FIX) circulating half-life (e.g. long-acting FIX) and biologic function (e.g. FIX-Padua).

Aims: We investigated whether evading plasma-based inhibitors (e.g. antithrombin, AT) once FIX is converted to the protease FIXa would be a safe and effective strategy to mitigate the HB phenotype.

Methods: We altered the FIX zymogen to protease transition through mutagenesis at position 16 or 17 (chymotrypsin numbering) and generated a panel of variants that were characterized *in vitro* assays.

Results: In the absence of FVIIIa, all variants have reduced active site function relative to wild-type (wt)-FIXa and were zymogen-like. Importantly, the variants had reduced reactivity with AT as assessed by ELISA and prolonged biologic or "activity" half-life in plasma (6-20-fold > wt-FIXa). Consistent with work examining the FX zymogen to protease transition, the procoagulant activity of the FIXa variants could be partially rescued when incorporated into the intrinsic FXase complex. Following characterization in plasma-based systems, FIX-V16L appeared most promising and was evaluated *in vivo*. In a tail-clip model in which blood is collected for 10 min, intravenous administration of either FIX-V16L or wt-FIX zymogens into HB mice (n=10;

250 μg/kg; p< 0.05) reduced blood loss equally *vs*. PBS control (n=10). However, in a tail vein transection model where blood loss is assessed over 60 min, FIX-V16L (n=6-7; 75 or 125 μg/kg) was significantly more efficacious compared to wt-FIX (n=7-8; 75 or 125μg/kg) especially when comparing blood loss at >40 min. FIX-V16L appears to be safe, as thrombin-AT and D-dimer levels were not elevated following protein injection.

Conclusions: These data show that extending the biologic half-life of FIXa has a therapeutic benefit in vivo. We conclude that tuning of the FIX(a) zymogen-protease state is an effective way to evade physiologic inhibitors and yield variants with attractive biotherapeutic properties.

PB 149 | Evaluation of Recombinant FVIIIFc-VWF-XTEN (BIVV 001) Activity in One-stage Clotting and Chromogenic Assays and its Correlation with in vivo Efficacy in Hemophilia A Mice

Y. Buyue, A. van der Flier, D. Rabinovich, S. Bardan, Z. Liu, E. Seth Chhabra, J. Salas, J. Sommer, R. Peters

Bioverativ, Waltham, MA, United States

Background: Recombinant FVIIIFc-VWF-XTEN (BIVV 001) is a novel fusion protein consisting of the FVIII binding D'D3 domains of VWF fused to a single chain rFVIIIFc and two XTEN linkers. BIVV 001 was engineered such that thrombin activation removes both the VWF and XTEN moieties, resulting in a similar activated form as rFVIIIFc. In hemophilia A (HemA) mice preclinical studies, BIVV 001 showed >3-fold half-life extension relative to Advate®.

Aims: To evaluate the activity of BIVV 001 in one-stage clotting assays (OS) using different APTT reagents and chromogenic assays (CS) and assess activity correlation with in vivo efficacy in HemA mice

Methods: BIVV 001 was generated, purified and characterized at Bioverativ. OS and Siemens CS were performed on Siemens Sysmex CA1500 instruments. All other CS assays were done manually. The WHO 8th FVIII concentrate standard was used as calibrator for all assays. In vivo acute efficacy by tail clip bleeding model was determined after dosing HemA mice at select doses with either BIVV 001 or Advate.

Results: For OS, we observed 27.6% CV among the 3 major APTT reagents that collectively account for 94% of FVIII assays performed in US clinical hemostasis laboratories. The CS activities from 4 FVIII chromogenic kits were similar with 8.5% CV. The molar specific activity for BIVV001 by CS is similar to Advate and CS:OS ratio is ~2.2. BIVV 001 demonstrated equivalent in vivo efficacy to Advate when activity for dosing was determined by Actin FSL based OS.

Conclusions: BIVV 001 retains the molar specific activity equivalent to conventional FVIII molecules when assessed by CS, a two-stage assay utilizing an initial thrombin activation step, demonstrating that the FVIII portion is fully functional. The addition of the VWF and XTEN moieties appear to reduce the specific activity as assessed by OS, however OS is shown to be more physiologically relevant as it correlates with in vivo efficacy. Therefore the potency of BIVV 001 is assigned using OS, which will be used for all future studies.

PB 150 | Evaluation of Impact of Codon-Optimization on the Functional Activity of the Blood Coagulation Factor VIII by Clotting, Chromogenic and Thrombin Generation Assays

S. Shestopal[1], Y. Liang[1], M. Lin[1], M. Ovanesov[1], T. Lee[1], J. McVey[2], A. Sarafanov[1]

[1]U.S. Food and Drug Administration, Center for Biologics Evaluation and Research, Silver Spring, United States, [2]University of Surrey, School of Biosciences and Medicine, Surrey, United Kingdom

Background: Codon-optimization is a useful approach to increase the production of recombinant proteins expressed at low levels. However, the change of codon usage may affect protein folding, post-translation modifications and functional properties. We evaluated the impact of codon-optimization on the activity of a B-domain deleted (BDD) coagulation factor VIII (FVIII) as a global measure of correct protein structure.

Aims: To compare the activities of the BDD-FVIII variants expressed from a codon-optimized (CO) or the wild-type cDNA (WT).

Methods: Each of WT and CO was produced in three preparations from the respective independent CHO clonal cell lines; the protein concentrations were determined by ELISA and confirmed by absorbance at 280 nm. The preparations were tested using chromogenic, one stage clotting and thrombin generation assays using the 8th International Standard for FVIII Concentrate as standard; in parallel, we tested two commercial BDD-FVIII variants as controls.

Results: By the chromogenic assay, the average specific activity of the CO preparations was about 1.5-fold higher than WT, though this difference was not statistically significant. Because the deletion of the B domain can be associated with assay-dependent discrepancy in the FVIII activity, the proteins were tested by other assays. All samples of WT, CO, and the control BDD-FVIII variants, generated similar amounts of thrombin and had similar clotting time-derived activities. Compared to the control BDD-FVIII variants, thrombin generation by the WT and CO started earlier, suggesting differences in purity between the control and in-house samples.

Conclusions: The codon-optimization of the BDD-FVIII did not affect negatively the functional activity, supporting structural similarity of the CO and WT. We hypothesize that the apparently higher specific activity of the CO reflects its better structural preservation due to significantly higher concentrations during the production. *Disclaimer: our contributions do not bind or obligate FDA.*

PB 151 | An *In silico* and *In vitro* Approach to Elucidate the Impact of Residues Flanking the Cleavage Scissile Bonds of FVIII

B. Pezeshkpoor, U. Schreck, A. Biswas, J. Driesen, A.-C. Berkemeier, A. Pavlova, J. Müller, J. Oldenburg

University Clinic Bonn, Institute of Experimenal Hematology and Transfusion Medicine, Bonn, Germany

Background: Coagulation Factor VIII is activated by an ordered limited thrombin proteolysis with different catalytic efficiency at three P1 Arginine residues: Arg^{759}> Arg^{1708}>Arg^{391}, indicating the flanking residues of the latter to be less optimal.
Aims: This study aimed to investigate, *in silico* and *in vitro*, the impact of possessing hypothetically optimized residues at these three catalytic cleavage sites.
Methods: The structural impact of the residues flanking Arginine cleavage sites was studied by *in silico* analysis through comparing the cleavage cleft of the native site with the optimized sequence at each site. Moreover, recombinant FVIII proteins were prepared by replacing the sequences flanking native thrombin cleavage sites with a proposed cleavage-optimized sequence. FVIII specific activity was determined by assessing the FVIII activity levels in relation to FVIII antigen levels.
Results: Our *in silico* results show the impact of the residues directly in the cleavage bond, and their neighboring residues on the insertion efficiency of the loop into the thrombin cleavage cleft. Moreover, the *in vitro* analysis shows that the sequences flanking the Arg^{1708} cleavage site seem to be the most close to optimal residues for achieving the maximal proteolytic activation and profactor activity of FVIII. The residues flanking the scissile bonds of FVIIII affect the cleavage rates and modulate the profactor activation.
Conclusions: We were able to provide insights into the mechanisms of the specificity of thrombin for the P1 cleavage sites of FVIII. Thus, the P3-P3´ residues surrounding Arg^{1708} of FVIII have the highest impact on rates of thrombin proteolysis which contributes to thrombin activation of the profactor and eventually to the thrombin generation potential.

PB 152 | *In vitro* Characterization of the *Factor 8* Gene Mutations Associated with Assay Discrepancy

B. Pezeshkpoor, M. Gazorpak, A.-C. Berkemeier, J. Müller, A. Biswas, A. Pavlova, J. Oldenburg

University Clinic Bonn, Institute of Experimental Hematology and Transfusion Medicine, Bonn, Germany

Background: Haemophilia A is caused by lack or reduced amount of Factor VIII (FVIII). The severity of disease is closely correlated to the FVIII activity which can be measured with a one-stage or a two-stage assay. In 30% of patients with non-severe phenotype, a discrepancy between the results of the two assays is observed.
Aims: In vitro characterization of missense mutations in the *F8* associated with assay discrepancy.
Methods: *F8* variants were transiently expressed in COS-1 cells. FVIII specific activity of the variants was determined based on FVIII activity levels (FVIII:C) using two one-stage assays (FVIII:C_{1st} and FVIII:C_{Bonn}) or a chromogenic assay (FVIII:C_{chr}). Furthermore thrombin generation test (TGT) was used to investigate whether it could reflect the haemostatic potential of the variants.
Results: Thirteen missense mutations were analysed. Six mutations belong to the group 1, associated with higher one-stage assay values. Discrepant results were observed for p.T294I, p.R550H and p.P1844S. Group 2 mutations associated with higher chromogenic assay values consist of seven mutations. Discrepancy was confirmed for p.E739K, p.R1708H, p.S2138Y and p.V697L. Except for the p.R1768H mutation all variants of group 1 showed a significant reduction of thrombin peak in TGT. For variants of group 2, TGT was able to show differences in lag-time for p.E739K, p.R1708H, p.Y1669F and p.V697L. The thrombin generation potential was only reduced for the p.R546W. The variants p.S2138Y and p.D2150 showed similar results to FVIII wild-type.
Conclusions: In the majority of variants the *in vitro* results confirmed the assay discrepancy phenomenon observed *in vivo*. The inability to confirm the discrepancy in the rest of the mutation might be due to modifications in the artificial in vitro system leading to loss the discrepancy detected in patients' plasma.

PB 153 | Corn Trypsin Inhibitor Mediates Differential Effects on Thrombin Generation Parameters in Hemophilic Patients Compared with Healthy Volunteers

B. Tardy-Poncet[1,2,3], M. Piot[1], A. Montmartin[2], P. Chelle[1,4]

[1]Université de Lyon, Inserm U 1059 SAINBIOSE, Saint-Etienne, France, [2]Inserm CIC 1408, CHU Saint-Etienne, Saint-Etienne, France, [3]European Haemophilia Comprehensive Care Centre, CHU Saint-Etienne, Saint-Etienne, France, [4]Mines Saint-Etienne, Saint-Etienne, France

Background: Thrombin generation assay (TGA) is an important tool for evaluating the hemostatic potential of hemophilic patients. The addition of corn trypsin inhibitor (CTI) to collection tubes for blood samples intended for TGA was recommended by ISTH to abrogate the contact activation pathway when low tissue factor (TF) concentration is used. However, it has already been suggested that the impact of CTI on thrombin generation (TG) might differ between healthy volunteers and hemophilic patients.
Aims: To evaluate the impact of CTI on TG in hemophilic patients and healthy subjects.
Methods: This study was approved by a medical ethics committee. Forty healthy male volunteers (age 18-45), and 21 hemophilic patients (8 with severe and 13 with mild or moderate disease) were included after informed consent was obtained. Blood was collected into 3.2% citrate Monovette tubes with or without 1.45 µmol.L^{-1} CTI. TGA was performed in fresh platelet-rich plasma (PRP) and frozen platelet-poor plasma (PPP) with 1 pmol.L^{-1} TF. TG parameters were recorded using

the calibrated automated thrombogram method. Endogenous thrombin potential (ETP) and thrombin peak (P) measured in blood collected in tubes with or without CTI were compared by Student's paired t-test.

Results: In PPP, ETP and P values remained unchanged irrespective of CTI use in severely hemophilic patients, but were significantly reduced by CTI use in healthy volunteers ($p < 0.001$). In patients with mild or moderate hemophilia, CTI also had a statistically significant effect on ETP and P ($p < 0.01$) (Figures 1 and 2). The same results were obtained in PRP. The effect of CTI on TG varied from one volunteer to another in both PPP and PRP.

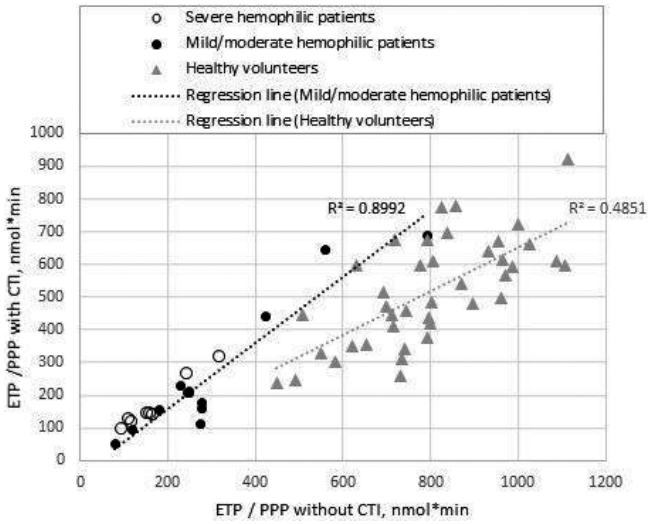

FIGURE 1 Influence of CTI addition to blood samples of healthy volunteers and hemophilic patients; ETP measured in PPP without CTI (x) and with CTI (y)

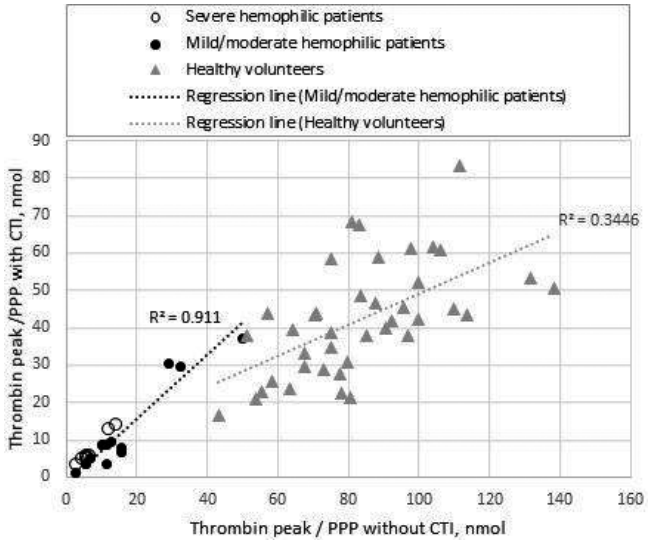

FIGURE 2 Influence of CTI addition to blood samples of healthy volunteers and hemophilic patients; Peak measured in PPP without CTI (x) and with CTI (y)

Conclusions:

- Values of TG in healthy volunteers cannot be determined in blood collected with CTI.
- TG in hemophilic patients can be evaluated in blood collected in Monovette tubes without CTI.

PB 154 | Influence of Pharmacodynamics of Factor VIII on Bleeding Phenotype of Children under Long-term Prophylactic Regimen

I. Fernandez-Bello[1], F. Rode[2], M.T. Alvarez-Roman[1], N.V. Butta[1,3], S. Rivas-Muñoz[1,4], A.L. Hernandez-Moreno[5,6], H. de la Corte Rodriguez[7], M. Martin-Salces[1], L.F. Larsen[2], V. Jimenez-Yuste[1]

[1]La Paz University Hospital, Haematology and Haemotherapy Department, Madrid, Spain, [2]Novo Nordisk A/S, Global Research, Måløv, Denmark, [3]NB is Supported by FIS-Fondos FEDER CP14/00024, Madrid, Spain, [4]Supported by a grant from the Spanish Society of Thrombosis and Haemostasis, Madrid, Spain, [5]Hospital General La Raza, Department of Pediatric Hematology, Mexico DF, Mexico, [6]Supported by a Grant from Novo Nordisk A/S, Copenhague, Denmark, [7]La Paz University Hospital, Department of Physical Medicine and Rehabilitation, Madrid, Spain

Background: Plasma factor VIII activity (FVIII:C) has limited value as a predictor of bleeding risk in patients with severe haemophilia A (SHA). In contrast, procoagulant capacity evaluated by global tests is emerging as a valuable parameter to predict bleeding phenotype in this population. This may suggest a superior significance of global procoagulant capacity over FVIII:C itself as guidance to personalization of prophylactic treatment. So far, this field has been poorly evaluated in the paediatric population.

Aims: To assess the influence of pharmacodynamics (PD) of FVIII evaluated by thrombelastography (TEG) on the bleeding phenotype of children with SHA on long-term prophylaxis (LTP).

Methods: Children with SHA on LTP were recruited. PD and pharmacokinetics (PK) of FVIII were evaluated by kaolin-activated-TEG in whole blood and by determining plasma levels of FVIII:C respectively before and 30 min, 4, 8, 24 and 48 h after one prophylactic infusion. EC50 (FVIII:C at which 50% of the maximal response is observed) was calculated for each patient. Annualised bleeding rate (ABR) was obtained retrospectively from patient diaries. The study was conducted in accordance with the Declaration of Helsinki and was approved by the hospital ethics committee. Written informed consent was obtained prior to any trial-related activity.

Results: Twenty children under LTP were included of which only 4 (bleeders) registered bleeding events during the previous 12 months. Overall, these patients displayed no significant difference in the FVIII half-life, but a lower FVIII recovery than the average patient. Most markedly K-time and alpha angle of bleeders displayed nine times higher EC50 values than the non-bleeders suggesting a lower response to FVIII:C.

Conclusions: TEG evaluations may be useful to detect SHA patients with lower response to FVIII which may contribute to a higher ABR in children on LTP. Further studies are needed to confirm if TEG evaluations may be useful to detect patient on prophylaxis at higher risk of bleeding.

PB 155 | Influence of Neighbourhood Socioeconomic Status on Mortality Is Mediated by Factor VIII: Results from a Cohort Study

B. Vučković[1], A. Eikenboom[2], L. Doetsch[2], F. Rosendaal[3], S. Cannegieter[3], W. Lijfering[3]

[1]Clinical Center of Serbia Center of Vojvodina, Department of Thrombosis, Haemostasis and Hematology Diagnostics, Novi Sad, Serbia, [2]Leiden University,

Leiden, The Netherlands, [3]Leiden University Medical Center, Department of Clinical Epidemiology, Leiden, The Netherlands

Background: Socioeconomic status (SES) is a major determinant of mortality

Aims: To investigate if the association between neighbourhood SES and mortality can be explained by the presence of cardiovascular risk factors, morbidity or factor VIII levels

Methods: A large cohort study followed 4225 patients with venous thrombosis and 5991 controls from a Dutch population-based case-control study for a median of 5.6 years. Neighbourhood SES was measured on postcode level by using a status score based on mean income level, percentage of households with low income, unemployment rate, and education level. Participants were categorized in 4 percentile groups (0-15, 15-30, 30-70, >70). Cox proportional hazard models were used to evaluate risk of death between groups. All analyses were adjusted for age and sex, and additionally for the possible mediators BMI, chronic disease, smoking, alcohol consumption, and factor VIII levels

Results: The relative risk of mortality increased with decreasing status score. The hazard ratio of death for each 1 unit decrease in status score was 1.11 (95% CI, 1.00-1.22) in patients, 1.24 (95% CI, 1.06-1.44) in controls, and 1.16 (95% CI, 1.07-1.26) in all participants. The risk of death was 1.59-fold increased (95% CI, 1.20-2.11) in all included participants with status score below ≤15th percentile in comparison with the reference group of participants with status score above 70th percentile. Adjustment for possible mediators showed strongest effect for factor VIII levels. Per one unit decrease in status score the HR of death was 1.16 (95% CI, 1.07-1.26) without correction and 1.07 (95% CI, 0.93-1.23) after correction for factor VIII. Smoking, and chronic diseases also led to attenuation, but to a lesser extent.

Conclusions: A lower neighbourhood SES was associated with a higher mortality risk in healthy individuals as well as in patients with prior venous thrombosis. Factor VIII and chronic diseases might serve as an explanation behind this association.

PB 156 | Novel F9 Gene Variants in Hemophilia B Patients from Turkey

S. Colakoglu[1,2], B. Koc[3], E. Berber[1], B. Zulfikar[4]

[1]Istanbul AREL University, Molecular Biology and Genetics, Istanbul, Turkey, [2]Marmara University, Medical Biology and Genetics, Istanbul, Turkey, [3]Kanuni Sultan Süleyman Education and Research Hospital, Istanbul, Turkey, [4]Istanbul University, Istanbul School of Medicine, Istanbul, Turkey

Background: Hemophilia B (HB) is an X'linked bleeding disorder affecting one in 30000 males. Carrier females with reduced FIX activity may also suffer from bleeding. including menorrhagia. It is associated with the mutations in the F9 gene. mutations are identified in 97% of the cases. 2% of the HB patients develop inhibitor associated with mainly large deletions or missense, nonsense, small deletions/insertions, splice site mutations. Molecular genetic analysis of F9 gene in HB patients is important to predict the inhibitor risk, for the carrier identification, prenatal diagnosis for the proper management with hemophilia.

Aims: There are 1050 registered HB patients in Turkey. 412 of them are clinically diagnosed as severe, 358 as moderate and 280 as mild HB patients but the genetic profile is not reported. The aim of the present study is to screen the F9 gene of 22 HB patients in İstanbul, Turkey to establish molecular genetics of HB in Turkey.

Methods: F9 gene of the HB patients was PCR amplified and analyzed by Sanger sequencing of exons, 5' and 3' untranslated regions and exon/intron junctions. Initially four patients clinically diagnosed as severe HB, with FIX:C is less than 0,01 IU/ml were screened.

Results: Sanger sequencing revealed 10 different variations in the patients. 8 patients had single variations including novel exon 6 delAAGCACCCAAT/insACAGCACTCAAAG, novel p.Arg43Thr, p.Arg191Cys, p.Thr194Ala, p.Arg75Ter, p.Gln237Ter, novel IVS4+7A>G, novel p.His415Pro. 2 of the patients had double variations p.Arg226Gln/ p.Thr194Ala, p.Arg162Ter/p.Thr194Ala.

Conclusions: F9 gene variations were identified in all of the patients. 60% of the variations are missense mutations and 30% are stop mutations.7 of the variations were known mutations except p.Thr194Ala which is an SNP associated with deep vein thrombosis. It is observed in 30% of the patients. The p.Arg43Thr was predicted to be highly damaging according to Polyphen analysis. In silico analysis of IVS4+7A>G and p.His415Pro will reveal their pathogenic effect.

PB 157 | Evaluations of the Activated Partial Thromboplastin Time-based One-stage Clot Assays for Monitoring of Half-life Extended Factors VIII and IX Formulations

Y. Fujimori[1], S. Madoiwa[2,3], N. Shinohara[4], C. Eda[4], S. Shinohara[5], N. Arai[5], M. Wakui[2], M. Murata[2]

[1]Keio University Hospital, Central Clinical Laboratory, Tokyo, Japan, [2]Keio University School of Medicine, Department of Laboratory Medicine, Tokyo, Japan, [3]Tokyo Saiseikai Central Hospital, Department of Clinical Laboratory Medicine, Tokyo, Japan, [4]Tokyo Saiseikai Central Hospital, Clinical Laboratory, Tokyo, Japan, [5]Sysmex Corporation, Kobe, Japan

Background: Coagulation factor activities of patients with hemophilia are commonly measured by the aPTT-based one-stage clot (OS) assays. Discrepancies have been reported among OS assays, and the modified factor VIII (FVIII) and factor IX (FIX) products for half-life extension may add to variabilities.

Aims: The objective of this study is to assess the characteristics of PEGylated, Fc-IgG and albumin (Alb) fusion constructs of FVIII and FIX formulations in various OS assays comparing with a chromogenic substrate (CS) assay.

Methods: FVIII deficient plasma was spiked *in vitro* with either octocog alfa, turoctocog alfa (B-domain deleted [BDD]), rurioctocog alfa pegol (PEGylated) or efraloctocog alfa (Fc-IgG fused BDD). A plasma lacking FIX was added with either nonacog alfa, eftrenonacog alfa (Fc-IgG fused), or albutrepenonacog alfa (Alb fused) with 0.1, 0.3 and 1.0 IU/mL based on labelled potencies. Samples were tested in OS assays

with each calibration on an automated blood coagulation analyzer (CS-2400) using APTT-SLA (SLA), ACTIN FS (FS), Coagpia APTT-N (APTT-N), SynthASil APTT (SynthASil), APTT-SP (SP), and PTT-LA. Recoveries were also assessed by CS assay using new reagents for FVIII and FIX activities.

Results: All of the FVIII products were recovered within ±25% in the assays of SLA, FS, and APTT-N, although recoveries for SynthASil, SP and PTT-LA were highly variable. Regarding FIX products, acceptable eftrenonacog alfa recovery was demonstrated in APTT-N, SynthASil, SP and PTT-LA, however, some overestimation was observed in SLA and FS. The target recoveries of 0.3 IU/mL albutrepenonacog alfa demonstrated 48.5±1.7% for OS assay with FS and 124.9±1.5% for CS assay.

Conclusions: FVIII can be measured in plasma samples containing modified products in OS assays using ellagic acid as an activator. Recovery of individual FIX products considerably depended on assay system. The choice of reagents for OS assays can affect the accurate measurement of activities for half-life extended factor products.

PB 158 | Population Pharmacokinetic Analysis of Perioperative Factor IX Dosing in Hemophilia B

T. Preijers[1], H.C.A.M. Hazendonk[2], R. Liesner[3], P. Chowdary[4], M.H.E. Driessens[5], D. Hart[6], D. Keeling[7], B.A.P. Laros-van Gorkom[8], F.J.M. van der Meer[9], K. Meijer[10], K. Fijnvandraat[11], F.W.G. Leebeek[12], P.W. Collins[13], M.H. Cnossen[14], R.A.A. Mathôt[15], for the OPTICLOT-Study Group

[1]Academic Medical Center Amsterdam, Clinical Pharmacology, Amsterdam, The Netherlands, [2]Erasmus University Medical Center - Sophia Children's Hospital, Pediatric Hematology, Rotterdam, The Netherlands, [3]Great Ormond Street Hospital for Children NHS Trust, Great Ormond Street Haemophilia Centre, London, United Kingdom, [4]Royal Free London NHS Foundation Trust, Katharine Dormandy Haemophilia Centre and Thrombosis Unit, London, United Kingdom, [5]Netherlands Hemophilia Patient Society, Nijkerk, The Netherlands, [6]The Royal London Hospital Barts Health NHS Trust, Department of Haematology, London, United Kingdom, [7]Oxford University Hospitals, Churchill Hospital Oxford, Oxford Haemophilia and Thrombosis Centre, Oxford, United Kingdom, [8]Radboud University Medical Center, Department of Hematology, Nijmegen, The Netherlands, [9]Leiden University Medical Center, Department of Thrombosis and Hemostasis, Leiden, The Netherlands, [10]University Medical Center Groningen, Department of Hematology, Groningen, The Netherlands, [11]Academic Medical Center Amsterdam, Department of Pediatric Hematology, Amsterdam, The Netherlands, [12]Erasmus University Medical Center Rotterdam, Department of Hematology, Rotterdam, The Netherlands, [13]Arthur Bloom Haemophilia Centre, Institute of Infection and Immunity, Cardiff, United Kingdom, [14], Erasmus University Medical Center - Sophia Children's Hospital Rotterdam, Department of Pediatric Hematology, Rotterdam, The Netherlands, [15]Academic Medical Center Amsterdam, Hospital Pharmacy-Clinical Pharmacology, Amsterdam, The Netherlands

Background: To maintain hemostasis in the peri-operative setting, hemophilia B patients receive replacement therapy with factor concentrates to normalize FIX activity levels (FIX:C). FIX exhibits high inter-patient pharmacokinetic (PK) variability, which may produce over- and underexposure.

Aims: In this study, we aimed to construct a population PK model for FIX, which allows the assessment of average PK parameters and their associated inter-patient variability (IIV) in the perioperative period.

Methods: Retrospective data of 118 hemophilia B patients (median (range) age 40.1 years (0.15-90.45), body weight 81.5 kg (5.3-132)), undergoing 255 surgical procedures was available from ten hemophilia treatment centers in the Netherlands and the United Kingdom. Average PK parameters were estimated using nonlinear mixed-effect modeling.

Results: FIX:C versus time profiles were adequately described using a three-compartment model. Population PK parameter estimates and IIV (%) were: CL: 293 mL/h/70kg (21.1%), V1: 5010 mL/70kg (16.8%), Q2:102 mL/h/70kg, V2: 4780 mL/70kg, Q3: 1310 mL/h/70kg, V3: 2080 mL/70kg. With rising age, CL and V1 decreased 0.8% and 1.2% per year, respectively, until the age of 32 years. Compared to the United Kingdom, V1 was 14.5% higher for patients treated in the Netherlands. Furthermore, an increase of 16.4% and 22.1% for CL and V1, respectively, was associated to the use a recombinant product. A complication, such as an infection or bleeding during the surgical procedure, resulted in 16.4% increase of CL.

Conclusions: Measured perioperative FIX:C were described adequately by the established population PK model. The estimated population PK parameters were different from those reported for prophylactic treatment. This model will be used in a prospective clinical trial to perform PK-guided dosing of hemophilia B patients undergoing a surgical procedure.

PB 159 | Which Tests Can Better Indicate Clinical Phenotype of Pediatric Patients with Hemophilia on Prophylaxis?

Y. Ay[1], E. Toret[1], S. Gozmen[1], D. Cubukcu[2], T.H. Karapinar[1], Y. Oymak[1], R.C. Vergin[1]

[1]Dr Behcet Uz Children's Hospital, Pediatric Hematology, Izmir, Turkey, [2]Dr Behcet Uz Children's Hospital, Physiotherapist, Izmir, Turkey

Background: Even if pharmacokinetic guided prophylaxis dosing of FVIII can opportunity to maintain a specific trough level, the variability of bleeding at different factor levels remain open issue.

Aims: The aim of this study is to assess whether global hemostasis tests, such as thrombin generation assay (TGA) and thromboelastography (TEG), can indicate bleeding pattern of severe hemophilia better than trough level and pharmacokinetic profile, particularly in the prophylactic setting.

Methods: The study group and healthy control group were consisted of 39 patients with hemophilia A (28 severe, 3 moderate, 8 mild) and 75 respectively. All patients for FVIII-inhibitor were negative. Basal or after washout (72 hours) factor (F) VIII, inhibitor level, TEG, TGA (platelet poor and rich plasma) of the participants were performed. Recombinant factor VIII product was administered to the patients at 40-50 IU/kg dosing for patients on prophylaxis. After factor replacement, the above tests were repeated at 30th minute, 6th, 24th and 48th hours.

Results: TGA and TEG parameters of the patients with mild and moderate hemophilia A were better than severe hemophilics. After administered factor concentrates, the patients with 48th hour FVIII < 3 % (n=10) and ≥ 3 % (n=12) were assessed with regard to annual bleeding

rate (ABR) and hemophilia joint health score (HJHS). ABR and HJHS were similar in these groups (P=0,368, and P=0,631 respectively). TGA and TEG parameters of these groups were also similar (ETP P=0,773, peak thrombin P=0,340). When the patients with 48th hour FVIII < 5 % (n=14) and ≥ 5 % (n=8) were evaluated in respect to ABR, HJHS, TEG and TGA parameters. We did not find a significant difference between two groups regarding above tests.

Conclusions: Neither pharmacokinetic profile with reduced number of samples nor trough levels may be correlate with clinical bleeding phenotype in patients with hemophilia A on prophylaxis. TGA and TEG promise for using clinical practice in these patients.

PB 160 | Acquired Haemophilia and Eosinophilic Fasciitis

M. Mrouki, S. Hamrouni, F. Ben Dahmen, Y. Cherif, M. Abdallah

Université Tunis El Manar, Faculté de Médecine de Tunis, Hôpital Régional de Ben Arous, Internal Medicine, Ben Arous, Tunisia

Background: Acquired haemophilia A (AHA) is an uncommon bleeding disorder, affecting predominately elderly patients. It results from developing autoantibodies to factor VIII. It is associated to autoimmune disorders, cancer, drugs, infections and often no underlying disease is found.

Aims: To present an uncommon association.

Methods: We present the case of AHA complicating eosinophilic fasciitis (EF).

Results: A 24-year-old patient diagnosed with EF as she complained from erythematous swelling of the extremities with thickened skin. Laboratory findings showed eosinophilia and a full-thickness wedge biopsy revealed infiltration of the deep fascia and the subcutis with lymphocytes, histiocytes and eosinophils.

The patient was treated with corticosteroids for 6 months with resolution of cutaneous symptoms; however, she developed cholestasis and cytolysis considered as a hepatic flare-up of the disease. Corticosteroids where increased to 1mg/kg/d of prednisone.

Two months later, while she was still taking 1mg/kg/d of prednisone, she presented diffuse ecchymosis.

Blood count cells and prothrombin time were normal, however, activated partial thromboplastin time (aPTT) was prolonged. Anti phospholipid antibodies were negative and Von Willebrand factor was normal. Factor VIII level was 1% and the screening of anti factor VIII was positive allowing the diagnosis of acquired haemophilia A.

Osteo-medullary biopsy performed to screen for malignant haemopathy associated with EF or AHA was normal.

Regarding the persistence of prolonged aPTT with a haemorrhagic syndrome despite high doses of corticosteroids, immunosuppressive therapy was proposed. The patient received 3 pulses of Cyclophosphamide relayed by azathioprine with resolution of the ecchymosis and normalisation of the aPTT.

Conclusions: Both EF and AHA are uncommon conditions that may be the first manifestation of hematologic malignancies. To our Knowledge, no such association were described. A prolonged follow up is necessary to screen malignant associated condition.

PB 818 | Efficacy, Safety, and Pharmacokinetics of a High-purity Plasma-derived Factor X (pdFX) Concentrate in the Prophylaxis of Bleeding Episodes in Children < 12 Years with Moderate to Severe Congenital Factor X Deficiency (FXD)

R. Liesner[1], M. Gattens[2], C. Akanezi[3], J. Payne[4]

[1]Great Ormond Street Hospital, Haemophilia Comprehensive Care Centre, London, United Kingdom, [2]Cambridge University Hospitals, The Cambridge Haemophilia and Thrombophilia Centre, Cambridge, United Kingdom, [3]Bio Products Laboratory Ltd., Elstree, United Kingdom, [4]Sheffield Children's NHS Foundation Trust, Department of Paediatric Haematology, Sheffield, United Kingdom

Background: Congenital FXD is a rare bleeding disorder characterized by spontaneous joint and mucocutaneous bleeding and gastrointestinal or intracranial hemorrhage. pdFX is a US- and EU-approved treatment for congenital FXD, but data in children < 12 y have been unavailable.

Aims: To investigate pdFX efficacy, safety, and pharmacokinetics in children < 12 y with moderate to severe congenital FXD.

Methods: In this 6-month, open-label, multicenter, phase 3, prospective study in children < 12 y, all subjects had a confirmed diagnosis of moderate to severe congenital FXD (basal FX:C < 5%), severe bleeding history, or an *F10* gene mutation causing a documented severe bleeding type. Subjects received routine prophylaxis at recommended 40-50 IU/kg twice weekly to maintain trough FX:C levels ≥5%. Each investigator assessed efficacy based on standardized criteria and presence of breakthrough bleeding. All subjects provided informed consent and the protocol was approved by appropriate independent ethics committees.

Results: Mean age of the 9 trial completers was 6.8 y. Eight subjects had severe and 1 had moderate FXD. Overall, 537 prophylactic infusions were administered; mean dose/child was 38.6 IU/kg. Ten bleeds in 3 of 9 children were reported: 6 minor, 3 major, 1 unassessed. Investigators rated overall pdFX efficacy as excellent in all subjects. Overall mean incremental recovery was 1.74 IU/dL per IU/kg. FX trough levels were maintained >5% after visit 4 (days 29-42) in all subjects.

A total of 28 treatment-emergent adverse events (TEAEs) were reported in 8 children; none were considered pdFX related. No significant changes were noted in vital signs, physical exams, or laboratory measurements. No evidence of inhibitor development was seen.

Conclusions: pdFX is efficacious in the prophylaxis of bleeding episodes in subjects < 12 y with moderate to severe FXD. Safety profile in this population is consistent with previous results in subjects ≥12 y.

Funding: Bio Products Laboratory

PB 819 | Characterization of an Aptamer Inhibiting Coagulation Factor XIa Identified through in vitro Screening of a Single-stranded DAN Library

D. Donkor[1,2], V. Bhakta[1,2], L. Eltringham-Smith[1,2], A. Stafford[3], J. Weitz[3], W. Sheffield[1,2]

[1]McMaster University, Pathology and Molecular Medicine, Hamilton, Canada, [2]Canadian Blood Services, Centre for Innovation, Hamilton, Canada, [3]McMaster University and Thrombosis and Atherosclerosis Research Institute, Hamilton, Canada

Background: Either factor XIIa or thrombin activate coagulation factor XI (FXI) to FXIa. FXIa then activates Factor IX (FIX). Animal model and epidemiological data support FXI/FXIa as a therapeutic target, because it appears to influence thrombosis more than hemostasis. Only protein and small molecule inhibitors of FXIa, but not nucleic acid-based agents, have been described to date.

Aims: To select and characterize DNA-based inhibitors of FXIa activity.

Methods: A 78 base, single-stranded DNA aptamer library containing a 40 base randomized core was iteratively screened. Candidates were selected for binding to FXIa and against active site-blocked FXIa in each round. The selected aptamer pool was then amplified using asymmetric PCR. After ten positive/negative rounds, individual sequences from the selected pool were synthesized and characterized.

Results: Six of 89 different selected aptamers inhibited chromogenic substrate S2366 cleavage by FXIa. Five of the six were highly homologous. The most active anti-FXIa aptamer had a 36 base central core of 5'- AACCTATCGGACTATTGTTAGTGATTTTTATAGTGT - 3' and was designated **F**actor **EL**even **I**nhibitory **AP**tamer (FELIAP). FELIAP, but not a scrambled aptamer control (SCRAPT), competitively inhibited FXIa-mediated S2366 cleavage, FIX activation, and complex formation with antithrombin. No effect of FELIAP on FXI activation was observed. FELIAP inhibited modified clotting and thrombin generation assays to a significantly greater extent than SCRAPT. Immobilized FELIAP bound FXIa with an equilibrium binding constant (K_D) of 1.9 ± 0.2 nM (mean ± SD, n= 3) as judged by surface plasmon resonance. Deletion of all 38 bases flanking FELIAP's central core abrogated anti-FXIa activity, but activity was retained in FELIAP derivatives with as few as 5 flanking nucleotides.

Conclusions: FELIAP binds FXIa with high affinity, at or near its active site. The first FXIa-inhibitory aptamer to be described, FELIAP will be optimized in length and composition to develop related aptamers for in vivo use.

PB 820 | Three Dimensional Thrombus Architecture Formed under Flow Conditions

L. Hardy[1], F. Macrae[1], E. Hethershaw[1], R. Ariens[1], R. Foster[1,2], H. Philippou[1]

[1]Leeds Institute of Cardiovascular and Metabolic Medicine LIGHT Laboratories, University of Leeds, Leeds, United Kingdom, [2]University of Leeds, School of Chemistry, Leeds, United Kingdom

Background: Various commercial and home-made microfluidic devices use extensional and steady state shearing forces to assess *in vivo* thrombus formation. Sometimes within these systems the thrombus has been imaged but is largely limited to two dimensions. To characterise the role of anti-platelet agents and anticoagulants on the three dimensional structure of thrombus formation under flow conditions, alternative methodologies need developing.

Aims: We aimed to therefore develop a flow model of thrombosis using confocal microscopy to determine the composition of fibrin and platelets in the three dimensional forming thrombus.

Methods: Channel slides were coated with 50 $\mu g.mL^{-1}$ fibrillar type I collagen in 500mM acetic acid pH 2.3 for 1 hour at 37°C. Slides were then blocked with a 1% w/v BSA solution in HBS buffer for 20 minutes at 37°C, and washed with HBS buffer. Hirudin or citrate blood samples were spiked with DiOC18(3) and $10\mu g.mL^{-1}$ Alexa Fluor 594 conjugated human fibrinogen and incubated for 30 minutes. Following addition of 7.5mM $CaCl_2$ and 3.75mM $MgCl_2$, blood was perfused through the coated chamber at varying shear rates. Flow was terminated at a maximum time of 10 minutes, and the thrombus was washed with HBS buffer supplemented with 1 $U.mL^{-1}$ heparin. Slides were mounted on a Zeiss LSM880 inverted microscope. Confocal z-stacks were recorded for both labelled platelets and conjugated human fibrinogen.

Results: We have generated confocal images that validate this approach to assessing the role of anticoagulants and anti-platelet agents on the composition of the thrombus under flow conditions. The images show that under normal circumstances, platelets are coated with fibrin layers on the interface of where the blood is flowing.

Conclusions: This study shows that for the first time it will be possible to determine the role of antithrombotic agents employing a more physiological approach to monitoring thrombus formation under flow conditions and aid the development of next generation antithrombotic agents.

PB 821 | Administration of Dexamethasone during Initial Exposure to Factor VIII Reduces Inhibitor Development in Hemophilia A Mice Via Thymic Tolerance Induction Mechanisms

M.T. Georgescu[1], P.C. Moorehead[2], K. Nesbitt[1], C. Hough[1], D.P. Lillicrap[1]

[1]Queen's University, Pathology and Molecular Medicine, Kingston, Canada, [2]Memorial University, St. John's, Canada

Background: The most severe complication of hemophilia A (HA) treatment is the development of inhibitory antibodies against factor VIII (FVIII). In a humanized HA model with a 30% likelihood of inhibitor incidence, administration of dexamethasone (Dex) during initial FVIII exposure results in long-term, antigen-specific tolerance.

Aims:

1. Determine if Dex administration during initial FVIII exposure reduces the FVIII immune response in a HA mouse model with a 100% likelihood of inhibitor incidence.

2. Determine short- and long-term treatment effects on lymphocytes.
3. Investigate treatment effects on thymic and splenic mRNA expression.

Methods: All experiments were performed in E16KO C57Bl6 HA mice. Mice received FVIII or FVIII+Dex (FVIII 6 IU/dose IV, Dex 75 µg/dose IP) for 5 consecutive days.

1. Blood was collected 5 weeks later. Plasma anti-FVIII antibody titers and inhibitory activity were measured.
2. Thymus, spleen and blood were collected either 3 days or 3 weeks later. Lymphocyte populations were assessed via flow cytometry.
3. Thymus and spleen were collected 3 days later. mRNA expression was assessed via NanoString.

Results:

1. 77% of FVIII+Dex mice v 100% of FVIII mice developed anti-FVIII IgG. FVIII+Dex mice had lower anti-FVIII IgG titers and inhibitory activity (p=0.08) than FVIII mice.
2. FVIII+Dex mice had a lower percentage of splenic $CD19^+$ cells than FVIII mice 3 days after treatment and an increased percentage of thymic $CD4^+CD8^-CD25^+FoxP3^+$, PD-$L1^+$ and PD-1^+ cells. No differences detected among blood lymphocytes at 3 days, or among lymphocytes from any source at 3 weeks.
3. FVIII+Dex mice had decreased mRNA expression of T cell development mediators in the thymus compared to FVIII mice. No differences in splenic mRNA expression were detected between the 2 groups. $p < 0.05$ unless stated otherwise.

Conclusions: Dex given during initial FVIII exposure reduces the anti-FVIII immune response in a second HA mouse model. This is associated with effects of Dex on lymphocyte populations and thymic gene expression.

PB 822 | Dual Mode of Interaction of Fibrinogen with the Staphylocoagulase•Prothrombin* Complex

A.A. Maddur[1], M. Voehler[2], P.R. Panizzi[3], J. Sheehan[2], I.M. Verhamme[1], J. Meiler[2], P.E. Bock[1]

[1]*Vanderbilt University Medical Center, Pathology, Microbiology and Immunology, Nashville TN, United States,* [2]*Vanderbilt University, Center for Structural Biology, Nashville TN, United States,* [3]*Auburn University, Harrison School of Pharmacy, Pharmacal Sciences, Auburn AL, United States*

Background: Fibrin deposition is a hallmark of staphylocoagulase (SC)-positive *S. aureus* endocarditis. The N-terminal SC(1-325) fragment activates prothrombin (ProT) non-proteolytically. The SC(1-325)•ProT* complex cleaves fibrinogen in the E-domain to form fibrin. Full-length SC(1-660) contains one pseudorepeat (PR) and 7 tandem repeat sequences (R1 to R7). It also binds fibrinogen, mediated by SC C-terminal repeat sequences.

Aims: The Aim was to identify the SC binding sequence(s) on fibrin(ogen).

Methods: We used size exclusion chromatography; native PAGE; fluorescence labeling; CD, NMR and mass spec analysis; and Ala scanning to study the interactions.

Results: SC(1-325) did not bind fibrinogen Fragment D (FragD), whereas SC(1-660) bound multiple Frag D molecules. SC(1-660) bound to fluorescein-labeled ProT ([5F]-FPRProT) and FragD in a ternary complex. Native-PAGE and fluorescence titrations showed no interaction of [5F]PR and [5F]R1 with FragD, whereas [5F]PR-R1, -R2, -R3, -R6, -R7, bound FragD with K_D 50 - 130 nM, and a 1:1 stoichiometry. PR-R1 bound to FragD in the presence of GPRP with K_D 17 nM, suggesting no binding to Frag D β- and γ- holes. The full length repeat [5]PR-(R1-R7) bound to Frag D with K_D 7 - 32 nM and a stoichiometry of 5. Competitive titrations of [5]PR-(R1-R7) and FragD with PR-R1R2R3, PR-R1R6R7, PR-R3R4R7 and PR-R3R6R7 showed that the constructs bound to FragD with K_D 7 - 42 nM and a stoichiometry of 3. CD analysis of PR-R7 and PR-(R1-R7) yielded spectra without a definite structure. Mass spec analysis of [pBpa]PR-R7 cross-linked to FragD yielded putative cross-linked sites VELEDWNGR and MFK on γ- and α- chains of FragD. NMR studies identified a minimal region within PR-R7, required for FragD binding. This peptide bound FragD with a K_D of ~5 µM. Ala scanning showed that substitution of VKYRD, AGTGIR, EYNDG, ARPT, YKKP and HADG in the minimal peptide abolished FragD binding.

Conclusions: The combined data identify two different modes of fibrinogen binding to the SC•ProT* complex.

PB 823 | Sensitive, Functional Assay for Detecting Polyphosphate in Plasma

C. Baker[1], S. Smith[1], M. Kalathottukaren[2], C. Haynes[2], J. Kizhakkedathu[2], J. Morrissey[1]

[1]*University of Illinois at Urbana-Champaign, Biochemistry, Urbana, United States,* [2]*University of British Columbia, Vancouver, Canada*

Background: Inorganic polyphosphate (polyP) is an important procoagulant and proinflammatory molecule released from platelets and other cells. Circulating polyP in disease or following trauma is of particular interest. However, facile methods are lacking for quantifying plasma polyP, particularly of the size secreted by platelets. We here demonstrate a sensitive assay for polyP in plasma.

Aims: A method for detecting and quantifying polyP in plasma.

Methods: Modified PT clotting assays were performed with dilute tissue factor (TF), with and without added tissue factor pathway inhibitor (TFPI). PolyP in plasma was found to abrogate the anticoagulant activity of TFPI in a dose-dependent manner. That this "TFPI resistance" was due to polyP was confirmed by clotting assays in the presence of polyP inhibitor (UHRA-2 or polybrene).

Results: Adding 135 ng/ml TFPI to normal plasma profoundly prolonged the clotting time, but adding increasing polyP concentrations rendered it increasingly resistant to TFPI anticoagulant effect (Figure, panel A). This functional "TFPI resistance" assay is sensitive to nanomolar concentrations of platelet-sized polyP. Clotting times of

unknown plasma samples containing polyP were quantified with and without TFPI, making sure their clot times fell within the range of the standard curve. To confirm that polyP is responsible for any observed TFPI resistance, the polyP inhibitors UHRA-2 or polybrene were used to reverse the ability of polyP to render plasma TFPI resistant (Figure, panel B).

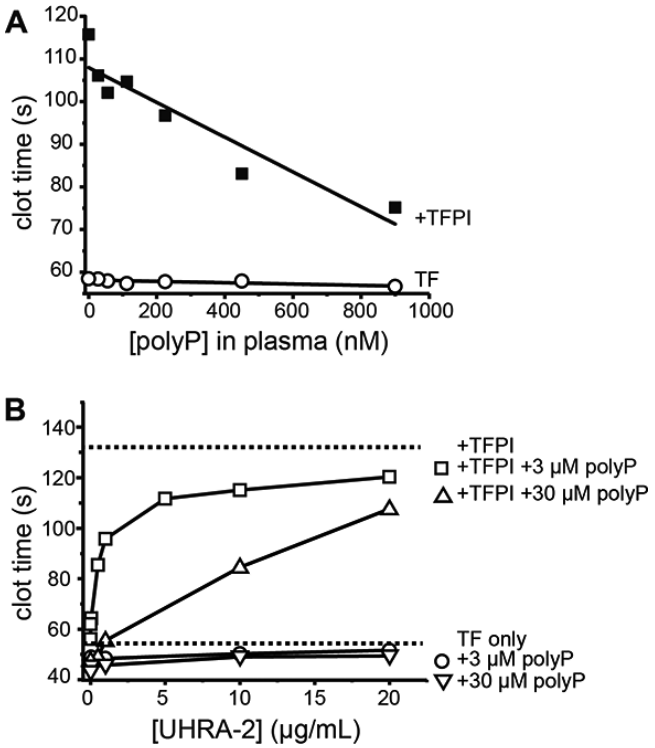

FIGURE 1 TFPI resistance (A) as a function of polyP concentration (B) reversed by polyP inhibitor

Conclusions: The effective concentration of polyP in plasma samples can be determined through this functional assay, using readily available equipment. We hope to gain further understanding of polyP's role in physiological events and, in turn, improve clotting-related diagnoses.

PB 824 | Combined IV and SC administration of Long-acting FVIIa (MOD-5014) Significantly Improves the Pharmacokinetics (PK), Pharmacodynamics (PD) and Pharmacological Long-term Outcome in Preclinical and Toxicological Models, Supporting the Initiation of a Clinical Study Combining Prophylactic and On-demand Treatments

M. Hoffmann, L. Israeli Yagev, A. Bar-Ilan, G. Hart

OPKO Biologics, Kiryat Gat, Israel

Background: OPKO Health is a clinical-stage public company developing bio-better long-acting versions of existing therapeutic proteins, utilizing a technology termed CTP. The technology involves fusion of the C-terminal peptide of hCG to a target protein.

Aims: The aim of this work was to extensively characterize intravenous (IV) and subcutaneous (SC) administrations of FVIIa-CTP (MOD-5014) for a potential combined prophylactic and on-demand treatment.

Methods: PK and PD were assessed following SC or IV administration in rats and monkeys using ELISA and clotting methods, respectively. MOD-5014´s long-term hemostatic effect following SC and IV injection utilizing tail-clip and survival model in hemophilic mice, as well as bioavailability, were also evaluated.

Results: MOD-5014 demonstrated significantly improved PK and PD profiles when injected IV and SC; following SC administration, half-life values were longer. The calculated bioavailability MOD-5014 injected SC was found to be approximately 40% in monkeys. The long-term hemostatic effect following SC administration, as observed in tail-clip studies as survival rates, bleeding intensity and bleeding duration, were prolonged in comparison to IV administration of MOD-5014 in rodent models.

Conclusions: Attachments of CTP to FVIIa led to enhanced PK and PD profiles when administered both SC and IV. A slower onset and prolonged half-life following SC administration indicate relatively slow absorption of MOD-5014 in comparison to IV administration, which is translated to a marked *in vivo* hemostatic effect. This suggests that SC administration could be used for prophylactic treatments, while IV administration could serve as an on-demand treatment during a bleeding episode due to the obtained quick onset, higher C_{max} and AUC. This potential combined treatment may be evaluated in an advanced clinical study.

PB 825 | Factors Influencing the Recanalization of Deep and Superficial Venous Thrombosis of Lower Limbs

A. Spirkoska, P. Poredos

University Medical Centre Ljubljana, Department of Vascular Diseases, Ljubljana, Slovenia

Background: Superficial (SVT) and deep venous thrombosis (DVT) represents one of the most frequent vascular diseases of lower limbs. Recanalization is a long-lasting process which depends on different factors and is important for chronic complications, such as post-thrombotic syndrome (PTS) and chronic venous insufficiency (CVI), therefore we investigated it further.

Aims: Aim of the study was to investigate the recanalization rate of SVT and DVT and the factors which are responsible for recanalization of thrombotic occlusions of veins, as well as the factors which inhibit lysis of thrombus.

Methods: Two groups of patients were included, one with idiopathic DVT, and one with SVT, with at least 10 cm thrombotic occlusion of affected superficial vein. We evaluated the recanalization rate and measured levels of systemic inflammatory markers and systemic fibrinolytic parameters.

Results: We showed that recanalization rate depends on thrombus load and is faster in distal thrombotic occlusions. We also showed that recanalization is faster and more frequent in females than in males. Recanalization of deep as well as superficial venous thrombosis is also influenced by endogenic fibrinolytic potential on the level of systemic inflammatory markers. Multivariate analysis of recanalization rate in patients with DVT showed that it is significantly influenced by level of interleukin 6 (IL-6) ($p< 0.001$) and P-selectin ($p=0.007$). Recanalization of SVT is also significantly related to levels of inflammatory markers: reactive protein (CRP) ($r=0, 39$, $p< 0.01$), IL-6 ($r=0,38$, $p< 0.01$) and tumor necrosis factor α (TNF- α) ($r=0,26$, $p=0.04$).

Conclusions: After acute thrombotic occlusion of superficial or deep veins, a process of recanalization starts which is long-lasting and depends on thrombus load, location of thrombosis and is influenced by gender. Recanalization is also significantly influenced by systemic levels of inflammatory markers, particularly levels of interleukins, which inhibits thrombolysis and diminishes recanalization rate.

PB 826 | Effect of Platelet Depletion and Thrombin Inhibition on Tail Bleeding in Wild Type and FXI-deficient Mice

J. Mueller, M.V. Schmidt, M. Visser, S. Heitmeier, C. Luecker, V. Laux

Bayer AG, Wuppertal, Germany

Background: Factor XI (FXI) deficiency is a rare disease with only a mild bleeding phenotype. Moreover, deficiency of FXI is related to a reduced risk of thrombotic events. Therefore FXI inhibition might represent an effective treatment option for thrombosis prevention in comparison to current therapeutic options. However, the bleeding risk of a targeted inhibition of FXI is unknown.

Aims: Target of the study was to evaluate the effect of platelet depletion alone or in combination with thrombin inhibition on bleeding tendencies in a tail bleeding model in wild type (WT) and FXI deficient ($FXI^{-/-}$) mice.

Methods: C57BL/6J (WT) and $FXI^{-/-}$ mice were treated with a platelet-depleting GPIbα antibody (R300 emfret) or control IgG and/or the direct thrombin inhibitor dabigatran. Agents were used at low doses to unravel additive effects on top of FXI-deficiency. Bleeding in mice was evaluated by using a standardized tail bleeding model. Tail was cut at 5 mm from the tip, bleeding intensity was measured over 30 min.

Results: Platelet depletion (> 95 %) resulted in an increased bleeding phenotype in WT mice (from 100 ± 96.6 % to 300.8 ± 105.8 %). The bleeding could be further increased by concomitant use of the direct thrombin inhibitor dabigatran (0.2 - 0.3 mg/kg, bleeding increase ≥ 50%). $FXI^{-/-}$ mice did not show an additional increase in tail bleeding compared to WT mice, neither after administration of the platelet-depleting antibody nor by additional administration of dabigatran.

Conclusions: A strongly reduced platelet count led to increased bleeding in WT mice. Interaction with the coagulation system by using a thrombin inhibitor further increased bleeding tendencies in platelet-depleted mice. The fact that no further bleeding increase in $FXI^{-/-}$ mice could be observed, indicates that FXI and its amplification by thrombin do not play a key role in primary hemostasis. Therefore, modulating FXI seems to be a unique and safe treatment option for the prevention of thrombosis.

PB 827 | Interrelation between Levels of Hemostatic Factors, Lipids and C-reactive Protein in Population Controls

V.M. Morelli[1], R. Li-Gao[1], W.M. Lijfering[1,2], F.R. Rosendaal[1,2,3], S.C. Cannegieter[1,2], A. van Hylckama Vlieg[1]

[1]Leiden University Medical Center, Department of Clinical Epidemiology, Leiden, The Netherlands, [2]Leiden University Medical Center, Einthoven Laboratory for Experimental Vascular Medicine, Leiden, The Netherlands, [3]Leiden University Medical Center, Department of Thrombosis and Hemostasis, Leiden, The Netherlands

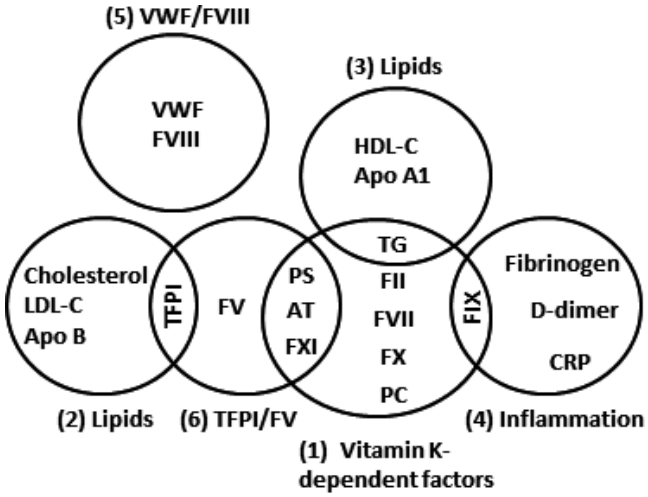
Background: Previous studies have shown that hemostatic factors cluster together. However, results were not consistent, probably due to differences in sample sizes and variables studied. Furthermore, since arterial and venous thrombosis share some traditional risk factors, we questioned if and how hemostatic factors cluster with lipids and C-reactive protein (CRP).

Aims: To assess the clustering of hemostatic factor levels and how these clusters relate to lipid and CRP levels.

Methods: We investigated 2,874 individuals (47% men) who had participated as population controls in a previous study. We imputed missing data on fibrinolytic factors which were measured only in a random subset of controls (n=733). Clusters of interrelated factors were identified by principal component analysis. A factor loading >0.40 was used as the marginal value to include factors in a cluster. Consent and ethical approval were obtained.

Results: We identified 3 clusters among the hemostatic factors: a vitamin K-dependent factor (VKDF) cluster (factors [F]II, VII, IX, X, protein C and protein S [PS]) that also included FXI and antithrombin (AT); another comprising fibrinogen, FVIII, von Willebrand factor (VWF) and D-dimer, and a third one including FV, tissue factor pathway inhibitor, PS and AT. The addition of lipid fractions and CRP (Fig. 1), led to two extra lipid clusters, with triglyceride (TG) also clustering with VKDFs. VWF and FVIII now formed a separate cluster, and CRP clustered with fibrinogen, D-dimer and FIX. When individuals with chronic diseases were excluded (n=570), the clustering pattern remained virtually the same. Upon addition of imputed fibrinolytic factors, plasminogen and α2-antiplasmin clustered with VKDFs, and tissue plasminogen activator and plasminogen activator inhibitor-1 formed a new cluster with FVII, TG and PS, with minor changes in the other clusters.

Conclusions: In this comprehensive study, we confirmed and extended cluster patterns of previous reports.



The six clusters were ranked by their eigenvalues from (1) to (6). Factor loadings within each cluster were ranked descendingly: **(1)** FX 0.79, PC 0.75, FII 0.68, FVII 0.66, FIX 0.65, TG 0.55, FXI 0.47, AT 0.45, PS 0.42; **(2)** LDL-C 0.93, Cholesterol 0.91, Apo B 0.89, TFPI 0.40; **(3)** HDL-C 0.97, Apo A1 0.91, TG -0.46; **(4)** CRP 0.79, Fibrinogen 0.73, D-dimer 0.65, FIX 0.42; **(5)** VWF 0.91, FVIII 0.91; **(6)** FV 0.63, TFPI 0.61, AT 0.54, PS 0.45, FXI 0.41.

FIGURE 1 Factor loading pattern of hemostatic factors, lipids and c-reactive protein (CRP)

PB 828 | Selective Inhibition of Protein S Anticoagulant Functions Restores in vitro Thrombin Generation in Haemophilia A and B Plasma

J. Lund[1], E. Waters[2], L.M. Andersen[1], G. Røder[3], B. Olsen Krogh[4], H. Demuth[5], M. Brunsgaard Hermit[6], H. Lindgreen Holmberg[7]

[1]*Novo Nordisk A/S, Haemophilia Enzymology, Maaloev, Denmark,* [2]*Novo Nordisk A/S, Haemophilia Research Bioanlysis, Maaloev, Denmark,* [3]*Novo Nordisk A/S, Screening & Bioassay Technology, Maaloev, Denmark,* [4]*Novo Nordisk A/S, Expression Technology, Maaloev, Denmark,* [5]*Novo Nordisk A/S, Analysis & Separation, Maaloev, Denmark,* [6]*Novo Nordisk A/S, Haemophilia Biology, Maaloev, Denmark,* [7]*Novo Nordisk A/S, Haemophilia Pharmacology, Maaloev, Denmark*

Background: Protein S is an important inhibitor of blood coagulation serving as a co-factor for activated protein C (APC) in the inactivation of Factor Va and VIIIa as well as for Tissue Factor Pathway Inhibitor-a (TFPI-a) in the inhibition of Factor Xa [Walker, JBC (1980), 255:5521-5524; Hackeng, PNAS (2006), 103:3106-3111]. Recently, Bologna et al. demonstrated that knock-out of the protein S encoding gene can rescue the haemophilic phenotype in haemophilia A and B mice [Bologna, Blood (2016), 128:79].

Aims: To further elucidate the possibility to ameliorate haemophilia by blocking protein S, we developed a monoclonal antibody (mAb) targeting the EGF1-domain of protein S.

Methods:

Results: This mAb essentially normalized thrombin generation *in vitro* in haemophilia A and B plasma and clot formation in haemophilia A-like whole blood as measured by thromboelastography. Interestingly, the anti-protein S mAb appeared to function both in an APC-dependent and

-independent manner in plasma. Further, the mAb dose-dependently increased the thrombin generation in plasma triggered with Factor Xa in the absence of functional Tissue Factor and Factor VIIa, conditions previously shown to be especially sensitive toward the TFPIa/Protein S-interactions [Thomassen, JTH (2015), 13:92-100]. However, while the APC-dependent mechanism was readily confirmed using purified coagulation factors, the mAb did not appear to perturb protein S interactions with TFPIa or Factor Xa under these conditions. Thus the effect observed in plasma may require interactions of an additional coagulation protein, potentially Factor V. In addition, the anti-protein S mAb did not affect protein S interactions with C4b-binding protein or negatively charged phospholipid surface.

Conclusions: In conclusion, our data underlines the importance of protein S for the down-regulation of blood coagulation making it a potential target for the treatment of haemophilia A and B. However, the high plasma concentration makes protein S a challenging target to saturate.

PB 829 | Treatment of a Subdural Hematoma and Long-term Secondary Prophylaxis in a Patient with Severe Factor X (FX) Deficiency Treated with a High-purity Plasma-derived Factor X (pdFX) Concentrate

K. Kavakli, C. Balkan, D. Yilmaz Karapinar

Ege University Faculty of Medicine, Children's Hospital, Department of Pediatric Hematology, Izmir, Turkey

Background: A male patient, born in 1991, with a basal FX activity of < 1% of normal due to a homozygous missense mutation in the *F10* gene, p.Gly262Asp, had an extensive history of spontaneous and traumatic bleeds. From 2011-2013, this patient participated in a phase 3 clinical trial of pdFX for on-demand treatment of moderate/severe FX deficiency.

Aims: To present pdFX treatment of a subdural hematoma and consecutive secondary prophylaxis.

Methods: After completing the phase 3 clinical trial, the patient received on-demand pdFX in an extension trial and under a compassionate-use program.

Results: On 10-Feb-2014, the patient presented with a severe headache for the past 2d that was unresponsive to analgesics (no recent history of head trauma). The patient immediately received 1000 IU (15 IU/kg) pdFX and was sent for a CT scan, which identified a 1.2-cm subdural hematoma in the left parietal-temporal-occipital region, with associated hemorrhagic lesions in the tentorium cerebelli. The patient

was admitted to the neurosurgical intensive care unit (ICU) and received a further 3000 IU (46 IU/kg) pdFX.

The patient remained in the neurosurgical ICU for 1wk and received daily doses of 2000-4000 IU (31-62 IU/kg) pdFX (no other administered hemostatic agents). The headache resolved 1d after admission. A second CT scan performed on 17-Feb indicated that bleeding had stopped and the hematoma had significantly regressed.

The patient was discharged on 18-Feb and began once-weekly routine prophylaxis with 2000 IU (25 IU/kg) pdFX for 5mos, on-demand therapy for 10mos, and now receives routine prophylactic treatment of 1800-1900 IU (≈25 IU/kg) pdFX every 2wks, with no bleeding episodes or long-term neurologic sequelae.

Conclusions: These results show that pdFX was safe and effective in treating a life-threatening bleed and as routine prophylaxis to reduce the frequency of spontaneous and traumatic bleeds in this patient with severe FX deficiency.

Funding: Bio Products Laboratory

PB 830 | Differential Coagulotoxic Effects of Asian Pitviper Snake Venoms: Evolutionary, Pathophysiology and Biodiscovery Implications

J. Debono, B. Fry

University of Queensland, Venom Evolution Lab, Biological Sciences, Brisbane, Australia

Background: Snakebite is a massive global burden and is the most neglected of all tropical diseases. Snake venom neurotoxins have been the subject of intense research efforts, but comparably much less is known about coagulotoxins. Limited knowledge into the mechanisms of action of snake venom hinders our understanding of the clinical pathologies, restricting our use of these powerful natural products as lead compounds in drug design and development. One success story has been Ancrod, a kallikrein-type serine protease from the venom of the Malayan pitviper *Calloselasma rhodostoma*. Through its selective fibrinogen-degrading activity it has been commercially developed into 'Arvin' used for treatment of stroke.

Aims: Investigate unique procoagulant properties from the wide ranging Asian pitviper clades for the use in novel biodiscovery and possible drug design.

Methods: 30 Asian pitviper venoms were screened for actions upon fibrinogen and clotting. Fibrinogen 1D SDS PAGE was performed to identify possible degradation of fibrinogen chains. A novel procoagulant assay was also developed utilising a Stago STA-R Max to accurately detect real time clotting in plasma.

Results: Gels showed effects ranging from rapid degradation of the α-chain only (Fig A1), full cleavage of α, β and γ chains to form a fibrin clot (disappearance of fibrinogen) (Fig A2-A4), abnormal degradation of all three chains simultaneously (Fig A5) or rapid degradation of the α-chain followed by slower degradation of β and γ chains, without the formation of a fibrin clot (Fig A6). Clotting times revealed that not all species which degraded all 3 chains to form a fibrin clot were able to rapidly clot plasma (Fig B, C).

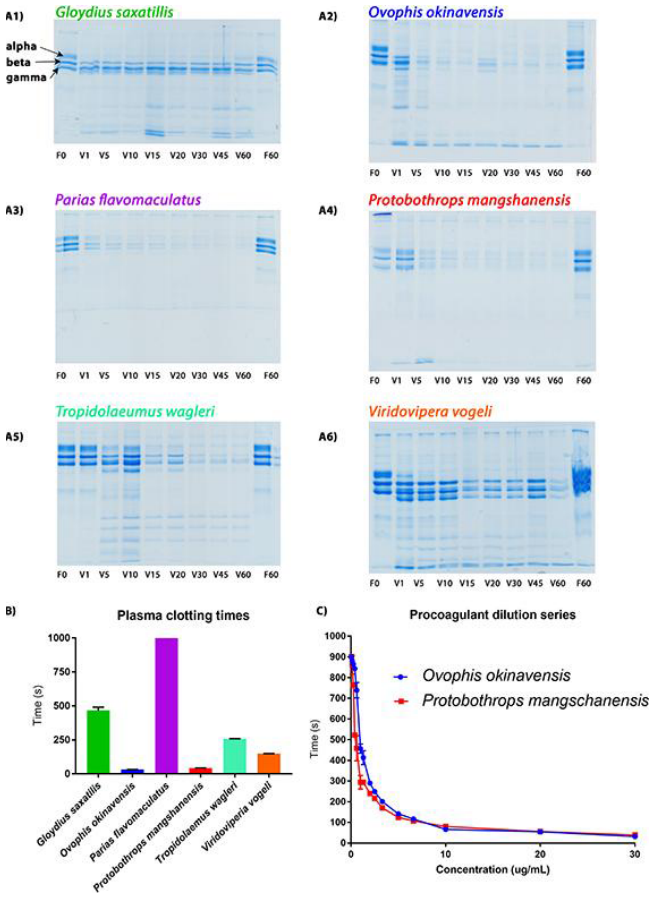


FIGURE A) Differential venom effects upon fibrinogen chains at 37°C, B) Time for venom (20 µg/ml) to induce plasma to clot at 37°C; C) clotting curves

Conclusions: Over 30 MY of evolution has subjected Asian pitvipers to rapid radiation and extensive venom diversification, leading to such properties as defibrinogenation and clotting. These results not only inform in regards to potential clinical effects by these neglected, medically important species but also provide a biodiscovery roadmap.

PB 831 | The Effect of Histone H4 on Coagulation Enzymes and Complexes in Purified Systems

S. Prior, S. Butenas

University of Vermont, Biochemistry, Burlington, United States

Background: It has been reported that histones interact with proteins of blood coagulation and fibrinolysis giving an overall procoagulant effect in whole blood.

Aims: To evaluate the effect of histone H4 on the amidolytic and proteolytic activity of coagulation enzymes and their complexes.

Methods: The effect of H4 on the amidolytic activity of purified enzymes FIIa, FVIIa and FXa was evaluated via chromogenic and fluorogenic assays. Similarly, the effect of H4 on the proteolytic activity of the enzymatic complexes intrinsic FXase, extrinsic FXase and prothrombinase was also evaluated. H4 titrations were performed for each of the enzymatic complexes to obtain their respective IC_{50} values.

Results: For purified enzymes tested, almost complete inhibition (95%) of amidolytic activity was observed for FVIIa while 29% inhibition was observed for FXa at saturating H4 concentrations. In contrast, a 28% increase in amidolytic activity was observed for FIIa. For the enzymatic complexes, complete inhibition was observed for both intrinsic and extrinsic FXase while only 56% inhibition was observed for prothrombinase. IC_{50} values were 0.13 μM, 0.45 μM and 0.40 μM, respectively.

Conclusions: In contrast to the effect observed in whole blood, H4 substantially inhibited the activity of 2 out of 3 coagulation enzymes and of all 3 enzymatic complexes tested. The observed contrast between purified systems and whole blood could potentially be related to the effects of cellular components and platelets that are present in blood.

PB 832 | CP-5-001: A Phase 1/2a, Open-Label, Multicenter, Dose Escalation Study to Assess the Safety, Pharmacokinetics and Pharmacodynamics Profile of a Long-acting Recombinant Factor VIIa (MOD-5014) in Adult Men with Hemophilia A or B

G. Young[1], D.V. Quon[2], M.A. Escobar[3], L.N. Boggio[4], M.E. Eyster[5], M.V. Ragni[6], N.P. Ewing[7], A. Shapiro[8], M.D. Tarantino[9], G. Hart[10], G. Kenet[11]

[1]University of Southern California Keck School of Medicine, Children's Hospital Los Angeles, Los Angeles, United States, [2]Orthopaedic Hemophilia Treatment Center, Los Angeles, United States, [3]University of Texas Health Science Center, Houston, United States, [4]Rush University Medical Center, Chicago, United States, [5]Hemophilia and Thrombosis Center of Central PA, Hershey, United States, [6]Hemophilia Center of Western PA, Pittsburgh, United States, [7]City of Hope Comprehensive Hemophilia Treatment Center, Duarte, United States, [8]Indiana Hemophilia & Thombosis Center, Indianapolis, United States, [9]Bleeding & Clotting Disorders Institute University of Illinois College of Medicine, Peoria, United States, [10]OPKO Biologics, Kiryat Gat, Israel, [11]Sheba Medical Center, Tel Hashomer, Israel

Background: OPKO is developing long-acting versions of therapeutic proteins using CTP. This technology involves fusion of the C-terminal peptide of hCG to proteins and was clinically validated for several drugs while maintaining biological activity. MOD-5014 is a long-acting form of recombinant FVIIa (rFVIIa-CTP) tested for the 1st time in hemophilic patients.

Aims: Assessment of acute safety, tolerability, PK and PD profiles of single intravenous (IV) administration of escalating MOD-5014 doses in hemophilic subjects with and without inhibitors.

Methods: Single-dose, open-label, dose-escalating study performed in 2 stages. Stage 1 included 3 doses (25, 50 and 100 μg/kg), with 4 subjects per group. Dosing of all subjects was followed by a 7-, 14- and 30-day safety observation period. Safety assessments included monitoring of adverse events (AEs), injection site reactions, vital signs, physical condition and laboratory assessments (e.g. hematology, biochemistry, coagulation panel, immunogenicity). Stage 2 includes 3 doses (200, 300 and 400 μg/kg).

Results: Study analysis includes safety, PK and PD data for patients that completed the 2 stages. In Stage 1, 75% of patients reported AEs, all considered unrelated or unlikely related to study medication; none led to premature study discontinuation. One severe AE was reported during MOD-5014 treatment and was considered unlikely related to study medication. Laboratory assessments supported of MOD-5014 tolerability; no significant overall changes were observed in hematology or chemistry. There was no consistent pattern for changes in any coagulation parameter during the study attributable to study intervention. MOD-5014 presents superior long PK and PD profile in comparison to for commercial FVIIa historical data.

Conclusions: Currently MOD-5014 demonstrates promising safety and tolerability profile following single IV administration of escalating MOD-5014 doses (25, 50, 100 and 200 μg/kg) in hemophilic subjects with and without inhibitors.

PB 833 | Age-related Variation in the Glycosylation of Alpha-2-Macroglobluin

L. Calvert[1,2], H. Atkinson[1,2], J. Macri[3], L. Berry[1,2], A. Chan[1]

[1]McMaster University, Pediatrics, Hamilton, Canada, [2]Thrombosis & Atherosclerosis Research Institute, Hamilton, Canada, [3]McMaster University, Pathology and Molecular Medicine, Hamilton, Canada

Background: Alpha-2-macroglobulin (a2m) is a plasma glycoprotein serine protease inhibitor shown to exhibit higher levels in newborns than adults. Although our previous studies did not reveal differences in glycan number per a2m molecule (macroheterogeneity) for newborns compared to adults, we discovered that newborn a2m had significantly more sialic acid (SA), indicating microheterogeneity between the age groups.

Aims: To examine differences in the glycan moieties between newborn and adult a2m.

Methods: To determine the heterogeneity in a2m charge, 2-dimensional (2D) gel electrophoresis was carried out on both newborn and adult plasma samples, followed by western blotting. A2m was then purified from plasmas by immunoprecipitation and subjected to fluorescence-assisted carbohydrate electrophoresis (FACE) to assess differences in glycan types for newborn vs. adult a2m molecules.

Results: 2D gel results revealed a change in net charge for the two molecules, with newborn a2m species migrating to a lower isoelectric point than adult. This result was consistent with the increased SA in newborn a2m observed previously. Additionally, FACE revealed a prominent band of sialylated biantennary glycans and a secondary population of larger glycans with increased branching. Analyses

showed that there was a significantly higher proportion of the more branched glycans in the newborn sample than adult.

Conclusions: This is the first study to identify specific carbohydrate characteristics between newborn and adult a2m. The results suggest that newborn a2m tends to have higher negative charge from increased SA capping more highly branched glycans. Such differences may partly account for the increased a2m plasma levels in newborns due to slower clearance resulting from reduced uptake by receptors that bind glycans missing SA or mannose in less branched structures.

PB 834 | First Evaluation of the Safety, Pharmacokinetics and Pharmacodynamics of BAY 1213790, a Full Human IgG1 Antibody Targeting Coagulation Factor XIa, in Healthy Young Men

D. Thomas[1], K. Thelen[2], D. van der Mey[2], S. Schwers[1], S. Schiffer[1], S. Unger[3], J. Heubach[4], A. Yassen[5], S. Boxnick[6]

[1]*Bayer AG, Drug Discovery, Experimental Medicine CV/HEM, Wuppertal, Germany,* [2]*Bayer AG, Drug Discovery, Clinical PK CV, Wuppertal, Germany,* [3]*Bayer AG, Development, Research & Clinical Sciences Statistics, Wuppertal, Germany,* [4]*Bayer AG, Development, Cardiovascular, Berlin, Germany,* [5]*Bayer AG, Drug Discovery, Clinical Pharmacometrics, Wuppertal, Germany,* [6]*CRS Clinical Research Services Wuppertal GmbH, Wuppertal, Germany*

Background: Anticoagulants are the cornerstone of prevention and treatment of thrombotic disorders, but those in clinical use are associated with a dose-dependent risk of bleeding, limiting their antithrombotic potential. Coagulation factor XI (FXI) contributes to the development of thrombosis, but plays only a minor role in hemostasis and is therefore an attractive target for antithrombotic therapy. Inhibition of FXIa offers the potential to reduce the risk of thrombosis while minimizing the risk of associated bleeding.

Aims: To evaluate the safety, pharmacokinetic (PK) and pharmacodynamic (PD) properties of BAY 1213790, a full human IgG1 antibody targeting FXIa, in healthy male volunteers.

Methods: In this randomized, single-blind, parallel-group, placebo-controlled dose-escalation study, BAY 1213790 (0.015-10 mg/kg) was administered as a 60-minute infusion to healthy male volunteers. Adverse events, in particular, spontaneous bleeding, infusion reactions and hypersensitivity were monitored; volunteers were followed up for 5 months. Key PK parameters included exposure (area under the plasma concentration-time curve), maximum plasma concentration and terminal half-life. The PD properties of BAY 1213790 were assessed using activated partial thromboplastin time, rotational thromboelastometry, FXI activity (clotting assay) and bleeding time. The study was approved by the local ethics committee and all volunteers provided written informed consent.

Results: BAY 1213790 demonstrated a favorable safety and tolerability profile, with a dose-dependent increase in exposure and a terminal half-life of approximately 30 days. All relevant coagulation biomarkers were influenced in a dose- and time-dependent manner. No cases of bleeding and only one case of mild infusion reaction were reported.

Conclusions: BAY 1213790 is a promising candidate for long-term and stable anticoagulation, showing no increased risk of bleeding in this first study in humans.

PB 835 | Case Study of Successful Transition to Human Cell Line Fc Fusion Factor IX Replacement without Premedication in an Adolescent Male with Severe Hemophilia B, Anaphylactoid Reaction to FIX Replacement, and Previous History of Inhibitor and Nephrotic Syndrome

A. Federizo

Hemophilia Treatment Center of Nevada, Las Vegas, United States

Background: The development of inhibitors to factor replacement in hemophilia continues to present significant challenges. While inhibitors develop with less frequency in Hemophilia B, this occurrence is often seen with the concurrent development of severe allergies to replacement, further compounding treatment challenges.

Aims: To describe an option for treatment of FIX deficient individuals with anaphylactoid reaction to FIX replacement and history of inhibitors.

Methods: A 12-year-old male with severe hemophilia B (missense mutation) presented with the following history: Initiation of prophylaxis with recombinant FIX at 8 months. At 10 months, he developed an intracranial hemorrhage with an inhibitor level of 5.5 Bethesda units. Daily immune tolerance induction with recombinant FIX and recombinant FVII was started. At 11 months, he developed severe allergies to FIX replacement. At 18 months, he developed nephrotic syndrome. At 3 years old, his regimen was changed to rituximab (off label), IVIG (off label), and plasma derived FIX. The inhibitor level decreased to undetectable; however, his allergy to infused FIX remained as did his risk and development of multiple line infections. At presentation, he was infusing recombinant FIX every other day with premedication before every dose. A trial of human cell line Fc Fusion FIX replacement was pursued.

Results: Fc Fusion FIX was dosed at 100units/kg without premedication. A pharmacokinetic study was completed and he was started on weekly infusions with a day 7 FIX activity of 4%. His port was removed under Fc Fusion FIX coverage and he continues weekly infusions without need for premedication.

Conclusions: This case highlights the need for further exploration of the use of human cell line therapies in hemophilia B patients with inhibitors and allergic phenotype. The decreased immunogenicity reported with human cell line derivative products may offer an opportunity for the development of improved treatment guidelines in this challenging subgroup.

PB 836 | Estimates of within-subject Biological Variation of Factor VIII, von Willebrand Factor Antigen, Fibrinogen, Prothrombin Time, INR and APTT in Pregnant Women

A.H. Kristoffersen[1,2], P. Hyltoft Petersen[2,3], T. Roraas[2], S. Sandberg[1,2,3]

[1]*Haukeland University Hospital, Laboratory of Clinical Biochemistry, Bergen, Norway,* [2]*Norwegian Quality Improvement of Laboratory Examinations (Noklus), Bergen, Norway,* [3]*University of Bergen, Department of Global Public Health and Primary Care, Bergen, Norway*

Background: In pregnancy and post-partum, interpretation of results from coagulation parameters can be difficult because of the physiological changes towards a hypercoagulable state.

Aims: The aim of this study was to describe the change in concentration of several coagulation parameters during healthy pregnancies, and to estimate and compare the within-subject biological variation (CV_I) of these parameters in healthy pregnant and non-pregnant women.

Methods: Blood samples were obtained every 4th week during pregnancy and 3 samples post-partum in 20 healthy women and every 4th week during 40 weeks in 19 healthy non-pregnant women. Activated partial thromboplastin time (APTT), prothrombin time (PT), PT-INR, Fibrinogen, Factor VIII clot (FVIII) and von Willebrand factor antigen (vWF) were analysed. Analysis of variance (ANOVA), with the statistical model for repeated subsampling, was used to calculate biological variation. Data was transformed into multiples of the median (MoM) to create a steady-state situation by adjusting for the physiological changes during pregnancy. Within-subject variations (CV_I) were estimated from the transformed lnMoM data after outlier exclusion. APTT, PT and INR were analysed by two different reagents, therefore two CV_I results are presented.

Results: During pregnancy, APTT, PT and PT-INR decreased or remained largely unchanged (dependent upon reagent). Fibrinogen, FVIII and vWF increased gradually during pregnancy and decreased abruptly after delivery. The CV_I (lnMoM) in pregnancy (post-partum period excluded) and in non-pregnant women were similar, except for Fibrinogen (Table 1).

TABLE 1 CVI (back transformed from SDs for lnMoM) in pregnant and non-pregnant women

	Pregnancy CVI (95%CI)	Non-pregnant CVI (95%CI)APTT2
APTT1	3.0 (2.7-3.4)	2.7 (2.4-3.0)
APTT2	2.2 (2.0-2.5)	2.1 (1.8-2.3)
PT1 (Owren Method)	2.9 (2.5-3.2)	3.3 (2.9-3.7)
PT2 (Quick Method)	2.5 (2.2-2.8)*	2.5 (2.3-2.8)
PT-INR1 (Owren Method)	3.2 (2.9-3.5)	3.0 (2.7-3.4)
PT-INR2 (Quick Method)	2.6 (2.3-2.9)*	2.5 (2.3-2.9)
Fibrinogen (Clauss)	7.2 (6.4-8.1)	9.3 (8.3-10.5)
Factor VIII clot	12.7 (11.6-14.2)**	11.7 (10.4-13.2)
von Willebrand factor antigen	11.3 (10.1-12.8)	11.1 (9.9-12.5)

*Not Gaussian distribution of the residuals, **Not variance homogeneity

Conclusions: Transformation of coagulation parameters in healthy pregnancies to MoM is a tool to establish a kind of steady-state. Although there is a physiological change in APTT, PT/INR, Fibrinogen, FVIII and vWF:Ag during pregnancy, the CV_I (lnMoM) was comparable with the CV_I (lnMoM) of non-pregnant women.

PB 837 | A Snake-venom Enzyme (Noscarin)-based Assay for APC-resistance Is Not Influenced by Non-vitamin K Antagonist Oral Anticoagulants (NOAC)

A.C. Brisset[1], C. Stocker[1], M. Janssen[1], W. Renner[2], H. Mangge[2], F. Prüller[3]

[1]*DSM Nutritional Products Ltd Branch Pentapharm, Aesch, Switzerland,* [2]*Medical University of Graz, Clinical Institute of Medical and Chemical Laboratory Diagnostics, Graz, Austria,* [3]*University Hospital Graz, Clinical Institute of Medical and Chemical Laboratory Diagnostics, Graz, Austria*

Background: Various coagulation assays are influenced by the presence of *non-vitamin K antagonist oral anticoagulants* (NOAC). In the case of APC-resistance (APCR) assays, the literature is not conclusive. Studies with either a small number of patient samples on either rivaroxaban (Ri) or dabigatran (Da) (Gessoni 2015) or samples spiked ex vivo with Ri (Hillarp 2011) using either aPTT based or noscarin-based APCR assays gave slightly discrepant findings. Noscarin-based APCR assay was shown not to be influenced by the presence of lupus anticoagulant (Wilmer 2004 and Schöni 2005).

Aims: To determine if NOACs could influence the results of noscarin-based APCR assay leading to misclassification of patients with known FV Leiden mutation receiving treatment with various NOACs (dabigatran, rivaroxaban, apixaban or edoxaban).

Methods: Plasma samples of patients (n=50) under NOAC treatment are collected at the Graz University Hospital and genotyped for FV Leiden mutation using a 5'-nuclease assay using specific primers and probes. The noscarin-based APCR assay (Pefakit APC-R Factor V Leiden) is performed in the absence of Ca^{2+} and phospholipid. It activates factor V via the factor V activating enzyme from *Vipera russelli* (RVV-V) by bypassing FXa, and prothrombin via noscarin from *Notechis scutatus*. These specific activation pathways reduce potential interferences in plasma. Plasma levels of NOACs are determined using Biophen DiXal assay for anti-Xa NOACs and Biophen DTI for anti-IIa NOACs with specific calibrators and controls. Agreement between phenotype results of noscarin-based APCR assay and FV Leiden genotyping has been analyzed.

Results: So far in the presence of NOACs 100% of samples (n=24) were correctly identified (wild-type, heterozygous, homozygous) by noscarin-based APCR assay compared to PCR genotyping.

Conclusions: Preliminary data suggest there is no interference of the NOACs tested in this study on the phenotyping for APCR with the noscarin-based clotting assay.

PB 838 | APC and TFPI Cofactor Activities of Thrombin-cleaved Protein S and C4BP-protein S Complex

N. Alshaikh, J. Rosing, T. Hackeng

Maastricht University / Cardiovascular Research Institute Maastricht (CARIM), Department of Biochemistry, Maastricht, The Netherlands

Background: Protein S is a non-enzymatic cofactor for APC in the inactivation of FVa and FVIIIa and for TFPI in the inhibition of FXa and TF-FVIIa. In plasma 60% of protein S (~ 200nM) is found in a high affinity complex with C4BP and 40% of protein S (~ 150 nM) circulates in a free form.

Aims: It has been reported that only free protein S expresses anticoagulant activity as a cofactor for APC and that this activity is inhibited by cleavage of thrombin-sensitive region of protein S. Alternatively, binding of protein S to C4BP results in specific inhibition of cleavage by APC at R506 of factor Va. However, regulation of protein S cofactor activity for TFPI is less well understood. In the current study we evaluated and compared the APC and TFPI cofactor activities of protein S, thrombin-cleaved protein S and C4BP-protein S complex in plasma and in model systems.

Methods: To quantify the APC cofactor activity, thrombin generation was measured in protein S-deficient plasma containing APC in the presence of different concentrations of the various forms of protein S both in the absence and presence of neutralizing antibodies against TFPI. The TFPI cofactor activity of native protein S, thrombin-cleaved protein S, and C4BP-protein S complex was quantified in model system by measuring the inhibition of Xa by TFPI. In addition, the ability of the different forms of protein S to act as TFPI cofactor was quantified in plasma by measuring thrombin generation in protein S-deficient plasma reconstituted with varying amounts of protein S.

Results: Thrombin-cleaved protein S showed full TFPI cofactor activity in the model system but C4BP-protein S was only partly active. In plasma, thrombin-cleaved protein S lacked APC cofactor activity but was fully active as TFPI cofactor. C4BP-protein S did not exhibit APC cofactor activity in plasma but was active as a TFPI cofactor.

Conclusions: In conclusion, this research gives more insight into the APC and TFPI cofactor activities of the various forms of protein S.

PB 839 | Anticoagulants Differentially Affect Procoagulant Platelet Formation

S. Wang[1], H. Campbell[2], G. Pennings[2], C. Reddel[2], L. Pasalic[3], V. Chen[2,4,5]

[1]University of New South Wales, Sydney, Australia, [2]ANZAC Research Institute, Sydney, Australia, [3]ICPMR, Westmead Hospital, Sydney, Australia, [4]University of Sydney, Sydney, Australia, [5]Concord Hospital, Haematology, Sydney, Australia

Background: Procoagulant platelets provide a surface for assembly of coagulation complexes at the platelet thrombus. Inability to form procoagulant platelets is associated with bleeding while excess is linked with pathological thrombosis. Heparins are used in acute management of myocardial infarction and venous thrombosis, while direct anticoagulants (DOACS) are used for acute venous but not arterial thrombosis. Both bleeding and efficacy rates of heparins are higher than DOACs and we hypothesised this related to procoagulant platelet function.

Aims: To explore the effect of anticoagulants on procoagulant platelet formation.

Methods: We adapted a procoagulant platelet flow cytometry assay based on novel cell death agent, GSAO (Hua et al., Blood, 2015), to measure procoagulant platelet formation in ex vivo whole blood. Whole blood from healthy volunteers was pre-incubated with anticoagulants or vehicle control at varying doses prior to stimulation with thrombin (2U/mL) and subjected to FACS analysis. Procoagulant platelets were defined as GSAO+/CD62P+.

Results: Compared with vehicle control, unfractionated and low molecular weight heparin both markedly reduced thrombin induced procoagulant platelet formation in a dose dependent manner (fold change 0.32±0.07, n=3, p=0.0098 and 0.46±0.04, n=3, p=0.0039). Dabigatran, a direct thrombin inhibitor also inhibited thrombin induced procoagulant platelet formation (0.26±0.13, n=6, p< 0.005). In contrast, the direct FXa inhibitor, rivaroxaban, did not significantly affect procoagulant platelet formation (0.95±0.14, n=9, p=0.0835). Apixaban demonstrated minor inhibition in procoagulant platelet formation (0.78±0.07, n=10, p=0.0054) at a "subtherapeutic" level of 49ng/mL.

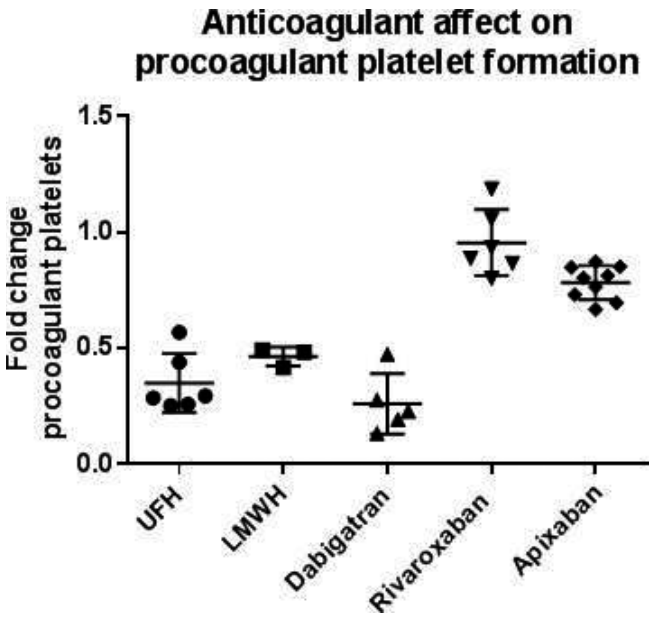

FIGURE 1: Heparins and dabigatran inhibit procoagulant platelet formation, while rivaroxaban and apixaban have minimal effect.

Conclusions: Anticoagulants used currently during acute myocardial infarction inhibit procoagulant platelet formation in addition to the known anticoagulant effects. These findings may help explain bleeding and efficacy profiles of heparins compared with oral anti-FXa agents rivaroxaban and apixaban.

PB 840 | A Novel Hypoxia Response Element Regulates Oxygen-related Repression of Tissue Factor Pathway Inhibitor Expression

X. Cui[1], G. Skretting[1], B. Stavik[1], M. Tinholt[1,2], A.E.A. Dahm[3,4], S. Kanse[1,5], N. Iversen[2], P.M. Sandset[1,4]

[1]Oslo University Hospital, Department of Haematology, Oslo, Norway, [2]Oslo University Hospital, Department of Medical Genetics, Oslo, Norway, [3]Akershus University Hospital, Lørenskog, Norway, [4]University of Oslo, Institute of Clinical Medicine, Oslo, Norway, [5]University of Oslo, Institute of Basal Medical Sciences, Oslo, Norway

Background: The expression of tissue factor pathway inhibitor (TFPI) is repressed under hypoxic conditions. In a previous study we identified the hypoxia response element (HRE) 5'-GACATG-3' located -1065 to -1060 within the TFPI promoter and that HIF-1α transcriptionally regulates TFPI gene expression under hypoxia through binding to this HRE. HIF-2α, also known as endothelial PAS domain-containing protein 1 (EPAS1), is another key transcription factor in hypoxia. Its role in the hypoxia mediated regulation of TFPI is unclear.

Aims: To explore the possible correlation of HIF-2α/EPAS1 and hypoxia-mediated repression of TFPI expression.

Methods: Quantitative RT-PCR, Western blot, luciferase reporter gene assay, chromatin immunoprecipitation (ChIP) and mutagenesis were used to study the role of HIF-2α in MCF7 breast cancer cells.

Results: Quantitative RT-PCR revealed that the TFPI mRNA level was decreased by overexpression of HIF-2α/EPAS1. Luciferase reporter gene assay and ChIP demonstrated a HIF-2α/EPAS1 responsive region located in the TFPI promoter region at -170 to +21 relative to the transcriptional start site. Using mutagenesis a functional hypoxia response element (HRE) 5'-AAACAGGA-3' for HIF-2α/EPAS1 was identified within the TFPI promoter at -45 to -38.

Conclusions: This study provides evidence that HIF-2α/EPAS1 transcriptionally downregulates TFPI gene expression through a novel HRE. The hypoxic microenvironment may induce aberrant activation of coagulation through repression of TFPI expression.

PB 841 | Impact of Thrombomodulin on Spatial Clot Growth and Fibrin Polymerization in Cirrhotic Patients

A. Lebreton[1,2], T. Sinegre[1,2], C. Duron[3,4], A. Abergel[3,4], A. Casini[5]

[1]CHU Clermont-Ferrand, Hematology, Clermont-Ferrand, France, [2]Université Clermont Auvergne, UMR 1019 INRA/UCA, Human Nutrition Unit, Team NutriVasc, Clermont-Ferrand, France, [3]CHU Clermont-Ferrand, Hepatology, Clermont-Ferrand, France, [4]Université Clermont Auvergne, CNRS UMR 6284, Clermont-Ferrand, France, [5]University Hospitals of Geneva, Division of Angiology and Haemostasis, Geneva, Switzerland

Background: Thrombin generation assays (TGA) with thrombomodulin (TM) demonstrated that cirrhotic patients have a hypercoagulable profile. The thrombodynamics assay (TD) gives a global assessment of coagulation by evaluating the growth of a fibrin clot after activation of tissue factor immobilized on a thin layer of a plastic surface. A recent study found that spatial clot growth was preserved in patients with cirrhosis without use of TM.

Aims: To evaluate spatial clot growth and fibrin polymerization in plasma of cirrhotic patients in presence of TM.

Methods: Nine healthy controls and 26 cirrhotic patients (9 Child-Pugh (CP) A, 10 CP-B and 7 CP-C) were enrolled. TGA were performed with calibrated automated thrombography using 5 pM of tissue factor and 4 mM of phospholipids, in presence and absence of 1 nM of TM. TD were performed without and with addition of 25 nM of TM. Fibrin polymerisation was evaluated by turbidimetry after thrombin activation
(0.5 U/ml).

Results: We confirmed a hypercoagulable state in cirrhotic patients gradually increasing from healthy controls to CP-C patients in TGA with TM. In TD without TM, the clot growth rate, the clot density and the clot size were preserved in cirrhotic patients. In TD with TM, the rate and the lag time of clot growth were decreased. The clot size was not modified by addition of TM in TD. A significant decrease in clot density was found in TD without and with TM for CP-C patients when compared to healthy controls ($p < 0.01$). No correlation with TG parameters was found. The fibrin polymerisation study revealed a significant decrease of maximal absorption without and with TM between healthy controls and CP-C patients ($p < 0.01$), strongly correlated with fibrinogen activity. TM significantly increased the lag time observed in polymerisation.

Conclusions: TM decreases several parameters of TD and turbidimetry analyses, although without differences between healthy controls and cirrhotic patients. There were no correlations with variables measured by TGA.

PB 842 | Biomechanisms of a Severe Hypersensitivity Reaction Induced by Factor IX in Hemophilia B Complicated by Factor IX Inhibitor

M. Cugno[1], M.E. Mancuso[2], A. Tedeschi[3], E. Santagostino[2], M. Lorini[1], V. Carbonelli[1], F. Peyvandi[1,2], P.M. Mannucci[2]

[1]Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico and University of Milan, Internal Medicine Department, Milan, Italy, [2]Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Milan, Italy, [3]A.O. Fatebenefratelli e Oftalmico, Internal Medicine, Milan, Italy

Background: Patients with hemophilia B who develop factor IX (FIX) neutralizing antibodies (inhibitors) after FIX infusion are at high risk of hypersensitivity reactions upon FIX re-exposure, but the underlying mechanisms are incompletely understood.

Aims: The study was aimed at identifying potential biomechanisms of hypersensititvity reaction induced by factor IX in a patient with severe hemophilia B complicated by newly developed inhibitor.

Methods: We employed an *in vitro* cellular antigen stimulation test (CAST) to evaluate leukotriene C4 (LTC4) release from basophils stimulated by FIX in three treated children with hemophilia B, one

of whom developed FIX inhibitor and experienced anaphylaxis following FIX re-exposure. Anti-FIX IgE and IgG antibodies and markers of complement activation (C5b9, C3d and iC3b) were measured in plasma, the last also after FIX infusion. Ten healthy children served as controls.

Results: The hemophilia B patient who developed anti-FIX inhibitors and anaphylaxis had a nonsense mutation in the FIX gene (p.Arg298Stop) and, compared to normal controls, had higher plasma levels of specific anti-FIX IgE (2.285 *vs* 0.084 $OD^{492\ nm}$), with a marked LTC4 release from his FIX-stimulated basophils (519.8 *vs* 39.9 pg/ml). Further, he had higher plasma levels of anti-FIX IgG of all the four subclasses (total IgG 1.180 *vs* 0.120 $OD^{492\ nm}$) with FIX neutralizing activity (1.5 BU); mild complement activation occurred during FIX-induced anaphylaxis (C5b9 increased from 258.5 to 351.1 ng/ml). The same parameters were normal in two hemophilia B patients who tolerated FIX infusion.

Conclusions: In the hemophilia B patient who experienced anaphylaxis after FIX, but not in the hemophilia B patients who tolerated FIX, the CAST assay showed FIX-induced LTC4 release, which was associated with high plasma levels of specific anti-FIX IgE and IgG antibodies.

PB 843 | The Thrombomodulin Resistance in Prothrombin Belgrade Mutation Carriers

V. Djordjevic[1], P. Miljic[2,3], Y. Takagi[4], A. Takagi[4], M. Gvozdenov[1], I. Pruner[1], J. Bodrozic[3], B. Tomic[1], D. Radojkovic[1], T. Kojima[4]

[1]Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Belgrade, Serbia, [2]Faculty of Medicine, University of Belgrade, Belgrade, Serbia, [3]Clinic of Hematology, University Clinical Center, Belgrade, Serbia, [4]Nagoya University Graduate School of Medicine, Department of Pathophysiological Laboratory Sciences, Nagoya, Japan

Background: The prothrombin Belgrade (FIIc.1787G>A) mutation leads to Arg596Gln substitution, which impairs binding of antithrombin to thrombin and results in antitrombin resistance in mutation carries. Besides antithrombin resistance, increased endogenous thrombin potential and decreased prothrombin clotting activity with normal prothrombin antigen was reported in carriers. However, the thrombin/thrombomodulin interactions in Belgrade mutation carriers have not been elucidated so far.

Aims: We aimed to analyze the effects of the prothrombin Belgrade mutation on thrombin/ thrombomodulin interaction in a large Serbian family with this mutation.

Methods: Plasma samples from 19 family members (10 mutation carriers and 9 non carriers) were tested. We tested thrombin/thrombomodulin interaction using previously described method based on fibrinogen clotting assay. The *Oxyuranus scutellatus* venom with phospholipid and $CaCl_2$ was used for prothrombin activation. The activity was determined by fibrinogen clotting assay performed with 20µg/mL recombinant soluble thrombomodulin (+TM) or without (-TM). The results were normalized with standard human plasma (100%) and residual activity ratio (+TM/-TM) was calculated.

Results: The residual activity ratio was significantly increased ($p < 0.001$) in mutation carriers (18.94±2.30) in comparison to non-carriers (14.5±2.91), indicating the presence of thrombomodulin resistance in prothrombin Belgrade mutation carries. The increased residual activity ratio was associated with prothrombin Belgrade mutation, regardless carriers' age and gender.

Conclusions: Our results indicate that both antithrombin and thrombomodulin resistance are involved in complex mechanism by which prothrombin Belgrade influences haemostatic balance and leads to thrombophilia.

PB 844 | Hereditary Factor X (FX) Deficiency in Females: Treatment with a High Purity Plasma-derived Factor X Concentrate

R. Kulkarni[1], A. James[2], M. Norton[3], A. Shapiro[4]

[1]Michigan State University, East Lansing, United States, [2]Duke University, Durham, United States, [3]Bio Products Laboratory Ltd., Elstree, United Kingdom, [4]Indiana Hemophilia and Thrombosis Center, Indianapolis, United States

Background: A high-purity plasma-derived FX concentrate (pdFX) has been developed for treatment of hereditary FX deficiency, an autosomal recessive disorder.

Aims: This post hoc analysis describes the pharmacokinetics, safety, and efficacy of pdFX in 10 female subjects with hereditary FX deficiency.

Methods: In this open-label study, subjects (10 female, 6 male) aged ≥12 years with moderate or severe FX deficiency (basal plasma FX activity ≤5 IU/dL) were enrolled and received 25 IU/kg pdFX for on-demand treatment of bleeding episodes or preventative use for up to 2 years. All subjects provided informed consent and the protocol was approved by appropriate independent ethics committees.

Results: Nine female subjects had severe and 1 had moderate FX deficiency, were aged 25.5 (median; range 14-58) y, and received a total of 267 pdFX infusions (178 for on-demand and 89 for preventative treatment). Male subjects (5 severe and 1 moderate FX deficiency) received a total of 159 pdFX infusions (64 on-demand; 95 preventative). The mean number of infusions per subject per month was higher among females (2.48) than males (1.62). The mean pdFX incremental recovery was similar between females and males (2.05 vs 1.91 IU/dL per IU/kg, respectively), as was mean half-life (29.3 and 29.5 h, respectively). Among females, 132 assessable bleeding episodes (61 heavy menstrual bleeding, 47 joint, 15 muscle, and 9 other) were treated with pdFX. Females reported a treatment success rate (ie, subject rating of "excellent" or "good" response to pdFX) of 98%, comparable to the 100% treatment success rate among males. After study completion, 2 subjects received pdFX for hemostatic cover during obstetric delivery. Additional infusion, bleed, and safety data will be presented.

Conclusions: These results show that in female subjects with moderate or severe hereditary FX deficiency, pdFX was safe and effective and had a pharmacokinetic profile similar to that of males.

Funding: Bio Products Laboratory

PB 845 | Factor VII Deficiency: A Center Experience

A.R. Fernandes[1], M. Antunes[1], M.J. Diniz[2]

[1]Hospital de São José, Serviço de Imuno-Hemoterapia, Lisboa, Portugal, [2]Hospital de São José, Serviço de Imuno-Hemoterapia, CHLC, Lisboa, Portugal

Background: Factor VII deficiency is the most frequent among rare inheritable bleeding disorders affecting 1/500000 people. Its prevalence is probably higher owing to the presence of asymptomatic patients. Mostly, surgical bleeding can be their first symptom, when spontaneous bleeding is negative. The diagnosis is determinate by FVII:C level; the clinical manifestations are heterogeneous. The reliable classification of bleeding severity activity levels is not still clear-cut, and there is an absence of a consistent correlation between symptoms and FVII clotting levels(FVII:C), that becomes so important, to achieve a safe and standardized substitution treatment for this congenital disorders.
Aims: Evaluat the clinical behavior of FVII deficiency patients,followed in Congenital Coagulopaties Center of HospitalSãoJosé
Methods: Review of the patients with FVII deficiency,followed in our Hospital,from January2007 until January2017,according FVII:C levels,bleeding complaints and the implemented replacement therapy.
Results: We observed 41 patients: 2 patients with FVII:C level< 1%:one male with severe bleeding disorder, mostly haemarthrosis that is receiving prophylactic therapy with rFVIIa (30µg/2xweek) with good results and one women with abundant menorrhagia before menopause, but without spontaneous bleeding, since then. All the others patients were mildly affected or asymptomatic, and no correlation was seen among the laboratory and clinical manifestations. We managed 28 high bleeding surgeries in 26 patients: In all of them was administered rFVIIa (15-30µg/kg) previously to the surgery. 1 or 2 administrations were sufficient in most patients. No adverse events were observed.
Conclusions: Despite de FVII:C level, the bleeding symptoms of our patients confirm what is read in the literature. All the surgeries occurred without complications. It is not well established the minimal level of FVII:C to guarantee the haemostasis in these patients, being the clinical bleeding history very important mostly if the FVII:C is > 20%.

PB 846 | ADP and ATP Inhibit Factor X Activation by Factor VIIa/Tissue Factor

Y. Wang, J. Morrissey

University of Illinois at Urbana-Champaign, Biochemistry, Urbana, United States

Background: ADP and ATP are released by activated platelets and make important contributions to platelet aggregation. ADP and ATP have both been shown to reduce the ability of certain membrane-interactive proteins such as synaptotagmin-1 to bind to negatively charged phospholipids like phosphatidylserine (PS). Factor X activation by the factor VIIa/tissue factor (VIIa/TF) complex is the initiation point of the blood coagulation cascade, and this reaction relies on membrane PS for function. We hypothesized that ADP and ATP may inhibit factor X activation by VIIa/TF by disrupting PS-binding by factor X and/or VIIa.
Aims: Investigate the effect of ADP and ATP on factor X activation by VIIa/TF.
Methods: We measured initial rates of factor X activation using various combinations of factor X, factor VIIa, TF and phospholipids in the presence of AMP, cAMP, ADP or ATP.
Results: Rates of factor X activation by VIIa/TF were significantly reduced, in a dose-dependent manner, by micromolar to low millimolar concentrations of ADP or ATP (Fig. 1), while equivalent concentrations of AMP, cAMP or soluble phosphoserine had no effect. Phospholipids were not required for this inhibitory effect, as assays using soluble TF without lipids yielded similar results. ADP and ATP had little to no impact on the amidolytic activities of Xa or VIIa/TF, so the effect is likely focused on recognition of factor X as a substrate by VIIa/TF. Interestingly, activation of factor X by factor VIIa without TF was only slightly reduced by ADP and was actually enhanced by ATP.
Conclusions: ADP and ATP inhibit factor X activation by VIIa/TF in a lipid-independent and TF-dependent manner. They may serve as allosteric regulators of VIIa/TF under certain conditions.

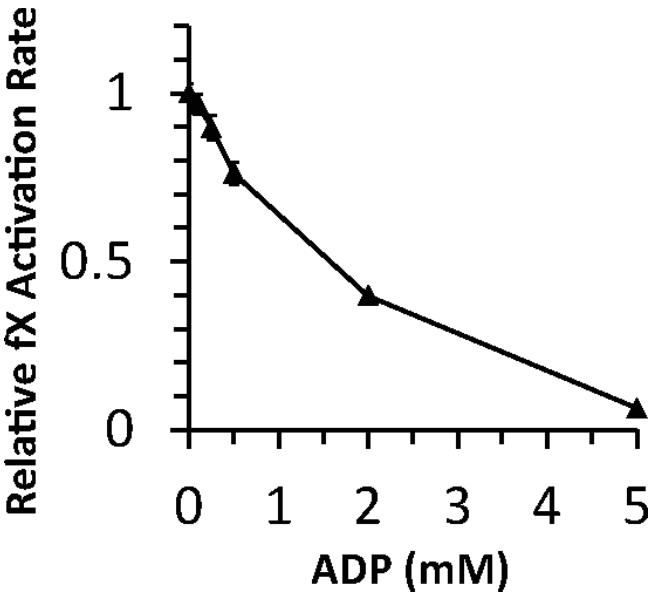

FIGURE 1 Factor X activation by factor VIIa + TF (relipidated in 85:15 PC:PS liposome) in the presence of ADP

PB 847 | Intracranial Hemorrhage in Neonates and Infants with Congenital Bleeding Disorders: The Experience of Çukurova University Hemophilia Center

B. Antmen, I. Sasmaz, B. Karagun, G. Leblebisatan, Y. Kilinc

Cukurova Universitesi, Pediatric Hematology, Adana, Turkey

Background: Intracranial hemorrhage (ICH) is a life threatening complication of hereditary bleeding disorders in childhood resulting in high rates of mortality and disabling sequelae.

Aims: In this study, we evaluated retrospectively of our patients with intracranial hemorrhage and compared with literature.

Methods: From 1995 to 2016, 16 patients with intracranial hemorrhage were diagnosed in Çukurova University Hemophilia Center. ICH episodes, the findings of physical examination, CT scan or MRI and treatment strategies including surgical interventions were evaluated retrospectively.

Results: We reported 17 episodes of ICH from 16 patients with hereditary congenital factor deficiencies (CFD). Age range was from 1 day to 24 months. Three patients were in the neonatal period. There were 12 patients with severe hemophilia A, 1 patients with severe hemophilia B, 1 patient with factor VII deficiency, two patients with factor X deficiency. Except one patient with hemophilia A, all patients had one ICH bleeding episode. One patient had a high titer inhibitor against factor VIII. The most important factor of ICH was trauma. A history of recent trauma was documented in 11 patients. Intracerebral and subdural hematoma were more frequently seen. The most frequent symptoms were seizure and loss of consciousness. The diagnosis of congenital bleeding disorders were established in 6 patients after intracranial hemorrhage who referred to our center with ICH. In 5 patients, hematoma was evacuated by surgery. The only one hemophilia patient died due to ICH and one patient presented late sequelae.

Conclusions: Intracranial hemorrhage is the most serious complication for hereditary bleeding disorders in childhood. Urgent establishing diagnosis and quick starting treatment with prompt doses of factors to initially maintain a normal level of circulating factor is mandatory. But, despite the prompt treatment, death and late sequelae can be seen in this patients group.

PB 848 | A Novel Mutation in the F7 Gene in a Tunisian Patient with Factor VII Deficiency

H. Elmahmoudi[1,2], C. Ouardani[1], M. Achour[1], A. Jlizi[3], H. Ben Neji[1], K. Zahra[1], B. Meddeb[1], A. Gouider[1]

[1]*UR14ES11, FMT, University of Tunis El Manar, Tunis, Tunisia,* [2]*National Center for Nuclear Sciences and Technologies, Tunis, Tunisia,* [3]*CHU La Rabta of Tunisia, Tunis, Tunisia*

Background: Factor VII deficiency (FVIID) is a rare genetic bleeding disorder caused by decreased or absence of FVII. Its clinical expression is highly variable and the severity of the hemorrhagic syndrome is not correlated with the residual levels of FVII activity. Mutation of the factor 7 (F7) gene is the primary cause of FVIID.

Were ported the case of A 50 years old woman, who was first diagnosed as having FVIID in the context of a preoperative assessment. She suffered from menorrhagia and hematoma. Her FVII activity level is of 6%.

Aims: Our aim is to provide the mutation analysis for this woman affected with FVIID.

Methods: DNA was extracted from peripheral blood samples from the proband using standard protocol. All exons and flanking sequence of the FVII gene were amplified with PCR and then subjected to direct sequencing.

Results: The diagnosis of FVIID was confirmed by genetic testing, which revealed a faux-sens mutation in exon 9 of F7 (c.1382T>C, p.P461L). To the best of our knowledge, this is a novel mutation that has not been reported previously. Our proband carries out the novel mutation in the homozygous state, additionally she was a heterozygous for the reported p. R413G mutation localized also in the same exon of *F7* gene.

Conclusions: More investigations of the novel mutation p.P461L are necessary in order to explain its impact on the Factor VII protein and also to identify the effect of its interactions with the reported mutation p. R413G on the protein structure which make us able to correlate with the phenotype data of our proband.

PB 849 | A Rat-human Cross-species Compatibility Study: Catalytic Efficiency for Activation of Rat FX Is Decreased for Human FVIIa Compared to Rat FVIIa

I. Tuneew[1], M. Kjelgaard-Hansen[2], J. Lund[1], L. Moreau Andersen[1]

[1]*Novo Nordisk A/S, Haemophilia Enzymology, Måløv, Denmark,* [2]*Novo Nordisk A/S, Haemophilia Biology, Måløv, Denmark*

Background: In vitro studies of cross species molecular interactions constitute an important tool for understanding the limits in pharmacological animal models used to test human proteins. Under normal conditions, activated coagulation factor VII (FVIIa) requires the binding of Tissue Factor (TF) to attain full catalytic activity towards activation of factor X (FX). Pharmacological doses of recombinant human FVIIa (hFVIIa) activate FX on the surface of activated platelets, independently of TF. Consequently, the use of animal models to test hFVIIa is dependent on the binding to and ability to activate endogenous FX.

Aims: Enzyme kinetic analyses of TF-dependent and TF-independent FX-activation by human and rat FVIIa using purified proteins and rat whole blood.

Methods: Recombinant rat FVIIa (raFVIIa) and soluble TF (sTF) were expressed and purified. Binding affinity between rat and human FVIIa-TF were assessed by surface plasmon resonance. Kinetic parameters for FVIIa proteolytic activity were evaluated for both the autologous (hFVIIa:hsTF, raFVIIa:rasTF) and heterologous (hFVIIa:rasTF, raFVIIa:hsTF) complexes, as well as for FVIIa alone, in the presence of phospholipids. Finally, pro-haemostatic effect of hFVIIa and raFVIIa were compared in rat whole blood thrombelastometry (RoTEM).

Results: hFVIIa was capable of activating rat FX both in the absence and presence of TF. However, the catalytic efficiency (k_{cat}/K_M) of FX-activation was 4-fold reduced for hFVIIa relative to the rat ortholog.

Moreover, hFVIIa demonstrated lower potency than raFVIIa in rat whole blood RoTEM. Binding kinetics of heterologous FVIIa:sTF complexes revealed considerably lower binding constants relative to autologous complexes.

Conclusions: hFVIIa is able of activating rat FX, although with a decreased catalytic efficiency compared to raFVIIa alone or in the presence of sTF. These kinetic parameters may explain the decreased potency of hFVIIa in the rat whole blood TEG analysis.

PB 851 | Investigations of Plasma-soluble Fibrin: Implications of Enhanced Functionally-assayed Fibrinogen Level, Erythrocyte Sedimentation, Fibrin Self-assembly, and Clot Lysis

D.K. Galanakis[1], C. Marmorat[2], L. Zhang[2], M. Golightly[1], M. Rafailovich[2]

[1]Stony Brook University, Pathology, Stony Brook, United States, [2]Stony Brook University, Materials Science and Engineering, Stony Brook, United States

Background: Fibrin(ogen) complexes, increased in various disorders, are poorly understood. We investigated complex-enriched (FgR) and depleted (FgD) fibrinogen (Fg) isolates each previously defined by its molecular imprint, solubility (4°), and fiber generation capacity.

Aims: Investigations in afibrinogenemic plasma (AP) of FgR and FgD effects on fibrin self-assembly, Fg assays, clot lysis, and erythrocyte sedimentation rate (ESR).

Methods: Isolates were ≥ 96% clottable, plasminogen-free, phenylmethylsulfonyl fluoride-treated, and their thrombin- or Reptilase-induced self-assembly was monitored by turbidity. Plasminogen activator-induced lysis of clots prepared in 20% AP containing 8 mM $CaCl_2$, and gel-sieved platelets $2x10^5$/μL, pH 7.4 was monitored by thromboelastography. For plasma Fg levels thrombin time (TT)- and prothrombin time (PT)-based assays were used. ESR of mixtures of 30% AP, pH 7.4, washed erythrocytes (Hematocrit 33%), Fg 1-4 mg/ml were monitored by a gravity-dependent procedure.

Results: FgR clots displayed shorter onset times and ~2x higher turbidity maxima, than those of FgD. By TT assay, FgR yielded Fg levels 2-2.5x higher (n=5) than predicted or those of FgD. By PT assay Fg levels were ~1.5x higher (n=2). Lysis was faster by FgR clots, n=3. For example, FgR and FgD clot lysis times were 12.67 and 37.75 minutes, respectively. FgR increased ESR, in contrast to FgD, n=4. For example, at Fg 3 mg/ml, ESRs were FgR 29, FgD 11, des-αC FgR 6, AP control 4 mm/hour, and at 0.5 and 4 FgR mg/ml, they were 5 and 47 mm/hour, respectively.

Conclusions: Faster FgR (than FgD) clot lysis is attributable to coarser fiber networks. TT-assayed Fg significantly above its actual level reflects rapid FgR self-assembly enhanced by plasma proteins. RBC-Fg links are αC-dependent, and accelerated ESR likely reflects the higher density of FgR- than of FgD-bearing RBCs. The plasma Fg level and ESR effects may also occur in clinical disorders with creased soluble fibrin and affect interpretations of corresponding test results.

PB 852 | Correlation Analysis of Standard Bethesda Method versus Modified Nijmegen Assay in Detecting Factor VIII Inhibitors, and Impact of Marginal Titer Inhibitors on FVIII Pharmacodynamics and Pharmacokinetics in Patients with Hemophilia A

A. Batorova[1], A. Morongova[2], D. Jankovicova[2], T. Prigancova[2], M. Mistrik[3]

[1]Faculty of Medicine, Comenius University and University Hospital, National Hemophilia Centre, Dept. of Hematology, Bratislava, Slovakia, [2]University Hospital, National Hemophilia Centre, Bratislava, Slovakia, [3]Faculty of Medicine, Comenius University and University Hospital, Dept. of Hematology, Bratislava, Slovakia

Background: Inhibitors of FVIII represent major complication of hemophilia replacement therapy.

Aims: To perform correlation analysis of inhibitors titres investigated by classical Bethesda and modified Nijmegen methods and to evaluate an impact of marginal inhibitor titres on pharmacodynamics and pharmacokinetics of administered FVIII.

Methods: We compared the results of 265 parallel inhibitor measurements by Bethesda and Nijmegen assay in 77 severe hemophilia A patients; out of them 60 patients with negative history of inhibitors (Group 1) and 17 patients with a history of inhibitors after inhibitor eradication by immune tolerance induction (ITI) (Group 2).

Results: Nijmegen method excluded a false positivity of low titer inhibitors between 0.51 and 0.9 BU/mL detected by Bethesda method and a good correlation between cut-off 0.7 Bethesda units/mL (BU/mL) and 0.5 Nijmegen BU/mL (NBU/mL) was confirmed. Comparison of 120 and 72 investigations of FVIII pharmacodynamics in Group 1 (inhibitor titre of 0.2±0.1 NBU/mL) and in Group 2 (inhibitor titre 0.5±0.15NBU/mL), respectively, showed in vivo recovery 109±19.4 (range 60-160)% and 86±32 (44-136)%, and incremental response 2.2±0,7 (1.4-3.5)%/1IU/kg and 1.6±0.6 (0.72-2.8)%/1IU/kg, respectively. Twenty pharmacokinetics studies in 20 patients from Group 1 and 30 studies in 14 patients from Group 2 showed a half life of 11,5±1,8 (8,2-16.2) h and 8.14±3.61 (2.9-16.4) h, respectively, and a clearance of 3.7±1.2 (2,6-6,5) mL/kg/h v.s. 6.48±2.24 (2.9-11.9) mL/kg/h, respectively ($p < 0.05$).

Conclusions: The Nijmegen assay is now a reference method for inhibitor testing with negativity cut-off 0.5 NBU/mL. Despite inhibitor eradication by the ITI in several patients inhibitor negativity does not correlate with pharmacodynamics and pharmacokinetics of FVIII suggesting the persitence of inhibitors undetectable by classical coagulation methods. For reliable ITI success evaluation more sensitive and specific methods are required.

PB 853 | Differences in Levels of Markers of Inflammation and Endotelial Damage between the Blood from Varicose Veins and Systemic Blood

A. Spirkoska[1], P. Poredos[2], M.K. Jezovnik[3]

[1]University Medical Centre Ljubljana, Department of Vascular Diseases, Ljubljana, Slovenia, [2]University Medical Centre Ljubljana, Department of Vascular Disease, Ljubljana, Slovenia, [3]University Medical Centre Ljubljana, Ljubljana, Slovenia

Background: Varicose veins (VV) represent one of the most frequent vascular diseases and are in most cases benign. However advanced disease is frequently associated with complications including thrombosis of the superficial veins. The pathogenic mechanisms responsible for development of thrombotic complication remain unclear.

Aims: The aim of our study was to investigate changes of blood constituents in VV and compare them to the systemic markers of inflammation and endothelial damage.

Methods: The study included 50 patients with primary VV. Local blood samples were taken from the leg, obtained from the dilated varicose great saphenous vein and systemic blood samples from the cubital vein.

Results: In VV, the following markers of inflammation and endothelial damage were significantly increased in comparison to systemic blood: hsCRP (2,05 ± 1,84 mg/L vs. 1,96 ± 1,90 mg/L, p =0,05), IL-6 (3.62 ± 2.74 ng/L vs. 2.30 ± 1.80 ng/L, p < 0,001), IL-8 (21,15 ±15,28 ng/l vs. 18,74±12,30 ng/L, p=0,025), vWF (118.4±27 % vs. 83.2±22 %, p< 0.05), NGAL (316,93±88,68 mg/mL vs. 299,18 ± 107,33 ng/mL, p=0,002), TNFR1 (0,52±0,13ng/mL vs. 0,50 ± 0,15 ng/mL, p=0,021), D-dimer (247,56 ± 410,24 ng/mL vs. 67,66 ± 325,74 ng/mL, p =0,019) and PAI-1 (3,32±3,56 IU/ml vs 2,99 ± 3,36 IU/ml, p=0,043).

Conclusions: In the blood of VV, some inflammatory markers and indicators of endothelial dysfunction are increased. This is most probably the consequence of deteriorated blood flow in dilated and tortuous superficial veins and increased venous pressure. Damage to the venous wall, which causes a chronic inflammatory response, together with the procoagulant properties of local blood may promote further progression of the disease and thrombotic complications.

PB 854 | Intracranial Hemorrhage in an Infant with Factor V Deficiency

E. Turkkan, F. Aygun, Y. Turkmenoglu

Okmeydani Research and Training Hospital, Pediatrics, Istanbul, Turkey

Background: Congenital deficiency of factor V is a rare, autosomal recessive hereditary coagulation disorder. Affected patients become symptomatic in early childhood with spontaneous or post-traumatic bleeding complications. Bleeding usually occurs when the factor V level is below 20% of normal.

Aims: In this report, the case of an infant with an intracranial hemorrhage due to congenital factor V deficiency is reported.

Methods: Two months old girl infant, presented with recurrent seizures. At admission, her coagulation parameters were as follows: activated partial thromboplastin time was 173.9 seconds (control 33 seconds), prothrombin time 65.6 seconds (control 14 seconds) with international normalized ratio of 5.6. Hemoglobin level was 5.7 gr/dl, platelet count 615.000/mm3.

Results: Subsequent coagulation assays revealed a plasma factor V activity of %9 with all other coagulation factors in the normal range. All other blood and chemistry tests were normal. Computerized tomography scan showed a parenchymal hematoma at the right superior fronto-parietal region, She was managed conservatively with fresh frozen plasma (FFP) and supportive management. Transfusions of FFP and platelet concentrate caused a temporary normalization of coagulation profile and then the hematoma was drained. Postoperatively, she was treated with FFP daily for two weeks.

Conclusions: We also wanted to take note that a patient with factor V deficiency can be seen with intracranial bleeding. Prolonged PT and PTT and normal platelet count would be an initial pointer towards an inherited disorder of coagulation such as factor V deficiency. As there is no specific concentrate available, the mainstay of treatment for severe factor V deficiency is FFP. Platelets also contain factor V, though their use should be reserved for life threatening bleeding and prior to surgery. Regular infusions of FFP are required in patients with a history of severe bleeding complications.

PB 855 | Detection of Specific and Non-specific Inhibitors in Patients of Hemophilia A

A. Naz[1], F. Ahmed[2], S. Ansari[2], T. Shamsi[2]

[1]National Institute of Blood Disease and Bone Marrow Transplantation, Coagulation and Hemostasis, Karachi, Pakistan, [2]National Institute of Blood Diseases and Bone Marrow Transplantation, Coagulation and Hemostasis, Karachi, Pakistan

Background: Inhibitors are antibodies that the immune system develops because it sees the infused clotting factor as a foreign substance that needs to be destroyed. People with severe hemophilia A are more likely to develop inhibitors.

Aims: To screen and measure the F.VIII antibodies, Dilute Russell's viper venom test (DRVVT) and anticardiolipin-antibodies (ACLA) in patients of moderate to severe Hemophilia A(HA).

Methods: This cross sectional and descriptive study was conducted at NIBD Karachi in accordance with Declaration of Helsinki. Inhibitor screening was performed by activated partial thromboplastin time (APTT), mixing studies using normal pool plasma immediately and after 2 hours incubation at $37C^0$ after receiving request of clinicians. Bethesda assay for quantification of factor VIII inhibitors, DRVVT, ACLA (IgM/IgG) were performed on samples which were positive with screening tests.

Results: Total 19 patients were included in this cross sectional with mean age 13 ± 8 SD. All these patients had prolonged APTT were later requested for inhibitors screening in lab .Out of 19, 11 patients (58%) were positive for specific inhibitors and results noted after 2hrs.

The remaining 8 patients (42%) were positive for non-specific inhibitors including 5 patients with positive ACLA IgM antibodies and 3 had DRVVT. Patients with positive specific inhibitors (36%) were low responders (< 5 Bethesda units) with a mean Bethesda units of 2.3+1.1 SD, while 7 patients (64%) were high responders (>5 Bethesda units) .Bleeding manifestation was moderate to severe in all patients with positive inhibitors.

Conclusions: The inhibitor development in patients with hemophilia A receiving recombinant factor VIII concentrates therapy is more crucial in first fifty therapies. The development of inhibitory antibodies in patients with HA still remains a major complication of therapy.

PB 856 | Interim Safety of a Long-acting Recombinant Factor VIIa (MOD-5014): A Phase 1 Study in Adult Subjects Following Subcutaneous Administration

G. Hart[1], R. Arison[1], L. Binder[1], G. Kenet[2]

[1]*OPKO Biologics, Kiryat Gat, Israel,* [2]*Sheba Medical Center, Tel Hashomer, Israel*

Background: OPKO is a clinical-stage company developing long-acting versions of therapeutic proteins utilizing CTP technology. This involves fusion of the hCG C-terminal peptide to proteins. The technology was clinically validated for several drugs while maintaining their biological activity. MOD-5014 is a long-acting form of recombinant FVIIa (rFVIIa-CTP) being tested for the first time in healthy volunteers using subcutaneous (SC) administration.

Aims: To assess the acute safety, tolerability, pharmacokinetic (PK) and pharmacodynamic (PD) profiles of single SC administration of escalating MOD-5014 doses in healthy subjects.

Methods: A single-dose, open-label, dose-escalating study was performed at MOD-5014 doses of 100, 200, 400 and 600 µg/kg, with 6 subjects in each dose group on active treatment and two receiving placebo. Dosing of all subjects in each cohort was followed by a 7-, 14- and 30-day safety observation period. Safety assessments included regular monitoring of adverse events (AEs), injection site reactions, vital signs and physical condition, as well as laboratory assessments such as hematology, biochemistry, coagulation panel and immunogenicity.

Results: The interim analysis included safety data for all subjects that were doses with 100, 200 and 300 µg/kg. The reported AEs were all considered unrelated or unlikely related to study medication and none led to premature study discontinuation. Laboratory assessments supported the tolerability of MOD-5014 treatment, and no significant overall changes were observed in hematology or chemistry profiles. There was no consistent or meaningful pattern for changes in any coagulation parameter during the study attributable to the study intervention.

Conclusions: MOD-5014 demonstrates promising safety and tolerability profile following single SC administration of escalating MOD-5014 doses (100, 200 and 400 µg/kg) in healthy subjects with no unexpected AEs considered to be related to MOD-5014.

PB 857 | Replacement Therapy in ALL Patients Treated with L-asparaginase

A. Freixo[1], P. Chorão[2], C. Monteiro[1], M. Carvalho[1], L. Gonçalves[1], F. Principe[2], J.E. Guimarães[2], M.C. Koch[1]

[1]*São João University Hospital, Thrombosis and Heamostasis Center, Porto, Portugal,* [2]*São João University Hospital, Heamatology Department, Porto, Portugal*

Background: L-Asparaginase (L-Asp) therapy is associated to both thrombotic and hemorrhagic events during treatment of acute lymphoblastic leukemia (ALL). In this setting, balance between the risk of bleeding and thrombosis requires a careful approach. In 2016 our group adapted the protocol described by Biddeci et al. for prophylactic replacement therapy with Fibrinogen (FI) Concentrate and Antithrombin (AT) Concentrate.

Aims: To evaluate transfusion needs and its impact after protocol implementation.

Methods: From 2014, a total of 26 patients (15 males, 11 females; median age 35 years, 22 Bprecursor-ALL, 4 T-ALL) were treated with intensive chemotherapy (22 HOVON 100, 4 CLCG protocol) comprising scheduled doses of L-Asp. During L-Asp treatment, Prothrombin Time, activated Partial Thromboplastin Time, FI and AT were determined in all patients. After 2016, we also introduced anti-Xa and Maximum Clot Firmness (MCF) at FIBTEM to help transfusion decision.

FI Concentrate was transfused when FI was < 100mg/dL (Clauss test) and MCF at FIBTEM thromboelastogram ≤5 and AT Concentrate was given when AT was < 50% and anti-Xa levels were < 0.2 with Low Molecular Weight Heparin (LMWH).

Results: 10 of the 26 patients were enrolled after the protocol implementation. There were no differences between the 2 groups (before and after protocol) concerning age, gender, ALL phenotype, risk, hyperleukocytosis, LDH level, SNC involvement, coagulation at diagnosis and treatment response. All patients but 1 started prophylactic LMWH during L-Asp therapy in the protocol group but only 7 (44%) were given LMWH before 2016. A total of 5 thrombotic and haemorrhagic events were recorded (only 1 in the protocol group, χ^2 p=0.35). In the protocol group AT levels were inferior (median 0.50 vs 0.64, p< 0.05) and these patients were less transfused, namely with plasma.

TABLE 1 Replacement therapy transfusion differences between the 2 groups. SD = standard deviation

	Before Protocol	After Protocol	
	(mean ± SD)	(mean ± SD)	t-test
Fibrinogen Concentrate (g)	3.6 ± 3.7	4.4 ± 4.7	0.664
Plasma (units)	1.1 ± 2.2	5.3 ± 7.2	0.046
Antithrombin Concentrate (UI)	3000 ± 2000	5100 ± 5850	0.204

Conclusions: Although there were no differences in haemorrhagic or thrombotic events, there was a trend to transfuse less when MCF at FIBTEM and anti-Xa levels were determined.

PB 858 | Hemarthrosis in Rare Factor Deficiencies

Z. Salcioglu[1], H. Şen[1], G. Aydoğan[1], F. Akıcı[1], Z. Başlar[2]

[1]*Kanuni Sultan Süleyman Education and Research Hospital, Pediatric Hematology and Oncology Clinic, Istanbul, Turkey,* [2]*Istanbul University, Cerrahpasa Medical School, Internal Medicine Department, Istanbul, Turkey*

Background: Hemarthrosis is severe and debilitating manifestations occurring in patients with rare factor deficiencies(RFDs). Despite its clinical importance, little has been published on the frequency and complication.

Aims: The aim of this study was to retrospectively collect data on patients affected with RFDs who had hemarthrosis.

Methods: In this study, our purpose is to assess 17 patients retrospectively, who were diagnosed and treated rare factor deficiencies presenting hemarthrosis between 1990 and 2016. Information of patients with hemarthrosis were retrieved from patient files and from the records contained in the electronic information processing environment created after 2005.

Results: We identified 24 episodes of hemarthrosis in 17 patients. Eleven (65%) of the patients were male and 6 (35%) were female. The median age of the group was 8 (range, one month to 24 year). The presenting ages were ranging between one month to 17 years. There were 9 patients with FVII deficiency, 3 patients with FX deficiency, 3 patients with afibrinogenemia, one patient with FV+FVIII deficiency, one patient with FXIII deficiency. All patients had one bleeding episode, except seven patients with six FVII and one FX deficiency. The levels of Factor:C were as follows: 10 (59 %) patients; < 1%, 3 (17.5%) patients; 1-5% and 4 (23.5 %) patients; >5%. Among 24 hemarthrosis, knee localization were the most common site (n=15, 62.5%). It is followed by ankle (n=5, 20.9%), elbow (n=2, 8.%) and shoulder (n=2, 8.3%). A history of trauma was documented in two cases (8.3%). Recurrent hemarthrosis were observed in five patients. All patients were submitted to replacement therapy. Prophylaxis was applied to 8 patients (47%).

Conclusions: Hemarthrosis is less common than hemophilia, although the characteristics of joint destruction are similar in the RFDs. In our study, we discussed the treatment hemarthrosis in RFDs and evaluated the conditions which required prophylaxis.

PB 859 | Amyloidosis Induced Abnormal Coagulopathy Associated with Multiple Coagulation Factor Deficiencies

U.Y. Malkan, H. Demiroglu, S. Aksu, I.C. Haznedaroglu, N. Sayinalp

Hacettepe University, Ankara, Turkey

Background: When amyloidosis leads to a coagulopathy, it is most often acquired factor X deficiency, but there are rare reports of amyloidosis being associated with other acquired factor deficiencies.

Aims: Herein, we aimed to report an amyloidosis induced abnormal coagulopathy associated with multiple coagulation factor deficiencies.

Methods: 51 years old women had applied to our clinic for investigation of her bleeding diathesis.

Results: 8 months before the admission, she had abnormal bleeding episode during a surgical procedure in another hospital. After this procedure, she also had gingival bleeding and extensive bleeding during upper gastrointestinal endoscopy. She had 8 healthy children with no history of abortion. She had hypermenorrhoea for last 8 months. In her laboratory test in our clinic was resulted as; hemoglobin 10 gr/dl, white blood cell $13x10^3$/µl, platelet $653x10^3$/µl, transferrin saturation %6, APTT 34 s, APTT mixing 28 s, INR 1.4, ALT 11 u/l, AST 26 u/l, creatinine 1.4 mg/dl, factor VII 61%, factor X 68%. Her thrombocyte aggregation was abnormal with ADP and epinephrine. In her blood film was normal. In her urine protein electrophoresis (PE) glomerular proteinuria was detected. Her serum PE was non-specific. Rectal biopsy resulted as focal active colitis, renal biopsy revealed renal amyloidosis. Colchicine was started for our patient.

Conclusions: In systemic AL-amyloidosis with acquired factor X deficiency, and the baseline factor X level is not predictive of bleeding risk. Although amyloidosis is frequently associated with factor deficiency, combined factor deficiencies are rarely seen with amyloidosis. Our patient had F-VII and F-X deficiencies as well as platelet aggregation disorder which lead to bleeding diathesis. To conclude, herein we have presented an amyloidosis induced abnormal coagulopathy case associated with multiple coagulation factor deficiencies.

PB 860 | Protein S Inhibits Apoptosis of Islet β Cells via Regulating BIRC3 Expression and AKT Signaling

T. Yasuma[1], A. Takeshita[2], K. Nishihama[2], C.N.D. Gabazza[1], M. Toda[1], K. Fujiwara[3], E. Harada[1], T. Kobayashi[3], Y. Yano[4], E.C. Gabazza[1]

[1]*Mie University Graduate School of Medicine, Immunology, Tsu, Japan,* [2]*Mie University Graduate School of Medicine, Metabolism and Endocrinology, Tsu, Japan,* [3]*Mie University Graduate School of Medicine, Pulmonary and Critical Care Medicine, Tsu, Japan,* [4]*Mie University Graduate School, Metabolism and Endocrinology, Tsu, Japan*

Background: Protein S (PS) is a vitamin K-dependent anticoagulant protein. It functions as a cofactor of activated protein C to inactivate FVa and FVIIIa. PS can also regulate inflammatory responses and apoptosis. The effect of PS on glucose tolerance is unknown.

Aims: To evaluate the effect of PS on streptozotocin(STZ)-induced diabetes by *in vitro* and *in vivo* studies.

Methods: *In vivo* experiments were performed using human PS transgenic and wild type(WT) mice . Diabetes was induced by i.p. injection of STZ for 5 consecutive days. Mice were categorized into 4 groups; WT/SAL, PS/SAL,WT/STZ and PS/STZ. Glucose tolerance test and glucose-induced insulin secretion test were performed. Mice were killed after 4 weeks of injection. Immunostaining of insulin was performed and apoptosis of β cells in islets was assessed by TUNEL

method. *In vitro* experiments were performed using MIN6 cells, murine β cell line. Apoptosis was induced with STZ in the presence of hPS or SAL. Apoptotic cells were assessed by flow cytometry after staining with annexin-FITC and PI. Phosphorylation of Akt/PKB and IκB was assessed after treating MIN6 cells with and without hPS (20 μg/ml) by flow cytometry and Western blot. Expression of anti-apoptotic proteins including BIRC3 were assessed by RT-PCR.

Results: Significant high insulin secretion and amelioration of glucose tolerance were observed in PS/STZ compared with WT/STZ. The insulin stained area was significantly increased, whereas the area with apoptotic cells was significantly decreased in PS /STZ compared with WT/STZ. Apoptosis of MIN6 cells induced by STZ was significantly suppressed in the presence of hPS. There was increased phosphorylation of Akt/PKB and IkB treated with hPS compared with controls. The expression of BIRC3 was significantly increased by hPS compared to controls.

Conclusions: hPS protects pancreatic islet β-cells from apoptosis and attenuates STZ-induced diabetes via stimulating the activation of the AKT pathway and by enhancing the expression of BIRC3 anti-apoptotic protein.

PB 861 | Spatiotemporal Modulation of the Protease Activated Receptors Signaling Protects against Diabetic Nephropathy

S. Ghosh[1], T. Madhusudhan[2], H. Wang[3], J. Manoharan[1], D. Gupta[1], B. Isermann[1]

[1]Institute of Clinical Chemistry and Pathobiochemistry, Otto-von-Guericke-University, OVGU, Magdeburg, Germany, [2]Center for Thrombosis and Hemostasis (CTH), University Medical Center Mainz, Mainz, Germany, [3]Tongji Medical College, Huazhong University of Science and Technology, Cardiology, Tongji Hospital, Wuhan, China

Background: Podocytes are terminally differentiated and form a crucial component of the glomerular filtration barrier. Cytoskeletal changes in these specialized epithelial cells lead to gross morphological changes in the podocyte foot processes and subsequent proteinuria in diabetic nephropathy (DN).

Aims: We recently established that the coagulation protease activated protein C (aPC) protects mice from diabetic nephropathy. aPC's cytoprotective response is achieved through its modulation of G protein coupled receptor-protease activated receptor (GPCR-PAR) signaling.

Methods: Here we show that PAR's cellular response can be regulated spatiotemporally by aPC. Upon ligand binding, PAR2 and PAR3 are activated at the plasma membrane and initiate downstream signaling as seen in IP-WB. Upon internalization into early endosomes (observed in PLA and colocalization analyses) their trimeric G protein signaling is maintained for an extended period of time leading to the activation of RhoAGTPases, which is detrimental to the complex cytoarchitecture of the podocytes.

Results: Sustained signaling of PARs leads to enhanced albuminuria, glomerular basement membrane (GBM) thickening and podocyte foot process effacement.Further details regarding the endocytotic signaling of PARs in podocytes will be presented.

Conclusions: The current studies are expected to provide new insight into the endosomal GPCR-G protein system, potentially identifying therapeutic approaches which are more effective than global targeting of cell surface signaling.

PB 862 | Overexpression of Protein S Exacerbates Carbon Tetrachloride-induced Liver Injury and Fibrosis in Mice

T. Totoki[1], C.N. D'Alessandro-Gabazza[2], R. Mifuji-Moroka[1], K. Nishihama[3], A. Takeshita[3], T. Yasuma[2], Y. Takahashi[4], K. Fujiwara[4], M. Toda[2], M. Nakamura[1], N. Horiki[1], M. Iwasa[1], T. Kobayashi[4], Y. Takei[1], E.C. Gabazza[2]

[1]Mie University School of Medicine, Gastroenterology and Hepatology, Tsu, Japan, [2]Mie University School of Medicine, Immunology, Tsu, Japan, [3]Mie University School of Medicine, Diabetes, Metabolism and Endocrinology, Tsu, Japan, [4]Mie University School of Medicine, Pulmonary and Critical Care Medicine, Tsu, Japan

Background: Protein S (PS) is a vitamin K-dependent plasma protein with anticoagulant, anti-inflammatory and anti-apoptotic properties. PS regulates the inflammatory response and apoptosis by binding and activating the (Tyro-3, Axl, Mer) TAM family of receptor tyrosine kinases. We have recently shown that protein S is involved in alcohol-induced liver injury by activating and inhibiting apoptosis of liver natural killer T cells. However, the effect of protein S on liver fibrosis is unknown.

Aims: The purpose of this study was to investigate the effect of protein S on liver fibrosis by comparing the degree of fibrosis induced by carbon tetrachloride (CCl4) between protein S overexpressing transgenic mice and wild type mice.

Methods: To induce liver fibrosis CCl4 was injected intraperitoneally twice a week for six weeks in wild type and protein S transgenic mice both under C57BL/6 background. The experimental protocol was approved by the Institutional Committee for Animal Investigation and followed approved international guidelines.

Results: Compared with wild-type mice, human protein S transgenic mice were more susceptible to both acute and chronic CCl4-induced liver injury, as shown by higher levels of plasma transaminases, greater numbers of apoptotic hepatocytes, and more extended necroinflammatory foci. Human protein S transgenic mice also displayed a greater degree of liver fibrosis after chronic CCl4 injection compared to wild-type mice. Wild-type mice infused with human protein S exhibited exacerbated liver inflammation and fibrosis.

Conclusions: Protein S is involved in acute and chronic liver injury and subsequent liver fibrosis induced by CCl4.

PB 863 | Signal through the Regulatory Subunits of PI3Kinase Endows Coagulation Protease Activated Protein C with Hormone Like Function

M. Thati[1,2], H. Wang[1], S. Ghosh[1], W. Dong[1], W. Ruf[2], B. Isermann[1]

[1]Institute of Clinical Chemistry and Pathobiochemistry, Otto-von-Guericke-University Magdeburg, Magdeburg, Germany, [2]Center for Thrombosis and Hemostasis (CTH), University Medical Center of the Johannes Gutenberg University, Mainz, Germany

Background: Impaired insulin signaling in renal epithelial cells (podocytes) disrupts the physiological unfolded protein response (UPR) causing maladaptive endoplasmic reticulum (ER) processing and renal dysfunction. Pathways rescuing impaired insulin signaling remain poorly understood.

Aims: Given the nephroprotective effect of the coagulation protease activated protein C (aPC) in acute and diabetic kidney disease (DKD), we here investigated the role of aPC in regulating maladaptive ER-signaling which is mechanistically linked to DKD.

Methods: Compensatory cytoprotective effect of aPC in DKD was evaluated in mouse models with podocyte specific genetic deletion of the insulin receptor (INSR) and its signaling intermediates PI3K p85α and p85β. After 26 weeks of persistent hyperglycaemia in both type-1 (Streptozotocin-induced) and type-2 (db/db mice) diabetic mice, markers of DKD were determined and tissue samples were isolated for *ex vivo* analysis.

Results: We find that aPC rescues impaired renal insulin signaling by restoring insulin-dependent ER-homeostasis. In mice lacking the INSR in podocytes aPC efficiently restores ER-homeostasis by selectively targeting INSR downstream signaling intermediates p85α and p85β. Akin to insulin, aPC signaling through p85-subunits promotes nuclear translocation of the cytoprotective ER-transcription factor sXBP1. Genome-wide mapping of XBP1-transcriptional regulatory patterns demonstrated induction of concordant UPR-configurations involved in maintenance of ER-proteostasis by insulin and aPC.

Conclusions: These results demonstrate that coagulation protease signaling co-opts components of the insulin signalosomes, p85α and p85β, to combat insulin-resistance through ER-reprogramming.

PB 864 | Rivaroxaban Ameliorates Neuroinflammation

M. Merker[1], S. Eichler[1], A.M. Herrmann[1], H. Wiendl[1], C. Kleinschnitz[2], K. Göbel[1], S.G. Meuth[1]

[1]University of Münster, Neurology, Münster, Germany, [2]University Hospital Essen, Essen, Germany

Background: Multiple Sclerosis (MS) is a demyelinating, autoimmune disorder in humans, characterized by immune cell trafficking into the central nervous system (CNS). Pathophysiological analyses revealed MS lesions with cellular infiltrates that lead to demyelination and axonal damage. As a consequence, studies concerning pathogenesis and therapy focused on these cells so far. While the triggers of MS have not yet been identified, recent studies suggest that the coagulation system might be involved in MS development. For instance, it was shown that various coagulation factors like fibrinogen, thrombin and factor XII are involved in neuroinflammation.

Aims: Factor X (FXa) is another central constituent of the coagulation cascade, which is also known to be involved in inflammation and several diseases, e.g. inflammatory bowel disease. Within this project, we therefore further addressed the role FXa in CNS autoimmunity, using its direct, highly selective inhibitor rivaroxaban in a MS animal model, experimental autoimmune encephalomyelitis (EAE).

Methods: Therefore, Lewis rats were immunized with myelin basic protein and subjected to rivaroxaban-containing diet (2.1 mg/kg body weight) 7 days prior immunization over the course of the experiment.

Results: Treatment with rivaroxaban renders rats less susceptible to EAE and was accompanied by reduced infiltration of T cells, as well as microglia activation within the CNS, as shown by immunohistochemistry. However, flow cytometry analysis showed no alterations in the peripheral immune compartment.

Conclusions: Altogether, our study further supports the hypothesis of a cross-link between coagulation and inflammation and identifies FX as a possible therapeutic target in neuroinflammatory diseases, like MS.

PB 865 | Novel Role of Protein S in Clot Retraction: Induction of Apoptosis in Activated Platelets

V. Pilli[1], A. Datta[1], E. Lazartigues[2], R. Majumder[1,3]

[1]Louisiana State University Health Science Centre, Biochemistry and Molecular Biology, New Orleans, United States, [2]Louisiana State University Health Science Centre, Pharmacology, New Orleans, United States, [3]LSU HSC, Biochemistry, New Orleans, United States

Background: Protein S (PS) is a gamma-carboxyglutamate domain-containing anticoagulant. PS also binds to phosphatidylserine residues of the cell membrane and, in so doing, promotes survival, apoptosis, and efferocytosis. Phosphatidylserine has a number of vital functions in platelet biology, including activation, clot formation, and clot retraction. In the current work, we elucidated a novel function of PS, *i.e.*, PS induces an apoptotic-like pathway in activated platelets that promotes clot retraction.

Aims: To investigate a role for PS in regulating activated platelets and clot retraction.

Methods: Platelet activation, ELISA, immunoblotting, FACS, clot retraction assay.

Results: We used an ELISA assay to demonstrate activation of platelets with extracellular ADP or with Par4 and convulxin. Activation of platelets induced mitochondrial depolarization, and a PS antibody reversed the mitochondrial depolarization. Further, PS induced an apoptotic-like pathway in the activated platelets, which we identified by immunoblotting and probing for phosphorylated p53, cleaved caspase, and cleaved PARP. This apoptotic-like pathway was inhibited by PS antibody. Clot retraction assays confirmed that the PS-mediated apoptotic-like pathway in the activated platelets is essential for clot retraction.

Conclusions: Our results demonstrated that, upon activation, platelets secrete PS into the extracellular milieu, it enhances phosphatidylserine exposure on the platelet surface, and PS induces an apoptotic-like pathway that is essential for clot retraction.

PB 866 | Thrombomodulin Dependent PC Activation Protects from a Senescence-like Tubular Phenotype in Diabetic Nephropathy (dNP)

M.M.A. Al-Dabet[1], K. Shahzad[1], I. Gadi[1], S. Kohli[1], A. Elwakiel[2], F. Bock[1], S. Nazir[1], B. Isermann[1]

[1]*Magdeburg University Hospital, Ins. of Clinical Chemistry and Pathobiochemistry, Magdeburg, Germany,* [2]*Magdeburg University Hospital, Ins. of Clinical chemistry and pathobiochemistry, Magdeburg, Germany*

Background: The coagulation protease activated protein C (aPC) protects against glomerular damage in dNP. While the importance of tubular damage in diabetic nephropathy (dNP) is increasingly recognized, the role of thrombomodulin (TM) dependent protein C activation for tubular cell damage in dNP remains unknown. Tubular cell damage in dNP is characterized by a proliferative arrest, senescence and hypertrophy. Whether these hallmarks are regulated by TM-dependent PC activation remains unknown.

Aims: To evaluate aPC's effect on tubular damage (tubular fibrosis, hypertrophy and senescence) in dNP.

Methods: Wild type (Wt) and $TM^{Pro/Pro}$ (mice with severely reduced TM-dependent protein C activation) mice were used in this study. Type-1 diabetes (DM) was initiated using streptozotocin (STZ) and maintained for 22 weeks, followed by tubular morphometrical and ex-vivo analyses.

Results: While detailed histological analyses did not reveal a basal phenotype in non-diabetic $TM^{Pro/Pro}$ mice, tubular damage was increased in diabetic $TM^{Pro/Pro}$-DM mice as compared to Wt-DM mice. In addition, $TM^{Pro/Pro}$-DM mice displayed increased expression of the tubular injury marker KIM-1 and prominent fibrosis (Masson´s Trichrome staining). Enhanced tubular damage in $TM^{Pro/Pro}$-DM mice is associated with increased tubular hypertrophy (higher tubular surface area and tubular size, but constant number of nuclei/tubule). The proliferation marker (Ki-67) was decreased in WT-DM mice as compared to non-diabetic WT mice, and was even further reduced in $TM^{Pro/Pro}$-DM mice. Tubular senescence (SA-βgal. staining and p21 expression) was enhanced in $TM^{Pro/Pro}$-DM mice.

Conclusions: These data shed the light on the tubular-specific protective effect of coagulation protease aPC. Furthermore, they establish a mechanistic relevance of aPC´s for the premature ageing-like phenotype in the diabetic renal tubular cells.

PB 867 | Coagulation Proteases are Potential Regulators in the Development of Exercise-associated arterial Endofibrosis

J.J. Posthuma[1], J.J.N. Posma[1], G. Schep[2], M. Bender[3], R. van Oerle[1], H. ten Cate[1], H.M.H. Spronk[1]

[1]*Cardiovascular Research Institute Maastricht, Maastricht University, Laboratory for Clinical Thrombosis and Haemostasis, Maastricht, The Netherlands,* [2]*Maxima Medisch Centrum, Sports medicine, Veldhoven, The Netherlands,* [3]*Maxima Medisch Centrum, Surgery, Veldhoven, The Netherlands*

Background: High performance athletes can develop symptomatic arterial flow restriction during exercise, caused by endofibrosis. The latter characterized by fibrosis of the external iliac artery (EIA). Pathophysiological processes involved in the development of endofibrosis are unknown. However, evidence shows that coagulation enzymes such as thrombin and factor Xa (FXa) can influence pro-fibrotic processes, mediated through activation of protease activated receptors (PARs).

Aims: To determine immunohistochemical characteristics of endofibrosis to elucidate the potential role of coagulation factors and PARs in development of endofibrosis.

Methods: 19 arterial endofibrotic specimens were collected during endarteriectomy. As control 20 arterial segments of the EIA were collected post mortem from individuals, with no medical history of cardiovascular disease. Acquired arteries were used for immunohistochemical staining. Data were analyzed using a Mann-Whitney U test. Data is presented as median [IQR]. A 2-tailed $p< 0.05$ was considered as statistically significant.

Results: Endofibrotic segments contained a neo-intima, resulting in intraluminal stenosis (42%[33-51]). Compared to controls, endofibrotic lesions were highly positive for collagen (47%[31-63] vs 17%[10-19]) and elastin (41%[28-46] vs 14%[11-21]). These findings were accompanied by significantly increased alpha smooth muscle actin (51%[45-58] vs 38%[23-47) (Fig 1), which morphologically appeared to be myofibroblasts in endofibrotic lesions; which were hardly present in controls. In addition, PAR1 (55%[35-65] vs 23%[11-28]) and PAR4 (41%[38-55] vs 13%[10-16]) were significantly upregulated and pro-enzyme form of their activators, prothrombin (18±9% vs 3±2%) and factor X (23%[16-28] vs 5%[4-6) were abundantly present.

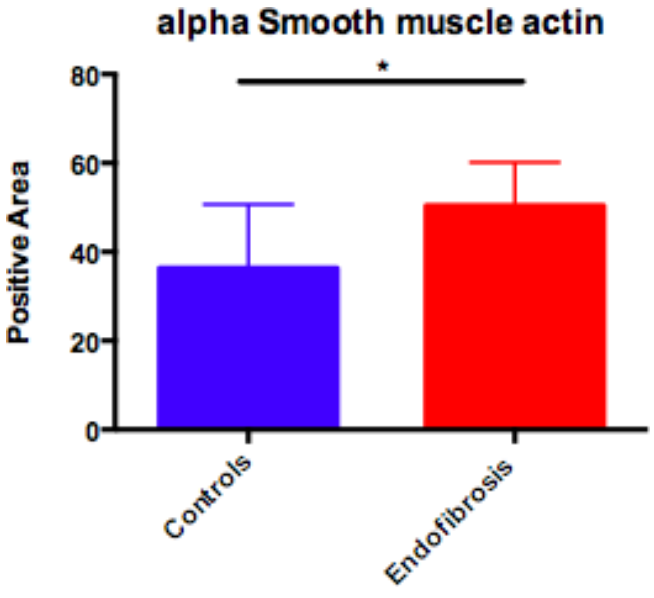

FIGURE 1: Significantly increased alpha Smooth muscle actin expression in endofibrotic lesions. *p<0.05

Conclusions: This is the first study to show that myofibroblasts might be a key factor in the development of endofibrosis. The special association suggests that these processes may be regulated through activation of PARs by coagulation proteases.

PB 868 | Biochemical and Pharmacological Differentiation of APC and Recombinant Thrombomodulin with Reference to the Effect on the Hemostatic and Fibrinolytic Processes

J. Fareed[1], D. Hoppensteadt[1], W. Jeske[2], O. Iqbal[1], S. Abro[1], D. Clarizio[1], S. Raghuvir[1], R. Wasmund[1], K. Tanaka[3], K. Tsuruta[3]

[1]*Loyola University Medical Center, Pathology, Maywood, United States,* [2]*Loyola University Medical Center, Thoracic and Cardiovascular Surgery, Maywood, United States,* [3]*Asahi Kasei Pharma America Corporation, Waltham, United States*

Background: Both the thrombomodulin and activated protein C play an important role in the regulation of hemostasis. Recombinant version of both the thrombomodulin (rTM) and activated protein C (rAPC) have been developed for clinical applications. Marked differences in their biochemical and pharmacological profiles exist.

Aims: The aim of this study is to demonstrate differences between a clinically developed rTM (ART-123, Asahi Kasei Pharma, Tokyo, Japan) and a plasma derived APC (Haematologic Technologies, Burlington, VT, USA).

Methods: The anticoagulant profile of both agents was investigated in native whole blood using the ACT, TEG and global anticoagulant profile using TT, PT and APTT assays at a concentration range of 0-10 ug/ml. The global anticoagulant profile and antiprotease (Xa and IIa) inhibitory studies were also carried out. A modified TEG system was used to study the modulation of fibrinolysis by these agents.

Results: In the ACT assays APC produced a much stronger anticoagulant effect in a concentration range of 0-10 ug/ml with a doubling time at 3 ug/ml. Whereas rTM produced marginal effects on this parameter. The TEG profile of APC exhibited much stronger anticoagulant effects in comparison to rTM. APC also facilitated fibrinolysis in contrast to rTM. rTM showed a concentration dependent inhibition of fibrinolysis. In the APTT assay APC produced a much stronger anticoagulant effect whereas TM produced relatively weaker effects. Both agents did not produce any modification of agonist induced platelet aggregation. In terms of anticoagulant potency the APC exhibited 70 ± 6 USP U/mg whereas the rTM was much weaker < 10 USP U/mg.

Conclusions: These studies demonstrate that APC is a much stronger anticoagulant in comparison to rTM. In addition both agents produced different modulation of fibrinolytic and hemostatic processes. These observations suggest that at therapeutic levels each of these agents may have differential impact on hemostatic balance.

PB 869 | Plasminogen-deficient Patients

H. Kızılocak[1], G.N. Özdemir[1,2], G. Dikme[1], B. Koç[1], G. İskeleli[3], B. Dönmez Demir[4], N.M. Christiansen[5], M. Ziegler[5], H. Özdağ[4], V. Schuster[5], T. Celkan[1]

[1]*Istanbul University, Cerrahpasa Medical Faculty, Pediatric Hematology-Oncology, Istanbul, Turkey,* [2]*Kanuni Sultan Süleyman Education and Research Hospital, Pediatric Hematology Oncology Dept., Istanbul, Turkey,* [3]*Istanbul University, Cerrahpasa Medical Faculty, Ophthalmology, Istanbul, Turkey,* [4]*Ankara University, Biotechnology Institute, Ankara, Turkey,* [5]*University of Leipzig, Leipzig, Germany*

Background: Congenital plasminogen (Plg) deficiency is a rare autosomal recessive disorder that leads to the development of ligneous membranes on mucosal surfaces.

Aims: Here we report our experience with local and intravenous fresh frozen plasma (FFP).

Methods: Our cohort consisted of 14 patients and their 8 first-degree relatives. The patients have been diagnosed between 3 months and 18 years of age, and the median age at the time of first clinical manifestation was 4.5 months (range 3 days to 12 months).

Results: Conjunctivitis is the main complaint, hydrocephalus and hearing loss follow. In 10 patients, ligneous membranes were surgically removed but all recurred. Nine patients were treated with intravenous and conjunctival FFP. Two patients had no complaints after treatment. Most patients needed transfusion with FFP every three weeks. Only one patient had severe endophthalmitis and lost vision in one eye before treatment. Two female patients and one male patient had undergone multiple surgeries for ligneous conjunctivitis despite being treated with FFP. The response rate to FFP treatment was 6/9 (66%). Another 8-year-old female with severe bronchial membranes was treated with FFP and t-PA through bronchoscopy. Venous thrombosis did not occur in any of the patients. Nine have consanguineous parents. The genetic evaluation of our patients revealed heterogeneous mutations as well as polymorphisms.

Conclusions: The diagnosis and treatment of Plg deficiency is challenging, and there is no consensus on treatment. Topical and iv FFP may be used with good clinical outcome.

PB 870 | Direct Factor Xa Inhibitor Apixaban Prevents Endothelial Activation and Damage Associated with Chronic Kidney Disease

S. Torramade-Moix[1], M. Palomo[1,2], M. Vera[3], A. Cases[3], G. Escolar[1], M. Diaz-Ricart[1]

[1]*CDB, Hospital Clinic, IDIBAPS, University of Barcelona, Hemotherapy and Hemostasis, Barcelona, Spain,* [2]*Josep Carreras Leukaemia Research Institute, Hospital Clinic, University of Barcelona Campus, Barcelona, Spain,* [3]*Hospital Clinic, IDIBAPS, University of Barcelona, Nephrology, Barcelona, Spain*

Background: Chronic kidney disease is a multisystemic condition resulting in endothelial dysfunction and enhanced cardiovascular risk. We have established a model of endothelial dysfunction in uremia characterized by a proinflammatory and prothrombotic phenotype and enhanced oxidative stress. Apixaban is a direct oral anticoagulant inhibiting factor Xa. Anti-Xa strategies may exert anti-inflammatory actions on some cell lineages.

Aims: To explore the protective effect of apixaban on the endothelial dysfunction associated with uremia.

Methods: Endothelial cells were exposed to media containing sera from healthy donors or uremic patients, in the absence and presence of apixaban (from 10 to 100ng/mL), to evaluate changes in: the expression of VCAM1 and ICAM1 on the surface, presence of von

Willebrand Factor (VWF) on the extracellular matrix (ECM), presence of intracellular eNOS, and the production of reactive oxygen species (ROS).

Results: Exposure of cells to uremic media resulted in an increased expression of VCAM1 and ICAM1 at their surface (of 47% and 65% vs controls); production of ECM enriched with VWF (increase of 30% vs control); decrease of intracellular eNOS (of 35% vs control) and higher production of ROS (% of increase of 35% vs control). Preventive treatment of cells with apixaban inhibited the endothelial damage caused by uremic media. Levels of VCAM1, ICAM1, VWF and ROS were diminished to control levels and eNOS was normalized ($p< 0.01$ for all parameters with 60ng/ml apixaban).

Conclusions: Apixaban prevented endothelial damage triggered by the uremic milieu, exhibiting anti-inflammatory and antioxidant properties. The protective effect of apixaban was noticeable at concentrations lower than those currently used for anticoagulation. Apixaban may provide an alternative therapeutic approach to prevent the endothelial dysfunction caused by uremia, and also by other pathological conditions with elevated cardiovascular risk.

PB 871 | A Factor X Activator from Caterpillar Triggers Cell Survival on Fibroblasts in Response to Serum Deprivation by Inhibition of Apoptosis

M.P. Alvarez-Flores[1,2], R.V. Bosch[1], D.A. Maria[1], A.M. Chudzinski-Tavassi[1,2]

[1]*Butantan Institute, Laboratory of Biochemistry and Biophysics, Sao Paulo, Brazil,* [2]*Butantan Institute, Center of Excellence in the New Target Discovery, Sao Paulo, Brazil*

Background: Fibroblasts are the main cellular component of connective tissues and play important roles in health and disease through the production of extracellular matrix (ECM) components. rLosac is a recombinant hemolin with factor X (FX) activation activity from the caterpillar *Lonomia obliqua*. In HUVECs, rLosac induced proliferation and cell survival.

Aims: To study the effect of rLosac on cell survival and cell migration of fibroblast submitted to serum deprivation.

Methods: For cell survival: MTT assay. For cell cycle, apoptosis, production of reactive oxygen species (ROS) and mitochondrial membrane potential (MMP): flow cytometer. For morphological changes: immunocytochemistry and scanning and transmission electron microscopy. For cell migration: wound scratch test assay.

Results: A reduction of Losac's activity on FX lead to a reduction on cell survival activity. rLosac has activity in serum deprivation conditions but not when nutrient is sufficient and caused an apparent dose-dependent increase in cells in the S phase of the cell cycle and a significant reduction of cells with fragmented DNA. Furthermore, treatment with rLosac results in a significant decrease in the production of ROS and MMP and up-regulation of Bcl-2 and a down-regulation of Bax protein levels. rLosac treatment reduces the morphological changes induced by prolonged serum deprivation (apoptotic bodies, nucleus fragmentation, cytoplasmic vacuolization and loss of ECM organization). Moreover, rLosac could enhance wound healing *in vitro*.

Conclusions: Altogether, these findings suggest that rLosac strongly induces cellular protection in conditions of stress by serum deprivation by inhibiting apoptosis. This finding opens a new perspective to further understand the role of this FX activator during cellular processes such as cell migration. Funding Agencies: Fapesp, Capes.

PB 872 | Protective Effect of Protein S against the Development of Diabetic Nephropathy in Mice

A. Takeshita[1], K. Nishihama[1], T. Yasuma[1,2], K. Fujiwara[3], E. Harada[2], C.N. D'Alessandro-Gabazza[2], M. Toda[2], T. Kobayashi[3], Y. Yano[1], E.C. Gabazza[2]

[1]*Mie University Graduate School of Medicine, Diabetes, Metabolism and Endocrinology, Tsu, Japan,* [2]*Mie University Graduate School of Medicine, Immunology, Tsu, Japan,* [3]*Mie University Graduate School of Medicine, Pulmonary and Critical Care Medicine, Tsu, Japan*

Background: Diabetic nephropathy (DN) has long been recognized as the leading cause of end-stage renal disease, but the efficacy of available strategies for the prevention of DN remains poor. Protein S (PS) is a vitamin K-dependent anticoagulant protein. It functions as a cofactor of activated protein C to inactivate activated factor V (FVa) and activated factor VIII (FVIIIa). PS can also regulate inflammatory responses and apoptosis.

Aims: We evaluated the effect of PS on STZ -induced DN.

Methods: In one experiment, human PS (hPS) transgenic mice and wild type (WT) mice underwent unilateral nephrectomy and after 4 weeks of recovery, diabetes was induced using intraperitoneal injection of STZ. Mice were categorized into 4 groups: WT/saline (WT/SAL), hPS/saline (hPS/SAL), WT/STZ, hPS/STZ groups. After 8 weeks of hyperglycemic condition, the mice were sacrificed.

In a separate experiment, WT mice underwent unilateral nephrectomy and were made diabetic with STZ or kept as controls with saline after 4 weeks of recovery. Mice were then treated with either hPS or saline subcutaneously through osmotic minipumps for 4 weeks before they were sacrificed. Mice were categorized into 4 groups: saline/pump saline (SAL/p-SAL), saline/pump hPS (SAL/p-hPS), STZ/pump saline (STZ/p-SAL), STZ/pump hPS (STZ/p-hPS).

Results: In one experiment, compared with WT/STZ group, plasma creatinine concentration and the renal tissue concentration of hydroxyproline were significantly lower and renal fibrosis was histologically improved in hPS/STZ group.

In another experiment, the plasma creatinine concentration and the renal tissue concentration of collagen and hydroxyproline were significantly lower and renal fibrosis was histologically improved in STZ/p-hPS group compared with STZ/p-SAL group. Relative renal mRNA expression of TGF-β1 was significantly elevated, whereas that of podocin was reduced in STZ/p-SAL group compared with STZ/p-hPS.

Conclusions: Administration of exogenous PS or kidney overexpressing PS can prevent the development of DN.

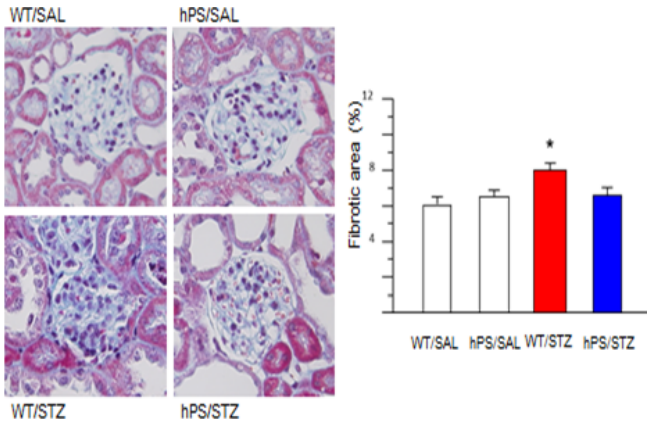

FIGURE 1 Overexpression of hPS is protective against DN. Collagen deposition was assessed by Masson trichrome stain. *P<0.05 vs. hPS/STZ group

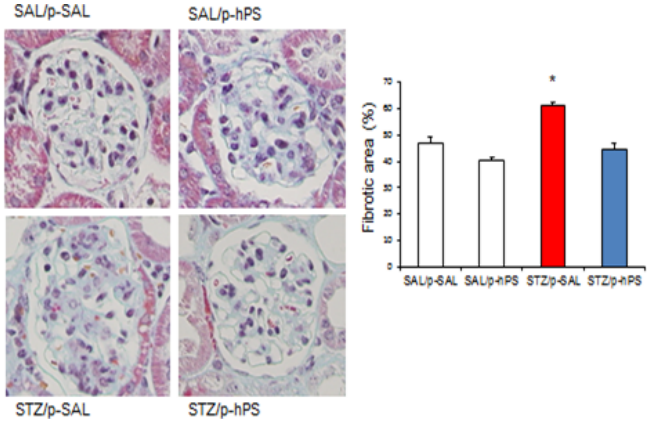

FIGURE 2 Exogenous hPS attenuates the development of DN. Collagen deposition was assessed by Masson trichrome stain. *P<0.01 vs. STZ/p-hPS group.

PB 873 | A Significant Change in Laboratory Markers of Thrombosis Very Early in the First Trimester of Pregnancy May be Linked to a Concurrent Increase in Estradiol

C.N. Bagot[1], E. Leishman[1], C.C. Onyiaodike[2], F. Jordan[2], D.J. Freeman[2]

[1]*Glasgow Royal Infirmary, Haematology, Glasgow, United Kingdom,* [2]*University of Glasgow, Institute of Cardiovascular and Medical Sciences, Glasgow, United Kingdom*

Background: Pregnancy is associated with an increased risk of venous thrombosis. Previous data have shown that levels of laboratory markers of thrombotic risk change during normal pregnancy, but it is unknown exactly how early in pregnancy these changes occur. Furthermore, pregnancy associated thrombosis may be secondary to high estrogen levels, resembling users of exogenous estrogen, however estrogen levels remain uncharacterised in very early pregnancy.

Aims: To characterise laboratory markers of thrombosis and estradiol during the early first trimester.

Methods: Blood samples were taken from 22 women, just prior to conception and five times during very early pregnancy (up to Day 59 gestation), who were undergoing natural cycle *in vitro* fertilization and gave birth at term following a normal pregnancy.

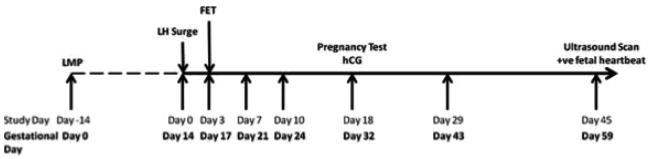

FIGURE 1 Timeline of blood sampling

The study was approved by the local medical ethics committee and informed consent obtained. Analysis included thrombin generation, Protein S, factor VIII, D-dimer, fibrinogen and estradiol. To counter inter-individual variability, the change between the pre-pregnant and pregnant state in each parameter was measured over time.

Results: Three thrombin generation parameters (Endogenous Thrombin Potential, Peak thrombin, Velocity index), Protein S and fibrinogen significantly changed from baseline by approximately Day 32 gestation ($p < 0.01$) and D-dimer by Day 43 ($p < 0.01$), which for all, persisted to Day 59 ($p < 0.0001$). Factor VIII increased by Day 59 ($p < 0.0001$). Estradiol significantly increased by Day 43 gestation ($p=0.003$) with a non-significant mean increase of 67% and 130% by Day 24 and Day 32 respectively. All laboratory markers of thrombosis correlated significantly with estradiol ($p < 0.001$).

Conclusions: We are the first to demonstrate that laboratory markers of thrombosis begin to change during the 5th gestational week, and that this change may be linked to a concurrent early rise in estradiol. Women at high risk of thrombosis should commence thromboprophylaxis as early as possible in pregnancy.

PB 874 | Analysis of Estrogen Mediated Expression of TFPI-2 by miRNAs in Breast Cancer Cells

M.S. Andresen[1,2], N. Iversen[3], M. Tinholt[1,3], C.F. Myklebust[1,2], K.K. Sahlberg[4,5], B. Stavik[1,2], P.M. Sandset[1,2,6], G. Skretting[1,2]

[1]*Oslo University Hospital, Rikshospitalet, Dept. of Hematology, Oslo, Norway,* [2]*Oslo University Hospital, Rikshospitalet, Institute of Internal Medicine, Oslo, Norway,* [3]*Oslo University Hospital and University of Oslo, Dept. of Medical Genetics, Oslo, Norway,* [4]*Oslo University Hospital, Institute for Cancer Research, Dept. of Cancer Genetics, Oslo, Norway,* [5]*Vestre Viken, Dept. of Research, Drammen, Norway,* [6]*University of Oslo, Institute of Clinical Medicine, Oslo, Norway*

Background: Tissue factor pathway inhibitor type 2 (TFPI-2) has been linked with breast cancer pathogenesis. We have recently reported that estrogens significantly upregulated TFPI-2 expression in a breast cancer cell line (MCF-7) through the involvement of estrogen receptor alpha (ERα). Accumulating evidence indicates that activation of the

ERα signalling by estrogens may modulate the expression of target genes indirectly through microRNAs (miRNAs).

Aims: To identify miRNAs involved in the estrogenic regulation of TFPI-2.

Methods: miRNA prediction algorithm was used to identify miRNAs potentially regulating *TFPI2* expression. Pearson correlation analysis of *TFPI2* and miRNA expression (SurePrint G3 Human GE 8x60K one-color microarray, Human miRNA Microarray Kit, Agilent Technologies) was performed in a breast cancer data set of 151 patients. Functional studies of selected miRNAs will be performed in MCF-7 cells in order to examine their effect on *TFPI2* expression using qRT-PCR. Potential effects of 17β-estradiol and/or the ERα antagonist fulvestrant on relative miRNA levels in MCF-7 cells will also be assessed by qRT-PCR. To investigate the interaction of selected miRNA(s) with their predicted target sites within the *TFPI2* 3‘ untranslated region (UTR), a luciferase reporter construct containing the full length *TFPI2* 3‘ UTR will be co-transfected with miRNA mimics and luciferase activity will be measured.

Results: Negatively correlated miRNAs having potential target sites in the *TFPI2* 3‘ UTR and also previously reported to be dysregulated by ER were found in tumors of ER positive breast cancer patients (miR-15a, miR-16, miR-23a, miR-93, and miR-195).

Conclusions: The identification of several miRNAs within the 3‘ UTR of *TFPI2* as being negatively correlated with the TFPI-2 level indicates their involvement in the regulation of the gene. Cell experiments are in progress and the results will be presented.

PB 875 | Comparative Studies on the Inhibition of Thrombin by Recombinant Thrombomodulin in Activated Protein C and Whole Blood Plasma

J. Fareed[1], W. Jeske[2], D. Hoppensteadt[1], J. Walenga[2], P. Maia[1], K. Tanaka[3], K. Tsuruta[3]

[1]Loyola University Medical Center, Pathology, Maywood, United States, [2]Loyola University Medical Center, Thoracic and Cardiovascular Surgery, Maywood, United States, [3]Asahi Kasei Pharma America Corporation, Waltham, United States

Background: Recombinant thrombomodulin (rTM) and activated protein C (APC) are important modulators of coagulation and fibrinolysis. Both agents have been developed for various clinical indications. Beside their direct effect on coagulation, these agents also modulate other components of hemostatic processes to mediate their pharmacologic actions.

Aims: The aim of this study is to compare the differential inhibition of thrombin generation (TG) by a clinically available rTM (ART-123, Asahi Kasei Pharma, Tokyo, Japan) and a plasma derived APC (Haematologic Technologies, VT, USA).

Methods: Native blood from healthy volunteers (n=5) was supplemented with rTM and APC at levels of 0-2.5 ug/ml. TG was triggered by adding diluted APTT (Triniclot) and reaction was stopped after 3 minutes. TG markers such as F1.2 and TAT were measured using ELISA methods. In the citrated plasma studies both agents were supplemented at a 0-2.5 ug/ml. TG studies were carried out using a fluorimetric assay (TGA, Techniclone, Vienna, Austria). Lag time peak TG and area under the curve (AUC) were measured. The IC50 values for each of the agents was calculated.

Results: In the whole blood systems both the APC and rTM produced a concentration dependent inhibition of TG markers such as F1.2 and TAT. APC produced a slightly stronger inhibition of TG as measured by F1.2, IC50 = 0.55 ug/ml compared with thrombomodulin, IC50 = 0.70 ug/ml. In the plasma based system the IC50 for peak thrombin inhibition was 0.46 ug/ml for APC and 0.97 ug/ml for rTM. Additional differences in the lag phase and AUC profiles were also noted.

Conclusions: Beside the direct anticoagulant effects both the APC and rTM are capable of inhibiting the TF mediated thrombin generated in whole blood and plasma based systems. APC exhibits slightly stronger inhibitory effects in TG assays in both plasma and whole blood. These studies suggest that modulation of thrombin and other proteases contribute to the clinical effects of both rTM and APC.

PB 876 | Activation of the Hepatocyte Growth Factor/c-met Pathway during Experimental Envenomation of Rats with Bothrops Jararaca or Crotalus Durissus Terrificus Snake Venoms

B. Prezoto[1], L. Gonçalves[2], S. Sampaio[2], I. Sano-Martins[2]

[1]Butantan Institute, Pharmacology, Sao Paulo, Brazil, [2]Butantan Institute, Physiopathology, Sao Paulo, Brazil

Background: Hepatocyte growth factor (HGF)/c-met pathway regulates cell growth, motility, and morphogenesis of various types of cells, protecting epithelial and non-epithelial organs via anti-apoptotic and anti-inflammatory signals. Thrombin is the main physiological activator of this pathway, and in some pathological conditions such as disseminated intravascular coagulation, increased plasma concentration of active HGF have been reported.

Aims: Since consumption coagulopathy and thrombin generation are usual phenomena in viperid snakebites, we hypothesized that circulating HGF would be increased in plasma of rats envenomated with Crotalus durissus terrificus (Cdtv) or Bothrops jararaca (Bjv) venoms.

Methods: Three experimental groups (n=5, each) of male adult Wistar rats were injected (s.c.) with 500 µL containing (a) 0.9% NaCl solution or sub-lethal doses (1.6 mg/kg) of Cdtv (b) or Bjv (c). After 3 hours, hemostatic function of recalcified whole blood samples was analyzed by means of the INTEM profile of the thromboelastometric assay. Simultaneously, plasmatic fibrinogen (colorimetric assay) and total HGF (ELISA) were evaluated.

Results: Total HGF concentrations were almost 6-fold higher ($p < 0.05$) in both Bjv- and Cdtv-injected groups, when compared with control values (68 ± 18 pg/mL). While in Bjv group these increased levels of total HGF correlated well with severe coagulopathy and hypofibrinogenemia, in the Cdtv group only moderated hypofibrinogenemia was observed.

Conclusions: Presence of thrombin-like toxins in these venoms and of prothrombin and factor X activators in Bjv would explain at least in part the significant increase in plasma concentration of HGF. In addition, active factor X is reported to release soluble HGF from

granulocytes. This study would shed new light on some aspects of the pathophysiological mechanisms induced by these venoms.

PB 877 | Targeted Inhibition of Activated Protein C by an Exosite Antibody to Treat Hemophilia

X.-Y. Zhao[1], A. Wilmen[2], X. Wang[3], L. Linden[2], U. Egner[4], J. Glueck[2], K. McLean[1], S. Yegneswaran[1], X. Jiang[1], V. Evans[1], I. Ivens[1], Y. Xu[1], A. Hesslein[5], V. Laux[6], C. Patel[1]

[1]*Bayer, US Innovation Center, San Francisco, United States,* [2]*Bayer AG, Biologic Research, Cologne/Wuppertal, Germany,* [3]*Tsinghua University, Beijing, China,* [4]*Bayer AG, Structural Biology, Berlin, Germany,* [5]*Bayer, Biologic Development, Berkeley, United States,* [6]*Bayer AG, TRG-Cardiology/Hematology, Wuppertal, Germany*

Background: Activated Protein C (APC), a plasma serine protease, can have antithrombotic and cytoprotective functions.

Aims: To test the hypothesis that anti-APC antibodies (Abs) specifically inhibiting its anticoagulant function but not cytoprotective activities have desirable therapeutic effects for hemophilia therapy

Methods: Surface plasmon resonance (SPR) and X-ray crystallography were used for the Ab binding and epitope mapping studies. Ab activity was measured using activated partial thromboplastin time (APTT) and thrombin generation assay (TGA). Ab efficacy was tested in induced hemophilia A cynomolgus monkeys.

Results: The 2 types of anti-APC monoclonal Abs selected (type I and type II) bound to APC at ~10 nM binding affinity (KD) by SPR. X-ray crystallography studies reveal that they bind to distinct epitopes on APC (type I on active site vs type II on exosite). The type I Ab was shown to fully block APC enzyme activities and promote thrombin generation by TGA and plasma clotting by APTT. The type II Ab was shown to interfere with APC-mediated cleavage of the physiologic substrates activated factor VIII (FVIII) and activated factor V, thereby preserving both cofactors' activities in APC-mediated inactivation assays using purified systems as well as plasma-based assays. Most importantly, the type II Ab preserved APC's cytoprotective function as measured by histone-mediated cytotoxicity assay in primary human umbilical vein endothelial cells. In normal monkeys, the type I Ab was found to cause adverse effects in the vascular systems. In contrast, the type II antibody was well tolerated and showed prophylactic and dose-dependent efficacy at 3, 10, and 30 mg/kg in anti-FVIII Ab-induced hemophilia A monkeys in a 10-day study.

Conclusions: Our data suggest that cytoprotective function of APC is important and that the type II anti-APC exosite Ab can specifically inhibit APC's anticoagulant function without compromising its cytoprotective function, offering therapeutic opportunities for persons with hemophilia.

PB 878 | Silencing of Anticoagulant Protein C Evokes Low Incident but Spontaneous Atherothrombosis in Apolipoprotein E Deficient Mice

M. Heestermans[1,2], A.B. Ouweneel[3], R.A.F. Verwilligen[3], M. Gijbels[4], P.H. Reitsma[1,2], M. van Eck[3], B.J.M. van Vlijmen[1,2]

[1]*Leiden University Medical Center, Department of Internal Medicine, Division of Thrombosis and Hemostasis, Leiden, The Netherlands,* [2]*Leiden University Medical Center, Einthoven Laboratory for Experimental Vascular Medicine, Leiden, The Netherlands,* [3]*Leiden Academic Centre for Drug Research, Division of Biopharmaceutics, Cluster BioTherapeutics, Leiden, The Netherlands,* [4]*Amsterdam Medical Center, Department of Pathology, Amsterdam, The Netherlands*

Background: Mouse atherosclerosis models do not spontaneously develop atherothrombotic complications.

Aims: To investigate whether acute silencing of natural anticoagulation allows pre-existing atherosclerotic plaques to progress towards an atherothrombotic phenotype.

Methods: In atherosclerotic apolipoprotein E (*Apoe*-/-) deficient mice on a Western-type diet, protein C was acutely lowered using small interfering (si) RNA (si*Proc*).

Results: Upon lowering of protein C levels, in a pilot study 1 out of 4 *Apoe*-/- mice displayed a large, organized, and fibrin- and leukocyte-rich thrombus on top of an advanced atherosclerotic plaque in the aortic root. Although again at low incidence, similar thrombi at the same location were observed in a second independent experiment (3/25 mice). In addition, 7/25 si*Proc* mice featured clots in the left atrium of the heart. Within this group of 25 mice, platelets numbers ($1629x10^9$ platelets/L ±70 vs. $1832x10^9$ platelets/L ±58; $P>0.05$, si*Proc* treated mice without thrombi vs. si*Proc* treated mice with thrombi, resp.), fibrinogen levels (178 U/dL ±8 vs. 189 U/dL ±14; $P>0.05$), and thrombin-antithrombin complex levels (45 ng/L ±3 vs. 43 ng/L ±5; $P>0.05$) were comparable. Other organs (liver, lungs, kidneys) did not show thrombotic lesions. Moreover, aortic plaques in si*Proc* mice with thrombi had collagen content (18.6% ±1.3 vs 15.6% ±1.9; $P>0.05$), necrotic area (20.9% ±1.1 vs. 23.3% ±3.9; $P>0.05$) and macrophage content (3.7% ±0.3 vs. 4.0% ±0.9; $P>0.05$) comparable to plaques in si*Proc* mice without thrombi. Albeit again at low incidence, in a third independent experiment identical thrombi in the aortic root (6/20 mice) and clots in the left atrium (5/20) were observed.

Conclusions: Transient silencing of *Proc* in *Apoe*-/- mice creates a condition that allows the occurrence of spontaneous low-incidence atherothrombosis. Lowering natural anticoagulation in atherosclerosis models may help to discover factors which increase atherothrombotic complications.

PB 879 | Protection of the Endothelial Protein C Receptor (EPCR) against Inactivation by P.*falciparum* Erythrocyte Membrane Protein 1 (PfEMP1) Domains with a Non-inhibitory Anti-EPCR Antibody

J. Barber-Singh[1], E.A.M. Bouwens[1], J.E.V. Petersen[2,3], K.F.E. Lee[4], P. Cowan[4], H. Gock[4], H. Weiler[5], K. Fukudome[6], L. Turner[2,3], T. Lavstsen[2,3], L. Mosnier[1]

[1]*The Scripps Research Institute, Department of Molecular Medicine, La Jolla, United States,* [2]*University of Copenhagen, Department of International Health, Immunology & Microbiology, Copenhagen, Denmark,* [3]*Rigshospitalet/Copenhagen*

University Hospital, Department of Infectious Diseases, Copenhagen, Denmark, [4]St. Vincent's Hospital, Department of Medicine, Melbourne, Australia, [5]Blood Research Institute, Milwaukee, United States, [6]Saga University Organization for General Education, Department of Life Science, Saga, Japan

Background: Expression of PfEMP1 variants during *P. falciparum* infection that bind to EPCR is associated with severe malaria complications. The inhibition of (activated) protein C ((A)PC) binding to EPCR by PfEMP1 domains is considered to be a major contributing factor. Thus, approaches to protect normal EPCR functions may attenuate severe malaria symptoms.

Aims: To identify a functional non-inhibitory EPCR antibody (Ab) that specifically blocks PfEMP1 binding but permits normal EPCR-dependent functions of (A)PC.

Methods: PfEMP1 domain CIDRa1.1 binding to EPCR was determined by ELISA, on EA.hy926 endothelial cells (EC) and in human EPCR (hEPCR) transgenic mice. EPCR function was determined by PC activation, PAR1 cleavage and barrier function on EC.

Results: Of the 19 anti-EPCR Abs screened, 4 Abs demonstrated significant inhibition of CIDRa1.1 binding to sEPCR with negligible effects on APC binding. Of the 4 Abs, #19 showed the most favorable dose response for selective inhibition of CIDRa1.1 but not APC binding to sEPCR and EC. Ab #19 restored EPCR-dependent protein C activation on EC that was inhibited by CIDRa1.1. Ab #19 also improved APC-mediated PAR1 cleavage on EC. In EC barrier assays as a measure of EPCR-dependent APC cytoprotective effects, #19 had no effect on APC's barrier protective activity in the absence of CIDRa1.1 and protected EPCR against inhibition by CIDRa1.1, thus permitting normal APC barrier protective effects. In vivo, infusion of CIDRa1.1 in hEPCR mice resulted in rapid accumulation of CIDRa1.1 in the lung that could be detected up to 2 days later. A single bolus of #19 (5 mg/kg) reduced CIDRa1.1 accumulation in the lung >3-fold when given 48 hrs before CIDRa1.1 and >5-fold when given 1 hr before.

Conclusions: Ab #19 selectively inhibited CIDRa1.1 to EPCR and protected normal EPCR functions against inhibition by CIDRa1.1. In vivo, #19 provided long lasting protection of EPCR against CIDRa1.1 binding, suggesting that EPCR targeting to attenuate severe symptoms in malaria may be feasible.

PB 880 | Characterization of an In vivo Mouse Model for the Binding of P. *falciparum* Erythrocyte Membrane Protein 1 (PfEMP1) Domains to the Endothelial Protein C Receptor (EPCR)

J. Barber-Singh[1], L. Turner[2,3], K.F.E. Lee[4], P. Cowan[4], H. Gock[4], H. Weiler[5], T. Lavstsen[2,3], L. Mosnier[1]

[1]The Scripps Research Institute, Department of Molecular Medicine, La Jolla, United States, [2]University of Copenhagen, Department of International Health, Immunology & Microbiology, Copenhagen, Denmark, [3]Rigshospitalet/Copenhagen University Hospital, Department of Infectious Diseases, Copenhagen, Denmark, [4]St. Vincent's Hospital, Department of Medicine, Melbourne, Australia, [5]Blood Research Institute, Milwaukee, United States

Background: Severe malaria due to *P. falciparum* infection is associated with PfEMP1's binding to EPCR. In vitro, PfEMP1 domains inhibit (activated) protein C ((A)PC) binding to EPCR required for PC activation and APC cytoprotective effects. Proof for the contribution of a defective PC system to severe malaria in vivo is hampered by the lack of a rodent model for the PfEMP1-EPCR interaction.

Aims: To develop a mouse model for the PfEMP1-EPCR interaction, and to validate the model using the soluble (s) E86A-EPCR decoy strategy.

Methods: Human EPCR (hEPCR) transgenic and WT mice were injected with the EPCR-binding PfEMP1 domain CIDRa1.1 and non-EPCR-binding CIDRa1.2. Accumulation of PfEMP1 domains in organs and plasma was determined by ELISA, W-blot and histology.

Results: PfEMP1 domains do not bind to mouse EPCR, therefore PfEMP1 domains were injected i.v. in hEPCR transgenic mice. CIDRa1.1 accumulated preferentially in the lung and to a lesser extent in the spleen and liver of hEPCR but not WT mice, a pattern matching the hEPCR expression in these organs. Accumulation of CIDRa1.1 (0.4-2.0 mg/kg) was dose- and time-dependent and could be observed as early as 5 min and as late as 2 days after injection. No accumulation of CIDRa1.2 (2.0 mg/kg) was observed. Histology confirmed vascular accumulation of CIDRa1.1. Clearance of CIDRa1.1 was ~3 min in WT mice but extended 4-fold in hEPCR mice due to binding to soluble (s) hEPCR. The non-(A)PC binding E86A-sEPCR restored EPCR-dependent (A)PC functions on cells in the presence of CIDRa1.1. In vivo, E86A-sEPCR (0.4 mg/kg) reduced CIDRa1.1 (0.4 mg/kg) accumulation in the lung 5-fold when given 5 min before and 3-fold when given 15 min after CIDRa1.1.

Conclusions: This mouse model showed high affinity binding of PfEMP1 domains to EPCR in vivo and permitted testing of the efficacy of EPCR protective strategies in vivo. The model also provides a framework for studies on the contribution of the PfEMP1-EPCR interaction to the pathogenesis of severe malaria.

PB 881 | Antithrombin and Protein C Plasma Levels at Admission Are Associated to Mortality at Six Months in Patients with Pulmonary Embolism with and without Malignant Disease

S. Obradovic[1], B. Dzudovic[1], B. Subotic[1], M. Stavric[2], V. Subota[2], D. Mikovic[3]

[1]Military Medical Academy, School of Medicine, University of Defense, Clinic of Emergency Medicine, Belgrade, Serbia, [2]Military Medical Academy, School of Medicine, University of Defense, Institute of Biochemistry, Belgrade, Serbia, [3]Institute of Transfusion Medicine, Hemostasis Department, Belgrade, Serbia

Background: The association between hemostasis parameters and death in patients with pulmonary embolism (PE) is unknown.

Aims: To investigate the association of haemostasis parameters at admission and the mortality at 6 months in patients with PE.

Methods: Two hundred and thirty four consecutive patients with PE who were admitted in the intensive care unit of the tertiary

hospital were enrolled in the study. Plasma activity of antithrombin (AT), Proteins C (PC), factor II, VII, VIII and fibrinogen concentration were determined in the majority of patients (between 165-186 depends on the parameter) after admission without the storage of plasma. The results were split into the tertiles for the estimation of significant difference at 6-month mortality. The results were presented in whole group and in subgroups with and without malignancy.

Results: The 6-month mortality was 15/60 (25.0%) and 15/59 (25.4%); 6/63 (9.5%) and 8/59 (13.6%); 7/63 (11.1%) and 5/61 (8.2%) across the tertiles of AT (I< 0.75IU/L, III>0.97IU/L) and PC (I< 0.81IU/L and III>1.2IU/L) with Log Rank test p_{AT}=0.031 and p_{PC}=0.039, respectively. The significant difference between the mortality at six months were found across the tertiles of AT (I-22.6% vs II-3.8% and III-7.1%, p=0.009) for subgroup without malignancy (159 patients). However, in patients with malignancy (26 patients), mortality at six months was significantly different only across the tertiles of PC (I-70% vs II-44.4% and III-0.0%, p=0.030).

Conclusions: The low plasma levels of AT and PC are associated to mortality at six months in patients with PE. In the PE patients with malignant disease only low PC activity is associated to 6-month death.

PB 882 | Positive Correlation of Plasma Protein S Levels to Apolipoprotein C-II in Middle-aged Obese Women and Non-obese Young Women

Y. Otsuka[1], M. Ueda[1], E. Nakazono[2], T. Tsuda[3], X. Jin[3], K. Noguchi[1,4], H. Miyazaki[4], S. Nakano[1,4], H. Tsuda[1,4]

[1]Nakamura Gakuen University, Graduate School of Health and Nutrition Sciences, Fukuoka, Japan, [2]Fukuoka College of Health Sciences, Department of Health and Welfare Sciences, Fukuoka, Japan, [3]Shinotest Corporation, R&D Center, Sagamihara, Japan, [4]Nakamura Gakuen University, Health Promotion Center, Fukuoka, Japan

Background: Protein S is a vitamin K-dependent plasma glycoprotein functions as a non-enzymatic co-factor to activated protein C in the degradation of factors Va and VIIIa. In plasma, protein S is present in two forms, free form and in a complex with C4b-binding protein, and has been reported to associate with triglyceride-rich lipoproteins but not with LDLs and HDLs.

Aims: To elucidate the physiological relevance of the association of protein S and lipoproteins, we performed correlation studies of plasma protein S levels with atherosclerosis-related factors including adiposity indicators, metabolic parameters, and inflammatory markers

Methods: The relationships between plasma total and free protein S antigen levels and adiposity indicators, blood pressure, estradiol, lipoproteins, glucose, insulin resistance, adipocytokines, inflammattory markers, and hemostatic factors were examined in middle-aged obese women (n=62) and non-obese young women (n=160).

Results: Total and free PS antigen levels in middle-aged obese women correlated negatively with estradiol and positively with triglyceride, total cholesterol, LDL cholesterol, apoA-II, apoB, apoC-II, apoC-III, apo E, HbA1c, and protein C, whereas there was no correlation with HDL cholesterol, apoA-I, body mass index, visceral fat area, blood pressure, or factor VII. Stepwise multiple linear regression analyses revealed that protein C, apoC-II, and fibrinogen were significant predictors of total protein S antigen levels, accounting for 51.9% of variance. ApoC-II was selected as a single significant predictor for free protein S antigen levels, accounting for 18.6% of variance. In non-obese young women, apoC-II was also selected as a significant predictor of total protein S antigen levels, but not of free protein S antigen levels.

Conclusions: Correlation studies revealed a strong positive relationship between plasma protein S antigen levels and apoC-II, an essential cofactor for lipoprotien lipase present mainly on triglyceride-rich lipoproteins.

PB 883 | Hepatocyte Growth Factor Reduces Protein C Inhibitor Expression in HepG2 Cells via MEK and PI3 Kinase

T. Hayashi[1], N. Akita[2], T. Okamoto[3], J. Nishioka[4], K. Suzuki[5]

[1]Mie Prefectural College of Nursing, Department of Biochemistry, Tsu, Japan, [2]Suzuka University of Medical Science, Faculty of Medical Engineering, Suzuka, Japan, [3]Shimane University Faculty of Medicine, Department of Pharmacology, Izumo, Japan, [4]Suzuka University of Medical Science, Department of Clinical Nutrition, Suzuka, Japan, [5]Suzuka University of Medical Science, Faculty of Pharmaceutical Science, Suzuka, Japan

Background: Protein C inhibitor (PCI) regulates the anticoagulant protein C pathway by neutralizing activated protein C (APC) and thrombin-thrombomodulin complex in the human hemostatic system. Hepatocyte growth factor (HGF) plays an important role in tissue repair and regeneration, is activated by HGF activator (HGFA), and then promotes proliferation of hepatocyte *via* c-Met. Recently, we indicated that PCI regulates liver regeneration by inhibiting HGFA *in vitro* and *in vivo*, but it is unclear whether HGF itself affects the proHGFA (HGFA precursor) and PCI expressions in hepatocytes.

Aims: We investigated the effect of HGF on proHGFA and PCI expressions in hepatocytes, and elucidated the detailed signal transduction process of the HGF-induced change of their expressions.

Methods: Confluent HepG2 cells were treated with HGF, or HGF plus various signal transduction inhibitors, and then culture supernatants were collected by centrifugation at 15,000 rpm for 10 min. The concentrations of proHGFA and PCI in culture supernatants of HepG2 cells were determined by specific ELISA. The mRNA expressions of proHGFA and PCI in HepG2 cells were evaluated by specific Real-time PCR analysis.

Results: HGF had no effect on proHGFA production in hepatocytes and hepatoma cell line, HepG2 cells. However, it decreased the PCI production in both cells. Real-time PCR analysis showed that this HGF-induced change of PCI production in HepG2 cells is transcriptionally regulated. Furthermore, NFkB inhibitor did not recover the HGF-induced decreased PCI expression in HepG2, and inhibitors of p38MAPK and JNK also did not do so. However, c-Met, PI3 kinase and MEK inhibitors did recover HGF-induced decreased PCI expression in HepG2 cells. In addition, ERK inhibitor had no effect on HGF-induced decreased PCI expression in HepG2 cells.

Conclusions: These findings suggest that HGF decreases PCI expression in HepG2 cells *via* c-Met, which is subsequently followed by PI3 kinase, and MEK signaling whose downstream is not ERK activation.

PB 884 | Differential Modulation of Plasminogen Activator Mediated Thrombolysis by Recombinant Thrombomodulin and Activated Protein C

J. Fareed[1], Z. Siddiqui[1], S. Raghuvir[1], R. Wasmund[1], O. Iqbal[1], W. Jeske[2], D. Hoppensteadt[1], K. Tanaka[3], K. Tsuruta[3]

[1]Loyola University Medical Center, Pathology, Maywood, United States, [2]Loyola University Medical Center, Thoracic and Cardiovascular Surgery, Maywood, United States, [3]Asahi Kasei Pharma America Corporation, Waltham, United States

Background: Urokinase (UK) and tissue plasminogen activator (tPA) mediate thrombolytic actions by activating endogenous plasminogen. Thrombomodulin (TM) complexes with thrombin to activate Protein C and thrombin activatable fibrinolysis inhibitor (TAFI). Activated Protein C (APC) modulates coagulation by digesting factors V and VIII and activates fibrinolysis by decreasing PAI-1 functionality. Recombinant versions of TM (rTM) has been developed for therapeutic purposes.
Aims: To compare the effects of rTM and APC on urokinase and tPA mediated thrombolysis utilizing thromboelastography.
Methods: Native whole blood was activated using a diluted intrinsic activator (APTT reagent, Triniclot). The modulation of thrombolysis by tPA and UK (Abbott, Chicago, USA) was studied by supplementing these agents to whole blood and monitoring TEG profiles for 3 hours. To investigate effect of APC (Haematologic Technologies, VT, USA) and rTM (Asahi Kasai Pharma, Tokyo, Japan) these agents were also supplemented to the activated blood. The modulation of tPA and UK induced thrombolysis by APC and rTM was also studied.
Results: In comparison to rTM, APC produced a stronger anticoagulant effect in terms of r time, k time, angle and MA. Fibrinolysis was assessed in terms of LY30(%) and LY60 (%). At concentrations of up to 2.5ug/ml rTM and APC did not produce any direct fibrinolytic effects. APC also produced strong augmentation of the lytic of effects of tPA and urokinase in a concentration dependent fashion. rTM at concentrations of less than 10ug/ml produced stabilization of clot resisting fibrinolysis.
Conclusions: These studies demonstrate the differential anticoagulant and procoagulant effects of APC and rTM. APC is a stronger anticoagulant than rTM and facilitates thrombolysis. rTM is a much weaker anticoagulant and modulates clot stability branding it resistant to fibrinolysis. These observations suggest that while APC may impair hemostasis, rTM restores hemostasis via TAFI activation.

PB 885 | G-quadruplex-Directed Aptamer Selection against Activated Protein C (APC)

N. Shahidi Hamedani[1], S. Gasper[1], J. Oldenburg[1], G. Mayer[2], B. Pötzsch[1], J. Müller[1]

[1]Institute of Exp. Haematology and Transfusion Medicine,University of Bonn Medical Center, Bonn, Germany, [2]Kekulé-institute for Organic Chemistry and Biochemistry, University of Bonn, Bonn, Germany

Background: Aptamers are single stranded DNA/RNA molecules which are able to bind to different target molecules with high affinity and specificity. Aptamers are typically selected from randomized libraries of nucleic acids using a procedure termed Systematic Evolution of Ligands by Exponential Enrichment (SELEX). The procedure is completed by identification and evaluation of individual aptamer sequences.
Aims: To identify aptamers that bind to distinct epitopes of APC that can be used for selective and/or bivalent targeting of APC.
Methods: To figure out the effect of the composition of the starting library on the structure of the selected aptamer(s), two distinct ssDNA libraries, namely a completely randomized as well as a G-rich one, were used in capillary electrophoresis-based SELEX (CE-SELEX) against APC. The enrichment of high-affinity aptamers during selection was assessd using next generation sequencing (NGS). Selected aptamers were characterised in terms of binding to APC, its zymogen Protein C, and the structurally related serine proteases thrombin and activated factor VII. In addition, competition experiments were performed to find out the binding site of the aptamers on APC.
Results: Enrichment of 3 aptamers (NB1, NB2, and NB3) demonstrating high binding affinities to APC (0.2 to 20 nM) was confirmed by NGS analysis. Structural and fluorescence analysis using G-quadruplex (G4)-binding thioflavin T suggest that NB3 consists of a distinct G-quadruplex structure while NB1 and NB2 were predicted to form highly conserved stem-loop structures. Binding experiments revealed high APC-specificity of the NB-aptamers and identified the heparin binding site of the enzyme as the common target region.
Conclusions: The identified aptamers represent distinct high-affinity ligands specifically binding to APC. Further characterization will reveal their characterisitcs with respect to the modulation of APC functional activity as well as the development of diagnostic APC assays.

PB 886 | The Protective Effect of Activated Protein C as the Baised Agonism in Activation of Protease-activated Receptor 1

L. Gorbacheva[1,2], S. Strukova[2]

[1]Pirogov Russian National Research Medical University of Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation, [2]Lomonosov Moscow State University, Moscow, Russian Federation

Background: Activated protein C (APC) isn't only a main component of anticoagulant system, but it plays important role in inflammatory, neurodegeneration, proliferation and etc. Protease-activated receptor 1 (PAR1) is a common receptor for thrombin (Th) and APC, via which these proteases regulate cell functions. Why Th and APC demonstrate different effects via PAR1 isn't clear.
Aims: In the present work, we studied the biased activation of PAR1 by APC, we hypothesized that PAR1-dependent signaling by APC

involves a novel cleavage of the receptor's N-terminal domain, differing from that of thrombin.

Methods: The work was performed on different models: neuronal exitotoxicity, ischemia in vitro (astrocyte culture), acute inflammation and proliferation of keratinocytes. Thrombin, APC and peptides of tethered ligand with different amino acid sequences were used for activation of PAR1.

Results: It has been shown recently that the multidirectional effects of thrombin and APC may be due to biased agonism under the action of thrombin and APC proteases on the PAR1 in endothelial cells. Under conditions of biased agonism, APC-specific noncanonic cleavage at Arg46 has been identified in the PAR1 exodomain instead of the canonic cleavage by thrombin at Arg41.

We have shown for the first time that a noncanonical PAR1 ligand (NPNDKYEPF amide) protects neurons at glutamate-induced toxicity, mast cells at acute inflammation, astrocytes at ischemia and stimulates the proliferative activity of keratinocytes, like protease APC. These effects of new peptide were abolished by blockage of PAR1. Canonical peptide (TRAP6) has demonstrated proinflammatory and toxic effects on astrocytes, mast cell and neurons, similar to Th.

Conclusions: Thus the new peptide-agonist PAR1 simulates APC-induced but not thrombin-induced signaling on different cell types.

This work was supported by Russian Foundation for Basic Research № 16-04-01869.

PB 887 | Function and Prevalence of Host-derived Coagulation Factors on the Virus Surface

B.H. Lin[1,2], M.R. Sutherland[1,2,3], E.L.G. Pryzdial[1,2,3]

[1]University of British Columbia, Department of Pathology and Laboratory Medicine, Vancouver, Canada, [2]Centre for Blood Research, Vancouver, Canada, [3]Canadian Blood Services, Centre for Innovation, Vancouver, Canada

Background: Numerous viruses are known to alter the hemostatic system. To explain this link, we have shown that the envelope of three herpesviruses acquire the initiators of coagulation from the host, tissue factor (TF) and anionic phospholipids (aPL). Viral TF and aPL act as cofactors for clotting factor VIIa-mediated factor X (FX) activation, ultimately leading to clot formation and cell signaling. Using herpes simplex virus 1 (HSV1) as a model envelope virus, virus TF was previously shown to enhance infection. HSV1 encoded glycoprotein C (gC) has also been implicated in FX activation.

Aims: The aims of the current research are to:

1) dissect the role of gC on HSV1-mediated FX activation; and

2) investigate the ubiquity of viral TF and aPL on enveloped viruses.

Methods: TF^+/TF^- HSV1 variants and dengue virus (DENV) propagated in cell culture were purified and characterized. The FX activating roles of viral TF and a soluble form of gC were assessed by chromogenic and plasma clotting assays. Immunogold electron microscopy was used to simultaneously visualize TF, aPL, and a virus-encoded marker on the virus surface.

Results: In plasma, HSV1 and DENV induced TF-mediated clotting. Viral TF was required for optimal FX activation, and was essential for HSV1 gC-mediated enhancement. This was confirmed using soluble gC and purified membrane-bound TF. Both TF and aPL were incorporated into HSV1 and DENV particles.

Conclusions: Virus surface TF function is enhanced by gC to contribute to FX activation and clot formation. Identification of TF on both HSV1 and DENV demonstrates the viral acquisition of host constituents and suggests the ubiquity of TF on enveloped viruses. Combined with the prior observation that virus TF enhances infection, the data presented here may support targeting viral TF as a broad-spectrum anti-viral agent.

PB 888 | Decryption of Hepatocyte Tissue Factor Procoagulant Activity by Bile Acids Requires Non-apoptotic Phosphatidylserine Externalization

K. Baker[1,2], A. Kopec[2,3], N. Joshi[2,3], H. Cline-Fedewa[3], J. Luyendyk[1,2,3]

Background: Liver parenchymal cells (i.e., hepatocytes) express tissue factor (TF) in an encrypted form that lacks procoagulant activity. TF-dependent coagulation occurs in cholestatic liver disease, where bile flow is disrupted. However, the timing and mechanism of decryption of hepatocyte TF procoagulant activity is not known.

Aims: We tested the hypothesis that exposure of hepatocytes to pathologic levels of bile acids rapidly increases TF procoagulant activity.

Methods: Ligation of the common bile duct (BDL) was utilized to induce obstructive cholestasis in wild-type mice. Coagulation was assessed 15 minutes after BDL or sham surgery. The impact of pathologically relevant concentrations of the bile acid sodium taurocholate (TCA) on TF procoagulant activity was examined in primary mouse hepatocytes.

Results: Increased hepatic fibrin(ogen) deposits indicated intrahepatic coagulation within 15 minutes of BDL. This occurred without detectable liver injury. Treatment of primary mouse hepatocytes with 1 mM TCA increased TF-dependent procoagulant activity within 15 minutes in the absence of necrosis or apoptosis. TCA driven TF procoagulant activity was not affected by inhibitors of transcription nor recapitulated by direct activation of the bile acid nuclear receptor farnesoid X receptor. Inhibitors of PI3K, ERK1/2, p38 and PKC failed to inhibit TCA-triggered TF procoagulant activity. TCA treatment triggered rapid externalization of phosphatidylserine (PS), independent of caspase 3 activation, and the TCA-mediated increase in TF activity was blocked by addition of the high-affinity PS-binding protein lactadherin.

Conclusions: The results indicate that TCA causes rapid decryption of hepatocyte TF activity through a mechanism involving PS

externalization. This suggests a mechanism whereby nontoxic bile acids could play a key role in triggering intrahepatic coagulation in disease settings associated with cholestasis.

PB 889 | Clustering of CD98 on Monocytic THP1 Cells Increases Tissue Factor Procoagulant Activity

F. Langer[1], B. Spath[1], C. Lehr[1], B. Sievers[1], W. Ruf[2,3]

[1]*Universitätsklinikum Eppendorf, Hamburg, Germany,* [2]*Center for Thrombosis and Hemostasis (CTH), Mainz, Germany,* [3]*The Scripps Research Institute, La Jolla, United States*

Background: We have previously shown that rabbit antithymocyte globulin (ATG) rapidly activates monocyte tissue factor (TF) in a complement- and thiol-disulfide exchange-dependent manner. Full TF activation by ATG required lipid raft integrity, intact surface-located protein disulfide isomerase (PDI) activity, and phosphatidylserine (PS) membrane exposure, suggesting that concerted interactions between heterotypic proteins were involved.

Aims: Since ATG is a polyclonal rabbit IgG targeting ubiquitous epitopes, we aimed to identify additional proteins involved in the regulation of cellular TF procoagulant activity (PCA).

Methods: Cell surface expression of CD98 and PS was analyzed by flow cytometry. TF activity was measured by single-stage clotting and Xa generation assays.

Results: Preincubation of THP1 cells with ATG abolished binding of a fluorescently labeled CD98 monoclonal antibody (mAb), indicating that CD98 is recognized by ATG on cell surfaces. Cross-linking of the CD98 heavy chain with mouse anti-CD98 mAbs LT98 or UM7F8 followed by goat-anti mouse IgG $F(ab')_2$ increased PS externalization and cellular TF PCA or TF-mediated Xa generation by 2- to 6-fold. This effect was not prevented by complement (anti-C5) or PDI (rutin) inhibition. Similarly, cross-linking of ATG with goat-anti rabbit IgG $F(ab')_2$ increased PS exposure and TF-dependent Xa generation 4-fold on THP1 cells, but significantly attenuated ATG-induced TF PCA in the clotting assay from 39- to 3-fold, suggesting that blocking ATG Fc portions by the $(Fab')_2$ prevented complement activation for full cellular TF procoagulant function. CD98 clustering did not increase TF PCA in solid cancer cell lines with relatively low CD98 expression.

Conclusions: Our findings implicate CD98, a heterodimeric transmembrane protein involved in amino acid transport and signaling of integrins, in the regulation of monocyte TF PCA.

PB 890 | A First-in-Human (FIH) Study of the Safety, Tolerability, Pharmacokinetics (PK) and Pharmacodynamics (PD) of PF-06741086, an anti-TFPI Monoclonal Antibody, Following Administration of Single Subcutaneous or Intravenous Doses in Healthy Adult Male Volunteers

M. Cardinal[1], C. Kantaridis[2], T. Zhu[3], P. Sun[3], D. Pittman[1], J. Murphy[1], S. Arkin[1]

[1]*Pfizer Inc, Rare Disease Research Unit, Cambridge, United States,* [2]*Pfizer Inc, Pfizer Clinical Research Units, Brussels, Belgium,* [3]*Pfizer Inc, Early Clinical Development, Cambridge, United States*

Background: Tissue factor pathway inhibitor (TFPI) is a protease inhibitor of tissue factor-activated coagulation factor VII (FVIIa) and activated factor X (FXa). PF-06741086 is a monoclonal antibody that targets TFPI to reduce inhibition of the extrinsic coagulation pathway and increase clotting activity in bleeding disorders such as hemophilia.

Aims: This study (protocol B7841001, approved by the comité d´éthique hospitalo-facultaire Erasme - ULB) was a randomized, double-blind, sponsor-open, placebo-controlled, single intravenous (IV) or subcutaneous (SC) dose escalation study to evaluate the safety, tolerability, pharmacokinetics, and pharmacodynamics of PF-06741086, done in compliance with the Declaration of Helsinki.

Methods: Volunteers who signed informed consent were assigned to cohorts with ascending dose levels. A single SC dose level was studied in a cohort of Japanese volunteers. Safety endpoints included treatment emergent adverse events (TEAEs), infusion/injection site reactions, and coagulation laboratory parameters. PK and PD endpoints included concentrations of PF-06741086 in plasma and measures of PF-06741086 pharmacology.

Results: Forty-one volunteers were recruited overall. Thirty-two were dosed with PF-06741086 at escalating IV or SC dose levels, beginning with 30 mg SC. All doses were safe and well-tolerated. TEAEs were mild or moderate in severity, laboratory abnormalities were transient, there were no infusion/injection site reactions and no stopping criteria were met.

Plasma exposures of PF-06741086 increased greater than proportionally with dose under the same dosing route. Coagulation pharmacology was demonstrated via Dilute Prothrombin Time, D-Dimer, Prothrombin Fragment 1.2 and Thrombin Generation.

Conclusions: Single doses of PF-06741086 at multiple dose levels were safe and well tolerated in a healthy adult male population. The safety, PK and PD data from this study support progression to a multiple dose study in hemophilia patients.

PB 891 | Hypoxia Augments Tissue Factor Expression in Inflammatory Stimulated Macrophages but Not in Smooth Muscle Cells or in Endothelial Cells

K. Maekawa[1], A. Yamashita[1], K. Hatakeyama[2], K. Nishihira[3], Y. Asada[1]

[1]*University of Miyazaki, Faculty of Medicine Pathophysiology, Miyazaki, Japan,* [2]*Nara Medical University, Diagnostic pathology, Nara, Japan,* [3]*National Cerebral and Cardiovascular Center Hospital, Suita, Japan*

Background: We recently reported that tissue factor (TF) and hexokinase II (HK-II) expression in coronary arteries correlated with coronary

thrombus size. However, the underlying conditions in atherosclerotic plaques remain unclear.

Aims: First, to identify TF and HK-II expression under hypoxia and/or inflammatory stimuli in plaque cells. Second, to demonstrate expression of TF and HK-II in thrombotic plaque components in aspirated coronary thrombi from patients with acute coronary syndrome (ACS).

Methods: TF and HK-II expression were assessed with THP-1 macrophages, human umbilical artery smooth muscle cell (HUASMC)s, and in human umbilical vein endothelial cell (HUVEC)s. Cultured cells were stimulated by tumor necrosis factor-a (20ng/mL) and interferon-g (10ng/mL) under normoxic (21% O_2) or hypoxic (1% O_2) conditions. Human coronary thrombi were aspirated from culprit lesions during percutaneous coronary intervention for ACS (n=11, age range:53-85, male:10, female:1). The paraffin sections were immunohistochemically stained with anti-CD68, smooth muscle actin (SMA), TF and HK-II antibodies.

Results: The hypoxic condition augmented TF mRNA and protein expression and TF activity in the cytokine-stimulated THP-1 macrophages, but not in HUASMCs or HUVECs. The hypoxic condition mildly enhanced TF expression in non-stimulated THP-1 macrophages, and markedly enhanced HK-II expression and lactate production in the stimulated and non-stimulated THP-1 macrophages but not in HUASMCs or HUVECs. All thrombotic plaques expressed TF and HK-II in CD68-positive macrophages in the aspirated thrombi. TF expression was also noted in necrotic tissue in the plaques. There were no smooth muscle cells in the aspirated thrombi and plaques.

Conclusions: Hypoxic and inflammatory conditions in atherosclerotic plaque may markedly enhance TF and HK-II expression in macrophages but not smooth muscle cells or endothelial cells, and contribute to symptomatic coronary events.

PB 892 | BAY 1093884 Binds to the Kunitz 1 and 2 Domain Interface of Tissue Factor Pathway Inhibitor and Inhibits its Function

S. Yegneswaran[1], V. Evans[1], X. Jiang[1], L. Leong[1], H. Steuber[2], U. Egner[2], M. Koellnberger[3], C. Patel[1], T. Marquardt[2]

[1]Bayer, US Innovation Center, Hematology Research, San Francisco, United States, [2]Bayer AG, Structural Biology, Berlin, Germany, [3]Bayer AG, TRG-Cardiology/ Hematology, Wuppertal, Germany

Background: BAY 1093884 is a fully human monoclonal antibody against tissue factor pathway inhibitor (TFPI) developed as a bypass agent for patients with hemophilia with or without inhibitors. BAY 1093884 restores a sufficient thrombin burst which leads to stable clot formation in hemophilic conditions and effectively stops bleeds in vivo.

Aims: Here we investigated the mechanism by which BAY 1093884 inhibits TFPI activity.

Methods: BAY 1093884-TFPI interactions were studied by crystallography and surface plasmon resonance (SPR). Functional assessment was performed via thrombin generation assay and dilute prothrombin time clotting assay.

Results: Cocrystallization of BAY 1093884-TFPI complex revealed that BAY 1093884 binds at the interface of the Kunitz 1-Kunitz 2 (K1-K2) domains of TFPI. These observations were supported by SPR data which showed BAY 1093884 competes with TFPI binding to factor VIIa (FVIIa) bound to soluble tissue factor (TF). In functional assays, BAY 1093884 restored the amidolytic activities of both factor Xa (FXa) and FVIIa bound to soluble TF, corroborating the biophysical observations. Further, BAY 1093884 dose-dependently improved thrombin generation in hemophilia A plasma, both in the presence and absence of endothelial cell surfaces. The maximum amount of thrombin generated by BAY 1093884 was significantly higher than that of BAY 1093889, another antibody that binds only to the K2 domain of TFPI. This was reflected as faster clotting times in dilute prothrombin time clotting assays.

Conclusions: Our data suggest that BAY 1093884 binds to TFPI via the K1-K2 domains of TFPI and inhibits its interactions with both FVIIa and FXa. Further, targeting K1-K2 domains of TFPI may have an advantage over targeting only the K2 domain of TFPI by increasing the thrombin peak in patients with hemophilia.

PB 893 | mTOR Inhibitors Reduce Expression of Tissue Factor Isoforms in Neuroendocrine Tumors of the Pancreas

C.S. Lewis[1], H. Elnakat Thomas[1], M. Orr-Asman[1], L.C. Green[1], F.V. Lucas[2], N. Mackman[3], H.H. Versteeg[4], V.Y. Bogdanov[1]

[1]University of Cincinnati, Department of Internal Medicine Division of Hematology/ Oncology, Cincinnati, United States, [2]University of Cincinnati, Department of Pathology & Laboratory Medicine, Cincinnati, United States, [3]University of North Carolina at Chapel Hill, Department of Internal Medicine Division of Hematology/ Oncology, Chapel Hill, United States, [4]Leiden University Medical Center, Einthoven Laboratory for Experimental Vascular Medicine, Department of Internal Medicine, Leiden, The Netherlands

Background: Full-length Tissue Factor (flTF) and alternatively spliced TF (asTF) contribute to malignant growth. flTF and asTF are overexpressed in pancreatic ductal adenocarcinoma (PDAC). Interactions between asTF and β1 integrins promote activation of Akt and p42/44 MAPK, potentiating cancer cell migration and proliferation. It is unknown whether, aside from PDAC, flTF and/or asTF also contribute to the pathobiology of pancreatic neuroendocrine tumors (pNET).

Aims: Assess expression of TF in pNET and potential utility of targeting intracellular pathways activated by TF in pNET.

Methods: 6 human pNET specimens were immunostained for flTF and asTF. Human pNET cell lines QGP1 and BON (gift of Dr. Courtney Townsend, UTMB) were evaluated for TF expression and responsiveness to mTOR inhibition using the mTORC1/2 ATP-site competitive inhibitor MLN0128. TF cofactor activity was assessed via two-step FXa generation assay. BON were stably transfected with an inducible asTF expression construct (BON-asTFi) to assess the efficacy of MLN0128 in the context of asTF overexpression.

Results: All pNET tissue specimens stained positive for flTF and asTF; normal pancreas tissue exhibited minimal TF staining. BON and QGP1 expressed both TF isoforms with BON expressing much higher levels of flTF and asTF mRNA and protein. Treatment of QGP1 and BON with MLN0128 markedly suppressed the levels of flTF and asTF protein and reduced phosphorylation of several mTOR targets including Akt, S6K1, 4E-BP1, and ULK1. Treatment of BON with 100 nM and 400 nM MLN0128 reduced TF cofactor activity by 64% and 83%, respectively. Treatment of BON-asTFi with MLN0128 significantly reduced secretion of asTF.

Conclusions: TF isoforms are expressed in pNET. In BON cells, MLN0128 reduces TF protein levels, TF cofactor activity, and asTF secretion. Further studies are thus warranted to evaluate the functional significance of tumor derived TF isoforms in pNET, and the utility of MLN0128 as a therapeutic agent for pNET management.

PB 894 | High Plasma Concentration of Activated Factor VII-antithrombin Complex is Associated with an Increased Activated Factor X Generation

F. Stefanoni[1], M. Baroni[2], B. Lunghi[2], A. Castagna[1], N. Ziliotto[2], F. Tosi[1], D. Minguzzi[1], S. Udali[1], B. Woodhams[3], D. Girelli[1], O. Olivieri[1], N. Martinelli[1], F. Bernardi[2]

[1]University of Verona, Department of Medicine, Verona, Italy, [2]University of Ferrara, Department of Life Sciences and Biotechnology, Ferrara, Italy, [3]Haemacon Ltd, Bromley, Kent, United Kingdom

Background: activated factor VII-antithrombin (FVIIa-AT) complex has been proposed as an indicator of tissue factor (TF) exposure to the blood, thus being a potential biomarker of prothrombotic diathesis. High plasma levels of FVIIa-AT have been associated with an increased thrombin generation and predicted total and cardiovascular mortality in patients with coronary artery disease (CAD).

Aims: to evaluate in CAD patients the relationship between FVIIa-AT levels and activated factor X generation (FXaG) at low TF concentration, and by inhibiting tissue factor pathway inhibitor (TFPI) or activated protein C (APC) with the aim to highlight procoagulant components.

Methods: within the framework of the Verona Heart Study we selected 40 male CAD patients (mean age 62.4±10.0 years) not taking anticoagulant drugs and with data of FVIIa-AT levels measured by ELISA. FXaG in plasma was evaluated at 1 pM TF by addition of a specific FXa fluorogenic substrate, and also in the presence of an anti-TFPI RNA aptamer (TFPI-aptamer) or an anti-APC DNA aptamer (APC-aptamer).

Results: among the parameters estimated from the analysis of FXaG curves only the area under the curve (FXa-AUC) showed a significant correlation with FVIIa-AT levels. The FXa-AUC increased progressively across FVIIa-AT quartiles, from 4031±210 Rfu in the lowest to 4268±84 Rfu in the highest (P=0.007 by ANOVA with polynomial contrasts for linear trend, confirmed after adjustment for traditional cardiovascular risk factors). The addition of either TFPI-aptamer or APC-aptamer produced a marked increase of FXaG with shorter time parameters (P< 0.001). The increase of FXa-AUC across FVIIa-AT quartiles was confirmed in both TFPI-aptamer or APC-aptamer assays (TFPI-aptamer, P=0.019; APC-aptamer, P=0.014).

Conclusions: in male CAD patients high plasma levels of FVIIa-AT are associated with an increased FXaG at low TF concentration. The increase of FXa-AUC across FVIIa-AT quartiles is still maintained after potentiation of procoagulant pathways by inhibiting TFPI or APC.

PB 895 | Renin-angiotensin System Blockade Downregulates Tissue Factor Expression Induced by γ-Glutamyltransferase in Human Peripheral Blood Mononuclear Cells Exposed to High Glucose

V. Scalise, C. Balia, S. Cianchetti, T. Neri, V. Carnicelli, R. Zucchi, A. Celi, R. Pedrinelli

University of Pisa, Department of Surgical, Medical and Molecular Pathology and Critical Care Medicine, Pisa, Italy

Background: Consistent epidemiological studies demonstrate the power of gamma-glutamyltransferase(GGT) as cardiovascular risk predictor suggesting its causal role in the development of acute thrombotic events to which Tissue Factor(TF), a major regulator of blood coagulation, contributes. In agreement with that possibility, GGT upregulates TF expression in human peripheral blood mononuclear cells(PBMCs)(Thromb J. 2016;14:45),a non-enzymatic,NFkB-dependent behavior susceptible to modulation by pharmacological renin-angiotensin system (RAS)blockade or high glucose (HG)conditions, as reported for other proinflammatory agents.

Aims: To assess the effect of RAS blockade by Aliskiren(ALI),a direct renin inhibitor, Zofenopril(ZOF),an ACE inhibitor and Olmesartan(OLM),an AT1R blocker,on GGT-induced TF expression in PBMCs exposed to either normal (NG,10mM) or HG (30mM)concentrations.

Methods: PBMCs obtained from healthy donors incubated with enzymatically inactive human recombinant GGT(0.5ng/μl),either alone or in presence of RAS blockers (10^{-6}M).TF PCA(1-stage clotting assay, arbitrary units),ag(ELISA,ρg/mL)and mRNA (real-time PCR,normalized-fold expression)were the evaluation variables.

Results: HG amplified GGT-induced TF expression (mRNA:from 0.05±0.04 to 0.4±0.1,n=8,p< 0.001; PCA:from 0.3±0.2 to 1.6±0.9, n=8,p< 0.001; TFag:from 251±101 to 457±149,n=8,p< 0.001 vs NG) that ALI (mRNA: -11±8%,n=4,p< 0.05; PCA: -25±19%,n=6,p< 0.05; TFag:-24±23 %,n=6,p< 0.05), ZOF(mRNA: -12±3 %,n=4,p< 0.001; PCA:-39±22%,n=6,p< 0.001; TFag:-40±26 %,n=6,p< 0.01) and OLM (mRNA: -12±2%,n=4,p< 0.001; PCA:-49±33%,n=6,p< 0.01; TFag:-43±30%,n=6,p< 0.01) downregulated.

Conclusions: GGT-induced TF expression is sensitive to modulation by HG and is inhibited by RAS blockers. While confirming the direct TF stimulating effect of GGT, the data unveil insofar unknown links with RAS, a behavior close to that reported for other proinflammatory agents whose pathophysiological and clinical implications need further studies.

PB 896 | Over-activation of Src1 Mediates Tissue Factor-induced Apoptosis in Endothelial Cells

A. Ethaeb, J. Greenman, C. Ettelaie

University of Hull, School of Life Sciences, Hull, United Kingdom

Background: Accumulation of tissue factor (TF) within cells can impede the release of TF in cell-derived microvesicles and can lead to cellular apoptosis through a mechanism that involves the activation of p38. However, the signalling process linking TF and p38 activation is unknown.

Aims: In this study we examined the ability of Src1 and Rac1 to mediate TF-signalling in the activation of p38 and cellular apoptosis.

Methods: The pCMV6-AC-TF-tGFP plasmid was mutated to express TF with a Ser253 to Ala substitution to prevent TF release. Human dermal blood endothelial cells (HDBEC; 1.5×10^5) were transfected to express the TF_{Wt}-tGFP, TF_{Ala253}-tGFP, tGFP or used un-transfected. The cells were then activated with PAR2-agonist peptide (SLIGKV-NH; 20 μM), harvested at intervals up to 120 min and the phosphorylation of Src1 and Rac1 assessed by western blot. Samples of transfected cells were then pre-incubated with pp60c Src inhibitor (TSTEPQpYQPGENL; 0-500 μM) or a control peptide (TSTEPQWQPGENL) prior to activation with PAR2-AP. The phosphorylation of p38 and cellular apoptosis was then analysed. Samples of cells were also co-transfected to express TF_{Ala253}-tGFP together with a specific Src1 siRNA or a control siRNA, activated as above and the cellular apoptosis measured.

Results: Activation of PAR2 in HDBEC led to the phosphorylation of Src1 and Rac1 proteins at 60 min regardless of TF expression. Moreover, Src1 phosphorylation was prolonged up to 100 min in the presence of TF, with a significantly higher magnitude following mutation of Ser253. Either inhibition of Src1 function, or suppression of Src1 expression reduced p38 phosphorylation and prevented cellular apoptosis in the activated cells, expressing the mutant TF.

Conclusions: Our data suggest that Src1, but not Rac1 mediates TF-induced activation of p38 and can promote cellular apoptosis in endothelial cells. This identifies a further step in the mechanism of TF-induced apoptosis particularly during inflammatory conditions such as cancer and vascular disease.

PB 897 | Indoleamine 2,3-dioxygenase 1 Enhances Tissue Factor Expression in Coronary Atherosclerotic Plaque

A. Yamashita[1], Y. Watanabe[2], K. Maekawa[1], K. Kitamura[2], Y. Asada[1]

[1]Miyazaki University, Faculty of Medicine, Pathology, Miyazaki, Japan, [2]Miyazaki University, Faculty of Medicine, Internal Medicine, Miyazaki, Japan

Background: Unstable plaque morphologies with tissue factor (TF) expression are crucial factors for the development of atherothrombosis. Clinical studies revealed that alteration of kynurenine (Kyn) pathway, a tryptophan (Trp) metabolism, is associated with cardiovascular events. However, the roles of the kynurenine pathway on vascular wall thrombogenicity remain unknown.

Aims: This study is to identify the role of indoleamine 2,3-dioxygenase 1 (IDO-1), a rate-limiting enzyme of the Kyn pathway, on thrombogenicity in human coronary atherosclerotic plaques and cultured macrophages.

Methods: We immunohistochemically evaluated expression and localization of IDO-1 and TF in coronary atherosclerotic lesions in the patients with stable angina pectoris (SAP) and unstable angina pectoris (UAP). Trp and Kyn levels in the cultured medium, expression of IDO-1, thrombogenic factors were assessed with THP-1 macrophages activated with interferon (INF)-g and tissue necrosis factor (TNF)-a. TF activity was measured with factor Xa generation.

Results: IDO-1 expressed mainly in CD68 positive macrophage and closely localized with TF. Immunopositive areas for TF, IDO-1, CD3 positive T lymphocyte were significantly larger in coronary plaques in patients with UAP than those with SAP. INF-g and TNF-a markedly upregulated IDO-1 expression and increased Kyn/ Trp ratio, and enhanced TF expression and activity, but not tissue factor pathway inhibitor expression. Epacadostat, an IDO-1 inhibitor, significantly reduced Kyn/Trp ratio, and inhibited the cytokine induced TF expression and activity in the activated macrophages.

Conclusions: Enhanced IDO-1 expression in coronary atherosclerotic plaque may contribute to atherothrombosis through TF upregulation in activated macrophages.

PB 898 | Application of a Quantitative Systems Pharmacology (QSP) Model of Human Blood Coagulation to Understand the Response of Clinical Biomarkers from a Recent Anti-TFPI Trial in Healthy Subjects

S. Nayak[1], T. Zhu[1], C.N. Lim[1], D.D. Pittman[1], M.H. Cardinal[1], S.W. Martin[1], L.O. Harnisch[2], S. Arkin[1], J. Murphy[1]

[1]Pfizer Inc, Cambridge, United States, [2]Pfizer Inc, Sandwich, United Kingdom

Background: We have developed and validated a mechanistic QSP model of the human blood coagulation system which allows simulation of the effects of pro- and anti-coagulant therapies. The current model can simulate both *in vivo* biomarkers (e.g., prothrombin fragment 1+2 or PF12) and *ex vivo* biomarkers such as the thrombin generation assay (TGA) parameters of peak thrombin, TGA lag time, activated partial thromboplastin time (aPTT) and dilute prothrombin time (dPT) clotting times.

Aims: To validate the QSP model of the human coagulation system with clinical data for *in vivo* and *ex vivo* biomarkers from a recently conducted clinical trial (NCT02531815).

Methods: The model was used to simulate the effect of single dose administration of an anti-TFPI antibody therapy on clinical biomarkers. The inhibition of TFPI in this clinical study was predicted using

drug and drug-complex pharmacokinetics modeling. Inhibition of TFPI was then used as an input into the QSP model to simulate *in vivo* and *ex vivo* biomarkers.

Results: A comparison of model predictions at different observation times showed that the results matched the clinical observations for TGA peak thrombin, TGA lag time, and dPT clotting times very well. Additionally, the model did not predict any significant changes in aPTT, a measure of modulation of the intrinsic pathway, which matched the observations in the clinical study.

Conclusions: Predictions from a computational model of human blood coagulation matches results obtained from a recently concluded clinical trial using an anti-TFPI compound. These results provide us with confidence in the ability of the model to estimate variability likely to be observed in a future clinical trial using techniques such as sensitivity analyses.

PB 899 | Coagulation and Angiogenesis Parameters in Essential Thrombocythemia

D. Rość[1], G. Gadomska[2], K. Stankowska[1], J. Boinska[1], J. Filipiak[1]

[1]Nicolaus Copernicus University in Toruń, Faculty of Pharmacy, Department of Pathophysiology, Bydgoszcz, Poland, [2]Nicolaus Copernicus University in Toruń, Faculty of Medicine, Department of Hematology and Malignant Diseases of Hematopoietic System, Bydgoszcz, Poland

Background: Recent studies suggest that VEGF may be involved in the thrombotic process, by stimulating the expression of tissue factor (TF) in vascular endothelial cells. It also known that TF can stimulate the growth of transcription of the gene encoding VEGF.

Aims: The aim of the study was to evaluate selected coagulation and angiogenesis parameters in ET patients.

Methods: The study group consisted of 130, newly diagnosed patients with essential thromobocythemia (mean age 61 years; F/M=84/46). Patients were recruited from the Department of Hematology and Malignant Diseases of Hematopoietic System, Bydgoszcz, Poland. Essential thrombocythemia was diagnosed according to the World Health Organization (2008) criteria. The control group consisted of 25 healthy volunteers (mean age 51 years; F/M=17/13). All parameters were measured using immunoenzymatic method (ELISA).

Results: The median concentration of TF Ag was 3 fold higher in ET patients than in the controls (Me=457.26 pg/ml vs Me=145.34 pg/ml, p< 0.000001), and the activity of TF was more than 15 fold higher than in controls (Me=49.13pM vs Me=3.22 pM, p< 0.000001). There were no statistically significant differences in the values of TFPI concentration and activity between ET patients and controls. VEGF-A was significantly increased in patients with ET (p < 0.000001) and the median in ET patients was more than 5 times higher than found in the control group (Me= 137.33 pg/ml vs Me= 23.00 pg/ml). Analysis of correlations revealed a positive correlation between VEGF-A concentration and TF Ag (R= 0.27; p= 0.09) as well as a positive correlation between VEGF-A concentration and TFPI activity in the group of ET patients (R= 0.26; p=0.01).

Conclusions: The simultaneous increase of TF concentration/activity and VEGF-A concentration as well as a positive correlation between TF and VEGF-A indicate activation of TF-dependent blood coagulation and its relationship with angiogenesis in ET patients.

PB 900 | Simulation of Factor X Activation by Extrinsic Tenase on Phospholipid Vesicles: Size Matters!

T. Kovalenko[1,2], M. Panteleev[1,2,3], A. Sveshnikova[1,2,3]

[1]Faculty of Physics, Lomonosov Moscow State University, Moscow, Russian Federation, [2]Center for Theoretical Problems of Physicochemical Pharmacology, Russian Academy of Sciences, Moscow, Russian Federation, [3]National Scientific and Practical Centre of Pediatric Hematology, Oncology and Immunology named after Dmitry Rogachev, Moscow, Russian Federation

Background: It is widely reported that TF-rich circulating microparticles have increased concentration in bloodstream in various pathological conditions such as sepsis, cancer, etc. On the surface of such vesicles TF and FVIIa could assemble into the enzyme - extrinsic tenase. Its substrate, factor X, can reversibly bind to negatively charged phospholipid membrane. Thus circulating microparticle makes a potential constant source of active factor Xa in the bloodstream. To analyze the role of the stream in the activation of blood coagulation by circulating microparticles the diffusion of factors, their mixing and their distribution between the membrane and solution have to be taken into account.

Aims: Construction of a comprehensive computational model of factor X activation on the surface of a 3D microparticle moving in a bloodstream.

Methods: The model was a set of partial differential equations in three dimensions based on a scheme of reactions including extrinsic tenase formation and factor X delivery via two-dimensional diffusion on the membrane.

Results: The model was validated using reported experimental data (Hathcock et al. Biochemistry, 2005).

It was found that apparent equilibrium dissociation constant (K_d) for interaction of FX/FXa with phospholipid membrane of microparticles in bloodstream rises with the vesicle radius. In the approximation of collision limit theory (Abbott et al. Biochemistry, 1987) the apparent association constant is inversely proportional to the vesicle radius, so K_d could rise with the vesicle radius. As a result the factor X activation is faster on smaller vesicles than on the large ones while keeping the total lipid concentration constant (many small vesicles or a few large vesicles).

Conclusions: The binding of FX/FXa is better for smaller vesicles than for larger ones. Thus the big population of 30nm-diameter TF-containing circulating microparticles would lead to 25% faster FX activation than small population of large vesicles.

PB 901 | Rutin (quercetin-3-rutinoside) Modulates Hemostatic Disturbances and Reactive Species Levels in Experimental *Bothrops jararaca* Envenomation

A.T.A. Sachetto[1,2], M.L. Santoro[1,2]

[1]*Instituto Butantan, Laboratory of Pathophysiology, Sao Paulo, Brazil,* [2]*College of Medicine - University of São Paulo, Sao Paulo, Brazil*

Background: Snakebites are a major public health problem worldwide. In Brazil, patients bitten by *Bothrops* snakes manifest bleeding disorders associated with thrombocytopenia, consumptive coagulopathy, increased plasma tissue factor (TF) levels, and oxidative/nitrosative stress (ONS), a secondary complication of envenomation. Specific antivenom does not combat ONS, which in turn may induce additional hemostatic disorders. Thus, it is important to search for new complementary treatments, such as rutin, a natural antioxidant that also inhibits protein disulfide isomerase (PDI), an enzyme that has been proposed to control TF encryption/decryption.

Aims: To investigate the potential of rutin as an ancillary therapeutic agent for snake envenomation, and its effects on ONS and hematological/hemostatic disturbances evoked in mice injected with *B. jararaca* venom (BjV).

Methods: Swiss mice were allocated in 5 experimental groups (n=6/group/time) and were injected s.c. with: saline (group 1), propylene glycol (group 2), rutin (14.4 mg/kg b.w., group 3), BjV (1.6 mg/kg b.w., group 4) or BjV and rutin (group 5). After 3, 6 and 24 h, blood and tissues were collected for biochemical and hemostatic assays. Furthermore, *in vitro* assays were carried out to test whether rutin inhibits the activity of snake venom metalloproteinases, serine proteinases, and L-amino acid oxidases.

Results: As expected, envenomation evoked hematological/hemostatic disturbances and ONS. Interestingly, incubation of BjV with rutin (a) inhibited the activity of important venom proteins that engender envenomation; (b) shortened the recovery time in red blood cell destruction and plasma fibrinogen consumption; (c) inhibited the generation of reactive species; and (d) altered TF and PDI protein expression in heart and skin.

Conclusions: Rutin abbreviated the hemostatic and ONS disturbances, suggesting that it and may be used as a supplementary treatment for snakebites. Financial support: São Paulo Research Foundation (FAPESP), CNPq and CAPES.

PB 902 | Measurement of Tissue Factor Molecules and Factor Xa Generation on Vascular Cells

M. Rosas[1], C.P. Thomas[1], D.A. Slatter[1], V. Jenkins[2], V.B. O'Donnell[1], P.W. Collins[1]

[1]*Cardiff University, Systems Immunity Research Institute and Division of Infection and Immunity, Cardiff, United Kingdom,* [2]*Cardiff and Vale University Hospital, Department of Haematology, Cardiff, United Kingdom*

Background: Tissue factor (TF) is a transmembrane protein that initiates coagulation. It is expressed constitutively on extravascular cells (fibroblasts, smooth muscle cells (SMC)) and induced by inflammatory stimuli on endothelium and monocytes. The plasma membrane modulates the pro-coagulant activity of TF by providing a source of phosphatidylserine (PS) and phosphatidylethanolamine (PE).

Aims: The number of TF molecules on individual cells is not well defined and, although PS/PE are readily demonstrated on activated platelets, there are limited data on the amount of PS/PE present on TF bearing cells.

TABLE 1 Expression of TF molecules on vascular cells compared to FXa generation and externalisation of PS/PE measured by Annexin V binding

	TF molecules/cell Mean (SEM)		FXa generation (nM/min) by 104 cells Mean (SEM)		Percentage of cells binding annexin V (SEM)	
Cell Type	Unstimulated	TNFα	Unstimulated	TNFα	Unstimulated	TNFα
Fibroblasts (HCA2)	70260 (6955)	Not done	0.48 (0.07)	Not done	2.50 (0.25)	Not done
Smooth Muscle Cells (HPASMC)	3591 (352)	Not done	0.14 (0.03)	Not done	0.31 (0.09)	Not done
Edothelial cells (HUVEC)	414 (41)	4534 (907)	0.03 (0.01)	0.12 (0.01)	0.20 (0.03)	4.47 (0.22)
Primary Monocytes	0.0	1175 (156)	0.0	0.01 (0.005)	0.13 (0.02)	3.90 (0.49)
THP-1 cells (monocytic)	6769 (29)	13968 (115)	0.04 (0.004)	0.06 (0.01)	1.30 (0.01)	1.83 (0.23)

Methods: The number of TF molecules/cell was measured by flow cytometry on live cells. Quantum™ Simply Cellular® beads (Bangs Laboratories) were used to determine the antibody binding capacity (ABC) of an anti-TF mouse IgG monoclonal antibody on cells and the number of TF molecules/cell determined from a standard curve. Annexin V and lactadherin were used to detect externalised PS/PE. TF-FVIIa mediated FXa generation was measured using Z-GGR-AMC substrate (Bachem).

Results: Results are shown in the table. Fibroblasts had the most TF molecules/cell while smooth muscle cells (HPASMC) and THP-1 also expressed high levels of TF constitutively. TF was not detected on resting monocytes and was very low on resting HUVEC. After stimulation with TNFa there was a marked increase in TF molecules/cell on monocytes and HUVEC and similar results were seen with IL-1β (data not shown). Only a low proportion of TF bearing cells were positive for Annexin V or Lactadherin and this did not change substantially on stimulation.

FXa generation correlated better with the number of TF molecules/cell (r^2=0.9) than the proportion of annexin V positive cells (r^2=0.04).

Conclusions: We report a novel method for measuring the number of TF molecules on individual healthy cells. Externalised PS/PE on TF-bearing cells was below the limit of detection for our assay on almost all cells, however, despite this TF-initiated FXa generation was supported.

PB 903 | Tissue Factor Pathway Inhibitor Polymorphism 399C>T Predisposes to Idiopathic DVT in Young Indians

R. Saxena, K. Kishor, A. Sharma, R. Ranjan, P. Mishra, M. Mahapatra

All India Institute of Medical Sciences, Hematology, New Delhi, India

Background: Low Tissue factor pathway inhibitor (TFPI) is a predisposing factor of Deep Vein Thrombosis (DVT) in the West. However, its role in Idiopathic Indian DVT is not yet defined. Furthermore, the role of gene polymorphisms affecting its plasma levels is controversial.

Aims: To look for association of TFPI with the Idiopathic DVT in Indians and to elucidate the role of TFPI polymorphisms with TFPI plasma levels.

Methods: Doppler proven idiopathic DVT patients (age< 45 years) and age and sex matched healthy controls were studied. Exclusion criteria included patients on anticoagulants or those with history of malignancy, pregnancy or sepsis. Plasma TFPI levels were determined by ELISA and its normal range determined (Mean±2SD of TFPI levels in controls). TFPI gene polymorphisms (-33 T>C, 536 C>T) were detected by PCR-RFLP and 399 C>T by allele specific PCR.

Results: 90 DVT subjects, median age 35 years range (20-43 years) and M: F (59:31) were recruited. DVT was seen in lower limb in 78 patients and upper limb in 11 patients. Mean TFPI levels in DVT patients, (33.55±23.4 ng/ml) was significantly lower than controls (48.05±27.2 ng/ml, p=0.001). Moreover, 17 patients (18.8%) with DVT had low TFPI (< 20.85 ng/ml), whereas no control had low TFPI. CT and TT genotype of 399C>T polymorphism were found in 35.5% of patients and 12.2% of controls (p=0.001). TC and CC genotype of -33T>C polymorphism were found in 50% of patients and 67.7% of controls (p=0.038). TFPI 536 C>T polymorphism was absent in our population. Relation between the TFPI levels and their genotypes in subjects are shown in table.

TABLE Distribution of TFPI levels according to their genotypes in subjects

	TFPI levels ng/ml Mean±SD	
Polymorphisms	Patients (n=90)	Controls (n=90)
TFPI 399 C>T: CC, CT+TT	30.0±13.5, 35.4±10.2; p=0.021	49.1±14.0, 40.1±7.10; p=0.032
TFPI -33 T>C: TT, TC+CC	27.0±8.10, 40.0±11.2; p= <0.001	38.9±8.93, 52.0±13.8; (p=<0.001
TFPI 536 C>T: CC, CT+TT	-	-

Conclusions: As in the West, low TFPI level predisposes to DVT and -33 T>C polymorphism has a protective role in Idiopathic DVT in Indians. However, unlike earlier studies, CT and TT genotype of 399 C>T polymorphism may be associated with low levels of TFPI and DVT. Thus TFPI 399C>T polymorphism detection may help in identifying young Indians having high risk of DVT.

PB 904 | Role of Tissue Factor 603A>G and 5466A>G Polymorphisms in the Development of DVT in Young Indians

K. Kishor, A. Sharma, R. Ranjan, H. Pandey, P. Mishra, R. Saxena

All India Institute of Medical Sciences, Hematology, New Delhi, India

Background: Deep Vein Thrombosis (DVT) is a multifactorial disease and leading cause of morbidity and mortality worldwide. Tissue factor (TF) is a transmembrane protein considered to be responsible for the initiation of coagulation. Elevated levels of TF have been associated to cardiovascular disease whereas its association with DVT is controversial. In addition, the role of TF with DVT in India is not yet studied.

Aims: To analyze the distribution of TF polymorphisms and their impact on TF plasma level, and to assess the association between TF and risk of DVT in young Indians.

Methods: 90 Doppler proven idiopathic DVT patients (< 45 years) and equal number of age and sex matched healthy controls were studied. Exclusion criteria included patients on anticoagulants or those with history of malignancy, pregnancy or sepsis. Plasma TF levels were determined by ELISA. TF gene polymorphisms (603A>G and 5466A>G) were detected by PCR-RFLP.

Results: Mean TF levels (pg/ml) in DVT patients, (84.95±17.16) was significantly higher than controls (70.55±15.87, p=0.001. 603A>G polymorphism was found in 64.4% of patients and 46.6% of controls (p=0.001). The distribution of 5466A>G polymorphism was not significant between patients (16.6%) and controls (7.7%, p=0.118). TF plasma level was significantly higher in patients and controls with G allele than A allele of 603 A>G polymorphism (patients; AG+GG: 93.4±12.55, AA: 69.22±13.03 p=< 0.001, controls AG+GG: 76.42±17.16, AA: 64.90±12.22 p=< 0.001). However 5466A>G polymorphism was not associated with TF plasma level (patients; AG+GG: 83.05±18.24, AA: 85.36±17.01 p=0.607, controls; AG+GG: 68.75±18.2, AA: 70.70±15.7 p=0.739).

Conclusions: High plasma level of TF was significantly associated to DVT in young Indian. TF 603 G allele was associated with its high plasma levels and risk of DVT. Whereas 5466A>G polymorphism neither associated with TF levels nor DVT. A study with larger sample size is required to confirm these findings.

PB 905 | Tissue Factor Gene Polymorphisms (A603G, C1322T, C1812T, G1442C) in Healthy Individuals and Patients with Erysipelas in Transbaikalian Region

A. Emelianov[1], A. Emelianova[2], Y. Vitkovsky[1]

[1]Chita State Medical Academy, Normal Physiology Department, Chita, Russian Federation, [2]Chita State Medical Academy, Infectious Diseases Department, Chita, Russian Federation

Background: It is known that the erysipelas is characterized with disorders of haemostasis and development of immune response. Considering that the skin represents the most powerful macrophage system and its activation accompanied by expression of tissue factor which leads to hypercoagulability in erysipelas. Genetic polymorphism of tissue factor is reflected in the quantitative and qualitative indicators of macrophage activation.

Aims: The aim was to study the genetic polymorphism of TF (A603G, C1322T, C1812T, G1442C) in healthy individuals and patients with erysipelas in Transbaikalian region.

Methods: The study was performed at 96 patients with erysipelas and 82 healthy residents of Transbaikalian region. Tissue factor gene polymorphism was detected by PCR method.

Results: At was established that of homo- and heterozygous SNP of TF gene were spreading to Hardy-Weinberg equilibrium (p>0,05). It was founded that alleles and genotypes of SNP TF A603G, C1322T, C1812T, G1442C did not differ in healthy individuals and patients with erysipelas. Alleles and genotypes of SNP of TF gene A603G, C1322T, C1812T, G1442C didn´t effect on tissue factor expression.

Conclusions: Thus, SNP of TF (A603G, C1322T, C1812T, G1442C) not influence on TF activity in healthy individuals and patients with erysipelas.

PB 1682 | Chemical Footprinting Reveals Conformational Changes Following Activation of Factor XI

I. Stroo[1], A. Marquart[1], A. Meijer[1,2], J. Meijers[1,3]

[1]Sanquin Research, Plasma Proteins, Amsterdam, The Netherlands, [2]Utrecht Institute for Pharmaceutical Sciences, Utrecht University, Pharmaceutics, Utrecht, The Netherlands, [3]Academic Medical Center, University of Amsterdam, Experimental Vascular Medicine, Amsterdam, The Netherlands

Background: Coagulation factor XI (FXI) is activated by FXIIa or thrombin resulting in a conformational change that converts the catalytic domain into its active form and exposing exosites for FIX on the apple domains. Although crystal structures of FXI and the catalytic domain of FXIa are available, the structure of the apple domains and hence their interactions with the catalytic domain in FXIa are unknown.

Aims: Identify regions involved in stability or enzymatic activity of FXIa.

Methods: We employed chemical footprinting on recombinant FXI(a). Equal amounts of FXI and FXIa were labeled with lysine-directed isobaric tandem mass tag (TMT)-126 or -127, respectively. After proteolysis by chymotrypsin, peptides were analyzed by mass spectrometry.

Results: Fifty-two unique peptides were identified, covering 37 of 41 lysine residues present in FXI. TMT-modified peptide TLRLCKM with lysine residue 357 had the highest TMT-127/TMT-126 ratio indicating that this peptide is more accessible following cleavage of FXI. In the catalytic domain, we identified peptide QKAKIPLVTNEECQKRY with lysine residues 516, 518 and 529 to have a TMT-127/TMT-126 ratio < 1, suggesting that this peptide is hidden in FXIa. The crystal structures of FXI(a) suggest that K516 interacts with E380 and that this region is covered by the N-terminus of the light chain of FXIa. To study the role of the identified regions, we generated FXI variants K357A, K516A, K516E, E380K, and E380K/K516E. Cleavage by thrombin or FXIIa of these FXI variants was similar or slightly improved, except for FXI-K516E (by thrombin) and FXI-K357A (both by thrombin or FXIIa). Interestingly, in a purified system the cleaved FXI variants K516E, E380A, and E380K had reduced chromogenic activity, while this was rescued in the double variant E380K/K516E.

Conclusions: We have identified several regions in FXI that undergo a conformational change upon activation.

PB 1683 | Acute Lowering of Factor XII Induces Accelerated Spontaneous Venous Thrombosis in Mice: New Evidence for the Contact System that "Idles"?

M. Heestermans[1,2], K.F. Nickel[3], R. van Oerle[4], H.H. Versteeg[1,2], P.H. Reitsma[1,2], T.A. Fuchs[3], T. Renné[3], H.M. Spronk[4], B.J.M. van Vlijmen[1,2]

[1]Leiden University Medical Center, Einthoven Laboratory for Experimental Vascular Medicine, Leiden, The Netherlands, [2]Leiden University Medical Center, Department of Internal Medicine, Division of Thrombosis and Hemostasis, Leiden, The Netherlands, [3]University Medical Center Hamburg - Eppendorf, Institute of Clinical Chemistry and Laboratory Medicine, Hamburg, Germany, [4]Maastricht University, Department of Internal Medicine and Biochemistry, Maastricht, The Netherlands

Background: We reported on an unexpected prothrombotic effect upon acute lowering of coagulation factor XII (FXII), which has been introduced as a novel therapeutic target to prevent thrombosis, in a mouse model for spontaneous venous thrombosis (VT, Heestermans et al. *Blood*, 2016).

Aims: To investigate the mechanism underlying the prothrombotic response upon impact acute lowering of FXII. We hypothesized that acute inhibition of FXII affects the clearance of its target protein coagulation factor XI (FXI), in a similar fashion as shown for prekallikrein (PK), another target of FXII (Revenko et al. *Blood*, 2011).

Methods: C57BL/6 mice without FXII (*F12*-/-) or mice treated with siRNAs against *F12* (si*F12*) were analyzed for (1) their response to siRNAs targeting protein C and antithrombin (which trigger spontaneous VT), (2) tissue factor (TF) and ellagic acid induced thrombin generation, and (3) plasma levels and activity of components of the contact system.

Results: Unlike si*F12* treated mice, *F12*-/- mice did not demonstrate an earlier onset of spontaneous VT (*F12*+/+ controls: 9 out of 11 vs. *F12*-/-: 9 out of 11, *P*=1.0. For siNEG: 0/8 vs. si*F12*: 7/8 after 2 days, *P*< 0.01). Interestingly, in si*F12* mice, thrombin generation (induced

by 1pM TF) was significantly increased compared to siNEG, *F12*+/+, and *F12*-/- mice (peak heights siNEG: 69.8±3.4 nM thrombin, si*F12*: 88.1±3.8 nM, *F12*+/+: 66.2±9.4 nM, *F12*-/-: 63.7±1.7 nM, *P*< 0.01). This coincided with mildly increased plasma PK levels (140.0±17.0% of siNEG (100±14.9%), n=3) and higher plasma FXI activity (165.5±50.1% of siNEG (100±58.0%), *P*=0.01). In addition, spontaneous VT in mice appeared responsive to FXI deficiency (*F11*+/+: 9/11 vs. *F11*-/-: 5/11 and acute weight loss: 2.1g ±0.52 vs 1.2g ±0.33, *P*< 0.01).

Conclusions: In mice, acute lowering of FXII induces an unexpected prothrombotic shift, characterized by high FXI activity. This suggests that FXII, in absence of a challenge, modulates plasma FXI (and PK), thus providing new evidence for a contact system that "idles".

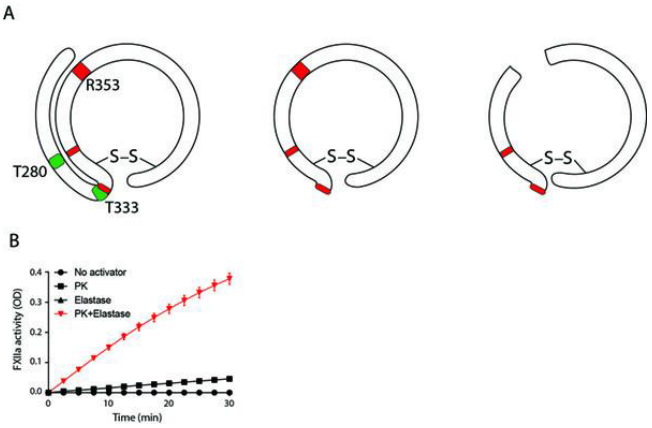

FIGURE 1 A) Two-step activation model. Cleavage sites for Elastase in Green, for PK in red. B) Synergism between elastase and PK in FXII activation.

PB 1684 | A Two-step Mechanism for Factor XII Activation in Solution

S. de Maat[1], Z.L.M. Hofman[1], N. Parr[1], G. Pasterkamp[1], T. Renné[2,3], C. Maas[1]

[1]*University Medical Center Utrecht, Clinical Chemistry and Haematology, Utrecht, The Netherlands,* [2]*Karolinska Institutet and University Hospital, Department of Molecular Medicine and Surgery, Stockholm, Sweden,* [3]*University Medical Center Hamburg-Eppendorf, Institute of Clinical Chemistry and Laboratory Medicine, Hamburg, Germany*

Background: The plasma contact system is named after its interaction with negatively charged surfaces. Under specific conditions, this system also becomes activated in solution. We previously identified that pathogenic mutations in the proline-rich region of factor XII (FXII) enhance its activation in solution, resulting in uncontrolled bradykinin production. We hypothesized that this reflects a physiological fluid-phase activation mechanism for FXII without mutations.

Aims: To uncover a general mechanism for fluid-phase activation of FXII.

Methods: FXII-variants were produced by transient transfection in HEK cells and affinity-purified. FXII activation was monitored by chromogenic substrates and with an in-house developed capture ELISA. FXII fragmentation was investigated by western blotting.

Results: Detailed investigation of the pathogenic mutant FXII-T309K by plasmin revealed that this actually is a two-step process: first, plasmin cleaves the proline rich region to remove a large shielding sequence. This does not directly activate FXII, but primes it for a subsequent activating cleavage (after R353). In *silico* predictions indicated several cleavage sites for various enzymes in the proline-rich region of FXII. These enzymes include neutrophil elastase (NE), cathepsin K, MMP-9 and calpain 1. Exposure of FXII to NE in buffer and plasma cleaves FXII into two fragments, which destroys its procoagulant activity. As before, this cleavage does not directly activate FXII. The resulting truncated FXII zymogen (single-chain, but lacking its surface-binding domains), becomes highly susceptible to fluid-phase activation by low levels of plasma kallikrein (Fig. 1). Identical data were obtained with cathepsin K.

Conclusions: We propose a unified two-step model for fluid-phase activation of FXII. In the first step, FXII becomes primed for activation by enzymatic removal of a large sequence that includes the surface-binding domains. This exposes site R353 for rapid cleavage by plasma kallikrein, culminating in FXII activation.

PB 1685 | Cell Receptor Interactions of the Contact System

J. Emsley[1], A. Slater[2], B. Kaira[2], K. Mccrae[3], M. Searle[2]

[1]*University of Nottingham, Pharmacy, Nottingham, United Kingdom,* [2]*University of Nottingham, Nottingham, United Kingdom,* [3]*Lerner Research Institute, Cleveland, United States*

Background: Complement receptor gC1qR, coagulation factor XII (FXII) and kininogen (HK) interact and play important roles in innate immunity, thrombosis and inflammation. Complement receptor gC1qR is present on the surface of endothelial cells, platelets and in platelet microparticles. High molecular weight kininogen (HK) is an important co-factor for the contact pathway localising factors to the correct surface. Domain 5 of HK binds to endothelial cell surface through the gC1q-R receptor, whilst domain 6 interacts with the proteases prekallikrein and factor XI. gC1qR also interacts with factor XII. gC1q-R is a trimeric, acidic receptor that binds HK and factor XII at the cell surface.

Aims: To understand the molecular mechanism of receptor interaction of the contact factors HK and FXII and thus understand cell surface localisation an contact activation.

Methods: Surface plasmon resonance (SPR) and isothermal titration calorimetry (ITC) was used to obtain affinity binding constants for protein interactions and protein crystallography was used to determine crystal structures.

Results: We characterised in detail the binding interaction between recombinant FXII and domain 5 of HK and identified the interaction with a gC1q-R trimer as having multiple binding sites. Truncations of domain 5 along with point mutations within the acidic loop regions of gC1q-R have been made in an attempt to pinpoint the exact binding interface between these two proteins. We also report the first complex structure of a domain from FXII with gC1qr showing the detailed receptor interactions.

Conclusions: These studies on HK D5 together with experiments characterising the interaction with FXII define gC1qR as a unique zinc ion sensing trimeric receptor landing platform capable of assembling the contact system.

PB 1686 | Endothelial Cell Serpins, Including PAI-1, Form a Complex with Fxia Blocking its Activity and Inducing the Clearance, Internalization and Degradation of FXIa

C. Puy[1], A. Ngo[1], E. Tucker[1], D. Gailani[2], A. Gruber[1], O. McCarty[1]

[1]*Oregon Health & Science University, Portland, United States,* [2]*Vanderbilt University School of Medicine, Vanderbilt, United States*

Background: Platelets can bind factor XI (FXI) supporting FXI activation. In contrast, it has been suggested that endothelial cells can not bind FXI nor promote its activation or enzymatic activity.

Aims: Characterization of FXI activation on the surface of endothelial cells.

Methods: To measure FXIa activity we used a FXIa chromogenic assay. Human umbilical vein endothelial cells (HUVEC) were incubated with vehicle or FXIa for 2h at 4°C. Immunofluorescence microscopy was used to measure FXIa binding to HUVECs; FXIa from either the supernatant (SN) or the cell lysate (CL) was immunoprecipitated and complexes were detected by western blot (WB) using an anti-FXIa catalytic domain or light chain (LC) antibody or an anti-plasminogen activator inhibitor 1 (PAI-1) antibody.

Results: FXIIa was able to activate FXI bound to the surface of the empty wells or platelets, but not to HUVECs. FXIIa was able to activate prekallikrein bound to the surface of either the empty wells, platelets or HUVECs. HUVECs blocked the activity of FXIa but not the activity of either kallikrein or FXIIa. FXIa was able to bind to the surface of HUVECs and the FXIa-LC, which has a molecular weight of ~30 kDa, formed a complex with two serpins generating two bands at ~80 kDa and ~70 kDa. After incubation of HUVECs with FXIa at 4°C, cells were incubated at 37°C for different times. The formation of FXIa-serpin complexes disappeared from the surface of HUVEC and only the band at ~80 kDa appeared in the SN in a time-dependent manner. WB for PAI-1from the SN and CL detected a band at ~80 kDa while the expression of PAI-1 on the HUVEC surface decreased after incubation with FXIa. Immunofluorescence analysis found that FXIa bound to the surface of HUVECs disappeared after 2h at 37°C.

Conclusions: Our data suggest that FXIa forms a complex with PAI-1 and a yet-unidentified serpin on the surface of endothelial cells inducing the release of the complex to the SN while also inducing internalization and degradation of FXIa.

PB 1687 | Characterization of Polyphosphate in Endothelial Cells under Cellular Stress

R. Rigg[1], L. Labberton[2], K.F. Nickel[2,3], A.T. Long[3], L.M. Butler[2,3], O.J.T. McCarty[1], T. Renne[2,3]

[1]*Oregon Health & Science University, Portland, United States,* [2]*Karolinska Institutet, Stockholm, Sweden,* [3]*University Medical Center Hamburg-Eppendorf, Hamburg, Germany*

Background: Polyphosphate polymers are stored in platelet dense granules and released upon platelet activation, whereupon they act as a scaffold for coagulation factor assembly and activation. Compared to platelet polyphosphate, little is known about the role of endothelial cell polyphosphate and its function in the vasculature under normal or disease conditions.

Aims: This project seeks to identify and localize endothelial cell polyphosphate and determine if cellular stress can up- or down-regulate the production of polyphosphate in endothelial cells.

Methods: Polyphosphate binding domain (PPX_Δ12) was generated as a recombinant deletion mutant of E. coli exopolyphosphatase (PPX) containing domains 3 and 4 only. In HUVECs or EA.hy926 endothelial cells, polyphosphate was probed with PPX_Δ12 and visualized with confocal immunofluorescence. To determine polyphosphate chain length, cell lysates were characterized via urea polyacrylamide gel electrophoresis. To assay the functional role of endothelial polyphosphate, EA.hy926 or ECV304 cells were exposed to cold or heat shock for one hour to determine changes in polyphosphate content, characterized by malachite green assay for monophosphate content.

Results: Polyphosphate was visualized in endothelial cells in the cytosolic compartment in a punctate pattern and was resistant to digestion with shrimp phosphatase. Endothelial cell polyphosphate was shown to migrate on urea acrylamide gels as a long smear of chain length greater than 400 phosphate units that was resistant to digestion by shrimp phosphatase but partially digestible by PPX. Heat or cold shock did not up- or down-regulate polyphosphate expression in endothelial cells.

Conclusions: Significant amounts of polyphosphate of long chain length is present in endothelial cells and was not demonstrated to respond to conditions of cellular stress; thus, further studies are warranted to interrogate the functional role of endothelial polyphosphate in the vasculature.

PB 1688 | Identification of *F11* Gene Variations Involved in the Interindividual Variability of Factor XI in Subjects with Congenital Deficiency Caused by Recurrent Mutations

S. Salloum-Asfar[1], J. Esteban[2], M.E. de la Morena-Barrio[1,3], A. Miñano[1], J. Padilla[1], V. Vicente[1,3], J. Corral[1,3]

[1]*Servicio de Hematología y Oncología Médica, Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, Murcia, Spain,* [2]*Servicio de Hematología. Hospital Virgen del Castillo de Yecla, Murcia, Spain,* [3]*CIBERER, Madrid, Spain*

Background: High FXI levels increase the risk of venous thrombosis, while its deficiency may protect against it. This and the huge interindividual variability of FXI levels have encouraged us to search new elements involved in their control. Current data only show *F11* SNVs with mild and conflictive functional role.

Aims: We identified 183 subjects with FXI deficiency, carrying 4 recurrent mutations, with a remarkable variability of FXI, even in carriers of the same family. We aimed to analyze gene variations of *F11* in these patients and new mechanisms involved in the variability of FXI levels.

Methods: Plasma FXI was evaluated by 4 clotting assays and Western Blot in 85 individuals with FXI deficiency. The whole *F11* gene was sequenced by NGS (Ion Torrent platform).

Results: 114 SNVs were identified, 22 new (all intronic and mostly restricted to isolated cases). The p.E226R (MAF: 0.002) reported as nonfunctional SNV was identified in a family carrying the p.C398Y mutation. Interestingly, compound heterozygous displayed about 50% lower FXI levels compared to single carriers.

TABLE Carriers of F11 mutations identified in our study. The variability of FXI levels of each group is indicated

FIGURE Compound heterozygosity. A) Pedigree. Heterozygous for p.Cys398Tyr (Blue) or p.Glu226Arg (Red). B) FXI levels in control (C) and family members

rs2289252 and rs2036914, associated with high levels of FXI in non-deficient subjects, also increased (5%) FXI levels in deficient carriers. rs925451 and rs4253399, in linkage disequilibrium D=0.8, were significantly associated with higher (17%) FXI levels (p= 0.02). This effect was particularly strong in p.C56R, a CRM- type 3 with the lowest FXI levels.

Conclusions: The study of *F11* gene in congenital FXI deficiency carriers is an excellent and sensitive model to find new elements and mechanisms involved in the modulation of FXI levels. We suggest that rs925451 and rs4253399, both previously assotiated with stroke, increase FXI levels. Moreover, the dominant negative effect of p.C398Y mutation may be exacerbated if the other allele carry the p.E226R mutation, revealing that the functional consequences of a mutation may depend on the genetic profile.

PB 1689 | Long-chain Polyphosphate Promotes FXII-dependent Platelet Consumption under Shear Flow

J. Zilberman-Rudenko[1], S.E. Reitsma[1], C.P. Wiesenekker[1], C. Puy[1], A.T.P. Ngo[1], S.A. Smith[2], E.I. Tucker[1,3], R.J. Travers[2], C. Maas[4], R.T. Urbanus[4], D. Gailani[5], J.H. Morrissey[2], A. Gruber[1,3,6], O.J.T. McCarty[1,6]

[1]Oregon Health & Science University, Biomedical Engineering, Portland, United States, [2]University of Illinois, Biochemistry, Urbana, United States, [3]Aronora, Inc., Portland, United States, [4]University Medical Center Utrecht, Department of Clinical Chemistry and Hematology, Utrecht, The Netherlands, [5]Vanderbilt University School of Medicine, Nashville, United States, [6]Oregon Health & Science University, Division of Hematology, Portland, United States

Background: Bacterial sepsis is a prevalent cause of hospital mortality with terminal complications that include development of consumptive coagulopathy and thrombocytopenia leading to organ hypoperfusion and bleeding. Bacterial constituents, including long-chain polyphosphates (polyP), have been shown to activate the contact pathway of coagulation in plasma. Recent work has shown that activation of the contact pathway is capable of promoting thrombin generation and platelet activation and consumption in whole blood distal to thrombus formation under shear *ex vivo* and *in vivo*.

Aims: Determine whether long-chain polyP-induced contact pathway activation promotes platelet activation and consumption in the bloodstream.

Methods: Human whole blood was collected into citrate, recalcified and studied in open and closed systems. Platelet activation, microaggregation and consumption in the bloodstream were assessed by FACS and thrombus growth was visualized by microscopy.

Results: Presence of long-chain polyP in whole blood enhanced platelet aggregation on immobilized collagen surfaces under shear flow, enhanced fibrin formation and shortened clotting times. Long-chain polyP promoted platelet P-selectin expression, microaggregate formation and platelet consumption in the bloodstream under shear in a FXII-dependent manner. Moreover, long-chain polyP accelerated thrombus formation on immobilized collagen surfaces under shear flow. Distal to the sites of thrombus formation, platelet consumption was dramatically enhanced in the presence of long-chain polyP in the bloodstream. Inhibiting contact activation of the coagulation pathway reduced fibrin formation on collagen as well as platelet consumption in the bloodstream distal to the site of thrombus formation.

Conclusions: This study demonstrates that bacterial-type long-chain polyP promotes FXII-mediated thrombin generation and platelet activation in the flowing blood and could exaggerate sepsis-associated consumptive coagulopathy and thrombocytopenia.

PB 1690 | Fibrin is a strong activator of FXII

H. Kozarcanin[1], K. Nilsson Ekdahl[1,2], B. Nilsson[1], K. Fromell[1]

[1]*Uppsala University, Immunology, Genetics and Pathology, Uppsala, Sweden,* [2]*Linnaeus University, Linnaeus Centre for Biomaterials Chemistry, Kalmar, Sweden*

Background: FXII has recently been shown to participate in a positive feedback mechanism involving the intrinsic pathway, which generates thrombin that influences the structure of the clot. Polyphosphate from activated platelets has been reported to be the trigger of FXII. We have previously demonstrated that clotting of whole blood and plasma generates FXIIa-antithrombin (AT) complexes, while FXIIa-C1inhibitor (C1INH) are detected after blood contact with different material surfaces (i.e. glass, kaolin and polyphosphate). The latter confirms that b-XIIa preferentially is inactivated by C1INH. FXIIa-AT is also generated when platelets in platelet-rich plasma are activated by Thrombin/TRAP and if fibrin is added to plasma.

Aims: Identifying the functional requirement for FXII activation in the clot.

Methods: In order to investigate the mechanism of FXIIa-AT generation, the interaction of FXII with fibrin and fibrinogen was studied using QCM-D, activation assay, ELISA and Simple western.

Results: The results show that FXII, α-FXIIa and β-FXIIa bind to fibrin, in close to equimolar ratio. After binding to fibrin, FXII shows comparable AT-binding capacity as pre-activated FXIIa, indicating that native FXII has been activated to FXIIa by the fibrin. By contrast, neither FXII nor any of the FXII activation products bound to fibrinogen. The enzymatic activity of FXII was assessed by using the chromogenic substrate S-2302, confirming that strong activation occurred upon contact with fibrin and glass, but very little activation occurred on polystyrene. When measuring FXII-serpin complex formation after incubation of normal human plasma on fibrin-coated surfaces, high levels of FXIIa-AT and moderate levels of FXIIa-C1INH were found.

Conclusions: Our results show that fibrin is a strong binder and activator of FXII, thereby being an candidate for triggering FXII activation in the clot. The study also shows that activation of FXII by fibrin is regulated by AT and that FXIIa-AT is a biomarker for blood clotting.

PB 1691 | Increased Kallikrein Generation Potential in Patients Suffering from Hereditary Angioedema

D. Biltoft[1], J.J. Sidelmann[1], A. Bygum[2], Y. Palarasah[1], J.B. Gram[1]

[1]*University of Southern Denmark, Department of Public Health, Unit for Thrombosis Research, Esbjerg, Denmark,* [2]*Odense University Hospital, Department of Dermatology and Allergy, HAE Centre Odense, Odense, Denmark*

Background: Hereditary angioedema (HAE) type 1 & 2 is an autosomal dominant disease resulting in deteriorated function of C1-esterase inhibitor, the main inhibitor of the contact activation and complement systems. HAE patients experience potentially fatal swellings in various body parts. Previous studies suggest contact activation as the cause of the swellings, as these have been associated with increased plasma levels of kallikrein and FXIIa-inhibitor complexes and bradykinin.

Aims: In this study, we measured the plasma kallikrein generation potential (KGP) of HAE patients in the resting state of the disease, and compared the results to the KGP of normal individuals.

Methods: Plasma from both groups (n = 6+6) was investigated using the calibrated kallikrein generation method.

Results: The KGP in HAE patients was considerably higher than in healthy individuals. The area under the curve, i.e. the total kallikrein activity generated over time, was significantly higher in plasmas from HAE patients compared to controls (p = 0.001) (Fig. 1). Furthermore, the median peak height, indicating the highest kallikrein activity measured, was significantly higher than the median peak height of the controls (p = 0.041). Lastly, the median lag time, indicating the time until kallikrein activity could be measured, was borderline significantly lower in HAE patients (p = 0.07).

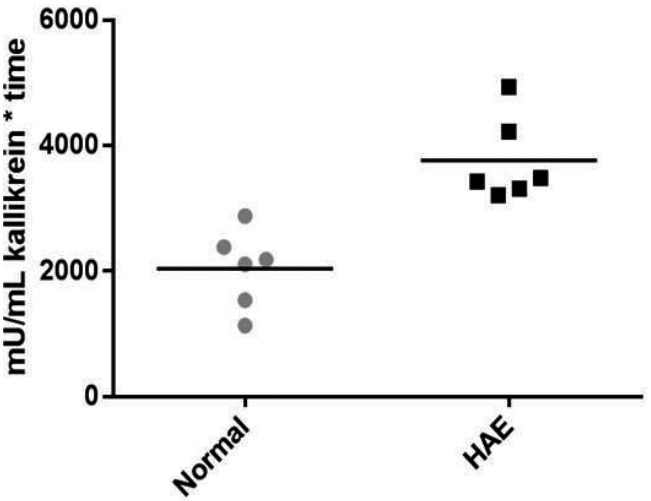

FIGURE 1 The area under curve values obtained from the two groups. A significant difference between the groups was observed (p = 0.001).]

Conclusions: The KGP in plasma from HAE patients, in the resting state of the disease, is significantly increased compared to normal individuals. This suggests that the KGP could be a valuable marker in studies of patients suffering from HAE and possibly other bradykinin-mediated edemas.

PB 1692 | Red Cell and Platelet Microvesicles Activate the Contact System of Coagulation

D. Noubouossie, M. Piegore, M. Henderson, M. Mooberry, N.S. Key

University of North Carolina at Chapel Hill, Medicine, Chapel Hill, United States

Background: Contact system (CS) activates coagulation via the intrinsic pathway and is comprised of factor XII (FXII), prekallikrein and high molecular weight kininogen (HMWK). Although the CS is dispensable for normal hemostasis, animal models suggest that FXII plays a role in thrombosis. In humans, CS contributes to activation of coagulation and thrombosis in the setting of extracorporeal circulation devices.

Aims: Determine how red blood cell (RBC) and platelet (PLT) microvesicles (MV) activate the CS of coagulation.

Methods: Platelet rich plasma (PRP) and RBCs were isolated from whole blood collected in citrate, corn trypsin inhibitor (CTI) and PPACK. Purity of PRP and RBC in buffer was confirmed using an automatic cell counter. PRP or RBC were incubated for 1H with 10µM ionophore. After removal of RBC or PLT, MVs were isolated and washed to remove residual CTI and PPACK. RBC or PLT MVs were counted using flow cytometry. Washed MVs were re-suspended in re-calcified normal pooled platelet free plasma (PFP) or deficient plasmas to assess thrombin generation (TG). They were also re-suspended in a synthetic CS reconstructed by diluting purified FXII, FXI and HMWK at their physiological concentration in buffer. After 1H incubation, 3µM purified C1-inhibitor esterase (C1INH) was added followed by addition of 25µM PPACK 30min later. CS activation was assessed using an in house ELISA assay to detect FXIIa-C1INH complexes.

Results: As shown in Fig.1, both RBC-MVs and PLT-MVs triggered TG in normal pooled and FVII deficient, but not FXI deficient plasma. No TG was observed in FXII deficient plasma containing RBC-MVs while some was still detectable with PLT-MVs. Higher FXIIa-C1INH complexes were detected in the presence of both types of MVs as compared to their absence.

Conclusions: In addition to confirming that RBC- and PLT-MVs activate the contact pathway, this study suggests that RBC-MVs may activate FXII while PLT-MPs may activate FXII and FXI. The mechanism of MV-induced CS activation is currently under investigation.

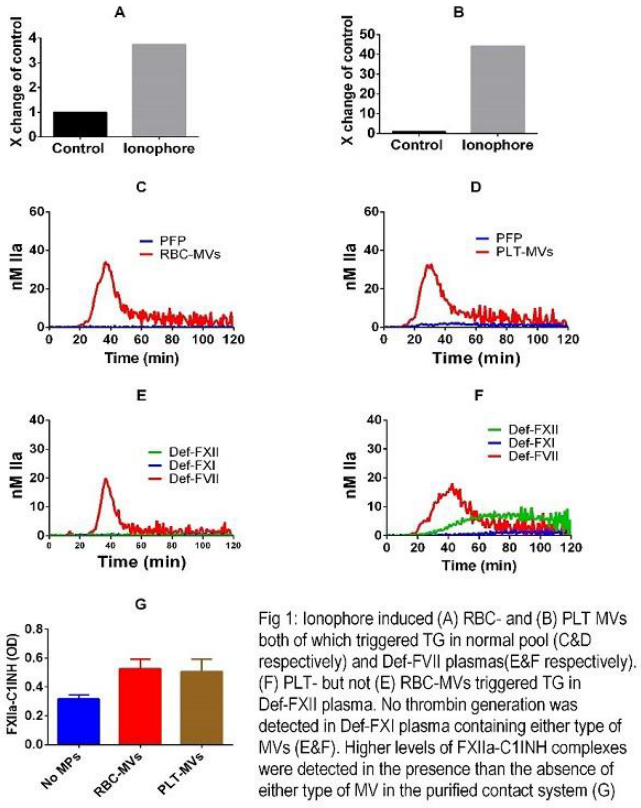

Fig 1: Ionophore induced (A) RBC- and (B) PLT MVs both of which triggered TG in normal pool (C&D respectively) and Def-FVII plasmas(E&F respectively). (F) PLT- but not (E) RBC-MVs triggered TG in Def-FXII plasma. No thrombin generation was detected in Def-FXI plasma containing either type of MVs (E&F). Higher levels of FXIIa-C1INH complexes were detected in the presence than the absence of either type of MV in the purified contact system (G)

FIGURE 1 Procoagulant activity of red blood cell and platelet microvesicles

PB 1693 | Contaminating Silica Particles Contribute Substantially to the Procoagulant Activity of DNA Isolated Using Commercial Kits

S. Smith[1], C. Baker[2], R. Breitenfeld[2], J. Morrissey[2]

[1]University of Illinois, Urbana, United States, [2]University of Illinois, Biochemistry, Urbana, United States

Background: Extracellular DNA and RNA are implicated as initiators of the contact pathway of blood clotting and markers of inflammation and sepsis. Most studies have employed commercial, silica-based spin columns to purify cellular DNA.

Aims: Compare the procoagulant activities of cellular nucleic acids.

Methods: DNA was purified from HEK-293 cells and human neutrophil extracellular traps (NETs) using either phenol/chloroform extraction or DNeasy Blood and Tissue kits (Qiagen). Procoagulant activity was determined by mixing samples with citrated plasma in a 96-well microplate, incubating 3 min at 37°C, then recalcifying and monitoring time to clot formation.

Results: HEK-293 and NET DNA purified using Qiagen kits exhibited substantial (albeit variable) procoagulant activity, while DNA purified by phenol/chloroform extraction had very limited procoagulant activity. The procoagulant activity of kit-purified DNA was only slightly diminished after digestion with nuclease or boiling in acid. When water was applied (in lieu of cellular lysates) to DNeasy columns, the eluates exhibited substantial procoagulant activity. Analyses of these eluates by inductively coupled plasma mass spectrometry identified significant concentrations of silicon. Silica particles and the homogenized matrix material from the DNeasy columns were highly procoagulant.

Conclusions: The clotting activity of cellular DNA that we purified using a commercial kit employing silica-based spin columns appeared to be due to the combination of the very limited clotting activity of DNA plus the much more substantial clotting activity of finely divided silica particles that were found to contaminate such DNA preparations. Some investigators have also used silica-based spin columns to

purify polyphosphate from cells, and these preparations may also be contaminated with silica particles. Conventional means of isolating cellular DNA or polyphosphate (e.g., phenol/chloroform extraction) are recommended when studying the procoagulant activities of these substances.

PB 1694 | Genetic Determinants of Levels of Contact Activation Coagulation Factors

J.L. Rohmann[1], H.G. de Haan[2], A. Algra[2,3,4], F.R. Rosendaal[2], B. Siegerink[1,2]

[1]*Charité Universitaetsmedizin Berlin, Center for Stroke Research Berlin, Berlin, Germany,* [2]*Leiden University Medical Center, Dept. of Clinical Epidemiology, Leiden, The Netherlands,* [3]*University Medical Center Utrecht, Brain Center Rudolph Magnus, Departments of Neurology and Neurosurgery, Utrecht, The Netherlands,* [4]*University Medical Center Utrecht, Julius Centre for Health Sciences and Primary Care, Utrecht, The Netherlands*

Background: The complex, interdependent contact activation system has become increasingly interesting for its role in thrombotic disease. Few genetic determinants of the levels of proteins from this system are known.

Aims: To study the influence of *F11*, *F12*, *KLKB1* and *KNG1* variants on FXI activity (C) and FXI, FXII, prekallikrein (PK), and high-molecular-weight kininogen (HK) antigen (ag) levels.

Methods: We analyzed samples from 630 healthy individuals who participated as controls in one of our studies (RATIO), in which 43 tagging single nucleotide variants (SNVs) were genotyped to represent common genetic variation in *F11*, *F12*, *KLKB1* and *KNG1*. Antigen and activity levels were measured with sandwich ELISA-based and one-stage clotting assays. We performed single variant, age-adjusted, linear regression analyses per trait assuming additive inheritance and then conditioned on the lead SNV to identify independent associations. Haplotypes were based on the lead SNV and all independently associated SNVs per trait.

Results: We identified multiple novel associations in addition to replicating existing findings; lead SNVs and results from conditional analyses are shown in Tables 1 and 2. We found that *F11* SNVs rs2036914 and rs1593 influence FXI:C via FXI:ag, whereas rs4253399 was independently associated with FXI:C and FXI:ag. One *F12* SNV was independently associated with FXII:ag and two *KLKB1* SNVs with PK:ag levels. Additional associations observed between *KLKB1* SNVs and FXI levels are likely explained by linkage between *KLKB1* and *F11* SNVs. We identified three associations between *KNG1* SNVs and HK:ag in addition to lead SNV rs5030062. SNV rs5030062 was also associated with FXI:C, FXI:ag, and PK; although the latter two were largely mediated by HK:ag levels. Haplotype analysis revealed a large joint effect of rs5030062 and rs5029980 on HK:ag (ß=25.22, p< 0.0001).

Conclusions: This study adds to current knowledge of how genetic variation influences levels of contact system proteins and clarifies interdependencies.

TABLE 1 Lead variants associated with contact system proteins

Trait	Gene	Lead variant	Major/ minor alleles	Minor allele frequency	$ß_{singleSNV}$	95% CI	p-value

PB 1695 | Role of the Platelet Surface in the Activation of FXI by FXIIa

S.E. Reitsma[1], C. Puy[1], R.T. Urbanus[2], D. Gailani[3], E. Tucker[1,4], A. Gruber[1], O.J.T. McCarty[1]

[1]Oregon Health & Science University, Department of Biomedical Engineering, Portland, United States, [2]University Medical Center Utrecht, Department of Clinical Chemistry and Hematology, Utrecht, The Netherlands, [3]Vanderbilt University School of Medicine, Nashville, United States, [4]Aronora Inc., Portland, United States

Background: Activation of coagulation factors on the platelet surface plays an essential role in hemostasis. Yet, select members of the contact activation pathway, such as factor (F)XII, seem to be dispensable for hemostasis despite the fact that targeted inhibition of or deficiency in FXII is protective in thrombosis models. In contrast, a minor bleeding phenotype is associated with FXI-deficiency, suggesting that FXI plays some role in hemostasis. Thus, it remains a mystery as to why activation of FXI by FXIIa contributes to thrombosis but not hemostasis. It is also unknown whether platelets perform a differential role in contact pathway activation.

Aims: Characterize the role of platelets in the activation of FXI by FXIIa.

Methods: Human FXI (30nM) and isolated washed platelets (1.5×10^8 plt/mL; resting or activated with 1nM alpha-thrombin) were incubated with activated FXII (FXIIa; 3nM) for 1h at 37°C in the presence of 10μM Zn^{2+}. Corn trypsin inhibitor (CTI; 20μg/mL) was added to stop the reaction before a FXIa chromogenic substrate was added and FXIa generation was measured at 405nm.

Results: The results show that in the absence of platelets, a linear response in FXIIa-mediated FXIa generation was observed; furthermore, the presence of resting platelets had no effect on the rate of FXIa generation. The presence of activated washed platelets completely abolished FXIa activity. Moreover, the supernatant from activated platelets likewise eliminated FXIa activity. Yet, when purified FXIa was added directly, only the platelet supernatant retained the ability to inhibit FXIa activity, while an increase in FXIa activity was observed in the presence of activated platelets.

Conclusions: Our results suggest that the platelet surface pacifies the activation of FXI by activated FXIIa, while protecting the activity of FXIa. Moreover, our findings suggest that activated platelets secrete inhibitors to block FXI activation by FXIIa or FXIa activity, such as protease nexin 2.

PB 1696 | Contribution of Intrinsic Coagulation Factors on ex vivo Thrombus Formation and Lysis

J. Konings[1,2], J.M. Cosemans[2], B. de Laat[1,2], H. ten Cate[3], Y. Dargaud[4], J.W. Govers-Riemslag[2,3]

[1]CARIM, Maastricht University, Synapse Research Institute, Maastricht, The Netherlands, [2]CARIM, Maastricht University, Department of Biochemistry, Maastricht, The Netherlands, [3]CARIM, Maastricht University Medical Center, Department of Internal Medicine, Laboratory for Clinical Thrombosis and Hemostasis, Maastricht, The Netherlands, [4]Unité d'Hémostase Clinique, Hôpital Cardiologique Louis Pradel, Hospices Civils de Lyon, Bron, France

Background: Coagulation factor XI (FXI) and FXII are identified as targets for antithrombotic therapy, but the exact mechanisms by which these proteins contribute to clot formation and lysis are still unclear.

	FR (% decline/min)	5.3 [3.7-7.8]	6.2 [4.8-8.0]	10.8 [9.0-17.6] C	C=0.01	3.3 [0.9-7.2]	3.0 [1.7-10.0] C	C=0.03

Data are expressed as Median [min-max]. CT: Clotting time; MCF: Maximum clot firmness; LT: Lysis time; LOT: Lysis onset time; FR: Fibrinolysis rate FR=75/(LT-LOT) A: P <0.05, Factor deficiency vs. 100% corrected Factor deficiency (Wilcoxon); B: P <0.05, Factor deficiency vs. Control ((Mann Whitney); C: P <0.05 100% corrected Factor deficiency vs. Control (Mann Whitney).

Aims: To determine the role of coagulation FXI and FXII in ex vivo clot formation and lysis.

Methods: Blood was drawn from patients with a severe deficiency in FXI or FXII and healthy controls. Thrombin generation (TG) was determined in platelet rich plasma (PRP) using 0.5 pM TF or 1μM sulfatides. Purified FXI or FXII was added to correct deficiency towards normal. ROTEM parameters were determined ± addition of tPA using 15 pM TF or 4μM sulfatides. Fibrinolysis rate (FR, %decline/min) was calculated from the ROTEM parameters lysis onset time and lysis time.

Results: Both in FXII and FXI deficiency TG was delayed, peak and ETP were reduced in FXII deficiency, not in FXI deficiency, upon activation with sulfatides; neither condition had any effect on TG induced by TF(Table1). Addition of 100%FXI led to higher ETP values in patients compared to controls (TF and sulfatides), while addition of 100%FXII higher ETP values are only obtained when activated with sulfatides, but not with TF. In whole blood ROTEM experiments only the clotting time was significantly prolonged in both FXII- and FXI deficients upon sulfatide stimulation(Table2); neither showed any difference in fibrinolysis between patients and controls. Upon correction of the deficiency towards 100%, the FR was higher when initiated with sulfatides in FXII deficient patients and lower in FXI deficient patients versus controls.

Conclusions: TG in PRP was impaired both in FXII and FXI deficient patients after contact activation; correction towards 100% resulted in an overcompensation of ETP. While ROTEM only showed a delay in CT in FXII deficient patients, neither deficiency had impact on fibrinolysis. Correction of FXII enhanced fibrinolysis, in contrast, correction of FXI lowered fibrin degradation probably due to a firmer clot due to more thrombin formation.

PB 1697 | Generation of a Monoclonal Antibody against "Fast Form" Alpha-2-macroglobulin and Development of a Method to Measure Artificial Surface Driven Protease Activation in Plasma

D. Biltoft, J.J. Sidelmann, J.B. Gram, Y. Palarasah

University of Southern Denmark, Department of Public Health, Unit for Thrombosis Research, Esbjerg, Denmark

Background: Human alpha-2-macroglobulin (α_2M) is a 725 kDa broad-spectrum inhibitor, targeting almost any protease in plasma. The mechanism of inhibition conducted by α_2M is a unique and multi-step process resulting in an irreversible conformational change of α_2M into a complexed or "electrophoretic fast-form" (F-α_2M).

Aims: Because of its involvement in coagulation, fibrinolysis, contact activation, and inflammation, we hypothesized that detection of F-α_2M could be a valuable marker for the *in vitro* evaluation of the blood/plasma compatibility of artificial surfaces.

Methods: Generation and characterization of a F-α_2M specific monoclonal antibody without interference with native α_2M and development of a sandwich ELISA to measure F-α_2M levels.

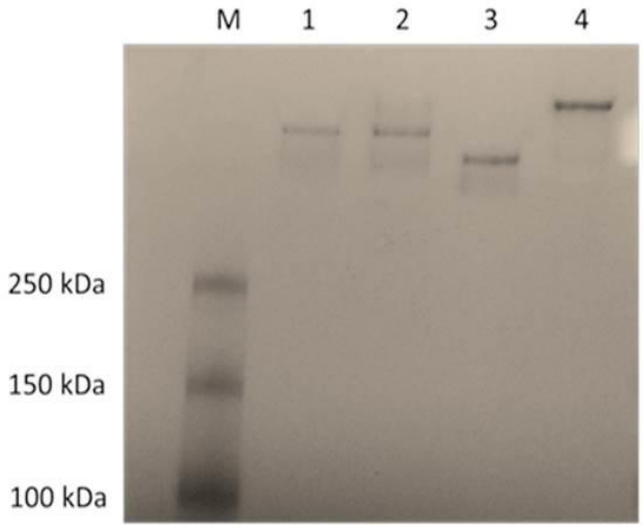

FIGURE 1 Native PAGE of a2M and F-a2M in presence or absence of 16-11-17. 1: α2M; 2: α2M + 16-11-17; 3: F-α2M; 4: F-α2M + 16-11-17.

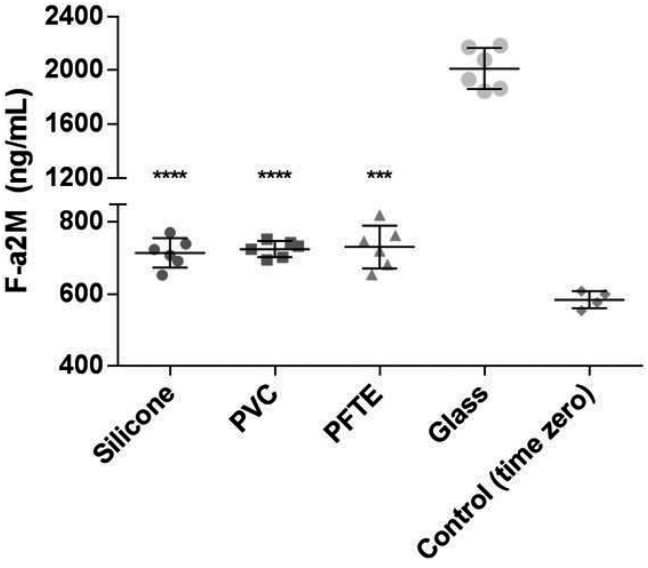

FIGURE 2 F-α2M levels in plasma after incubation with artificial materials. Stars indicate a significant difference compared to the control sample

Results: The specificity of the antibody was evaluated with native PAGE, demonstrating that antibody 16-11-17 recognized F-α_2M, but not native α_2M (Fig. 1).

Furthermore the antibody showed reactivity to recombinant receptor binding domain region of F-α_2M, which is hidden in native α_2M. The F-α_2M levels of plasma samples incubated, in the absence of calcium, with commonly used artificial surfaces were evaluated. F-α_2M levels in plasma samples incubated in silicone (n = 6), polyvinylchloride (PVC) (n = 6), and polytetrafluoroethylene (PFTE) (n = 6) tubings, as well as glass tubes, were significantly higher than control samples ($p < 0.001$) (Fig. 2), indicating activation of calcium independent proenzymes by the artificial surfaces.

Conclusions: A F-α_2M specific antibody was developed and used for F-α_2M measurements in plasma by ELISA. We demonstrate that the F-α2M level in plasma is a useful marker of blood/plasma compatibility of artificial surfaces in the absence of calcium.

PB 1698 | Haemocompatibility Properties of Polyethersulfone Based Haemodialysis Membrane with Different Amounts of Polyurethane

F. Kamal[1], S.H. Sheikh Abdul Kadir[2], M.H.D. Othman[3], S. Mansur[3], G. Pei Sean[3]

[1]*University of Technology MARA, Pathology, Sungai Buloh, Malaysia,* [2]*University of Technology MARA, Institute of Molecular Biology, Sungai Buloh, Malaysia,* [3]*University of Technology Malaysia, Advanced Membrane Technology Research Centre, Skudai, Malaysia*

Background: The study will explore the haemocompatibility of a haemodialysis membrane based on polyethersulphone (PES) when polymerised with different amounts of polyurethane (PU) and comparing the it with control membrane which is of PES/ PVP (Polyvinylpyrrolidone).

Aims: The aim of the study is to find the PES/ PU based membrane with the best haemocompatibility characteristics.

Methods: PU will be blended with PES and fabricated into hollow fibre membrane for haemodialysis application. To test for biocompatibility, flat sheet rather than hollow membrane will be used in the experiment, which would include testing for protein adhesion using the Micro BCA™ Protein Assay Kit, clotting time using automated blood coagulation analyser, thrombin -antithrombin generation and complement activation using enzyme-linked immunosorbent assay (ELISA).

Results: Preliminary data from this study showed that the BSA adsorption amounts increased with the increased PU in the modified membranes. SEM images analysis for a qualitative measure of platelet adhesion on fabricated PES/PVP/PU composite membrane shows the most significant amount of platelet that adhered and spread on the surface of the membrane are not activated. As more PU loading occur, the platelet adhesion on the surface of the membrane was decreased. In addition, membrane incorporated with PU showed lower TAT generation as compared to its control. In addition, clotting time is shown to be prolonged with different PU loading and there is a significant decrease in concentration of activated C3a in PES/PVP with higher PU percentage as compared to the neat PES/PVP membrane.

Conclusions: Based on this study, it can be suggested that membrane incorporated with PU has better anticoagulant property compared to control. However, this study also showed that protein adsorption is increased with higher PU loading, which could be due to the surface roughness of the membrane that are produced during phase inversion processes.

PB 1699 | Comparison of Nine Different Blood Collection Tubes for Contact Activation of Coagulation

C. Kluft[1,2], J. Jespersen[2], J.W. Govers-Riemslag[3], J.J. Sidelmann[2]

[1]Good Biomarker Sciences, Leiden, The Netherlands, [2]University of Southern Denmark, Unit for Thrombosis Research, Department of Public Health, Esbjerg, Denmark, [3]Maastricht University Medical Center, Laboratory for Clinical Thrombosis and Haemostasis, Department of Biochemistry, Cardiovascular Research Institute Maastricht, Maastricht, The Netherlands

Background: Blood collection induces low grade contact activation of coagulation interfering with tests with low activation triggering.

Aims: To evaluate contact activation differences among collection tubes, we collected nine different and one duplicate tube from 10 healthy volunteers.

Methods: Tubes: Monovette® vacuum and aspiration tubes and Becton Dickinson (BD) plastic tubes all with and without corn trypsin inhibitor (CTI) added immediate after collection, Greiner plastic tubes, coated glass tubes from BD and SCAT® tubes containing citrate + CTI. Tests: NAPTT, thromboelastography with recalcification (NATEM), thrombin generation assay (TGA) with low tissue factor concentration (TGA®-RCH).

Results: CTI increased NAPPT four times; rate of clotting (-CTI) varied among individuals (CV 28%) and variability by tube was smaller (CV 10%). Rate of clotting in the different tubes (- CTI) correlated (R^2 : 0.64-0.93). NATEM showed increased clotting time and decreased alpha angle in the presence of CTI, whereas MCF showed no differences among tubes. TGA showed CTI to be most effective in Monovettes® vacuum and less in BD and SCAT® tubes in reducing signals to nihil. TGA was elevated in some individuals using Monovettes® aspiration tubes with CTI.

In tubes without CTI, time variables (lag, time to peak) were not very different among tubes, but peak height, AUC and in particular velocity to peak showed distinct differences.

Coated glass tubes showed the highest TGA-values, and both B&D and Greiner tubes showed higher values than Monovette® tubes.

Conclusions: We conclude that the rate of thrombin and clot formation is variably affected by the tubes, but the differences are smaller than the differences between individuals. Interestingly, the NAPTT records the individual differences suggesting to be a test for individual differences in potency of the contact system.

TGA is particularly sensitive to tube differences. Monovette® vacuum showed the lowest contact activation among the tested tubes.

PB 1700 | CD40L Induces Association of PRDX-2 and TRAF-2 to CD40 of Platelets from IBD Patients

Y. Limami[1], F. Marhoume[2], M. Oudghiri[3], A. Naya[3], N. Senhaji[4], A. Alami Chentoufi[5], H. Laarej[6], Y. Zaid[7,8]

[1]University of Health Sciences MED VI, Research Center, Faculty of Medicine, Casablanca, Morocco, [2]Faculty of Sciences and Technology, Hassan I University, Settat, Integrative and Computational Neuroscience Team, Laboratory of Biochemistry and Neuroscience, Marrakech, Morocco, [3]Faculty of Sciences, University of Hassan II, Immunology, Casablanca, Morocco, [4]Faculty of Medicine, University of Hassan II, Casablanca, Morocco, [5]University of Health Sciences MED VI, Research Center, Casablanca, Morocco, [6]University of Health Sciences MED VI, Pneumology, Casablanca, Morocco, [7]University of Health Sciences MED VI, Research Centre, Faculty of Medicine, Casablanca, Morocco, [8]Montreal Heart Institute, Montreal, Canada

Background: Although platelets are well known for their role in hemostasis, there are a rising number of studies supporting their considerable role as inflammatory amplifiers in chronic inflammatory conditions. Indeed, platelets circulate in an activated state in patients with inflammatory bowel disease (IBD), but their role in the pathogenesis of IBD remains unclear. It is well established that the CD40L-CD40 complex, a key regulator and amplifier of immune reactivity, is activated in inflammatory bowel disease (IBD) mucosa.

Aims: We have demonstrated by this study that different signaling pathways are triggered downstream of the CD40L-CD40 complex, involving several intraplatelet proteins.

Methods: Platelets from blood of IBD patients and healthy subjects were freshly isolated to evaluate the involvement of TRAFs in response to CD40L-CD40 interaction.

Results: Tumor necrosis factor receptor-associated factor-1 (TRAF-1), TRAF-2 and TRAF-6 are overexpressed in platelets from IBD patients versus control. Furthermore, CD40L-CD40 interaction induces the association of TRAF-2 and PRDX-2 with platelet CD40.

Conclusions: This study adds new insights into the role of TRAFs and PRDX-2 in platelets downstream of CD40-CD40L complex.Thus, the CD40L/CD40/TRAFs-PRDX-2 axis in platelets may represent a critical regulator of platelet function and inflammation.

PB 1701 | Short-term Increase in Factor (F)XIa-dependent Procoagulant Activity in Citrate Blood

S. Prior[1], K. Mann[2], S. Butenas[1]

[1]University of Vermont, Biochemistry, Burlington, United States, [2]Haematologic Technologies, Inc., Essex Junction, United States

Background: It has been observed that in the absence of contact pathway inhibition, the procoagulant activity of fresh citrate blood increases within several minutes.

Aims: To compare changes in thrombin generation potential and its response to FXIa inhibition in citrate blood from healthy donors kept for up to 75 min either in standard plastic vacutainer tubes or in polypropylene conical tubes.

Methods: Fresh blood from 4 healthy donors (2 male and 2 female) was collected into standard 3.2% sodium citrate plastic vacutainer tubes (BD catalog #363083). In one set of experiments, blood was kept at room temperature in such tubes for up to 75 minutes with CTI quenching of aliquots every 15 minutes. Alternatively, blood from the same 3 of 4 donors was immediately transferred to 15 mL polypropylene conicals and the same CTI quench scheme was applied. Thrombin generation (WB-TG) and clot formation (ROTEM) were evaluated. For

selected blood draws, FXIa concentration was quantitated from the response to an inhibitory αFXIa antibody.

Results: For blood kept in vacutainer tubes, a time-dependent increase in procoagulant activity was observed which was partially FXIa-dependent. The most pronounced increase in procoagulant activity occurred in the first 15 minutes post-draw to which the addition of CTI prevented any further increase. No increase in procoagulant activity was observed over the entire 75 minute incubation period when blood from the same donors was kept in polypropylene conical tubes in the absence of CTI.

Conclusions: Fresh citrate blood from healthy donors kept in citrate vacutainer tubes at room temperature leads to an increase in contact pathway-dependent procoagulant activity that is partially FXIa-dependent. The incubation of citrate blood from the same individual in a polypropylene conical tube prevents this contact activation and subsequent increase in procoagulant activity.

PB 1703 | Temporal Contribution of the Platelet Body and Balloon to Thrombin Generation

E.O. Agbani, I. Hers, A.W. Poole

University of Bristol, School of Physiology, Pharmacology and Neuroscience, Bristol, United Kingdom

Background: Ballooned platelets are present in the primary haemostatic plug and subsequent clot after blood vessel injury in human subjects. We recently demonstrated the functional relevance of platelet ballooning to haemostasis and thrombosis, by showing that it coincided with procoagulant microvesiculation and spreading, which massively increased the procoagulant surface area and enhanced thrombin generation.

Aims: It is presently not clear whether the procoagulant nidus of the ballooned platelet is the 'ballooned membrane' or a part of the platelet, termed the 'cap', which we previously described as the remnant 'platelet body'. Here, we aimed to establish the temporal contribution of the platelet body and balloon to thrombin generation.

Methods: 4D fluorescence live-platelet imaging and scanning electron microscopy.

Results: Phosphatidylserine was predominantly expressed on the 'platelet body' or 'cap' at earlier stages of ballooning, whereas the balloon surface itself formed the predominant procoagulant surface at later time points. Both platelet body or 'cap' and balloon form distinct procoagulant 'cauliflower-like' surfaces that support thrombin generation; and unlike classical capping, 'capped platelet' formation is irreversible.

Conclusions: Both ballooned platelet membrane and the platelet body or ,cap' provide important 'cauliflower-like' procoagulant surfaces, but are temporally separated. Furthermore, classical capping is not associated with ballooned platelet formation, therefore the use of 'cap' in the platelet context may need reconsideration.

PB 1704 | Mechanism of Growth and Inhibition of Plasma Clots Growing from a Surface with Immobilised Tissue Factor

C. Kluft[1], N.A. Podoplelova[2], N.M. Dashkevich[3,4], F.I. Ataullakhanov[2,4]

[1]Good Biomarker Sciences, Leiden, The Netherlands, [2]Dmitry Rogachev National Research Center of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation, [3]HemaCore Labs LLC, Moscow, Russian Federation, [4]Center for Theoretical Problems of Physicochemical Pharmacology, Moscow, Russian Federation

Background: Clot formation in plasma in test tubes usually is started with tissue factor homogeneously mixed in the plasma. Clot formation from a surface coated with tissue factor is another phenotype and can be tested in the thrombodynamics analyser where clot growth is recorded by video.

Aims: We evaluated the characteristics of this growth process and its inhibition.

Methods: Citrated plasma was depleted of microvesicles, and corn trypsin inhibitor and excess (4μM) lipids were added before recalcification was starting the process with exposure to surface-bound tissue factor.

The layer formation can be analysed for several variables:

(a) time and rate of initial clot formation in the first 1-2 minutes,

(b) further growth represented by layer thickness reached in 50 minutes and deceleration of the rate of clot growth.

Results: Contact factor, factor XI deficient plasma and normal plasma collected on CTI behaved similar indicating absence of participation of the intrinsic pathway in the test. In FV deficient plasma growth was absent. Adding activated protein C to normal plasma inhibited growth after 1-2 minutes strongly.

In the first 1-2 min after the initiation of clot growth there was no difference between normal control and deficiency in factors VIII, IX. In factor VIII and IX deficient plasma the layer thickness reached in 50 minutes is about 65% of normal, and further continuation of thickening was reduced.

Inhibition by dabigatran delayed clotting, but effects on growth were nihil; rivaroxaban delayed clotting and showed no growth inhibition in factor IX deficient plasma, only inhibited the factor IX dependent growth. Enoxaparin inhibited growth in normal and factor IX deficient plasma.

Conclusions: It is concluded that growth after tissue factor initiation has a core process dependent of factor IX and X, while inhibitors show unique profiles for inhibition of growth.

The test system can be used to evaluate growth inhibitors directed to activation and activity of factor IXa and factor Xa.

PB 1705 | Co-operative Binding of VWF to the TSP8 and CUB Domains of ADAMTS13 is Required for its Conformational Activation

K. South, M. Freitas, D. Lane

Imperial College London, London, United Kingdom

Background: The von Willebrand factor (VWF) cleaving protease, ADAMTS13, circulates in a closed conformation, maintained by an interaction between its N-terminal spacer domain and its C-terminal domains. Conformational activation is mediated by the binding of VWF to the ADAMTS13 C-terminal domains, which causes their dissociation from the spacer domain.

Aims: We aimed to characterize the interaction of the ADAMTS13 spacer domain and it C-terminal domains to further understand the molecular basis of ADAMTS13 conformational activation.

Methods: Binding between isolated ADAMTS13 CUB domain fragments (CUB1, CUB2 and CUB1-2) and MDTCS (an ADAMTS13 N-terminal fragment lacking its C-terminal tail) was analysed by surface plasmon resonance (SPR). The auto-inhibitory potential of the CUB domains was determined by examining their ability to inhibit MDTCS, as well as spacer domain variants, in FRETS-VWF73 assays. The binding of ADAMTS13 and its truncated variants to VWF-D4CK (the binding partner of the ADAMTS13 C-terminus) was analysed by SPR.

Results: SPR analysis revealed that both CUB1 and CUB2 bind to WT-MDTCS. Binding of either CUB1 or CUB2 is inhibited by specific point mutations of the spacer domain exosite (R568/F592/R660/Y661/Y665).

Only CUB1 is able to inhibit the conformationally active variant WT MDTCS. Both CUB1 and CUB2 bind to the VWF-D4CK domains. However, the affinity of VWF-D4CK for ADAMTS13ΔCUB2 and ADAMTS13ΔCUB1-2 is similar (K_D of 176.9 ± 31.6 nM and 181.8 ± 25.3 nM, respectively) to its affinity for WT ADAMTS13 (K_D of 148.5 ± 38.1 nM). In contrast, variants lacking the TSP8 domain exhibit a marked reduction in affinity for VWF-D4CK and the in frame deletion of TSP8 abolishes conformational activation of ADAMTS13.

Conclusions: While both CUB1 and CUB2 interact with the spacer domain, only CUB1 is responsible for mediating the partially inactive conformation. Both CUB1 and CUB2 bind to VWF-D4CK. Conformational activation of ADAMTS13 also requires binding of VWF-D4CK to its TSP8 domain.

PB 1706 | α-Synuclein Binds to Human α-Thrombin and Inhibits Thrombin-mediated Platelet Aggregation: Possible Implications in Parkinson's Disease

G. Pontarollo[1], L. Acquasaliente[1], F. Uliana[1], A. Negro[2], V. De Filippis[1]

[1]University of Padua, Department of Pharmaceutical and Pharmacological Sciences, Padua, Italy, [2]University of Padua, Department of Biomedical Sciences, Padua, Italy

Background: α-Synuclein (αSyn) is an intrinsically unfolded protein expressed in the presynaptic terminals of neurons and is the major component of protein deposits in Parkinson›s disease (PD), a neurodegenerative disease characterized by αSyn overexpression. αSyn is also expressed in platelets, where it is associated with the secretory α-granules. α-Thrombin (αT) is the most potent platelet activator and exploits exosite2- to anchor on the GpIbα platelet receptor. After PAR1- cleavage, αT induces α-granule release and platelet aggregation. Notably, αT-induced platelet degranulation is inhibited by αSyn (Park et al. 2002) and clinical evidences show that patients with PD exhibit a reduced tendency to platelet aggregation and are less susceptible to ischemic stroke (Sharma et al. 1991).

Aims: Establish whether αSyn interacts with αT and study the effect of αSyn on αT-induced platelet aggregation.

Methods: αSyn was expressed in *E. coli* and purified by RP-HPLC. Binding measurements were carried out by fluorescence spectroscopy and Surface Plasmon Resonance (SPR). The effect of αSyn on platelet aggregation was studied on whole blood by Multiple Electrode Aggregometry (MEA).

Results: Fluorescence measurements indicate that full-length αSyn and the synthetic αSyn(103-140) peptide bind to αT with similar K_d values (1.04±0.25 μM). Fluorescence and SPR displacement experiments, carried out with αT specific binders at exosite-1 (hirugen), exosite-2 (fibrinogen g′-peptide), and active site (hirudin fragment 1-47), indicate that both αT exosites participate in αSyn binding. Strikingly, MEA measurements indicate that full-length αSyn (20 μM), but not αSyn(103-140), dose-dependently inhibits αT-induced platelet aggregation, up to 80%.

Conclusions: Our results suggest that αSyn impairs platelet activation by competing with platelet GpIbα receptor for binding to αT exosite-2, thus helping to rationalize earlier clinical evidences showing that PD patients display a reduced risk of thrombotic events.

PB 1707 | The Effect of Short Chained Polyphosphates on Coagulation Activation in a Whole Blood Model

I.I. Høiland[1], R.A. Liang[1], N. Latysheva[1,2], S. Beck Jensen[1], B. Østerud[1], S.A. Smith[3], J.H. Morrissey[3], T.E. Mollnes[1,4,5], O.-L. Brekke[1,4], J.-B. Hansen[1,2], K. G. Jebsen - Thrombosis Research and Expertise Center (TREC), Department of Clinical Medicine, UiT - The Arctic University of Norway, Tromsø

[1]The Arctic University of Norway, Tromsø, K. G. Jebsen - Thrombosis Research and Expertise Center (TREC), Department of Clinical Medicine, Tromsø, Norway, [2]University Hospital of North Norway, Division of Internal Medicine, Tromsø, Norway, [3]University of Illinois, Urbana, Department of Biochemistry, Illinois, United States, [4]Nordland Hospital, Bodø, Research Laboratory, Bodø, Norway, [5]Oslo University Hospital and University of Oslo, Department of Immunology, Oslo, Norway

Background: Human platelets contain short chain (SC, 60-100 units) inorganic polyphosphate (SC-polyP) stored in dense granules that is released on the cell surface upon activation and trigger coagulation. SC-polyP is shown to facilitate coagulation activation by promoting FXI activation by thrombin and augmenting FV activity, whereas longer chain polyP, not present in blood under physiological conditions, is able to activate FXII.

Aims: To investigate whether SC-polyP is able to trigger coagulation activation in human blood and reveal underlying mechanisms.
Methods: Blood was collected in lepirudin tubes (50 µg/mL) from healthy fasting individuals. Blood was incubated at 37°C by different concentrations of SC-polyP (0-100 µM) for different time intervals (0-120 min), at physiological calcium concentrations. Coagulation activation was stopped by adding 10 mM EDTA (final concentration) and monitored by measuring prothrombin fragment 1+2 (Enzygnost® F1+2, Siemens). Factor XII (FXII)-dependent activation of coagulation was inhibited by Infestin® (CSL Behring). The effect of SC-polyP on TF synthesis was assessed by TF mRNA by qPCR and TF activity in monocytes by a chromogenic assay. The effect of SC-polyP was also evaluated in platelet free plasma (PFP).
Results: SC-polyP added to whole blood showed a dose- ($p < 0.01$) and time- ($p < 0.001$) dependent increase in plasma F1+2 levels where incubation of 100 µM SC-polyP for 60 min generated 1939 ± 252 pmol/mL F1+2. Pre-incubation of whole blood with FXII inhibitor before SC-polyP stimulation, reduced F1+2 levels by 94±2 % ($p < 0.005$). Incubation of whole blood with SC polyP did not increase the expression of TF mRNA or cell surface TF activity in isolated monocytes. SC-polyP had no effect on coagulation activation in PFP isolated from lepirudin anticoagulated blood.
Conclusions: SC-polyphosphates trigger coagulation activation through factor XII in a whole blood model at physiological calcium concentrations, but not in a plasma system.

PB 1709 | Evidence for Direct and Indirect Modulation of Haemostatic Factors by miR-494

J. Tay[1,2], W. Lui[1], J. Tian[1,2], Q. Hughes[1,2], J. Tiao[1,2], R. Baker[1,2]

[1]*Murdoch University, Western Australian Centre for Thrombosis and Haemostasis, Murdoch, Australia,* [2]*Perth Blood Institute, Nedlands, Australia*

Background: Oestrogen can modulate Protein S (*PROS1*) expression via miR-494 in *in vitro* models. Several biological functions have been ascribed to miR-494 and we had previously postulated a role for it in oestrogen-mediated acquired Protein S deficiency.
Aims: This study aims to: 1. Characterise the effects of miR-494 on the expression of coagulation factors at the mRNA and protein level. 2. Determine if miR-494 indirectly regulates coagulation factors by directly inhibiting transcriptional factors AP1, SP1 and/or STAT5B.
Methods: HuH-7 human hepatoma cells were transfected with synthetic negative control miRNA (miR-NC) or miR-494, and the levels of mRNA and protein were determined with qPCR and Western blot, respectively, for; PS (*PROS1*); Plasminogen (*PLG*); and Tissue Factor (*F3*) at 48-72h post transfection. *In silico* analyses of 3'UTR sequences of transcription factors AP1 (*JUN*), Sp1 (*SP1*) and STAT5B (*STAT5B*) were performed to identify putative miR-494 binding sites. Computational transcription factor binding analyses (PROMO) was also performed on *PLG* and *F3* promotor regions.
Results: Treatment of HuH-7 cells with miR-494 significantly down-regulated *PROS1*, *PLG*, *SP1* and *STAT5B* mRNA levels, and reduced *PROS1* and plasminogen protein levels, with no changes observed for *JUN*. In contrast, *F3* mRNA expression was significantly increased with miR-494 treatment. *JUN*, *SP1* and *STAT5B* 3'UTRs contained putative miR-494 binding sites, and PROMO analyses identified predicted AP1 binding sites in *PLG* and *F3* promoters, and Sp1 binding sites in the *F3* promoter. No *STAT5B* binding sites were identified.
Conclusions: Coagulation regulation by miR-494 is mediated via direct and indirect targeting of multiple coagulation factors. Direct targets such as *PROS1*, *SP1* and *STAT5B*, results in indirect regulation of *PLG* and *F3*, demonstrating a prothrombotic role for miR-494 and strongly suggests important clinical implications of raised miR-494 levels under high circulating oestrogen levels such as pregnancy.

PB 1710 | Situation-adjusted Anticoagulant Release System with Response to Different Coagulation Factors

M.F. Maitz[1], J. Zitzmann[1,2], J. Hanke[1], C. Renneberg[1], M.V. Tsurkan[1], C. Sperling[1], U. Freudenberg[1], C. Werner[1]

[1]*Leibniz-Institute of Polymer Research Dresden, Institute Biofunctional Polymermaterials, Dresden, Germany,* [2]*Technische Hochschule Mittelhessen, Institut für Bioverfahrenstechnik und Pharmazeutische Technologie, Gießen, Germany*

Background: Healthy vascular endothelium is considered the most effective anti-thrombogenic surface, as it can adjust its anticoagulant properties to the local requirements. Implants or biomedical devices in flowing blood always require an anticoagulant fitting of the surface. This ideally also should respond to the actual coagulation situation.

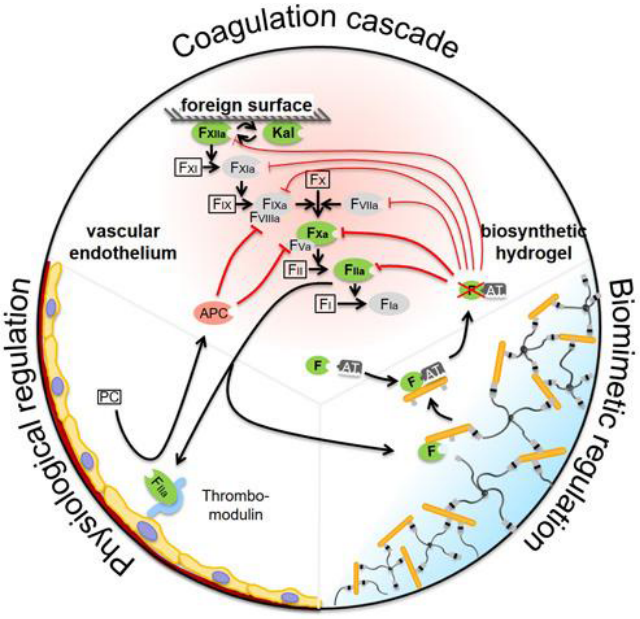

FIGURE 1 Physiological and biomimetic coagulation regulation

A biohybrid hydrogel of starPEG crosslinked with heparin using thrombin-cleavable linker peptides shows such behavior: Thrombin cleaves the linker peptides and releases heparin; this inhibits the thrombin activity and interrupts further degradation of the hydrogel.

Since thrombin is a late enzyme in the coagulation cascade, the timing of the heparin release by this trigger may be suboptimal for thromboprotection.

Aims: Hydrogels with faster release kinetics for a more efficient anticoagulant response.

Methods: starPEG-Heparin hydrogels were prepared using the previously described thrombin-cleavable peptide, a peptide with faster turn-over, a non-cleavable scrambled sequence of the peptide, a factor FXa cleavable, and a kallikrein/FXIIa cleavable peptide as responsive linkers. They were characterized for their general response behavior and for the performance in whole blood.

Results: At equal concentration of the respective enzymes, the kallikrein responsive hydrogel was degraded fastest, followed by the FXa responsive gel and the different thrombin responsive gels. In whole blood, the kallikrein-responsive gel also showed best anticoagulation, associated with highest heparin release, what is attributed to the low feedback effect of heparin on the contact phase system. The FXa- and the standard thrombin-responsive hydrogel had equal anticoagulant properties, but the FXa responsive system achieved this with lower heparin release due to the improved timing of the degradation.

Conclusions: Responsive anticoagulant hydrogels responding on FXa as trigger show a favorable profile of thromboresistance and inhibitor release.

PB 1711 | Liver Hypoxia Regulates Protein S Levels in Obese Patients

V. Pilli[1], A. Dorsey[1], H. Chodavarapu[2], E. Lazartigues[2], R. Majumder[1]

[1]*Louisiana State University Health Science Centre, Biochemistry and Molecular Biology, New Orleans, United States,* [2]*Louisiana State University Health Science Centre, Pharmacology, New Orleans, United States*

Background: Protein S is a vitamin K-dependent plasma protein, produced mainly in the liver; Protein S circulates in the blood at a concentration of 450 nM. Protein S is an anticoagulant, serving as a cofactor for APC and TFP, and as an inhibitor of Factor IX (FIXa). Protein S deficiency causes deep vein thrombosis (DVT), and, because DVT is a complication commonly observed in obese individuals, Protein S deficiency might be associated with obesity.

Aims: To identify a correlation between Protein S abundance and obesity, and identify the cause(s) for the correlation.

Methods: Immunoblots, ELISA, EMSA, CHIP, aPTT assay, and thrombin generation assay.

Results: By ELISA, we measured a decrease in Protein S level in obese mice compared with wild type mice. In obesity, the liver becomes hypoxic, thus, we hypothesized that hypoxia and hypoxia inducible factor 1 alpha (HIF1α) may regulate Protein S expression in obesity. We found that a high fat diet induced HIF1α stability in mice. HIF1α levels were inversely proportional to Protein S levels, suggesting that HIF1α is a negative regulator of Protein S expression. We further identified a putative HIF1α binding site in the Protein S promoter, and, by using *in vitro* and *in vivo* assays, we demonstrated that HIF1α binds directly to the Protein S promoter and suppresses transcription. We further confirmed HIF1α-mediated Protein S transcriptional regulation *in vivo*, Plasma Protein S levels are increased in the liver-specific HIF1α knockout mouse whereas, liver-specific overexpression of HIF1α reduced the concentration of Protein S in the plasma.

Conclusions: We conclude that HIF1α regulates Protein S expression in mouse liver and in obesity. Inhibition of HIF1α or intravenous injection of Protein S may reduce the occurrence of DVT in obese individuals.

PB 1712 | Thrombin is a Selective Inducer of Heparanase Release from Platelets and Granulocytes *via* Protease-activated Receptor-1

M. Tatour[1], M. Shapira[2], E. Axelman[1], S. Ghanem[1], A. Keren-Politansky[1], L. Bonstein[1], B. Brenner[1], Y. Nadir[1]

[1]*Rambam Health Care Campus, Haifa, Israel,* [2]*Hillel Yaffe Medical Center, Hematology Laboratory, Hadera, Israel*

Background: Heparanase, known to be involved in angiogenesis and metastasis, was shown to form a complex with tissue factor (TF) and to enhance the generation of factor Xa. Platelets and granulocytes contain abundant amounts of heparanase that may enhance the coagulation system upon discharge.

Aims: To identify the inducer and pathway of heparanase release from these cells.

Methods: Platelets and granulocytes were purified from pooled normal plasma and were incubated with ATP, ADP, epinephrine, collagen, ristocetin, arachidonic acid, serotonin, LPS and thrombin. Heparanase levels were assessed by ELISA, heparanase procoagulant activity assay and western blot analysis. The effects of selective protease-activated receptor (PAR)-1 and 2 inhibitors and PAR-1 and 4 activators were studied. An in-house synthesized inhibitory peptide to heparanase was used to evaluate platelet heparanase involvement in activation of the coagulation system.

Results: Heparanase was released from platelets only by thrombin induction while other inducers exerted no such effect. The heparanase level in a platelet was found to be 40% higher than in a granulocyte. Heparanase released from platelets or granulocytes increased factor Xa generation by 3 folds. PAR-1 activation *via* ERK intracellular pathway was found to induce heparanase release.

Conclusions: Heparanase is selectively released from platelets and granulocytes by thrombin interacting with PAR-1. Heparanase derived from platelets and granulocytes is involved in activation of the extrinsic coagulation pathway. The present study implies on a

potential anticoagulant effect, in addition to anti-platelet effect, of the new clinically studied PAR-1 inhibitors.

PB 1713 | Effects of Exercise and Erythropoietin on Thrombotic Risk in Well-trained Cyclists

J.A.A.C. Heuberger[1], J.J. Posthuma[2], J.I. Rotmans[3], P. Gal[1], F.E. Stuurman[1], J. van't Westende[1,4], T.E. Post[1,4], J.M.A. Daniels[5], M. Moerland[1], M.L. de Kam[1], J. Burggraaf[1,4], H. ten Cate[2], A.F. Cohen[1,3]

[1]Centre for Human Drug Research, Leiden, The Netherlands, [2]Cardiovascular Research Institute Maastricht, Maastricht University, Laboratory for Clinical Thrombosis and Haemostasis, Maastricht, The Netherlands, [3]Leiden University Medical Center, Internal Medicine, Leiden, The Netherlands, [4]Leiden Academic Centre for Drug Research, Leiden, The Netherlands, [5]VU University Medical Center, Pulmonary Diseases, Amsterdam, The Netherlands

Background: Recombinant human erythropoietin (rHuEPO) is forbidden in sports, even though the effects on performance are not indisputably proven. In addition, it is unknown if rHuEPO increases thrombotic risk.

Aims: To investigate the effects of rHuEPO on thrombotic risk in well-trained cyclists.

Methods: Forty-eight healthy, well-trained male cyclists were randomly allocated to subcutaneous rHuEPO (mean dose 6000IU/week) or placebo for 8 weeks. Venous blood was collected at rest and after maximal exercise tests. Effects on erythropoiesis were assessed by measuring haemoglobin (Hb) and haematocrit (Ht). Thrombotic risk was established by determination of activated partial thromboplastin time (aPTT), prothrombin time (PT), fibrinogen, D-dimer, beta-thromboglobulin (bTG), E-selectin, P-selectin, Factor VIII (FVIII), platelet factor 4 (PF4), thrombomodulin (TM), von Willebrand factor (vWf), prothrombin activation fragment 1+2 (F1+2) and thrombin:antithrombin (TAT).

Results: Mean Hb (9.7mmol/L vs 9.0mmol/L) and Ht (48% vs 44%) were significantly higher in the rHuEPO group compared to placebo. Treatment with rHuEPO significantly increased baseline levels of E-selectin (+8.6% [2.0;15.7%]) and P-selectin (+7.8% [1.5;14.5%]) as compared to controls. Exercise showed a clear association independent of treatment with haemostatic alterations, as reflected by reduced aPTT (-13% [-14;-11%]) and PT (-2% [-3;-1%]) and increased levels of FVIII (+125% [106;146%]), TAT (+593% [413;836%]), F1+2 (+97% [65;135%]), D-dimer (+46% [24;71%]), fibrinogen (+7% [4;10%]), E-selectin (+6% [3;10%]), vWf (+79% [65;95%]), P-selectin (+13% [10;16%]), bTG (+115% [76;163%]) and PF4 (+216% [152;297%]) after maximal exercise test. Increment in TM after maximal exercise was reduced after rHuEPO treatment (+10% vs +15%).

Conclusions: This study is the first to show that rHuEPO, affects biomarkers of pro-thrombosis in well-trained cyclists, which may be considered an indication for increased risk for thrombosis.

PB 1714 | Fibrinogen Polymorphisms Predict Fibrinogen and Clot-related Phenotypes Independently and through Interactions with IL-6

H.T. Cronjé[1], C. Nienaber-Rousseau[1], L. Zandberg[1], Z. de Lange[1], F.R. Green[2], M. Pieters[1]

[1]North-West University, Centre of Excellence for Nutrition, Potchefstroom, South Africa, [2]University of Manchester, Division of Cardiovascular Sciences, School of Medical Sciences, Faculty of Biology, Medicine & Health, Manchester, United Kingdom

Background: The identification of single nucleotide polymorphisms (SNPs) that functionally contribute to fibrinogen-related phenotypes in Europeans has been hindered by high linkage disequilibrium (LD) in the fibrinogen gene cluster. African population data can be utilised to overcome this limitation through its great genetic variability and low LD. Furthermore, apart from independent SNP functionality, fibrinogen SNPs alter the magnitude of interleukin-6 (IL-6)-induced

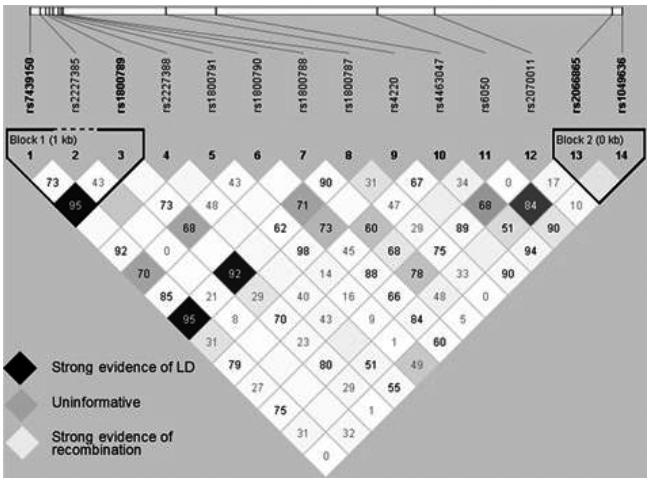

FIGURE 1 Pairwise LD structure of 14 fibrinogen SNPs, illustrated by D' values on an r2 colour scheme

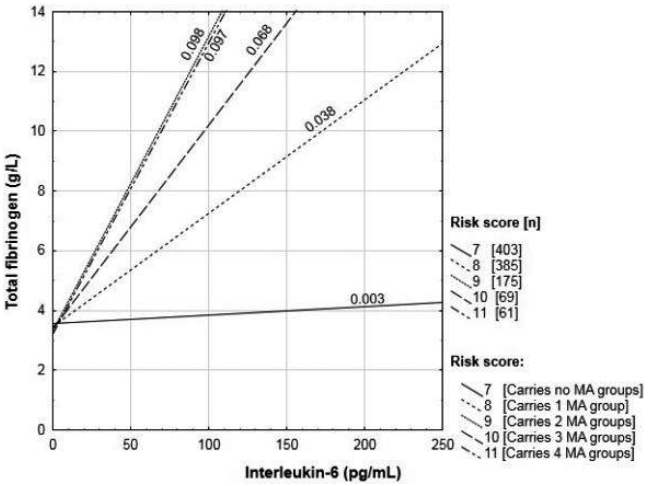

FIGURE 2 Association of total fibrinogen concentrations with circulating interleukin-6 by minor allele (MA) risk score groups

fibrinogen expression. Investigating these relationships in an African population with high basal fibrinogen and IL-6 concentrations could provide valuable insight into expressionrelated fibrinogen SNP functionality.

Aims: To identify SNPs that functionally contribute to fibrinogen's quantitative and qualitative phenotypes independently and through IL-6 interactions.

Methods: Twelve fibrinogen SNPs previously investigated for functionality, and two novel African SNPs were analysed cross-sectionally in 2010 Africans in terms of their independent and IL-6-interactive associations with fibrinogen concentrations and turbidity-derived clot properties.

Results: No complete LD or common European fibrinogen haplotype were observed in this population (Fig 1). SNPs of particular functional relevance were *FGB*rs7439150, $1420_{G/A}$ and $148_{C/T}$. These SNPs significantly associated with fibrinogen concentrations and altered clot properties, with several of these associations influenced by IL6. In addition, harbouring more minor alleles concurrently resulted in greater increases in IL-6-induced fibrinogen expression (Fig 2).

Conclusions: The lack of LD and haplotypes in the fibrinogen genes of this African population allowed for the identification of independent functional SNPs. The additive nature of harbouring risk alleles concurrently, in the presence of IL-6 is shown for the first time. When investigating the phenotypic relevance of fibrinogen genetics, possible additive SNP effects and the contribution of modulating factors should be considered.

PB 1715 | Integrative Analysis of Hemostatic Gene Regulation in the Human Liver

M. Olsson, T.M. Stanne, M. Davila, C. Jern

University of Gothenburg, Gothenburg, Sweden

Background: Most coagulation factors are produced in the liver. Tight regulation of these genes is crucial to avoid thrombus formation which can lead to ischemic stroke. In the present study, we utilized high resolution gDNA-, mRNA-, and DNA methylation sequencing (-seq) of human liver tissue to identify mechanisms regulating hemostatic genes by analyzing allele-specific DNA methylation (ASM) and allele-specific gene expression (ASE). Furthermore, we investigated associations between genetic variants and gene expression (eQTL), genetic variamts and DNA methylation (meQTL), and gene expression and DNA methylation (eQTM). Candidate variants identified in this project will be analyzed for association to ischemic stroke and other thrombotic events.

Aims: To identify novel cis-regulatory variants and DNA methylation patterns regulating coagulation and other hemostatic genes in the human liver.

Methods: We have collected biopsies of human liver tissue from adults undergoing liver surgery at the Sahlgrenska University Hospital (n=70). For the first set of samples (n=19) we isolated genomic DNA (gDNA) and total RNA. We designed a targeted approach in order to enrich and sequence 77 selected genes that are important for hemostasis, including upstream and downstream regions, and their corresponding mRNA transcripts. SNPsplit (Babraham Inst.) was used for ASM analysis and ASE ReadCounter (GATK, Broad Inst.) was used to call ASE. The R package Matrix eQTL was used to assay eQTLs, meQTLs and eQTMs.

Results: 60% of the 77 selected genes displayed an ASM bias of >30% between the two alleles. Genes with the highest number of ASM were PLG and VWF. ASE was identified in 80% of the genes analyzed. Initial results from the QTL analyses revealed approximately 4446 cis-meQTL associations (70 genes), 1172 cis-eQTLs (45 genes), and 247 eQTMs (29 genes).

Conclusions: The present study provides novel insights into the mechanistic relationships between genetic variation, DNA methylation and expression of hemostatic genes in the human liver.

PB 1716 | Effects of the fibrinogen γ' C-terminal Peptide on Thrombin-catalyzed Activation of Factor XI, Factor XIII and TAFI

F. Omarova[1], J. Rosing[1], R.A.S. Ariens[1,2], H.R. McPherson[2], R.M. Bertina[3], E. Castoldi[1]

[1]Maastricht University, Cardiovascular Research Institute Maastricht (CARIM), Department of Biochemistry, Maastricht, The Netherlands, [2]University of Leeds, Leeds Institute of Cardiovascular and Metabolic Medicine, Thrombosis and Tissue Repair Group, Leeds, United Kingdom, [3]Leiden University Medical Center, Department of Thrombosis and Haemostasis, Leiden, The Netherlands

Background: Thrombin is a multifunctional enzyme that converts fibrinogen to fibrin and activates platelets, coagulation factors (F) V, VIII, XI and XIII, the anticoagulant protein C and thrombin activatable fibrinolysis inhibitor (TAFI). The two exosites of thrombin are crucial for substrate recognition and for the regulation of thrombin activity. The C-terminus of the fibrinogen γ' chain binds with high affinity to thrombin exosite II, thereby inhibiting thrombin-catalyzed activation of platelets, FV, FVIII and protein C.

Aims: To determine how fibrinogen γ' affects the other functions of thrombin.

Methods: The effects of the fibrinogen γ' chain C-terminal peptide on thrombin-catalyzed activation of FXI (in the presence of dextran sulfate), FXIII (in the absence and presence of fibrinogen) and TAFI (in the presence of thrombomodulin) were investigated in model systems using purified proteins. The involvement of the thrombin exosites in these reactions was probed using aptamers specifically targeting either exosite.

Results: The fibrinogen γ' peptide and both aptamers inhibited FXI activation by thrombin/dextran sulfate and TAFI activation by thrombin/thrombomodulin in a dose-dependent manner. Conversely, the peptide did not affect FXIII activation in the absence or presence of fibrinogen. Aptamer HD1 (targeting exosite I) inhibited FXIII activation only in the presence of fibrinogen, while aptamer HD22 (targeting exosite II) was effective both with and without fibrinogen.

Conclusions: In summary, the fibrinogen γ' peptide inhibits thrombin-catalyzed activation of platelets, FV, FVIII and FXI (anticoagulant effects), protein C (procoagulant effect) and TAFI (profibrinolytic effect),

but does not affect FXIII activation. These findings may help explain the risk of venous thrombosis associated with decreased fibrinogen γ' levels.

PB 1717 | Characterization of GGCX Mutations Identified in the First Clinical Case of a VKCFD Patient

D.-Y. Jin, B. Ingram, D.W. Stafford, J.-K. Tie

University of North Carolina at Chapel Hill, Biology, Chapel Hill, United States

Background: Vitamin K-dependent coagulation factors deficiency (VKCFD) is an autosomal recessive bleeding disorder resulting from decreased levels of coagulation factors II, VII, IX and X, as well as natural anticoagulants (protein C, S and Z). Two types of VKCFD have been identified based on the mutations of enzymes in the vitamin K cycle. VKCFD1 is associated with functional defects in gamma-glutamyl carboxylase (GGCX), whereas VKCFD2 arises from defects in vitamin K epoxide reductase (VKOR) activity. Although the first clinical case of VKCFD was described in 1966 (PMID: 5936414), the causative mutations in that case have remained unestablished.

Aims: Here, we report identification and characterization of the causative mutations in the first described clinical case of VKCFD.

Methods: Exome sequencing was used to identify mutations in the patient's genomic DNA. Cell based assays, protein biochemistry and fluorescence confocal microscopy imaging were used to characterize the mutant proteins.

Results: Five mutations in the GGCX gene were identified. Two compound heterozygous mutations have not been previously reported. One is a deletion of an adenine at position c.1657 (C.1657ΔA) in exon 12 - which causes a reading frame shift and the early termination of the translation of GGCX. The other is an intronic mutation at c.1889 G-6A in intron 13. Minigene splicing assay results suggest that the c.1889 G-6A mutation causes mis-splicing and retention of 4 intronic bases in exon 14. Functional characterization of these two mutants shows that the c.1657ΔA mutant lacked GGCX activity, while the activity of the c.1889 G-6A mutant was significantly reduced. Importantly, higher vitamin K concentrations were found to restore the carboxylation activity of the c.1889 G-6A mutant up to 80%.

Conclusions: Our results, consistent with the patient's clinical results, suggest that the patient has type I VKCFD and that the c.1889 G-6A mutation in GGCX is the causative mutation for the patient's clinical phenotype.

PB 1718 | Comprehensive Identification of miRNA-gene Interactions Reveals Extensive Regulation of the Plasmatic Coagulation Network

J. Nourse[1,2], J. Braun[3], S. Hüttelmaier[3], S. Danckwardt[1]

[1]*University Medical Center Mainz, Center for Thrombosis and Hemostasis, Mainz, Germany,* [2]*University Medical Center Mainz, Institute for Clinical Chemistry and Laboratory Medicine, Mainz, Germany,* [3]*Martin Luther University Halle (Saale), Halle, Germany*

Background: Through the post-transcriptional fine-tuning of gene expression miRNAs confer robustness to the complex molecular networks regulating biological functions. However despite the ubiquitous involvement of miRNAs in almost all biological processes, their global role in blood coagulation has remained poorly defined, with studies in the field largely focusing on the effects of small numbers of miRNAs on single genes.

Aims: Here we set out to comprehensively identify miRNAs regulating both pro- and anti-coagulatory components of the hemostatic system in an unbiased manner.

Methods: To investigate systemic roles of miRNAs unbiased and extensive methodologies are required. In contrast to widely applied association and in silico studies, we have utilised an integrative assay approach that combines functional aspects of miRNA silencing with physical interaction studies based on RNA pull downs coupled to next generation sequencing and finally validation of specific miRNA-gene interactions.

Results: This analysis initially revealed over one third of the examined hemostatic genes to exhibit significant Dicer-mediated silencing activity, suggestive of targeting by miRNA. Further investigation revealed numerous miRNAs to physically interact with these genes of which luciferase assays confirmed approximately 50 specific miRNA/UTR interactions to result in significant levels of silencing.

Conclusions: These results suggest that the hemostatic system is widely controlled by miRNAs targeting multiple genes that may act as regulatory target hubs within the plasmatic coagulation network. These findings provide the first comprehensive analysis deciphering the role of miRNAs in the systemic control of blood coagulation and provide a foundation for the development of novel therapeutic approaches for the correction of de-regulated hemostasis in the future.

PB 1719 | Resolving the Roles of Platelets and (Anti)Coagulation Pathways in Whole-blood Fibrin Formation under Flow to Phenotype Hemostatic Disorders

J.P. van Geffen[1], F. Swieringa[1,2], S.L.N. Brouns[1], R.W. Farndale[3], K.J. Clemetson[4], E. Castoldi[1], P.E.J. van der Meijden[1], M.E.J. Kuijpers[1], J.W.M. Heemskerk[1]

[1]*Maastricht University / Cardiovascular Research Institute Maastricht (CARIM), Department of Biochemistry, Maastricht, The Netherlands,* [2]*Leibniz Institute for Analytical Sciences - ISAS-e.V., Department of Bioanalytics, Dortmund, Germany,* [3]*Cambridge University, Department of Biochemistry, Cambridge, United Kingdom,* [4]*Inselspital, University of Bern, Department of Haematology, Bern, Switzerland*

Background: The interactive roles of platelet responses and (anti)coagulation mechanisms in fibrin clot formation under flow are difficult to study *in vivo*.

Aims: Establish key interactions between platelets and coagulation pathways in human blood perfused over an array of adhesive and coagulation-modulating surfaces.

Methods: Human blood was perfused at defined shear rates over microspotted platelet-adhesive and pro/anti-coagulant surfaces, collagen I (COL1), GPO+VWF-BP (collagen mimicking peptide, CMP), collagen III (COL3), rhodocytin+VWF-BP (RHO), laminin+VWF-BP (LAM), thrombomodulin (TM) and activated protein C (APC) with/out tissue factor (TF). Fibrin-thrombus formation was determined by multicolor fluorescence microscopy. Data modelling resulted in a beta matrix of determinants of coagulation pathways.

Results: At high shear rate (1000/s) kinetics of fibrin clot formation on microspots decreased in the order of COL1>CMP>COL3>LAM,RHO with(out) TF. At low shear rate the positions of CMP and RHO reversed, in agreement with high platelet activity of CLEC-2 surfaces. Measurements of time to first fibrin formation showed kinetics in the same order. Regardless of the shear rate, the presence of TF and of PS-exposing platelets were independent determinants of fibrin formation. With TF triggering, both anticoagulant TM and APC prolonged and diminished fibrin clot formation. Inhibition of the extrinsic (active-site-inhibited FVIIai) but not intrinsic (CTI) pathway reversed all TF effects. Without TF, either CTI or FVIIai suppressed fibrin formation in the order of CMP>COL1,COL3>LAM,RHO with limited effect on platelet deposition. Roles of intrinsic, extrinsic and anti-coagulation pathways were verified with blood from patients.

Conclusions: Modelling revealed surface- and shear-dependent parameters that were strongly determined by extrinsic and anti-coagulation pathways. A prediction model was built of surface- and platelet-dependent fibrin formation for phenotyping of patients with bleeding disorders.

PB 1720 | Temperature Effects on Thrombin Generation

M. Moorlag[1,2], R. Kremers[1,2], B. de Laat[1,2], H.C. Hemker[1,2]

[1]*Synapse Research Institute, CARIM, Maastricht University, Maastricht, The Netherlands*, [2]*Maastricht University / Cardiovascular Research Institute Maastricht (CARIM), Biochemistry, Maastricht, The Netherlands*

Background: Thrombin generation (TG) is now implemented in more than 1000 (research) laboratories worldwide. TG data are used in a variety of fields from clinical research to mathematical modeling. Mathematical modelers generally assume TG to be chemically controlled, meaning that it abides to the van ´t Hoff rule and doubles the reaction velocity for every 10°C increase in temperature.

Aims: To investigate the temperature dependence of TG, thereby elucidating the rate limiting factors of thrombin formation.

Methods: TG was measured in normal pooled and defibrinated, platelet poor plasma (PPP) at 1, 5 & 10pM tissue factor. A dedicated temperature controller was built into the fluorometer. It consists of a PID controller that steers a resistive heater attached to an aluminum mold. The mold decreases the overall temperature variation throughout the 96 wells plate to < 0.1°C.

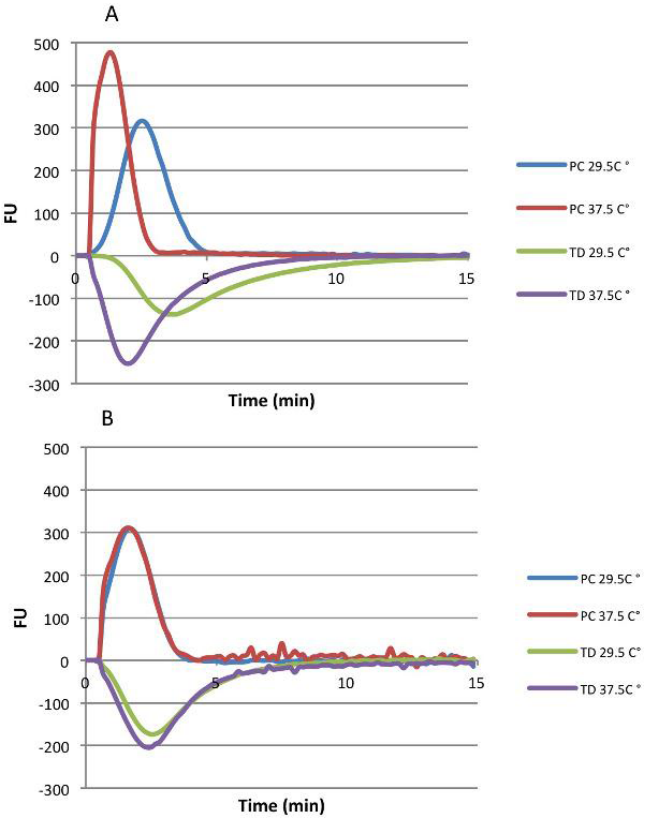

FIGURE 1 Prothrombin Conversion (PC) and Thrombin Decay (TD) in PPP (A) and defibrinated PPP (B) at 37.5C° and 29.5C°

Results: The calibrator curves obey to the rules of chemical control and increase by 10% in activity, for every 1°C increase in temperature over the biological range (29.5 - 37.5°C). Thrombin decay is more affected by temperature in PPP compared to prothrombin conversion, i.e. 84% decrease compared to a 51% increase in through/peak levels at 37.5°C compared to 29.5°C. In defibrinated plasma, the peak of prothrombin conversion was not affected and thrombin decay had a 17% lower through, see figure 1 for details.

Conclusions: Analysis of prothrombin conversion and decay separately reveals that thrombin decay is inhibited stronger by a reduction in temperature then thrombin formation, causing TG parameters to increase at reduced temperatures. Interestingly, this effect is much less apparent in defibrinated plasma with a much less pronounced difference between the parameters for thrombin formation and decay at different temperatures.

PB 1721 | Thrombin Generation in Schizophrenia Patients Treated with Antipsychotic Medications

S. Allen[1], S. Okigbo[2], K. Egan[1], A. Al Zadjali[1], D. Kenny[3], P. Maguire[1], B. Kevane[4], F. Ni Ainle[4], J. Thakore[2]

[1]*University College Dublin/Conway Institute, Dublin, Ireland*, [2]*St Vincent's Hospital, Dublin, Ireland*, [3]*Royal College of Surgeons in Ireland, Dublin, Ireland*, [4]*Mater Misericordiae University Hospital, Dublin, Ireland*

Background: Schizophrenia patients have reduced life-expectancy, commonly due to cardiovascular disease (CVD). Intriguingly, antipsychotic medications have been reported to reduce death from CVD and inhibit platelet aggregation responses. However, the effect of these medications on plasma thrombin generation (TG) is unknown.
Aims: To compare plasma thrombin generation in schizophrenia patients receiving anti-psychotic medications with matched controls.
Methods: Medicated schizophrenia patients (n=18) and matched controls (n=6) were recruited. TG in platelet rich (PRP) and platelet poor plasma (PPP) was characterized using calibrated automated thrombography. Patients receiving haloperidol/risperidone (H/R) and clozapine/olanzapine (C/O) (n=6 for each drug) were grouped for analysis in view of similar side-effect profiles.
Results: In the absence of a tissue factor (TF) stimulus, lag time to initiation of TG was prolonged (17.6±1.4 v 13.7±0.7min; p=0.015) and velocity index, ETP and peak thrombin were decreased (60±16 v 154±13nmIIa/min, p=0.0014; 1403±193 v 1901±82nmIIa, p=0.012 and 199±37 v 373±18nmIIa, p=0.0002 respectively) in H/R PPP v controls. Peak thrombin was also decreased in C/O patients (291.7±42nmIIa vs 373±18nmIIa; p=0.047) but velocity index and ETP were similar to controls. In the presence of a TF stimulus, lag time was prolonged in both H/R and C/O v controls (7.1±0.2 (C/O) and 8.2±0.4 (H/R) vs 5.8±0.2 min; p=0.0001 and 0.0004 respectively) but velocity index, ETP and peak thrombin were unchanged. In PRP, similar patterns were observed but absolute differences were smaller.
Conclusions: Medicated schizophrenia patients exhibit reduced plasma thrombin generation compared with matched controls. This may represent an additional potential mechanism underlying the observed cardioprotective effect of these medications.

PB 1722 | Blood Clot Contraction is Reduced in Sickle Cell Disease due to Increased Rigidity of Erythrocytes

V. Tutwiler[1,2], R. Litvinov[1], C. Nagaswami[1], E. Russell[1], D. Seigel[1], C. Villa[1], D. Pan[1], V. Muzykantov[1], J. Weisel[1]

[1]University of Pennsylvania, Philadelphia, United States, [2]Drexel University, Philadelphia, United States

Background: Blood clot contraction or retraction, which is the volumetric shrinkage of the clot, has been implicated to play a role in hemostasis and thrombosis. The cellular and molecular composition of the clot, including red blood cells (RBCs), influences the extent and rate of the three phases of clot contraction. Thus, there is a need to examine the effects of diseases where RBCs differ from those of healthy individuals, such as sickle cell disease (SCD). SCD is associated with a hypercoagulable state that contributes to vaso-occlusive events in microcirculation and an increased risk of venous thromboembolism.
Aims: The aim of this study was to examine differences in clot contraction in blood samples from SCD patients compared to healthy donors.
Methods: To follow clot cot contraction, we used an optical tracking methodology that allows for the quantitative tracking of clot size with time. Blood clotting and contraction were initiated using 2 mM $CaCl_2$ and 1 U/ml thrombin and contraction was followed for 20 minutes.
Results: The blood clots of SCD patients were examined and on average had a 53% decrease in the extent of clot contraction, and contracted 2.4 times slower during Phase 2 and 2.7 times slower Phase 3 when compared to healthy subjects. We hypothesized that the reduction in clot contraction could be due to increased RBC stiffness in SCD patients. Consistent with this idea, the addition of naturally rigid llama ovalocytes to human platelet rich plasma and the addition of antibodies to the Wright b epitope, which increase RBC rigidity, resulted in a decrease in extent of clot contraction compared to normal untreated human RBCs.
Conclusions: These results demonstrate that clot contraction is altered in SCD and suggest that the RBC rigidity contributes to the observed reduction in extent of clot contraction. A better understanding of RBC deformability in the process of clot contraction may inform the development of more targeted treatments for thrombosis in patients with altered RBC mechanical properties.

PB 1723 | Tissue Factor-dependent Heme-induced Whole Blood Coagulation Activation: A Thromboelastometry Study

B.W. Hounkpe[1], G.R. de Souza[1], M.M.L. Fiusa[1], M. Pereira Colella[2], J.M. Annichino-Bizzacchi[1,2], F. Traina[3], F. Ferreira Costa[1,2], E.V. De Paula[1,2]

[1]University of Campinas, Faculty of Medical Sciences, Campinas, Brazil, [2]University of Campinas, Hematology and Hemotherapy Center, Campinas, Brazil, [3]University of Sao Paulo, Ribeirao Preto, Brazil

Background: Recently, free heme emerged as one of the potential triggers of inflammation in hemolytic anemias such as sickle cell disease (SCD). In hemostasis, heme has been shown to exert both pro- and anti-coagulant effects, although the mechanisms underlying these effects are yet to be determined. We have recently demonstrated that heme induces a hypercoagulable state detected by thromboelastrometry and thrombin generation assays.
Aims: Herein, we investigated whether these effects are dependent on tissue factor (TF).
Methods: Citrated whole blood samples from healthy volunteers were stimulated by vehicle or heme (30μM), with or without inhibitory tissue factor antibody or control IgG (10μg/ml), and incubated for 4h at 37°C. Rotem was performed using a non-activated thromboelastometry procedure in a ROTEM®instrument, from which parameters of different stages of clotting were obtained.
Results: When compared to an isotype control, the use of an anti-tissue factor inhibitory antibody abrogated the effect of heme in coagulation activation, resulting in increase in clotting time (Fig1a) and in a decrease in the time to maximal velocities (Fig1c). Inhibition had no

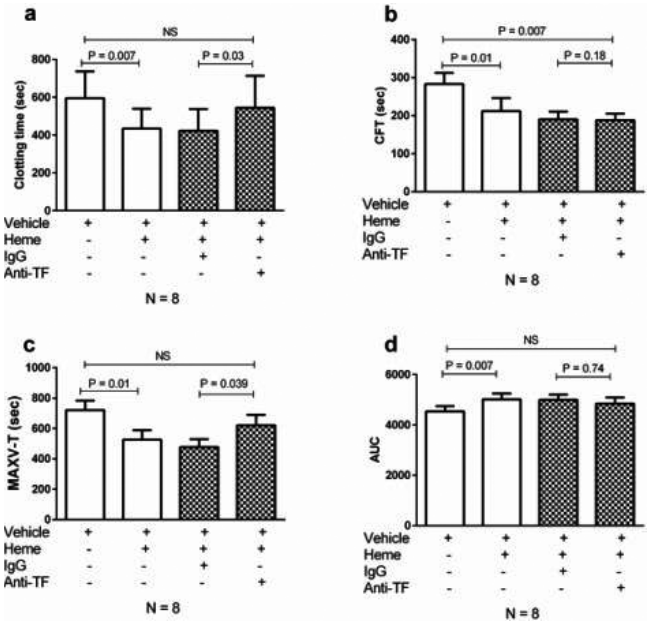

FIGURE 1 Heme triggered-coagulation activation is tissue factor-dependent

effect on clot formation time (Fig1b) or in the area under the Rotem curve (Fig1d).

Conclusions: Using global hemostasis assay capable of detecting clinically relevant changes in hemostasis, we demonstrated that heme was capable of inducing coagulation activation of whole blood in a TF-dependent fashion, influencing predominantly the kinetic of clot formation. These results support the concept that free heme could play a relevant role in coagulation activation in SCD, and in other pathological conditions. Further studies are necessary to elucidate the mechanism of this heme influencing effect in hemostasis.

PB 1724 | Salivary EV: A New Link between Primary and Secondary Hemostasis

Y. Yu[1], E. Gool[2], R. Berckmans[1], A. Sturk[1], A. Barendrecht[3], C. Maas[3], R. Nieuwland[1]

[1]*Academic Medical Center, Clinical Chemistry, Amsterdam, The Netherlands,* [2]*Academic Medical Center, Biomedical Engineering & Physics, Amsterdam, The Netherlands,* [3]*University Medical Center Utrecht, Clinical Chemistry and Haematology, Utrecht, The Netherlands*

Background: Human saliva contains extracellular vesicles (EV) exposing tissue factor (TF; Blood. 2011; 117: 3172-80). This TF triggers coagulation in platelet-depleted plasma, but whether salivary EV interact with platelets to promote coagulation is hitherto unexplored.

Aims: We hypothesized that the TF-exposing EV from saliva interact with platelets exposing P-selectin, as described earlier for TF-exposing EV from tumor cells in a mouse model of vascular injury (J Exp Med. 2009; 206: 1913-27), thus making the platelets procoagulant.

Methods: To test this hypothesis, we investigated the presence of P-selectin glycoprotein ligand-1 (PSGL-1) and CD24, two known ligands of P-selectin, on salivary EV.

Results: While the presence of PSGL-1 on salivary EV was below the detection limit when analyzed by high-resolution flow cytometry, CD24 was exposed abundantly ($p < 0.05$). Removal of CD24-exposing EV by immune-depletion resulted in the complete removal of the TF coagulant activity as measured by fibrin generation test (n=5), indicating that CD24 and TF are co-localized on EV. This co-localization of CD24 and TF was confirmed by immune-transmission electron microscopy. In a whole blood flow model, salivary EV accumulated on the surface of aggregated platelets, and the deposited EV promoted fibrin generation (n=5). The involvement of EV-CD24 and platelet P-selectin in the interaction is under study by using inhibitory antibodies. Finally, most (70%) of the CD24+ salivary EV originate from granulocytes ($CD66b^+$).

Conclusions: Collectively, we demonstrate that $CD24^+/TF^+$ EV may be a novel link between primary (platelet processes) and secondary (coagulation) hemostasis at a site of vascular injury.

PB 1725 | Heme-regulated Proteins within the Blood Coagulation Cascade: Insights into the Molecular Basis of Protein Binding to Free Heme

D. Imhof, S. Mai, C.A. Bäuml, A. Wißbrock

University of Bonn, Bonn, Germany

Background: Recently, biochemical research has focused strongly on the role and action of heme as a regulatory effector of proteins [1]. The extracellular release of large amounts of heme cannot be dealt with appropriately by scavenging heme-binding proteins. Consequently, transient binding of free heme to proteins was shown to significantly change a protein´s function. We demonstrated that distinct sequence stretches on the protein surface are responsible for the interaction with heme [2-5].

Aims: Based on the screening of a combinatorial peptide library we predicted motifs for heme binding as well as respective proteins as potential targets [2]. These efforts led us to have a closer look on proteins of the blood coagulation cascade. Indeed, the procoagulant activity of factor VIII was earlier shown to be inhibited by heme [6]. Distinct heme-regulatory motifs, however, have not been characterized thus far.

Methods: UV-vis, EPR, resonance Raman, and NMR spectroscopy studies revealed the existence of different binding modes for heme-peptide/protein complexes [3-5]. Thus, apart from examining the impact of heme on the protein activity structural studies are required to evaluate the heme-binding capacity of the target proteins.

Results: We report attempts to identify and characterize heme binding to Von Willebrand factor (vWF), FVIII and vitamin K dependent protein C. The binding data, structural characteristics and impact on the respective protein activity will be discussed.

Conclusions: The ability of transient heme binding of the target proteins may have serious pathophysiological relevance and needs to be considered in vivo.

PB 1726 | Heparan Sulfate Chains Contribute to an Anticoagulant Milieu in Malignant Pleural Effusion

E. Hardak[1], E. Peled[1], Y. Crispel[1], S. Ghanem[1], J. Attias[1], I. Kogan[1], B. Brenner[1], Y. Nadir[2]

[1]Rambam Health Care Campus, Haifa, Israel, [2]Rambam Health Care Campus, Thrombosis and Haemostasis Unit, Haifa, Israel

Background: While malignant pleural effusion (MPE) is a common and significant cause of morbidity in cancer patients, current treatment options are limited. Coagulation system is a major contributing factor to tumor growth and angiogenesis. Human heparanase, involved in angiogenesis and metastasis, cleaves heparan sulfate (HS) side chains on the cell surface and in the extracellular matrix, yielding HS fragments of still appreciable size (5-7 kDa).

Aims: Our study explored the coagulation milieu in MPE and infection pleural effusion (IPE).

Methods: Samples of 30 patients with MPE and 44 with IPE were evaluated in comparison to those of 33 patients with transudate pleural effusions, using heparanase ELISA, heparanase procoagulant activity assay, thrombin and factor Xa chromogenic assays and thromboelastography. A cell proliferation assay was performed. A cell line of mouse breast cancer (EMT-6) was injected to the pleural cavity of mice. Peptide 7, inhibiting heparanase activity, was administered subcutaneously.

Results: Levels of heparanase, factor Xa, thrombin and procoagulant activity were significantly higher in exudate than transudate. Thromboelastography detected no thrombus in MPE samples. This effect was reversed when the assay was performed with bacterial heparinase, degrading HS chains to small chains that have no effect in coagulation system. Proliferation of human glioma (U87) and human breast carcinoma (T47D) cell lines was higher with addition of exudate than transudate. IPE induced greater proliferation than MPE ($p<0.001$); however, the difference was reversed when bacterial heparinase was added to MPE. Tumors in the pleural cavity of mice treated with peptide 7 were significantly smaller compared to control ($p<0.0001$).

Conclusions: HS chains, possibly released by heparanase, could create an anticoagulant milieu in MPE, preventing local thrombosis and fibrosis. Inhibition of heparanase might provide a therapeutic option for patients with recurrent MPE.

PB 1727 | Myeloperoxidase (MPO) is a Negative Regulator of Phospholipid-dependent Coagulation

L. Beckmann[1], C. Dicke[1], B. Spath[1], B. Sievers[1], C. Lehr[1], A. Klinke[2], S. Baldus[2], V. Rudolph[2], F. Langer[1]

[1]Universitätsklinikum Eppendorf, Hamburg, Germany, [2]Herzzentrum der Universitätsklinik Köln, Köln, Germany

Background: MPO is a heme protein with positive surface charge abundantly expressed in neutrophils, where it plays a critical role in anti-microbial host defense by catalyzing the production of hypochlorous acid from H_2O_2 and Cl^-. Extracellular MPO also contributes to vascular inflammation, but its direct effects on the blood clotting process are unknown.

Aims: To investigate coagulation in the presence of MPO/H_2O_2.

Methods: We used single-stage clotting, factor Xa and thrombin generation assays to study the effect of purified leukocyte-derived MPO on tissue factor (TF)-dependent and -independent coagulation.

Results: In the presence of H_2O_2, MPO inhibited the procoagulant activity (PCA) of lipidated recombinant human TF (rhTF) in a time- (0-30 min) and concentration-dependent (0-10 µg/mL) manner by >90%. MPO also exerted inhibitory activity towards rhTF in the absence of H_2O_2, albeit to a lesser extent than equimolar concentrations of the phosphatidylserine (PS) binding protein, annexin V. MPO/H_2O_2 synergized with inhibitory TF monoclonal antibody in neutralizing the PCA of monocyte-derived microvesicles isolated from LPS-stimulated whole blood, suggesting that modification of procoagulant phospholipids (PLs) rather than interference with the TF/FVIIa initiation complex was involved. Consistently, MPO/H_2O_2 inhibited the PCA of activated platelets from healthy donors and rabbit brain cephalin, a PL preparation devoid of measurable TF activity. Finally, the PCA of disrupted myelomonocytic HL60 cells and patient-derived myeloblasts was significantly enhanced, when cell lysis was carried out in the presence of the MPO inhibitor, 4-ABAH.

Conclusions: Our findings indicate that MPO is a negative regulator of PL-dependent coagulation and suggest that both the catalytic activity and non-catalytic properties of the enzyme, presumably via electrostatic interactions with the negatively charged head groups of PS, are involved in this process.

PB 1728 | Procoagulant Properties of Microparticles Produced by Monocytes, Granulocytes, Platelets and Endothelial Cells

A. Mazurov[1], O. Antonova[1], N. Golubeva[1], S. Khaspekova[1], O. Shustova[1], V. Yakushkin[1], I. Alchinova[2], M. Karganov[2]

[1]Russian Cardiology Research and Production Complex, Moscow, Russian Federation, [2]Institute of General Pathology and Pathophysiology, Moscow, Russian Federation

Background: Membrane microparticles (MPs) released by activated or apoptotic cells exhibit coagulation activity since they express phosphatidylserine and some of them – tissue factor (TF).

Aims: We compared procoagulant properties of MPs derived *in vitro* from monocytes, granulocytes, platelets and endothelial cells (ECs).

Methods: MPs were produced by activated monocytes, granulocytes and platelets, isolated from donors' blood, and by activated cultured THP-1 monocytic cells and ECs. MPs were sedimented from the culture media and cell supernatants at 20000 g for 30 min. MPs were counted by flow cytometry and their size was evaluated by dynamic light scattering. Coagulation activity of MPs was examined using modified plasma recalcification assay. TF activity was measured by its ability to activate factor X.

Results: All MPs significantly accelerated plasma coagulation in a recalcification assay with the shortest lag times for MPs from monocytes, intermediate – for MPs from THP-1 cells and ECs, and the longest – for MPs from platelets and granulocytes. Coagulation activity of all MPs was completely inhibited by a phosphatidylserine blocker – lactadherin. Average diameters of MPs ranged within 400-600 nm. The largest MPs were produced by ECs and granulocytes, smaller – by monocytes, and the smallest – by THP-1 cells and platelets. The highest TF activity was detected in MPs from monocytes, lower activity – in MPs from ECs and THP-1 cells, and no activity – in MPs from platelets and granulocytes. Anti-TF blocking antibody extended plasma coagulation lag times for MPs from monocytes, ECs and THP-1 cells and equalized them with those for MPs from platelets and granulocytes.

Conclusions: Significant differences of coagulation activity were revealed between MPs of different cellular origin. Higher activity of MPs from monocytes, THP-1 cells and ECs in comparison with MPs from platelets and granulocytes was mainly determined by the presence of active TF.

PB 1729 | Ventricular Assist Devices without Anticoagulation: An Impossible Dream?

P.A. Coghill[1], Z. Azartash-Namin[1], J.R. Stanfield[1], T.A. Snyder[1], J.W. Long[2]

[1]*Vadovations, Inc, Oklahoma City, United States,* [2]*Integris Baptist Medical Center, Advanced Cardiac Care, Oklahoma City, United States*

Background: Heart failure patients who receive a ventricular assist device (VAD) often require anticoagulation to prevent pump thrombosis and thromboembolism. However, 40% of patients also suffer from bleeding complications. The result is a fine balance between hemorrhage and stroke with a tipping point that allows for a minimal margin of error in anticoagulation monitoring.

Aims: The aim of this study was to characterize the thrombogenic potential of materials and coatings for use in a prototype miniaturized VAD.

Methods: Blood bank whole blood units were supplemented with heparin at 0.75U/mL and recalcified to 0.5M. Recalcified blood was incubated with or without material samples and rocked at 1Hz. Platelet-rich plasma, isolated from samples collected at 0, 30, 60, 90 and 120 minutes, was run in a modified thrombogram assay. At 2h, materials were gently rinsed in phosphate buffered saline and assessed for platelet adhesiveness through visual inspection and by lysing adhered platelets in 2% Triton X-100 and assaying the resulting solution for lactate dehydrogenase. The thrombogenicity of VAD prototypes was investigated by implanting healthy ovines with the device for up to 90 days with no anticoagulation, followed by a full necropsy.

Results: Materials approved for use in VAD prototypes displayed a minimum 50% reduction in thrombin generation rate compared to bare titanium. Visual inspection after 2h in recalcified blood showed significantly less thrombus adhesion than bare titanium. LDH assays performed on platelet lysate solutions from these materials showed a minimum reduction of 60% in LDH activity over bare titanium. Healthy ovines implanted with prototype VADs survived 90 days with no anticoagulation, and full necropsies showed no evidence of thromboembolic events.

Conclusions: Strict attention to material properties combined with explicit standardized requirements for pre-clinical device testing offer the potential of a VAD that will not require patients to receive anticoagulation.

PB 1730 | Beta-adrenergic Receptor Blockage Reduces Exercise-induced Alterations in Haemostasis

J.J. Posthuma, J.J.N. Posma, R. van Oerle, H.M.H. Spronk, H. ten Cate

Cardiovascular Research Institute Maastricht, Maastricht University, Laboratory for Clinical Thrombosis and Haemostasis, Maastricht, The Netherlands

Background: Exercise-induced alterations in haemostasis enhances the risk of thrombotic events, such as deep venous thrombosis and pulmonary embolism. The latter is associated with elevated catecholamines during exercise.

Aims: To investigate the potential of inhibiting catecholamine effects with beta-adrenergic receptor blocker propranolol on exercise-induced haemostatic alterations.

Methods: Healthy males (n=6) assessed maximal exercise tests in addition of propranolol (40mg) and without propranolol as control. Performance was measured by maximal power output (MPO) and maximal oxygen uptake (VO2max). Blood was collected before, 1 min and 4 hours after exercise. Coagulation profile was assessed by thrombin generation, levels of coagulation factor VIII (FVIII), thrombin-antithrombin (TAT) and prothrombin fragment 1+2 (F1+2). Platelet function was evaluated with platelet count, platelet factor 4 and P-selecti levels. Data was analyzed by Wilcoxon matched-pairs signed rank test a 2-tailed $p< 0.05$ was considered statistically significant.

Results: Propranolol not significantly affects on MPO (300±45Watt vs 310±60Watt) and VO2 max (3919±820mL/min vs 4051±830mL/min).

Nevertheless, thrombin generation potential was reduced upon propranolol addition, reflected by lower endogenous thrombin potential (ETP), peak height and velocity index directly after exercise (table 1). Compared to pre-exercise, the altered thrombin generation potential in controls persisted at 4 hours after exercise, which was prevented by propranolol (table 2). In addition, coagulation activity markers significantly less elevated in the propranolol group upon exercise (table 1). Furthermore, significantly lower platelet count was found after exercise upon propranolol usage (18±7% vs 27±9%), where platelet activation markers remained unchanged in both groups.

TABLE 1 Differences in thrombin generation potential and coagulation activation markers pre- vs 1 min post exercise. *p<0.05

	Propranolol (Median [IQR])	Controls (Median [IQR])	p-value
Peak Height	+26%[19-45]	+98%[43-125]	0.03*
ETP	+10%[6-14]	+41%[19-57]	0.03*
Velocity Index	+35%[20-94]	+144%[64-231]	0.03*
TAT	+18%[9-40]	+35%[16-133]	0.03*
F1+2	+11%[10-23]	+23%[21-56]	0.03*
FVIII	+17%[13-21]	+127%[95-187]	0.03*

TABLE 2 Differences in thrombin generation potential pre- vs 4 hours post exercise. *p<0.05

	Propranolol (Median[IQR])	Controls (Median[IQR])	p-value
Peak Height	+16%[13-19]	+66%[40-94]	0.03*
ETP	+1%[0-7]	+11%[4-29]	0.03*
Velocity Index	+22%[16-32]	+86%[63-124]	0.03*

Conclusions: Our study shows inhibitory effects of beta-adrenergic blockage on exercise-induced haemostatic alterations. However, potential clinical relevance needs to be elucidated in future studies.

PB 1731 | The Modification of Thrombin Generation Assay Parameters in Patients with Recurrent Pregnancy Loss

D. Bahri, H. Baccouche, A. Chakroun, Z. Manai, S. Mahjoub, N. Ben Romdhane

Rabta Hospital, El Manar University, Department of Hematology, Tunis, Tunisia

Background: Previous investigations of the role of genetic thrombophilic markers in unexplained pregnancy loss have yielded conflicting results. The thrombin generation test (TGT) is an attractive alternative to better explore the hemostatic pathway.

Aims: This study aimed to characterize the underlying prothrombotic potentiel of patients with unexplained recurrent pregnancy loss (RPL) through thrombin generation assessment.

Methods: Women aged 18-40 years who had experienced three or more unexplained miscarriages < 14 weeks or one loss >14 weeks of pregnancy were prospectively recruited from September to December 2016. Venous blood samples were obtained outside the pregnancy and after a minimum of six weeks following pregnancy loss.

Patients were compared to healthy women with no history of pregnancy loss.

Thrombin generation in platelet poor plasma was analysed using two reagents: PPP REAGENT (optimal concentration of tissue factor 5pm and phospholipids 4 nM) and PRP REAGENT (Without adding phospholipids).

TGT parameters analyzed were: lag time, time to peak (ttPeak), Peak height of thrombin (Peak), area under curve (ETP) and velocity index.

Results: Fifty two women provided data for the study (32 subjects and 20 controls) were included. There was no difference in mean ages (29.7 vs 29.6 years). With PPP reagent, there was no significant difference in lag time (2.33 vs 2.11; p=0.19) and ttPeak (4.31 vs 4.08; p=0.3) between controls and subjects groups. While Peak, ETP and velocity index were less increased in controls than patients: respectively (212.5 vs 265; p=0.009, 827.9 vs 1056.3; p=0.003 and 107.01 vs 140.5; p=0.009).

With PRP reagent, the only significant difference was observed in ETP (943.51 vs 1143.4; p=0.037).

Conclusions: In our study, women with RPL had a relative hypercoagulable states assessed by the TGT. It seems that microparticules play a role in this prothrombotic potential. TGT could be usefull in identifying wowen with risk of RPL.

PB 1732 | Desmopressin Administration in a Splenectomised Hemophilia A Patient Does Not Affect FVIII, VWF and tPA Plasma Levels: An Evidence for an Indirect Effect of DDAVP

T. Shahani[1,2], Z. Pirdel[2], H. Dinmohammadi[2], L. Salarilak[2], M. Karimi[3], M. Jacquemin[4]

[1]Zanjan Pharmaceutical Biotechnology Research Center, Zanjan University of Medical Sciences, Zanjan, Iran, Islamic Republic of, [2]Department of Genetics and Molecular Medicine, Zanjan University of Medical Sciences, Zanjan, Iran, Islamic Republic of, [3]Hematology Research Center, Shiraz University of Medical Sciences, Shiraz, Iran, Islamic Republic of, [4]Department of Cardiovascular Sciences, Center for Molecular and Vascular Biology, KU Leuven, Leuven, Belgium

Background: Despite four decades of desmopressin acetate (DDAVP) prescription for the management of bleeding disorders, its mechanism of the effect on FVIII, VWF and tPA plasma level enhancement remains largely elusive. There are strong evidences for VWF and tPA concomitant release from endothelial weible-palade bodies in direct response to DDAVP. However, reported observations of vasopressin 2 receptor (V2R) expression on some endothelial cell types (ECs) does not explain the 2-3 fold increase in VWF and tPA levels upon DDAVP administration.

Aims: It's been proposed that DDAVP might drive its VWF/tPA raising property in response to an intermediate agonist which is released from V2R expressing cells. We hypothesized, based on various evidences that those DDAVP responding cell might reside in the Spleen.
Methods: A splenectomised 27-years old male patient affected with FVIII deficiency and β-thalassemia was recruited. PT, APTT, INR, FVIII:C, FVIII inhibitor, VWF: Ag and tPA: Ag levels were assessed in patient plasma samples, collected prior to, and 1, 2 and 4 hours following intravenous administration of 0.3 µg per Kg body weight of Desmopressin Acetate over 30 minutes. The study was conducted in accordance with the Helsinki Declaration and approved by Zanjan University of Medical Sciences Ethics Committee (ZUMS.REC.1395.68; 31 May 2016).
Results: As shown in table 1, no changes in FVIII:C, VWF and tPA antigen levels was observed in patient plasma before and after DDAVP administration. No FVIII inhibitor was detected in patient plasma.

TABLE 1 Patient's laboratory data measured before and after DDAVP administration at various time points

		After DDAVP Administration		
Laboratory test	Before DDAVP Administration	1 hour	2 hours	4 hours
PT patient	13.9	14.5	14.1	14.9
PT Normal	12.8	12.8	12.8	12.8
APTT patient	56.8	60	60.6	62
APTT Normal	30	30	30	30
APTT mixed	36.1	36.5	36.2	35.7
FVIII:C (U/dl)	2.94	2.58	2.15	1.85
VWF:Ag (U/ml)	1.08	0.91	0.99	1.01
tPA:Ag (µg/ml)	4.31	3.84	4.09	4.06

Conclusions: Although it has been shown that DDAVP does not affect FVIII:C levels in patients with moderate hemophilia A, we were still expected to observe a significant (2 to 3 fold) raise in VWF:Ag and tPA levels if the spleen is not important for an indirect response to DDAVP. *In vitro* studies are ongoing to further clarify molecular details of the proposed mechanism.

PB 1734 | Haemostatic Function after Spontaneous Intracerebral Haemorrhage

S.V. Lauridsen[1], A.M. Hvas[2], E. Sandgaard[2], T. Gyldenholm[2], C. Rahbek[3], N. Hjort[4], E.K. Tønnesen[1], C.L. Hvas[1]

[1]Aarhus University Hospital, Dept. of Anaesthesiology and Intensive Care, Aarhus, Denmark, [2]Aarhus University Hospital, Centre for Haemophilia and Thrombosis, Dept. of Clinical Biochemistry, Aarhus, Denmark, [3]Aarhus University Hospital, Dept. of Neuroradiology, Aarhus University Hospital, Aarhus, Denmark, [4]Aarhus University Hospital, Dept. of Neurology, Aarhus, Denmark

Background: The haemostatic function after acute intracerebral haemorrhage (ICH) is not fully elucidated.
Aims: Firstly, we aimed to describe haemostatic function in ICH patients at admission and compare this with healthy individuals. Secondly, to analyse changes in haemostasis during the first 24 hours. Our hypothesis was that ICH-patients display a systemic activated haemostatic function acutely compared to healthy individuals.
Methods: From 2014 to 2016, this prospective, observational study included 41 non-anticoagulated patients with ICH at Aarhus University Hospital, Denmark. Patients admitted to hospital within 6 hours of symptom onset were enrolled. Blood samples were collected on admission, 6 and 24 hours after symptom onset.
Thromboelastometry (ROTEM®) was performed and thrombin generation was quantified by Calibrated Automated Thrombogram®. Thromboelastometry and thrombin generation data on healthy individuals was obtained from Department of Clinical Biochemistry, Aarhus University Hospital.
Results: On admission, maximum clot firmness (MCF) was significantly increased compared with healthy individuals (EXTEM p< 0.0001; INTEM p< 0.0001; FIBTEM p< 0.0001). Thrombin generation results showed a higher endogenous thrombin potential (p=0.01) and peak thrombin (p< 0.0001) on admission compared with healthy individuals. The thromboelastometry parameters did not change significantly between admission and 24 hours after symptom onset. In contrast, thrombin generation results showed a decrease in endogenous thrombin potential (p< 0.0001) and peak thrombin (p< 0.0001) within 24 hours.
Conclusions: Thromboelastometry and thrombin generation indicated a subtle systemic activation of coagulation in the acute phase of ICH compared with healthy individuals. The total thrombin-generating capacity decreased significantly at 24 hours compared with symptom onset.

PB 1735 | Anticoagulant effects of peptide Pro-Gly-Arg in aging rats

T. Obergan, M. Grigorjeva

Lomonosov Moscow State University, Biological Department, Moscow, Russian Federation

Background: It is known that aging is accompanied by depression of the anticoagulation system of organism (DAS), resulting in hypercoagulability of blood, which can lead to the thrombosis. It was found that the regulatory peptides glyproline are involved in the activation of the anticoagulation system, preventing the formation of blood clots and have fibrinolytic and anticoagulant effects in the organism.
Aims: To evaluate the anticoagulant effects of the peptide Pro-Gly-Arg (PGR) and its influence on the parameters of blood coagulation in aging rats with DAS.
Methods: Male Wistar rats of the two age groups ("young rats" - 3-month-old, and "old rats" - 12-month- old) were used in this study. PGR-treated old rats received peptide PGR (1 mg/kg on the body weigth) by intranasal way during 3 days. Untreated old rats (control) and young rats (normal) received 0.85% saline. Blood samples were taken 1 h after 3rd administration of drugs. Anticoagulant activity of

blood plasma was estimated by standard clotting methods: APTT, Prothrombin time (PT) and Thrombin time (TT). All experiments were complied with the Declaration of Helsinki.

Results: We confirmed DAS in untreated old rats: there were hypercoagulation and acceleration of clot formation in blood (APTT decreased by 35%, prothrombin time - by 47% and thrombin time - by 16% from young normal rats). PGR-treatment led to a marked enhancement of anticoagulant activity of blood: APTT raise by 26% from untreated old rats. This was accompanied by a more significant increase of prothrombin and thrombin time by 89% and 50% respectively from control levels.

Conclusions: Thus, the peptide PGR participates in the regulation of coagulant processes and restores the functional state of the anticoagulation system in aging animals with DAS. The PGR-treatment impact on all phases of blood coagulation, with more alters the activity of prothrombinase and the final stage of coagulation slowing the rate of conversion of fibrinogen to fibrin.

PB 1736 | A Polydeoxynucleotide Derived Drug Defibrotide Inhibits Nucleosome Generation in Whole Blood. Implications in the Management of VOD

J. Fareed[1], U. Cornelli[2], D. Hoppensteadt[1], A. Walborn[2], J. Walenga[3], M. Iacobelli[1], W. Jeske[3]

[1]*Loyola University Medical Center, Pathology, Maywood, United States,* [2]*Loyola University Medical Center, Pharmacology, Maywood, United States,* [3]*Loyola University Medical Center, Thoracic and Cardiovascular Surgery, Maywood, United States*

Background: Defibrotide (Defitelio, Jazz Pharmaceutical, Palo Alto, CA) is a single stranded deoxyribonucleic acid derived antithrombotic and anti-ischemic drug of mammalian tissue origin. VOD represents a catastrophic complication of HSCT and is often fatal due to multi-organ failure. Hepatic cellular apoptosis and cell death in VOD results in the generation of nucleosomes which contribute to the propagation of this disease by enhancing thrombotic and vascular complications.

Aims: The aim is based on the assumption that defibrotide may reduce the generation of nucleosomes and modulate their thrombotic and inflammatory responses.

Methods: Defibrotide was obtained in powdered form (Gentium, Villa Guardia, Italy) and dissolved in saline to obtain working concentrations of 10 mg/mL. A commercially available ELISA PLUS, Cell Death Assay was used to measure plasma nucleosome levels. Blood samples were supplemented with this agent at varying concentrations of 0-100 ug/mL. E. Coli and S. Enterica lipopolysaccharide B were used to trigger the generation of nucleosomes in whole blood for 15 minutes at 37 C, and nucleosome levels were measured using a commercial ELISA method.

Results: Both the E.Coli and S. Enterica lipopolysaccharides produced a concentration-dependent increase in the generation of nucleosomes. At 1 ug/mL, the nucleosome levels were in the range of 40-70 AU/mL (47 ± 11). Defibrotide at a concentration of 100 ug/mL produced almost a complete inhibition of the generation of nucleosomes with an IC50 of 35 ug/mL. The level of nucleosome generated in different normal individuals showed wide variations.

Conclusions: These studies suggest that beside other pharmacological effects, defibrotide may blunt the generation and functionality of nucleosome which contribute to its observed therapeutic effects in HSCT associated VOD. Since defibrotide is a single stranded DNA derived agent it may compete with the DNA component of nucleosome and / or interact with the histone.

PB 1737 | Influence of Polyamidoamine (PAMAM) Dendrimers on the Activity of Key Enzymes of the Coagulation System *in vitro*

L. Mukhametova[1,2], R. Aisina[1], E. Ivanova[1], E. Zakharyan[1], K. Gerchkovich[3]

[1]*Lomonosov Moscow State University, Chemical Department, Moscow, Russian Federation,* [2]*Bauman Moscow State Technical University, Moscow, Russian Federation,* [3]*Emanuel Institute of Biochemical Physics of RAS, Moscow, Russian Federation*

Background: PAMAM dendrimers are often used for drug delivery in various diseases. Recently it is shown that cationic high generation (G7) PAMAM dendrimers cause platelet aggregation, inhibit thrombin generation and act directly on fibrinogen to form dense aggregates of fibrinogen. Mechanism of this coagulopathy is not currently clear. Influence of PAMAM dendrimers on activity of enzymes of the coagulation system is not known.

Aims: Studying the effect of anionic and cationic PAMAM dendrimers on activity of key enzymes of the coagulation system *in vitro*.

Methods: Effect of cationic (G1, G2 and G3) and anionic (G1.5, G2.5 and G3.5) PAMAM dendrimers (0 - 0.4 mM) on the amidolytic activities of thrombin and FXa, thrombin time and prothrombin time was studied.

Results: Activity of thrombin against Z-Ala-Ala-Arg-pNA was significantly increased with increasing concentration and generation of cationic dendrimers, whereas it was inhibited by anionic dendrimers: K_i 1.44, 0.7 and 0.28 mM, respectively, for G1.5, G2.5 and G3.5. The increasing concentration of anionic and cationic dendrimers caused marked decrease in activity of FXa against Z-D-Arg-Gly-Arg-pNA (K_i 1.21 mM for G3.5). Both cationic and anionic dendrimers inhibited the clotting activity of thrombin. For example, with increasing concentration of G3 and G3.5 dendrimers up to 0.4 mM, the clotting time of fibrinogen by thrombin in a buffer was gradually increased, while the clotting time of blood plasma by thrombin began to increase sharply at concentrations of the dendrimers higher than 0.3 mM and this effect was more potent. Cationic and anionic dendrimers elongated prothrombin time to a lesser extent than thrombin time.

Conclusions: Cationic and anionic low generation PAMAM dendrimers reduce clotting activities of thrombin and FXa *in vitro* that is likely mediated through electrostatic interactions between the densely charged surface of dendrimers and opposite charged sites of thrombin, FXa and fibrinogen.

PB 1738 | Repetitive Strenuous Exercise Leads to Exhaustion of Haemostatic System

A. Miszta[1,2], V. Strijbis[1,3], L.N. van der Vorm[1,2,4], D. Huskens[1,2], S. Zwaveling[1,2], P. G. de Groot[1], M. Roest[1,2], B. de Laat[1,2,4]

[1]CARIM, Maastricht University, Synapse Research Institute, Maastricht, The Netherlands, [2]CARIM, Maastricht University, Department of Biochemistry, Maastricht, The Netherlands, [3]Department of Biochemistry, CARIM, Maastricht University, Maastricht, The Netherlands, [4]Gelre Hospital, Department of Clinical Chemistry and Hematology, Apeldoorn, The Netherlands

Background: Physical exercise is beneficial for health and is thought to decrease the risk of cardiovascular disease. However, strenuous exercise could be a risk for thrombosis. It influences the pro- and anticoagulant processes that increase risk of myocardial infarction, ischemic stroke or venous thrombosis. Previous studies showed that one day of strenuous exercise accelerates thrombin generation, activates platelets and affects fibrinolytic activity.

Aims: To study whether repetitive strenuous exercise increases procoagulant processes.

Methods: We measured thrombin generation, platelet activation, plasmin generation, Factor VIII (FVIII) and Von Willebrand Factor (VWF) levels in plasma for 3 subsequent days before and after 80km cycling in hilly environment. Our study protocol was approved by the local medical ethical board. All 7 individuals gave full informed consent.

Results: After the first day of exercise we observed a significant increase in thrombin generation peak FVIII, VWF, platelet activation and plasmin generation with decreased total amount of formed thrombin. Interestingly all measured parameters except for platelet activation recovered to the pre-exercise levels. After the second and third day of exercise all measured parameters were increased again although less than at the first day. Platelets remained activated during the whole study.

Conclusions: Our results demonstrated that daily strenuous exercise leads to exhaustion and rebalancing of the hemostatic system, especially with respect to the fibrinolytic system and endothelium. Exercise had a major but transient impact on FVIII and VWF levels, which increased after exercise and recovered to base line in the next morning. Platelets showed increased activity after repetitive exercise, which did not recover the next morning. Our findings might help to understand the risk of development of thrombotic event during daily strenuous exercise.

PB 1739 | Absence of Thrombotic Events in the Gastric Signet-ring Cell Adenocarcinoma Patients with High Expression of Heparanase

S. Shah[1], C. Fourgeaud[1], S. Derieux[1], S. Mirshahi[2], G. Contant[2], C. Pimpie[1], I. Aldybiat[1], R. Lo Doco[1], C. Eveno[1], J. Soria[1], M. Pocard[1], M. Mirshahi[1]

[1]INSERM U 965, University of Sorbonne Paris Cité, Paris 7, Oncology, Paris, France, [2]Stago, Oncology, Gennevilliers, France

Background: Gastric signet ring cell adenocarcinoma (SRCA) is characterized by high fibrosis, rapid progression and high frequency of metastasis to the peritoneum.

Aims: To analyze heparanase (Hep) gene expression in tissue and cell line (KATO-III) of SRCA and to investigate the incidence of venous thromboembolism (VTE) in these patients.

Methods: Hep gene expression was investigated in tumoral and peritumoral tissue from patients with SRCA (n=11) and in different cancer cell lines (n=10) including KATO-III using RT-PCR and qPCR. Hep level was evaluated by ELISA in ascites of patient with SRCA (n=5), non-gastric SRCA (n=3) and colic cancer (n=6). Human phospho-Kinase array was done to observe effect of exogenous Hep in phosphorylation profiles of various kinases of KATO-III. in paralell, we interviewed the database of "Federation Française de Cancerologie Digestive, FFCD" for SRCA and for gastric adenocarcinomas.

Results: High expression of mRNA hep was found in KATO-III, in non-SRCA (n=10) and SRCA (n=11) cancer tissues ($p < 0.001$). Hep level was very high in the ascites of patients with SRCA. Phospho-kinase array showed that only 6/45 kinases were highly phosphorylated in non-treated KATO-III cells. After treatment with active Hep, 2 were upregulated (HSP60 and C-Jun) and 4 (GSK-3α/β, β-catenin, Chk-2 and AMPkal-1) were down regulated. Suramin has no antagonist effect in phosphorylation pathway induced by Hep. Despite the high levels of Hep mRNA in SRCA tumor tissues, no VTE was detected in the patients. In view of the significant increase in Hep levels in ascites and in tumors of SRCA patients, as compared to adenocarcinomas,. The results from FFCD showed that preoperatively, there is no more risk of VTE in patients with SRCA: 3.1% pulmonary embolism, 1% Deep vein thrombosis in controls versus 4.1% and 2.9% in patients with SRCA (n=97) and 3.9% and 3.0% in other adenocarcinomas (n=205).

Conclusions: The increase of Hep expression in SRCA was not correlated to thrombotic events.

PB 1740 | Anti-TFPI Antibody Targeting the Kunitz-2 Domain of Human TFPI Efficiently Recovers FVII Activity Comparing Kunitz 1 Domain Targeted TFPI Antagonist

S. Lee, H. Kwak, S.-H. Hwang

Mogam Institute for Biomedical Research, Rare Disease Team, Yongin, Korea, Republic of

Background: Tissue factor pathway inhibitor (TFPI) is a single-chain polypeptide which can reversibly inhibit Factor Xa (FXa). TFPI consists of three tandem linked Kunitz domains (KD). Among the three kunitz domains, KD1 is well known for binding to FVII directly and KD2 is for FXa or FX. MG1113 is a human IgG4 type antibody targeting KD2 of human TFPI.

Aims: The purpose of this study was investigate the difference of molecular mechanisms between TFPI KD1 and KD2 targeted antibody. For the verification we have established several enzymatic assay.

Methods: we checked FVII activity in the presence of anti- KD1 or anti-KD2 antibody for the verification whether the blocking of KD2 can activate the FVII. FVIIa activity was measured in the presence of

anti- KD2 or anti- KD1 antibody. Activated FVII is also checked to see whether it affects FXa or not. Through FXase activity assay, we measured the recovery of FX activity by blocking TFPI. Since TFPI can bind and inhibit TF/FVIIa/FX complex, we also measured how much FX is activated through the complex in the presence of anti-KD2 antibody.

Results: Although FVII directly binds to KD1 of TFPI, blocking KD2 by anti- KD2 antibody was much more efficient to recover FVIIa activity than blocking KD1. Activated FVII is efficiently recovered by anti-KD2 antibody in the condition of presence of FXa. These assays demonstrate that anti- KD1 antibody is less efficacy than anti- KD2 antibody in the same condition. In FXase assay, FXa was generated with increasing concentrations of anti- KD2 antibody. FXa was also increased by anti- KD2 antibody treatment through the formation of TF/FVIIa/FX complex.

Conclusions: KD2 targeting is not for direct blocking to binding epitope of FVII and TFPI. However, It shows more efficient recovery of FVII activity than anti-KD1 antibody. Moreover, FXa helps to recover FVIIa when TFPI is blocked by anti-KD2 antibody. Our results suggest the TFPI KD2 targeted antibody is more effective on the coagulation initiation phase for the clot formation.

PB 1741 | The State of Hemostasis after Nonselective Thrombolysis in Patients with Ischemic Stroke

S. Sinkov, K. Zibin

Kuban State Medical University, Department of Anaesthesiology, Krasnodar, Russian Federation

Background: Based on the data of international guidelines, using of any antithrombotic drugs contraindicated during first 24 hours after thrombolysis; this is determine high frequency of re-thrombosis (about 25%) in the first 24 hours after successful thrombolysis.

Aims: To examine the state of hemostas in patients with ischemic stroke during 24 hours of system thrombolysis.

Methods: Was study 83 patients (47 men and 36 female) aging 52-72 years with acute cerebrovascular diseases, treated in intensive care. All patient has 10-17 units of NIHSS score. All patients match to therapeutic window, and, according to National Guidelines, receive system thrombolysis. Parameters of hemostas (activated partial thrombin time, prothrombin time, fibrinogen, platelet count, thromboelastography parameters) was monitored before injection of Actilyse®, and during first 24 hours on 3rd, 12th and 24th hours after injection. Data was statistically processed with Newman-Keuls method.

Results: Retrospective analysis shown results, depicted in the table 1. Biochemical parameters of hemostas has not statistically significant changes during 24-hours period. But after thrombolysis thromboelastography shown significant disbalance between coagulation and fibrinolysis, leads to change of structural properties of forming clot. On admission to ICU hemostas state was characterized as trend to the hypocoagulation with normal or slightly activated fibrinolysis on the background of loose clot formation. Such changes represent compensatory reaction of stable hemostas to the ischemic injury. After system thrombolysis in an 3 hours all patients shown unidirectional changes to the hypercoagulation on the background of expressed activation of fibrinolysis and formation of a dense clot. That direction of changes reflect embolism risk depend on tromboelastography.

Conclusions: Thereby it is expedient to conduct further study of using of the antithrombotic agents in early post-thrombolysis period.

COAGULATION SIGNALING & IMMUNITY

PB 581 | Complement Factor H, Extracellular Nucleosomes, ADAMTS13 and the Regulation of von Willebrand Factor Size in Young Patients with Ischemic Stroke and Myocardial Infarction

B.M. Luken[1], T. Hoppenbrouwers[2], M.A. Sonneveld[2], G.J. van Mierlo[1], S. Zeerleder[1,3], F.W.G. Leebeek[2], D. Wouters[1], M.P. de Maat[2]

[1]Sanquin-AMC Landsteiner Laboratory, Immunopathology, Amsterdam, The Netherlands, [2]Erasmus MC, Hematology, Rotterdam, The Netherlands, [3]Academic Medical Center, University of Amsterdam, Hematology, Amsterdam, The Netherlands

Background: High VWF and low ADAMTS13 levels are associated with an increased risk of arterial thrombosis (ischemic stroke and myocardial infarction). Recent *in vitro* studies indicated that complement factor H (FH) binds to VWF and affects VWF multimer length, either as a reductase or by affecting the proteolysis of VWF by ADAMTS13.

TABLE 1 Correlation between VWF:ratio, FH, ADAMTS13 activity, nucleosomes, CRP, VWF:CBA and VWF:Ag in patients with arterial thrombosis. *: p<0.05, **:p<0.01

	VWF:CBA	VWF:Ag	VWF:Ratio	ADAMTS13 activity	FH	Nucleosomes	CRP
VWF:CBA	-	0.76**	0.29**	-0.08	0.03	0.03	0.06
VWF:Ag	0.76**	-	-0.34**	-0.02	0.12*	-0.02	0.17**
VWF:Ratio	0.29**	-0.34**	-	-0.12*	-0.15**	-0.13*	-0.14*
ADAMTS13 activity	-0.08	-0.02	-0.12*	-	-0.06	-0.004	-0.15**
FH	0.03	0.12*	-0.15**	-0.06	-	0.13*	0.22**
Nucleosomes	0.03	-0.02	-0.13*	-0.004	-0.13*	-	0.11*
CRP	0.06	0.17**	-0.14*	-0.15**	0.22**	0.11*	-

Histones and DNA were also found to bind to VWF, and may by competing with ADAMTS13 potentially also influence VWF size.

Aims: To evaluate the relationship between FH, nucleosomes (DNA+histones), ADAMTS13, and VWF (Ag, CBA and VWF:CBA/Ag ratio) in arterial thrombosis.

Methods: In a case control study of 563 young patients with a first arterial thrombotic event and 463 healthy controls the plasma levels of FH and nucleosomes, VWF antigen (VWF:Ag), VWF collagen binding activity (VWF:CBA), VWF:CBA/Ag ratio, C-reactive protein (CRP) and ADAMTS13 activity were measured using (bio)ELISA, and relations analyzed using Spearman rank correlation and linear regression.

Results: FH and nucleosome levels were similar in cases and controls. ADAMTS13 activity was significantly lower in cases than in controls. The VWF:ratio was negatively correlated with both ADAMTS13 activity, FH, nucleosomes, and CRP in the cases (see table). FH levels were also significantly correlated with CRP, VWF:Ag and nucleosomes in cases, while only CRP was significantly correlated in the controls, in line with potential binding of FH to CRP. Nucleosomes positively correlated with CRP and VWF:Ag, however there was a negative correlation with VWF:ratio.

Conclusions: In young patients with arterial thrombosis, reduced levels of ADAMTS13, circulating FH and nucleosomes relate to increased VWF:ratio and thus VWF multimer size.

PB 582 | The Effect of Short Chained Polyphosphates on Complement Activation in Plasma and Human Whole Blood

I. Høiland[1], R.A. Liang[1], N. Latysheva[1,2], S. Beck Jensen[1], S.A. Smith[3], J.H. Morrissey[3], B. Østerud[1], O.-L. Brekke[1,4], T.E. Mollnes[1,4,5], J.-B. Hansen[1,2], K. G. Jebsen - Thrombosis Research and Expertise Center (TREC), Department of Clinical Medicine, UiT - The Arctic University of Norway, Tromsø

[1]The Arctic University of Norway, Tromsø, K. G. Jebsen - Thrombosis Research and Expertise Center (TREC), Department of Clinical Medicine, Tromsø, Norway, [2]University Hospital of North Norway, Division of Internal Medicine, Tromsø, Norway, [3]University of Illinois, Urbana, Department of Biochemistry, Illinois, United States, [4]Nordland Hospital, Bodø, Research Laboratory, Bodø, Norway, [5]Oslo University Hospital and University of Oslo, Department of Immunology, Oslo, Norway

Background: Human platelets contain short chain (SC) (60-100 units) inorganic polyphosphate (polyP) stored in dense granules that is released upon activation. In an experimental system with 2% serum monitoring complement activation by erythrocyte lysis, polyP was shown to inhibit complement activation by blocking the formation of the terminal C5b-9 membrane attack complex (MAC), the final step of the complement cascade. We wanted to investigate whether platelet sized polyP affected complement activation under physiological conditions.

Aims: To investigate whether platelet sized SC-polyP affect complement activation in human blood and platelet free plasma (PFP).

Methods: Blood was collected in lepirudin tubes (50 µg/mL) from healthy fasting individuals (n=10). Blood was incubated with and without 1×10^7 *E. coli*/mL and different concentrations of SC-polyP (0-40 µM) at 37°C for different time intervals (0-60 min) and at physiological calcium concentrations. Complement activation was terminated by adding 10 mM EDTA (final concentration) and monitored by measuring C3bc and the terminal complement complex (TCC) by enzyme-immunoassays. The effect of SC-polyP was also evaluated in platelet free plasma (PFP).

Results: SC-PolyP added alone did not induce complement activation assessed by C3bc and TCC neither in PFP nor in whole blood. *E.coli*-incubation of both PFP and whole blood induced a time-dependent increase in C3bc and TCC ($p< 0.0001$). In PFP, combined incubation with 40 µM SC-PolyP and *E.coli* increased plasma levels of C3bc (52±12%, $p< 0.01$) and TCC (25±11%, $p< 0.05$) compared to *E.coli* incubation alone. In whole blood, combined *E. coli* incubation and 40 µM SC-PolyP and *E.coli* showed no effect on TCC or C3bc.

Conclusions: Short chained polyP facilitated *E.coli*-induced complement activation in plasma, but not in a whole blood at physiological calcium concentrations.

PB 583 | Extracellular Histones Can Inhibit Complement Activation through C4 Binding

Y. Qaddoori[1], S. Abrams[1], D. Su[1], T. Liu[1], Y. Alhamdi[1], G. Wang[1], C.-H. Toh[1,2]

[1]University of Liverpool, Institiute of Infection and Global Health, Liverpool, United Kingdom, [2]Roald Dahl Haemostasis & Thrombosis Centre, Royal Liverpool University Hospital, Liverpool, United Kingdom

Background: Histones are essential building blocks in forming chromatin, but are extremely toxic once released into the circulation following extensive cellular damage. Extracellular histones can play a role in immune responses in bacterial killing and Toll-like receptor signalling, to induce inflammasome activation and cytokine release. Using histone-conjugated beads, we show histones can bind to complement component 4 (C4) in plasma.

Aims: Since complement activation is important in the innate immune response, the aim of this study was to understand the pathophysiological relevance of extracellular histones in interacting with the complement pathway.

Methods: Histone-C4 binding was confirmed by gel overlay assay and surface plasmon resonance (SPR) determined binding affinities. The physiological relevance was then determined by measuring complement activity in serum using functional assays for each pathway.

Results: H3 [KD = 0.76±0.12 nM] and H4 [KD = 0.91±0.07 nM] had much higher binding affinity to C4 than equimolar concentrations of H1 [KD = 7.26±0.80 nM] and H2B [KD = 9.45±1.43 nM], with weak binding to H2A [KD = 12.67±0.59 nM]. Histones significantly inhibited classical and mannose-binding lectin (MBL) but not the alternative pathway, with H1, H2B and H3 and H4 showing the most significant effects. To demonstrate the specificity of histones, anti-histone single chain variable fragment antibody (ahscFv) and heparin were used, which have been shown to specifically inhibit histone toxicity *in vitro* and *in vivo*. Both ahscFv and heparin significantly rescued histone-induced inactivation of classical and MBL pathways.

Conclusions: Mechanistically, extracellular histones bind to complement component C4. Functionally, histones inhibit the classical and

MBL but not the alternative pathway. Translationally, anti-histone treatment may hold therapeutic promise for recovering complement activation as well as blocking histone-induced toxicity in critically ill patients.

PB 584 | Complement Activation in Patients with Venous Thromboembolism

M. Efthymiou[1], I. Mackie[1], A. Chitolie[1], P. Lane[1], T. Gkouleli[1], H. Cohen[1,2]

[1]University College London, Haemostasis Research Unit, Department of Haematology, London, United Kingdom, [2]University College London Hospitals NHS Foundation Trust, Department of Haematology, London, United Kingdom

Background: The complement system, activated via the classical, alternative and lectin pathways (CP, AP and LP, respectively), interacts with the haemostatic system at various levels. Complement activation (CA) may play a role in the pathogenesis and progression of VTE. We have previously shown raised CA markers in venous thromboembolism (VTE) patients with antiphospholipid syndrome (APS), but the role of CA in non-APS VTE patients is undefined.

Aims: To assess CA in non-APS patients with previous VTE.

Methods: EDTA plasma samples were collected from 41 patients with previous VTE without antiphospholipid antibodies; 34 on warfarin treatment (28 target INR 2.5; 6 INR 3.5), and 7 on rivaroxaban 20 mg/day. CA markers were measured as C3a, C5a, and SC5b-9 (markers for all pathways) and Bb fragment (a specific marker of AP activation) by commercial ELISA (MicroVue kits, Quidel Corp). Results were compared with 56 APS patients (receiving warfarin, target INR 2.5) with previous VTE. Normal ranges (55 normal controls: NC) were: C3a 27-96ng/mL; C5a 0.8-13.0ng/mL; sC5b-960-164ng/mL; Bb 0.7-1.7ug/ml.

Results: C3a, C5a and SC5b-9 were higher in non-APS and APS patients compared to NC ($p< 0.0001$), with the exception of Bb that was raised in APS ($p< 0.0001$) but not non-APS patients. In non-APS patients: C3a, C5a, SC5b-9 and Bb were elevated in 9 (22%), 17 (42%), 16 (39%) and 2 (5%) patients, respectively; C3a, C5a and SC5b-9 were raised in 3 patients; C5a and SC5b-9 in 7; all 4 markers in 1 patient. In comparison, our previous study in 56 APS VTE patients receiving warfarin showed C3a, C5a, SC5b-9 and Bb elevation in: 20 (36%), 19 (34%), 42 (75%) and 14 (25%), respectively.

Conclusions: The data suggest that some non-APS VTE patients have CA despite anticoagulant therapy. CA was less frequent in non-APS VTE than in APS VTE patients and rarely involved the AP of complement, suggesting a different pathophysiology.

PB 585 | C5B9 Deposits on Endothelial Cells for the Evaluation of Complement Function in Thrombotic Microangiopathies of Different Origin and Therapy Monitorization

M. Palomo[1,2], M. Blasco[3], P. Molina[2], G. Escolar[2], J. Campistol[3], M. Diaz-Ricart[2]

[1]Josep Carreras Leukaemia Research Institute, Barcelona, Spain, [2]Hospital Clinic, Centre de Diagnostic Biomedic (CDB), Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIPABS), Hemotherapy and Hemostasis, Barcelona, Spain, [3]Hospital Clinic, Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIPABS), Nephrology and Renal Transplantation, Barcelona, Spain

Background: Atypical hemolytic uremic syndrome (aHUS) is a rare, progressive, life-threatening form of thrombotic microangiopathy (TMA) caused by dysregulation of the alternative pathway of the complement system. Nonetheless, there is wide evidence that complement activation has a role in other TMA.

Aims: A reliable method is needed to evaluate complement activation to monitor eculizumab therapy in aHUS and to explore the indication of this treatment in other TMA.

Methods: Complement activation was assessed by exposing endothelial cells (ECs) to patients' sera or to patients' plasma samples mixed with a control sera pool (1:1). C5b9 deposits on ECs were analyzed through immunofluorescence and expressed as fold increase (mean±SEM) vs. control samples .

Results: Exposure of ECs to aHUS plasma resulted in a significant increase in C5b9 deposits (8±2, n=4, $p< 0.01$), which was prevented in samples from the same patients treated with eculizumab (0.7±0.1). Significant fibrin formation was observed together with C5b9 deposition. The specificity of the reaction was confirmed by its blockade with eculizumab and inhibitors of the intrinsic coagulation pathway. Notably, results obtained using plasma samples were much more remarkable and reproducible than those obtained with sera. C5b9 deposition was also increased using samples from HELLP syndrome patients (at acute phase, 6±2, n=4, $p< 0.01$) and 40 days later (3.2±1, $p< 0.01$), and both autoimmune (2.9±1, n=4, $p< 0.05$) and congenital thrombotic thrombocytopenic purpura (2.1±1, n=4). Complement activation was at control levels when analyzing samples from patients with malignant hypertension (0.8±0.2, n=5) or aHUS patients treated at regular doses of eculizumab (0.5±0.1, n=5) and lower (0.4±0.2, n=2).

Conclusions: This method could be useful to monitor therapy and to explore the indication of eculizumab to treat other TMA presenting complement activation. Further research is needed to clarify the basis for the colocalization of C5b9 and fibrin on ECs surface.

PB 586 | The Complement Lectin Pathway in Post Cardiac Arrest Patients: A Randomized Clinical Study

S. Haugaard[1], A.N. Jeppesen[2], A. Troldborg[3], H. Kirkegaard[4], S. Thiel[3], A.-M. Hvas[1]

[1]Aarhus University Hospital, Centre for Haemophilia and Thrombosis, Department of Clinical Biochemistry, Aarhus, Denmark, [2]Aarhus University Hospital, Department of Anesthesiology and Intensive Care Medicine, Aarhus, Denmark, [3]Aarhus University, Department of Biomedicine, Aarhus, Denmark, [4]Aarhus University Hospital, Research Centre of Emergency Medicine, Aarhus, Denmark

Background: Recent studies suggest that the complement system influence injury after out-of-hospital cardiac arrest. Lectin pathway proteins are an important part of the complement system, but the majority of these proteins have not been investigated in cardiac arrest patients.

Aims: To investigate levels of lectin pathway proteins in patients resuscitated after cardiac arrest compared with healthy individuals, and to examine whether the protein levels were influenced by 48 hours compared with 24 hours of targeted temperature management (TTM).

Methods: We conducted a randomized, outcome assessor-blinded study including 82 comatose out-of-hospital cardiac arrest patients. The patients were allocated to 24 hours (n=42) or 48 hours (n=40) of TTM at 33±1 °C. Blood samples were obtained 22, 46 and 70 hours after this temperature was reached. Informed consent was collected and the study was approved by the Central Denmark Region Committees on Health Research Ethics. Data from 82 gender matched healthy blood donors were used for comparison. Levels of the lectin pathway proteins MBL, M-ficolin, H-ficolin, CL-L1, MASP-1, MASP-2, MASP-3 and MAp44 were analyzed using time-resolved immunofluorometric assays (TRIFMA®).

Results: We found significantly higher levels of CL-L1, MASP-1, MASP-2 and MAp44 (p-values< 0.03), and lower M-ficolin levels (p=0.01) in cardiac arrest patients compared with healthy individuals. During 70 hours after cardiac arrest, significantly higher levels of MASP-2 and MASP-3, and lower levels of M-ficolin were demonstrated in the patients treated with 48 hours compared with patients treated with 24 hours of TTM. For the remaining proteins no significant differences were found.

Conclusions: The significantly higher levels of CL-L1, MASP-1 and MASP-2 in cardiac arrest patients indicate that cardiac arrest patients have a more activated lectin pathway compared with healthy individuals. However, the protein levels did not seem to be influenced by the duration of TTM.

PB 587 | The Effect of Platelets and Extracellular Vesicles on Complement Activation in Human Plasma

R.A. Liang[1], I.I. Høiland[1], N. Latysheva[1,2], B. Østerud[1], T.E. Mollnes[1,3,4], J.-B. Hansen[1,2]

[1]*K.G. Jebsen Thrombosis Research and Expertise Center (TREC), University of Tromsø - The Arctic University of Norway, Institute of Clinical Medicine, Tromsø, Norway,* [2]*University Hospital of North Norway, Division of Internal Medicine, Tromsø, Norway,* [3]*Oslo University Hospital and University of Oslo, Department of Immunology, Olso, Norway,* [4]*Nordland Hospital, Bodø, Research Laboratory, Bodø, Norway*

Background: Studies have shown platelets play an important role in regulation of complement activation, and platelet-derived extracellular vesicles (EVs) are able to promote complement activation. Whether EVs and platelets affect complement activation in a physiological plasma milieu is not clear.

Aims: To investigate the modifying effect of platelets and EVs on *E.coli*-induced complement activation in a plasma system.

Methods: Blood was collected in lepirudin tubes (50mg/ml) from healthy individuals. Blood was then centrifuged twice (3000*x*g for 10 min and 13500*x*g for 2 min) for preparation of platelet-free plasma (PFP). A part of PFP was centrifuged at 20000*x*g for 30 min to prepare EV-depleted plasma (EVDP). Platelet-rich plasma (PRP) was prepared by centrifugation at 140*x*g for 10 min. EVDP, PFP, PRP were incubated with *E.coli* (1 x 10^7/ml) at 37°C to examine complement activation for different time intervals (0-60 min). The reaction was stopped by adding EDTA (10mM). PRP was centrifuged at 3000*x*g for 10 minutes and all plasma samples were frozen at -80°C until analysis. Levels of complement activation products C3bc and TCC were measured using ELISA.

Results: *E.coli*-incubation showed a time-dependent increase (p< 0.01) in both complement activation products from 0 min to 60 min in all plasmas (C3bc: 24±6-131±7.9 CAU/ml in EVDP; 28±8.1-114±7.0 CAU/ml in PFP; 7.1±4.3-58±14.3 CAU/ml in PRP; TCC:1.9±0.1-23±1.5 CAU/ml in EVDP; 2.0±0.4-27±3.5 CAU/ml in PFP; 0.3±0.1-7.6±2.8 CAU/ml in PRP). Plasma levels of C3bc were 13.2±0.5% (p< 0.01) lower in PFP than in EVDP after 60 min incubation, while TCC levels in PFP did not differ significantly from EVDP, suggesting that EVs may limit initiation of complement activation. PRP had 55.8±10.3% (p< 0.01) and 64.9±15.4% (p< 0.01) lower C3bc and TCC levels, respectively, compared to EVDP after 60 min incubation.

Conclusions: *E.coli*-induced complement activation in plasma was lower in PRP than in EVDP suggesting a lower degree of complement activation in the presence of platelets and EVs.

PB 588 | Fibrinogen and Clot Structure is Affected by Eculizumab in Patients with Paroxysmal Nocturnal Haemoglobinuria

F. Macrae[1], P. Bowman[1], E. Linton[1], B. Peacock-Young[1], D. Newton[2], R. Ariëns[1], A. Hill[3]

[1]*University of Leeds, Thrombosis and Tissue Repair Group, Leeds, United Kingdom,* [2]*University of Leeds, Section of Experimental Haematology, Leeds, United Kingdom,* [3]*St James's University Hospital, Department of Haematology, Leeds, United Kingdom*

Background: Paroxysmal nocturnal haemoglobinuria (PNH) is a haematopoietic stem cell disorder. It leads to complement-driven intravascular haemolysis and severe thrombosis. Treatment with eculizumab which inhibits complement factor C5 reduces thromboembolic events in PNH, indicating that complement activation plays a role in the pathophysiology of thrombosis in this disease. Patients with other thrombotic disorders form denser fibrin clots that incur greater resistance to fibrinolysis. It is unknown if changes to clot architecture contribute to thrombosis in PNH.

Aims: Characterise fibrin clot structure in patients with PNH and determine the effect of eculizumab on clot structure.

Methods: 35 patients from the PNH National Service were recruited. Plasma samples were obtained and ex vivo fibrin clot structure was analysed by permeation, turbidity and confocal microscopy. Granulocyte clone size was measured by flow cytometry and fibrinogen (FGN) levels by Clauss.

Results: Granulocyte clone size correlated with FGN (r= -0.35, p=0.048), maximum absorbency (r= -0.34, p=0.046) and clot density (r= -0.36, p=0.04). 14/20 patients with large clone sizes were on eculizumab. Analysis of patients not on eculizumab showed a trend towards clone size correlating positively with fibrinogen levels (r=0.42, p=ns). Patients on eculizumab had lower fibrinogen levels (3.1±0.2 v 3.6±0.1g/L, P=0.02), maximum absorbance (0.31±0.1 v 0.40±0.1, p=0.028) and fiber density/100µm (18.5±4.4 v 23.9±4.2, p=0.006), indicative of a less dense clot.

Conclusions: Patients on eculizumab showed reduced FGN, fiber thickness and fiber density. Our data indicate that the beneficial effects of eculizumab in PNH is partly due to reduced complement activation and attenuated inflammatory response, leading to lower FGN levels and a less thrombotic fibrin clot structure.

PB 589 | Hemocompatibility Analysis of Silk Nanoparticles Leads to Different Results under Static and Flow Conditions

M.F. Maitz[1], F.P. Seib[1,2], M. Herklotz[1], C. Sperling[1], C. Werner[1]

[1]Leibniz-Institute of Polymer Research Dresden, Institute Biofunctional Polymermaterials, Dresden, Germany, [2]University of Strathclyde, Strathclyde Institute of Pharmacy and Biomedical Sciences, Glasgow, United Kingdom

Background: Nanomedicine often administers nanoparticles into the blood stream for diagnostic or therapeutic purposes. The high surface and curvature of these nanosized particles provides them different properties than the corresponding bulk materials. Depending on the type, pro- or anticoagulant properties of nanoparticles are described. Nanoparticles frequently tend to aggregate from nano- to microsized clusters, what may alter their interaction with the blood cascade systems and ultimately their hemocompatibility.

Aims: Test the effect of nanoparticle clustering on their hemocompatibility.

Methods: Silk nanoparticles and reference silica particles of about 100 nm each were incubated in human whole blood for two hours. The incubation was either under static conditions or under flow conditions in a Chandler loop set-up. The shear condition in the Chandler loop incubation keeps the nanoparticles better suspended than the static incubation. After the incubation, parameters of hemostasis and inflammation were determined.

Results: Coagulation activation, measured as prothrombin F1+2 fragment after silk nanoparticle incubation was generally low when compared to silica. For both materials, there was a trend for higher activation during static condition (Fig. 1A). The silk nanoparticles induced very high complement activation (C5a) under static condition, but it was almost completely suppressed under flow, where particles are dispersed (Fig. 1B). PEGylation of the particles did not sufficiently suppress aggregation and complement activation (Fig. 1B, C). Curvature of the single particles prevented the proper assembly of the complement complexes, whereas the bigger particle clusters allowed the complement complex formation. Due to the larger enzyme complexes, the complement system is more sensitive to this effect than the coagulation system.

Conclusions: Nanoparticle aggregation, as it happens under static test conditions, may cause higher activation of enzyme cascade systems than under physiological flow conditions.

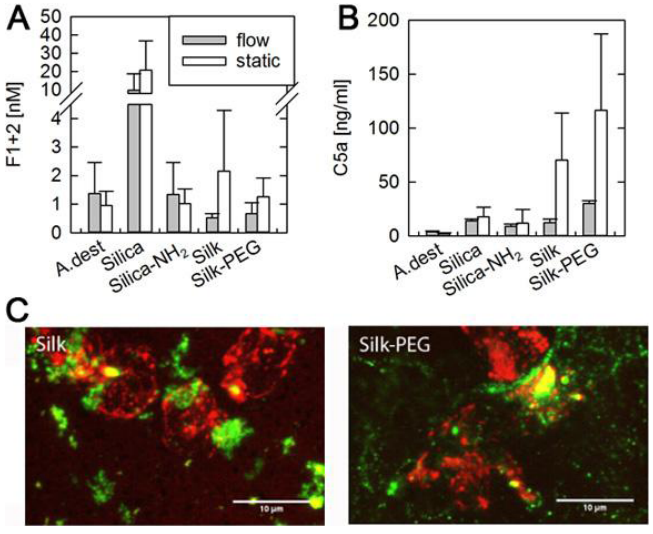

FIGURE 1 Incubation of nanoparticles with whole blood under static or under flow conditions

PB 590 | Character of Haemostatic System in Preterm Labor in Women with Thrombophylia

B. Kurbanov

Tashkent Pediatric Medical Institute, Haematology, Tashkent, Uzbekistan

Background: It is known that the haemostatic system during physiological pregnancy adaptive response is to increase the coagulation potential, primarily by increasing the concentration of clotting factors and platelet functional activity. These factors create additional conditions for the development of thrombosis on the background of already existing genetic thrombophylia.

Aims: To study the haemostatic system in women with preterm labor and trombophylia.

Methods: Haemostatic system was studied in 64 pregnant women with complicated obstetric history, and preterm delivery (study group). The control group consisted of 20 conditionally healthy women with uncomplicated pregnancy in gestation, corresponding to the III trimester. Assessment tests were used haemostatic system: determining the concentration of fibrinogen and platelet haemostasis research: determining the number of platelets in the peripheral blood, the study

of the functional activity of platelets under the influence of various stimulants of aggregation.

Results: The patients of the main group during gestation in the plasma link haemostasis observed significant increase in levels of fibrinogen, which is the time of inspection was higher than 1.2 times the control (respectively 3.8 ± 0.2 g / l and 3.1 ± 0.1 g / liter, P < 0.01). Platelet counts in the peripheral blood of these patients was significantly higher than in the control group (235,8 ± 6,6 · against · 203.6 ± 10.8 109 / L; Δ% = + 13,6; p < 0.05), which is obviously due to the activation of platelet haemostasis. Platelet aggregation in patients of the main group almost has not changed, practically no different from the control (respectively 97,1 ± 2,0 and 105,3 ± 3,2%, Δ% = - 7,8; P> 0.05).

Conclusions: The haemostatic system in pregnant women with thrombophylia characterized by the activation of platelet haemostasis by increasing the number of platelets, increased coagulation potential by increasing of fibrinogen.

PB 591 | Role of Protease-activated Receptor-1 in Poly I:C Induction of Tissue Factor Expression in Endothelial Cells and in the Activation of Coagulation in Mice

S. Subramaniam[1,2], S. Antoniak[1,2], H. Datler[3], C. Fletcher[2], N. Mackman[1]

[1]McAllister Heart Institute, University of North Carolina, Hematology/Oncology, Chapel HIll, United States, [2]University of North Carolina, Pathology and Laboratory Animal Medicine, Chapel HIll, United States, [3]University of Vienna, Physiology and Pharmacology, Vienna, Austria

Background: Viral infections induce tissue factor (TF) expression in monocytes (Mo) and endothelial cells (ECs) and this in turn activates the coagulation cascade as part of the host defense system. However, excessive activation of the coagulation cascade with some viral infections, such as Ebola, can lead to disseminated intravascular coagulation (DIC). A previous study showed that the TLR3 ligand polyinosinic:polycytidylic acid (poly I:C), which is a mimetic of dsRNA, induced TF expression in ECs but not Mo in vitro and activated coagulation in mice.

Aims: .To evaluate the role of PAR-1 in the expression of poly I:C induction of TF expression in ECs in vitro, and in the activation of coagulation in mice after administration of poly I:C.

Methods: In this study, we used poly I:C to mimic a viral infection in ECs in vitro and in vivo. ECs (EA.hy 926 cell line) were stimulated with poly IC with or without PAR-1 agonist peptide, thrombin and we measured TF mRNA and activity. Furthermore, we measured levels of plasma thrombin-antithrombin (TAT) complexes, as a marker of activation of coagulation, in WT and PAR-$1^{-/-}$ mice after injection of poly I:C.

Results: We found that PAR-1 activation by agonist peptide or thrombin enhanced poly I:C induced TF expression in ECs. The PAR-1 inhibitor vorapaxar abolished the enhanced expression. Poly I:C treatment increased levels of TAT in the plasma of WT and $PAR1^{-/-}$ mice, but levels were significantly lower in $PAR1^{-/-}$ mice. To identify the cellular sources of TF that activate coagulation after administration of poly I:C, we are determining the effect of deleting TF in ECs and hematopoietic cells ($TF^{fl/fl}$ Tie-2Cre), myeloid cells ($TF^{fl/fl}$ LysMCre) or ECs ($TF^{fl/fl}$ VE-cadherin) on TAT levels.

Conclusions: Our in vitro and in vivo studies indicate that activation of PAR-1 enhances poly I:C induction of TF expression in ECs and activation of coagulation in mice. Understanding how TF activates the coagulation cascade during viral infections may lead to novel strategies to prevent DIC.

PB 592 | Role of Helicobacter Pylori Eradication Therapy in Platelet Recovery in Chronic Immune Thrombocytopenic Purpura

I. Ujjan[1], S. Khan[1], A. Memon[1], A. Naz[2], F. Naz[1], I. Sheikh[1]

[1]Liaquat University of Medical and Health Sciences Jamshoro, Hyderabad, Pakistan, [2]National Institute of Blood Disease & Bone Marrow Transplantation, Karachi, Pakistan

Background: Idiopathic thrombocytopenic purpura (ITP) is a bleeding disorder, in which the immune system destroys nativeplatelets. In this condition an auto-antibody is generated against a platelet antigen. ITP affects women more often than men and is more common in children than adults.

Aims: To assess the effect of Helicobacter pylori eradication therapy (HPET) on platelet count in Helicobacter pylori associated chronic immune thrombocytopenic purpura (chronic ITP) in adult.

Methods: It is an interventional prospective study conducted at Liaquat University of Medical and Health Sciences, Jamshoro from 2014 to 2015.A set of 85 patients diagnosed with chronic ITP were included in the study via convenient sampling. Patients with platelets count < 100x 10^9/L for >3 months were selected. They were posed to first line investigations which comprised Complete blood count (CBC) and peripheral blood smear examination followed by second line tests including bone marrow examination and Helicobacter pylori stool specific antigen (HpSA - EIA).Standard H. pylori eradication therapy was offered and the patients were assessed at regular intervals for 6 months.

Results: Of the 85 study patients, 32(37.6%) were male and 53(62.3%) were female.Mean ages of H.pylori positive and negative subjects were 43.89± 7.06 and 44.75± 7.91 years,respectively. Bone marrow examination confirmed the diagnosis and excluded other related BM disorders. H.pylori stool antigen (HpSA) was detected in 34 (40%) patients and hence regarded as H. pylori positive; the rest were negative. - Treatment with Eradication therapy significantly improved the mean platelet counts from 48.56 ± 21.7 x10^9/l to 94.2 ± 26.8 x10^9/l.

Conclusions: We concluded that the anti- H. pylori eradication therapy improves blood platelet counts in chronic immune thrombocytopenia.

PB 593 | Intravascular Parasitic Worms and Hemostasis

A. Da'darah[1], R. Bhardwaj[1], B. Figueiredo[2], S. Oliveira[2], A. de Laforcade[1], P. Skelly[1]

[1]Tufts University, Cummings School of Veterinary Medicine, North Grafton, United States, [2]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil

Background: Schistosomes are intravascular parasitic worms (blood flukes) that currently infect over 200 million people globally. The adult parasites, although representing large foreign obstructions in host blood vessels, do not appear to provoke thrombus formation around them *in vivo*.

Aims: Using thromboelastography (TEG), we compared the clotting capability of blood that had been exposed to schistosomes versus blood that had not been exposed to the worms.

Methods: We found that the presence of the worms yielded blood that clotted more slowly and yielded relatively poor, though stable, thrombi. This TEG profile suggests that the worms can act as local anti-coagulants.

Results: Among the proteins identified in the surface membranes of the intravascular worms are a collection of enzymes that may impede coagulation. Using RNA interference to suppress the expression of *Schistosoma mansoni* genes encoding selected surface enzymes, we have shown that one tegumental enzyme, ATPdiphosphohydrolase1 (SmATPDase1), can cleave the pro-thrombotic molecule ADP. Recombinant SmATPDase1 likewise cleaves ADP. By effectively removing exogenous ADP, we hypothesize that SmATPDase1 helps to inhibit platelet activation and aggregation around the worms within the vasculature. Other schistosome surface proteins that may be important in regulating blood clot formation around the worms include housekeeping enzymes such as enolase (SmEno). While best known as a glycolytic enzyme, SmEno can additionally bind the plasma zymogen plasminogen and promote its activation (by tissue plasminogen activator (tPA)) to generate plasmin - a serine protease that cleaves fibrin and dissolves blood clots. Live parasites likewise mediate this effect.

Conclusions: Thus, acquiring host proteases by binding them to e.g. surface enolase may represent another mechanism that schistosomes employ to limit blood clot formation around them and so promote their survival.

PB 594 | Comparative Functional Studies of Thrombin and Staphylocoagulase in Terms of Clotting Kinetics and Properties of the Resultant Fibrin

C. Thelwell[1], Á.Z. Farkas[2], V.J. Farkas[2], K. Kolev[2]

[1]NIBSC, Biotherapeutics, Haemostasis Section, Potters Bar, United Kingdom, [2]Semmelweis University, Department of Medical Biochemistry, Budapest, Hungary

Background: *S. aureus* secretes staphylocoagulase (SC), a virulence factor associated with abscess formation, staphylococcal agglutination and sepsis. SC binds to and activates prothrombin (ProT); the SC-ProT complex converts fibrinogen (Fgn) to fibrin (Fn), circumventing the physiological coagulation cascade. Fn deposition typically represents an innate host immune defence, which is in contrast to the proposed role of SC in pathogenesis.

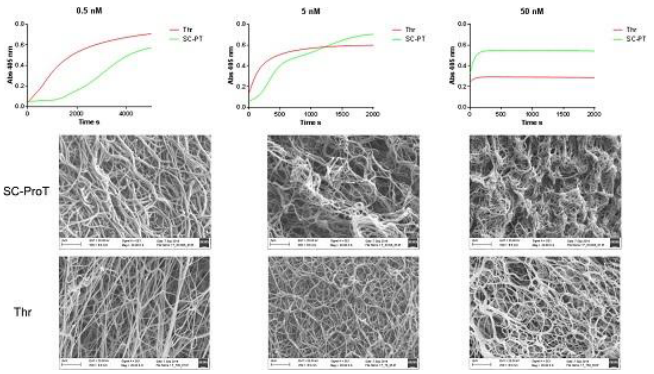

FIGURE 1 Turbidimetric clotting curves and fibrin product SEM for SC-ProT and Thr

Aims: To investigate the enzyme kinetics of SC-ProT, and the physical properties of the Fn product, compared to Thrombin (Thr).

Methods: Recombinant SC expressed in *E. coli*. Kinetic chromogenic assays (S-2238) and turbidimetric clotting assays (Fgn and human plasma) over a range of Thr and SC-ProT concentrations (0.5-50 nM). Fn structure assessed by scanning electron microscopy SEM (fibre diameter), pressure-driven permeation (gel porosity) and oscillation rheology (viscoelastic properties).

Results: Against S-2238 the specific activity of SC-ProT was equivalent to Thr. Against Fgn, based on 50% clotting times, SC-ProT potency was 3-fold less than Thr. The Fn product of SCG-ProT has thicker fibres compared to equimolar Thr, with higher concentrations producing thinner fibres and less porous clots.

Concentration dependence of fibre size is preserved in both Fgn and plasma, and the difference in permeability persists at higher enzyme concentrations, although Thr forms less permeable clots from plasma than from pure Fgn. Compared to Thr, the Fn product of SCG-ProT forms softer clots that are easier to deform, less viscous and less resistant to mechanical forces.

Conclusions: The marked differences in the kinetics of Fn polymerisation by Thr and SC-ProT, and the different structural and physical properties of the Fn products, could play an important role in the severity of S. aureus infections. Thr Fn forms a protective barrier to infection and resists shear, SC-ProT Fn may serve as a deformable shell to enhance microbial replication and dissemination.

PB 595 | Liver Fibrosis and Thrombophilia: Is There a Real Connection? Preliminary Results among HIV/HCV Co-infection

S. Perés, F. Aranda, M. Moiana, C. Julian, A. Lucero, K. Bendezu, G. de Larrañaga

Hospital of Infectious Diseases F. J. Muñiz, Hemostasis and Thrombosis Laboratory, Buenos Aires, Argentina

Background: Thrombin is intimately related to liver fibrogenesis both by a direct effect on hepatic stellate cells and through fibrosis

TABLE 1 Structural characteristics of the fibrin product of SC-ProT and Thr

		Thrombin			SC-ProT		
		5nM	50nM	100nM	5nM	50nM	100nM
	Plasma clot	6.91 (2.00)	4.14 (1.36)	3.52 (0.48)	5.91 (3.98)	5.30 (2.91)	6.04 (1.80)
Permeability coefficient		0.5nM	5nM	50nM	0.5nM	5nM	50nM
(Ks, 10^{-9} cm^2), Mean (SD)	Fibrin clot	40.8 (12.7)	27.8 (14.9)	18.5 (5.05)	49.8 (4.95)	39.7 (11.0)	33.7 (13.8)
		SC-ProT (5nM)	Thr (5nM)	SC-ProT (12nM)	Thr (12nM)		
Viscoelastic properties (Oscillation rheometry)	Storage modulus G´, Pa, Mean (SD)	22.15 (4.87)	39.66 (8.44)	31.43 (2.72)	57.17 (13.49)		
	Loss modulus G", Pa, Mean (SD)	3.95 (0.61)	6.86 (1.14)	4.21 (0.30)	9.26 (1.86)		
	Delta, Mean (SD)	10.28 (1.12)	9.91 (0.79)	7.67 (0.70)	9.27 (0.48)		
	Critical shear stress Pa, Mean (SD)	65.36 (12.29)	178.20 (18.01)	103.80 (9.65)	204.20 (31.25)		

associated with ischemic parenchymal extinction. In fact, it has been reported that anticoagulant therapy may attenuate the progression to liver fibrosis (LF). Besides, it is well known that HIV/HCV patients experience a faster progression to LF.

Aims: We aimed to assess if prothrombotic genetic variants are associated with the development of LF in HIV/HCV patients.

Methods: We performed a case-control study. We studied the genotypic distributions of Factor V Leiden (FVL), Prothrombin 20210A (II20210A), Fibrinogen-γ´10034T (FGG10034T) and Factor XI 7872C (FXI7872C) in 24 HIV/HCV patients. Among them, 13 were categorized as „with liver fibrosis" (LF+) and 11 as „without liver fibrosis" (LF-). The latter group only included patients with a clinical history of, at least ten years of HCV infection. The stage of liver fibrosis was assessed by the results of indirect ultrasonic liver elastography. Furthermore, we studied a reference group (n=223) to estimate the genotypic distributions in general population (RG).

Results: Table 1 describes the most relevant findings for the LF+/LF- groups.

TABLE 1 Clinical characteristics of patients with "liver fibrosis" (LF+) and "without liver fibrosis" (LF-).

Variables (Median with quartiles or %)	LF + (n=13)	LF - (n=11)	p
Age (years)	47 (41-53)	43 (41-46)	0.352
Male sex (%)	61.5 (8/13)	54.5 (6/11)	0.729
Body mass index (kg/m2)	28 (24-32)	27 (24-37)	0.990
Duration of HIV infection (years)	11 (4-13)	16 (14-18)	< 0.01
T cells CD4+ counts (cel/ul)	199 (143-346)	397 (210-585)	0.020
T cells CD4+ counts nadir (cel/ul)	115 (70-187)	202 (149-310)	0.050
Alcohol >20g/day (%)	59 (7/13)	64 (7/11)	0.628
Smoking (%)	83 (11/13)	56 (6/11)	0.106

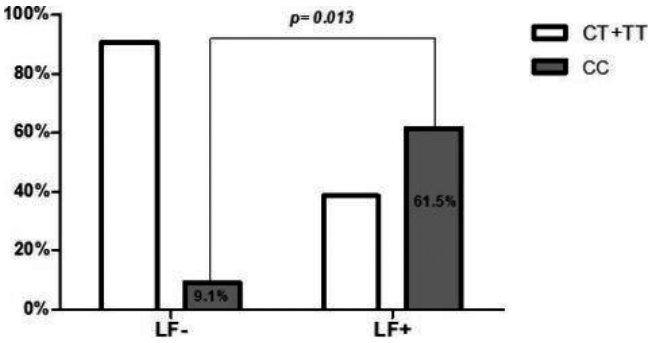

FIGURE 1 Genotype distribution of FXI7872C among patients without (LF-) and with (LF+) liver fibrosis

The distribution of the FXI7872 CC genotype showed significant differences between LF+/LF- (61.5%,8/13 vs 9.1%,1/11, p=0.013) and LF+/RG (61.5%,8/13 vs 32.0%,71/223, p=0.036). (Fig. 1).

No differences were observed in the distributions of FVL, II20210A and FGG10034T.

Conclusions: Our results suggest that the carriage of the FXI7872 CC genotype, that has been associated with an increased expression of FXI and a higher risk of deep venous thrombosis, might also be associated with the development of LF in HIV/HCV patients. This effect might be probably mediated by the presence of a pro-coagulant state. These results are preliminary and the sample size needs to be increased. If further confirmed, this finding would help in the early identification of patients who could benefit from anticoagulant therapy.

PB 596 | Anticoagulants Increase Alveolar Hemorrhage after Influenza A Infection in Mice

K. Tatsumi[1,2], S. Antoniak[1], S. Subramaniam[1], B. Gondouin[1], S. Neidich[1], M. Beck[1], J. Mickelson[1], D. Monroe[1], J. Bastarache[3], H. Kaji[2], N. Mackman[1]

[1]University of North Carolina at Chapel Hill, Department of Medicine, Chapel Hill, United States, [2]Kindai University Faculty of Medicine, Department of Physiology and Regenerative Medicine, Osaka-sayama, Japan, [3]Vanderbilt University School of Medicine, Department of Medicine, Nashville, United States

Background: Influenza A virus (IAV) infection is a common respiratory tract infection that causes considerable morbidity and mortality. While viral infections are generally associated with activation of coagulation, alveolar hemorrhage has been reported in patients with influenza pneumonia and in mice infected with IAV. We have recently reported that expression of the procoagulant protein tissue factor (TF) in lung epithelial cells maintains lung hemostasis after IAV infection (Antoniak et al JTH 2016). However, studies on the impact of anticoagulant therapy on the severity of illness and outcomes from influenza are lacking.

Aims: In this study, we investigated the effect of anticoagulants on alveolar hemorrhage after IAV infection of wild-type mice.

Methods: Wild-type mice were anticoagulated with either warfarin via drinking water or the direct thrombin inhibitor dabigatran etexilate (DE) via chow and then infected intranasally with a mouse-adapted IAV (A/Puerto Rico/8/34 H1N1). Activation of coagulation and alveolar hemorrhage were assessed by measuring the levels of thrombin-antithrombin complex (TATc) and hemoglobin in the bronchoalveolar lavage fluid (BALF), respectively. We also measured lung vascular permeability by Evans blue test and viral genomes in the lung, as well as white blood cells counts, inflammatory mediators, and protein in BALF. Furthermore we monitored survival and body weight changes of the mice for 14 days after IAV infection.

Results: Mice receiving either warfarin or DE had decreased activation of coagulation and increased alveolar hemorrhage compared to infected controls after IAV infection. Warfarin but not DE increased vascular permeability and mortality of influenza A-infected mice. Anticoagulation did not affect levels of IAV genomes, white blood cells, inflammatory mediators, or protein in the BALF.

Conclusions: Our results suggest that chronic anticoagulation could contribute to more severe alveolar hemorrhage in the setting of influenza pneumonia.

PB 597 | Comparison of Fibrin Generation Markers in Septic Shock

G. Lissalde-Lavigne, E. Cochery-Nouvellon, S. Bouvier, E. Mercier, J.-C. Gris, Sepsi-Coag Group

University Hospital, Haematology, Nîmes, France

Background: Septic shock is associated with an activation of the haemostatic system which markers may have a prognostic value.

Aims: To compare the prognostic value of fibrin generation markers FGM assayed at diagnosis in patients with septic shock, both isolated and integrated into the ISTH DIC score.

Methods: We have recruited a multicentric prospective cohort (SepsiCoag study; *NCT01231672*) to validate the prognostic scores we had previously derivated from retrospective cases (*J Thromb Haemost 2008;6:645-53*). In the present ancillary study, automated assays for FGM, *i.e.* D-dimers (DDi: STA®-Liatest® D-Di), fibrinogen-fibrin degradation products (FDP: STA®-Liatest® FDP) and fibrin monomers (FM: STA®-Liatest® FM) were performed in 780 patients entering ICU with a septic shock diagnosis. Their abilities to predict early death at D7 and late death at D30 were analysed, isolated then integrated into their corresponding ISTH DIC scores.

Results: 18.5% and 38.6% of the included patients were dead at D7 and D30, respectively. DDi and FDP values were highly correlated (0.943) whereas correlations between DDi and FM (0.690) or FDP and FM (0.678) were weaker. Values of DDi, FDP and FM were associated with survival on D7 ($p=0.0061$, 0.0179 and < 0.0001 respectivelly) but only FM values were associated with survival on D30 ($p=0.0001$). For death at D7 (D30), areas under ROC curves were 0.563 (0.525), 0.565 (0.531) and 0.647 (0.617) for DDi, FDP and FM respectively. DIC scores computed with each of the FGM were associated with survival on D7 and D30 but the one based on FM had a better prediction ability.

Conclusions: In patients entering ICU with septic shock, FM, used isolated or integrated into the ISTH DIC score, is the FGM best correlated with clinical prognosis.

PB 598 | Thoracic Manifestations in Behcet's Disease

L. Belhadj[1], A. Hariz[1], I. Boukhris[1], I. Kechaou[1], M. Mrouki[2], S. Azzabi[1], L. Ben Hassine[1], E. Cherif[1], N. Khalfallah[1]

[1]Charles Nicolle Hospital, Internal Medicine B, Tunis, Tunisia, [2]Hôpital Régional El Yasminat, Ben Arous, Internal medicine, Tunis, Tunisia

Background: Vascular involvement is the leading cause of death in Behcet's disease (BD).

Aims: Pulmonary vasculitis in Behcet's syndrome is unusual but serious. It is related to the well known vascular tropism of the disease.

Methods: Seventy five patients, who fulfilled the criteria of the International Study Group for diagnosis of BD and who were hospitalised in the Internal medecine B department of Charles Nicolle hospital were recruited . We studied the clinical characteristics of patients with pulmonary manifestations.

Results: Three patients had a thoracic event in our study distributed in superior vena cava involvement, pulmonary thrombosis and pulmonary aortic anevrysm. The mean age of diagnosis of the pulmonary event was 35 years. All patients were males. Mean disease duration before the thoracic event was 5,66 years.

An association to another vascular involvement was found in two cases. No ocular neihther neurologic involvement were observed in the three cases. HLA B50 was found in two cases. Corticosteroid treatment was used in 2 cases and immunosuppressive tratment in only one case.

Conclusions: Thoracic involvement of Behcet´s disease is unusual but serious. It may involve the superior vena cava, pulmonary arteries,

aorta and subclavian vessels. Imaging is useful for diagnosis and assess the degree of thoracic involvement. CT scan and MRI are obviously more accurate than angiography.

PB 599 | Macrophages Release Tissue Factor-bearing Microparticles upon Stimulation with *Histophilus somni*

J.J. Rivera Rivas[1], C. Czuprynski[2]

[1]*UW-Madison, Pathobiological Sciences, Madison, United States,* [2]*University of Wisconsin, Pathobiological Sciences, Madison, United States*

Background: *Histophilus somni* is a gram negative coccobacillus of cattle diffuse vasculitis and intravascular thrombosis that can lead to multiple organ failure. Macrophages are important cellular mediators of fibrin deposition and removal at sites of inflammation. Recently, it has become evident that macrophages and other cells release microparticles that have an array of biological activities. We sought to determine the role of macrophage-derived microparticles in *H. somni* induced fibrin clot formation *in vitro*.

Aims: Determine whether monocyte-derived macrophages exposed to *H. somni* release microparticles that activate the clotting cascade resulting in thrombus formation.

Methods: Bovine monocyte-derived macrophages were incubated with *H. somni* (at a 1:10 ratio) in RPMI with 10% heat inactivated fetal bovine serum for 6 hr at 37°C with 5% CO_2. Membrane-shed microparticles were isolated from the conditioned media of monocyte-derived macrophages incubated with or without *H. somni*, washed twice with Ca^{2+} and Mg^{2+} free HBSS, and procoagulant activity assessed by a one-step recalcified plasma clotting assay.

Results: We observed greater procoagulant activity for microparticles from *H. somni* stimulated macrophages than from unstimulated control macrophages. Microparticle procoagulant activity was inhibited by addition of an anti-tissue factor antibody. We also observed co-localization of fluorescein-labeled *H. somni* and Annexin V staining as evaluated by confocal microscopy.

Conclusions: These results suggest that exposure to *H. somni* cells causes bovine monocyte-derived macrophages to release microparticles that contain tissue factor. We infer this process might amplify thrombus formation in bovine histophilosis.

PB 1358 | Identification of a Novel Regulator Platelet $P2Y_{12}$ Receptor Function: Tetherin, a Lipid-raft Organizing Protein Negatively Regulates Receptor Activity

X. Zhao[1], D. Alibhai[1], J.L. Hutchinson[1], S. Cross[1], R. Aungraheeta[1], C.M. McKinnon[1], A. Poole[1], G. Banting[2], S.J. Mundell[1]

[1]*School of Physiology, Pharmacology and Neuroscience, Faculty of Biomedical Sciences, University of Bristol, Bristol, United Kingdom, Bristol, United Kingdom,* [2]*School of Biochemistry, University of Bristol, Bristol, United Kingdom, Bristol, United Kingdom*

Background: The function of a number of platelet receptors, including the $P2Y_{12}$ (1), is dependent upon their residence in lipid rafts although little is known about the molecular mechanisms regulating their membrane surface compartmentalisation. Tetherin (also known as CD317 or BST2) is a lipid raft-associated transmembrane protein that regulates host response to viral infection by inhibiting viral particle release (2). This integral membrane protein which also plays a role in lipid raft organization (3) is expressed in platelets although its physiological function is unknown.

Aims: To characterize tetherin-dependent regulation of platelet $P2Y_{12}R$ function in tetherin (-/-) mice and establish interaction between these proteins in both cell line models and platelets.

Methods: Platelet ADP receptor activity was assessed in tetherin (-/-) mouse platelets as previously described (4). $P2Y_{12}R$ and tetherin interaction was assessed by confocal, TIRF and FRET-FLIM microscopy and co-immunoprecipitation (Co-IP) approaches in cells expressing human $P2Y_{12}R$ and full length or mutant tetherin constructs.

Results: ADP-stimulated platelet aggregation and $P2Y_{12}R$ activity was enhanced in tetherin (-/-) mouse platelets. In cell lines overexpression of tetherin attenuated $P2Y_{12}R$ signalling and internalization. FRET-FLIM microscopy and Co-IP established that $P2Y_{12}R$ and tetherin interact directly with a glycosyl-phosphatidylinositol anchor at the C-terminus of tetherin required for protein-protein interaction. Intriguingly receptor activation reduced tetherin-receptor interaction.

Conclusions: Tetherin negatively regulates platelet $P2Y_{12}R$ function and represents a potential new target in regulating platelet activity.

PB 1359 | Platelet Endocytosis in Immune Responses to Viral Infection

M. Banerjee, S. Whiteheart

University of Kentucky, Molecular and Cellular Biochemistry, Lexington, United States

Background: Thrombocytopenia correlates with clinical outcomes of viremia and bacteremia. Chronic viral infections significantly increase the risk of acute myocardial infarction (MI). Likely, these infections initiate some level of platelet activation, contributing to increased thrombotic potential. This could be due to the platelets' ability to detect Pathogen and Damage Associated Molecular Patterns (PAMPs and DAMPs). Viral or bacterial DNA/RNA is recognized by Toll-like Receptors (TLR) 7 and 9; an ill-defined process in platelets, since these receptors are intra-platelet and not at the surface. Platelets endocytose virions but the machinery required and its subsequent effects are unclear.

Aims: We sought to understand whether platelet endocytosis is required for their responses to TLR agonists and viral particles.

Methods: Assays on of platelets from transgenic mice.

Results: We examined platelet responses to TLR agonists, loxoribine (for TLR7) and unmethylated CpG oligonucleotides (for TLR9), which activated $I_\kappa B$ kinase (IKK) and PI3K-Akt pathways (*i.e.*, phophorylation of $I_\kappa B$, SNAP-23 and Akt). Each also elicited an attenuated secretory response, which was sufficient to form platelet-leukocyte aggregates (PLAs), as shown by FACS. Inhibitor (Dynasore and NH_4Cl) studies and analysis of platelets from endocytosis-defective mice (VAMP-$3^{-/-}$ and Arf$6^{-/-}$) demonstrated the importance of platelet endocytic trafficking in regulating the responses of these intracellular TLRs. We used HIV-1 pseudovirions to model platelet-viral interactions and showed that platelets endocytose and degrade retroviral particles to release TLR agonists, which initiates platelet activation (IKK and Akt activation), secretion, and PLA formation. HIV-1 pseudovirion uptake and subsequent activation were abolished in VAMP$3^{-/-}$ or Arf$6^{-/-}$ platelets.

Conclusions: Our studies suggest how platelets can act at early stages of pathogen recognition and are not only able to internalize pathogens but are also able to process them to initiate an immune response.

PB 1360 | Pharmacologic Blockade of Platelets Reduces Neuroinflammation in an Animal Model of Multiple Sclerosis

S. Eichler[1], H. Böhnlein[1], K. Loser[2], H. Wiendl[1], B.E. Kehrel[3], K. Göbel[1], S.G. Meuth[1]

[1]University of Muenster, Department of Neurology, Muenster, Germany, [2]University of Muenster, Department of Dermatology, Muenster, Germany, [3]University of Muenster, Department of Anesthesiology, Intensive Care and Pain Medicine, Experimental and Clinical Hemostasis, Muenster, Germany

Background: Multiple sclerosis (MS) is the most frequent inflammatory demyelinating disease of the central nervous system (CNS). While the pathogenesis of MS is still not completely understood, emerging new concepts identified platelets as crucial players in MS pathophysiology that actively assist and amplify inflammatory response. Recent studies showed that platelet depletion reduces disease severity and inflammation in experimental autoimmune encephalomyelitis (EAE), a classical animal model to study MS. Furthermore, platelets occur along with an increased activation status in MS patients.

Aims: In this study, we challenge the relevance of platelet inhibition under pathophysiological conditions *in vivo*.

Methods: 30 or 300 mg/l of the irreversible cyclooxygenase inhibitor acetylsalicylic acid (ASA) were orally administered for 35 days to mice that were subjected to actively-induced EAE.

Results: Here, we demonstrate that pharmacologic blockade of platelets with ASA renders mice less susceptible to autoimmune CNS inflammation. While disease onset was unaltered, oral treatments with high and low-doses of ASA were both associated with a reduced disease maximum and less inflammatory infiltrates within the CNS. At high doses of ASA, amelioration was further accompanied by reduced numbers of interleukin-17A- and interferon-γ-producing T-helper cells as disclosed via intracellular cytokine staining at the disease peak. Thus, ASA at high concentration was related to more pronounced ($P < 0.01$) reduction of disease progression compared to treatment with low doses of ASA ($P < 0.039$), but flow cytometric analysis showed for both no significant difference in the number of infiltrated platelets within the CNS of ASS treated mice compared to control mice.

Conclusions: Indeed, further investigations are needed to reveal the underlying mechanisms of platelet inhibition.

Overall, our findings show that the inhibition of platelet activation is beneficial in animal model of MS and thus indicate a novel therapeutic strategy to combat MS.

PB 1361 | Exploring Pro-thrombotic HMGB-1 Release from Platelets

J. Davies, M. Harper

University of Cambridge, Department of Pharmacology, Cambridge, United Kingdom

Background: Released HMGB-1 acts as damage-associated molecular pattern. HMGB-1 can be passively released from necrotic cells or actively secreted. Platelet-derived HMGB-1 can act as a pro-inflammatory signal, that exacerbates thrombosis. However, the mechanism of HMGB-1 release from platelets is unclear.In this study, we investigated HMGB-1 surface exposure in activated platelets.

Aims: To understand agonist driven HMGB-1 plasma membrane exposure.

Methods: Washed platelets were stimulated with ADP, U46619, thrombin, cross-linked collagen-related peptide (CRP-XL), thrombin-plus-CRP-XL, or the calcium ionophore, A23187. Platelets were co-stained against HMGB-1, CD62P (a marker of a-granule secretion) and CD41, and analysed by flow cytometry.

Results: Platelet stimulation triggered HMGB-1 surface exposure, a-granule secretion and microparticle release in an activator-dependent manner.

The relatively weak activators, ADP or U46619, did not trigger a detectable increase in HMGB-1 surface exposure. Under these conditions, ADP and U46619 triggered weak a-granule secretion or little micro particle release.

Thrombin, Thrombin-plus-CRP-XL and A23187 all induced a greater increase in HMGB-1 surface exposure, while CRP-XL did not. However, all of these activators triggered increased maximal surface CD62P, indicating that HMGB-1 release does not correlate with a-granule secretion.

Intriguingly, under stimulation conditions that led to substantial microparticle release, HMGB-1 appeared to be restricted to the platelets and excluded from the microparticle surface. This contrasts with CD62P, which was found on surface of platelets and micro particles.

Conclusions: In summary, strong platelet activation leads to increased HMGB-1 surface expression. However, the mechanism of this does not directly correlate with platelet a-granule secretion. The apparent exclusion of HMGB-1 from micro particles suggests that its surface exposure is regulated in a complex manner.

PB 1362 | Platelets Enhance Distinct Dynamics of Effector Cell Responses of Naive and Effector Memory CD4$^+$ T cells

S. Tan, C.-L. Liu, Y. Min, X. Liu, N. Li

Karolinska Institutet, Department of Medicine-Solna, Clinical Pharmacology Group, Stockholm, Sweden

Background: Platelets exert a bi-phasic regulation on effector cell responses of the total CD4$^+$ T cells, but little is known on their impact on naïve and effector memory CD4$^+$ T cells.

Aims: To investigate how platelets differentially regulate effector cell responses of naïve and effector memory CD4$^+$ T cells.

Methods: Human naïve and effector memory CD4$^+$ T cells were challenged with CD3/CD28 MAbs, and cultured without or with platelets (ratio at 1:250) during 7 days. CD4$^+$ T effector cell responses were assessed by Th1, Th2, Th17 and Treg cell phenotyping on day 0, 1, 3, 5, and 7.

Results: T cell receptor (TCR)-challenge evoked marked CD4$^+$ T cell activation and proliferation, seen as increases of cell numbers and T cell aggregate formation from day 3 on. Platelet co-culture did not alter cell proliferation but markedly enhanced cell activation on day 5 and 7, as evidenced by increased T cell aggregate sizes of both subsets. In naïve CD4$^+$ T cells, TCR stimulation mildly enhanced Th1 cell activation, which increased Th1 phenotype from 0.3±0.1% at basal to 2,2±0.7% on day 5. Platelet co-culture markedly enhanced the response, and elevated Th1 to 9.3±3.4%. Platelets accelerated TCR-stimulated Treg activation, and increase Treg from 8.3±2.2% to 33.9%±10.9% on day 5. In effector memory CD4$^+$ T cells, TCR stimulation evoked rapid effector cell responses. Thus, Th1 cells were already evelated to 7.9±5.1%, and further enhanced by platelets to 10.7±5.7% on day 1. Treg cells were also elevated quickly, at 4.5±2.3% on day 1 and with marked enhancements by platelets on day 3 and 5. Neutralization of transforming growth factor 1b (TGF1b) diminished platelet-enhanced Treg activation, but potentiated Th1 responses. TCR stimulation induced only mild increases of Th2 and Th17 responses in the present settings.

Conclusions: Platelets enhance delayed effector cell responses of naïve CD4$^+$ T cells, but promote rapid effector cell responses of effector memory CD4$^+$ T cells.

PB 1363 | The Staphylococcal Toxin Panton-Valentine Leukocidin (PVL) Induces Neutrophil Extracellular Trap (NET) Formation that Leads to Platelet Activation

A. Bertling[1], S. Niemann[2], M.F. Brodde[1], F. Anke C.[3], H. Van de Vyver[2], B. Schlott[4], C. Heilmann[2], G. Peters[2], B. Löffler[5], B.E. Kehrel[1]

[1]University Hospital Muenster, Anaesthesiology, Intensive Care and Pain Medicine, Muenster, Germany, [2]University Hospital Muenster, Medical Microbiology, Muenster, Germany, [3]Heinrich Heine University Duesseldorf, Pharmacology, Duesseldorf, Germany, [4]Leibniz Institute on Aging, Leibzig, Germany, [5]Medical University Jena, Microbiology, Jena, Germany

Background: Expression of the toxin PVL by *Staphylococcus aureus* has been linked to thrombosis in association with osteomyelitis especially in young immunocompetent patients.

Aims: We therefore tested the effect of PVL on human platelets and neutrophils.

Methods: The effect of recombinant PVL on platelet activation and microparticle formation in the presence or absence of autologous neutrophils was measured by flow cytometry. PVL induced lysis of neutrophils was assessed by propidium iodide. ELISA detected release of neutrophil myeloperoxidase and defensins. NET formation was analyzed by a fluorogenic assay using the fluorescent dye Syto13 binding to nucleic acids, a sandwich ELISA against histone-DNA complexes and by microscopy. The influence of known inhibitors of alpha defensin and of FDP-lysine carrying proteins induced platelet activation was studied.

Results: The toxin PVL strongly induced platelet activation, but only in the presence of human neutrophils**.** Labelled PVL *subunit* S (LukS) bound to the neutrophil surface, but not to platelets. Complete PVL induced neutrophil lysis and NET formation as well as the release of alpha defensins and myeloperoxidase, known mediators of platelet activation. Neutrophil NETs were decorated with alpha defensin 1-3 and stained for FDP-lysine. PVL-induced platelet activation in the presence of neutrophils was inhibited by known defensin inhibitors as well as by the antioxidants resveratrol and glutathione (GSH). PVL actions were blocked by anti-PVL-antibodies in the plasma of some adult blood donors.

Conclusions: Our data provide one possible explanation how thrombosis and osteomyelitis are connected in PVL-*S. aureus* infections and why especially young osteomyelitis patients with a presumably low antibody titer against PVL suffer more from this complication than adults. As the mechanism described might be a more general one, other bacterial toxins are under further investigation.

PB 1364 | Platelets Play a Protective Role in the Host Defense against *Burkholderia pseudomallei* (Melioidosis)

E. Birnie[1], T.A.M. Claushuis[1], G.C.K.W. Koh[2], J. Ware[3], A.F. de Vos[1], T. van der Poll[1], C. van ,t Veer[1], W.J. Wiersinga[1]

[1]University of Amsterdam, Academic Medical Center, Center for Experimental Molecular Medicine, Amsterdam, The Netherlands, [2]University of Cambridge, Department of Medicine, Cambridge, United Kingdom, [3]University of Arkansas for Medical Sciences, Arkansas, United States

Background: Melioidosis, caused by the gram-negative bacterium *Burkholderia pseudomallei*, is an important cause of community-acquired pneumonia and sepsis in Southeast Asia with a mortality of up to 40%. So far nothing is known about the role of platelets in this disease.

Aims: To assess the role platelets in the host response during *B. pseudomallei* infection.

Methods: Platelet counts were determined in 34 patients with culture-proven melioidosis and 52 controls. Mice treated with a low or high dose platelet depleting antibody or IgG control were infected via the airways with *B. pseudomallei* and sacrificed at several time-points. In addition, we investigated the role of GPIb, the Von Willebrand factor receptor. IL4-R/Ibα mice (which lack mouse GPIbα without the associated macrothrombocytopenia) and WT mice were infected with *B. pseudomallei*.

Results: Clinical melioidosis was associated with significant thrombocytopenia. Low platelet counts strongly associated with mortality. Murine melioidosis was also characterized by thrombocytopenia. Platelet depletion towards a level of either < 5% or < 1% of normal resulted in increased bacterial counts at the primary site of infection with increased dissemination towards the liver. Platelet depletion also increased inflammatory responses, but pulmonary neutrophils influx was reduced. Platelets are important for the formation of neutrophil extracellular traps (NETs). In the lungs of infected mice, NET formation however did not differ between groups. Mice lacking GPIbα showed decreased platelet-neutrophil complex formation, but also lower platelet counts. GPIbα deficient mice showed increased bacterial growth in the lung, but not to a similar extent as platelet depleted mice.

Conclusions: Admission thrombocytopenia is associated with enhanced mortality in melioidosis patients. During experimental melioidosis, platelets play a protective role in the host defense, possibly in part via GPIb and neutrophil interactions.

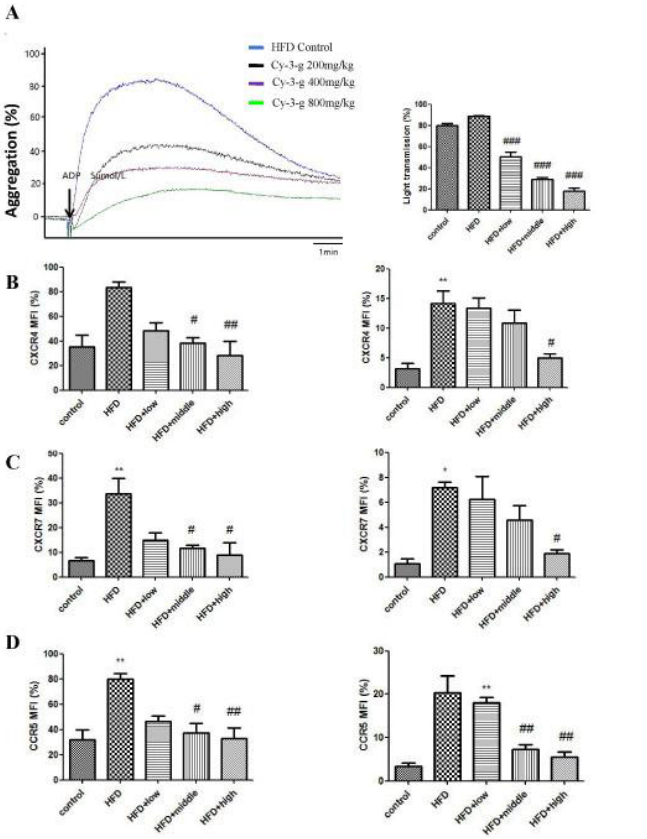

Figure 1 The effects of Cy-3-g on platelet aggregation and chemokine receptors in ApoE-/- mice. Platelet aggregation of PRP stimulated by 5 μmol/L ADP (A). The surface expressions of CXCR4, CXCR7, CCR5 on leukocytes and platelets via flow cytometry (B, C and D). Values are mean ± SD, n = 5 per group. # $P < 0.05$, ## $P < 0.01$, ### $P < 0.001$, as compared to the HFD group. * $P<0.05$, ** $P<0.01$, as compared to the control.

PB 1365 | Plant Food Cyanidin-3-glucoside Attenuates Atherosclerosis via Inhibiting Platelet-derived Chemokines and Chemokine Receptors in ApoE-/- Mice

Y. Yanling[1], Z. Xiandan[1], Y. Fuli[1], C. Binlin[1], L. Qing[1], L. Dan[1], L. Wenhua[1], Q. Zhang[2], P. Xu[3], Y. Yan[1]

[1]*Sun Yat-Sen University, Department of Nutrition, Guangzhou, China,* [2]*SunYat-sen University, The Key Laboratory of Gene Engineering of Education Ministry, Guangzhou, China,* [3]*Sun Yat-sen University, The Key Laboratory of Gene Engineering of Education Ministry, Guangzhou, China*

Background: Platelet-derived chemokines play crucial roles in atherosclerosis (AS). Plant food anthocyanin, the main bioactive component of which is cyanidin-3-glucoside (Cy-3-g), possesses anti-platelet effects and cardiovascular protection. Our previous study has shown the inhibitory effects of anthocyanins on platelet chemokines in hypercholesterolemic individuals, however, the effects of Cy-3-g on platelet chemokines in AS need to be clarified.

TABLE 1 Effects of Cy-3-g on plasma levels of platelet chemokine in ApoE-/- mice

	Control	HFD	HFD+ 200mg/kg Cy-3-g	HFD+ 400mg/kg Cy-3-g	HFD+ 800mg/kg Cy-3-g	P value
CXCL4 (ug/mL)	3.109 ± 0.645	9.651 ± 5.516	5.644 ± 3.822	3.219 ± 0.866	2.636 ± 0.253	0.002
CXCL7 (pg/mL)	486.758 ± 71.777	1370.800 ± 122.398	1206.467 ± 135.415	892.383 ±39.183	712.342 ± 102.630	<0.001
CCL5 (pg/mL)	6.262 ± 0.498	14.42 8± 6.957	9.920 ± 3.006	7.630 ± 2.392	5.170 ± 1.211	0.001
CXCL5 (pg/mL)	291.111 ± 53.527	4530.370 ± 1666.098	1460.926 ± 623.991	760.834 ±310.050	239.722 ± 194.655	<0.001
CXCL12 (pg/mL)	2.734 ± 0.050	3.573 ± 0.283	3.104 ± 0.058	3.010 ± 0.050	2.882 ± 0.054	<0.001
CCL2 (pg/mL)	477.444 ± 187.540	3489.279 ± 1780.539	2056.729 ± 1418.911	1042.118 ± 308.976	624.113 ± 258.365	0.001

The data are expressed as the mean ± SD (n=7-9). HFD: high fat diet. All P values were calculated by Student´s t-test.

Aims: To study the inhibitory effects of Cy-3-g on platelet chemokines and chemokine receptors in ApoE-/- mice.

Methods: ApoE-/- mice (6 week old, male) were fed a high-fat diet (HFD; 21% fat, 0.15% cholesterol) that mixed with different doses of Cy-3-g (0, 200, 400 and 800 mg/kg) for 16 weeks. The control were fed with a normal diet. Arteries were separated to determine plaque histology by Oil-Red-O dying. Blood routine were tested by Multispecies Hematology Systems. Platelet aggregation was observed by aggregometer. The levels of serum lipid and platelet chemokines were detected by test or ELISA kits. The expressions of chemokine receptors CXCR4, CXCR7 and CCR5 were analyzed via flow cytometry.

Results: Compared with HFD group, the plasma levels of TG, T-CHO, LDL were inhibited by 800 mg/kg Cy-3-g, while HDL increased markedly. The plasma levels of CXCL4, CXCL5, CXCL7, CXCL12, CCL2, CCL5 were significantly reduced (all $P < 0.002$, Tab. 1). Platelet aggregation (all Cy-3-g groups) and WBC counts (400 and 800 mg/kg groups) were inhibited. The expressions of CXCR4, CXCR7, CCR5 on leukocytes, CCR5 on platelets were attenuated in 400 and 800 mg/kg groups, and obvious inhibition of CXCR4, CXCR7 on platelets in 800 mg/kg group (Fig. 1).

Conclusions: Cy-3-g regulates platelet activities via inhibiting platelet chemokines and chemokine receptors in ApoE-/- mice. Dietary intake of Cy-3-g may have protective effects against the development of AS, and further studies are required to investigate the underlying mechanisms.

PB 1366 | Platelets Promote Immunosuppression and Colorectal Tumor Formation: Inhibition by Clopidogrel

L. Servais[1], C. Delierneux[1], O. Wéra[1], A. Gothot[2], A. Nchimi[1], P. Lancellotti[1,3], C. Oury[1]

[1]*University of Liège, Laboratory of Thrombosis, Haemostasis and Valvular Diseases, GIGA-Cardiovascular Sciences, Department of Cardiology, CHU Liège, Liège, Belgium,* [2]*University of Liège, Laboratory of Hematology, CHU Liège, Liège, Belgium,* [3]*Gruppo Villa Maria Care and Research, Anthea Hospital, Bari, Italy*

Background: Clinical and preclinical data strongly suggest that antiplatelet drugs may mitigate colorectal cancer development and improve outcome.

Aims: To investigate the mechanisms of clopidogrel-mediated inhibition of colitis-associated carcinogenesis in mice.

Methods: Colorectal cancer was induced in mice upon treatment with azoxymethane/dextran sulphate sodium (AOM/DSS) for 65 days. Clopidogrel (30 mg/kg/day) was administered continuously via the drinking water. Inflammatory score, dysplasia and adenocarcinoma formation were analysed. Changes in blood cell counts, platelet activation and reactivity were monitored throughout the protocol. Colon infiltration by myeloid and T cells were analysed by immunohistochemistry. Phenotype and immunosuppressive activity of splenic myeloid cells were analysed by RT-qPCR and mixed lymphocyte reaction assays.

Results: Clopidogrel efficiently inhibited cancer-elicited platelet activation and limited diarrhea without inducing intestinal bleeding. It significantly reduced dysplasia and the numbers of adenocarcinoma. It prevented the accumulation of immunosuppressive myeloid cells in tumors, while the numbers of anti-tumor cytotoxic T cells were augmented in dysplasic areas. Interestingly, in blood, clopidogrel reduced the appearance of tumor-induced low-density neutrophils, and it decreased the levels of platelet-neutrophil aggregates. Myeloid cells isolated from spleen of clopidogrel-treated mice failed to inhibit T cell proliferation *ex vivo*, and displayed reduced mRNA expression of immunosuppressive markers, TGF-β, C/EBP β and arginase-1. Platelets isolated from tumor-bearing mice promoted immunosuppression by immature myeloid cells, and were able to annihilate the inhibition of their activity by clopidogrel.

Conclusions: The antiplatelet drug clopidogrel may inhibit colitis-induced carcinogenesis by affecting platelet-dependent regulation of immunosuppressive myeloid cell function, thereby improving antitumor immunity.

PB 1367 | Interplay between Platelets, Neutrophils and Coagulation in Bleeding in a Mouse Model of Inflammatory Bowel Disease

O. Wéra[1], C. Delierneux[1], L. Servais[1], A. Hego[1], C. Lecut[2], P. Delvenne[3], A. Nchimi[1], P. Lancellotti[1,4], C. Oury[1]

[1]*University of Liège, Laboratory of Thrombosis and Hemostasis and Valvular Heart Diseases, GIGA-Cardiovascular Sciences, Department of Cardiology, CHU Liège, Liège, Belgium,* [2]*University of Liège, Department of Laboratory of Hematology, CHU Liège, Liège, Belgium,* [3]*University of Liège, Department of Pathology, CHU Liège, Liège, Belgium,* [4]*Anthea Hospital, Gruppo Villa Maria Care and Research, Bari, Italy*

Background: Inflammatory bowel diseases (IBD) are associated with a persistently elevated risk of thrombosis. Because IBD patients are also at high risk of major gastrointestinal bleeding, thromboprophylaxis management of these conditions remains a challenge. Current recommendations include the use of heparins. There is no data on direct oral anticoagulants. A better understanding of the mechanisms underlying inflammatory bleeding could help to develop tailored antithrombotic approaches. In mouse models of inflammation, it has been reported that platelets and neutrophils are involved in the maintainance and in the loss of vascular integrity.

Aims: To investigate the respective contribution of platelets, platelet receptors, neutrophils, and coagulation to intestinal bleeding in IBD

Methods: We used a mouse model of IBD induced by oral administration of dextran sodium sulfate for 7 days. The effects of platelet or neutrophil-depleting antibodies, clopidogrel (30mg/kg/day), GPVI depletion, P2X1 deficiency, and of rivaroxaban (10mg/kg/day) were compared on the following parameters: disease activity index (diarrhea, bleeding, weight loss), differential blood cell counts, and hematocrit. Histopathology and immunohistochemistry analyses were performed.

Results: Platelet depletion, P2X1 deficiency, or treatment with rivaroxaban provoked intestinal bleeding that resulted in hematocrit drop, which did not occur in control colitic mice. This drop in hematocrit was inversely correlated with levels of neutrophil infiltration in colon. Rivaroxaban treatment and P2X1 deficiency both worsened tissue

damage and increased neutrophil-to-lymphocyte ratio in blood. In agreement with a role for neutrophils in bleeding, neutrophil depletion limited blood loss in P2X1-deficient mice. Neither GPVI depletion nor clopidogrel treatment aggravated bleeding.

Conclusions: Neutrophils, platelets, and P2X1 receptors intervene in anticoagulant-elicited bleeding of the inflamed intestine.

PB 1368 | Platelet-leukocyte Interactions after Major Trauma Primarily Involve Platelet-derived Microvesicles and Are More Frequent in Patients with Poor Clinical Outcomes

P. Vulliamy[1], P.C. Armstrong[2], S. Gillespie[1], H.E. Allan[2], T.D. Warner[2], K. Brohi[1]

[1]Queen Mary University of London, Centre for Trauma Sciences, London, United Kingdom, [2]Queen Mary University of London, William Harvey Research Institute, London, United Kingdom

Background: Platelets play important roles in both coagulation and inflammation, but their contribution to these processes in trauma patients is poorly understood.

Aims: To characterise platelet-leukocyte interactions in injured patients and to determine whether these are associated with adverse outcomes.

Methods: Patients meeting criteria for the highest tier of trauma team activation were included and had blood drawn within two hours of injury. Healthy volunteers acted as a control group. Platelet interactions with leukocytes in whole blood were scored from imaging flow cytometry by a blinded assessor, and recorded as a proportion of the number of neutrophils, monocytes and T-lymphocytes. Platelet-derived microvesicles (PMV) were defined as CD61-positive material measuring < 1μm on fluorescence imaging.

Results: In trauma patients (n=25) PMV attached to leukocytes were more common than whole platelet-leukocyte aggregates among monocytes, neutrophils and T-cells ($p< 0.01$ for each group). Within leukocytes, PMV were more common on monocytes (39±8% of the population) than on neutrophils (23±7%, $p=0.02$) or T-cells (10±3%, $p< 0.001$). The frequency of whole platelet-monocyte aggregates was similar in trauma patients (14±5%) and healthy volunteers (11±3%, $p=0.26$). In contrast, PMV-monocyte aggregates were markedly elevated in the trauma population (39±8%) compared to volunteers (4±3%, $p< 0.001$). Significantly more PMV-monocyte aggregates were found in patients who developed multiple organ dysfunction (MOD) or died within 48 hours (49±10%) than in those who had uncomplicated outcomes (20±9%, $p=0.004$). A similar pattern was observed with PMV-neutrophil aggregates (MOD/death: 33±10% vs no MOD: 13±6%, $p=0.01$), although aggregates with T-cells occurred at a similar frequency irrespective of outcome.

Conclusions: Major injury induces widespread platelet-leukocyte interactions which principally involve PMV and monocytes. The functional consequences of PMV-leukocyte aggregation in trauma patients require further investigation.

PB 1369 | Complete Attenuation of PrP(106-126)-mediated Pathological Responses by Flufenamic Acid in Platelets

R.L. Mallick[1,2], S.N. Chaurasia[2], D. Dash[2]

[1]Kathmandu University/Birat Medical College and Teaching Hospital, Department of Biochemistry, Biratnagar, Nepal, [2]Banaras Hindu University/Institute of Medical Sciences, Department of Biochemistry, Varanasi, India

Background: PrP(106-126) is amyloidogenic amino acid sequence released from prion proteins in Prion disease. As PrP is expressed in blood following leakage from brain tissue, PrP(106-126) exerts its biological effects. PrP(106-126) shows a rise in intracellular calcium, $[Ca^{2+}]i$, in platelets which is attributable to influx from extracellular fluid. Calcium mobilization then stimulates calpain that partially cleaves cytoskeleton-associated protein talin and extensive shedding of microparticles. As surface of platelet-derived microparticles are enriched with phosphatidylserine and hence are pro-coagulant, exposure to prion favoures thrombogenic state.

Aims: As TRPC proteins reside in platelets, the present study aims to investigate their involvement in prion-induced pathology and therapeutic effect of flufenamic acid (FFA).

Methods: Platelets were isolated from human blood. Aggregation study, measurement of $[Ca^{2+}]_i$, confocal microscopy, flow cytometry and western blot analysis were done.

Results: Addition of PrP(106-126) (20 μM) to platelet suspension under stirring condition at 37°C in aggregometer elicited a rise in light-transmittance to 75±8%. Platelets preincubated with 1 mM $CaCl_2$ following treatment with PrP(106-126) showed 30-fold rise in $[Ca^{2+}]_i$. Fura-2 loaded cells treated with 10 μM Hyp9 in presence of 1 mM calcium demonstrated 7-fold rise in $[Ca^{2+}]_i$. Remarkably, PrP(106-126)-induced rise in $[Ca^{2+}]_i$ was completely prevented by preincubation of cells with 100 μM FFA, an inhibitor of TRPC isoforms except TRPC6, which was suggestive of involvement of non-TRPC6 isoform in PrP(106-126)-mediated Ca^{2+} entry.

Conclusions: Remarkably, when freshly prepared platelets were preincubated with FFA, PrP(106-126)-induced rise of $[Ca^{2+}]_i$ was almost precluded. Our observation, therefore, was strongly indicative of significant role of different TRPC isoforms (except TRPC6). Hence it is tempting to suggest that FFA, an anti-inflammatory drug, is effective therapy against prion-mediated pathological responses.

PB 1370 | Platelet Functional Activity Is Altered in Multiple Sclerosis

L. Schüngel[1,2], S. Eichler[2], M.F. Brodde[1], C. Korsukewitz[2], S.G. Meuth[2], K. Göbel[2], B.E. Kehrel[1]

[1]University Hospital Muenster, Department of Anaesthesiology; Exp. and Clin. Haemostasis, Muenster, Germany, [2]University Hospital Muenster, Department of Neurology, Muenster, Germany

Background: Multiple sclerosis (MS), an inflammatory autoimmune disease of the central nervous system, is a main cause of disability in

young adults. In the last decade, the role of platelets in MS pathology came into focus of research as platelets get activated by inflammatory compounds and can modulate inflammation themselves. Langer *et. al.* proved the presence of platelets in chronic active MS lesions and could show that blocking platelets GP IIb/IIIa reduces experimental autoimmune encephalomyelitis, the mouse model of MS.

Aims: To understand more about the role of platelets in MS we studied platelet functional activity in patients with different stages of MS.

Methods: In this ongoing study, the response of platelets from so far 46 patients suffering from MS in different stages of disease and healthy controls, to different platelet agonists was analyzed by flow cytometry. Different markers for platelet activation as fibrinogen binding, microparticle formation and platelet-lymphocyte association, as well as granule secretion were measured.

Results: Platelets from patients suffering from MS responded less to collagen, ADP, epinephrine and arachidonic acid in an apparently disease state dependent way than control platelets. The platelets of the four patients with an acute relapse did not respond to epinephrine at all. The response to stimulation with thrombin did not differ between MS patients and healthy controls.

Conclusions: These results indicate an *in vivo* preactivation with several platelet agonists leading to an exhaustion of platelet response to these agonists. As the platelet response to stimulation with thrombin is still normal, it is unlikely that increased thrombin formation causes such a preactivation. Probably reactions linked to inflammatory processes during the progression of disease might be the cause of preactivated platelets in MS. Platelets respond to inflammation and can mediate inflammation wherefore they may be a player in the inflammatory processes underlying the primary pathology of MS.

PB 1371 | Contributions of von Willebrand Factor to the Development of Angiotensin II-induced Vascular Inflammation

J. Lagrange[1], S. Kossmann[1,2], T. Münzel[2], Z. Ruggeri[3], W. Ruf[1,4], P. Wenzel[1,2]

[1]*Center for Thrombosis and Hemostasis (CTH), University Medical Center Mainz, Johannes Gutenberg-University, Mainz, Germany,* [2]*Center for Cardiology - Cardiology 1, University Medical Center Mainz, Mainz, Germany,* [3]*The Scripps Research Institute, Department of Molecular Medicine, La Jolla, United States,* [4]*The Scripps Research Institute, Department of Immunology and Microbiology, La Jolla, Germany*

Background: We recently uncovered a coagulation-inflammation circuit that promotes vascular dysfunction through factor XI (FXI)-thrombin amplification loop highlighting the possible utility of FXI-targeted anticoagulant in treating hypertension. The role of von Willebrand Factor (vWF) and its interaction with platelets during adhesion to the vascular endothelium in the proinflammatory context of hypertension is unknown.

Aims: We explored the role vWF in the development of angiotensin II (AngII)-induced vascular dysfunction.

Methods: The role of vWF was explored in mice with human GPIbα replacing the endogenous homologue (hGPIbα) mice) compared to mouse GPIbα and mice infused with AngII (1 mg× $kg^{-1\times}$ d^{-1} for 7 days using osmotic minipumps). hGPIbα mice have a prolonged tail bleeding time, explained by the decreased mouse vWF A1 domain affinity for human as compared to mouse GPIbα.

Results: Interestingly, hGPIbα mice were protected from AngII-induced endothelial dysfunction, vascular inflammation (as assessed by *Ccl2*, *Vcam-1* and *Ly6c* mRNA upregulation) and oxidative stress, but infusing human vWF restored the full response to AngII treatment. To delineate whether a normal vWF-GPIbα interaction also influenced the FXI-thrombin loop, we assessed the endogenous thrombin potential (ETP) in PRP of hGPIbα mice infused or not with hvWF. After AngII infusion the ETP did not increase in untreated hGPIbα mice, but it increased in those pretreated with hvWF to the same extent as control C57BL/6.

Conclusions: We showed here that the presence of vWF as GPIbα ligand is required for localized thrombin generation and is crucial in the development of AngII-induced vascular dysfunction.

PB 1372 | Platelets Are Effectors of Articular Degradation in Rheumatoid Arthritis

E. Petito[1], E. Falcinelli[1], A. Alunno[2], S. Momi[1], E. Bartoloni[2], A. Marturano[1], F. Luccioli[2], G. Mirabelli[2], R. Gerli[2], P. Gresele[1]

[1]*University of Perugia, Department of Medicine, Section of Internal and Cardiovascular Medicine, Perugia, Italy,* [2]*University of Perugia, Department of Medicine, Section of Rheumatology, Perugia, Italy*

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease causing progressive articular destruction. Activated platelets and platelet-derived microparticles (PMPs) have been found in synovial fluid (SF) of RA patients. However, the mechanism by which platelets reach SF, get activated and whether they contribute to joint damage have not been investigated yet. Matrix metalloproteinases (MMPs) are primary drivers of cartilage and bone degradation in RA. Platelets contain and release several MMPs (e.g. MMP-2) and trigger MMP-synthesis by other cells.

Aims: To assess platelet contribution to articular degradation in RA exploring the hypothesis that platelets are actively recruited in the arthritic joint where they induce an increased release of MMP-2.

Methods: Knee joint SF was collected from 47 patients with RA and 49 patients with osteoarthritis (OA): platelet and PMPs count, platelet P-selectin and heterotypic platelet aggregates were measured by flow-cytometry, and MMP-2 levels by zymography. Synovial fibroblasts (FLS) were cocultured with platelets and MMP-2 level in cell-free supernatants was measured. Platelet migration towards RA SF was assessed using the *in vitro* transwell assay. The role of platelet MMP-2 in joint degradation was tested in a mouse model of collagen-antibody induced arthritis.

Results: SF from RA patients contains significantly more activated platelets and MMP-2 compared with SF from OA. RA SF exerts a strong significant chemotactic and activating effect on platelets. Platelet-FLS coculture induces platelet activation. Activated platelet-released MMP-2 acts on FLS proteinase-activated receptor 1 (PAR1) inducing MMP-2 release by FLS. Selective depletion of platelet MMP-2 strikingly reduces cartilage degradation and articular platelet recruitment in murine arthritis.

Conclusions: Platelets are effectors of joint destruction in RA by enhancing MMP-2 generation in the synovial space. The blockade of platelet penetration and/or activation in SF may represent a new therapeutic target in RA.

PB 1373 | Procoagulant Extracellular Vesicles Impair Trophoblast Function by a Thrombo-inflammatory Pathway

S. Kohli, M.M. Al-Dabet, F. Lochmann, P. Marmeyer, S. Ranjan, K. Shahzad, B. Isermann

Otto-von-Guericke University Magdeburg, Institute of Clinical Chemistry and Pathobiochemistry, Magdeburg, Germany

Background: Procoagulant extracellular vesicles (EVs) and platelet activation have been associated with pregnancy complications. We have recently identified a thrombo-inflammatory pathway inducing a pre-eclampsia (PE) like phenotype. EVs induce platelet mediated placental inflammasome activation. Whether this thrombo-inflammatory pathway alters trophoblast differentiation and function remains unknown. **Aims:** To identify whether the EV induced thrombo-inflammatory pathway modulates trophoblast proliferation, differentiation, and invasion. **Methods:** We injected C57BL/6 mice with endothelial or platelet-derived EVs to study the role of *EVs in vivo*. We exposed human and mouse trophoblast cells to EVs and platelets to study their role *in vitro*. Trophoblast proliferation was studied using Ki-67 immunostaining and BrdU incorporation assays. RT-PCR for trophoblast differentiation marker genes (PL-II, Tpbpa, Gcm1) was done to study trophoblast differentiation. Matrigel based tube formation assays were used to assess trophoblast invasion. **Results:** Injection of EVs into pregnant mice results in platelet activation and accumulation of activated platelets in the placenta. EV treatment impaired trophoblast differentiation and proliferation both *in vitro* and *in vivo*. These effects were platelet dependent as platelet depletion and genetic (NFE2-/-, Gαa-/-) or pharmaceutical (Apyrase) platelet inhibition abolished these effects. EV treatment resulted in impaired trophoblast tube formation indicating impaired trophoblast invasion. Furthermore, EVs induced inflammasome activation in trophoblast cells, and NLRP3 or caspase-1 deficiency or IL-1 receptor antagonist (Anakinra) abolished these effects of EVs.

Conclusions: These results demonstrate that EV-mediated platelet activation impairs trophoblast function by reducing trophoblast proliferation, differentiation and invasion through activation of the inflammasome. These results support the pathophysiological relevance of enhanced maternal platelet activation at the feto-maternal interface.

PB 1374 | Procoagulant Platelets as a Biomarker in Suspected Sepsis - A Pilot Study

L. Pasalic[1,2,3], A. Shetty[4,5], E. Lau[3,6], S. Sparenberg[7,8,9], V. Chen[10,11,12], J. Iredell[4,5]

[1]ICPMR, Westmead Hospital, Haematology, Sydney, Australia, [2]Westmead Hospital, Haematology, Sydney, Australia, [3]Sydney Centres for Thrombosis and Haemostasis, Westmead, Australia, [4]Westmead Hospital, Emergency Medicine, Sydney, Australia, [5]Westmead Millennium Institute, NHMRC Centre for Research Excellence in Critical Infection, Sydney, Australia, [6]ICPMR, Westmead Hospital, Haematology, Westmead, Australia, [7]University of Sydney, Westmead Clinical School, Sydney, Australia, [8]Westmead Hospital, Emergency Medicine, Westmead, Australia, [9]Rijksuniversiteit, Groningen, The Netherlands, [10]Concord Hospital, Haematology, Sydney, Australia, [11]ANZAC Research Institute, Platelet and Thrombosis Research Laboratory, Sydney, Australia, [12]University of Sydney, Sydney, Australia

Background: Sepsis is associated with significant morbidity and mortality. Platelets play a pivotal role in sepsis pathogenesis; however, the procoagulant platelet (PP) subset has not been extensively evaluated.

TABLE 1 Patient demographics

Number of patients, n	12
Age, median (range)	64.5 (46.5-78.0)
Gender (male), n (%)	6 (50)
Sequential Organ Failure Assessment (SOFA), median (range)	1.5 (0.5-3.0)
Sepsis (SOFA>2.0), % (95% CI)	50 (25.4-74.6)
Mortality in ED Sepsis (MEDS), median (range)	7 (2.5-11.5)
Charlson Comorbidity Score (CCS), median (range)	3.5 (2.0-5.0)
Platelet count x 10^9/L, median (range)	245 (204-316)
Hospital length of stay (LOS), days, median (range)	6 (1-12)
Death/intensive care unit (ICU) admission, % (95% CI)	41.7 (19.3-68.1)

TABLE 2 Correlation coefficients (CC). * denotes significant correlation

Variables	MEDS	CCS	Platelet Count	PP - Thrombin (0.5 U/mL)	PP - Thrombin (0.5 U/mL) + Collagen (10 µg/mL)	PP - Thrombin (2 U/mL)	PP - Thrombin (2 U/mL) + Collagen (10 µg/mL)
SOFA, CC (p-value)	-	-	-0.02 (0.94)	-0.08 (0.81)	0.57* (<0.05)	0.52 (0.08)	0.59* (0.04)
MEDS, CC (p-value)	-	-	0.45 (0.14)	0.53 (0.08)	0.58* (<0.05)	0.43 (0.16)	0.57* (<0.05)
Hospital LOS, CC (p-value)	0.7* (0.01)	0.5 (0.09)	-0.06 (0.85)	0.33 (0.3)	0.44 (0.15)	0.37 (0.24)	0.69* (0.01)
Death/ICU admission, CC (p-value)	0.38 (0.23)	0.43 (0.17)	0.05 (0.89)	0.15 (0.64)	0.42 (0.18)	0.58* (<0.05)	0.5 (0.1)
Platelet count, CC (p-value)	-	-	-	0.21 (0.52)	0.04 (0.9)	0.07 (0.84)	0.04 (0.9)

Aims: To explore the utility of PP subset as a biomarker in suspected sepsis.

Methods: We adapted a flow cytometry assay based on novel cell death agent, GSAO (PMID 26474813), to measure PP formation ex vivo in whole blood. Blood from patients presenting to Emergency Dept (ED) with suspected sepsis (inclusion criteria per PMID 27073105) was incubated with low (0.5 U/mL) or high (2 U/mL) dose thrombin ± collagen (10 μg/mL) and assayed by FACS. PP subset was defined as GSAO+/CD62P+ and expressed as % all platelets. Outcome measures included severity scores (SOFA, MEDS, CCS), hospital LOS, and a composite of death/ICU admission. Correlation between PP subset and outcomes was examined by Kendal's Tau method and multiple regression analyses.

Results: Demographics and outcome measures for 12 evaluable patients are summarized in Table 1. Correlation coefficients (CC) for PP against outcomes are summarized in Table 2. Thrombin plus collagen-induced PP subsets showed moderate correlation with sepsis severity scores. MEDS and high-dose thrombin plus collagen response were equally correlated with hospital LOS; however, only the association with MEDS remained significant in multiple regression model (p=0.01). In contrast, high-dose thrombin PP response was superior to MEDS and CCS with respect to death/ICU admission in logistic regression analysis (OR 1.22, p=0.03) with a high area under ROC of 0.86 (95% CI 0.54-0.99, p=0.03).

Conclusions: PP subset in whole blood showed moderate association with sepsis severity scores and LOS in an ED cohort of patients with suspected sepsis. The thrombin-induced PP subset was superior to the more complex MEDS with respect to death/ICU admission outcome. These findings support further evaluation of PP subset as a biomarker and may lead to development of improved sepsis severity scores.

PB 1375 | Contraction of Blood Clots is Promoted by Tissue Factor-expressing Activated Monocytes

A. Peshkova[1], L.M. Giang[1], V. Tutwiler[2,3], I. Andrianova[1], J. Weisel[2], R. Litvinov[2]

[1]Kazan Federal University, Kazan, Russian Federation, [2]University of Pennsylvania Perelman School of Medicine, Philadelphia, United States, [3]Drexel University, Philaelphia, United States

Background: Platelet-driven reduction in blood clot volume (clot contraction or retraction) has been implicated to play a role in hemostasis and thrombosis. Although these processes are often linked with inflammation, the role of inflammatory cells in contraction of blood clots and thrombi has not been investigated.

Aims: The aim of this work was to study the influence of activated monocytes on clot contraction.

Methods: Clotting of whole citrated blood and clot contraction were initiated *in vitro* with the addition of 2 mM $CaCl_2$ and 1 U/ml human thrombin. Quantitative optical tracking was used to follow volume changes in blood clots with time. Monocytes were isolated from blood and activated with phorbol-12-myristate-13-acetate (PMA) to induce tissue factor (TF) expression. Untreated or PMA-treated monocytes were added back into citrated whole blood. To inhibit TF expression by blocking of signaling pathways, isolated monocytes were incubated with PPARα prior to addition of PMA, whereas anti-TF IgG was added following activation of cells with PMA to block the procoagulant activity of TF. TF expression was assessed using flow cytometry.

Results: When a physiological number of isolated human monocytes pre-activated with PMA were added back into whole blood, the extent and rate of clot contraction were increased compared to addition of non-activated cells. Inhibition of TF expression or its inactivation on PMA-treated monocytes reduced the extent and rate of clot contraction back to control levels with non-activated monocytes. The addition of TF to whole blood, which was used to mimic the TF expression on PMA-activated monocytes, caused a dose-dependent increase in the extent and rate of clot contraction; this effect was abrogated in the presence of anti-TF antibodies.

Conclusions: These data suggest that the activated inflammatory cells through expression of tissue factor can directly affect hemostasis and thrombosis by modulating the size of intra- and extravascular clots and thrombi.

PB 1376 | Different Cytokine and Chemokine Patterns in Pediatric Patients with Acute and Chronic Immune Thrombocytopenia (ITP) Compared with Healthy Children

N. Gölz[1], J.M. Eekels[1], M.L. Rand[2], M. Schmugge[1], O. Speer[1]

[1]Children's Hospital Zürich, Haematology, Zürich, Switzerland, [2]Hospital for Sick Children, University of Toronto, Toronto, Canada

Background: Primary ITP is an autoimmune disease, mainly caused by autoantibodies against platelet surface receptors, leading to platelet clearance by macrophages. Some studies showed that also autoreactive B cells and $CD4^+$ T-helper (Th) cells, and specifically their cytokines, are associated with ITP. Cytokines and chemokines are known to be important players in the immune response.

Aims: To study the interplay between the immune system and the reduction of platelet count in ITP by screening the different cytokine/chemokine pattern in ITP patients vs controls.

Methods: Informed consent was obtained from patients and controls, and the study was approved by the Hospital Ethics Board. To measure plasma concentrations in chronic and acute ITP patient groups vs healthy controls, we used Luminex technology and analyzed 42 cytokines/chemokines in total.

Results: Significantly increased levels of TNF-α ($p< 0.05$), as well as Eotaxin ($p< 0.05$), IP-10 ($p< 0.05$), MCP-1 ($p< 0.05$) were identified in acute ITP patients compared to chronic ITP patients. The cytokines MDC ($p< 0.05$) and TNF-α ($p< 0.05$) were significantly increased in acute ITP patients as compared to healthy children. There were no significant differences between chronic ITP and healthy children.

Conclusions: Increased plasma levels of the cytokines and chemokines TNF-α, Eotaxin, IP-10, MCP-1 and MDC were observed in ITP patients at initial presentation, suggesting that these cytokines contribute to the pathogenesis of the disease. It is well known these cytokines, TNF- α, IP-10, MCP-1, Eotaxin, are key players in mediating acute inflammatory response by activation of neutrophils and monocytes, at sites of inflammation. Higher plasma levels in acute ITP patients are signs for an acute inflammatory response, consistent with the current model of ITP, in which activated macrophages induce B and T cells to produce anti-platelet autoantibodies.

PB 1377 | Therapeutics of Multiple Ssclerosis, Eexcept of Gglatiramer Acetate, Are Unlikely to Alter Platelet Functional Activity

L. Schüngel[1,2], S. Eichler[2], S.G. Meuth[2], B.E. Kehrel[1], K. Göbel[2]

[1]*University Hospital Muenster, Department of Anaesthesiology; Exp. and Clin. Haemostasis, Muenster, Germany,* [2]*University Hospital Muenster, Department of Neurology, Muenster, Germany*

Background: Multiple sclerosis (MS) is an inflammatory autoimmune disease of the central nervous system (CNS). To date MS is remediless but there are numerous therapeutics that help to improve clinical outcome and health-related quality of life. MS patients often show platelet abnormalities like thrombocytopenia along with well-known side effects of subcutaneous applied drugs (e.g. thrombosis and skin lesions) which might indicate a modulating effect of MS therapeutics on platelet functional activity. Starossom *et. al.* showed altered thrombin induced platelet activity after treatment with glatiramer acetate (GA) but not with interferon-beta.

Aims: To elucidate the underlying effects of MS therapeutics we studied the impact of different compounds on ADP and collagen stimulated platelet functional activity.

Methods: The MS therapeutics humanized antibodies alemtuzumab, natalizumab and daclizumab, two interferon beta-1a compunds, glatiramer acetate, and teriflunomide were used. The functional activity of platelets from healthy donors pretreated *in vitro* with MS therapeutics was analyzed by flow cytometry. Additionally the endogenous thrombin potential (eTP) and the lag-time of thrombin formation in plasma prepared from blood preincubated with MS drugs were measured.

Results: Platelets pretreated with GA showed diminished response to stimulation with ADP and collagen. In addition the eTP was reduced in comparison to controls. The lag-time of thrombin formation was increased in GA treated plasma. Responsiveness of platelets pretreated with the other analyzed drugs was normal compared to controls. In addition, eTP and lag-time were unaltered.

Conclusions: The functional activity of platelets was altered by GA but not with interferon-beta or other studied MS therapeutics. These findings indicate that MS compounds except of GA are unlikely to cause differences in platelet functional activity in MS.

PB 1378 | Anticoagulant and Anti-inflammatory Properties of the Novel Antimicrobial Peptide Centrocin 1 from Green Sea Urchin

E. Andreassen[1], B. Østerud[2], K.-E. Eilertsen[3]

[1]*UiT - The Arctic University of Norway, Department of Medical Biology, Tromsø, Norway,* [2]*K.G. Jebsen -Thrombosis Research and Expertise Center (TREC), UiT - The Arctic University of Norway, Department of Medical Biology, Tromsø, Norway,* [3]*Norwegian College of Fishery Science, UiT - The Arctic University of Norway, Tromsø, Norway*

Background: Antimicrobial peptides (AMPs) play a pivotal role in the immune system. In addition to their role as bactericidal agents, AMPs are important contributors to the inflammatory response. In the present study we have explored the effect of Centrocin 1, an AMP peptide from the green sea urchin *Strongylocentrotus droebachiensis*, on the expression of LPS-induced tissue factor (TF) and cytokines in monocytes as well as on platelet activation in whole blood.

Aims: To study the biological functions of Centrocin 1 using an ex-vivo whole blood model stimulated with LPS.

Methods: Blood was collected in Fragmin (10 U/ml). Aliquots were immediately stimulated with LPS (5 ng/ml) for 2 hrs at 37 °C with constant agitation at 37 °C in the presence or absence of Centrocin 1. After the incubation period, reactions were terminated by adding EDTA to a final concentration of 5 nM. TF activity was measured in isolated frozen and thawed mononuclear cells, and plasma samples were studied both at the transcriptional and translational level.

Results: Centrocin 1, at concentrations above 2 ug/ml, reduced LPS-induced TF activity of monocytes in whole blood in a dose -dependent manner (max 35 %, $p < 0.05$) and TF mRNA (max 30%, n.s.). Similarly, LPS-induced TNFα secreted to plasma was reduced at peptide concentrations above 0.05 ug/ml (max 34%, $p < 0.05$) at the same time as TNFα mRNA was reduced by peptide concentrations above 2 ug/ml (max 34%, $p < 0.05$).

A combination of flow cytometry and cell counting analysis of LPS-stimulated blood, incubated with and without Centrocin 1, revealed an increase in the number of free platelets compared to the control. However, no aggregates of monocytes and platelets were found to be markedly affected by Centrocin 1.

Conclusions: Centrocin 1 has significant anti-inflammatory as well as anti-coagulant properties. This is demonstrated in an ex-vivo whole blood model system, showing a dose-dependent inhibition of both selected anti-inflammatory markers as well as LPS-induced TF in monocytes.

PB 1379 | Deficiency of Sirtuin 3 Elevates Mitochondrial ROS in Neutrophils and Platelets but Does not Exacerbate NETosis or Venous Thrombosis

H. Hayashi[1,2], D. Cherpokova[1,2], K. Martinod[1,2], T. Witsch[1,2], S.L. Wong[1,2], M. Gallant[1], S.M. Cifuni[1], L.P. Guarente[3], D.D. Wagner[1,2]

[1]Boston Children's Hospital, Program in Cellular and Molecular Medicine, Boston, United States, [2]Harvard Medical School, Pediatrics, Boston, United States, [3]Massachusetts Institute of Technology, Paul F. Glenn Center for the Science of Aging, Cambridge, United States

Background: Inflammation is a common denominator in chronic diseases of aging. Yet, how inflammation fuels these diseases remains unknown. Neutrophil extracellular traps (NETs), decondensed chromatin released by neutrophils, have been shown to induce tissue injury and thrombosis.

Aims: To uncover the link between thrombosis, whose occurrence increases with aging, and age-related alterations in neutrophil and platelet function, it is necessary to investigate the role of aging-related genes such as Sirtuin 3 (Sirt3).

Methods: Expression of Sirt3 in neutrophils and platelets was shown by western blotting. Intracellular ROS levels were evaluated by flow cytometry with or without stimulation in the presence of ROS indicators. NET formation was analyzed after stimulation of neutrophils with PMA or ionomycin. Platelet aggregation induced by collagen, ADP and thrombin was analyzed by aggregometry. Venous thrombosis was evaluated by inferior vena cava stenosis for 3 hours.

Results: Both mouse platelets and neutrophils express Sirt3. More mitochondrial ROS were generated in platelets and neutrophils of Sirt3-/- mice compared to WT, when stimulated with a low concentration of PMA and a high concentration of thrombin, respectively. There were no differences in NETosis, with or without stimulation. Platelet aggregation was mildly augmented in Sirt3-/- mice compared to WT mice, when stimulated with a low concentration of collagen. No differences were observed in venous thrombus formation after inferior vena cava stenosis between WT and Sirt3-/- mice. However, we observed a significantly elevated neutrophil count and reduced platelet count in Sirt3-/- mice during thrombosis.

Conclusions: We propose that Sirt3 does not considerably impact NET formation, platelet function or venous thrombosis in healthy young mice. However, Sirt3 modulates the host response to thrombosis.

PB 1380 | Neutrophil Extracellular Traps (NETs) in Septic and Burn Patients

T. Kaufman[1], D. Magosevich[2], C. Moreno[3], A. Guzman[4], P. D´Atri[1], A. Carestia[1], F. Palizas[3], C. Fondevila[3], M. Schattner[1]

[1]Instituto de Medicina Experimental - CONICET - Academia Nacional de Medicina, Ciudad Autonoma de Buenos Aires, Argentina, [2]Sanatorio Sagrado Corazon, Ciudad Autonoma de Buenos Aires, Argentina, [3]Clinica Bazterrica, Ciudad Autonoma de Buenos Aires, Argentina, [4]Hospital de Quemados, Ciudad Autonoma de Buenos Aires, Argentina

Background: NET formation (NETosis) is a mechanism of host defense against microbes associated with tissue damage. Besides pathogens, NETs are triggered by mediators of sterile inflammation and activated platelets.

Aims: We determined the presence of NETs in septic and burn patients and correlated them with organ damage, patient evolution, platelet activation and pro-inflammatory cytokines.

Methods: 25 septic and 23 burn patients were studied at 1 and 4 days post admission (dpa) to the intensive care unit and 30 healthy donors as control. Plasmatic nucleosomes and Human Neutrophil Elastase (HNE)-DNA complexes were measured as indirect and direct NETosis indicators, respectively (ELISA). Ex vivo NETosis was studied by DNA release (fluorometry); platelet P-selectin and toll like receptor 4 (TLR4) by cytometry and IL6 and TNFα by ELISA.

Results: Plasmatic nucleosomes and HNE-DNA complexes were elevated in septic and burn patients at 1 dpa remaining high at 4 dpa and a positive correlation between them was found in septic but not in burn patients. Nucleosomes from septics correlated with SOFA score

TABLE 1 Results table

	Circulating NET indicators		Ex vivo DNA release (μg/ml)			Platelets		Cytokines	
	Nucleosomes (μg/ml)	HNE-DNA complexes (OD)	Neutrophils	Neutrophils + platelets + LPS	Neutrophils + TNFα	P-selectin expression (MFI)	TLR4 expression (MFI)	TNFα (pg/ml)	IL6 (pg/ml)
Control	0.01±(0.00; 0.11)	0.01±(0.00; 0.01)	0.22±(0.11; 0.29)	0.36±(0.24; 0.71)†	0.52±(0.33; 0.64)†	4±(3;5)	5±(4;5)	18±(1;51)	0±(0;1)
Septic 1 dpa	0.19±(0.00; 0.38)*	0.02±(0.00; 0.08)*	0.46±(0.24; 0.80)*	0.39±(0.23; 0.79)	0.51±(0.24; 1.3)	5±(4;8)*	7±(4;13)*	109±(0;291)*	291±(61;447)*

Burn 1 dpa	0.10±(0.04; 0.32)*	0.02±(0.01; 0.12)*	0.27±(0.16; 0.65)	0.24±(0.16; 0.53)	0.31±(0.22; 0.48)	5±(4;7)*	4±(4;5)	90±(24;150)*	58±(15;156)*
Burn 4 dpa	0.17±(0.06; 0.35)	0.01±(0.00; 0.01)	0.29±(0.18; 0.66)	0.21±(0.15; 0.56)	0.15±(0.10; 0.35)	5±(4;8)	8±(5;14)#	89±(21;172)	46±(24;327)

Results are expressed as median±(IQR). *p<0,05 vs. Control, #p<0,05 vs. Patients 1dpa, †p<0.05 vs. Unstimulated neutrophils (Kruskal-Wallis). OD: optical density, MFI: mean fluorescence intensity.

Neutrophils (5X10e5/ml) were incubated alone, with LPS-stimulated platelets or TNFα (20ng/ml) for 1 or 3 hs, respectively in a humidified incubator at 37°C with CO2 (5%). DNA in the supernatant was quantified by fluorometry using SYBR Gold. Patients 4dpa were compared with 1dpa.

at 1 dpa (p< 0.05) and were significantly associated with mortality within 30 dpa (p< 0.05, logistic reg.).

Spontaneous DNA release was elevated in neutrophils from septics and while their stimulation with platelets+LPS or TNFα triggered DNA release in the control group, neutrophils from septic or burn did not respond.

While P-selectin exposure was increased in both patients groups through the study, higher platelet TLR4 expression was found in septics at 1 dpa.

TNFα levels were elevated in septic and burn patients. IL6 levels were high in both groups at 1dpa and decreased in septics by 4dpa. Neither platelet activation markers nor cytokine levels correlated with nucleosomes or HNE-DNA.

Conclusions: Nucleosomes could be an organ damage indicator and predictor of mortality in septic but not in burn patients. Platelet activation and pro-inflammatory cytokines appear not be key mediators of NETosis in these groups of patients.

PB 1382 | Platelets Release Pathogenic Serotonin in Response to Immune Complexes

N. Cloutier[1], I. Allaeys[1], G. Marcoux[1], B. Mailhot[1], T. Levesque[1], Y. Becker[1], M. Rondina[2], S. Mckenzie[3], F. Cote[4], B. Nieswandt[5], W. Khan[6], F. Matthew[7], P. Newman[8], S. Lacroix[1], P. Fortin[1], E. Boilard[1]

[1]Université Laval, Centre de Recherche du CHU de Québec, Québec, Canada, [2]University of Utah, Salk Lake City, United States, [3]Thomas Jefferson University, Cardeza Foundation for Hematological Research, Philadelphia, United States, [4]Université Paris Descartes, Institut Imagine, INSERM U 1163 CNRS ERL 8254, Paris, France, [5]University Hospital and Rudolf Virchow Center, Department of Experimental Biomedicine, Wuerzburg, Germany, [6]McMaster University, Department of Pathology & Molecular Medicine, Hamilton, Canada, [7]Cancer and Blood Disease Institute, Division of Experimental Hematology and Cancer Biology, Cincinnati, United States, [8]Blood Research Institute, BloodCenter of Wisconsin, Wisconsin, United States

Background: There is a growing appreciation for the contribution of platelets to immunity; however, our current knowledge mostly relies on platelet functions associated with vascular injury and the prevention of bleeding.

Aims: While circulating immune complexes (ICs) contribute to both chronic and acute inflammation in a variety of clinical conditions, their impact on platelet responses is unclear.

Methods: We scrutinized platelet responses to systemic ICs in the absence of tissue and endothelial wall injury in mice. We used heat-aggregated IgG as surrogate to ICs, and injected LPS in LPS-immunized mice as an active model of IC-mediated response. Response to ICs was assessed by examining the mouse phenotype, and by intravital investigations of the vasculature using two-photon microscopy. To decipher the mechanism underlying platelet response in vivo, we included candidate transgenic mice, depleting antibodies, and pharmacological approaches to our study.

Results: Injection of ICs in mice resulted in systemic shock, characterized by temperature loss, severe lethargy, and blood vessel vasodilatation. Systemic shock by circulatory ICs in mice critically required platelet activation through a mechanism implicating expression of FcγRIIA by platelets. While diverse components from both alpha- and dense granules were released on IC activation, ICs-driven shock was dominantly dependent on release of serotonin from platelet dense granules secondary to platelet outside-in signaling by αIIbβ3 and its ligand fibrinogen. Intriguingly, although thrombi were evident in lungs during shock, their contribution to shock was not significant.

Conclusions: Our observations demonstrate that platelets are instrumental in the inflammatory response implicating ICs. We propose that the key cellular and molecular players downstream of IC-mediated activation, revealed in this study, may be conserved during chronic and acute systemic inflammation, implicating ICs in conditions such as rheumatic diseases, septic shock and viremia.

PB 1383 | Influence of Intravenous Immunoglobulin and Methylprednisolone on Cytokines Secreted by T Lymphocyte in Children ITP

M. Jingyao, C. Zhenping, W. Runhui

Beijing Children's Hospital Capital Medical University, Hematology Oncology Center, Beijing, China

Background: About 20-30% ITP progress into chronic stage in children. Studies proved auto-antibodies against glycoproteins existed. However, not all the patients had positive results. Current studies paid more attention to T lymphocyte abnormalities, including TH1/TH2 imbalance. Studies shown that patients suffering from polarized Th1 or Th2 response and cytokine deregulation. Due to children ITP often have severe onset of thrombocytopenia, we prescribed IVIG at the first day of hospitalization to prevent hemorrhage, as well as MP. For this reason, T lymphocyte function evaluation might be interrupted by treatment. In this study, we explored the influence of IVIG and MP on cytokines in children ITP.

Aims: Our study was designed to explore the influence of IVIG and MP on cytokines secreted by T lymphocyte in children ITP.

Methods: We enrolled children ITP at the onset of their disease from our department between December 2011 and March 2013. We followed them until 12months, choosing the patients whose ultimate duration less than 3 months and no recurrence. Cytokines measurement by cytometric bead array included IL-2, IL-4, IL-6, IL-10, TNF, IFN and IL-17. We divided patients into 3 groups according to the treatment they received before testing cytokines level, then we compared T cell cytokines' level among these groups.

Results: We enrolled 38 boys and 24 girls, age range 2-178 months, median 33 months). We found IL-2 level decreased in both group treated with MP for 1 day (N=29, P=0.042) and group in which patients treated with IVIG for 1 day (N=18, P=0.048) compared with group without any treatment (N=15).

Conclusions: As for children ITP, although pathways of MP and IVIG in treating thrombocytopenia were different, they both could decrease IL-2 in children ITP ultimately. As a representative cytokine of TH1

cell, IL-2 has been demonstrated to be important in lymphocyte activation and mobilization. So we considered that MP and IVIG can reduce the T cell activation and production of auto-antibodies by decrease IL-2.

PB 2248 | Clopidogrel Does Not Protect Mice from Sepsis or Septic Shock

Y. Rabouel[1,2], S. Magnenat[1], F. Lefebvre[1], J. Boisramé-Helms[1,2], F. Meziani[2], B. Hechler[1], C. Gachet[1]

[1]*Université de Strasbourg, INSERM, EFS Grand Est, FMTS, BPPS UMR-S 949, Strasbourg, France,* [2]*Service de Réanimation Médicale, Nouvel Hôpital Civil, Hôpitaux Universitaires de Strasbourg, FMTS, Strasbourg, France*

Background: Thrombocytopenia frequently occurs in patients with sepsis and is associated with worsened outcome and thrombocytopenic mice have increased signs of sepsis as compared to controls. Data indicate that septic patients under aspirin may have a better outcome. However the multiple and contradictory roles of platelets during sepsis remain to be elucidated.

Aims: In the present study, we evaluated the effects of antiplatelet therapy with clopidogrel during sepsis in mice.

Methods: Septic shock or more moderate sepsis were induced by cecal ligation and puncture (CLP) with ligation of 100% of cecal length and double puncture (high grade form of CLP) or ligation of 50% of cecal length and simple puncture (mid-grade form of CLP), respectively. Clopidogrel (50mg/kg) or vehicle was administered *per os* the day before and 2h prior to surgery. Analyses were performed 20h later.

Results: In high grade CLP, clopidogrel- and vehicle-treated mice displayed a similar 30% decrease in mean arterial blood pressure (MAP) indicating systemic hypotension and organ failure characteristic of shock. Plasma concentrations of pro-inflammatory cytokines (TNFα, IL6) and myeloperoxidase (MPO) were similarly increased in clopidogrel- and vehicle-treated mice, indicating comparable increase in systemic inflammation. Thrombin-antithrombin (TAT) complexes reflecting thrombin generation and liver damage evaluated by aspartate aminotransferase (ASAT) levels in plasma were also similarly increased in both groups of mice. In mid-grade CLP, where MAP is not decreased, all parameters were similarly increased in both groups, although their levels were significantly lower than those reached in the high grade CLP.

Conclusions: Clopidogrel does not protect mice from sepsis or sepsis shock indicating that the $P2Y_{12}$ receptor does not contribute to the pathogenesis of sepsis and suggesting that anti-platelet therapy with $P2Y_{12}$ receptor antagonists may not be beneficial in patients with sepsis or septic shock.

PB 2249 | Dysregulation of NET Formation Following Thermal Injury and its Association with Multiple Organ Failure

R. Dinsdale[1,2], J. Hazeldine[1,3], K. Altarrah[1,2,4], P. Hampson[1,2], A. Devi[1,2], C. Wearn[1,2,4], A. Bamford[2,4], J. Bishop[3], J. Lord[1,2], N. Moiemen[2,4], P. Harrison[1,2]

[1]*University of Birmingham, Institute of Inflammation and Ageing, Birmingham, United Kingdom,* [2]*The Scar Free Foundation, The Scar Free Foundation Centre for Burns Research, Birmingham, United Kingdom,* [3]*NIHR Surgical Reconstruction and Microbiology Research Centre, University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom,* [4]*Queen Elizabeth Hospital Birmingham, University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom*

Background: Uncontrolled neutrophil extracellular trap (NET) formation is associated with thrombosis & multiple organ failure (MOF), which is the leading cause of delayed mortality following major trauma. DNAse activity, responsible for the breakdown of NETs, is regulated by the actin scavenging system, which consists of gelsolin (GSN) & vitamin D binding protein (VDBP).

Aims:

1. Determine if excessive NET formation is associated with MOF
2. Investigate the ability of neutrophils to produce NETs following thermal injury &
3. Investigate DNAse activity in post-burn serum samples.

Methods: 64 consecutive patients with thermal injuries (≥15% TBSA) were recruited into a prospective cohort study. Blood was taken from day of injury up to 12 months post-injury. Levels of plasma nuclear DNA (ncNDA) were quantified by PCR. DNAse activity was quantified as serum- induced NET degradation *in vitro*. Actin was measured in plasma by SDS-PAGE analysis. Levels of plasma VDBP & GSN were quantified by ELISA. 100 μg/ml GSN was incubated with actin spiked serum to restore DNase activity.

Results: ncDNA was elevated on day 1 & day 7 to month 2 in patients with MOF. Isolated neutrophils from patients generated significantly fewer NETs on day 3 & day 7 vs healthy controls. DNase activity was reduced from day 1-28 post-injury and significantly longer in patients with MOF. Actin was detectable on day 1 & during secondary complications. GSN & VDBP were significantly lower in septic patients, in turn predisposing them to the build-up of actin, low DNase activity & MOF. Incubation of actin spiked serum with GSN restored DNase activity.

Conclusions: Thermal injury induces actin release that inhibits DNase activity predisposing patients to uncontrolled NETosis. Elevated levels of NET markers can further the pathogenesis of MOF & are a potential therapeutic target to reduce delayed mortality. Restoring the actin scavenging system by administration of GSN or VDBP has the potential to restore DNase activity & improve patient outcomes.

PB 2250 | Hageman Factor Regulates Inflammatory Responses in Human Lungs

L. Wujak[1], R. Hess[1], C. Hesse[2], K. Sewald[2], S. de Maat[3], C. Maas[3], F. Bonella[4], K. Preissner[1], P. Markart[1], M. Wygrecka[1]

[1]*Justus Liebig University Giessen, Giessen, Germany,* [2]*Fraunhofer Institute for Toxicology and Experimental Medicine ITEM, Hannover, Germany,* [3]*University Medical Center Utrecht, Utrecht, The Netherlands,* [4]*University of Duisburg-Essen, Essen, Germany*

Background: Increased procoagulant activity in the lung alveolar compartment and uncontrolled inflammation are hallmarks of acute respiratory distress syndrome (ARDS).

Aims: To investigate whether the contact system of coagulation is activated and may regulate inflammatory responses in ARDS lungs.

Methods: Components of the contact system in bronchoalveolar lavage fluids (BALF) from 54 ARDS patients and 43 controls were characterized by ELISA and western blotting, and their impact on cytokine/chemokine expression in human precision cut lung slices (PCLS) was assessed by a PCR array and ELISA.

Results: Activation of the contact system, associated with high levels of Hageman factor (FXII), plasma kallikrein and bradykinin, in ARDS lungs occurred rapidly after the onset of the disease and virtually normalized within one week from the time of diagnosis. FXII levels in BALF were higher in ARDS non-survivors than survivors and were positively correlated with tumor necrosis factor (TNF)-α concentration. FXII induced the production and release of interleukin (IL)-8, IL-1β, IL-6, leukemia inhibitory factor (LIF), C-X-C motif chemokine ligand (CXCL) 5 and TNF-α in human PCLS in a kallikrein-kinin-independent manner.

Conclusions: Accumulation of FXII in ARDS lungs may contribute to the release of pro-inflammatory mediators and is associated with clinical outcome. FXII inhibition may thus offer a novel and promising therapeutic approach to antagonize overwhelming inflammatory responses in ARDS lungs without interfering with vital hemostasis.

PB 2251 | Differential Impact of Triggers on the Risk of Incident Venous Thromboembolism in Hospitalized Subjects with and without Acute Infection - Results from a Population-based Case-crossover Study

G. Grimnes[1,2], T. Isaksen[1,2], V. Tichelaar[1,3], S.K. Braekkan[1,2], J.B. Hansen[1,2]

[1]UiT - The Arctic University of Norway, K. G. Jebsen Thrombosis Research and Expertice Center, Tromsø, Norway, [2]University Hospital of North Norway, Division of Internal Medicine, Tromsø, Norway, [3]University of Amsterdam, Academic Medical Center, Department of Vascular Medicine, Amsterdam, The Netherlands

Background: Hospitalization with acute infections often occurs concomitant with short-term triggers of venous thromboembolism (VTE) such as immobilization and surgery. It is not known to what extent these triggers affect the risk of VTE in patients without and with acute infection.

Aims: To investigate the differential impact of VTE-triggers in hospitalized patients without and with acute infection.

Methods: We conducted a case-crossover study of VTE-patients (n=707) recruited from the general population (The Tromsø study). All hospitalizations and triggers were registered within each subject during the last 90 days before VTE diagnosis and in four preceding 90-day comparison periods. A 90-day washout period between the comparison- and VTE-periods was used to avoid potential carry-over effects. Conditional logistic regression was used to obtain odds ratios (ORs) for each trigger in subjects without and with acute infection in the VTE-period. Each patient served as their own control, thus allowing for within-subject adjustment for fixed covariates.

Results: There were 326 (46%) patients diagnosed with acute infection during the VTE-period. When comparing the VTE-period with comparison periods, traditional triggers had a greater impact on the VTE risk in patients without compared to those with acute infection. Triggers such as immobilization (OR 100.0, 95% CI 44.3-226.0 vs. OR 2.9, 95% CI 1.0-8.2), major surgery (OR 9.2, 95% CI 4.8-17.6 vs. OR 0.4, 95% CI 0.1-0.9), central venous catheters (OR 19.9, 95% CI 2.4-163.5 vs. OR 1.4, 95% CI 0.4-4.5), and transfusions (OR 27.3 95% CI 6.2-119.5 vs. OR 2.2 95% CI 0.7-6.5) had a greater impact in those patients without than in those with acute infections, respectively.

Conclusions: We found that established triggers for VTE had a stronger impact on the VTE-risk in patients without than in those with acute infection in the VTE-period. Our findings suggest that acute infections during hospitalization in itself are a strong risk factor for VTE that outweighs other trigger factors.

PB 2252 | Inhibition of the Major Endothelial Cell Integrin αVβ3, Both Pre- and Post-infection, Prevents Bacterial Binding in 2D Dynamic and 3D ex vivo Models of Sepsis

C. Garciarena[1], A. Wong[2], S. Peter[2], S. Kerrigan[1]

[1]Royal College of Surgeons in Ireland, Cardiovascular Infection Research Group, Irish Centre of Vascular Biology, Dublin, Ireland, [2]Johns Hopkins University, Department of Materials Science and Engineering, Institute for Nanobiotechnology, Baltimore, United States

Background: Sepsis is a life threatening-fast progressing disease characterised by vascular dysregulation caused by bacterial binding to endothelial cells (EC). *S. aureus* and *E. coli* are the most common causes of sepsis. Previously, we demonstrated that treating EC with an αVβ3 antagonist prior to bacterial infection prevented binding, suggesting this drug may have potential for pre-emptive treatment in patients with high risk of developing sepsis.

Aims: The aim of this study was to explore the effectiveness of an αVβ3 antagonist in preventing or displacing bacterial binding after infection using a 2D and 3D *ex vivo* model of sepsis.

Methods: EC were grown in microfluidic chambers. Fluorescently labelled *E. coli* and *S. aureus* were used to assess binding by real time epifluorescence microscopy in the presence and absence of the αVβ3 antagonist. Further experiments were carried out using 3D cylindrical microvessels (150μm diameter). Barrier permeability was assessed by TR-dextran extravasation.

Results: *S. aureus* and *E. coli* attached to the EC under flow within 15sec. Pretreatment of the EC with an αVβ3 antagonist significantly reduced this binding (94±4% and 77±4% vs control; respectively, $P < 0.05$). Furthermore, addition of *S. aureus* or *E. coli* to the EC for 30sec or 180sec prior to the addition of the αvβ3 antagonist still resulted in

a significant reduction in bacterial binding to the EC in flow chambers (90±3%, P< 0.05; *S. aureus and 87±6%, P< 0.05; E. coli*) and in the 3D vessel (80%, *S. aureus*). Similar inhibition post infection was obtained when whole blood was used (82±7%, P< 0.05). Remarkably, vascular permeability as a result of bacterial binding rose by 70±3% (P< 0.05) within 3min of infection.

Conclusions: Blocking endothelial αVβ3 effectively and promptly reduced bacterial binding to EC under flow, both pre and post infection. These results suggest that blocking the major integrin αVβ3 on EC presents potential as a new strategy for the treatment of established sepsis and as prophylaxis in patients at risk.

PB 2253 | RNA and Histones in Dead Cells Synergistically Provoke FSAP Activation in Serum

G. Marsman[1], I. Bulder[1], F. Stephan[1], B. Luken[1], S. Zeerleder[1,2]

[1]*Sanquin Research, Dept of Immunopathology, Amsterdam, The Netherlands, and Landsteiner Laboratory, Academic Medical Center, University of Amsterdam, Amsterdam, The Netherlands,* [2]*Academical Medical Center, Department of Hematology, Amsterdam, The Netherlands*

Background: The plasma serine protease Factor VII-activating protease (FSAP) has been implicated in thrombosis and vascular remodeling. Moreover, FSAP is crucially involved in the release of chromatin from dead cells. FSAP circulates in an inactive form and is activated upon contact with late apoptotic or necrotic cells. FSAP binds to purified negatively charged molecules, e.g. RNA and DNA, and positively charged molecules, e.g. histones, which have both been implicated in the auto-activation of FSAP albeit through different mechanisms.

Aims: To identify the component(s) from dead cells that mediate FSAP auto-activation in serum.

Methods: Binding of FSAP to late apoptotic Jurkat cells treated with RNase and DNase was studied using (confocal) microscopy and flow cytometry. Live Jurkat cells were subjected to subcellular fractionation and treated with DNase, RNase and proteinase K. FSAP activation in serum was determined by detecting FSAP- α2-antiplasmin complexes in ELISA.

Results: Digestion of RNA in late apoptotic cells markedly reduced the binding of FSAP to these cells, and concurrently the activation of FSAP induced by these cells was also reduced. In contrast, DNA digestion strongly enhanced both the binding and activation of FSAP. Upon cellular fractionation, the cytoplasmic fraction containing most RNA did not induce FSAP activation, whilst the nuclear fractions that predominantly contained histones did induce the activation of FSAP. In serum, the addition of histones induced FSAP activation, whilst activation did not occur upon addition of RNA. However, when RNA was combined with histones this markedly enhanced the activation of endogenous FSAP in serum.

Conclusions: Our results indicate that both RNA and histones are involved in the activation of FSAP by dead cells. RNA does not directly induce the auto-activation of FSAP, but may promote/facilitate auto-activation of FSAP induced by histones.

PB 2254 | Impact of Acute Infection during Hospitalization on the Risk of Incident Venous Thromboembolism - Results from a Population-based Case-crossover Study

G. Grimnes[1,2], T. Isaksen[1,2], V. Tichelaar[1,3], S.K. Braekkan[1,2], J.B. Hansen[1,2]

[1]*UiT - The Arctic University of Norway, K. G. Jebsen Thrombosis Research and Expertice Center, Tromsø, Norway,* [2]*University Hospital of North Norway, Division of Internal Medicine, Tromsø, Norway,* [3]*University of Amsterdam, Academic Medical Center, Department of Vascular Medicine, Amsterdam, The Netherlands*

Background: Acute infection is a well-established risk factor for venous thromboembolism (VTE), but little is known about the impact of different infectious foci on the risk of the separate VTE entities, deep vein thrombosis (DVT) and pulmonary embolism (PE).

Aims: To investigate the impact of hospitalization with acute infections, and the most common infectious foci (respiratory- (RTI) and urinary- (UTI) tract infections) on the risk of VTE.

Methods: We conducted a case-crossover study of VTE-patients (n=707, 299 PEs and 408 DVTs) recruited from the general population (The Tromsø study). All hospitalizations and triggers were registered within each subject during the last 90 days before the VTE diagnosis and in four preceding 90-day comparison periods. Acute infection was recorded when described in the medical notes, or if the patient received antibiotic treatment (except for prophylactic purposes). Conditional logistic regression was used to obtain odds ratios (ORs) for infection, RTI and UTI as triggers for VTE, DVT and PE. Each patient served as their own control, thus allowing for within-subject adjustment for fixed covariates such as age, anthropometric measures and chronic co-morbidities.

Results: Acute infection was registered in 326 of the VTE-periods and in 128 of the comparison periods. The OR for having infection in the VTE-period compared to preceding periods was 25.0 (95% CI 18.3-34.2), and after adjustment for cancer and surgery the OR was 19.1 (95% CI 13.7-26.5). The OR for having RTI in the VTE-period was 23.7 (95% CI 14.2-39.5) and the OR for having UTI in the VTE-period was 13.6 (95% CI 9.1-20.4). For DVT, the OR for infection was 20.1 (95% CI 13.8-31.3), for RTI 10.7 (95% CI 5.5-20.8) and for UTI 14.6 (95% CI 8.6-24.9). For PE, the OR for infection was 31.4 (95% CI 19.2-51.2), for RTI 54.6 (95% CI 22.1-135.4) and for UTI 12.3 (95% CI 6.6-22.8).

Conclusions: We found that acute infection is a strong trigger for VTE and that RTIs seem to be an especially important trigger for PE.

PB 2255 | C-reactive Protein and Risk of Venous Thromboembolism - Results from a Population-based Case-crossover Study

G. Grimnes[1,2], T. Isaksen[1,2], V. Tichelaar[1,3], S.K. Braekkan[1,2], J.B. Hansen[1,2]

[1]*K.G Jebsen Thrombosis Research and Expertice Center, Dep of Clinical Medicine, Tromsø, Norway,* [2]*University Hospital of North Norway, Division of Internal Medicine, Tromsø, Norway,* [3]*University of Amsterdam, Academic Medical Center, Department of Vascular Medicine, Amsterdam, The Netherlands*

Background: C-reactive protein (CRP) has not been shown to predict future venous thromboembolism (VTE) in prospective studies with long-term follow up. Inflammation is, however, a common feature in several conditions known to increase the risk of VTE, such as cancer and acute infection. The impact of CRP, as a downstream biomarker of pro-inflammatory triggers, on short-term risk of VTE is scarcely investigated.

Aims: To investigate the impact of CRP on the short-term risk of VTE.

Methods: We conducted a case-crossover study of VTE-patients (n=707) recruited from the general population (The Tromsø study). All hospitalizations and corresponding blood tests were registered during the last 90 days before the VTE diagnosis and in four preceding 90-day comparison periods. The highest measured CRP-value within each period was used in the analysis. Subjects admitted less than 3 days before date of VTE where excluded, to avoid reverse causation. Conditional logistic regression was used to obtain odds ratios (ORs) per 25, 50, 75 and 100 mg/L increase in CRP. Each patient served as their own control, thereby allowing for within-subject adjustment for fixed covariates.

Results: CRP was measured in 329 of the comparison periods (mean 57.1 mg/L), and in 286 of the VTE-periods (mean 122.6 mg/L). The OR increased with increasing CRP levels, and was 1.18, (95% CI 1.11-1.27) per 25mg/L, 1.40 (95% CI 1.22-1.60) per 50mg/L, 1.66 (95% CI 1.35-2.03) per 75 mg/L, and 1.96 (95% CI 1.50-2.57) per 100 mg/L increase in CRP, when comparing the VTE-period with all comparison periods. We also compared the CRP-levels in the VTE-period with each comparison-period separately, and there was no trend for change in OR according to time between the risk- and comparison periods.

Conclusions: CRP, as a biomarker of unspecified pro-inflammatory triggers, is associated with increased short-term risk of VTE. This may suggest that acute inflammation, regardless of cause, is an important trigger for VTE.

PB 2256 | DNA and Factor VII-activating Protease Protect against the Cytotoxicity of Histones

G. Marsman[1], H. von Richthofen[1], I. Bulder[1], F. Lupu[2], J.A. Hazelzet[3], B.M. Luken[1], S. Zeerleder[1,4]

[1]Sanquin Research, Department of Immunopathology, Amsterdam, The Netherlands, [2]Oklahoma Medical Research Foundation, Oklahoma, United States, [3]Erasmus Medical Center, Department of Public Health, Rotterdam, The Netherlands, [4]Academic Medical Center, Department of Hematology, Amsterdam, The Netherlands

Background: Circulating histones have been implicated as major mediators of inflammatory disease due to their strong cytotoxic effects. Histones form the core of nucleosomes, however it is unclear whether free histones and nucleosomes are equally cytotoxic. Nucleosomes are found in the circulation upon inflammation, however the presence of free histones has never been addressed. Notably, Factor VII-activating protease (FSAP) is activated in serum upon contact with histones and subsequently proteolyzes histones.

Aims: To determine the role of FSAP in the regulation of histone and/or nucleosome induced cytotoxicity.

Methods: Purified histones or nucleosomes were incubated with purified FSAP, or healthy donor, FSAP deficient, or FSAP depleted serum, added to HEK293 cells and LDH release was detected. Moreover, we added benzonase nuclease to nucleosomes to release histones, or added DNA to histones. Histone proteolysis was studied on blot using anti-H3 antibody. Nucleosomes were isolated from serum of *E. coli* challenged baboons and meningococcal disease patients using an immobilized anti-dsDNA antibody, whereafter remaining free histones were precipitated.

Results: FSAP protected against histone-induced cytotoxicity by cleaving free histones also in serum. Histones as part of nucleosome complexes were not cytotoxic, whilst DNA digestion of nucleosomes restored cytotoxicity. Incubation of nucleosomes with FSAP resulted in clipping of the N-terminal tail of histone H3. The specific isolation of either nucleosomes or free histones from serum of *E. coli* challenged baboons and patients with meningococcal sepsis, revealed that histones were present in the form of nucleosomes, whilst free histones were not detected. Notably, in both baboons and patients histone H3 in nucleosomes was clipped, and of similar size as observed with FSAP-treated nucleosomes *in vitro*.

Conclusions: Our results suggest that DNA and FSAP jointly limit histone cytotoxicity, and that free histones do not circulate in appreciable concentrations in sepsis.

PB 2257 | Nucleated Platelet Response to a Single Stranded RNA Viral Product through Pattern Recognition Receptors Revealed by RNA Sequencing

F. Ferdous, C. Saski, W. Bridges, M. Burns, K. Elliott, H. Dunn, T. Scott

Clemson University, Clemson, United States

Background: Thrombocytes express Toll-like receptors (TLRs) and respond to agonists of various origins. These cells are equivalent to enucleated platelets and can serve as a model for platelet response to bacterial or viral infections.

Aims: This study was performed to comprehend the role of thrombocytes stimulated with a TLR7/8 agonist (single stranded viral RNA analog) on gene expression.

Methods: Isolated chicken thrombocytes were treated with thymidine homopolymer phosphorothioate oligonucleotide (Poly(dT)). Highly sensitive RNA-sequencing technologies were used, and Panther derived gene ontology (GO-slim terms) was used for broad classification of biological processes, protein classes and biochemical pathways.

Results: Alignment of sequences with the *Gallus gallus* genome database revealed thrombocytes expressed 14,326 gene transcripts. After 1 hr stimulation with Poly(dT) 1,013 genes were up-regulated and 249 genes down-regulated with ≥ 1-fold change relative to unexposed

thrombocytes. Analysis of GO functional categories demonstrated that there were 13, 25 and 93 categories up-regulated for biological processes, protein classes and biochemical pathways, respectively; while 13, 22 and 53 categories that were respectively down-regulated for biological processes, protein classes and biochemical pathways. In addition to gene transcripts for TLR, nucleotide binding oligomerization domain-like receptor and retinoic acid-inducible gene 1-like receptor signaling pathways; gene transcripts for cytokines, chemokines, colony stimulating factors, and co-stimulatory markers were also detected.

Conclusions: Thrombocytes express many gene transcripts associated with anti-viral response through PRR signaling pathways. The information generated with this cellular model could be of enormous significance for both veterinary and human medical applications related to early platelet response during viral infections and rapid test diagnostics to intervene with onset of septicemia.

PB 2258 | MiR146a-5p Deficiency Exacerbates Neutrophil Extracellular Trap Formation

A.B. Arroyo Rodríguez[1], A.M. De los Reyes García[1], N. García Barberá[1], V. Roldán[1], R. Teruel Montoya[1], V. Vicente[2], R. González Conejero[1], C. Martínez[1]

[1]Servicio de Hematología y Oncología Médica, Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, Murcia, Spain, [2]Servicio de Hematología y Oncología Médica, Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, CB15/00055-CIBERER, Murcia, Spain

Background: Neutrophils extracellular traps (NETs) are released to prevent sepsis but they are also involved in several immune and inflammatory diseases. Indeed, NET perpetuation contributes to tissue damage and prothrombotic state although the underlying mechanism of NET formation is not fully understood. MiR146a-5p is an important brake of immune and inflammatory diseases through blocking TLR/NFkB pathway and it is involved in higher risk of cardiovascular events.

Aims: To evaluate the role of miR-146a-5p in NETs formation *in vivo* and *in vitro*.

Methods: For evaluating NET release *in vivo*, blood samples were collected after endotoxemic induction (LPS 0111/B4, 1mg/Kg, 24h) in wild-type (WT) (N=10) and miR-146$^{-/-}$ (N=10) mice. *In vitro* NET evaluation was done in bone marrow isolated neutrophils from WT (N=8) or miR146$^{-/-}$ (N=8) mice, after stimulation with PMA (20 nM, 2h). Cells were permeabilized and stained for citrullinated Histone 3 (citH3). In parallel, stimulated neutrophils were incubated with MNase to free NETs from neutrophils. Circulating or released DNA in the supernatants and blood plasma samples were quantified using SYTOX green assays. Neutrophil elastase activity (NE) in plasma was measured by ELISA. Soluble citH3 was further detected by western blot (WB) and quantified by densitometric analysis.

Results: After LPS treatment, miR-146$^{-/-}$ displayed higher levels of cfDNA (1606±310 vs 457±74 ng/mL, p< 0.001), NE (2458±57 vs 1525±61 ng/mL, p< 0.001), and citH3 (WB densitometric area: 1 *vs* 1.55, p< 0.05) than WT mice. Moreover, PMA-treated neutrophils from miR-146$^{-/-}$ mice showed higher cfDNA and NET levels (% ratio citH3 positive cells) than from WT littermates (3671±337 *vs.* 2841± 284 ng/mL, p< 0.05 and 5.7± 0.3 *vs.* 3.7± 0.4 %, p< 0.01, respectively).

Conclusions: miR-146a-5p modulates NETs formation and can contribute to increase the prothrombotic state. Unraveling the mechanisms involved in this regulation could help to control pathological NETs response.

ISCIII y FEDER (P14/00253), Fundación Séneca 19873/GERM/15

PB 2259 | Inflammation Augments NFκB Dependent Production of TF in Preadipocytes

T. Sovershaev[1], C. Ramberg[1], M. Wabitsch[2], L. Wilsgard[1], N. Latysheva[1], J.-B. Hansen[1,3]

[1]UiT The Arctic University of Norway, K.G. Jebsen TREC, Tromso, Norway, [2]University Medical Center Ulm, Division of Pediatric Endocrinology and Diabetes, Department of Pediatrics and Adolescent Medicine, Ulm, Germany, [3]University Hospital of North Norway, Division of Internal Medicine, Tromso, Norway

Background: Observational studies have shown a strong and consistent association between obesity and risk of venous thromboembolism. The underlying mechanism is unknown, but it is feasible to assume that low-grade chronic inflammation in obesity may promote a prothrombotic phenotype of the adipose tissue with systemic impact.

Aims: To investigate whether inflammation, induced by tumour necrosis factor (TNF), influences tissue factor (TF) production in preadipocytes.

Methods: The SGBS cells are human cells derived from a patient with Simpson-Golabi-Behmel syndrome. Those cells retain characteristics of human preadipocytes and have the ability to differentiate into adipocyte-like cells. SGBS were cultivated according to the recommendations by the manufacturer (DMEM/F12 supplemented with 10% FCS, panthotenat, biotin and penicillin / streptomycin). Cells were treated with TNF, and / or JSH-23. F3 gene expression was assessed by RT-PCR. TF antigen levels were assessed by IMUBIND TF ELISA. TF activity was measured using a validated FXa generation assay.

Results: SGBS preadipocytes constitutively expressed high levels of tissue factor under resting conditions. TNF stimulation led to a time-dependent increase in both TF mRNA and TF antigen levels which peaked after 24 hrs, implicating an autoregulatory mechanism of TF upregulation. The levels of TF mRNA were 2,6 higher than time matched vehicle controls(p< 0,001). The increased expression of TF mRNA was accompanied by a significant increase in TF antigen levels vs control (12,4 vs 7,1 ng TF/ mg protein, p< 0,01). Importantly, TF activity levels were also significantly elevated (46% increase vs vehicle, p< 0,01). The observed effects appear to be dependent on the activation of NFkB transcription factor, as application of an inhibitor of NFκB, JSH-23, completely reversed the actions of TNF on TF production in preadipocytes.

Conclusions: Inflammation can directly affect the thrombogenicity of adipose tissue by increasing the production of TF in human preadipocytes.

PB 2260 | Evaluation of the Impact of Hypofibrinolysis Induced by Tranexemic Acid in Murine Experimental Sepsis

Y. Alves Campos Nogueira[1], B. Wilfried Hounkpe[1], F. Loureiro Andrade Orsi[1], C. Emilio Levy[1], J.M. Annichinno Bizzacchi[1,2], E. Vinicius De Paula[1,2]

[1]*University of Campinas, Faculty of Medical Sciences, Campinas, Brazil,* [2]*University of Campinas, Hematology and Hemotherapy Center, Campinas, Brazil*

Background: Coagulation activation is an integral part of the immune response to infections, and is thought to contribute to innate immunity by both containing the spread of pathogen foci, and by generating antimicrobial peptides from cleaved coagulation proteins. Although PAI-1-induced hypofibrinolysis has been long recognized as a hallmark of sepsis, little is known about the role of the firbinolytic system in the pathogenesis of this condition. Of note, the cooption of fibrinolysys pathways as virulence factors of several pathogens suggests that fibrinolysis is a relevant element in the pathogenesis of sepsis.

Aims: Using the cecal ligation and puncture (CLP) model associated with the inhibitor of fibrinolysis, tranexamic acid (TnxAc), we investigated the impact of hypofibrinolysis on murine experimental sepsis.

Methods: C57Bl/6J mice were treated with tranexemic acid or vehicle from two days before CLP induction until the end of the study. Animals were evaluated for clinical and laboratory parameters of sepsis severity.

Results: TnxAc-induced hypofibrinolysis was confirmed by a prolongation of the euglobulin lysis time and an increase in TAT levels beyond those observed in sepsis alone. TnxAc 100mg/kg did not change 7-day survival or a clinical sepsis score, while a higher dose (600mg/kg) was associated with increased mortality. At 24h post-sepsis induction, no differences were observed in biochemical or histological parameters of sepsis severity in TnxAc-treated animals. TnxAc was associated with a lower pathogen burden in liver and blood, and lower levels of IL-6 and MCP-1. At 24h post-sepsis, histological and laboratory markers of disseminated intravascular coagulation were not changed by TnxAc treatment

Conclusions: TnxAc induced a hypofibrinolytic state in mice submitted to the CLP model, which was associated with a lower pathogen burden, but a similar clinical course in murine sepsis. At supra-pharmacologic dose, TnxAc an increased mortality in the CLP model.

PB 2261 | Elevated Levels of Endogenous Activated Protein C Predict Mortality in Septic Shock

J. Müller[1], B. Pötzsch[1], J. Oldenburg[1], D. Loßnitzer[2], T. Becher[2]

[1]*University of Bonn, Institute of Exp. Haematology and Transfusion Medicince, Bonn, Germany,* [2]*University Medical Center Mannheim, 1st Department of Medicine Cardiology, Mannheim, Germany*

Background: Activation of the coagulation cascade in septic shock is a common occurrence that may lead to life threatening events such as disseminated intravascular coagulation. Due to its anticoagulant and anti-apoptotic properties, activated protein C (APC) is believed to play a major role in the course of septic shock.

Aims: To assess the prognostic value of plasma APC measurements in patients with septic shock.

Methods: 48 consecutive patients presenting with septic shock were included in the study. Blood samples were drawn on admission (day 1) and on day 2, day 4 and day 7. Plasma APC levels were measured using an oligonucleotide (aptamer)-based enzyme-capture assay (OECA). Further analysis included the measurement of plasma levels of protein C, thrombin-antithrombin-complexes (TAT), prothrombin fragment 1.2 (F1.2), and D-Dimer by routine laboratory assays.

Results: APC levels were markedly elevated in 45 of the 48 (93.8%) patients of whom 19 (39.6%) died of septic shock. Non-survivors had significantly higher plasma APC levels on admittance (0.95 vs. 0.44 ng/ml, $p < 0.005$) and significantly higher individual peak APC levels (1.37 vs. 0.58 ng/ml, $p = 0.008$) measured during the course of sepsis. Also levels of TAT were higher on admission (19.4 vs. 10.1 ng/ml, $p = 0.01$) and when comparing individual peak levels (25.5 vs. 16.5 ng/ml, $p = 0.04$) during the course of sepsis in non-survivors to survivors. However, ROC curve analysis revealed the highest AUC (0.76) for APC levels on admission, consistent with a satisfactory discriminative diagnostic capacity. APC levels above a cutoff of 0.74 ng/ml during the course of sepsis were associated with increased mortality within 30 days (OR 7.8, 95% CI 2.8 - 22.0, $p < 0.001$).

Conclusions: Levels of APC are increased in patients with septic shock. Peak APC levels above a cutoff of 0.74 ng/ml measured during the course of sepsis were found to be associated with an increased 30-day mortality.

PB 2263 | In vitro Disruption of Endothelial Barrier Integrity by Serum from Patients with Septic Shock

M.M.L. Fiusa[1], L.N.G. Costa[1], G.R. de Souza[1], R.N. Angerami[1], M.A. Carvalho-Filho[1], D. Garcia-Weber[2], J. Millán[2], E.V. de Paula[1,3]

[1]*University of Campinas, Faculty of Medical Sciences, Campinas, Brazil,* [2]*Universidad Autónoma de Madrid, Centro de Biología Molecular Severo Ochoa, Consejo Superior de Investigaciones Cientificas, Madrid, Spain,* [3]*University of Campinas, Hematology and Hemotherapy Center, Campinas, Brazil*

Background: Endothelial barrier (EB) breakdown is a hallmark of sepsis, and pathways that participate in the regulation of EB integrity are emerging as promising targets in septic shock. However, little data is available about EB breakdown in human sepsis.

Aims: Here we investigated the effect of serum from patients with septic shock on EB function.

Methods: Serum was obtained from patients with septic shock (n=18) and healthy volunteers (n=11). EB function was assessed by electric

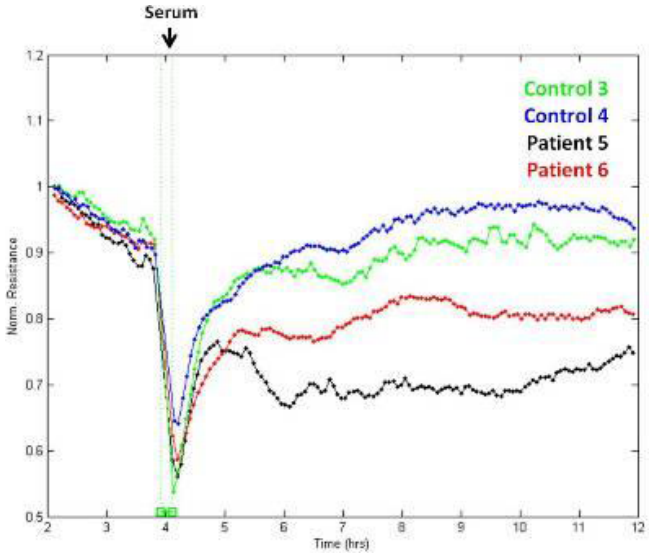

FIGURE 1 Representative figure shows the effect of serum from two patients and two healthy individuals in endothelial barrier resistance.

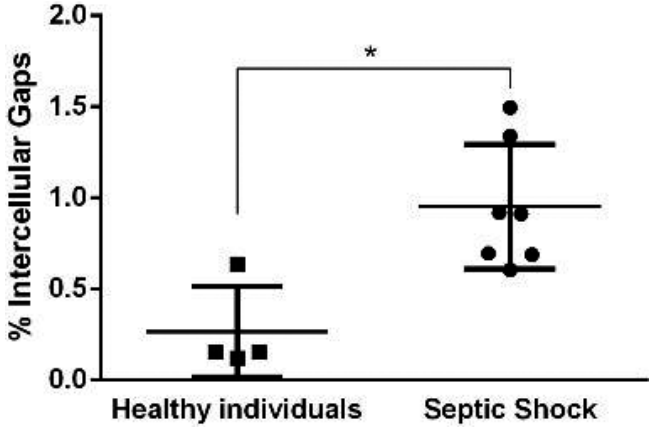

FIGURE 2 Extension of intercellular gaps was significantly higher in cells incubated with serum from septic shock patients (*P = 0.01)

cell-substrate impedance sensing, which measures the transendothelial electrical resistance (TEER) of endothelial cell monolayers, and by immunofluorescence-based studies of cell-cell junctions. Serum levels of VEGF-A and angiopoietin 2 (Ang-2) were also evaluated, to investigate the mechanisms of EB breakdown.

Results: Serum from patients with septic shock caused a stronger decrease in TEER than serum from healthy volunteers after 4h (21.52 ± 12.71 vs. 10.93 ± 10.69; P= 0.03) and 6h (22.08 ± 13.24 vs. 12.32 ± 9.86; P= 0.04) of incubation with HUVEC monolayers (Fig 1).

These functional alterations were associated with an increase in the extension of intercellular gaps (0.265 ± 0.247% vs. 0.950 ± 0.342%; P=0.01) (Fig 2).

EB disruption could not be directly attributed to VEGF-A or Ang-2 in serum, since no correlation was observed between TEER and these proteins despite a marked increase of Ang-2 levels in serum from patients with septic shock (14,391 ± 4,192 vs. 2,594 vs. 788; P< 0.0001).

Conclusions: Our study provides direct evidence that serum from patients with septic shock is capable to induce functional and morphological changes associated with EB disruption, but that additional mechanisms other than VEGF-A and Ang-2 are associated with these changes. As EB regulation is increasingly regarded as a therapeutic target in sepsis, additional studies are warranted to identify the mechanisms associated with these findings.

PB 2264 | The Potential Roles of IL-33 and TGF-β1 in the Pathogenesis of Stevens-Johnson Syndrome/ Toxic Epidermal Necrolysis

O. Iqbal[1], C. Bouchard[2], M. Mosier[3], S.D. Till[4], J. Fareed[1]

[1]Loyola University Medical Center, Pathology, Maywood, United States, [2]Loyola University Medical Center, Ophthalmology, Maywood, United States, [3]Loyola University Medical Center, Surgery, Maywood, United States, [4]Loyola University Medical Center, Stritch School of Medicine, Maywood, United States

Background: Stevens Johnson Syndrome (SJS) and Toxic Epidermal Necrolysis (TEN) are rare, life-threatening and often drug-induced severe cutaneous adverse reactions with long-term ocular and other organ sequelae utilizing significant healthcare resources taking into account World Health Organization's introduction of the concept of a disability-adjusted life year (DALY). Given the increased morbidity and mortality due to multi-organ failure and sepsis, its pathogenesis still remains elusive and not completely understood. While the roles of IL-33 and TGF-β1 have been well defined for a variety of pro-inflammatory and apoptotic epidermal diseases, their roles in the apoptotic pathway of SJS/TEN remain unexplored. Based on this background we hypothesize that IL-33 and TGF-β1 play crucial roles in the pathogenesis of this syndrome.

Aims: To determine the potential roles of IL-33 and TGF-β1 in the apoptotic pathway of SJS/TEN.

Methods: Under an IRB approved protocol, collected and archived unstained slides of skin from patients with biopsy confirmed SJS/TEN were used for this study. Immunohistochemical analysis was performed using IL-33 and TGF-β1 antibodies followed by imaging on a DeltaVision microscope. ELISA analysis was used to determine the levels of IL-33 and TGF-β1 expression in citrated plasma samples. Statistical analysis was performed using linear regression analysis, ANOVA, and Turkey's *post-hoc* tests on STA-TA software.

Results: ELISA analysis of SJS/TEN patient plasma samples showed no marked elevation of TGF-β1 or IL-33 compared to normal human plasma (p= 0.41 and 0.26 respectively). Immunofluorescent microscopy of SJS/TEN skin biopsy samples revealed elevated levels of both TGF-β1and IL-33 in the epithelium compared to lichen planus skin biopsy samples. The results of this study may enhance our understanding of the pathogenesis of SJS/TEN and lead to the development of new treatment modalities for this disease.

Conclusions: TGF-β1and IL-33 play a crucial role in the apoptotic pathway of SJS/TEN.

PB 2265 | Assessment of the Concentration and the Functional Activity of Plasma Inter-alpha Trypsin Inhibitor in Patients with Inflammatory Diseases

J.-L. Plantier, V. Devos, S. Jorieux

LFB Biotechnologies, Therapeutic Innovation, Les Ulis, France

Background: Inter-alpha trypsin inhibitor (ITI) is a plasma proteoglycan, composed of 1 or 2 various heavy chains (HCs) linked through a chondroitin sulfate to the light chain, bikunin. Bikunin is the protease inhibitor chain and HCs can be transferred to hyaluronic acid (HA) in presence of TSG-6 to form HC-HA complexes. Such circulating complexes were found increased in acute inflammatory state. If the exact role of ITI is still unclear, anti-inflammatory properties of ITI have been described.

Aims: We compared the concentrations of circulating ITI components and their activity by measuring the transfer capacity of HC to HA from ITI present in plasmas of normal donors vs patients with auto-immune disease (AID).

Methods: Plasma ITI levels were quantified by using sandwich ELISA tests for the bikunin and HCs. TSG-6 level was measured using a commercial kit. The HCs to HA transfer was assessed using an ELISA method developed in the lab.

Results: The plasma amounts of ITI, as determined by bikunin measurement, in patients with AID (SLE, Crohn's or Cystic fibrosis) were slightly higher than that of normal donors (mean ± SD: 286 ± 43.6 µg/ml, n=33 vs 235 ± 36.7 µg/ml, n= 42). In normal plasma, the level of TSG-6 measured to 6.9 ± 4.1 ng/ml whereas in plasma from SLE, Crohn's, and cystic fibrosis the level of TSG-6 was significantly increased to 11.7 ± 12.1 ng/ml (n=20), 10.37 ± 4.37 ng/ml (n=10), and 15.6 ± 3.8 ng/ml (n=3), respectively. Using control and AID plasmas, binding of HCs to HA was found very faint. The addition of TSG-6 in plasma induced a large increase in level of HCs to HA transfer but without difference between control and AID plasmas.

Conclusions: No difference, except a slight increased amount of ITI in plasma of patients with AID, in ITI composition and HCs to HA binding capacity was observed in plasma of normal or patients with AID. However, due to the extreme sensitivity of the transfer activity of ITI to TSG-6, the situation might be different in tissues where TSG-6 is locally secreted.

PB 2266 | 2',3-dihydroxy-5-methoxybiphenyl Suppresses fMLP-induced Superoxide Anion Production and Cathepsin G Release by Targeting the β-subunit of G-protein in Human Neutrophils

H.R. Liao[1], I.-S. Chen[2], Y.-J. Day[3], S.-Z. Lin[1], C.-P. Tseng[4]

[1]Graduate Institute of Natural Products, College of Pharmacy, Kaohsiung Medical University, Tao-Yuan, Taiwan, Republic of China, [2]Graduate Institute of Natural Products, College of Pharmacy, Kaohsiung Medical University, Kaohsiung, Taiwan, Republic of China, [3]Chang Gung Memorial Hospital Linkou, Department of Anesthesiology, Tao-Yuan, Taiwan, Republic of China, [4]Graduate Institute of Medical Biotechnology, College of Medicine, Chang Gung University, Tao-Yuan, Taiwan, Republic of China

Background: Neutrophils are a major cellular component of innate immune response and play a crucial role in the elimination of invading microorganisms by producing reactive oxygen species.

Aims: This study investigates the effect and the underlying mechanism of 2',3-dihydroxy-5-methoxybiphenyl (RIR-2), a lignan extracted from the roots of *Rhaphiolepis indica* (L.) Lindl. *ex* Ker var. *tashiroi* Hayata *ex* Matsum. & Hayata (Rosaceae), on fMLP-induced respiratory burst in human neutrophils.

Methods: Signaling pathways regulated by RIR2 on neutrophils were evaluated by an interaction between β-subunit of G-protein and downstream signaling induced by fMLP, Src family kinases activities and by immunoblotting analysis of the downstream targets of G-protein.

Results: RIR-2 inhibited fMLP-induced superoxide anion production (IC_{50}=2.57±0.22 µM), cathepsin G release (IC_{50}=18.72±3.76 µM) in a concentration dependent manner. Further, RIR2 specifically suppresses fMLP-induced Src family kinases phosphorylation, -Raf/ERK phosphorylation, by inhibiting an interaction between β subunit of G-protein. However, RIR-2 was not found to inhibition of Src kinases activities. Consequently, RIR2 attenuated the downstream targets of Src kinase, such as Tec translocation from the cytosol to the inner leaflet of the plasma membrane, phosphorylation of AKT, P38, PLCγ2, PKC and membrane localization of $p47^{phox}$ and $P40^{phox}$, furthermore, RIR-2 attenuated fMLP-induced intracellular calcium mobilization. RIR2 was not a competitive or allosteric antagonist of fMLP. On the other hand, PMA-induced phosphorylation of Src, AKT, P38, PKC and membrane localization of $p47^{phox}$ and $P40^{phox}$ remained unaffected.

Conclusions: In conclusion, RIR2 specifically modulates fMLP-mediated neutrophil superoxide anion production and cathepsin G release by inhibiting an interaction between β subunit of G-protein and which subsequently interferes with the activation of intracellular calcium, PLCγ2, AKT, p38, PKC, ERK, $p47^{phox}$ and $p40^{phox}$.

PB 2267 | A Comparison of Scoring Systems and Surrogate Markers of Death in a Cecal Ligation and Puncture Sepsis Model

D.J. Dwivedi, S.H.C. Mai, M. Khan, A.E. Fox-Robichaud, P.C. Liaw

McMaster University and Thrombosis and Atherosclerosis Research Institute, Medicine, Hamilton, Canada

Background: Despite increasing standards for conducting ethical, humane research involving animals, death is still considered the only valid endpoint in murine sepsis studies. Recently, the Mouse Clinical Assessment Score for Sepsis (M-CASS), Murine Sepsis Score (MSS), and Mouse Grimace Scale (MGS) were developed as potential surrogate endpoint tools for assessing disease severity in models of sepsis.

Aims: To assess the validity of the M-CASS, MSS, and MGS for evaluating disease severity and predicting death in a resuscitated cecal ligation and puncture (CLP) model of sepsis.

Methods: Healthy C57BL/6 mice were subjected to CLP, a surgical procedure involving two punctures of the ligated cecum to induce sepsis, or a control, non-septic sham surgery (no ligation or puncture). Mice were resuscitated using Ringer´s lactate and continuously monitored every 4 hours post-surgery for potential surrogate markers of death until endpoint or 24 hours post-operatively. M-CASS, MSS, and MGS scores were assigned every 4 hours and the utility of the systems was determined.

Results: Around 50% of septic mice expired within 16 hours post-CLP and 100% expired within 20 hours post-CLP. M-CASS, MSS, and MGS increased in a time-dependent manner in septic mice and all scores were 0 in non-septic mice over 18 hours. The following components of the scoring systems were considered to be informative indicators of disease severity: responsiveness of mice to external stimuli, posture, facial grimace markers, and fur condition. Temperature was a reliable, objective marker to assess disease progression. Vocalizations, chest sounds, cyanosis, and restlessness/tremor did not correlate with disease progression in our CLP model.

Conclusions: The M-CASS, MSS, and MGS are effective tools for assessing disease severity in the CLP model. Efforts should be made towards using these assessment tools as well as other relevant surrogate markers as valid endpoints rather than mortality.

PB 2269 | High Altitude Venous Thromboembolism

N. Pandit[1], M. Singh[2], L. Seetoh[2]

[1]Tan Tock Seng Hospital, Internal Medicne, Singapore, Singapore, [2]Tan Tock Seng Hospital, Singapore, Singapore

Background: Ascent to high altitude (HA) is often complicated by acute, chronic mountain sickness, HA pulmonary & cerebral edema, which are well known entities. However, HA venous thromboembolism (VTE) is relatively unknown & is yet evolving in terms of knowledge, pathophysiology & management. Most literature are retrospective studies from the high mountainous regions of the Himalayas, where given the topography, access to advanced medical care is challenging. Singapore, a tropical island in the South China sea is an unusual location for patients to be seen with HA VTE.

Aims: We study of the presentation, management of 3 patients who presented with breathlessness after recent moderate altitude mountaineering.

Methods: This is a retrospective study of patients presenting with VTE with no apparent risk factor but high altitude mountaineering.

Results: All patients were young females, with no previous personal/family history of VTE. Neither did patients have any traditional risk factors associated with VTE. They presented with breathlessness of 1-4 weeks duration and were investigated for VTE as common causes were negative and had an elevated d-dimer. All had pulmonary embolism, with/ without DVT. They were all treated with anticoagulation for 6 months and all had resolution of the VTE.

Considering the idiopathic or lesser known entity of HA VTE, all had a thrombophilia screen performed after anticoagulation was discontinued, which was negative. At an average of 6 months follow up, none developed a recurrence of VTE.

Conclusions: A high index of suspicion is required for patients presenting with breathlessness after ascent to a high altitude to differentiate aetiologies. After diagnosing VTE, work up for underlying thrombophilia is warranted to exclude co-existent conditions. Duration of anticoagulation is recommended for a minimum of 6 months followed by a discussion about the risks Vs benefits of continued anticoagulation and lifestyle changes.

PB 2270 | Venous Involvement in Behcet's Disease: A Retrospective Analysis of 75 Cases

L. Belhadj[1], A. Hariz[1], I. Boukhris[1], I. Kechaou[1], M. Maroua[2], S. Azzabi[1], L. Ben Hassine[1], E. Cherif[1], N. Khalfallah[1]

[1]Charles Nicolle Hospital, Internal Medicine B, Tunis, Tunisia, [2]Hôpital Régional El Yasminat, Ben Arous, Internal medicine, Tunis, Tunisia

Background: Vascular involvement is the leading cause of death in Behcet's disease (BD)

Aims: The vascular involvement in Behcet´s disease (BD) varies from 7, 7 to 43% depending on ethnicity. Venous lesions are the most frequent vascular manifestation in BD. In this study, we looked at the pattern and outcome of venous events in BD.

Methods: Seventy five patients, who fulfilled the criteria of the International Study Group for diagnosis of BD, were recruited. We studied the characteristics of patients with thrombotic venous events. Clinical data parameters were recorded, including age at onset and extra-vascular manifestations of the disease.

Results: Twenty six from 75 patients had vascular event. Twenty three of these patients had a venous event. The mean age of the patients at the first venous event was 32 years. There were 22 males and 4 females. The first venous event occurred before BD diagnosis in one case and in the same time of onset of the disease in 2 cases. In the other cases, venous event occurred in patients followed for BD and the mean disease duration was 5, 82years. The mean number of recurrence of venous events was 1, 46. Deep vein thrombosis was the most frequent single vascular event (76, 92%). The most frequent localizations were in legs (23 cases).Four patients had cerebral vein thrombosis.A pulmonary venousinvolvement, a Budd-Chiari syndrome,an inferior and superior vena cava syndrome and arms thrombosis were found in only one case each one. An arterial event was associated in 2 cases. An association with ocular manifestations was observed in 26, 9% patients and neurologic manifestations in 11, 53%.

Conclusions: Although there is no agreement on the frequency rate of the vascular lesions in the littérature, most the vascular lesions in the litterature, most of the reported series indicate that the venous lesions are by far, more common than the arterial lesions.

In conclusion, the frequency of vascular complications of BD in our patients is similar to those reported around the world.

PB 2271 | Arterial Involvment in Behcet's Disease: A Retrospective Study of 75 Cases

L. Belhadj[1], A. Hariz[1], I. Boukhris[1], I. Kechaou[1], M. Mrouki[2], S. Azzabi[1], L. Ben Hassine[1], E. Cherif[1], N. Khalfallah[1]

[1]*Charles Nicolle Hospital, Internal Medicine B, Tunis, Tunisia,* [2]*Hôpital Régional El Yasminat, Ben Arous, Internal medicine, Tunis, Tunisia*

Background: Vascular involvement is the leading cause of death in Behcet's disease (BD).

Aims: Vascular involvement is the leading cause of death in Behcet's disease (BD). The vasculitis may involve large, medium and small vessels of both the arterial and venous circulation. We aimed to explore in this study the arterial involvement in Behcet's disease.

Methods: Seventy five patients, who fulfilled the criteria of the International Study Group for diagnosis of BD were recruited. We studied the clinical characteristics of patients with arterial manifestations. Clinical data parameters were recorded, including age at onset, the vascular and extra-vascular manifestations of the disease.

Results: We identified 26 patients with vascular involvement among the 75 patients (34, 6%). Four patients had arterial involvement (15% of all vascular manifestations). The mean age at the diagnosis of the arterial event was 52, 5 years. All patients were males. Mean disease duration before the arterial event was 22 years . The arterial events were divided in arterial thrombosis and anevrysm found in two cases each. The arterial events were pulmonary artery thrombosis,pulmonary artery anevrysm, femoral artery thrombosis and abdomianl aortic anevrysm in one case each one. An association with a venous event was found with two patients. An association with ocular manifestations was observed in 40%. No neurologic manifestation was observed. HLA B 5 was found in 40% cases. Cortisteroid treatment was used in 40% cases and immunosuppressive treatment in only one case.

Conclusions: As previously reported, we found a male predominance in BD patients with arterial involvement. We found a preferential location on the aorta, the femoral, and pulmonary arteries. Saadoun et al. reported in their cohort a prevalence of 40% of deaths with thoracic aorta and pulmonary arteries. Aortitis is infrequent in BD and was not found in our cohort.

Arterial involvement represented 15% of vascular manifestations in our cohort of BD.

PB 2272 | Self Extracellular RNA and Exogenous Danger Signals Act Synergistically to Induce Cytokine Production in Macrophages

H.F. Noll[1], J. Behnke[2], K.T. Preissner[1], S. Fischer[1]

[1]*Justus-Liebig-Universität Giessen, Biochemisches Institut, Giessen, Germany,* [2]*Justus-Liebig-Universität Giessen, Giessen, Germany*

Background: Self-extracellular RNA (eRNA) released from stressed or injured cells during ischemia-reperfusion or other pathologies has been shown to act as an alarmin by inducing proinflammatory responses.

Aims: Studies were performed to investigate whether self-eRNA can sensitize macrophages to amplify their inflammatory reactions towards damaged- or pathogen-associated patterns (DAMP, PAMP) like toll-like receptor (TLR)-agonists.

Methods: Mouse macrophages were differentiated from bone marrow-derived stem cells by mouse colony stimulating factor and characterized by CD68-, F4/80- and CD11b-staining using FACS analysis. Highly purified RNA was harvested from NIH3T3 cells and used as eRNA. Cytokines were quantified by ELISA.

Results: In macrophages, various doses (10 pg/ml - 1 µg/ml) of isolated agonists of TLR2 (Pam2CSK4), TLR3 (PolyIC), TLR4 (LPS), or TLR7 (R848) induced the release of TNF-a in a concentration-dependent manner. In the presence of eRNA, a considerable shift to the left of the dose-response curve of Pam2CSK4 (Pam) was observed. At low Pam-concentrations, eRNA synergistically enhanced the cytokine liberation dramatically. The synergistic activation of TLR2 by eRNA was confirmed by using other TLR2-agonists; this effect was much weaker for TLR4-, but not existent for TLR3-, or TLR7-agonists. The synergistic action of Pam-eRNA was prevented by RNase1, whereby Pam alone or together with eRNA was blocked by antibodies against TLR2 or by an inhibitor of the NFkB-signaling pathway. Since inhibition of p38MAP-kinase by SB203580 or of the ERK-kinase by PD98059 significantly reduced the combined eRNA-Pam response, several pathways feed the TLR2-NFkB signaling route.

Conclusions: eRNA considerably enhances the sensitivity of macrophages towards DAMPs/PAMPs, particularly involving TLR2-NFkB-signaling mechanisms. Thus, the presence of self-eRNA sensitizes innate immune responses and may thereby contribute to the onset or progression of vascular disease.

PB 2273 | Neutrophil Extracellular Trap (NET) Formation in Patients with Behcet's Disease

Y. Boulaftali[1], A. Lejoncour[2], S. Loyau[1], N. Le Lay[1], L. Venisse[1], M.-C. Bouton[1], A. Dossier[3], F. Domont[2], T. Papo[3], M. Jandrot-Perrus[1], P. Cacoub[2], N. Ajzenberg[4], D. Saadoun[2]

[1]*INSERM U1148, Laboratory for Vascular Translational Science, Paris, France,* [2]*AP-HP, Groupe Hospitalier Pitié-Salpêtrière, Département de Médecine Interne et Immunologie Clinique, Paris, France,* [3]*CHU Xavier Bichat, Département de Médecine Interne, Paris, France,* [4]*CHU Xavier Bichat - INSERM 1148, Département d'Hématologie et d'Immunologie Biologiques, Paris, France*

Background: Behçet´s disease (BD) is a systemic inflammatory disorder characterized by recurrent episodes of oral and genital ulcers, uveitis as well as thrombosis. The etiology of BD is poorly understood but activated neutrophils have been proposed to contribute to the disease. However, evidence supporting a role for primed neutrophils in BD-associated thrombotic risk is scant. To respond to inflammatory

insults, neutrophils release web-like structures, known as neutrophil extracellular traps (NETs), which are prothrombotic.

Aims: To evaluate the role of NETs in the thrombotic complications in BD disease.

Methods: Blood samples were collected from BD patients and healthy controls (HC). Cell free DNA (CfDNA), myeloperoxidase (MPO) and DNA complexes were measured in plasma using Picogreen assay and ELISA. NETosis was assessed in purified neutrophils from BD patients and HC, and analyzed by microscopy after immunostaining of MPO and DNA.

Results: BD patients (n=73) had elevated plasma CfDNA levels compared to HC (n=15) (928.7 ± 36.3 vs 711.3 ± 28.4 ng/ml, respectively p< 0.001). MPO-DNA complexes were significantly increased in BD plasma (n=73) compared to HC plasma (n=15) (0.383 ± 0.10 vs 0.065 ± 0.01 OD, respectively, p< 0.001). Purified neutrophils from BD patients exhibited spontaneous NETosis compared to HC (31.7 ± 4.4% vs 5.4 ± 1.9% respectively, p=0,004). Consistently, PMA-activated neutrophils from BD patients have increased NET formation compared to neutrophils from HC (41.8 ± 2.7% vs 18 ± 3.8% respectively, p=0.002). Thrombin generation in BD plasma was significantly increased and positively correlated with MPO-DNA complexes (r^2= 0.9, p=0.002). Importantly, DNAse treatment significantly decreased thrombin generation in BD plasma but had no effect in HC plasma suggesting a procoagulant role of NETs.

Conclusions: Our data show that circulating NETs are elevated in BD patients. Targeting NETs may represent a potential therapeutic target for the reduction or prevention of BD-associated thrombotic risk.

PB 2274 | A Basal-state Monocyte Gene Transcription Profile Is Associated with Circulating Levels of Th1 Cells: The Multi-Ethnic Study of Atherosclerosis (MESA)

N.C. Olson[1], A. Ellis[1], L.M. Reynolds[2], M.F. Doyle[1], C.L. Wassel[1], B.M. Psaty[3,4], Y. Liu[2], R.P. Tracy[1,5]

[1]Robert Larner, M.D. College of Medicine, University of Vermont, Pathology and Laboratory Medicine, Burlington, United States, [2]Wake Forest School of Medicine, Department of Epidemiology & Prevention, Public Health Sciences, Winston-Salem, United States, [3]University of Washington, Departments of Medicine, Epidemiology, Health Services, and Cardiovascular Health Research Unit, Seattle, United States, [4]Group Health Research Institute, Group Health Cooperative, Seattle, United States, [5]Robert Larner, M.D. College of Medicine, University of Vermont, Department of Biochemistry, Burlington, United States

Background: Differentiation of CD4+ T helper cells into distinct effector subtypes, including T helper type 1 (Th1) cells, is an incompletely understood process involving antigen presentation, co-stimulation, and transcriptional regulation pathways. Monocyte signaling is known to play a role in T-cell polarization, but details are poorly understood.

Aims: We aimed to identify a gene transcriptomic profile expressed by monocytes associated with Th1 cell polarization.

Methods: 238 white, African-American, and Hispanic MESA participants (aged 54-93 years) had measures of circulating Th1 cells and monocyte mRNA expression. Th1 cells were measured in blood by flow cytometry as CD4+interferon-gamma+ lymphocytes. Monocytes were isolated using magnetic separation with anti-CD14 antibody. Genome-wide monocyte mRNA expression (*n*=10,898 genes) was determined by HumanHT-12 v4 Expression BeadChip in 14,619 transcripts. Cross-sectional associations between monocyte transcripts and Th1 cell level was estimated by linear regression, adjusted for age, sex, race/ethnicity, expression chip, contamination with non-targeted cells, and the first 4 ancestry principal components (false discovery rate = p< 0.05).

Results: 6 genes expressed by circulating monocytes were associated with Th1 cells. Granzymes H ($p=6x10^{-5}$) and K ($p=3x10^{-3}$) and CD8α ($p=2x10^{-4}$) were associated with higher Th1 cell levels; lymphoid enhancer binding factor-1 (*LEF1*) ($p=2x10^{-3}$), myelin and lymphocyte protein (*MAL*) ($p=7x10^{-3}$), and C-C chemokine receptor 7 (*CCR7*) ($p=1x10^{-2}$) were associated with lower Th1 levels. Ingenuity pathway analysis identified the Communication Between Innate and Adaptive Immunity Pathway as enriched among these genes, supporting their potential role in Th1 cell polarization.

Conclusions: Our results suggest a basal gene transcription profile expressed by monocytes influences Th1 cell polarization. If confirmed, findings may have implications in modulating Th1 cell-mediated inflammatory diseases.

PB 2275 | Proinflammatory Polarized Macrophages Have Reduced Microvesicles and Coagulatory Function

P. Hohensinner, J. Kirchbacher, J. Baumgartner, L. Hell, I. Pabinger, W. Speidl, J. Wojta

Medical University of Vienna, Vienna, Austria

Background: Microvesicles are small particles deriving directly from the cellular membrane of the cell by an active budding process involved in cell to cell communication and activation of the coagulation cascade. Macrophages can be polarized differentially according to their surrounding environment leading to different function and behavior of macrophages.

Aims: To identify changes in macrophage coagulatory function and microvesicle production under different polarization conditions.

Methods: Primary human macrophages were polarized towards a pro-inflammatory state (M1) using LPS and IFN-gamma, alternatively polarized macrophages (M2) were generated using IL4 and IL13.

Results: Unpolarized macrophages constantly produce microvesicles. Upon M1 polarization however, microvesicle production is significantly reduced whereas M2 polarization leads to increased shedding of microvesicles. Microvesicle production in all polarization conditions is independent from Ca^{2+} signaling including activation of Caspase-3. In addition, inhibition of Rho did not change cellular microvesicle production regardless of polarization condition. Unpolarized and M2 macrophages had 24% and 22% microvesicles positive for phosphatidylserine respectively, M1 polarized macrophages displayed only

13% positive microvesicles. However, tissue factor activity in the microvesicle fraction was highest in M2 macrophages followed by M1 macrophages and unpolarized macrophages. This was also confirmed on the protein level.

Conclusions: Our data indicate that macrophages are a constant source of microvesicles. Alternative polarization induces microvesicle production together with an increase in tissue factor and tissue factor bearing microvesicles. Proinflammatory activation leads to opposite behavior culminating in reduced tissue factor acitivity together with reduced microvesicle shedding. This suggests that alternative activation of macrophages leads to a procoagulatory macrophage phenotype.

PB 2276 | Modulation of Macrophage Functions by Thrombin

M. Lopez[1,2], J. Rodriguez[1], H. Cabrera-Fuentes[1,3], K. Preissner[1]

[1]Justus Liebig University Giessen, Biochemical Institute, Giessen, Germany, [2]Instituto Venezolano de Investigaciones Científicas, Caracas, Venezuela, [3]National Heart Center Singapore, Singapore, Singapore

Background: Besides its role in blood coagulation, thrombin is known to act as a cell signaling molecule via activation of protease-activated receptors (PARs), thereby connecting this coagulation protease to immune/inflammatory responses. Previous studies demonstrated that thrombin activates adhesion and promotes release of interleukin 6, monocyte chemotactic protein or tissue factor pathway inhibitor 2 in macrophages. However, gene expression changes and cytokine/chemokine profiles of thrombin-stimulated macrophages have not been systematically studied so far.

Aims: The aims of this work were to analyze gene expression and cytokine secretion profiles in macrophages following thrombin treatment and to investigate whether thrombin induces polarization changes in macrophages.

Methods: Bone marrow-derived macrophages were generated from bone marrow cells of C57BL/6J mice cultured in DMEM containing macrophage colony stimulating factor (M-CSF). On day 7 in culture the cells were replated in DMEM media (without M-CSF) for one day, followed by stimulation with thrombin. Subsequently, real-time PCR was performed using specific primers and cytokines in pooled cell culture supernatants were assessed using a cytokine array Kit.

Results: Several proinflammatory cytokines (e.g. IL1α, TNFα) and chemokines (MIP1α, MIP2, IP10) were differentially expressed in macrophages in response to thrombin. Moreover, high thrombin concentration promoted differentiation of macrophages towards the M1-phenotype, whereas low concentrations induced cell differentiation into the M2 phenotype. In a concentration-dependent manner, thrombin also influenced the expression of PARs in macrophages. Thrombin-stimulated macrophages exhibited pro-coagulant and anti-fibrinolytic properties by upregulation of tissue factor and plasminogen activator inhibitor-1 mRNA levels.

Conclusions: Our results provide new experimental evidence on the existent link between coagulation and innate immunity

PB 2277 | Interleukin-6 in the Development of Venous Thrombosis

S.H. Karbach[1,2], R. Schüler[2,3], A. Gabele[3,4], F. Ridder[3,4], L. Hobohm[5], K. Schäfer[4], H. Rossmann[6], T. Korn[7], H.M.H. Spronk[8], B. Lämmle[4], T. Münzel[1], A. Waisman[3], P. Wenzel[1,4]

[1]University Medical Center, Center of Cardiology - Cardiology I, Mainz, Germany, [2]University Medical Center, Center for Thrombosis and Hemostasi, Mainz, Germany, [3]University Medical Center, Institute of Molecular Medicine, Mainz, Germany, [4]University Medical Center, Center of Thrombosis and Hemostasis, Mainz, Germany, [5]University M;edical Center Mainz, Center of Cardiology, Cardiology 1, Mainz, Germany, [6]University Medical Center Mainz, Institute of Clinical Chemistry and Laboratory Medicine, Mainz, Germany, [7]TU Munich, Department of Neurology, München, Germany, [8]Maastricht University, Departments of Biochemistry and Internal Medicine, Cardiovascular Research Institute Maastricht, Maastricht, The Netherlands

Background: Interleukin-6 (IL-6) is of crucial relevance in inflammatory processes, especially in the recruitment of myelomonocytic cells. IL-6 was described to accelerate thrombus development.

Aims: The aim of our study was to analyse the role of IL-6 in the development of deep vein thrombosis (DVT).

Methods: Mice overexpressing IL-6 in myelomonocytic cells (LysM-IL-6$^{ind/+}$, controls: IL-6$^{ind/+}$) and IL-6 deficient mice (IL-6KO, controls: C57BL/6 mice) were analysed for the development of DVT after one week of ligation of the inferior vena cava (IVC ligation stenosis model). DVT development was analysed by ultrasound. We performed histological as well as FACS analysis and rtPCR measurements of the cellular infiltrate in thrombi and venous wall. Thrombin generation and coagulation factors were analysed in citrated blood as well as cytokine levels.

Results: We found elevated levels of IL-6 in thrombus and venous wall in C57BL/6 mice after IVC ligation compared to sham-treated mice. Interestingly LysM-IL-6$^{ind/+}$ mice had no thrombus development after IVC ligation. Overexpression of IL-6 in myelomonocytic cells resulted in a bleeding phenotype with prolonged aPTT levels (LysM-IL-6$^{ind/+}$: 79s, IL-6$^{ind/+}$: 29s) and a slightly but significantly increased INR (LysM-IL-6$^{ind/+}$: 0,69, IL-6$^{ind/+}$: 0,65) partially due to mildly reduced levels of clotting factor II (LysM-IL-6$^{ind/+}$: 101%, IL-6$^{ind/+}$: 124%), and moderately reduced levels of clotting factor V (LysM-IL-6$^{ind/+}$: 522%, IL-6$^{ind/+}$: 957%), and IX (LysM-IL-6$^{ind/+}$: 93%, IL-6$^{ind/+}$: 145%). There was an increase in vonWillebrand Factor in LysM-IL-6$^{ind/+}$ and elevated levels of fibrinogen and antithrombin compared to IL-6$^{ind/+}$ mice. In parallel, IL-6 KO mice had a normal DVT development after IVC ligation compared to control mice.

Conclusions: Overexpression of IL-6 in LysM+ cells prevents DVT formation in IVC-ligated mice. Further analyses will follow on the bleeding phenotype of the LysM-IL-6$^{ind/+}$ mice and the influence of downstream IL-6 signaling on coagulation.

PB 2278 | The First Year after Diagnosis of Anti-Neutrophil Cytoplasmic Antibody (ANCA)-Associated Vasculitis is Critical for Development of Venous Thromboembolism (VTE) in These Patients

A. Antovic[1], E. Svensson[1], O. Börjesson[1], A. Bruchfeld[2], J. Antovic[3], I. Gunnarsson[1]

[1]*Karolinska Institutet, Dept. of Medicine, Rheumatology Unit, Stockholm, Sweden,* [2]*Karolinska Institutet, Dept. of Renal Medicine, Stockholm, Sweden,* [3]*Karolinska Institute, Stockholm, Sweden*

Background: Patients with anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitides (AAVs) entail an increased incidence of venous thromboembolism (VTE) compared to the general population.
Aims: To investigate the influence of the ANCA-specificity, disease duration and classical VTE risk factors on the development of VTE in AAV-patients.
Methods: The occurrence of VTE was evaluated in the retrospective cohort study of AAV-patients at the Karolinska University Hospital, Stockholm, Sweden. 187 ANCA-positive patients with granulomatosis with polyangitis (GPA) or microscopic polyangitis (MPA) diagnosed between 2005 and 2014 were included. We assessed haemostasis in a pilot study using two global haemostatic methods: endogenous thrombin potential (ETP) and overall fibrinolytic potential (OFP) in AAV-patients with active flare (n=19), sex- and age matched AAV-patients during inactive period of the disease (n=15) and healthy controls (n=15).
Results: 28 VTEs occurred in 24 patients over a total follow-up time of 1020 person-years, rendering a total incidence rate of 2.74 cases of VTE per 100 person-years. A majority of the VTEs occurred in close temporal proximity to the AAV-diagnosis, with more than half of the patients having a VTE within the first year after the AAV-diagnosis. ANCA-specificity was not significantly associated with VTE development, nor were AAV-diagnosis (GPA/MPA), sex or renal involvement. High age ($p < 0.01$) and previous VTE
($p < 0.05$) were significantly more common in the VTE group.
Conclusions: The main finding of this study is the striking prevalence of VTE in AAV-patients within the first year after the AAV-diagnosis. High age at AAV-diagnosis and previous VTE should be taken into account when estimating VTE-risk. Prothrombotic condition is present in active AAV-patients, where ETP and OFP may be useful markers for identifying patients at high risk.

PB 2279 | Protein Arginine Deiminase-4 Does Not Influence Antibacterial, Inflammatory or Procoagulant Responses during Gram-negative Pneumonia Derived Sepsis

T.A.M. Claushuis[1], A.L. Luitse[1], L.A. van Vught[1], J. Horn[2], O.J. de Boer[3], J.M. Lankelma[1], L. Boon[4], A. Zychlinsky[5], A.F. de Vos[1], C. van ,t Veer[1], T. van der Poll[1,6]

[1]*Academic Medical Center, Center for Experimental and Molecular Medicine, Amsterdam, The Netherlands,* [2]*Academic Medical Center, Division of Intensive Care, Amsterdam, The Netherlands,* [3]*Academic Medical Center, Department of pathology, Amsterdam, The Netherlands,* [4]*Bioceros, Utrecht, The Netherlands,* [5]*Max Planck Institute for Infection Biology, Berlin, Germany,* [6]*Academic Medical Center, Division of Infectious Diseases, Amsterdam, The Netherlands*

Background: Neutrophil extracellular traps (NETs) can capture and kill bacteria. NET formation is regulated by Protein arginine deiminase 4 (PAD4). NETs can aid in host defense in skin and liver infection; their role during pneumonia is less well known.
Aims: We aimed to investigate the contribution of PAD4 to antibacterial, inflammatory and procoagulant responses during pneumonia derived sepsis.
Methods: Intensive Care patients with either pneumosepsis or non-infectious critical illness without lung pathology were subjected to a non-directed bronchoalveolar lavage. Lavage fluid was assessed for formation of NETs. Isolated neutrophils were stimulated with phorbol myristate acetate (PMA), Klebsiella pneumoniae, Pseudomonas aeruginosa or Lipopolysaccharide (LPS) and NET formation was assessed. PAD4 deficient and wild-type mice were infected with Klebsiella or Pseudomonas via the airways.
Results: Patients with pneumosepsis, but not patients with non-infectious disease, had NETs in their airways. Klebsiella, Pseudomonas and LPS induced NET formation by human neutrophils, albeit to a lesser extent than PMA. PAD4 deficient mice had reduced NET formation in the lung, but had similar levels of bacterial growth during infection with Klebsiella or Pseudomonas. Cell free DNA levels correlated to some extent with NET formation, whereas nucleosomes levels were not different between PAD4 deficient and wild-type mice.. PAD4 deficiency reduced platelet activation but did not prevent sepsis induced thrombocytopenia or alter activation of coagulation or distant organ damage.
Conclusions: These results suggest that NETs are present in the airways during human and murine pneumosepsis and that this may be a direct effect of causative pathogens. However, PAD4 mediated NET formation does not play a role in antibacterial defense during gram-negative pneumonia, suggesting that other immune functions are more dominant during this type of lung infection.

PB 2280 | NETs, FSAP and their Complicity in the Context of Immunity and Thrombosis

S. Grasso[1], A. Neumann[2], M. von Köckritz-Blickwede[2,3], S. Kanse[1]

[1]*University of Oslo, Department of Molecular Medicine, Oslo, Norway,* [2]*University of Veterinary Medicine Hannover, Department of Physiological Chemistry, Hannover, Germany,* [3]*Research Center for Emerging Infections and Zoonoses (RIZ), Hannover, Germany*

Background: Neutrophils can release neutrophil extracellular traps (NETs), which are a web-like meshwork composed of nucleosomes, and decorated with neutrophil granules components and anti-microbial proteins. They are involved in a broad variety of patho-physiological processes, including atherosclerosis, thrombosis, autoimmune and

infectious diseases. Factor VII Activating Protease (FSAP) is a plasma circulating serine protease, considered to be involved in haemostasis, inflammation and vascular remodeling. Key activators of zymogen FSAP *in vivo* are histones and nucleosomes which are also the main components of NETs.

Aims: We have investigated the bidirectional interactions between FSAP and NETs.

Methods: Human neutrophils were stimulated with phorbol 12-myristate 13-acetate (PMA) and various NET-related responses were measured.

Results: FSAP showed binding to NETs and promoted NET formation in response to PMA. FSAP-bound NETs were protected against degradation by *S. aureus* nuclease even though the microbicidial activity of NETs was not influenced by FSAP. Surprisingly, NETs did not activate zymogen FSAP even though they consist of known activators. However, upon DNAse treatment of NETs, there was a robust activation of purified pro-FSAP and plasma FSAP. FSAP in turn degraded histones and neutralized their cytotoxicity towards endothelial cells. We found no evidence of nucleosome releasing activity of FSAP.

Conclusions: FSAP modulates the activity of NETs by boosting their formation, binding and protecting them from degradation. On the other side, NETs bind to FSAP but do not activate it except when histones are released by DNAse. Presumably, the DNA-histone complex formation neutralizes both components with respect to FSAP activation. In this system we did not find any evidence for the nucleosome release activity of FSAP that has been described in a number of earlier reports. This study gives new insights on interactions involved in the regulation of NET functions in vascular biology.

PB 2281 | Immunology Studies on Recombinant Factor VIII Fc Fusion Protein

K. Kis-Toth[1], A. Simpson[1], K. Henry[2], C. Loh[1]

[1]*Bioverativ, Waltham, United States,* [2]*Biogen, Cambridge, United States*

Background: The main complication of prophylactic replacement therapy with factor in hemophilia A is the formation of inhibitors (neutralizing anti-factor VIII antibodies) in ~30% of severe hemophilia A patients. Further understanding of how the immune system responds to FVIII is an ongoing effort in hemophilia research. The extended half-life recombinant factor VIII Fc fusion protein (rFVIIIFc) is an effective and safe therapy to prevent and control bleeding episodes. The Fc region of this molecule is not only responsible for increasing rFVIII half-life, but also seems to promote antigen-specific tolerance, as shown in a preclinical animal model (Krishnamoorthy et al., Cell Immunol 2016), and suggested in immune tolerance induction case reports (Malec et al., Haemophilia 2016; Ragni et al., Haemophilia 2016).

Aims: The goal of this study is to characterize the interactions of the Fc portion of rFVIIIFc with the immune system.

Methods: Peripheral blood-derived human and bone marrow-derived mouse antigen presenting cells (APCs) were used to investigate the effects of rFVIII on Fc receptor (FcR) binding, signaling and cytokine production, as well as subsequent interactions and effects on T cells *in vitro*.

Results: rFVIIIFc engages FcRs on APCs, as indicated by the loss of cell surface receptor levels monitored by flow cytometry. Further, phosphorylation signals immediately downstream of the receptors were observed. These signals do not induce pro-inflammatory cytokines as seen with immune complexes, but instead induce cytokines, such as TGFβ and IL-10, and other molecules which are involved in dampening immune responses. rFVIIIFc-treated APCs co-cultured with naïve T cells influence differentiation towards a regulatory T cell phenotype.

Conclusions: The Fc portion of rFVIIIFc appears to influence the phenotype and function of antigen presenting cells.

PB 2282 | Luminex© Bead-based Assay for Early Detection of GPIIbIIIa Allo-immunization in Glanzman Thrombasthenia

A. Dupuis[1], E. Le Toriellec[2], M. Schwebel[3], A. Parrisiadis[3], H. Ansart-Pirenne[2], R. d'Oiron[4], C. Lavenu Bombled[5], C. Gachet[1], P. Bierling[2,6], L. Croisille[2]

[1]*Université de Strasbourg, INSERM, EFS Grand Est, BPPS UMR-S 949, FMTS, Strasbourg, France,* [2]*Laboratoire HLA-ILP, EFS île de France, site Hôpital Henri Mondor, Créteil, France,* [3]*Laboratoire HLA, EFS Grand Est, Site de Strasbourg Spielmann, Strasbourg, France,* [4]*Centre de Traitement des Hémophiles, CHU Bicêtre, AP-HP, Université Paris Sud, Le Kremlin Bicêtre, France,* [5]*Service d'Hématologie Biologique, Centre de Référence Pathologies Plaquettaires, AP-HP, Hôpital Bicêtre, Université Paris Sud Paris Saclay, Inserm Unité 1176, Le Kremlin Bicêtre, France,* [6]*INSERM U 955, Université Paris XII, Hôpital Henri Mondor, Créteil, France*

Background: Glanzmann Thrombasthenia (GT) is a severe hemorrhagic disorder due to a quantitative or qualitative defect of platelet integrin αIIbβ3 (GPIIbIIIa). In case of GPIIbIIIa deficiency, the patients are likely to develop allo-antibodies against GPIIbIIIa after platelet transfusion. To date, MAIPA (monoclonal antibody-specific immobilization of platelet antigen) test remains the gold standard method to identify antibodies in all contexts of platelet immunization.

Aims: Recently a new Luminex© bead-based platelet antibody detection assay (PAKLx©) has been designed for detection of anti HPA-1, -2, -3, -4, -5, GPIV and HLA class I allo-antibodies. We evaluated this new tool in comparison with MAIPA for detection of GPIIbIIIa allo-antibodies and follow-up of GT patients.

Methods: 52 samples from 44 GT patients (diagnosis in Strasbourg and Paris) were tested in MAIPA and PAKLx assays.

Results: MAIPA and PAKLx results were concordant in 38 cases (73%), with 24 positive and 14 negative samples, whether patients were presenting a type 1, 2 or variant Glanzmann disease. In two patients (3 samples), MAIPA result was at the threshold or positive, whereas the Luminex was negative. In 11 samples (21%), anti-GPIIbIIIa was only identified by Luminex (MFI 1000-3000) with a negative MAIPA (OD < 0.2). This group included 3 adult patients with positive MAIPA in their childhood, including one pregnant woman. For this patient, the detection of anti-GPIIbIIIa with PAKLx only (MFI around 1500), has been followed by a strongly positive result in both MAIPA (OD>1) and PAKLx (MFI> 5500) early after effective platelet transfusion for delivery.

Conclusions: Our results suggest that the PAKLx is more sensitive than the MAIPA to detect GPIIbIIIa antibodies in GT. It may be of special interest for early detection of GPIIbIIIa allo-immunization in GT during pregnancy, and help in the management of patients in obstetrical, surgical and bleeding contexts. Further studies are necessary to confront PAKLx results to platelet transfusion efficiency.

PB 2283 | Tranexamic Acid Blocks Fibrinolysis but Not Overall Plasmin Generation and Modulates the Immune Response in Patients Undergoing Coronary Artery Surgery. A Sub-study of the "Aspirin and Tranexamic Acid for Coronary Artery Surgery" (ATACAS) Trial

D.F. Draxler[1], G. Hanafi[1], S. Zahra[1], S. Vorontsov[1], B. Niego[1], H. Ho[1], M. Daglas[1], I. Goncalves[1,2], H. Tran[1,2], S. Wallace[3], M. Plebanski[4], P. Myles[3], R.L. Medcalf[1]

[1]Monash University, Australian Centre for Blood Diseases, Melbourne, Australia, [2]Alfred Hospital, Department of Clinical Haematology, Melbourne, Australia, [3]Alfred Hospital, Department of Anaesthesia and Perioperative Medicine, Melbourne, Australia, [4]Monash University, Department of Immunology, Melbourne, Australia

Background: Cardiac surgery is associated with increased fibrinolysis resulting in enhanced bleeding, and immunosuppression making patients susceptible to infection. We reported that plasmin inhibits the ability of dendritic cells (DCs) to mediate an allogeneic response. Hence, anti-fibrinolytic agents (tranexamic acid; TXA) used to reduce blood loss, might also modulate the immune response.
Aims: To evaluate the temporal effects of TXA on plasmin generation, fibrinolysis and the immune response after cardiac surgery.
Methods: Blood was taken from 41 cardiac surgery patients randomised to TXA in the ATACAS trial. Plasma obtained prior to surgery, post-operatively, 24 and 72 h was tested for D-dimer, plasmin-anti-plasmin complex (PAP) and by clot lysis assays (CLA). Flow cytometry was performed for functional markers of myeloid and lymphoid cell populations. Multiplex ELISAs were used to detect cytokine levels. The effects of TXA (1 g, oral) was also determined in 10 healthy volunteers.
Results: TXA completely inhibited fibrinolysis (reduced D-dimer and CLA) in all patients (n=22) at the post-OP and 24h time points. However, PAP levels were increased at the same time points. As TXA inhibits lysine-dependent plasmin generation, these data indicate that lysine-independent mechanisms exist for plasmin formation in the cardiac surgery setting. Flow cytometry showed that TXA significantly increased expression of the activation marker CD83 on both classical monocytes and DCs, suggesting enhanced immune competence. Baseline levels of pro-inflammatory cytokines TNF-α and IL-6 were significantly reduced by TXA in healthy volunteers, indicating a role for lysine-dependent plasmin formation for controlling cytokine expression.
Conclusions: TXA effectively blocks fibrinolysis and modulates the immune system in healthy volunteers and cardiac surgery patients. Plasmin formation still occurs via lysine-independent mechanisms and the consequences of this finding remain to be determined.

PB 2284 | Impact of Systemic Inflammation in Lung Transplant Outcome

J. Walenga[1], W. Jeske[1], E. Lowery[2], A. Walborn[3], M. Yong[2], A. Rodrigues[1], W. Vigneswaran[1]

[1]Loyola University Medical Center, Thoracic and Cardiovascular Surgery, Maywood, United States, [2]Loyola University Medical Center, Pulmonary and Critical Care Medicine, Maywood, United States, [3]Loyola University Medical Center, Pharmacology, Maywood, United States

Background: Primary graft dysfunction (PGD) is the leading cause of early post-lung transplantation (LTx) morbidity and mortality. Although the diagnosis of PGD has improved, its etiology remains controversial. It is hypothesized that pro-inflammatory mediators released post-LTx modulate the innate and adaptive immune responses and predispose the patient to chronic lung allograft rejection. There have been limited studies to date.
Aims: To investigate a battery of cytokines in the same patient to well characterize the inflammatory status early post-LTx, and to determine if patient subgroups who respond differently to the donor organ, as shown by the etiologies of the end-stage lung disease, have a different host immune status.
Methods: Individuals undergoing LTx for cystic fibrosis (CF) or idiopathic pulmonary fibrosis (IPF) were enrolled, excluding patients >65 yrs or undergoing re-transplantation. Serum collected pre-operatively, 1-2, 24 and 72 hrs, 7, 30 and 90 days following LTx was analyzed for inflammatory cytokines using the Randox bio-chip array. ISHLT-defined PGD grade at 24 and 72 hrs, rejection episodes, pulmonary infection and development of bronchiolitis obliterans syndrome were documented.
Results: At 72 hrs post-transplant, 2/10 CF patients and 4/12 IPF patients had PGD score ≥2. Mean serum levels of IL-6, IL-8, IL-10, VEGF, TNFα (100-500 vs < 100 pg/mL) and MCP-1 (500-800 vs 300-400 pg/mL) were notably higher in CF patients compared to those with IPF. Difference between CF and IPF patients was most striking for PGD scores ≥2. In CF patients, IL-6, IL-8, IL-10, TNFα and MCP-1 increased with increasing PGD score (2-3 vs 0-1). Higher VEGF levels were observed in CF patients with lower PGD scores.
Conclusions: Cytokine activation in the early post-transplant period is different among subsets of LTx patients. If validated, identifying the specific early cytokine response of the host can guide individualized treatment to reduce PGD and late graft failure.

PB 2285 | Protease Activated Receptor-2 (PAR-2) Serves as a Dominant Receptor for Factor VII Activating Protease (FSAP)

K. Byskov, S.M. Kanse

University of Oslo, Institute of Basic Medical Sciences, Oslo, Norway

Background: Protease Activated Receptors (PARs) mediate signaling for many factors from the hemostasis system and are important drug targets in vascular biology. The mechanism of action of FSAP on cells

is largely unknown but some preliminary studies suggest that PARs may be involved. To date, there are no methodical studies investigating the interaction between FSAP and PARs.

Aims: To investigate the role of PARs in mediating the cellular effects of FSAP.

Methods: HEK293 and A549 cells were transfected with PAR-1 and PAR-2 constructs with an N-terminal soluble alkaline phosphatase (SEAP)-tag. FSAP-mediated secretion of SEAP as well as ERK1/2 activation using Western blotting was determined. Point mutations were introduced in the N-terminal tethered ligand part of PAR-1 and -2 using site-directed mutagenesis to determine the exact cleavage sites involved.

Results: The cleavage of PAR-2 was much more extensive than that of PAR-1. Even though PAR-1 was a poor receptor for FSAP, ERK1/2 signaling was observed when SEAP-PAR1 was expressed in cells. In PAR-2 over-expressing cells a robust FSAP- mediated ERK1/2 activation was observed. Recombinant serine protease domains (SPD) of wild type (WT) FSAP, but not the Marburg I isoform of FSAP, could cleave and signal through PAR-2. Arg31, Arg36, Lys34 and Lys41 in the N-terminal of PAR-2 were mutated to Gly to further identify the exact cleavage sites. PAR-2*K34G* completely abolished, PAR-2*R36G* partially abolished and the others exhibited no differences in the FSAP mediated cleavage and ERK1/2 signaling compared to WT PAR-2.

Conclusions: FSAP cleaves PAR-1 and PAR-2 and induces ERK1/2 signaling in cells. PAR-2 serves as a dominant receptor for FSAP and K34 and R36 in PAR-2 are important for the FSAP mediated cleavage and cell signaling. PAR-3 and PAR-4 are currently being tested. This molecular characterization of the actions of FSAP via PARs will help to define the broad spectrum of the actions of FSAP beyond hemostasis.

PB 2286 | Protective and Detrimental Effects of Anticoagulation in a Mouse Model of Multiple Sclerosis

S. Wang, M. Henderson, B. Reeves, N. Mackman, R. Pawlinski

University of North Carolina at Chapel Hill, Chapel Hill, United States

Background: Multiple sclerosis is an autoimmune disease of the central nervous system. Blood-brain barrier damage, activation of coagulation and extravascular fibrin deposition have been demonstrated in a mouse model of disease (experimental autoimmune encephalomyelitis - EAE). Inhibition of thrombin or fibrin-microglia interactions reduces severity of EAE.

Aims: Determine the mechanism by which tissue factor (TF)-dependent activation of coagulation contributes to the EAE progression.

Methods: To induce EAE, 10 weeks old C57Bl/6J female mice (n=15-25 per each group) were immunize with MOG35-55 peptide. A clinical score reflecting the degree of paralysis was recorded daily for 30 days. Spinal cords were collected for histological evaluation of myelin loss and inflammatory cells infiltration. mRNA expression of chemokine/cytokines and markers of immune cells were also analyzed. Genetic and pharmacologic approaches were used to inhibit the TF-thrombin pathway.

Results: Clinical score, neuronal damage and macrophages and T cells infiltration into the spinal cord were significantly reduced in EAE mice expressing low levels of TF (1% of wild type) as compared to EAE mice with normal levels of TF. CCL2, CCL20, IL-17A, TNFA mRNA expression were lower in EAE low TF mice. Treatment with the anti-TF antibody (20mg/kg, ip, every 3 days) or the thrombin inhibitor dabigatran (60 or 120mg/kg, daily, oral gavage) provide similar protection in EAE mice. However, all anticoagulant approaches resulted in bleeding complications in 15-20% of EAE mice. In contrast, astrocyte-specific deletion of TF or total deficiency of PAR-2, reduced EAE progression without bleeding complications. PAR-1 deficiency provided only a modest protection whereas PAR-4 deficiency had a detrimental effect in EAE mice.

Conclusions: Our study suggests that various components of the TF-initiated coagulation response differentially regulates central nervous system hemostasis and autoimmune inflammation during EAE.

PB 2287 | Crosstalk between Epidermal Growth Factor Receptor (EGFR) and TF/FVIIa/PAR2 Pathway Mediates Chemotherapy Resistance in Cervical Cancer

R.Q. Monteiro[1], L.R. Almendra[1], I. Guimarães[2], A.C. Pires[3], A. Melo[2], S. Ortiz-Costa[4], C. Sternberg[2], V.H. de Almeida[2]

[1]Federal University of Rio de Janeiro, Institute of Medical Biochemistry, Rio de Janeiro, Brazil, [2]National Cancer Institute, Clinical Research Division, Rio de Janeiro, Brazil, [3]Fonte Medicina Diagnostica, Rio de Janeiro, Brazil, [4]Centro Universitario Augusto Motta, Rio de Janeiro, Brazil

Background: Cervical cancer (CC) is the fourth most common cancer in women worldwide. Cisplatin-based chemotherapy has been established as the standard treatment for advanced disease. However, these patients have survival rates lower than 50% and novel therapeutic strategies are needed. EGFR is an oncogene overexpressed in CC. In addition, it was reported that thrombin transactivates EGFR in other models.

Aims: We have employed CC cell lines and malignant tissues to evaluate the role of EGFR, tissue factor (TF), factor VIIa (FVIIa) and protease activated receptor-2 (PAR2) in resistance to cisplatin.

Methods: The expression of EGFR and TF was evaluated by immunohistochemistry in malignant tissues biopsied from 11 patients. In CASKI and C33A cell lines, the expression of EGFR, TF and PAR2 was analyzed by qRT-PCR and Western Blot. SLIGKL-NH2 peptide and FVIIa were used as PAR2 agonists, while cetuximab was used as EGFR inhibitor. The activation of EGFR-ERK signaling pathway was monitored by Western Blot. The sensitivity to cisplatin was evaluated by cell death assays.

Results: The more aggressive cell line, CASKI, showed high expression levels of EGFR, TF and PAR2 when compared to C33A. PAR2 agonists activated ERK and EGFR, and induced expression of protumoral genes through an EGFR-dependent mechanism. PAR2 agonist peptide protected CASKI cells against apoptosis induced by cisplatin, while cetuximab reversed this phenomenon. Treatment of CASKI cells

with cetuximab also decreased TF expression levels, suggesting that EGFR activation upregulates TF. Lastly, analysis of TF and EGFR expression in malignant tissues showed that EGFR is expressed in all tumors, while TF is expressed in 8/11 tumors (73%).

Conclusions: Our results suggest that EGFR is an effector of TF/FVIIa/PAR2 pathway in CC cells, promoting chemoresistance. EGFR also upregulates TF expression, revealing the presence of a positive feedback loop. EGFR, TF and PAR2 emerge as novel targets for CC treatment.

PB 2288 | Monocyte Activation by Thrombin Leads to an Upregulation of Molecules Involved in Fibrinolysis

B. Thaler[1], P. Hohensinner[1], J. Baumgartner[1], C. Schörgenhofer[2], B. Jilma[2], M. Fischer[3,4], W. Speidl[1], J. Wojta[1,5]

[1]Medical University Vienna, Internal Medicine II, Vienna, Austria, [2]Medical University Vienna, Clinical Pharmacology, Vienna, Austria, [3]Medical University Vienna, Clinic for Blood Group Serology and Transfusion Medicine, Vienna, Austria, [4]Danube University Krems, Department for Health Science and Biomedicine, Krems, Austria, [5]Ludwig Boltzmann Cluster for Cardiovascular Research, Vienna, Austria

Background: Thrombin, a serine protease, plays a crucial role in hemostasis and inflammation. Next to its ability to activate fibrinogen, it also functions as a signal molecule via the activation of protease-activated receptors PAR1,3 and 4 on a variety of cell types including monocytes. Monocytes can be divided into three subsets: classical monocytes (CM, CD14++,CD16-), intermediate monocytes (IM, CD14++,CD16+) and non-classical monocytes (NCM, CD14+,CD16+).

Aims: The aim of this project was to evaluate how thrombin acts on monocytes and monocyte subsets in vivo and in vitro.

Methods: LPS treated and untreated whole blood samples were stained with antibodies against CD14, CD16 and PAR1, 3 and 4 and were analysed via flow cytometry. Moreover, whole blood samples were incubated with brefeldin A and were then stimulated with LPS for 4h. Subsequently, samples were stained for flow cytometry. In addition, monocytes were stimulated in vitro with TRAP-6 or additionally pre-treated with LPS and RNA was isolated for qPCRs. Furthermore, monocytes were isolated from blood samples of volunteers who received a dose of vorapaxar prior to LPS infusion and RNA was isolated for qPCRs.

Results: CD16 positive monocytes, namely IMs and NCMs have significantly more PAR1 compared to CMs. IMs also express significantly more PAR3 and NCM more than CMs. All three subsets show a similar expression pattern for PAR4. When monocytes are activated with LPS they respond with an upregulation of PARs on their surface in vitro and in vivo and experiments with brefeldin A showed that this might be because of an intracellular storage pool. When activated with LPS and stimulated with TRAP-6, monocytes react with an increased expression of PAI-1, uPA and TFPI. When PAR1 activation is blocked by vorapaxar in vivo, PAI-1 and TFPI are significantly down regulated.

Conclusions: In conclusion, based on our data, thrombin is not just involved in coagulation and inflammation but also activates fibrinolytic genes in monocytes.

PB 2289 | Activated Protein C (APC) via PAR1 Protects Neurons from Death in the Model of Neuroinflammation in vitro

I. Babkina[1], L. Gorbacheva[2], S. Strukova[1], V. Pinelis[3], G. Reiser[4]

[1]Lomonosov Moscow State University, Faculty of Biology, Department of Physiology, Moscow, Russian Federation, [2]Lomonosov Moscow State University; Pirogov Russian National Research Medical University, Department of Physiology, Moscow, Russian Federation, [3]Scientific Center of Children's Health, Ministry of Health of Russian Federation, Moscow, Russian Federation, [4]Otto-von-Guericke University, Institute for Inflammation and Neurodegeneration, Magdeburg, Germany

Background: The hemostasis system is involved in important processes: inflammation, tissue repair, clot formation, and others. Serine proteases, thrombin and activated protein C (APC) play an important role in regulation of the inflammatory process. These proteases via the activation of specific protease-activated receptors (PAR) demonstrate the multidirectional effect due to biased agonism. Activation of PAR1 may be realized by peptides - analogs „tethered ligand". At contrast to thrombin isn't clear what types of peptides can demonstrate the protective effect on cells like APC.

Aims: The aim of this study is to investigate the influence of APC and synthetic peptide, liberated by APC from PAR1 on neurons in the model of neuroinflammation induced by the toxic effects of endotoxin-activated mast cells.

Methods: The effects of APC (10 nM) and peptide NPNDKYEPF-amide (AP9, 10 μM) on survival of neurons were estimated at toxicity induced by the lipopolysaccharide (LPS)-activated mast cells. Morphological assay of neuronal death by Syto-13 (vital dye), Hoechst 33342 (apoptosis) and EthD (necrosis).

Results: Using a model of the neuroinflammation we shown that APC and AP9 protect neurons from death induced by LPS-activated mast cells. The pretreatment activated mast cells with APC(10nM) or AP9 (10μM) decreased the number of apoptotic neurons to 1,9 and 1,8 fold, respectively. Receptor mechanism of APC and AP9 action was identified by the blocking of PAR1 on mast cells or neurons by anti-PAR1 antibodies or PAR1-inhibitor SCH 79797. We shown that the blockage of PAR1 abolished protective effects of APC and AP9 and increased apoptotic cells at 1,4 and 2,8 fold, respectively. Thus, PAR1 was required for the protective effect of the APC and AP9.

Conclusions: Thus, at the first time we have demonstrated the neuroprotective effects of APC and AP9 in the neuroinflammation. The protective effects of APC and AP9 on mast cells and neurons are the same and realized through PAR1. Thus, the new peptide AP9 is a functional analog of APC.

PB 2290 | Role of Protease-activated Receptor 4 in Regulating Platelet-leukocyte Interactions in Whole Blood

R.A. Rigg[1], A. Mitrugno[1], L.D. Healy[1], A.T.P. Ngo[1], M.T. Duvernay[2], C.W. Lindsley[2,3], H.E. Hamm[3], A. Gruber[1], O.J.T. McCarty[1]

[1]*Oregon Health & Science University, Portland, United States,* [2]*Vanderbilt University School of Medicine, Nashville, United States,* [3]*Vanderbilt University, Nashville, United States*

Background: Activated platelets bind leukocytes such as neutrophils and monocytes via expression of P-selectin on the platelet surface, which binds to leukocyte PSGL-1. Platelet aggregation to monocytes or neutrophils may be a more sensitive marker of disease states such as atherothrombosis than platelet-platelet aggregation. The thrombin receptor PAR-4 is an emerging target in thrombosis, although the effect of PAR-4 inhibition on platelet-leukocyte interactions is unknown.
Aims: This project aims to determine the effect of PAR-4 inhibition on platelet P-selectin expression, dense granule release, and platelet binding to neutrophils and monocytes.
Methods: Novel small molecule PAR-4 inhibitors were used to determine the role of PAR-4 in platelet activation, dense granule secretion, and platelet-leukocyte binding. Platelet dense granule secretion was assessed by luminescent ATP detection assay. Flow cytometric assays in washed platelets or whole blood were used to determine platelet P-selectin expression and platelet-leukocyte interactions using markers for platelets, neutrophils, and monocytes.
Results: Inhibition of PAR-4 impaired P-selectin expression following activation by PAR-4 agonist peptide but not by PAR-1 agonist peptide or collagen-related peptide (CRP), demonstrating inhibitor specificity. Platelet P-selectin expression induced by low but not high concentrations of thrombin was impaired by PAR-4 inhibitors. Platelet binding to neutrophils or monocytes was also impaired by PAR-4 inhibitors following activation by PAR-4 agonist peptide but not by PAR-1 agonist peptide or CRP. PAR-4 inhibitors demonstrated a similar inhibition of platelet dense granule secretion following stimulation with PAR-4 agonist peptide or low concentration thrombin but not PAR-1 agonist peptide or CRP.
Conclusions: Our results demonstrate inhibition of PAR-4 via small molecule inhibitors impairs platelet P-selectin expression, dense granule release, and platelet-neutrophil and platelet-monocyte interactions.

PB 2291 | Activation of PAR2 by Factor Xa Increases the Permeability across Cultured Endothelial Cell Monolayers

N. Benelhaj[1], A. Maraveyas[1], M. Johnson[1], C. Ettelaie[2]

[1]*University of Hull, Hull York Medical School, Hull, United Kingdom,* [2]*Univeristy of Hull, School of Life Sciences, Hull, United Kingdom*

Background: It has been shown recently that activated factor Xa (fXa) exerts direct influences on a wide variety of cells through activation of protease activated receptor 2 (PAR2). In this study, we have explored the influence of PAR2 activation on the permeability of human artery endothelial cells, and compared this to the outcome from incubation with VEGF.
Aims: To examine the influence of activation of PAR2 on the permeability of endothelial cell monolayer.
Methods: Human coronary artery endothelial cells (6×10^4) were seeded out within Transwells® with permeable membrane (pore size 3 μm) and placed in 24-well plates and cultured in endothelial growth medium for 4 days to attain impermeable monolayers. The cells were then adapted to serum-free medium for 2 h prior to assaying. To assess the change in the permeability across the monolayer, blue dextran MW 2×10^6 (1 μg/ml final concentration) was added to the upper chamber. The cells were then incubated with PAR2-agonist peptide (AP) (SLIGKV-NH; 20 μM), fXa (10 nM), VEGF (25 ng/ml) or used without activation. The activator reagents were added to the upper chambers and incubated at 37°C for up to 60 min. The seepage of dextran blue across the monolayers was then monitored by measuring the absorption of the medium in the lower chambers at 640 nm.
Results: The permeability of endothelial cell monolayer progressively increased on incubation with PAR2-AP reaching 36% and 45% at 15 and 30 min, respectively. Furthermore, incubation of the endothelial cell monolayer with fXa resulted in a delayed increase in permeability, reaching < 2% and 85% at 15 and 30 min, respectively. Finally, incubation of cells with VEGF induced a rapid but transient increase in permeability reaching 82% and 60% at 15 and 30 min, respectively.
Conclusions: In conclusion the activation of PAR2 on endothelial cells either through fXa activity or using a synthetic activator peptide promotes endothelial cell permeability which is comparable to that observed by using VEGF.

PB 2292 | The Influences of Diabetes and Inflammation on the Effects of Thrombin and Activated Protein C on Mast Cell Secretion

I. Goliako[1], L. Gorbacheva[1,2]

[1]*Lomonosov State University, Department of Physiology, Moscow, Russian Federation,* [2]*Pirogov Russian National Research Medical University of Ministry of Healthcare of the Russian Federation, Department of Physiology, Moscow, Russian Federation*

Background: According to World Health Organization, over 422 million people have diabetes. This disease has many complications such as retinopathy, nephropathy, diabetic foot ulcers, etc. Most of them are accompanied with inflammation. Mast cells (MC) are important participants of inflammatory response. It is known serine proteases of hemostasis via protease-activated receptors (PAR) regulate the activity of mast cells. But it isn´t clear what role of thrombin (Th) and activated protein C (APC) play in the regulation of mast cell functions at diabetes.
Aims: The aim of this work is to study the influence of diabetes on the Th and APC-regulated secretion of MC at inflammation.

Methods: The experiment was performed on the male Wistar rats (250-300g). Diabetes was induced by a single injection of streptozotocin (STZ, 60 mg/kg). Inflammation was modulated by 4% thioglycolate. MC were obtained from rats peritoneal cavity. The level of MC´s secretion was estimated by the analyze of released β-hexosaminidase from cells.
Results: The single administration of STZ leads to the development of diabetes after week and the increase of the plasma glucose levels and the decrease of the body weight compared to control group rats confirms this. At present study we found inflammation leads to increase a spontaneous secretion of MC at 2-fold. At the same time the diabetes doesn´t influence on a spontaneous secretion of MC. The effects of Th (50nM) and APC (10nM) on MC secretion are different at inflammation and diabetes. The proteases induce the raise of MC secretion at inflammation, but at diabetes Th and APC lead to lower the secretion of MC compared to control rats. The analyze of the proteases effects on MC at inflammation and diabetes at the same time shows that the MC´s responses are similar to their response at diabetes alone, while the spontaneous secretion is similar to their reactions at inflammation.
Conclusions: Thus, the impact of diabetes on the effects of PAR1-agonists is more pronounced with compare to inflammation.

DIAGNOSTICS AND OMICS

PB 399 | Failure of Wells Score and D-dimer to Safely Exclude Diagnosis of Deep Vein Thrombosis: A Single Centre Experience of over 3500 Patients

S. Badle[1], E. Friedman[2], L. Bowles[2], P. MacCallum[1]

[1]Barts and the London School of Medicine and Dentistry, Queen Mary University of London, London, United Kingdom, [2]Barts Health NHS Trust, London, United Kingdom

Background: In England diagnosis of deep vein thrombosis (DVT) is guided by the National Institute of Health and Care Excellence (NICE) recommendations that include a 2-level Wells score and D-dimer testing. Patients with Wells score < 2 (DVT unlikely) and negative D-dimer (< 500 μg/L) may be discharged without compression ultrasonography (CUS). DVT diagnosis at the Royal London Hospital includes additional consideration of risk factors before CUS is omitted. The resulting additional CUS scans enabled a comparison of this diagnostic pathway with that of NICE.
Aims: To estimate the failure rate for proximal DVT diagnosis had NICE guidance been followed using Wells score < 2 and D-dimer < 500 μg/L to omit CUS.
Methods: Data obtained from referrals to the DVT diagnostic service included patient demographics, DVT risk factors, Wells score and D-dimer. Data were analysed using MS Excel. We simulated a patient pathway to estimate diagnostic failure rate in the Wells unlikely group with negative D-dimer.
Results: 3837 referrals were made from 2010 to 2016. Upper limb DVT referrals or those with incomplete D-dimer or Wells score data (n=276) were excluded. Of 3561 referrals included, 3381 (95%) were scanned one or more times. 360 DVTs were diagnosed on 4282 scans. DVTs were more prevalent in those aged < 50 years compared to those aged >50 years (IR 12.0 v 8.6, p=0.009), with an overall median age of 53 years. In the Wells unlikely group with negative D-dimer (n=1156), 27 DVTs would have been missed had NICE guidance been followed (failure rate 2.3%; 95% CI 1.5-3.4%). In patients aged < 50 years the failure rate was higher (3.6%; 95% CI 2.3-5.3%, p=0.12).
Conclusions: Following NICE guidelines would have reduced the proportion of patients scanned from 95% to 70% but DVTs would have been missed in an unacceptably high number of patients. A possible explanation for this may be the higher prevalence of DVT in the younger patients. We suggest considering specific risk factors in addition to the Wells score before omission of CUS.

PB 400 | Residual Vein Thrombus Does Not Predict for Recurrent Vein Thrombosis in the ASPIRE Study

T. Brighton[1], A. Bosco[1], K. Robedo[2], R. Mister[2], W. Hague[2], A. Kirby[2], J. Eikelboom[3], J. Simes[2]

[1]Prince of Wales Hospital, Haematology, SEALS, Sydney, Australia, [2]NHMRC Clinical Trial Centre, Sydney, Australia, [3]McMaster University/Hamilton General Hospital, Hamilton, Canada

Background: In other studies Residual Vein Thrombosis (RVT) as assessed by ultrasound has been associated with recurrent vein thrombosis, other vascular events and mortality.
Aims: We examined whether RVT in the ASPIRE was associated with subsequent clinical events.
Methods: In the ASPIRE study 822 patients who had completed 6-24 months of anticoagulant therapy after a first unprovoked VTE were randomized to aspirin, 100 mg daily, or placebo for up to 4 years. At randomisation all patients with deep vein thrombosis (DVT) undertook an ultrasound assessment for RVT. Sites recorded the presence of RVT in local CRF. Additionally RVT reports were retrieved and reviewed for the presence and extent of RVT by 2 authors (TAB, AMB). The association of RVT with recurrent vein thrombosis was evaluated using Cox regression models.
Results: In the ASPIRE study, DVT was present in 583 of 822 patients (71%) enrolled. Sites recorded RVT data in 580 patients. Ultrasounds reports were available and reviewed in 412 patients with RVT reported in 265 (64%). The presence of RVT was more prevalent in males. There are 72 first recurrent VTE events, in the 412 patients with residual thrombosis data: 32/147 (22%) without RVT and 40/265 (15%) with RVT. There was no association between presence of RVT and time to first recurrent VTE event when adjusted for study treatment (HR = 0.76, 95% CI 0.48-1.21, p=0.25). Analysis of the 580 patients with site-recorded RVT information showed similar results. There was also no association between RVT and major vascular events (HR 0.88, 95% CI 0.56-1.38) or net clinical benefit (HR 0.96, 95% CI 0.62-1.47) after adjustment for treatment.

Conclusions: In patients who had completed anticoagulation therapy after unprovoked VTE the presence and the extent of RVT was not associated with recurrent vein thrombosis or other clinically important events.

PB 401 | Utility of Thromboelastometry Analysis in Patients with Mild Bleedings Disorders

A. Wieland Greguare-Sander[1], W.A. Wuillemin[1,2], M. Nagler[3]

[1]*Luzerner Kantonsspital, Luzern, Switzerland,* [2]*University of Bern, Bern, Switzerland,* [3]*Inselspital, Bern University Hospital, and University of Bern, Department of Haematology and Central Haematology Laboratory, Bern, Switzerland*

Background: Viscoelastic methods are regarded as promising concept to overcome the limitations of conventional laboratory assays in patients with haemostatic disorders, particularly in the perioperative setting. Their performance regarding frequently occurring mild bleeding disorders (MBD) such as von Willebrand disease, platelet function disorder, or mild haemophilia is however unknown.

Aims: We conducted a prospective cross-sectional study to investigate the value of thromboelastometry analysis for diagnosis and prognosis of MBD.

Methods: Thromboelastometry analysis (ROTEM®) was conducted in all consecutive patients referred between January 2011 and March 2013 with a suspected bleeding disorder. Diagnostic work-up was done according to current guidelines.

Results: MBD was diagnosed in 111 out of 217 patients (52.1%), median age was 40.1 years, IQR 28.9, 59.2; 67.6% were female. Possible or definite platelet function disorder was diagnosed in 50 patients (42.7%), von Willebrand disease (vWD) in 24 patients (11.1%), mild haemophilia in 4 patients (1.8%), mild factor XI deficiency in 2 patients (0.9%), low von Willebrand factor associated with blood group 0 in 13 patients (6.0%), anticoagulation treatment in 3 patients (1.4%), and a systemic disorder in 15 patients (6.9%). Presence of MBD was not associated with a significant difference in thromboelastometry parameters (CT EXTEM, MCF EXTEM, CT INTEM, MCF INTEM, MCF FIBTEM). In addition, no significant differences were observed with regard to categories of the ISTH bleeding assessment tool. Minor differences - all within the established ROTEM reference ranges - were noted for some MBD: mild haemophilia (MCF EXTEM, MCF INTEM, MCF FIBTEM), definite vWD type 1 (MCF FIBTEM), anticoagulation treatment (CT EXTEM), and systemic disorders (CT EXTEM).

Conclusions: Our data do not support the utility of thromboelastometry analysis for diagnosis, prognosis or management in patients with mild bleeding disorders, particularly in the perioperative setting.

PB 402 | Increased Maximum Lysis of ROTEM in Pregnancy: It Is Not Hyperfibrinolysis

J. Teryua[1], A. Shamshirsaz[2], H. Erfani[2], K. Fox[2], K. Bruzdoski[1], S.K. Hui[1], V. Kostousov[1]

[1]*Baylor College of Medicine/Texas Childrens Hospital, Pathology & Immunology, Houston, United States,* [2]*Baylor College of Medicine/Texas Childrens Hospital, Obstetrics and Gynecology, Houston, United States*

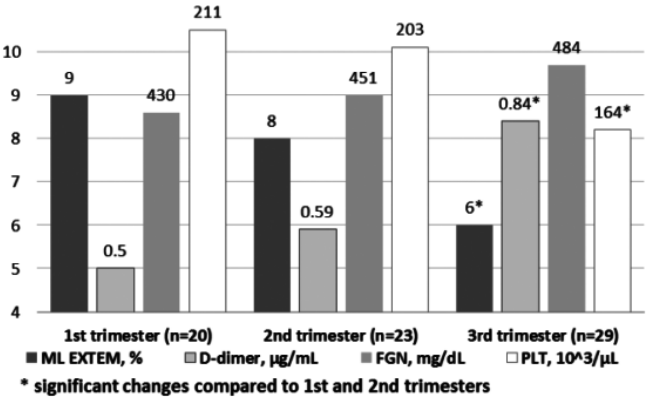

FIGURE 1 Changes in hemostatic tests across trimesters of pregnancy

Background: Thromboelastometry (ROTEM) analysis provides visual tracings of blood coagulation from clot formation, stabilization, until clot dissolution. While Maximum Lysis (ML) values on EXTEM >15% is usually attributed to hyperfibrinolysis, ML < 15% may still correlate with bleeding associated with excessive fibrinolysis.

Aims: The aim of the study was to evaluate ML in ROTEM variation during normal pregnancy and contribution of hemostatic system components in ML values.

Methods: Citrated blood was collected from 72 pregnant women of 32±4 years old and EXTEM, INTEM, and FIBTEM were performed on ROTEM (IL, USA), while routine coagulation tests were performed on STAR Evolution analyzer (Stago, USA) as a part of reference range establishment. Platelet count (PLT) was performed on Sysmex XE-5000 analyzer (Sysmex America, USA) in citrated specimen. All data are presented as mean±SD and data analysis was performed using one way ANOVA and Pearson correlation (SPSS v23, 2016, IBM, USA). P value of < 0.05 was considered as significant.

Results: There were 20 women in 1st (11±3 weeks of gestation), 23 in 2nd (21±5 weeks) and 29 in 3rd trimester (33±3 weeks) of pregnancy; no significant difference in ML EXTEM, fibrinogen (Fgn), PLT, or D-dimer was found between 1st and 2nd trimesters. ML EXTEM and PLT were lower, while Fgn and D-dimer were higher in the 3rd trimester (Figure 1). D-dimer and Fgn showed a negative correlation and PLT showed positive correlation with ML EXTEM or INTEM. ML showed the highest correlation with PLT to Fgn ratio (Table 1) and ML >10% is associated with average PLT/Fgn as 1:2, while ML < 5% with 1:3 ratio. ML FIBTEM was 3±2% in 1st trimester and 0% in 2nd and 3rd trimesters (p< 0.001).

TABLE 1 The correlation of ML with other hemostatic tests

Pearson correlation, p value	D-dimer	FGN	PLT	PLT/FGN ratio
ML EXTEM	-0.20, 0.09	-0.30, 0.001	0.41, <0.001	0.59, <0.001
ML INTEM	-0.29, 0.01	-0.37, 0.001	0.24, 0.04	0.56, <0.001

Conclusions: ML on EXTEM and INTEM in pregnant women does not reflect physiologic activity of fibrinolytic system as was estimated by D-dimer and ML FIBTEM remained 0. It rather reflects platelet clot retraction that is dependent on PLT to Fgn ratio in citrated plasma.

PB 403 | Significant von Willebrand Disease Can Be Missed if a von Willebrand Factor Activity Assay Is Not Performed

S. Platton

Barts Health NHS Trust, London, United Kingdom

Background: British Committee for Standards in Haematology guidelines for the diagnosis of von Willebrand disease (vWD) state that a diagnosis can be made when the von Willebrand factor (vWF) activity is less than 30iu/dL. On a recent World Federation of Hemophilia (WFH) twinning visit it was observed that some laboratories with restricted budgets may only perform assays for vWD in patients with reduced FVIII activity, and may only test for FVIII if the APTT is prolonged. In patients with prolonged APTT but normal FVIII and FIX, a diagnosis of "FXI or FXII deficiency" is assumed.

Aims: How many significant diagnoses would be missed if the observed regime was applied to samples already tested?

Methods: Results of 397 vWD screens performed over a 12 month period at our UK centre (including 147 samples from 108 patients with known vWD) were audited.

Results: 21 samples were found to have normal APTT (ratio ≤1.2) but reduced FVIII activity (< 50iu/dL), including 2 type 1 vWD, 6 mild vWF reductions, 12 type 2 vWD and one mild haemophilia A carrier.

26 samples had normal APTT and FVIII but low vWF antigen (< 50iu/dL): 2 type 1, 16 mild vWF reduction, 7 type 2 and one post Wilate.

21 samples had normal APTT, FVIII and vWF antigen but reduced vWF activity (< 50iu/dL): 5 mild vWF reduction, 10 type 2, 2 post Wilate and 4 normals.

Without a functional assay, only 10% of type 1 and 31% of type 2 patients would have been correctly identified as having vWD. Furthermore, 14% of type 1 and 9% of type 2 patients would have been misdiagnosed as having FXI or FXII deficiency. No patients with severe type 3 vWD would have been misdiagnosed.

Conclusions: When budgets are restricted, laboratories should use a functional activity assay for vWF such as that described in the Laboratory Manual available from the WFH in preference to a latex immunoassay, and should assay it in patients with a bleeding history regardless of the APTT or FVIII. If budgets are sufficient for a latex immunoassay, an activity assay is prefered to an antigenic one.

PB 404 | Validation of Flow Cytometric Mepacrine Uptake and CD63 Expression in the Diagnosis of Storage Pool Disease

I. van Asten[1], M. Blaauwgeers[2], L. Granneman[1], A. Huisman[1], G. Pasterkamp[1], H. Heijnen[1], S. Korporaal[1], R. Schutgens[2], R. Urbanus[1]

[1]University Medical Center Utrecht, Department of Clinical Chemistry and Haematology, Utrecht, The Netherlands, [2]University Medical Center Utrecht, Van Creveld Clinic, Utrecht, The Netherlands

Background: Storage Pool Disease (SPD) is a bleeding disorder characterized by a reduced number of platelet dense granules, resulting in impaired secondary platelet activation. Diagnosis of SPD depends on the measurement of platelet ADP content, since platelet aggregation is often normal in these patients. However, this test is time consuming, requires a large blood volume and cannot be performed in thrombocytopenia. Flow cytometric analysis of platelet uptake of mepacrine, a fluorescent acridine derivative with affinity for adenine nucleotides, and the dense granule marker CD63 have been suggested as alternatives, but these approaches lack standardization, which precludes their use in a diagnostic setting.

Aims: To compare standardized flow cytometric analysis of platelets mepacrine uptake and CD63 expression with measurement of platelet ADP content during the diagnostic workup for SPD.

Methods: Platelet dense granule content was assessed in 10 patients with known SPD with flow cytometry and TEM, and compared with platelet ADP content. Reference values for flow cytometry were based on the 2.5th percentile of the response in 60 healthy controls.

Results: All SPD patients had a reduced number of dense granules as determined with TEM. 8 out of 10 SPD patients showed decreased mepacrine uptake, whereas 9 out of 10 patients showed reduced CD63 expression after platelet stimulation. In contrast, only 5 out of 10 patients showed reduced P-selectin expression after platelet stimulation. Mepacrine binding was in good agreement with platelet ADP content (κ=0.722) and TEM (κ=0.800). Additionally, CD63 expression showed very good agreement with platelets ADP content (κ=0.851) and TEM (κ=0.900).

Conclusions: Standardized analysis of mepacrine uptake and CD63 expression with flow cytometry can be used to detect SPD in whole blood samples. Both require a minimal amount of blood and are promising tools in the diagnostic workup of SPD.

PB 405 | Post-analytical External Quality Assessment - Interpretation of UK NEQAS (Blood Coagulation) Results

I. Jennings, D. Kitchen, S. Kitchen, T. Woods, I. Walker

UK NEQAS (Blood Coagulation), Sheffield, United Kingdom

Background: External Quality Assessment (EQA) is a useful tool to improve and maintain standards of laboratory performance. EQA is usually directed at analytical processes, but evaluation of pre- and post-analytical phases is also required.

Aims: Post analytical processes are based on interpretation of results, and we describe here data from UK NEQAS for Blood Coagulation (BC) exercises in respect of data interpretation for screening tests, factor assays and genetic investigations.

TABLE 1

	Total number of patients, n	PE unlikely Wells score and negative AADD, n	PE prevalence, %	Mean age, y	Efficiency % (95% CI)	Failure rate % (95% CI)
All centers	6,756	2,347	22	56	33 (25-41)	0.89 (0.58-1.4)
D-dimer assays						
- INNOVANCE	1,458	402	18	63	25 (19-31)	0.25 (0.03-1.7)
- VIDAS	2,671	1,044	23	54	35 (23-43)	0.86 (0.44-1.6)
- STA-Liatest	613	189	31	61	30 (27-35)	0.46 (0.03-6.6)
- Tina-quant	2,014	712	25	53	35 (33-38)	1.4 (0.76-2.6)

Methods: Participants interpret INR, heparin dosage (HD) and D-Dimer data on their test result and brief patient details.

Results: For INRs >90% agreement on dosage is achieved in most exercises. In 1 exercise 73% of centres reported a patient adequately dosed and 26% overdosed -interpretation differed amongst centres using different reagents. For HD, a sample with 0.34u/ml anti-Xa activity was considered underdosed by 77% of 618 centres and adequate by 21% (of which 10% reported results below their therapeutic range). For D-Dimer, a sample which 93% of 641 centres reported as VTE unlikely was reported as VTE not excluded by 52% of centres using one reagent. There is >90% agreement in FVIII assay interpretations (normal or abnormal) when levels are normal or low, but for samples with borderline FVIII:C (44 -57u/dl) concurrence fell to 60% in one exercise. Sometimes interpretation of results does not correlate with reported reference ranges.

Historically, diagnostic errors up to 38% of centres were made in thrombophilia screening EQA; exercises in 2016 demonstrated >92% achieving a correct diagnosis. For centres performing genetic investigations for haemophilia, UK NEQAS BC exercises have shown interpretation failure rates average 2% in each survey, double the rate of analytical failures.

Conclusions: Post analytical EQA can highlight differences in reagent sensitivity, in use and application of reference ranges, and in interpretation of laboratory data, and is an important area in which standardisation and improvements are required.

PB 406 | Different D-dimer Assays Have Similar Performance Using the Age-adjusted Threshold for the Diagnosis of Pulmonary Embolism

N. Kraaijpoel[1], N. van Es[1], F.A. Klok[2], M.V. Huisman[2], P.M. Bossuyt[3], H.R. Büller[1]

[1]Academic Medical Center, University of Amsterdam, Vascular Medicine, Amsterdam, The Netherlands, [2]Leiden University Medical Center, Thrombosis and Haemostasis, Leiden, The Netherlands, [3]Academic Medical Center, University of Amsterdam, Clinical Epidemiology, Biostatistics, and Bioinformatics, Amsterdam, The Netherlands

Background: Among patients with clinically suspected pulmonary embolism (PE), imaging can safely be withheld based on a "PE unlikely" Wells score and a D-dimer below the age-adjusted D-dimer (AADD) threshold. Several D-dimer assays have been used to support AADD testing, but their performance in ruling out PE is unclear.

Aims: To compare the efficiency and failure rates of different D-dimer assays in ruling out PE using the AADD threshold.

Methods: Individual patient data from six prospective studies in which the diagnostic management of PE was guided by the Wells rule and D-dimer testing were used. The efficiency and failure rate of AADD testing were evaluated overall and for the four assays separately (INNOVANCE, VIDAS, STA-Liatest, and Tina-quant) in a one-stage random effects meta-analysis. Efficiency was defined as the proportion of patients in whom imaging could be withheld based on a "PE unlikely" Wells score and a D-dimer below the age-adjusted threshold, defined as ≤500 µg/L or as the patient's age times 10 µg/L in those >50 years. The failure rate was defined as the proportion of patients with a "PE unlikely" Wells score and negative AADD with confirmed venous thromboembolism (VTE) at baseline or during 3-month follow-up.

Results: Information on the D-dimer assay was available for 6,756 patients. The mean age was 56 years and 22% had PE. The efficiency ranged from 25% (95% CI 19-31%) for INNOVANCE to 35% (95% CI 33-38%) for Tina-quant (Table 1). Failure rates ranged from 0.25% (95% CI 0.03-6.6%) with INNOVANCE to 1.4% (95% CI 0.76-2.6%) for Tina-quant. In a multivariable analysis, adjusting for age, sex, immobilization, previous VTE, and cancer, no significant differences in efficiency between the assays were found (Table 2).

TABLE 2

D-dimer assay	Odds ratio* for efficiency (95% CI)
- INNOVANCE	1 (reference)
- VIDAS	1.1 (0.77-1.4)
- STA-Liatest	1.0 (0.82-1.3)
- Tina-quant	1.2 (0.89-1.6)

* adjusted for age, sex, immobilization, previous VTE, and cancer.

Conclusions: In this indirect comparison, all four evaluated D-dimer assays had a comparable efficiency and safety. Hence, for an AADD strategy all assays can be applied.

PB 407 | Safety of Multidetector Computed Tomography Pulmonary Angiography to Exclude Pulmonary Embolism in Patients with a Likely Pretest Clinical Probability

H. Robert-Ebadi[1], G. Le Gal[2], M. Righini[1]

[1]*Geneva University Hospitals and Faculty of Medicine, Division of Angiology and Hemostasis, Geneva, Switzerland,* [2]*Ottawa Hospital Research Institute, Ottawa, Canada*

Background: In patients with suspected pulmonary embolism (PE) classified as having a likely pre-test clinical probability, the necessity of performing additional testing after a negative multidetector computed tomography pulmonary angiography (CTPA) remains a matter of debate.

Aims: The aim of this study was to assess the safety of excluding PE by CTPA without additional imaging in patients with a likely pre-test probability of PE.

Methods: We retrospectively analysed patients included in two multicentre management outcome studies that assessed diagnostic algorithms for PE diagnosis.

Results: 2522 outpatients with suspected PE were available for analysis. Out of these 2522 patients, 845 had a *likely* clinical probability as assessed by the simplified revised Geneva score. Of all these patients, 314 had the diagnosis of PE excluded by a negative CTPA without additional testing, and were left without anticoagulant treatment and followed-up for three months. Two patients presented with a venous thromboembolic event (VTE) during follow-up. Therefore, the three-month VTE risk in likely probability patients after a negative CTPA was of 2 / 314 (0.6%; 95% CI 0.2%-2.3%).

Conclusions: In outpatients with suspected PE and a likely clinical probability, CTPA seems to be able to safely exclude PE, with a low three-month venous thromboembolic event rate, similar to the VTE rate following the gold standard pulmonary angiography. Additionnal testing may thus not be necessary in these patients.

PB 408 | Familial Multiple Coagulation Factor Deficiencies - Need for Deeper Clinical and Scientific Assessment

B. Preisler, B. Pezeshkpoor, I. Schwarze, R. Kuhlemann, J. Junen, R. Maurer, I. Radermacher, L. Rothbrust, J. Beckedahl, J. Oldenburg, A. Pavlova

University Hospital Bonn, Institute of Exp. Hematology and Transfusion Medicine, Bonn, Germany

Background: The familial multiple coagulation factor deficiencies (FMCFDs) are a group of rare haemostatic disorders of genetic origin, where deficiency of more than one coagulation factor is diagnosed. They may present significant challenges in laboratory diagnosis, prediction of bleeding risk and in treatment.

Aims: Collecting laboratory and clinical data of FMCFD patients.

Methods: NGS of FMCFD patients.

Results: 67 FMCFDs patients, categorized in three groups, have been diagnosed in our center. The 1-st group covers FMCFD patients arising from co-inheritance of independent coagulation factor deficiencies - FVII/FX(7), FV/FVII(4), FVIII/FG (3), FVII/FVIII(2), FVIII/FXI(2), FX/FV(2), FVIII/FX(1), FVIII/FIX(1), FXI/VW(1), FV/VWF(1), FXI/FXIII (1), FXI/FG(1), FX/FXIII(1), FII/FXI(1), FII/FVII(1), FV/FG(1), PC/PS(1), PC/FG(1), AT/VWF(2). The 2-nd group comprises FMCFDs arising from a single genetic defect, best represented with combined FV/FVIII(21) deficiency. The identified molecular genetic defects lay in either *LMAN1 or MCFD2* genes. Combined VKDCF deficiency is the second representative of the group: deficiency is connected with mutations either in *GGCX or VKORC1* genes. The 3-rd group FMCFDs includes deficiency due to cytogenetic abnormalities as large deletion of the chromosome 13 end, including FVII and FX (5).

Conclusions: As FMCFDs is an extreme rare disorder, collecting and deeper investigation of patients with such defects in the blood coagulation will provide important insights into the pathogenesis of the single coagulation factor deficiency disorders, will improve the clinical management of these patients and will facilitate prediction of inheritance patterns within kindred. All this emphasizes a clear need for co-operation between clinicians and scientists and establishment of FMCFDs as register allowing collection of valuable information on these disorders with respect to prevalence, diagnostic events, clinical manifestations, treatment strategies, as well as disease and treatment-related complications.

PB 409 | Performance of Anti-factor Xa Heparin Assays in External Quality Control Surveys

C. Bon[1,2], G. Matar[1], R. Meley[3], C. Sotta[1], J.C. Eynard[1], B. Poggi[1,2]

[1]*PROBIOQUAL, Lyon, France,* [2]*Hôpital de la Croix-Rousse, Service de Biochimie et Biologie Moléculaire, Lyon, France,* [3]*Hôpital Nord, Service d'Hématologie, St Etienne, France*

Background: The treatment of patients with, both unfractionated heparin (UFH) and low-molecular weight heparin (LMWH), is mostly monitored by the measurement of plasma anti-Factor X_a activity. The heparin assays use various reagents and methodologies.

Aims: The aim of this work is to describe the state-of-the-art of the main commercial methods and to have an overview of their standardization, by using external quality assessment (EQA) results of UFH and LMWH assays, obtained from ProBioQual (PBQ), a French proficiency testing association.

Methods: Participating laboratories (360 in 2016) received, per year, 16 human citrated plasmas lyophilized specimens (8 spiked with UFH;

8 with LMWH) at 4 different concentration levels. Statistical evaluation was performed according to the ISO guideline 13528 by applying robust algorithm A to calculate two consensus values: the mean of all participant's results (AP) or of peer group (PG). The methods imprecision is quantified by the inter-laboratories coefficient of variation (CV), and the inaccuracy is evaluated as median (bias50) and 90th percentile (bias90) bias of laboratory results from consensus value (AP or PG).

Results: The inter-laboratories dispersion is inversely proportional to the UFH level: the AP CV is 25.6% for 0.21 U/mL and 6.3% for 0.69 U/mL. This inverse relationship is less pronounced for LMWH: AP CV decreases from 12% to 6.9% for a range of 0.40 -1.00 U/mL.

The AP bias90 (41.10%) is much higher than the PG bias90 (25%) for 0.20 U/mL UFH. Between 0.39-1.03 U/mL, the AP and PG bias90 decrease, respectively, from 19.45% to 13.33% and from 15.59% to 10.21%. For LMWH, AP bias90 are always higher than the PG bias90, showing large dispersion between the different methods consensus values.

Conclusions: In this work we show that methods imprecision and inaccuracy are the highest for the lowest UFH and LMWH levels. In the EQA surveys, laboratories results should be assessed using, in priority, the PG consensus values.

PB 410 | Ex-vivo Plasma Clot Formation and Lysis as a Universal Measure for Anticoagulation in Patients on Vitamin-K-antagonist, Dabigatran, Rivaroxaban, Apixaban, or Low-molecular-Weight Heparin

O. Königsbrügge[1], G. Weigel[2], P. Quehenberger[3], I. Pabinger[1], C. Ay[1]

[1]*Medical University of Vienna, Medicine I, Clinical Division of Hematology and Hemostaseology, Vienna, Austria,* [2]*Medical University of Innsbruck, Central Institute of Medical and Chemical Laboratory Diagnostics, Innsbruck, Austria,* [3]*Medical University of Vienna, Clinical Institute of Medical and Chemical Laboratory Diagnostics, Vienna, Austria*

Background: There are specific tests for quantifying anticoagulation for vitamin-K-antagonists (VKA), low-molecular weight heparins (LMWH), and direct oral anticoagulants (DOACs) separately, but there is no consistent test across all.

Aims: To quantify ex-vivo plasma clot formation and lysis with one test, consistently across different anticoagulants.

Methods: We obtained citrate plasma samples from 328 atrial fibrillation (AF) patients on anticoagulation and 24 control AF patients but no anticoagulation. Anticoagulation intensity was measured by INR for VKA patients (all phenprocoumon), anti-Xa for LMWH patients, and by mass spectrometry for DOAC patients. Plasma clot formation and lysis were read on a photometer after addition of an activation mix (tissue factor 2pmol/l and tissue plasminogen activator 333ng/ml). We used linear regression and ANCOVA for correlation analysis.

Results: On treatment INR, anti-Xa levels, and DOAC concentrations are provided in table 1. The lag phase of clot formation was significantly prolonged (p< 0.001) in anticoagulated samples and positively correlated to specific measures of the respective anticoagulant (figure 1). The maximum rate and peak clot turbidity of clot formation were

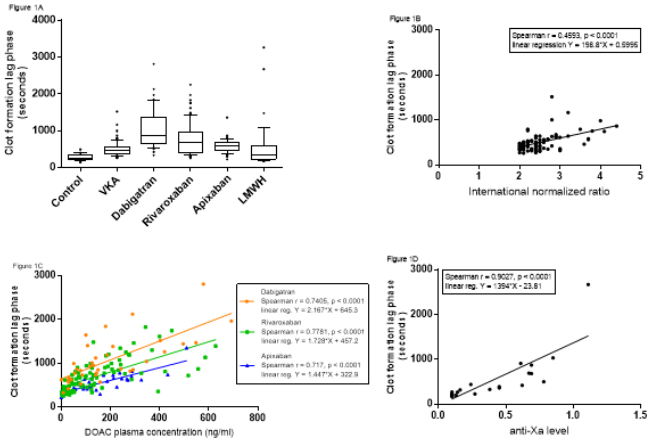

FIGURE (A) Clot formation lag phase comparison. (B) Lag phase versus INR in VKA patients, (C) versus DOAC concentration and (D) versus anti-Xa levels in LMWH

TABLE 1 Characteristics of patients on anticoagulation and controls

Characteristics, median (25th to 75th percentile)	Control (N=24)	Vitamin-K-antagonist (N=94)	Dabigatran (N=40)	Rivaroxaban (N=110)	Apixaban (N=42)	Low-molecular-weight heparin (N=42)
Age (years)	64.5 (59 - 73)	73 (68 - 79)	71.5 (62 - 79.5)	71 (66 - 78)	72 (64 - 75)	70 (63 - 76)
BMI (kg/m2)	27.6 (25.1 - 29.1)	27.8 (24.7 - 31.6)	27.2 (25.7 - 29.3)	27.9 (24.3 - 32.6)	27.2 (22.5 - 29.3)	26.2 (24.0 - 28.9)
CHA2DS2-Vasc	2 (2-4)	4 (3-5)	5 (3-7)	4 (2-6)	4 (3-5)	3 (2-4)
HAS-BLED	1 (1-2)	2 (1-2)	2 (2-3)	2 (1-2)	2 (1-2)	2 (1-3)
INR	1.1 (1.0 - 1.2)	2.4 (2.1 - 2.7)	n.a.	n.a.	n.a.	n.a.
DOAC concentration (ng/ml)	n.a.	n.a.	135.5 (54.3 - 280)	99.55 (33.3 - 205.5)	158.0 (94.6 - 246)	n.a.
Anti-Xa (U/ml)	n.a.	n.a.	n.a.	1.51 (0.49 - 1.51)	1.44 (0.88 - 1.51)	0.38 (0.1 - 0.69)
Time since drug administration (hours)	n.a.	22.0 (4.0 - 25.5)	3.9 (3.0 - 15.33)	9.66 (2.33 - 24.5)	4.75 (2.55 - 13.75)	5.25 (3 - 18)

significantly lower in anticoagulated samples (p=0.002 and p=0.045) and dependent on INR, anti-Xa, and DOAC concentration, respectively. Clot lysis time was not significantly different between controls and anticoagulated samples (p=0.3), but correlated positively with anti-Xa levels in LMWH samples (r=0.77, p< 0.001). At corresponding plasma concentrations, samples on dabigatran had significantly longer lag phases (p< 0.001), slower clot formation (p=0.002), lower peak clot turbidities (p=0.003), and longer clot lysis times (p=0.012) than samples on rivaroxaban and apixaban.

Conclusions: Ex-vivo plasma clot formation and lysis can directly compare between different anticoagulants. At corresponding drug concentrations, dabigatran exerted a stronger inhibition of clot formation than rivaroxaban and apixaban.

PB 411 | Thrombin Generation Response of rFVIIa in Haemophilia A Patient Plasma when Using Different Triggers and Phospholipids

L.F. Larsen, H. Østergaard, M.B. Hermit, V. Lind, M. Ezban

Global Research, Novo Nordisk A/S, Måløv, Denmark

Background: NovoSeven® (rFVIIa) shows high efficacy in the treatment of bleedings in haemophilia patients with inhibitors. In the standard commercial thrombin generation assay CAT (Calibrated Automated Thrombogram) using platelet poor plasma therapeutic relevant rFVIIa levels is expected to show a poor response [Turecek 2003]. We tested combinations of different triggers and phospholipids (PL) in the CAT assay including PL vesicles containing phosphatidic acid (PA) which has been reported to enhance the rate of FX activation by FVIIa [Tavoosi 2013].

Aims: To investigate the influence of different triggers and phospholipids on the thrombin generation response when monitoring therapeutic relevant rFVIIa levels in plasma from haemophilia A (HA) patients.

Methods: HA plasma (80 µL) spiked with rFVIIa (0-500 nM) was mixed with different combinations of TF/FXIa and commercial PL preparations/in-house prepared PL vesicles containing PS (phosphatidylserine, PC (phospatidylcholine), PE (phosphatidylethanolamine) and/or PA (4-60 µM). PS:PC (20:80), PS:PC:PE (20:40:40), PS:PA:PE (5:25:70), PS:PC:PA:PE (2:40:28:30). Thrombin generation was initiated by addition of a fluorogenic thrombin substrate containing CaCl2 and CAT was determined.

Results: The commercial PPP Reagent Low (1 pM TF + 4 µM PL, Thrombinoscope) resulted in a weak dose-response of rFVIIa. The same was observed for FXIa in combination with a commercial PL reagent

(4 µM PL, Rossix AB). For PS:PC:PE and PS:PC:PA:PE concentrations >20 µM in combination with FXIa the analytical window increased significantly, however with only a slight improvement in sensitivity. High concentrations of soluble TF (sTF) improved both the analytical window and the sensitivity significantly.

Conclusions: The dose-response of rFVIIa in thrombin generation assays is highly dependent on the trigger and the PL source used. With nM concentrations of sTF an assay with a significantly improved analytical window and a sensitivity of 1 nM rFVIIa was obtained.

PB 412 | Performances of the Hydragel 5 von Willebrand Multimers - A New within-Day von Willebrand Factor (VWF) Multimer Screening Method

A.E. Bowyer[1], K.J. Goodfellow[1], G. Nouadje[2], G. Beaulieu[2], S. Kitchen[1], M. Makris[1]

[1]Sheffield Haemophilia and Thrombosis Centre, Department of Coagulation, Sheffield, United Kingdom, [2]Sebia, Research and Development Department, Lisses, France

Background: Analysis of VWF multimers is essential for the diagnosis and classification of von Willebrand disease (VWD). Multimers analysis is currently non-standardised and laborious. The local in-house method takes 4 days to produce interpretable results. A novel semi-automated within-day VWF multimer test has recently become available.

Aims: The aim of this study was to assess the performance of the semi-automated Hydragel 5 VW multimers system (Sebia) as compared to in-house multimers in VWD diagnosis and classification.

Methods: Multimers analysis of 188 well characterised VWD patients or normal donors were performed in parallel. The in-house method routinely used 1.6% SDS agarose gel electrophoresis, followed by visualisation with alkaline phosphatase-conjugated antibody. Hydragel 5 VWF multimers were performed on the Hydrasys 2 semi-automated system. Patients were grouped according to the ratio of VWF activity/antigen with a ratio of < 0.6 equating to type 2 VWD.

Results: Concordance of 96.8% was demonstrated between methods. A normal multimer pattern was observed using Hydragel in all normal donors (n=31), 28/29 non-VWD patients, 53/54 type 1 VWD, 18/21 2M and all type 2N (n=10). Loss of multimers was observed in all types 2A (n=30), 2B (n=9) and 3 VWD (n=4). Five samples (including 3 type 2M patients) had normal multimer distribution using the in-house method and a slight loss of high molecular weight multimers (HMWM) with the Hydragel 5 VW multimers.

Conclusions: The Hydragel 5 von Willebrand multimers demonstrated excellent agreement with the in-house method for VWD classification and subtyping. The presence of a unique pattern for some type 2M individuals using the Hydragel 5 von Willebrand multimers may be related to the genetic mutation of the patient. Hydragel 5 von Willebrand multimers is suitable for inclusion in a routine screening program for VWD. The method saved on staff time, produced highly reproducible results and allowed for easy interpretation due to in-built densitometry.

PB 413 | The Selective Use of Computer-assisted Strain Gauge Plethysmography as an Additional Screening Test for Suspected DVT Can Decrease the Need for Compression Ultrasonography: A Validation Study

A. Hughes[1], B. Hall[1], C. Smith[1], V. Webb[1], J. King[1], K. Jennings[1], G. Page[1], S. Macdonald[1], F. Charova[2]

[1]North East London Foundation Trust, Community Haematology, Brentwood, United Kingdom, [2]Mid Essex Hospitals, Radiology Department, Chelmsford, United Kingdom

Background: In 2009 a DVT diagnostic service was set up in a community hospital in Brentwood, Essex, UK. Patients with suspected DVTs were screened with a Wells score (WS) and Point of Care (POC) quantitative d-dimer (DD). Compression Ultrasound (CUS) was carried out on site as per standard protocols. In the first two years >90% of CUS were negative in patients with discordance between the WS and DD. In two previous retrospective studies we showed that Strain Gauge Plethysmography (SGP), used as an additional screening test, had the potential to decrease the need for CUS as a negative SGP was highly predictive of a negative CUS.

Aims: To confirm in a new, prospective study whether the selective use of SGP in patients with discordance between the initial WS and DD screening tests could safely decrease the need for CUS.

Methods: From Jan 2015 to Mar 2016 with a revised protocol we assessed 615 patients presenting to a community clinic with suspected DVTs. All patients were screened with a 2-level WS and a POC DD. Patients with concordant negative results were discharged and those with concordant positive results had proximal CUS. Patients with discordance between the WS and DD had SGP performed. Patients with negative SGP were discharged and had a 90-day follow up to determine the subsequent incidence of VTE. If the SGP was positive a CUS was done.

Results: 237/615 patients (38%) had discordant screening tests. In 153 (65%) there was a valid SGP result of which 114 (74%) were negative. 101/114 were followed up at 90-days and none had developed a VTE. 13 patients could not be contacted but had not been referred back with suspected VTE.

Conclusions: With discordance between the WS and DD a negative SGP can safely exclude a proximal DVT without the need for CUS. In this group the CUS scanning rate was decreased by 48% improving the efficiency and cost effectiveness of the service. Although SGP was either not tolerated or produced an invalid result in ~1/3rd of patients there was still net overall benefit.

PB 414 | Semi-automated Platelet Aggregometry Employing the Sysmex CS-2x00; Preliminary Findings in a Multi-centre Study

A.N. McCormick[1], S. Platton[2], M. Bukht[2], D.A. Gurney[3], G.W. Moore[1]

[1]Viapath Analytics at Guy's & St. Thomas' Hospitals, Diagnostic Haemostasis and Thrombosis, London, United Kingdom, [2]Barts Health NHS Trust, London, United Kingdom, [3]Bristol Royal Infirmary, Bristol, United Kingdom

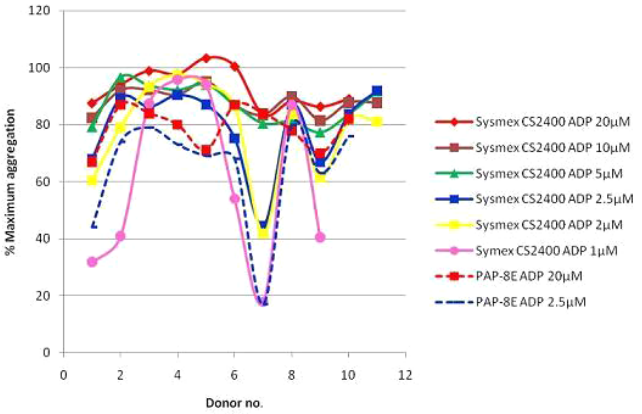

FIGURE 1 % Maximum aggregation in response to a range of ADP concentrations obtained using donor platelet rich plasma.

Background: The labour intensive technique of light transmittance platelet aggregometry has changed little since its inception in the 1960s. The requirements of meticulous technical skills and the need to test live platelets within 4 hours of venepuncture make it largely the remit of specialist laboratories.

Aims: Sysmex CS-2x00 series analysers permit, for the first time, a more standardised and automated approach. To assess the potential advantages of the Sysmex platform, three of the UK's specialist haemostasis laboratories at Bristol Royal Infirmary, Guy's & St. Thomas' Hospitals and The Royal London Hospital, are undertaking a multi-specialist site evaluation comparing analyser outputs and diagnostic outcomes from their traditional manual platelet aggregometry with automated aggregometry using Hyphen BioMed platelet agonist reagents.

Methods: Platelet rich plasma from volunteer donors with no known history of platelet disorders have been assessed using a wide range of concentrations for the routine agonists of ADP, epinephrine, collagen, arachidonic acid and ristocetin, and second-line agonists of TRAP, U46619 (TXA_2 mimetic) and calcium ionophore.

Results: Results have been compared to those obtained using the existing manual PAP-8E technique to ensure consistency of response across the separate platforms. The results obtained to date using a range of ADP agonist concentrations are plotted in Fig 1 and show broad agreement between the two testing platforms.

Conclusions: The study proposes to collate results from each laboratory as they perform their routine diagnostic analyses to establish the optimal agonist profile for diagnostic purposes and to establish robust reference ranges for platelet aggregometry. If diagnostic equivalence with manual platelet aggregometry is confirmed, it is envisaged that these expert centres could adopt automated platelet aggregometry as their standard technique. This is expected to lead to improved throughput and efficiency on platelet diagnostic testing.

PB 415 | The Impact of Repeated Freeze-thaw Cycles on Antiphospholipid Antibody Titer

K. Maelegheer, M. Luypaert, K. Devreese

Ghent University Hospital, Coagulation Laboratory, Department of Clinical Chemistry, Microbiology and Immunology, Ghent, Belgium

Background: Solid phase assays (SPA) for antiphospholipid antibodies (aPL) are mostly analyzed in batch. Guidelines advice to avoid repeated freeze-thaw cycles (FTC). However, in daily practice, FTC might be necessary. In contrast to the effect of freeze-thawing in phospholipid-dependent clotting assays used for lupus anticoagulants, there is only limited literature for SPA. Consequently, a validation on the effect of FTC could provide useful information.

Aims: Evaluating the effect of repeated FTC on anticardiolipin (aCL) IgM/IgG and anti-beta-2 glycoprotein 1 (aβ2GPI) IgM/IgG.

Methods: Sample selection (n=42) was based on routine results to cover a wide range for all four aPL. Patient samples were frozen after double centrifugation. All analysis were performed on aliquots never thawed before the experiment. Further, samples were analyzed five consecutive days with an additional, standardized FTC every day. Samples were collected between 2012 and 2017. All analysis were performed by an automated chemiluminescent assay (HemosIL® AcuStar, Instrumentation Laboratory, Bedford, MA, USA). Statistical analysis was done in Medcalc. A Mann-Withney U test for statistical differences ($p < 0.05$) between the first and following FTC was performed. If no statistical difference was found after five FTCs, a concordance correlation coefficient (CCC) was calculated.

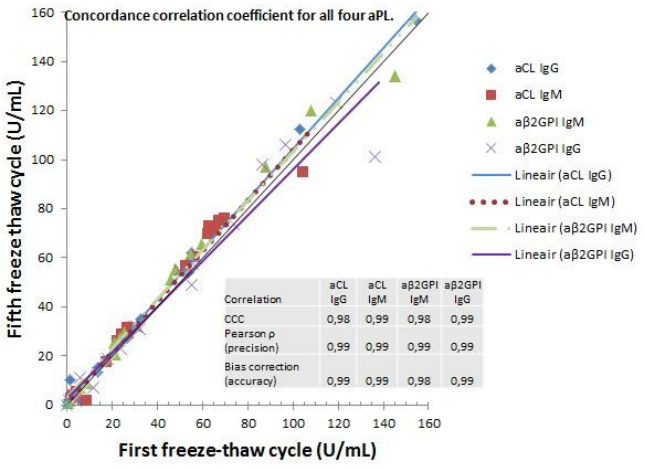

FIGURE 1 CCC between first and fifth FTC for all four aPL. Values above 200 U/mL are disregarded for visual purposes.

Results: APL titers showed no significant difference between earlier routine analysis and re-analysis at time of this study. After five FTC none of the samples, including those with values around the cut off, degraded from positive to negative. Mann-Withney U test for all analysis showed no statistical difference between the first and following repeated FTCs (table 1). The CCC between the first and fifth FTC were between 0.98 and 1 for all four aPL (figure 1).

Conclusions: ACL and aβ2GPI, over a broad titer range, are stable over time and after repeated FTC. With this study we excluded this pre-analytical factor as source for variability in aPL titer measured by SPA.

PB 416 | Suitability of a Liquid High-sensitivity Recombinant Human Prothrombin Time Reagent with Two Year Helf Life on an Automated Coagulation Laboratory Platform

K. Cawthern[1], C. Kung[1], R. Bottenus[1], V. Sarquella[2]

[1]*Instrumentation Laboratory, R&D, Orangeburg, NY, United States,*
[2]*Instrumentation Laboratory, Marketing, Bedford, MA, United States*

Background: In the management of vitamin K antagonist (VKA) therapy, few liquid prothrombin time (liqPT) options are available with comparable performance and shelf life to lyophilized (lyoPT) reagents. A 2 year shelf life liqPT provides benefits of reduced reconstitution variability versus lyoPT, user convenience and easier laboratory inventory control.

Aims: The study assesses the suitability of a ready-to-use high-sensitivity recombinant human liqPT reagent with two year shelf life versus a lyoPT predicate.

Methods: On automated coagulation laboratory platforms (ACL TOP series) at 9 large coagulation centers from five EU countries, PT results were obtained for a large cohort (N=3372) of normal donors, VKA patients, or donors with lupus anticoagulants (LA) to compare performance for the liqPT (ReadiPlasTin, ISI 0.97) vs. lyoPT (RecombiPlasTin 2G, multiple lots, ISI range 0.98-1.01).

TABLE 1 Results of 5 consecutive FTC. P-values were calculated with Mann-Withney U test. med: median, IQC: interquartile range

	FTC1 med(IQR)	FTC2 med(IQR)	p-value FTC 1-2	FTC3 med(IQR)	p-value FTC 1-3	FTC4 med(IQR)	p-value FTC 1-4	FTC5 med(IQR)	p-value FTC 1-5
aCL IgG	30(8-93)	32(13-263)	0.8692	33(13-274)	0.7418	35(147-237)	0.7349	34(13-276)	0.7143
aCL IgM	55(13-87)	57(11-88)	0.8528	58(11-90)	0.7650	59(11-86)	0.7259	57(8-76)	0.8481
aβ2GPI IgM	31(8-93)	28(9-98)	0.8234	31(8-99)	0.6908	29(9-102)	0.7784	31(8-81)	0.7949
aβ2GPI IgG	74(22-676)	73(18-724)	0.9354	79(15-694)	0.8642	74(11-748)	0.9058	74(13-723)	0.9551

Results: A method comparison of PT(sec) for liqPT vs. lyoPT (liqPT range 8.2-197.6 sec) yielded slopes within 2% of 1.00 (Table 1), indicating PT (sec) is independent of reagent form (liq or lyo).

TABLE 1 PT (sec) method comparison, liqPT vs. lyoPT

EU Location:	#samples(N)	Slope (liqPT vs. lyoPT)	Intercept	R^2
ALL	3372	1.01	0.129	0.995
Germany	1302	1.02	0.158	0.995
UK	557	1.02	-0.039	0.995
Benelux	1513	0.99	0.307	0.995

A liqPT vs. lyoPT PT (sec) comparison of the LA positive samples ranging from 11.1-13.4 sec gave results similar to Table 1 (slope = 1.02, int = -0.047, R^2 = 0.9923), indicating similarly low sensitivity performance to LA with both reagents. In Table 2, the mean vitamin K-dependent extrinsic factor recoveries from the VKA patient samples were comparable for both reagents with slopes within 6% of 1.00.

TABLE 2 Comparison, liqPT vs. lyoPT, % Factor Recoveries from VKA samples (N=7)

VKA Extrinsic Factor	Slope (liqPT vs. lyoPT)	Intercept	R^2	Range, liqPT Factor %
II	1.04	-0.842	0.996	14.4-108.2
VII	0.94	1.919	0.990	9.8-148.1
X	0.94	1.162	0.998	6.6-127.6

Conclusions: The results show excellent agreement between the liqPT reagent and reconstituted lyoPT predicate reagent, and demonstrate that a convenient ready-to-use liquid PT reagent with two year shelf life is a suitable replacement for the traditional lyophilized PT reagent in assessing VKA therapy on automated coagulation platforms.

PB 417 | Discrepancy in Optical and Impedance Platelet Count in Platelet Rich Plasma Prepared for Light Transmission Aggregation as a Possible Sample Quality Indicator

A. Mlinaric, D. Coen Herak, M. Milos, D. Rogic

University Hospital Centre Zagreb, Department of Laboratory Diagnostics, Zagreb, Croatia

Background: Mechanical forces during platelet rich plasma (PRP) preparation can activate platelets that subsequently form platelet clumps. We have observed differences in platelet counts measured with optical (PLT-O) and impedance (PLT-I) method, performed prior to light transmission aggregation testing. Currently, there is no recommendation on the preferred method for platelet count determination.
Aims: Aim was to explain observed differences by investigating platelet indices (PI) [mean platelet volume (MPV), platelet distribution width (PDW), platelet large cell ratio (PLCR)] in PRPs with discrepant PLT-O and PLT-I, compared to PRPs with consistent platelet counts.

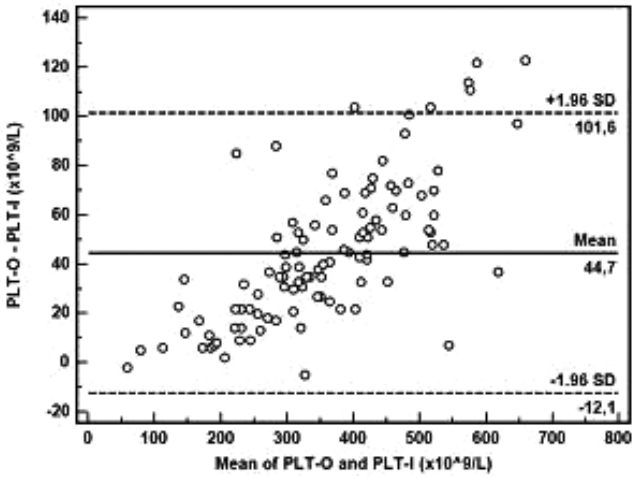

FIGURE 1 Comparison of optical (PLT-O) and impedance (PLT-I) platelet count according to Bland and Altman.

Methods: PRPs were prepared from 105 samples by centrifugation (200g, 10min). Platelet counts and PI were measured on Sysmex XE5000 analyzer (Sysmex, Japan). Total allowable error (13.4%) based on biological variation was used to discriminate PRPs with significantly different PLT-O and PLT-I. Kolmogorov-Smirnov test, Bland-Altman analysis, paired samples- and independent t-test, and Pearson correlation were used for statistical analysis. P< 0.05 was considered significant.
Results: PLT-O method gave consistently higher counts compared to PLT-I method (P< 0.001) with a mean difference of 44.7x10^9/L (Figure 1). Neither PLT-O nor PLT-I count correlated with PI. 50 of 105 (48%) PRPs showed significant difference between PLT-O and PLT-I with lower MPV, PDW and PLCR (P< 0.001 for all PI). All PI correlated weakly with the difference in PLT-O and PLT-I count (r=-0.37, r=-0.38, r=-0.35, respectively; P< 0.001).
Conclusions: The reason for discrepancies between PLT-O and PLT-I is not completely clear. Higher PLT-O counts could be due to platelet clumps that are only counted by optical method. Consequently, smaller platelets are counted using impedance method which explains lower PI in PRPs with discrepant platelet counts and greater difference between counts. This finding can be used as quality indicator of PRP prepared for aggregation testing.

PB 418 | Thrombophilia: Women-specific Reference Ranges May Prevent Overdiagnosis

C.S.B. Veen[1], M.J.H.A. Kruip[1], M.F. Durian[1], J.G. van Asten[1], M. Ahmadi[1], S. Petronia[1], W. Visser[2], M.P.M. de Maat[1]

[1]*Erasmus University Medical Center, Hematology, Rotterdam, The Netherlands,* [2]*Erasmus University Medical Center, Obstetrics and Gynaecology, Rotterdam, The Netherlands*

Background: Thrombophilia is a state where abnormalities of the haemostatic system are present that predispose to thrombosis. Some coagulation factors are generally lower in women than in men. Therefore, the use of standard reference ranges, based on male or

mixed-sex groups, may be misleading in the diagnosis of thrombophilia in women. This may be relevant in the analysis of thrombophilia after pregnancy complications. Therefore, the aim of this study was to evaluate the use of women-specific reference ranges in thrombophilia.

Aims: Investigate the effect of women-specific reference ranges on the interpretation of thrombophilia in women after an uncomplicated pregnancy or women who experienced preeclampsia.

Methods: Coagulant and anticoagulant parameters (Prothrombin Time; Antithrombin; Protein C-Activity; Protein S-Activity; Activated Protein C-resistance; Lupus anticoagulans with diluted Russell´s viper venom time and lupus-sensitive Activated Partial Thromboplastin Time; and anticardiolipin and β2-glycoprotein-I antibodies) were measured three months postpartum in 61 healthy women with an uncomplicated pregnancy and in 197 women who experienced preeclampsia (PE). Of the healthy women, 55 were also measured at least 6 months after an uncomplicated pregnancy. These measurements were used to calculate women-specific reference ranges. This study was approved by the Medical Ethics Committee of the Erasmus University Medical Center Rotterdam and informed consent was obtained at inclusion.

Results: In total, 52% of healthy women had abnormal results when using routine reference ranges compared to 8% when using women-specific reference ranges ($p < 0.05$). In the women with PE, there were abnormal results in 74% of PE women when using routine reference ranges compared to 26% when using women-specific reference ranges ($p < 0.05$) (See table 1).

TABLE 1 Number of prothrombotic abnormalities in women 3 months after pregnancy based on routine reference ranges (RRR) / women reference ranges (WRR)

	Uncomplicated pregnancy (n=61)			Preeclampsia (n=197)		
	RRR	WRR	p	RRR	WRR	p
Antithrombin (U/ml)	1	0		3	1	
Protein C activity (E/ml)	1	0		5	4	
Protein S activity (E/ml)	7	0		32	5	
APC-resistance ratio	26	1		88	15	
APTT-Lupus (sec)	1	0		2	1	
DRVVT Ratio	5	0		54	9	
Antiphospholipid antibodies	3	4		59	31	
Total of patients ≥ 1 abnormality	32 (52%)	5 (8%)	< 0.05	144 (74%)	51 (26%)	< 0.05

Conclusions: When using women-specific reference ranges less abnormalities are seen in women, which may prevent overdiagnosis of thrombophilia.

PB 419 | A New Chromogenic DTI Assay for the Quantitative Determination of Dabigatran in Human Plasma

J. Mueller, A. Hesse, I. Kieper-Rupp, D. Koch, J. Kurz, S. Vollmerhausen, D. Bussfeld

Siemens Healthcare Diagnostics Products GmbH, Marburg, Germany

Background: Dabigatran etexilate is an oral direct thrombin inhibitor used for the prevention of venous thromboembolism after elective hip and knee replacement, the prevention of stroke during arterial fibrillation, and the treatment of acute deep vein thrombosis. The active metabolite, dabigatran, has a predictable pharmacokinetic profile with no need for routine monitoring in general. Nevertheless, in certain clinical situations it is beneficial to quantify the dabigatran concentration in patient specimens.

Aims: The development of a reliable automated chromogenic assay for the quantitative detection of dabigatran in human plasma.

Methods: The new DTI Assay* is a thrombin-dependent assay using a chromogenic measuring principle and respective Standards* and Controls*. Applications were developed for Siemens BCS® XP System (BCS XP) and Sysmex® CS-2000i/2100i/CS-2500/CS-5100 Systems (CS-Systems). For verification of the assay performance the following studies were performed: Linearity, Limit of Quantitation, Precision, On-board Stability and Method Comparison to liquid chromatography tandem mass spectrometry (LC-MS/MS).

Results: The assay is calibrated in a range of 0-500 ng/mL dabigatran. A clinical reportable range (CRR) of 20-1000 ng/mL is achieved by sample predilution. On all systems, linearity was assessed over the whole CRR. A total precision CV of 5.73% (CS-Systems) and 6.90% (BCS XP) was shown for a sample with 50-60 ng/mL and 2.27% (CS-Systems) and 2.19% (BCS XP) for a sample with 340-370 ng/mL dabigatran. An on-board stability of assay reagents of 54 hours (CS-Systems) and 24 hours (BCS XP) was achieved. Method comparison to LC-MS/MS revealed a correlation coefficient of r=0.997 (BCS XP).

Conclusions: The new DTI Assay offers together with respective Dabigatran Standards and Controls a reliable method for the determination of dabigatran in human plasma.

(*) Due to regulatory reasons product availability varies by country. Not available for sale in the U.S.

PB 420 | Comparison of Thrombin Generation Profiles among Patients Treated with Three Different Direct Oral Anticoagulants and Warfarin

O. Paoletti, C. Dellanoce, A. Zimmermann, R. Morandini, E. Cancellieri, S. Zambelli, M. Tala, C. Beati, M. Stramezzi, S. Testa

Cremona Hospital, Haemostasis and Thrombosis Center, Department of Laboratory Medicine, Cremona, Italy

TABLE 1 Patient, clinical indications, drug levels and TG analysis. * p<0.0001 between DOAC vs Warfarin

Drugs	NVAF pt/n° VTE pt/n°	DOAC ng/ml warfarin PT/ INR mean (min-max)	Lag time (min) mean (min-max)	Peak (nM) mean (min-max)	ETP (nM-*min) mean (min-max)
dabigatran	NVAF/15 VTE/15	70.7 (15.2-207.7) 86.1 (31.9-94.2)	5.9 (2.3-8.8) 5.7 (3.3-7.8)	278 (150-383)* 290 (205-383)*	1484 (1070-1979)* 1547 (1439-1655)*
rivaroxaban	NVAF/15 VTE/15	37.0 (19.5-105.8) 25.7 (15.4-42.5)	4.5 (3.3-6.3) 4.9 (2.9-7.3)	124 (53-206) 160 (67-266)	1193 (609-1702)* 1674 (1135-2775)*
apixaban	NVAF/15 VTE/15	133(47.7-282.9) 117.2 (48-392.5)	5.7 (3.2-11.1) 5.03 (3.0-9.0)	82 (32-197) 118 (77.6-167)	1083 (647-1728)* 1312 (1097-1592)*
warfarin	NVAF/15 VTE/15	2.35 (2.1-2.9) 2.5 (2.0-2.9)	4.3 (2.7-7.3) 4.8 (3.1-7.0)	86 (46-156) 77 (37-113)	467 (259-836)* 421 (225-641)*

Background: Apixaban, dabigatran and rivaroxaban are three direct oral anticoagulants (DOAC) administered at fixed dose with different posology in relation to clinical indications, individual characteristics and renal function while warfarin daily dose is adapted to maintain the therapeutic range. Previous studies showed large inter/intra individual variability both at trough (Cthrough) and at peak (Cmax) in plasma DOAC levels measured with specific coagulation test.

Aims: To evaluate Thrombin Generation (TG) in patients affected by non valvular atrial fibrillation (NVAF) and venous thromboembolsim (VTE) treated with DOAC or warfarin.

Methods: 120 patients (60 NVAF and 60 VTE) were enrolled, 30 for each drug. Plasma samples were collected after three months from starting anticoagulant treatment at Cthrough for DOAC patients while, for warfarin patients, nearly 16 hours after the last dose intake. PT INR for warfarin, diluted thrombin time (dTT) calibrated for dabigatran, FXa calibrated for rivaroxaban or apixaban were performed. TG was assayed using the calibrated Automated Thrombogram (CAT-Stago). measuring lag time (min), endogenous thrombin potential (ETP- nM-*min) and peak (nM). The activation of coagulation was obteined by adding tissue factor 5pM.

Results: Results are shown in Table 1. High DOAC inter-individual variability, both in NVAF and in VTE patients, was found as measured with specific coagulation test (mean CV%= 52) and in TG analysis. Mean ETP was significantly higher in DOAC treatments both in NVAF and VTE, without differencies among them, compared with warfarin (p< 0.0001).

Conclusions: Our study confirms the high DOAC inter-individual variability as measured both with specific coagulation test than with TG analysis. In comparison with warfarin, ETP is significantly higher in patients treated with DOAC, suggesting a possible more stable coagulation inhibition associated to half life of warfarin. These data open the question if individualized patient dosing could improve the daily anticoagulant action.

PB 421 | Multicenter Evaluation of D-Dimer on Two New Coagulation Systems

T. Wissel[1], D. Christie[2], V. Janssen[1], K. Purr[1], U.-P. Schobel[1]

[1]*Siemens Healthcare Diagnostics Products GmbH, Marburg, Germany,* [2]*Formerly with Siemens Healthcare Diagnostics Inc., Glasgow, United States*

Background: D-dimer testing is widely utilized for exclusion of venous thromboembolism.

Aims: To evaluate the INNNOVANCE® D-dimer assay on two new coagulation systems in a multicenter study with 24 participating sites and to validate the exclusion of pulmonary embolism (PE) and of first event of deep vein thrombosis (DVT).

Methods: Frozen specimens were collected prospectively from consecutive outpatients presenting to the emergency or ambulatory department with a suspected PE or DVT. All potentially eligible patients were evaluated using the Wells´ rules to estimate their pre-test probability (PTP) with regard to PE or DVT. Patients with a high or likely PTP score were excluded from enrollment. Patients with no or a positive D-dimer result with the D-dimer assay used at the respective study center were evaluated by imaging methods, e.g. ultrasound, spiral CT or V/Q scan. Patients with a negative internal D-dimer result underwent imaging at the physician´s discretion. All patients with a negative diagnosis of PE or DVT were followed up after three months to evaluate potential DVT or PE. Patients with unobtainable follow-up data were excluded from analysis resulting in 1317 DVT and 1467 PE patients, respectively, available for analysis. A multiple imputation analysis was performed in order to investigate the possible impact of missing diagnosis of DVT and PE at follow up on the results.

Results: The overall prevalence was 6.1% for DVT and 6.9% for PE. The instrument specific sensitivity, specificity and negative predictive value (NPV) with their respective lower bound of the two-sided 95% confidence interval (LCL) were calculated. The results are shown in the tables below.

TABLE 1 First event of DVT

System	sensitivity	95% LCL	specificity	95% LCL	NPV	95% LCL
Sysmex CS-2100i	97.5	91.3	46.1	43.3	99.7	98.7
Sysmex CS-5100	97.5	91.3	45.1	42.3	99.6	98.7

TABLE 2 Pulmonary embolism

System	sensitivity	95% LCL	specificity	95% LCL	NPV	95% LCL
Sysmex CS-2100i	97.0	91.6	54.5	51.9	99.6	98.8
Sysmex CS-5100	98.0	93.0	54.5	51.9	99.7	99.0

Conclusions: In this study the results of the D-dimer assay fulfill the criteria of the CLSI Guideline H59-A for the exclusion of PE and first event DVT on both systems. The results of the multiple imputation analysis confirm the conclusions based on the complete case approach.

PB 422 | Innovative Method for the Description of Human Platelets Population

A. Litvinenko[1,2], V. Nekrasov[2], A. Moskalensky[1,2], D. Strokotov[2], V. Maltsev[1,2]

[1]Novosibirsk State University, Department of Physics, Novosibirs, Russian Federation, [2]Voevodsky Institute of Chemical Kinetics and Combustion, Cytometry and Biokinetics Department, Novosibirsk, Russian Federation

Background: Disorders of platelets may lead to serious pathologies and it could be difficult to diagnose, especially at the earliest stages of the disease. Currently, many methods have been developed for the evaluation of platelet function. These methods are usually based on platelets aggregation and blood coagulation. However, none of them could provide information about the shape of individual platelets. Although the shape change is the first reaction to different influences including special agonists.

Aims: To develop a new method for diagnostics of:

· morphological abnormalities of platelets' populations.

· risks of bleeding and thrombotic events related to platelets.

Methods: We used the light-scattering flow cytometry. This method is based on measurement of angle-resolved light-scattering patterns (LSPs) of individual cells and solution to the inverse light-scattering (ILS) problem. We measured LSPs with the Scanning Flow Cytometer. After we found the solution to ILS problem for each cell, we obtained the distribution of platelets over the shape aspect ratio. This distribution was used to characterize the shape change during activation and other external influences.

Results: The study of platelets with the scanning flow cytometry was performed for different donors. Informed consent was obtained. Also, we created a new mathematical model for the identification of platelets distribution based exclusively on cell shape. We described three different subpopulations of platelets in native blood (resting, partially activated and fully activated). We also studied find out a correlation between shape and volume during platelets activation. And, this method needs no use monoclonal antibodies for identified subpopulation.

Conclusions: The study of platelets is very important for diagnostics related to hemostasis. We tested new method for this study and got consistent results. This method allows us to study shape change in live platelets during their platelets activation.

PB 423 | Thromboelastometry to Detect Anticoagulant Effect of Apixaban in Patients with Non Valvular Atrial Fibrillation

M.C. Vedovati, M.G. Mosconi, F. Isidori, G. Agnelli, C. Becattini

University of Perugia, Perugia, Italy

Background: Rapidly available tests are needed to measure the anticoagulant effect of non-vitamin K oral anticoagulants in emergency

TABLE 1

Parameter (mean±SD, CV)	Control (15)	Peak sample (10)	Trough sample (10)	P *	P §	P +	AUC (95% CI)

SD= Standard Deviation; CV= Coefficient of Variation; CT= Clotting Time; CFT= Clot Formation Time; MCF= Maximum Clot Firmness; CTc= Clotting Time after anti-FXa catcher was added; Alphac= alpha angle after anti-FXa catcher was added; CFTc= Clot Formation Time after anti-FXa catcher was added; MCFc= Maximum Clot Firmness after anti-FXa catcher was added. AUC= area under the curve; CI= Confidence Interval. * comparison between controls and peak sample in patients; § comparison between controls and trough sample in patients; + comparison between trough sample and peak sample in patients.

situations (such as bleeding, emergency surgery and need for thrombolytic treatment). No global test is currently available to measure the anticoagulant effect of apixaban.

Aims: To assess the anticoagulant effect of apixaban by whole rotational thromboelastometry (ROTEM).

Methods: In patients with non-valvular AF treated with apixaban, peak and trough samples were obtained at steady-state. Healthy volunteers served as controls. Citrated blood samples were tested by ROTEM using diluted EXTEM assay with and without the addition of anti-FXa catcher. Clotting Time (CT), Alpha angle (Alpha), Clot Formation Time (CFT), Maximum Clot Firmness (MCF) were measured. Data are presented as means ± SD and comparisons were analyzed by Wilcoxon rank and Mann-Whitney tests. ROC curves for the evaluation of accuracy were performed.

Results: Ten patients and 15 controls were included. The mean CT of patients at trough was significantly longer than that of controls (Table). In patients, the mean CT was significantly shortened after addition of the anti-FXa catcher (peak CT 303.30±86.54 seconds without and 176.70±55.58 with anti-FXa catcher, p=0.005; trough CT 262.70±119.04 seconds without and 147.90±32.02 with anti-FXa catcher, p=0.009). CT, CT/CT+catcher (CTc) and CFT/CFT+catcher (CFTc) revealed a good accuracy in measuring apixaban anticoagulant activity AUC 0.917, 0.880 and 0.880, respectively. The CT/CTc and CFT/CFTc of patients were significantly higher compared to those of controls (p< 0.001 at peak in both and 0.011 and 0.005 at trough, respectively). The combination of a CT value >150 sec and a CT/CTc > 1.3 or a CFT/CFTc > 1.2 had a positive predictive value of 95% for antiXa activity in patients treated with apixaban (accuracy 92%).

Conclusions: Thromboelastometry showed a good accuracy in detecting apixaban activity in patients with non-valvular AF.

PB 424 | Assessment of Single-factor Deficiency Sensitivty of Three Thromboplastin Reagents

V. Juif[1], P.O. Sevenet[2], M. Lubineau[2], N. Masset[1]

[1]STAGO, R&D, Gennevilliers, France, [2]STAGO, Asnières, France

Background: Prothrombin time (PT) sensitivity for detecting isolated factor deficiency can vary according to different reagents, due to thromboplastin origin, composition and concentration in phospholipids.

Aims: Performances of single-factor deficiency sensitivity of three thromboplastin reagents from Stago were assessed, including STA®-NeoPTimal, the new Stago thromboplastin from brain rabbit origin with an ISI close to 1.0. Agreement with H47A2 CLSI recommendations were evaluated for each reagent.

Methods: For each exogenous factor (II, V, VII, X), normal pooled plasma containing normal level of factors underwent 8 serial dilutions in respective deficient-factor plasma to achieve ranges between 10 and 100%. Each sample was tested with STA®-NeoPTimal, rabbit brain origin (1 lot for each packaging: 5, 10 and 20mL), STA®-Neoplastin R, recombinant (2 lots of 15mL) and STA®-Neoplastin CI+, rabbit brain origin (3 lots of 10mL) on STA®-R analyser.

PT ratio was expressed by dividing the result in seconds by the Mean of Normal Prothrombin Time (MNPT) defined with 20 fresh plasma samples from healthy donor. The factor level of each sample was tested using one-stage clotting assay from Stago.

The sensitivity is defined as the maximum factor level producing a PT ratio result out of the reference range, i.e. > 1.2.

Results: For each factor/thromboplastin combination, the sensitivity obtained with different lots of reagents are consistent from one to each other.

All the 3 reagents reached H47A2 CLSI recommendations (factor sensitivity between 30% and 45%) except for factor X with STA®-Neoplastin R and STA®-NeoPTimal where factor sensitivity is slightly higher than 45%.

Conclusions: Results show a very good lot-to-lot consistency for single factor deficiency sensitivity with the 3 reagents from Stago, STA®-Neoplastin CI+, STA®-Neoplastin R, and STA®-NeoPTimal. Besides, this study strongly confirm the reliability of these reagents to CLSI guideline and attest their robustness for daily practice in the coag lab.

PB 425 | Genetic Analysis for Investigation of Heritable Bleeding Disorders - Update on the UK NEQAS (Blood Coagulation) Programme

I. Jennings[1], S. Kitchen[1], A. Goodeve[2], M. Hill[3], B. Theophilus[4], T. Cumming[5], I. Walker[1], D. Perry[6]

[1]UK NEQAS (Blood Coagulation), Sheffield, United Kingdom, [2]Sheffield Children's NHS Foundation Trust, Sheffield Diagnostic Genetics Service, Sheffield, United Kingdom, [3]Queens Medical Centre Campus, Nottingham University Hospitals NHS Trust, Blood Sciences, Nottingham, United Kingdom, [4]Birmingham Children's Hospital NHS Foundation Trust, Department of Haematology, Birmingham, United Kingdom, [5]Central Manchester University Hospitals NHS Foundation Trust, Molecular Diagnostics Centre, Central Manchester Haematology Service, Manchester, United Kingdom, [6]Cambridge University Hospital NHS Foundation Trust, Addenbrooke's Hospital, Cambridge Haemophilia & Thrombophilia Centre, Cambridge, United Kingdom

Background: Genetic analysis for investigation of heritable bleeding disorders is an important part of the diagnosis of haemophilia and accurate testing and interpretation of results is important. External Quality Assessment of such analysis can help improve laboratory performance, and highlight potential errors of interpretation.

Aims: The UK National External Quality Assessment Scheme (UK NEQAS) for heritable bleeding disorders distributes samples from patients with haemophilia A, B or vWD to both UK and non-UK genetics laboratories for investigation and reports are assessed by an expert panel of clinicians/clinical scientists.

Methods: We describe here the findings from the past 2 years of this EQA programme.

Results: Survey 26, May 2015, comprised samples from a Haemophilia A carrier with the *F8* IVS22 mutation and a wild type male. 1 centre failed this exercise by failing to identify the mutation in the carrier,

and 1 failed through incorrect interpretation of data for the wild type male. Survey 27, November 2015, comprised a sample from a haemophilia A donor with a *F8* c.575T>C mutation in exon 4, and discrepant 1-stage and chromogenic FVIII assay results. 1 centre failed this exercise through clerical errors in the report.

In survey 28, May 2016, comprised of a sample from a donor hemizygous for a *F8* c.541G>A substitution, 1 centre failed the exercise through an incorrect amino acid substitution in their report. A questionnaire distributed in 2014 revealed that 17/18 centres always repeat genetic investigations and therefore the impact of such errors may be minimised.

Conclusions: This programme assesses both the analytical phase of genetic investigations and also the post-analytical phase through interpretation of information based on a specific clinical scenario. Identification of errors by participants and evidence of improved quality of reporting since the introduction of this programme highlights the need for EQA programmes in this area of haemostasis investigation.

PB 426 | Platelet Reactivity in Patients on Aspirin and Clopidogrel Therapy Measured by a New Bed-side Whole Blood Assay

A. Polzin[1], C. Helten[1], S. Rehder[2], A. Mohring[1], L. Dannenberg[1], K. Görlinger[3,4], T. Zeus[1], M. Kelm[1], T. Hoffmann[2]

[1]*Heinrich Heine University Medical Center Düsseldorf, Division of Cardiology, Pulmonology, and Vascular Medicine, Düsseldorf, Germany,* [2]*Heinrich Heine University Medical Center Düsseldorf, Department of Experimental and Clinical Hemostasis, Hemotherapy, and Transfusion Medicine, Düsseldorf, Germany,* [3]*University Hospital Essen, Department of Anesthesiology and Intensive Care Medicine, Essen, Germany,* [4]*Tem International GmbH, Munich, Germany*

Background: There are various tests available for measuring on-treatment platelet reactivity. The pharmacologically most specific assays are time-consuming and require extensive laboratory skills. In this study, we implemented the novel ROTEM® platelet impedance aggregometry assay, a bed-side test which measures platelet aggregation in a whole blood sample within six minutes.

Aims: We aimed to investigate its ability to evaluate P2Y12- and cyclooxygenase-1 platelet inhibition and compare it to already established assays.

Methods: Platelet function was investigated in 93 patients after informed consent. 47 patients were on permanent aspirin therapy and 46 on dual antiplatelet therapy (DAPT) with aspirin and clopidogrel. We used ROTEM® platelet impedance aggregometry (ROTEM-PTL), light transmission aggregometry (LTA), Multiplate® electrode aggregometry (MEA) and VASP flow cytometry. Aspirin antiplatelet effects were evaluated by arachidonic acid, clopidogrel effects by adenosine diphosphate stimulation. The study was approved by the ethics committee of the Heinrich-Heine University Düsseldorf.

Results: ROC-analyses showed ROTEM-PTL differentiates well between patients on medication and healthy individuals: Aspirin: ROC_{AUC} 0.99; (95% CI, 0.97-1.01); p< 0.0001; DAPT treatment: ROC_{AUC} 0.80; (95% CI, 0.69-0.91); p< 0.001. Pearson regression analyses showed moderate correlations, for aspirin: MEA vs. ROTEM-PTL r^2=0.435, p=< 0.001; LTA vs. ROTEM-PTL r^2=0.048, p=0.180. For DAPT: MEA vs. ROTEM-PTL r^2=0.398, p=0.001; LTA vs. ROTEM-PTL r^2=0.409, p=0.001; VASP vs. ROTEM-PTL r^2=0.164, p=0.055).

Conclusions: The novel ROTEM® platelet assay excellently distinguished between treated patients and healthy individuals but correlated only moderately with other assays. By now, different studies failed to demonstrate superiority in tailored antiplatelet therapy guided by already established assays. Clinical trials are needed to investigate the ability of this new assay to identify patients at risk of adverse events.

PB 427 | Usefulness of Waveform Analysis of APTT on the ACL-TOP® When Troubleshooting Unexpected Abnormal APTT

N. Tokunaga[1], C. Inoue[1], T. Sakata[2], Y. Inoue[1], S. Akaiwa[1], H. Yoshida[1], T. Nakao[1], T. Doi[3]

[1]*Tokushima University Hospital, Division of Medical Technology, Tokushima, Japan,* [2]*IL Japan Co., Ltd., Coagulation Scientific Support, Tokyo, Japan,* [3]*Tokushima University Hospital, Division of Clinical Laboratory, Tokushima, Japan*

Background: Although atypical 2nd derivative curve on the ACL-TOP® family of hemostasis analyzers in the assay of activated partial thromboplastin time (APTT) is associated with coagulation abnormalities such as single factor deficiency, factor inhibitor, and lupus anticoagulant (LA), the reliability is not established until now (Solano C., et al. *Int J Lab Hematol*, 2011;33:67-78. Tokunaga N., et al. *Blood Coagul Fibrinolysis* 2016;27:474-6).

Aims: We assessed the usefulness of waveform analysis of the 2nd derivative curve of the ACL TOP® representative analyzer on the identification of causes of APTT prolongation by comparing the prevalence of abnormal curves among each group.

Methods: We measured APTT by the combination of APTT-SP® which includes silica and ACL TOP® (Instrumentation laboratory, Bedford, MA, USA), and then counted the presence of an atypical curve of the 2nd derivative curve in 28 patients with factor deficiency including FVIII (n=21), FIX (n=2), FXI (n=1), FV (n=1), von Willebrand factor (n=3), 6 patients with FVIII inhibitor, 70 patients with LA, 75 patients treated with unfractionated heparin, 151 patients treated with dabigatran (n=71) or ribaroxaban (n=80), and in 36 healthy volunteers.

Results: The prevalence of abnormal curve in the group of factor deficiency, factor inhibitor, or LA was 100.0% (28/28), 100.0% (6/6), 95.1% (67/70), respectively (Table). On the contrary, in the remaining groups including healthy volunteers, we never found an abnormal curve on the 2nd derivative curve of APTT assay.

TABLE. Frequency of an abnormal curve on the second derivative curve in APTT assay

Group	Number of sample	APTT-sec (Mean±SD)	Frequency of an abnormal curve
Factor deficiency	28	59.0±16.0	100.0% (28/28)
Factor VIII inhibitor	6	98.3±19.5	100.0% (6/6)
Lupus anticoagulant	70	46.8±17.3	95.7% (67/70)
Unfractionated heparin	75	62.7±37.6	0% (0/75)
Dabigatran	71	56.7±18.4	0% (0/71)
Rivaroxaban	80	44.5±6.3	0% (0/80)
Controls (Healthy volunteers)	36	31.8±2.8	0% (0/36)

Conclusions: We assessed the usefulness of waveform analysis on the 2nd derivative curve of ACL TOP® when troubleshooting an unexpected abnormal APTT by comparing the prevalence of abnormal curve in each patient group. The presence of an abnormal curve on the 2nd derivative curve suggests that APTT-prolongation might be caused by factor deficiency, factor inhibitor or LA.

PB 428 | Evaluating the Analytical Performance of Six New Coagulation Assays

S. Kitchen[1], U. Geisen[2], J. Kappelmayer[3], P. Quehenberger[4], R. Jones[5], A. Lowe[5], J. Boehm[6], G. Miles[7], G. Rozsnyai[8]

[1]Sheffield Haemophilia and Thrombosis Centre, Sheffield, United Kingdom, [2]University of Freiburg, Institute for Clinical Chemistry and Laboratory Medicine, Freiburg, Germany, [3]University of Debrecen, Debrecen, Hungary, [4]Medical University of Vienna, Dept of Laboratory Medicine, Vienna, Austria, [5]Sheffield Haemophilia and Thrombosis centre, Sheffield, United Kingdom, [6]Roche Diagnostics, Mannheim, Germany, [7]Roche Diagnostics, Indianapolis, United States, [8]Roche Diagnostics International Ltd, Rotkreuz, Switzerland

Background: Coagulation tests are widely used in healthcare, including for screening, diagnosis and assessment of coagulopathies, and monitoring of anticoagulant therapy. The ability to accurately, reliably and quickly measure indicators of haemostatic function is important for patient health.

Aims: We evaluated the analytical performance of 6 new coagulation assays, developed to measure prothrombin time (PT), fibrinogen, thrombin time (TT), antithrombin, D-Dimer, and PT-derived fibrinogen on the Roche Diagnostics cobas t 711 (high-throughput; 400 tests/hour) and cobas t 511 (mid-throughput; 200 tests/hour) analysers.

TABLE 1 Within-run precision and reproducibility of PT, TT, Fibrinogen and PT derived Fibrinogen using the cobas t 711 and cobas t 511 analysers

	within run precision acceptance criteria	within run precision Range of % CV or SD	within run precision Range of % CV or SD	Total reproducibility %CV (acceptance criteria ≤25%	Total reproducibility %CV (acceptance criteria ≤25%
		cobas t711	cobas t511	cobas t711	cobas t511
PT sec	CV ≤3%	0.2-0.7	0.1-0.4	1.9-3.2	2.2-3.7

Fib 400-600 mg/dl	CV≤6%	0.7-2.6	0.7-0.9	3.3	2.9
Fib >600 mg/dl	CV≤10%	1.8-2.6	0.6-1.4	4.3	4.3
PT derived Fib mg/dl	CV≤5%	0.4-1.4	0.4-1.3	1.4-2.2	1.1-3.1
TT sec	CV≤4%	0.6-2.9	0.6-4.1	1.1-4.5	0.9-4.0

TABLE 2 Within-run precision and reproducibility of DDimer and Antithrombin assays using the cobas t711 and cobas t511 analysers

	Within-run precison acceptance criteria	Within-run precision range of %CV or SD	Within-run precison range of % CV or SD	Total Reproducibility %CV (acceptance criteria: CV≤25%)	Total Reproducibility %CV (Acceptance criteria: CV≤25%)
		cobas t711	cobas t511	cobas t711	cobas t511
D-Dimer, µg FEU/ml	SD≤0.02 (<0.56µg FEU/ml)	0.0119-0.0172	0.0096-0.0160	3.5-8.6	3.3-6.7
D-Dimer, µg FEU/ml	CV≤3.5%(0.56-1.7µg FEU/ml)	1.5-2.4	1.4-1.5	5.4	5.5
D-Dimer, µg FEU/ml	CV≤3% (>1.7µg FEU/ml)	0.3-0.7	0.2-0.3	1.0-1.8	0.9-2.2
Antithrombin IU/dL	SD≤2.4IU/dL (Absolute ≤80 IU/dL)	0.727-1.359	1.06-1.35	2.3-5.8	2.5-6.3
Antithrombin IU/dL	SD≤3.0%(>80 IU/dL)	0.9-1.3	0.8-1.4	1.8-2.0	1.4-2.1

Methods: The analytical performance of the 6 assays was independently tested on the cobas t 711 (4 sites: UK/Germany/Hungary/Austria) and cobas t 511 analysers (2 sites: UK/Germany). Following a familiarisation phase, analytical performance was assessed by measuring within-run precision and reproducibility. Within-run precision: 2 controls and 5 human plasma pool samples of different analyte concentrations or clotting times were tested; 1 run was performed with 21 replicates from each sample. Reproducibility: 5 aliquots of each control/human plasma pool sample were prepared and tested over 5 days across the sites and evaluated in combination. Anonymised residual 3.2% (0.109M) sodium citrate plasma samples were used for all experiments. The coefficient of variance (CV) and standard deviation (SD) were calculated for within-run precision and reproducibility and compared against specified acceptance ranges.

Results: For all assays tested, within-run precision and reproducibility results were within the specified acceptance ranges (Table). Across all assays, the CVs for within-run precision were ≤4.1% and none of the CVs for reproducibility were over 8.6%.

Conclusions: All six coagulation assays demonstrated a good to very good analytical performance using the Roche Diagnostics cobas t 711 and cobas t 511 analysers.

PB 429 | Performance Evaluation of the microINR® Point-of-Care INR-testing System

J. Joubert[1,2], M.C. Van Zyl[1], J. Raubenheimer[3]

[1]*University of the Free State, Department of Haematology and Cell Biology, Bloemfontein, South Africa,* [2]*National Health Laboratory Service, Universitas Academic Laboratories, Department of Haematology and Cell Biology, Bloemfontein, South Africa,* [3]*University of the Free State, Department of Biostatistics, Bloemfontein, South Africa*

Background: Point-of-care (POC) International Normalised Ratio (INR) testing is becoming more varied and widely available. Multicentre validation of these instruments' performance is desirable, as it helps to confirm their suitability for clinical use in varied settings.

Aims: To evaluate the microINR® POC system for accuracy, precision, measurement repeatability, instrument & test chip variability, and error rates.

Methods: Venous blood INRs obtained with Thromborel® S on the Sysmex CS-2100i® analyser, were compared with capillary blood microINR® values, from 210 patients on warfarin. Precision was assessed using control materials and measurement repeatability was calculated on 41 duplicate finger-prick INRs. Triplicate finger-prick INRs using three different instruments (30 patients) and three different test chip lots (29 patients) were used to evaluate instrument & test chip variability.

Results: Linear regression analysis of microINR® and Sysmex CS2100i® values, showed a correlation coefficient of 0.96 ($p < 0.0001$) and a positive proportional bias of 4.4%. Dosage concordance (93.8%) and clinical agreement (95.7%) was high. All acceptance criteria based on ISO standard 17593:2007 system accuracy requirements were met. Control material Coefficients of Variation (CV) varied from 6.2% to 24.7%, depending on control type, and the capillary blood measurement repeatability CV was 7.5%. There was no significant instrument ($p=0.93$) or test chip ($p=0.81$) variability, and the error rate was low (2.8%).

Conclusions: The microINR® instrument is sufficiently accurate and precise, with adequate dosage concordance and clinical agreement, to monitor warfarin therapy. It has a low instrument & test chip error rate and is not subject to significant instrument or test chip variability.

PB 430 | Statistical Evaluation of APTT Clot Waveform Patterns (CWP) in Sequential Samples of Severe Haemophilia A Patients Receiving Long Acting Clotting Factor Concentrates (CFC) - An Observational Study

R. Phatale[1], S. Apte[2], S. Kannan[2], A. Raiyyani[2], D. Vaghasiya[2], H. Balar[2], B.C. Mahadev[2], D. Patel[2], N. Chaturvedi[2]

[1]*Sahyadri Speciality Lab, Haematology Department, Pune, India,* [2]*Sahyadri Speciality Hospital, Haematology and BMT Unit, Pune, India*

Background: We have evaluated APTT CWP on sequential samples of previously treated patients of Severe Haemophilia A, who were on prophylactic therapy of low dose long acting Fc fusion protein recombinant FVIII CFC on weekly basis.

Aims:

1) Statistical comparison between APTT CWP of control and patients

2) To evaluate changes in APTT CWP in sequential samples of the same patient at the trough levels of FVIII activity before the administration of CFC.

3) Anticipating the development of inhibitors from APTT CWP.

Methods: Total 290 APTT CWP of 34 patients along with 30 from normal healthy subjects (control) performed on ACL TOP 300 using Synthesil APTT reagent was evaluated on following parameters:

1) Primary(P) and Secondary(S+ & S-) Derivative evaluation on:

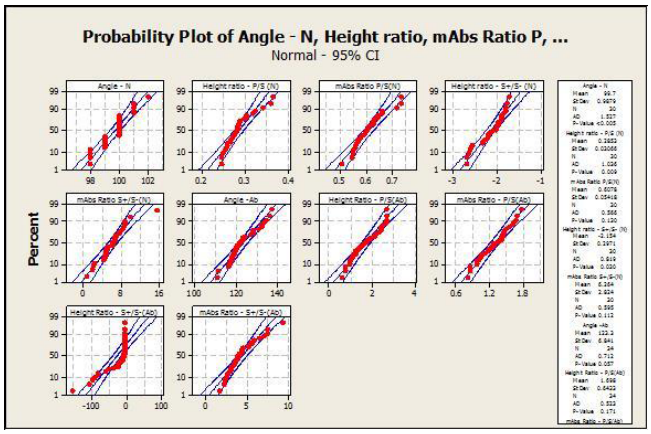

FIGURE 1 Plot 1: Probability plots for Angle, Area ratio, Height ratio, mAbs ratio within control and Haemophilia A

TABLE 1 showing Comparison Between Control and Haemophilia A APTT CWP data

Sample		Angle	Area ratio P/S+	Height Ratio P/S+	mAbs Ratio P/S+	Area Ratio S+/S-	Height Ratio S+/S-	mAbs Ratio S+/S-
Control	Mean	99.7	0.991666667	0.285314259	0.607759387	0.746666667	-2.153852157	6.264040461
Control	Standard Deviation	0.987857	0.131943184	0.030661102	0.054177589	0.043417249	0.297092108	2.82374574
Haemophilia A	Mean	123.2595	10.1903594	1.697696619	1.29191806	1.0604598	-27.432027	4.3471577
Haemophilia A	Standard Deviation	4.802224	4.19013906	0.605967474	0.243944142	0.5056843	60.13778183	1.83182041

Height, mAbs, Area under Curve (AUC), Ratios of AUC, Height, mAbs between P & S,

2) Angle of the Clot curve made with the baseline.

3) Changes in sequential APTT CWP within a patient so as to anticipate inhibitors.

Results: APTT CWP of control showed good correlation between AUC, Height and mAbs ratio between P & S and with angle of the clot curve. There was significant difference between mean of AUC ratio, Height ratio, mAbs ratio, between control and Patient samples. Height ratio and mAbs ratio was well correlated within sequential samples of a patient. Appearance of biphasic (P) with prolongation of plateau and variation in AUC ratio indicate possible presence of inhibitors. Since APTT value at the trough level was beyond 180 sec in many samples, correlation with APTT value was not possible.

Conclusions: Statistical evaluation of the APTT CWP is a reliable tool in anticipating the disease process in Haemophilia A patients. Long acting CFC do not change APTT CWP at the trough levels of factor VIII activity, although there is incidence of development of inhibitors in those patients which can be anticipated from APTT CWP.

Support: This study was supported by educational grant from Instrumentation Laboratory.

PB 431 | Divergence of Normal Ranges Using Thromboelastography as Measured by Clot Viscosity versus Clot Harmonic Resonance

G. Wool, K. Mikrut, J. Miller

University of Chicago, Pathology, Chicago, United States

Background: Thromboelastography measuring clot viscosity and resultant resistance to rotation has been used for many years (TEG 5000). Recently, an instrument utilizing harmonic resonance-based clot detection (TEG 6S) has been approved by the FDA for use in adult cardiac and cardiac surgery patients.

Aims: To compare manufacturer's normal range to a locally defined healthy donor range for both the TEG 5000 and TEG 6S systems.

Methods: 30 healthy donors (without bleeding/clotting history or use of antiplatelet/anticoagulant medications) were identified. Venous blood was collected and run on the TEG 5000 and TEG 6S (Haemonetics, Braintree, MA) instruments using the following activators: kaolin, kaolin with heparinase, kaolin with tissue factor (rapid TEG), and tissue factor with abciximab (functional fibrinogen). Two 5000 instruments and four 6S instruments were employed, rotating through the instruments. FDA approval of the TEG 6S was limited to certain curve parameters; software blocks reporting of non-approved parameters.

Relevant TEG 5000 and 6S curve parameters were analyzed by nonparametric statistics using Microsoft Excel and GraphPad Prism software.

Results: Our local normal ranges were generally narrower than the manufacturer recommended range. This is of particular relevance for the Lysis 30 parameter on the TEG 5000, which may allow detection of more cases of hyperfibrinolysis.

In most instances the 5000 and 6S normal ranges were not identical (Table).

TABLE Local TEG Parameter Normal Ranges Obtained using Kaolin Activator

	R (min)	K (min)	Angle (degrees)	MA (mm)	LY30 (%)
TEG 5000	4.0-8.0	1.0-2.1	60-73	57-74	0.0-5.0
TEG 6S	5.0-8.6	0.8-2.6	61-78	52-69	N/A

Specifically comparing the TEG 5000 and TEG 6S kaolin data, the tightest agreement is for maximal amplitude, with the R square reaching 0.613 (Figure). For the R, K, and Angle values, the scatter is much greater, with R square values of 0.189, 0.234, and 0.287 respectively.

Conclusions: Local donor ranges differ from manufacturer recommended ranges. While TEG 5000 and TEG 6S normal ranges are quite similar, results are not interchangeable as a single distribution does not apply to both TEG 5000 and TEG 6S data.

PB 432 | Identification of Triple Positivity Patients with Major Risk for Thromboses Is Dependent of Methodology Applied at the Lab Investigation

S.A.L. Montalvao, M.C.G.L. Fernandes, S. Soares, A.A. Oliveira, S.C. Huber, E.V. De Paula, F.L.A. Orsi, M.P. Collela, J.M. Annichinno-Bizzachi

Hematology and Hemotherapy Center, University of Campinas, Campinas, Brazil

Background: The diagnosis of antiphospholipid syndrome (APS) is based on the persistent detection of antiphospholipid antibodies (aPL), which two kinds of assays are applied: Functional assay Lupus anticoagulant (LA), and immunological assays anticardiolipin (aCL) and anti-β2 glicoprotein I (aβ2GPI). Due to the heterogeneous antibodies profiles, the aPL assays has high coefficient of variation, evidenced for external quality control programs, close to 50% for aCL/aβ2GPI.

Aims: In order to evaluated when the functional and immunological assays present better results concordance, the objective of this study was to compare the aCL and aβ2GPI performance with different methodologies, in two group of patients, LA(+) and LA(-).

Methods: The IgM/IgG aCL or aβ2GPI were tested by *in house* ELISA and by chemiluminescent (CU). The profiles of aPL antibodies were evaluated as: single positive (aCL-/aβ2GP1-/LA+), double positive (aCL-/aβ2GP1+/ LA+) and triple positive (aβ2GP1+/aCL+/LAC+).

Results: In a total, 280 patients, 140 patients were LA (+) evaluated in two times (12 weeks) and 140 LA (-). For LA (+) group, when the IgM/IgG aCL and IgM/IgG aβ2GPI were compared with both methods, close 35% of patients had results unmated, which rendered a discordant interpretation of the antibodies profile. The concordance of CU with LA (+) were higher when compared in house ELISA with LA (+). In general, most of samples showed false negative results for in house ELISA assay, table 1. The triple positivity was 3.5 folds higher for CU when compared with ELISA. When the persistence of antibodies was evaluated, some patient that has consecutive negative results for ELISA, also showed consecutive positive results for CU. For group LA(-), in house ELISA assay may role out patients who need of treatment.

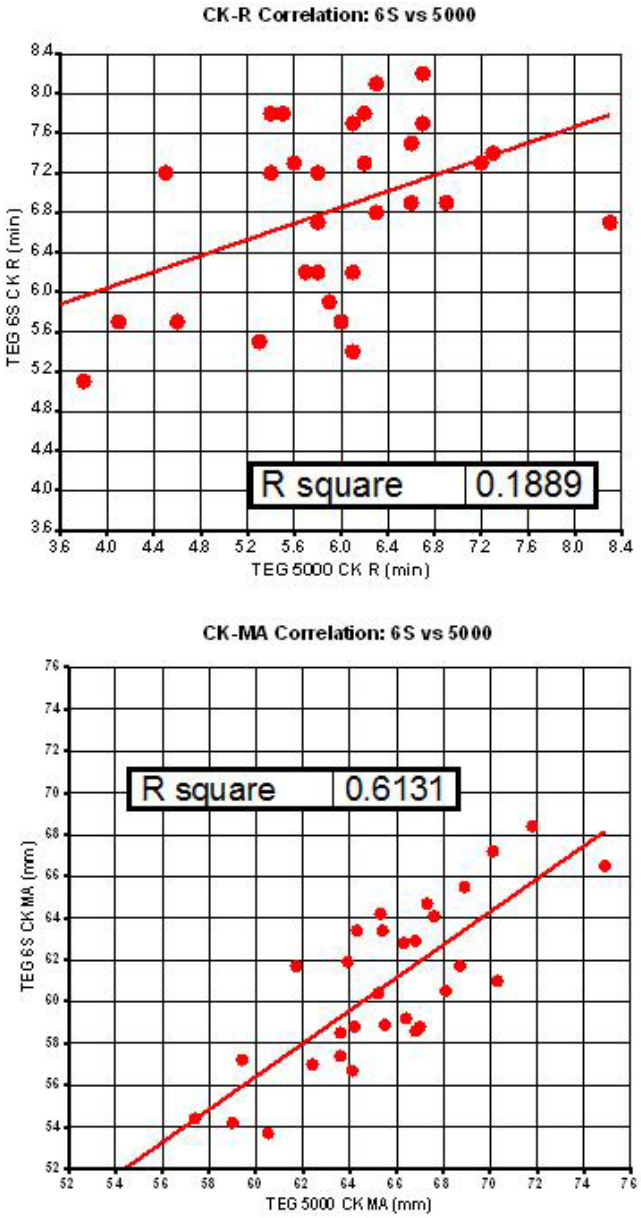

FIGURE 1 Correlation of TEG 5000 and 6S parameters R and MA using kaolin activator

TABLE 1 The aPL assays performed following the international guidelines ISTH for functional and immunological evaluation.

Group 1 LA(+)	Positive results N=140	Median (Minimum to Maximum) LA(+) and LA(-)	Antibodies profile (%)
In house ELISA Methodology			
Anticardiolipin IgG	7	15 GPL (5-50 GPL)	Triple 5%
Anticardiolipin IgM	1	15 GPL (5-40 GPL)	Duple 20%
Anti-β2 glicoprotein IgG/IgM	40	N.D	Single 65%
Chemiluminescent Methodology			
Anticardiolipin IgG	26	2.9 CU (2.6 to 2026.0 CU)	Triple 17%
Anticardiolipin IgM	13	2.5 CU (1.0 to 280 CU)	Duple 8%
Anti-β2 glicoprotein IgG	36	3.6 CU (3.6 to 4833.0 CU)	Single 65%
Anti-β2 glicoprotein IgM	14	1.1 CU (1.1 to 391.0 CU)	

Conclusions: Our results highlight the importance of assays election which presents adequate sensitivity and specificity for diagnosis, once these results affect the clinical decision to indicate continuous anticoagulation for these patients.

PB 433 | Performance Evaluation of the ZL 6000i Cone Plate Viscometer

J. Lee, S. Yu, S. Song, S. Oh, J. Shin, H. Kim, K. Jun, J. Lee

Inje University College of Medicine, Laboratory Medicine, Busan, Korea, Republic of

Background: Elevated whole blood viscosity (WBV) is associated with increasing blood flow resistance in the microcirculation and is used to predict the occurrence and outcome of cardiovascular diseases, such as myocardial infarction and stroke. The ZL 6000i (ZONCI Technology, Beijing, China) is a fully automated blood viscosity analyzer based on

the cone-plate method. We evaluated the analytical performance of the ZL 6000i to measure WBV.

Aims: We established a reference range and validated precision using quality control (QC) and human blood samples. Storage time and temperature effects were also evaluated.

Methods: Samples were collected from 287 normal adults (162 males and 125 females) to establish a reference range. We evaluated total precision for 20 days using QC viscosity materials at shear rates of 1, 50, and 200 s^{-1}, and within-run precision using phlebotomy subjects at shear rates of 1, 5, 30, and 200 s^{-1}. Aliquots of the phlebotomy samples were stored at room temperature and 5°C, respectively, for the stability analysis. All samples were tested at baseline (control) and 6, 24, 48, 72, and 96 hours later to assess changes over time.

Results: Reference intervals differed between males and females (Table 1).

TABLE 1 Reference intervals for specific shear rates in health men and women

	Male (n = 162)		Female (n = 125)	
Age (years)	43 ± 10.9		46 ± 11.0	
Hct (%)	46.2 ± 2.63		40.5 ± 2.29	
Shear rates	Median WBV	Central 95 percentile RI	Median WBV	Central 95 percentile RI
1	21.88	16.554-36.248	17.44	12.168-37.303
5	9.48	7.561-12.847	7.69	6.058-13.172
30	5.35	4.311-6.369	4.51	3.582-5.915
200	3.93	3.261-4.643	3.38	2.816-3.960

The coefficients of variation (CVs) for within-run and total precision with QC material and human whole blood were < 7.5% at all shear rates. The CVs for between-day precision with QC material were < 2.5% at all shear rates. WBV of the samples stored at room temperature for up to 6 hours and at 5°C for up to 2 days did not change compared to the control.

Conclusions: We recommend that separate reference intervals be used for men and women. The results indicate that the ZL-6000i provides rapid, accurate and reproducible WBV data. Viscosity measurements should be finished within 6 hours after sample collection, and samples that cannot be measured within the 6-hour window should be refrigerated until ready to test.

PB 434 | Standardization and Automation of Thrombin Generation Assay: on the Way to the Clinical Lab

J. Douxfils[1], J. Baudar[2], M. Guldenpfennig[2], B. Chatelain[2], J.-B. Nicolas[3], F. Mullier[2]

[1]University of Namur, Pharmacy, Namur, Belgium, [2]CHU UCL Namur, Hematology Laboratory, Yvoir, Belgium, [3]CHU UCL Namur, Department of Internal Medicine, Yvoir, Belgium

Background: Thrombin generation (TG) is known for more than 60 years. Several developments have been done through the years to improve its usability but it remains a research use tool because of a lack of standardization of methods. Typical inter-day precision of TG assays is around 10 to 30% depending on the parameter analyzed. It depends on the concentration and the source of tissue factor (TF) in the reagent, the use of external or local normal plasma to normalize the results, the operator as well as the method (1-2).

Aims: ST Genesia, a new analyzer intended to measure thrombin generation in a fully automated way, was evaluated in our lab for validation purposes.

Aside from biological outcomes of our protocol in the anticoagulant treatment setting, the purpose of this evaluation was also to determine how precise could become TG measurement.

Methods: 41 independent runs of measurement were performed with the same batch of STG - DrugScreen on ST Genesia. On each run, 3 freeze-dried samples were tested prior to testing fresh or frozen patient samples. 2 of these samples were internal quality control samples (hypocoagulable and normocoagulable) and 1 is intended to be used as reference plasma for normalizing results (2).

Results: Mean, standard deviation and coefficient of variation achieved are reported in table 1.

Conclusions: Automation, enhanced control of temperature throughout the assay and standardization of thrombin generation measurement help to achieve highly reproducible results, first step to introduce this assay in the clinical lab.

PB 435 | Accurate Recovery of N9-GP in a One-stage Ellagic Acid Based Clot Assay on the ACL Top Analyzer

A. Khan, M. Doyle, M. Triscott

Instrumentation Laboratory, Research & Development, Bedford, United States

Background: FIX activity measurements for N9-GP exhibit large variations in a one-stage clotting assay (OSCA) owing to reagent specific variability. Previous studies have shown the most accurate N9-GP recovery with SynthAFax [1], an ellagic acid based APTT reagent available for use on IL coagulation analyzers.

Aims: To demonstrate a new test application using SynthAFax on the ACL TOP Family hemostasis test systems that accurately measures FIX activity for N9-GP samples.

Methods: The ACL TOP analyzer was calibrated with Calibration plasma using 8 dilution levels. The FIX-SynthAFax (FIX-SFX) application showed linearity with N9-GP from 1 to 150%. N9-GP spiked samples were prepared at three levels (100, 40 & 5%, n=40 each level) and tested with SynthAFax as the APTT reagent over five days on two representative ACL TOP instruments.

A multi-site internal study was also conducted with three spiked N9-GP samples (100, 40 & 5%, n=50 each level) and the SSC/ISTH secondary standard over 5 days on the ACL TOP analyzer. Data was compared across sites and mean results from each site were subsequently used to calculate the percentage of target recovery. For the purpose of this study, a target recovery range of ± 30% was considered to be acceptable.

Results: The FIX-SFX calibration was validated and used for data analysis. Results from all N9-GP samples recovered with precision comparable to IL controls. N9-GP samples at 100% and 40% recovered values within the acceptance criteria of %CV within device ≤ 15%. Samples at all levels consistently recovered at 100± 30% of the target. Results from internal testing compared well across days and all sample levels. Percent target recovery calculated for each site, for each N9-GP level was comparable and consistent, recovering within the target range.

Conclusions: N9-GP showed consistent results and accurate recovery using the new FIX-SFX application on the ACL TOP test systems with the SynthAFax in an OSCA.

PB 436 | A Performance Evaluation of a New Lupus Sensitive APTT Reagent

C. Gardiner[1], E. Kinoshita[2], K. Akatsuchi[2], P. Lane[1], I. Patel[1,3], S.J. Machin[1], I.J. Mackie[1]

[1]*University College London, Haemostasis Research Unit, London, United Kingdom,* [2]*Sysmex Corporation, Kobe, Japan,* [3]*Sysmex UK, Milton Keynes, United Kingdom*

Background: We report on the performance of a new APTT reagent (NewAPTT, Sysmex Corp. Japan), containing ellagic acid and synthetic phospholipids, which is sensitive to lupus anticoagulant (LA).

Aims: To compare the performance of New APTT with two widely used APTT reagents; reagent A (LA sensitive) and reagent B (LA insensitive).

Methods: The performance of NewAPTT was compared to that of two commercial APTT reagents, both containing ellagic acid and purified phospholipids (Reagents A and B), on a Sysmex CS-5100 coagulometer.

Results: Normal reference ranges were established in 123 normal healthy donors (see table). Acceptable between-day imprecision was obtained for all 3 reagents and excellent on-board stability was observed. Good correlation was observed between NewAPTT and reagent A with NewAPTT showing greater sensitivity to LA. The sensitivity to deficiencies in FVIII, FIX, FXI and FXII was assessed by testing deficient plasmas supplemented with normal plasma to achieve a range of concentrations of 10 - 100%. The sensitivity of NewAPTT was similar to Reagent B and superior to Reagent A. All three reagents had similar sensitivity to coagulation defects in liver disease. NewAPTT and Reagent B had similar sensitivity to unfractionated heparin; both were more sensitive than reagent A.

TABLE 1

	NewAPTT	APTT Reagent A	APTT Reagent B
Normal range (s) n = 50	24.73 - 35.29	23.12 - 31.49	21.04 - 28.92
Between Day imprecision %CV normal QC; abnormal QC	0.34; 0.47	0.29; 0.45	0.36; 0.32
4 day on-board stability (% change from day 0 in 3 levels of QC material	0.33 to 1.46	0.55 to 0.76	1.26 to 3.09
Mean APTT ratio in LA plasmas (n=30)	1.75	1.30	1.10
Correlation vs reagent A (r)	0.92	-	0.36
Correlation vs reagent B (r)	0.19	0.36	-
% above normal range	70	60	20
Factor VIII, IX, XI & XII sensitivity %	62; 35; 55; 47	48; 13; 22; 20	60;28;60; 18

Conclusions: NewAPTT showed comparable or improved performance relative to two widely used APTT reagents and is suitable for use in the detection of LA, inherited factor II, V, VII and X deficiency and assessment of coagulopathy in liver disease.

PB 437 | Standardization and Automation of Thrombin Generation (TG) Assay Measured in Presence and Absence of Thrombomodulin: TG on its Way to the Clinical Lab

University of Padua, Department of Medicine, Padua, Italy

TABLE 1 Thrombin generation in quality controls

n=18	Sample 1 = STG - QualiTest Norm TS			Sample 2 = STG - QualiTest Low TS			Sample 3 = STG - QualiTest High TS		
	Mean	SD	CV	Mean	SD	CV	Mean	SD	CV
Lag time (min)	1.52	0.05	3.07%	1.97	0.07	3.73%	1.36	0.03	2.49%
Peak (nM)	231.75	19.89	8.58%	90.48	11.95	13.20%	419.37	14.23	3.39%
ETP (nM.min)	1198.33	93.27	7.78%	519.55	28.54	5.49%	1380.11	80.59	5.84%
ETP Inhibition induced by TM (%)	23.17	3.42	14.76%	39.42	5.92	15.02%	ND (many results < 5%)		
Lag time (ratio)	0.87	0.03	3.43%	1.12	0.05	4.32%	0.78	0.03	3.83%
Peak (%)	82.51	3.63	4.40%	32.18	2.74	8.51%	150.07	9.34	6.22%
ETP (%)	86.46	4.20	4.86%	37.64	3.01	8.00%	99.80	5.12	5.14%

Background: Thrombin generation (TG) is known for more than 60 years and remains a research use tool despite usability improvements done through the years. This is due to a lack of standardization of methods leading to impaired precision. Typical inter-day precision of TG assays is around 10 to 30% depending on the parameter analyzed. It depends on the concentration and the source of tissue factor (TF) in the reagent, the use of external or local normal plasma to normalize the results, the operator as well as the method (Perrin J *et al*, Thromb Res 2015).

Aims: ST Genesia, a new analyzer intended to measure TG in a fully automated way, was evaluated in our lab for validation purposes in thrombophilia patients.

Aside from biological and clinical outcomes of our protocol on how useful could be to evaluate the thrombotic risk in thrombophilia patients, with and without thrombomodulin (TM), the purpose of this evaluation was also to determine how precise could become TG measurement.

Methods: 18 independent runs of measurement were performed with the same batch of STG - ThromboScreen (medium TF activity in presence or absence of TM) on ST Genesia analyzer. On each run, 4 freeze-dried samples were tested prior to testing fresh or frozen patient samples. 3 of these samples were internal quality control samples (hypo-, normo- and hypercoagulable) and 1 is intended to be used as reference plasma for normalizing results (1) in absence of TM only.

Results: Mean, standard deviation and coefficient of variation achieved are reported in Table 1 and Table 2.

TABLE 2 Thrombin generation in reference plasma

n=18	Sample 4 = STG - RefPlasma TS		
	Mean	SD	CV
Lag time (min)	1.75	0.06	3.69%
Peak (nM)	280.96	21.84	7.77%
ETP (nM.min)	1387.78	109.47	7.89%
ETP Inhibition induced by TM (%)	NA	NA	NA
Lag time (ratio)	NA	NA	NA
Peak (%)	NA	NA	NA
ETP (%)	NA	NA	NA

Conclusions: Automation, enhanced control of temperature throughout the assay, normalization of results and standardization of TG measurement help to achieve more reproducible results all over the TG profile range. This is an important step to introduce this assay in the clinical lab.

PB 438 | Establishment of Oral Anticoagulant Monitoring Facility at Tertiary Care Teaching Hospital in Western India: Four Years Experience

A. Kelkar, A. Nisal, P. Doshi, A. Moses, N. Gaikwad, R. Nimbargi, N.S. Mani

Bharati Vidyapeeth University Medical College and Hospital, Pathology, Pune, India

Background:

- In India, majority of the patients requiring oral anticoagulation are on Vitamin K antagonists requiring monitoring of PT-INR. Establishment of regular facilities for **precise** monitoring of PT-INR is still a major concern.
- Our institutional coagulation laboratory (Routine) handles > 10,000 patients per annum with ~1500 requests for oral anticoagulation monitoring.
- Here we give an account of our experience of establishing quality systems in the coagulation laboratory, liasoning and coordination between different departments in the hospital, education of the Post-Graduate Students, Faculty and patients; resulting in better patient care.
- We believe and hope that our experience would be of practical benefit for establishing such facilities in other parts of the world.

Aims: To establish the systems for effective monitoring of patients on oral anticoagulants.

Methods: Our laboratory has a fully automated random access coagulation analyser and back up semi-automated instruments from IL. Following measures were implemented:

- Developing protocols for sample collection and processing.
- Establishing the „Quality Systems" in the coagulation laboratory.
- Training of the technical staff, resident doctors and faculty.

- Education of the patients.
- Coordination and liasoning protocols with clinical faculty.

Results:

- Steady increase in the number of patients regularly availing laboratory facilities reflecting the trust of clinicians and patients.
- Number of cases with untoward effects / complications decreased over the period of time.
- Patients´ education resulted in better compliance.
- Training of the doctors and coordination resulted in better patient care.

Conclusions:

- The monitoring of patients on oral anticoagulants improved with systematic efforts.
- Patients were benefited in terms of decreased overall cost of management due to accuracy of results, decreased morbidity and complications, decreased visits for check ups, reduced mental stress.
- Multi-pronged approach results in precise monitoring of patients on oral anticoagulants.

PB 439 | Do Chinese Patients with Heart Valve Replacement Benefit from Warfarin Pharmacogenetic Test: A Pilot Retrospective Study

Y. Hao[1], Y. Hu[1,2], X. Yan[1], S. Cao[1], Z. Zhang[1], L. Zhang[1], X. Zheng[1,2]

[1]Wuhan Asia Heart Hospital, Wuhan University, Department of Clinical Laboratory and Pathology, Wuhan, China, [2]Wuhan Asia Heart Hospital, Wuhan University, Laboratory of Molecular Cardiology, Wuhan, China

Background: How much the patients could benefit from warfarin pharmacogenetic test has been discussed for years since genetic backgrounds are different among races, and polymorphisms in CYP2C9/VKORC1 account for less than 70% of interindividual variability in warfarin dosing requirements.

Aims: We carried out a pilot retrospective study to investigate the in-hospital warfarin adjusting time according to pharmacogenetic test in Chinese patients.

Methods: Patients receiving heart valve replacement in Wuhan Asia Heart Hospital were included in analysis. Warfarin pharmacogenetic tests for CYP2C9*3 (rs1057910) and VKORC1 (-1639G>A) were applied before warfarin therapy. Recommended dose was calculated based on parameters according to IWPC pharmacogenetic algorithm. Therapeutic INR was determined by surgeons. Days for in-hospital adjusting warfarin dose were analyzed. Appropriate statistic tests were performed according to the data.

Results: 210 patients having genotype-guided warfarin adjustment were included in analysis. 100 patients following INR-guided warfarin adjustment were included as control.There were 187 patients with *1*1 (89.05%), 22 with *1*3 (10.48%), and 1 with *3*3 (0.48%) in CYP2C9*3 genotyping. 172 patients had AA (81.9%), and 38 had AG (18.10%) in VKORC1. Patients having genotype-guided warfarin adjusting reached their therapeutic INR in shorter time comparing with control (3.9±1.6 vs 4.9±2.8 days, P< 0.01). Pharmacogenetic test not only reduced adjusting time for those whose therapeutic dosing was lower than 5.0/day between investigation and control groups (3.9±1.6 vs 4.6±2.2 days, P< 0.01), it also cut off nearly two fold in adjusting time comparing with control when patients needed more than 5.0 mg/d for their warfarin therapy (4.7± 1.5 vs 11.6±5.3 days, P< 0.01).

Conclusions: Pharmacogenetic test could significantly reduce the in-hospital adjusting time for optimal warfarin dosing in Chinese patients with heart valve replacement, especially for those who may require high dose for warfarin therapy.

PB 440 | Analytical Performance of an Anti Xa Assay with Rivaroxaban Specific Calibrators

C. Duboscq[1], J. Ceresetto[2], C. Shanley[2], O. Rabinovich[2], S. Palmer[2], G. Stemmelin[2]

[1]Hospital Británico de Buenos Aires, Ciudad Autónoma de Buenos Aires, Argentina, [2]Hospital Británico de Buenos Aires, Servicio de Hematologia y Hemoterapia, Ciudad Autónoma de Buenos Aires, Argentina

Background: Rivaroxaban (RIVA) have been developed without the need of routine monitoring, although laboratory testing may be required in select situations. The gold standard method to measure this drug is de HPLC-Tadem mass spectrometry but some chromogenic methods have been developed to measure the RIVA concentration.

Aims: Evaluate the performance of anti Xa dependent chromogenic assay with no external antithrombin using RIVA calibrators.

Methods: RIVA level was measured by HemosiL Liq Anti Xa .Two levels of specific calibrators are used to create a 5-point calibration curve (HemosiL Rivaroxaban calibrators) on ACL TOP 500. Controls high (CH,313 ng/mL) and low (CL,83 ng/mL) (HemosiL Rivaroxaban controls) were used to assessment the precision and accuracy by EP15 A2. The linearity range were investigated by successive dilution of a patient sample with 845 ng/ml . Detection limit was also determined doing 60 runs during 5 days. Bilirubin and hemoglobin interference were investigated spiking them into three samples with different level of RIVA.

Population: 20 patients who were anticoagulated with RIVA 15 or 20 mg once daily.(4- 12 hs since last dose) and 10 healthy controls.

Results: RIVA test showed a CV inter assay 1,8 % for CH and 1,4 for CL ; the bias was 5,7 % for CL and 15,8 % for CH according EP 15 A2 CLSI protocol . The linearity range was 0 - 500 ng/mL without reflex test. The interference from hemoglobin was negligible up to 500 mg/dl instead no interference was observed for bilirrubin. In all normal samples RIVA levels was lower than 0,001 ng/ml and the detection limit was 8 ng /ml. The RIVA level detected in the patients was the expected according with the doses and the times from last intake.

Conclusions: In our experience this method with rivaroxaban specific calibrators has been a robust assay for detection rivaroxaban in plasma. The test has a satisfactory calibrator/control stability, good sample precision.with minimum interference from pre analytical variable.

PB 441 | Multicenter Study on the Interference of Spontaneous Hemolysis at Blood Sampling on Five Main Hemostasis Tests

C. Novelli[1], B. Morelli[1], M. Vidali[2], Study Group of Hemostasis and Thrombosis of Italian Society of Clinical Biochemistry and Molecular Biology (SIBioC)

[1]*Legnano Hospital - ASST Ovest Milanese, Transfusion Center and Haematology Laboratory, Legnano, Italy,* [2]*Borgomanero Hospital, Transfusion Center, Borgomanero, Italy*

Background: Hemolysis is the first cause of rejection in hemostasis samples. Many studies demonstrate the effect of hemolysis on coagulation tests using artificially hemolyzed samples. New coagulometers able to identify optical interferences in order to replace visual inspection have been released.

Aims: To evaluate the impact of spontaneous in vitro hemolysis on the main five hemostasis tests, hemolyzed samples (Es) were compared with another non-hemolyzed (NEs) specimen obtained from the same patient within 4h.

Methods: A multicenter study involved 15 hospitals for the collection of paired samples (Es + NEs). 200 pairs of frozen plasma were analyzed with ACL TOP 750 CTS (IL) for 5 tests: PT, aPTT, D-Dimer (DD), Fibrinogen (Fib) and Antithrombin (AT). Critical difference (CD) between Es and NEs for each analyte was calculated as $2.77x(CVa^2+CVi^2)^{1/2}$ (CVa=analytical coefficient of variation,CVi =within-subject biological variation). Bias between Es and NEs was evaluated by Bland-Altman analysis.

Results: Median values for all tests and median free hemoglobin (IQR, min-max) for Es and NEs are shown in Tab1. Mean bias (95% of the differences Es-NEs) was -0.1s(-7.9 to 7.6) for PT, -1.1s(-12.3 to 10.0) for aPTT, 1366ng/mL(-12650 to 15383) for DD, -4mg/dL(-130 to 122) for Fib and 1.2%(-17 to 19) for AT. Differences beyond critical limit based on CVa and CVi were 9.5% for PT, 37% for aPTT, 13% for DD, 5.5% for Fib and 5% for AT. Correlations (r) between free hemoglobin concentration and E-NE differences were 0.17(PT), 0.17(aPTT), -0.04(DD), 0.22(Fib) and -0.08(AT). All DD differences >10000ng/mL(n=10) had aPTT ratio < 0.86. Mean bias for DD, without these samples, falls to 61.7ng/mL(-1977 to 2100).

TABLE 1 Median values (IQR, min-max) for PT, aPTT, DD, Fib and AT and median free hemoglobin (IQR, min-max) for Es and NEs

	Hemolyzed samples Median (IQR; min-max)	Non Hemolyzed samples Median (IQR; min-max)	P (Paired-samples t-test)
PT sec	13.0 (11.5-21.0; 9.6-246.9)	13.0 (11.4-21.0; 9.9-286.8)	p=0.687
PT Ratio	1.14 (1.00-1.84; 0.84-21.7)	1.14 (1.00-1.84; 0.87-25.2)	p=0.691
aPTT sec	31.9 (28.2-37.5; 19.2-77.2)	33.5 (29.4-37.4; 22.0-80.6)	p=0.005*
aPTT Ratio	1.04 (0.92-1.22; 0.62-2.51)	1.09 (0.95-1.22; 0.71-2.62)	p=0.005*
D-Dimer ng/mL	412 (208-1016; 25-67784)	329 (188-762; 36-28695)	p=0.007*
Fibrinogen mg/dL	378 (304-506; 74-1098)	389 (304-506; 64-1050)	p=0.376
Antithrombin %	103 (88-116; 25-153)	102 (89-115; 26-186)	p=0.066
Free hemoglobin g/L	1.97 (1.34-3.14; 0.52-15.3)	0.29 (0.29-0.29; 0.13-1.47)	p<0.001*

Conclusions: Our data suggest that in vitro hemolysis does not affect PT, Fib and AT. A moderate bias and a significant difference was instead observed for DD, and to some extent to aPTT, but at least some largest discrepancies are likely due to interferences different than hemolysis, such as activation of the coagulative cascade.

PB 442 | Performance Evaluation of the Coag-Sense® Point-of-Care INR-testing System

J. Joubert[1,2], M.C. Van Zyl[1], J. Raubenheimer[3]

[1]*University of the Free State, Department of Haematology and Cell Biology, Bloemfontein, South Africa,* [2]*National Health Laboratory Service, Universitas Academic Laboratories, Department of Haematology and Cell Biology, Bloemfontein, South Africa,* [3]*University of the Free State, Department of Biostatistics, Bloemfontein, South Africa*

Background: Novel point-of-care (POC) instruments for International Normalised Ratio (INR) testing are regularly entering the market. New instruments should ideally be subjected to multicentre validation studies to confirm that they are fit for purpose.

Aims: To evaluate the Coag-Sense® INR monitoring system for accuracy, measurement repeatability, instrument & test strip variability, and error rates.

Methods: Capillary blood Coag-Sense® values from 202 patients on warfarin were compared with venous blood INRs obtained with Thromborel® S on a Sysmex CS-2100i® analyser. Control materials were used to assess precision, and measurement repeatability was calculated on 46 duplicate finger-prick values. Instrument & test strip variability was evaluated on triplicate finger-prick values obtained on three different instruments (30 patients) and three different test strip lots (28 patients).

Results: A correlation coefficient of 0.93 (p< 0.0001) and a positive proportional bias of 15.3% was found on linear regression analysis. Although overall dosage concordance was low (70.3%), broader clinical agreement was high (91.0%). Control material coefficients of variation (CV) varied from 3.6% to 19.0%, depending on the control type, and the capillary blood measurement repeatability CV was 17.6%. There was no significant instrument (p=0.59) or test strip (p=0.36) variability, but the error rate was high (16.4%).

Conclusions: The Coag-Sense® instrument is generally adequate in terms of accuracy, broader clinical agreement, precision and instrument & test strip variability. The measurement repeatability, dosage concordance, and instrument & test strip error rate, can be improved.

PB 443 | Thrombin Generation in Patients with Coronary Complications during the First Year after Percutaneous Intervention

T. Vavilova, V. Udina, O. Napalkova, E. Vasilieva, M. Karpenko

Federal Almazov North-West Medical Research Centre, Saint Petersburg, Russian Federation

Background: Thrombin generation test (TGT) may be useful for dynamic assessment of the patients undergoing percutaneous coronary intervention (PCI). However, data about differences between patients with and without stent thrombosis or restenosis are few.

Aims: To determine thrombin generation, measured by TGT, in patients after PCI according the presentation of stent thrombosis or restenosis during the first year of observation.

Methods: 100 patients with stable coronary artery disease and PCI were observed during first year: 13 with stent thrombosis or restenosis (group I), 87 - without any thrombotic events or restenosis (group II) and 28 healthy donors (group III). Lag time, min; ETP, nmol/min; Peak Thrombin, nmol; ttPeak, min and its' modifications with thrombomodulin (TM) were determined before PCI, on the 3, 7, 90, 180 and 365 days after by Thrombinoscope BV, Holland and ThermoFisher SCIENTIFIC, Finland.

Results: Before PCI: Group I and Group III were different in ETP (1947±74058 and 1644±28443, p=0.01), ETP with TM (1054±69772 and 724±52317, p=0.0008), Peak Thrombin with TM (191±3653 and 148±2864, p=0.04) and ttPeak with TM (5.8±0.5 and 5.3±0.4, p=0.03). Between Group II and Group III only a difference in ETP with TM were found (975±144994 and 724±52317, p=0.001). Both patients' groups showed the same dynamics after surgery: decrease ETP and ETP with TM from 3 to 90 days. However, Group I ETP seemed to be higher then in Group III (1794±53033 and 1644±28443, respectively, ns) in 90 days of observation. In Group II, the ETP reached those of healthy donors (1666±90761 и 1644±28443, respectively). The medium value of ETP with TM in groups I and II tended to decrease up to day 90, but was higher than in Group III (1037±104329, 1044±162742 and 724±52316, respectively).

Conclusions: ETP is the most informative component TGT suitable for dynamic observation of the coagulation activity in patients with different outcomes after PCI.

PB 444 | Prediction of Partial Thromboplastin Time (PTT) and Prothrombin Time (PT) on the Basis of Factor Assay Activities Using Data from a Clinical Data Warehouse

A. Obstfeld, M. Lambert

Children's Hospital of Philadelphia, Pathology and Laboratory Medicine, Philadelphia, United States

Background: Clinically, when a patient has multiple factor deficiencies it is unclear to what degree each factor influences the overall screening results. This is important when assessing complex patients with PT/PTT abnormalities who may have multiple factor deficiencies. The data repository at our hospital contains data from patients with tandem screening and factor assays. This data may be useful in determining PT/PTT results given multiple factor abnormalities.

Aims: To determine if factor assay activities can be used in combination to predict PT/PTT results using retrospective data from tested patients.

Methods: We collected 15 years' worth of data with >10,000 instances of tandem PT/PTT and factor assays. We created univariate models on log transformed values and then trained multivariate linear regression (LM) and random forest (RF) models with five-fold cross-validation to predict the PT/PTT value given factor assay results.

Results:

TABLE 1 Models for PT results

Factor	Beta	P-Value	R-Squared
Factor X	-7.549	6.01E -121	0.37372
Factor VII	-5.523	3.93E -288	0.43188
Factor V	-4.655	4.63E -32	0.09346
Fibrinogen	-2.474	1.08E -19	0.03082
Factor IX	-0.907	3E -12	0.03131
Factor XI	-0.169	0.11	0.00183
Factor XII	-0.023	0.879	-0.00178
Factor VIII	0.896	2.55E -45	0.02512

TABLE 2 Models for PTT results

Factor	Beta	P-Value	R-Squared
Factor XI	-18.55	2.59E -138	0.4921
Factor V	-17.9	1.91E -35	0.1125
Factor II	-15.35	1.27E -45	0.1722
Factor XII	-12.44	5.19E -23	0.1392
Fibrinogen	-10.63	1.19E -27	0.0468
Factor VII	-9.17	8.79E-66	0.1363
Factor X	-8.56	2.34E -17	0.0649
Factor VIII	-7.23	2.37E -211	0.1136

Tables 1 and 2 represent the results for univariate regression for PT and PTT, respectively. Factors X and VII associated strongly with PT results, as expected. While factor VIII was significantly associated with PT, the R^2 value indicated an overall poor correlation. Factor XI was found to be most strongly associated with PTT results. Interestingly factor VII was found to be associated with PTT as well, likely due to covariation with other liver dependent factors. Evaluation of multivariate models demonstrated fair performance of the LM for PT and PTT with R^2 values of 0.47 and 0.38, respectively. In contrast, the RF model performed significantly better with R^2 values of 0.65 and 0.47 for PT and PTT, respectively.

Conclusions: We found the expected relationship between factors and PT/PTT using retrospective laboratory data. Furthermore we created regression models that can be used to predict PT and PTT results. We hope to demonstrate the utility of these models in lab order decision making and in guiding coagulation reflex algorithms.

PB 445 | Use of a Synthetic Collagen to Monitor Platelet Function in Patients Receiving Dual Antiplatelet Therapy

W. Jeske, V. Escalante, W. Klein, C. Kartje, J. Walenga, M. Bakhos

Loyola University Medical Center, Cardiovascular Research Institute, Maywood, United States

Background: Patients with coronary artery disease (CAD) are treated with aspirin and a P2Y12 antagonist to prevent myocardial infarction or stent thrombosis. Variable clinical response to both types of agents has been reported. Existing assays to identify sub-optimal response to anti-platelet therapy do not meet reported medical needs.

Aims: To characterize the utility of a synthetic collagen (SynC) to monitor platelet function in patients on dual-antiplatelet therapy.

Methods: Blood samples from healthy individuals (n=5) and CAD patients treated with clopidogrel (75-600 mg) with or without aspirin (75-325 mg) (n=51) were centrifuged to produce plasmas for aggregometry studies (PAP 8E, Bio/Data Corp. Horsham, PA). The aggregation response to 20 µM ADP, 500 µg/ml arachidonic acid and 190 µg/ml Type 1 biologic collagen was compared to that induced by SynC (2-200 ng/ml; JNC Corp., Yokohama, Japan). The aggregation response was characterized in terms of % aggregation, slope and AUC.

Results: Using plasmas from healthy individuals and CAD patients, two lots of SynC produced a concentration-dependent aggregation response over a concentration range of 16 to 128 ng/ml. Patients treated with 81 mg aspirin and 75 mg clopidogrel (33 of 51 patients) were stratified into two groups based on their % aggregation response to SynC, using the median % aggregation as the cut point. While the two groups had a distinct response to SynC, the median responses to ADP, arachidonic acid and biologic collagen were nearly the same and there was a strong overlap between the responses to these agonists in the two sub-groups. This is most evident at the lower concentrations of SynC.

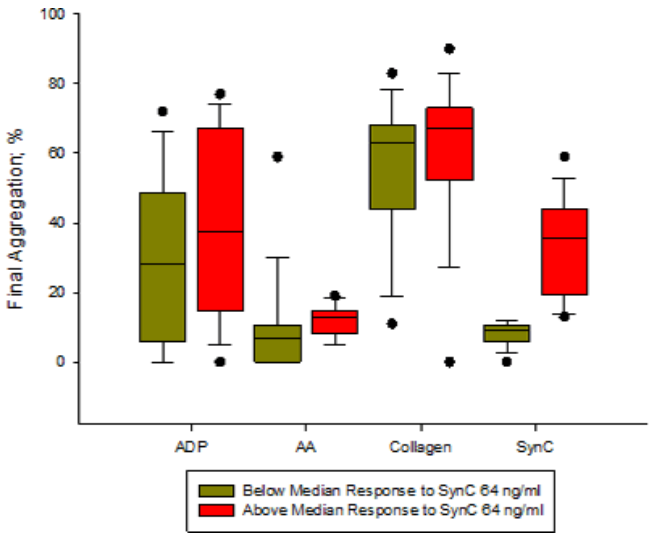

FIGURE 1

Conclusions: SynC-induced platelet aggregation may identify subgroups of patients with sub-optimal response to dual antiplatelet therapy that go undetected with traditional platelet agonists. Studies to clarify why biologic and synthetic collagens have different sensitivities to aspirin and clopidogrel are warranted.

PB 446 | Stability of TGA Parameters in Patients Treated with Anticoagulants Using the Fully Automated ST-Genesia System

J. Douxfils[1], J.-B. Nicolas[2], A.-S. Larock[3], B. Devalet[4], Y. Vandermeeren[5], V. Gérard[6], M. Guldenpfennig[7], K. De Fays[5], J. Baudar[7], F. Mullier[7]

[1]University of Namur, Department of Pharmacy, Namur, Belgium, [2]CHU UCL Namur, Department of Internal Medicine, Yvoir, Belgium, [3]CHU UCL Namur, Department of Pharmacy, Yvoir, Belgium, [4]CHU UCL Namur, Department of Hematology, Yvoir, Belgium, [5]CHU UCL Namur, Department of Neurology, Yvoir, Belgium, [6]CHU UCL Namur, Department of Emergency, Yvoir, Belgium, [7]CHU UCL Namur, Hematology Laboratory, Yvoir, Belgium

Background: Current thrombin generation assay (TGA) systems are semi-automated with samples tested in batch. Thus, the method lacks automation and standardization for homogeneity in results from study to study. TGA may be more informative than plasma concentration to assess the intensity of anticoagulation in a particular individual. A new automated and standardized TGA assay (i.e: ST-Genesia) has been recently developed by Stago.

Aims: To assess if TGA results in healthy subjects and patients treated by DOACs (dabigatran, rivaroxaban, apixaban), vitamin K antagonist (acenocoumarol) or LMWH (enoxaparin) are stable along time on samples stored at around -80°C during 10 months.

Methods: 6 healthy individuals and 30 samples of patients treated with anticoagulants were planned to be collected according to standard pre-analytical conditions. Samples were taken at peak and anticoagulant activity was measured according to current recommendations. Each sample were planned to be tested fresh (D0) and after storage at -80°C during 1 day (D1), 1 month (M1), 2 months, 3 months, 6 months, 9 months and 10 months. Impact of freezing (D1 vs D0) was to be assessed through paired-sample analysis (Student or Wilcoxon test) and stability through evaluation of trends overtime vs D1.

Results: Currently 6 healthy subjects, 7 apixaban, 3 dabigatran, 6 rivaroxaban, 5 VKA and 6 LMWH patients were included. Only results for D0, D1 and M1 are currently available. Table 1 summarizes, the mean difference relative to D0 or D1 and the range of relative deviations.

Conclusions: Freezing slightly affects all TG parameters. Once plasmas are frozen, TG parameters are also slightly influenced during the first month of storage. As it is frequently impossible to ensure that storage duration of samples is strictly equivalent throughout a study on a plasma bank, working with fresh samples would help in avoiding the outliers observed. This demonstrates the utility of a fully automatized TGA analyzer that could be integrated in the routine lab.

TABLE 1 Stability of TGA parameters after 1 day and 1 month storage at -80°C.

		Lag time (min)		Peak Height (nM)		Time to Peak (min)		ETP (nM.min)	
		D1 vs D0	M1 vs D1	D1 vs D0	M1 vs D1	D1 vs D0	M1 vs D1	D1 vs D0	M1 vs D1
Healthy subjects	Mean diff. (range)	-1% (-15 to 11%)	-8% (-12 to 4%)	-8% (-12 to 4%)	5% (0 to 7%)	-1% (-19 to 20%)	-7% (-10% to -3%)	-6% (-27% to 24%)	-2% (-8% to 3%)
Apixaban	Mean diff. (range)	0% (-10% to 12%)	1% (-20% to 33%)	15% (-4% to 28%)	-2% (-12% to 9%)	-4% (-12% to 6%)	1% (-8% to 15%)	2% (-9% to 7%)	0% (-23% to 18%)
Dabigatran	Mean diff. (range)	-10% (-14% to -4%)	-10% (-19% to 2%)	2% (-3% to 6%)	3% (-2% to 8%)	-7% (-12% to 1%)	-9% (-16% to -2%)	2% (1% to 3%)	-6% (-8% to -3%)

PB 447 | First European Evaluation of ClarityCor Plasma Set for Instrument to Instrument Reproducibility Assessment

M.M.W. De Sloovere, K.M. Devreese

Ghent University Hospital, Coagulation Lab, Department of Laboratory Medicine, Ghent, Belgium

Background: In Accreditation context, labs have to manage reproducibility between instruments.

To perform such testing, the lab can archive patient samples spanning the reportable range or can purchase pre-assayed validation plasma sets from commercial suppliers.

In this context, Stago (Asnières, France) has developed the ClarityCor (CC) Plasma Set, a set of frozen plasmas enabling to verify the correlation between different coagulation analysers.

Aims: Evaluation of CC Plasma Set to assess between-instrument reproducibility in comparison to locally selected frozen plasma samples.

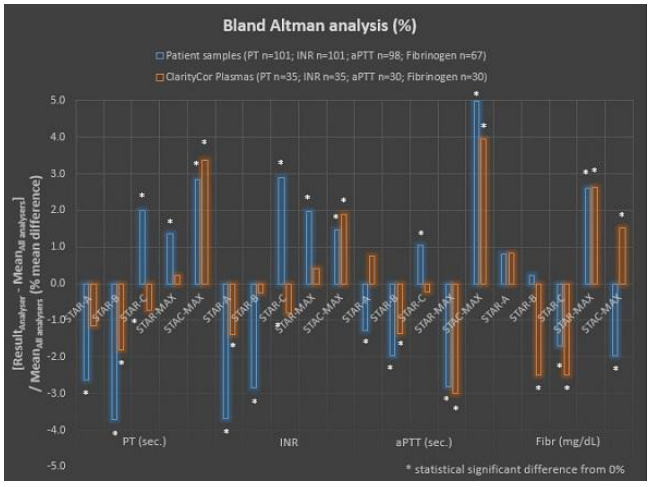

FIGURE 1 Overview of %mean bias comparing a single analyser (3 STAR Evolutions [A,B,C],STAR-MAX,STAC-MAX) with the mean of all analysers for routine parameters

Methods: One CC Plasma Set (n=30 for PT, INR, aPTT and Fibrinogen (Fibr) + n=5 for INR across the reportable range) was used for each instrument in the lab (Figure 1). In addition, citrated patient plasmas were collected. Method comparison to the mean of all analysers was done by Passing-Bablok (PB) regression and Bland-Altman (BA) analysis. Comparison was made between CC Plasma and patient sample datasets.

Results: Rank correlations (Rs) were between 0.967 and 0.999. PB slopes revealed no proportional bias for PT(sec) and INR of patient samples and CC Plasma Set except for STAR-MAX. 2/5 and 3/5 analysers showed concordant slope results between both data sets for aPTT and fibrinogen.. The %mean difference was ≤5% and ≤3.7% for all analyser/parameter combinations as compared to the mean and between datasets respectively (figure 1). All manufacturer's criteria were met (Rs>0.95, proportional(slope:0.9< x< 1.1) and systematic bias(BA %bias: 5-10%)).

Conclusions: Between instrument evaluation with CC Plasma Set results in sufficient data across the measuring range of PT, INR, aPTT and Fibrinogen. No major deviations were noted between frozen samples and CC Plasma Set. Given the advantages of sufficient plasma volume for all 3 parameters on a multitude of analysers and no need for time-consuming selection of suitable patient samples, the CC Plasma Set is a good alternative for local patient samples to evaluate between-instrument reproducibility.

PB 448 | Comparison of Activated Clotting Time Measured by I-STAT, Sonoclot and ACTPlus and Correlation with Anti-Xa during Cardiopulmonary Bypass Procedures

S. Vandendriessche[1], F. De Somer[2], H. Laverge[1], K. Devreese[1]

[1]*University Hospital Ghent, Clinical Biology, Ghent, Belgium,* [2]*University Hospital Ghent, Cardiac Surgery, Ghent, Belgium*

Background: Activated clotting time (ACT) is used to monitor anticoagulation therapy with high heparin concentrations.

Aims: This study evaluated ACT measurements by 3 point-of-care instruments [I-STAT (Abott), ACTPlus (Medtronic) and Sonoclot (Sienco, Inc)] and their correlation with anti-Xa values during cardiopulmonary surgery (CPS).

Methods: One ACTPlus instrument (measuring in duplicate) was compared with simultaneous, parallel measurements on two I-Stat and two Sonoclot. For 30 adults receiving heparin during CPS, ACT was measured at four time points: before heparin administration, 3min following administration, 15min and 45min after starting CPS. Acceptance criteria for duplicate (intra-assay, ACTPlus) and parallel (inter-assay, I-Stat and Sonoclot) measurements were set as ≤12% spread error. Anti-Xa was determined on citrated plasma by a chromogenic assay (BioPhen Heparin LRT) at each time point. Method comparison was done using Passing-Bablok regression analysis.

Results: Results per instrument type are displayed in the table. Overall, only 51,2% of ACTPlus measurements fulfilled the 12% acceptance criteria; large differences were observed in cases with >12% spread error (mean difference 143.1%). In comparison, 8.4% of parallel measurements on I-STAT and 32.8% on Sonoclot differed >12%. Correlation between anti-Xa and ACT was moderate for all instruments. Method comparison showed no proportional or systematic error between I-STAT and ACTPlus. However, we observed both proportional and systematic error when comparing Sonoclot with I-STAT and ACTPlus. For each time point, ACT values were significantly lower on Sonoclot in comparison with ACTPlus and I-STAT.

TABLE 1 Comparison of ACT measurements performed during cardiopulmonary surgery, per instrument type.

	ACTPlus	I-STAT	Sonoclot
Number of instruments	1	2	2
Type of measurement	Duplicate (D)	Parallel (P)	Parallel (P)
Number of measurements	119	119	120
D/P with valid result for both measurements	100 (84.0%)	112 (94.1%)	113 (94.2%)
Measurement ≤12% spread error	61 (51.2%)	102 (85.7%)	74 (61.7%)
Measurement >12% spread error	39 (32.8%)	10 (8.4%)	39 (32.5%)
Mean spread error between all D/P	143.1%	5.2%	30.6%
Minimum-maximum spread error between D/P	0.0 - 1781.5%	0.0 - 34.8%	0.0 - 800.0%
Correlation between anti-Xa and ACT (correlation coefficient; 95% CI)	R^2 = 0.57 (0.38 - 0.71)	R^2 = 0.62 (0.50 - 0.72)	R^2 = 0.45 (0.31 - 0.58)

Conclusions: Overall, I-STAT performed better than ACTPlus and Sonoclot for ACT measurement. Failed duplicate and parallel measurements were 48.8% on ACTPlus and 38.3% on Sonoclot. Correlation between anti-Xa and ACT was moderate for all instruments. These results are unacceptable in clinical practice and require further investigation.

PB 449 | Presence of Residual Venous Thrombus at Warfarin Withdrawal: A Predictor for Recurrence After a First Episode of Symptomatic Provoked Proximal Deep Venous Thrombosis in an Asian Population?

N. Sermsathanasawadi

Division of Vascular Surgery, Department of Surgery, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkoknoi, Thailand

Background: The presence of residual venous thrombus (RVT) has been associated with an increased risk of thrombotic recurrence in patients with venous thrombosis. Recurrent DVT occurs not only in previously thrombosed veins but at other sites as well. There are no reported clinical studies on the relation between RVT and the risk of recurrent DVT after a first provoked proximal DVT in an Asian population.

Aims: To assess the risk for deep venous thrombosis (DVT) recurrence by presence of residual venous thrombus (RVT) at warfarin withdrawal following symptomatic first provoked proximal DVT.

Methods: Medical records of 45 consecutive patients with symptomatic first provoked proximal DVTs who had undergone warfarin surveillance for ≥3 months were reviewed retrospectively. Altogether, 22 patients discontinued anticoagulation after ≥3 months regardless of duplex ultrasonography results or RVT diagnosed by compression US. Another 23 patients discontinued anticoagulation after the RVT disappeared. Primary outcome was recurrent DVT. The ethics committee of the Siriraj Institutional Review Board approved this study. This study was supported by the Faculty of Medicine Siriraj Hospital, Mahidol University. This study was supported by Chalermphrakiat grants, Faculty of Medicine Siriraj Hospital, Mahidol University.

Results: Four of the 45 patients experienced recurrent DVT (8.89%), including 2 (9.00%) of 22 patients who had discontinued anticoagulant regardless of duplex ultrasonography results and 2 (8.70%) of 23 patients who discontinued anticoagulation after RVT disappearance (p = 0.963). The survival analysis showed no differences in the recurrent DVTs between patients who had a surgically provoked risk factor and those who had non-surgically provoked risk factors (p = 0.997).

Conclusions: RVT at warfarin withdrawal was not a predictor for recurrence following a first symptomatic provoked proximal DVT.

PB 450 | Hemolyzed Samples: Should Be Accepted in Hemostasis Laboratories?

M.L. Iglesias Varela, M. Siracusa, C. Val, S. Gatti, D. Jacobsen, N. Salguero, L. Maggi

Rossi, Laboratory, Ciudad Autónoma de Buenos Aires, Argentina

Background: Spurious hemolysis reflects a generalized process of endothelial and blood cell damage during blood sample collection. This is a common phenomenon in many laboratories.Different authors

recommend reject them, but in the other hand some authors affirm that results from patients with in vivo hemolysis should be reported to avoid repeat.

Aims: We compared hemolytic samples from random patients, with samples without hemolysis from the same patients; over 24Hs of the rejection. Samples were collected all over 2015 year. a) We compared the flag levels in Prothrombin time (PT); APTT, Fibrinogen (FBG) and Factor VIII (VIII) performed employing optical automated analyzer. b.) We compared optical automated analyzer vs an electromechanical one.

Methods: In all samples (with and without hemolysis) PT, APTT, FBG and VIII were performed. All tests were carried out in an ACL TOP 300 coagulometer with IL reagents and Sta Compact with Stago reagents. Hemoglobin level (Hg) was measured in a Sysmex XR-2100 analyzer. A Deming regression was performed by using EP evaluator 9 software(Data innovations). As a quality requirement, allowed total error of 15 % (CLIA) for PT and APTT, 10% for FBG and VIII. Another established requirement was that confidence interval (CI) includes 1 value and intercept 0, so to get an R > 0.85, and to check as a quality requirement (QR) that each point was inside it.

Results:

TABLE 1 Samples results from ACL TOP 300/ Sta Compact]

Coagulometer	Test	n	R	Slope (95%CI)	Samples out of QR
ACL TOP 300	PT	51	0.63	0.96 (0.88-1.04)	2
	APTT	51	0.86	1.01 (0.86-1.17)	2
	FBG	50	0.84	1.07 80.84-1.24)	5
	VIII	51	0.86	1 (0.85-1.15)	13
Sta Compact	PT	32	0.97	0.88 (0.81-0.96)	1
	APTT	32	0.97	1.07 (0.98-1.18)	1
	FBG	30	0.72	0.65 (0.45-0.86)	3

Hg levels of hemolyzed samples were0.05-0.12 mg/dl. Samples results from ACL TOP 300 and STa Compact coagulometers are shown in table. QR for the comparison of samples with and without hemolysis were achieved for PT and APTT in both coagulometers, but not for VIII and FBG.

Conclusions: We did not find any differences between methods (optical and electromechanical). Our recommendation is to reject hemolytic samples for FBG and VIII and accept them for TP and APTT.

PB 451 | Coag S: A Professional INR Monitoring Device. Comparison with the Laboratory INR Testing

E. Pap[1], L. Nagy[2], Z. Vajda[3]

[1]County Hospital, Central Laboratory, Szentes, Hungary, [2]County Hospital, Cardiology, Szentes, Hungary, [3]Diagon Ltd., Research Development, Budapest, Hungary

Background: The deep vein thrombosis (DVT) still remains a challenge for the communities struggling for an aging population. The frequency and quality of OAC monitoring by prothrombin time is decisive.

Aims: The number of reports comparing the diagnostic performance of the POC devices is still not to be found in high number.

Diagon Ltd., (Budapest, Hungary) developed a small POC coagulometer ("Coag S"). The detection system is based on photooptical monitoring of fibrinogen-fibrin transition. A comparison was made between this POC and the traditional PT testing.

Methods: 100 patients were enrolled in this study. From the threated patient 50% were anticoagulated by Warfarin (Marfarin) and the other 50 % with acenocoumarol.

p { margin-bottom: 0.1in; direction: ltr; color: rgb(0, 0, 0); line-height: 120%; }p.western { font-family: „Liberation Serif","Times New Roman",serif; font-size: 12pt; }p.cjk { font-family: „Droid Sans Fallback"; font-size: 12pt; }p.ctl { font-family: „FreeSans"; font-size: 12pt; } The separated blood plasma was measured at the same time as the fingertip blood drop for prothrombin time. (TOA Sysmex 1500, Siemens recombinant thromboplastin, "Innovin".

Results: Regarding the INR results as continuous value, we performed Passing Bablok regression test and Blandt Altman difference plot. The Passing Bablok slope was 1.00, the intercept -0.075. The correlation coefficient square (R^2) was 0.955.

The Blandt Altman difference plot showed in average -0.0641 difference, without any graphical sign of a systemic bias, as the samples' INR-s were increasing.

The Cohen kappa coeff: was 0.7489 (C.I. 95%:0.621-0.8762).

Conclusions: This POC PT device has proven it´s equal value in comparison with laboratory PT method in the monitoring of coumarin therapy.

PB 452 | Evaluation of the New Tcoag Pre-calibrated TriniLIATM D-Dimer II Assay

H. Lewis[1], K. Harrison[1], J. Needham[2]

[1]Hampshire Hospitals NHS Foundation Trust, Haemophilia Haemostasis and Thrombosis, Basingstoke, United Kingdom, [2]Hampshire Hospitals NHS Foundation Trust, Haemophilia Haemostasis and Thrombosis Centre, Basingstoke, United Kingdom

Background: Plasmin degrades fibrin into various breakdown products including D-Dimer following the formation of a fibrin clot. D-Dimer is measured in suspected cases of disseminated intravascular coagulation and has been applied for a number of years as a negative predictive indicator (NPI) of venous thrombo-emboli (VTE) as a biological marker to exclude recent thrombus formation.

Aims:

1. To evaluate the new Tcoag TriniLIATM D-Dimer II for application in the routine diagnostic service as a NPI of VTE and the robustness of a pre-calibrated assay on the Tcoag DT100 and Destiny Max analysers.
2. To compare results of Tcoag TriniLIATM D-Dimer II with the Biomerieux Vidas D-Dimer Exclusion II (gold standard) and Tcoag Destiny Max TriniLIA D-Dimer.

Methods: D-Dimer assays were performed using citrated samples received routinely for patients with suspected VTE using pre-calibrated TriniLIATM D-Dimer II on the Tcoag DTI00 and Destiny Max analysers, TriniLIA D-Dimer on the TCoag Destiny Max and the Vidas D-Dimer Exclusion II using Biomerieux Vidas analyser. Where required assays were calibrated using reagent specific calibrators and quality control material.

Results: Results showed good correlation of the TriniLIATM D-Dimer II with current reagents and analytical platforms. Correlation of TriniLIATM D-Dimer II between DT100 and Destiny Max analyses r^2 = 0.98, between DT100 and Vidas r^2 = 0.94. Correlation of TriniLIATM D-Dimer II with TriniLIA D-Dimer performed on the DT100 and Destiny Max analyses r^2 = 0.90. There was no significant difference in results between TriniLIATM D-Dimer II and Vidas D-Dimer Exclusion II p = 0.72. All low and high quality controls run over a 6 month period were within acceptance range.

Conclusions: Study has demonstrated good performance of the TriniLIATM D-Dimer II against the gold standard. A robust pre-calibrated assay has advantages in a busy diagnostic laboratory with the need for rapid turnaround times of results. The proposed cut-off value for use as a NPI for VTE is 0.5ug/ml (FEU).

PB 600 | A Systems Biology Approach to Elucidate the Post-translational Regulome of Coronary Artery Disease

A. Sharma[1,2], V. Deshpande[3], M. Ghatge[2,3], R.K. Vangala[3]

[1]Thrombosis Research Institute, Bioinformatics and Biostatistics unit, Bangalore, India, [2]Manipal University, Manipal, India, [3]Thrombosis Research Institute, Bangalore, India

Background: Coronary artery disease (CAD) is the major cause of mortality and morbidity in the world and is at endemic levels in Indian population. There is an urgent need to comprehensive analysis of post translational regulation of genes and pathways associated with CAD which in turn may give better understanding of CAD.

Aims: Our aim was to evaluate the important post-translational modifications (PTMs) regulating all the pathways and genes associated with CAD.

Methods: Using PolySearch 995 genes were found to be associated with CAD (Integrative Cardiome database). The protein information was taken from SWISSPROT database using which distribution and co-evolution of PTMs were identified. The co-evolutionary PTMs were further used to construct the network and based on topological parameters regulatory PTMs and enzyme were validated by immunoprecipitation assays and ELISA in age and gender matched 300 CAD affected and 300 control subjects samples.

Results: Of all the PTMs regulating 995 genes, we found phosphorylation, ubiquitylation and acetylation and N glycosylation to be highly represented. The network construction and analysis of co-evolving and conserved PTMs, we found that serine phosphorylation, acetylation and n- glycosylation as important regulators. Immunoprecipitation assays performed CAD affected and control subjects demonstrated clear increase in serine phosphorylation in disease condition. The top 5 kinases involved in serine phosphorylation were GSK3beta, PRKCA, PRKCD, SRK and PRKACA. We identified that SK3B could be potential master regulator modulating several protein functions. Furthermore, a 1 U/l increase of phsophoGSK3B (on a log scale) increased the risk of CAD by 6.4 fold (OR, 6.349; 95% CI, 2.29-17.64; P=0.0003) upon adjustment with conventional risk factors and diet.

Conclusions: We have identified serine phosphorylation by GSK3B as highly enriched PTM regulating several pathways associated with CAD.

PB 601 | A Translational Approach for Identifying Shared Molecular Function and Pathways between CAD and its Risk Factors

A. Sharma[1,2], V. Deshpande[3], M. Ghatge[2,3], R.K. Vangala[3]

[1]Thrombosis Research Institute, Elizabeth and Emmanual Kaye Biostatistics and Bioinformatics Unit, Bangalore, India, [2]Manipal University, Manipal, India, [3]Thrombosis Research Institute, Bangalore, Bangalore, India

Background: Coronary artery disease (CAD) is multi factorial disease influenced by several classical risks factors. Herein we implemented a novel approach using gene ontology for understanding the link between CAD and conventional risk factors (CRFs) such as Hypertension, Obesity and Diabetes.

Aims: To understand pathway physiology between CAD and classical risk factors.

Methods: Gene ontology (GO) based approach has been used to identify interplay of pathway between CAD and CRFs. We extracted CAD associated genes from In-Cardiome database and CRFs associated genes from Text-mined Hypertension, Obesity, and Diabetes candidate genes database (T-HOD). GOIDs for each gene were extracted from Uniprot database which were further grouped into Functional communicating ontologies (FCO) based on same functions and processes. In order to identify the risk association with individual and combination of risk factors, patient samples were taken from IARS database and statistical analysis was performed using SPSS software.

Results: We have selected 10,217 patient samples for this study. For risk assessment model, a new variable with 8 different categories was created using all 3 CRFs followed by logistic regression to assess the risk predictive ability. The best risk association was found with the combination of all 3 CRFs

(OR: 29.848; 95% CI 24.64-36.15), with enriched functions as acute inflammatory response and calcium ion homeostasis. However, second highest odds ratio was found with ‚Hypertension+ Diabetes' category (OR: 15.16; 95% CI 12.25-18.77) with enriched functions as blood coagulation and disease mutation.

All models built were tested for best-fit using the Hosmer-Lemeshow test.

Conclusions: This novel approach enabled the identification of important pathways for the disease and its risk factors communication. The information derived from such bioinformatic analysis can give better understanding in predicting the CAD risk.

PB 602 | Electronic Alerts, Comparative Practitioner Metrics, and Education Effect on Thromboprophylaxis and Thrombosis in Community Hospitals

S. Woller[1,2], S. Stevens[1,2], R.S. Evans[1,2], D. Wray[3], J. Christensen[1,2], V. Aston[1], M. Wayne[4], J. Lloyd[1], E. Wilson[1], C.G. Elliott[1,2]

[1]*Intermountain Medical Center, Medicine, Murray, United States,* [2]*University of Utah School of Medicine, Internal Medicine, Salt Lake City, United States,* [3]*Twine Clinical, LLC, Park City, United States,* [4]*Audience Generation, Austin, United States*

Background: We previously reported an intervention to improve appropriate venous thromboembolism (VTE) chemoprophylaxis and reduce VTE in tertiary care teaching hospitals [Woller SC *Am J Med* 2016]. Yet, VTE chemoprophylaxis remains underutilized and even lower rates have been reported in community hospitals [Kahn SR *Thromb Res* 2007]. We now report the performance of this intervention in community hospitals.

Aims: Our three aims are to report the rate of appropriate thromboprophylaxis, thrombosis, and bleeding among hospitalized medical patients before and after implementation of a multifaceted intervention (**Table**).

TABLE 1

Components of the venous thromboembolism reduction intervention applied in community hospitals
An EMR chart interrogation tool generated a daily VTE risk score, and classified each patient as being at high risk for VTE or not, based on a validated VTE risk assessment tool^
A second EMR electronic tool interrogated the MAR daily for whether guideline-recommended# chemoprophylaxis or therapeutic anticoagulation was being administered
If the patient was at high risk for VTE and appropriate chemoprophylaxis was not ordered, then a text alert was sent to the hospitalist of record
A monthly audit and feedback performance report was provided to each hospitalist
A proprietary targeted online CME activity tailored to each hospitalist' performance was sent monthly
LEGEND: EMR: electronic medical record; VTE: venous thromboembolism; CME: continuing medical education ^Kucher N, etal. N Engl J Med 2005; 352:969-977 #Kahn SR etal. Chest 2012; 141:e195S-e226S

Methods: We prospectively enrolled sequential medical patients admitted to one of 3 hospitals from 2011-2013. Patients were members of the "control" (2011), "intervention" (2012), or "subsequent year" (2013) group. Beginning in the intervention period, if a patient was high risk and not receiving chemoprophylaxis, then a text alert was sent to their hospitalist. Hospitalists were credited with applying appropriate chemoprophylaxis if within 36 hours of an alert they prescribed appropriate chemoprophylaxis or identified a contraindication in the EMR. Anonymous comparative physician performance was communicated monthly along with educational content tailored to each physician's performance.

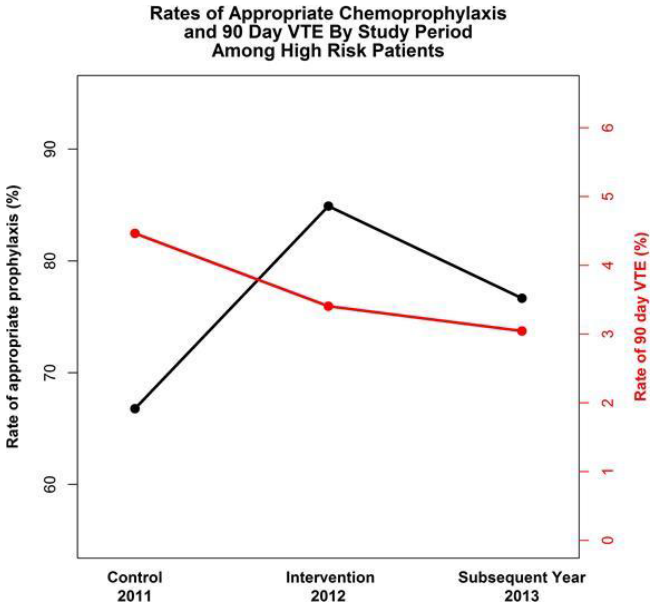

FIGURE 1 Rates of appropriate chemoprophylaxis and 90 day VTE among high risk patients

Results: 27,778 patients (35% high risk) constituted a total of 95,236 patient days. The rate of appropriate chemoprophylaxis among high risk patients increased then declined (67% control vs. 85% intervention vs. 77% subsequent year; p< 0.001). A reduction of 90 day symptomatic VTE was seen (4.5% control period, 3.4% intervention period, 3.0% subsequent year; p=0.008; **Figure**). No difference in major bleeding was seen (0.72% control, 0.84% intervention, 0.59% subsequent year; p=0.61).

Conclusions: Appropriate chemoprophylaxis among high risk patients improved during the intervention, but subsequently declined. Patient outcomes improved, but the proportion of improvement that resulted from the intervention is uncertain.

PB 603 | Efficiency of Bayesian Logic in Reagent Batch Change Management: Application to aPTT

F. Sobas[1], K. Bourazas[2], E. Jousselme[1], C. Nougier[1], C. Négrier[1], P. Tsiamyrtzis[2]

[1]*Hôpitaux Est de Lyon, Laboratoire d'Hématologie, Bron, France,* [2]*Athens University of Economics and Business, Department of Statistics, Athens, Greece*

Background: A preliminary study („Use of prior manufacturer specifications with Bayesian logic eludes preliminary phase issues in quality control: An example in a hemostasis lab", Blood Coagul Fibrinolysis 2015, 26: 590-596) showed how the conventional preliminary phase can be avoided using Bayesian logic. Two new Bayesian tools are introduced, aiming to identify such trends in the process. The dynamic nature of Bayesian IQC results management enables these new tools which are capable to identify persistent shifts and in case of no reaction to absorb them in longitudinal monitoring of IQC results during reagent batch change.

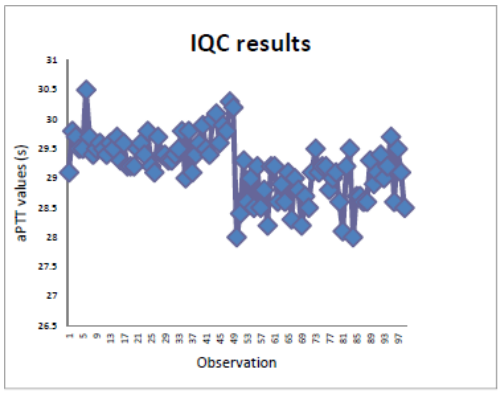

Figure 1 (a): Raw IQC results with reagent batch change at observation 50

FIGURE 1(A) Raw IQC results with reagent batch change at observation 50

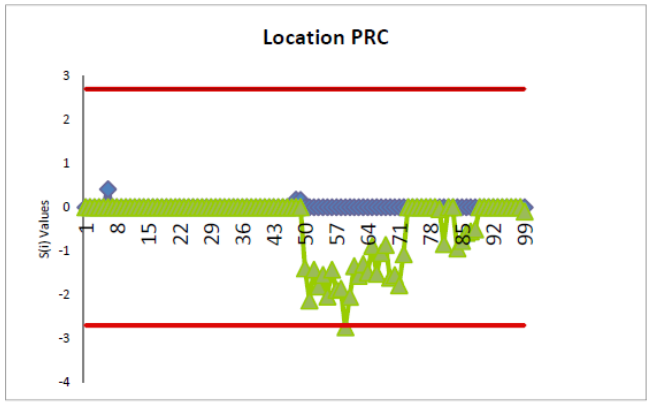

Figure 1 (b): Location PRC control chart with reagent batch change at observation 50

FIGURE 1(B) Location PRC chart with reagent batch change at observation 50

Aims: A case study is used to illustrate detection of a shift liable to impact patient results, and automatic updating of the control chart.
Methods: From Instrumentation Laboratory (IL), Bedford, MA, USA: ACL TOP 750 analyzer, HemosIL Synthasil and HemosIL Normal Control Assayed (aPTT (activated partial thromboplastin time) prior target = 29 seconds (s)). The 2016 ECAT screen exercises enable calculation of the acceptable bias size for z-score of 2 corresponding to a 30 s consensus value (ISO 17043). The last IQC result with the initial Synthasil batch is reported at control point 49, and the first result with the new reagent batch at control point 50.
Results: At the 10th IQC point, an alarm signaled that the reagent batch change was inducing a significant step change liable to impact patient results. From the 1st control point with the new reagent batch, a clear trend emerged, confirmed at the 2nd point. The laboratorian would thus have advance warning. The location PRC chart further identified a capacity for automatic updating of the control chart parameters in response to the reagent batch change (Figures 1(a) and 1(b)).
Conclusions: These new Bayesian tools enable efficient management of reagent batch change issues.

PB 604 | aPTT as an Independent Risk Factor for 30-day Survival for Patients on Extracorporeal Membrane Oxygenation (ECMO): 8-year Experience at Albert Einstein College of Medicine, Montefiore Medical Center

I. Francischetti[1], J. Szymanski[1], D. Rodriguez[2], M. Heo[1], L. Wolgast[1]

[1]*Albert Einstein College of Medicine & Montefiore Medical Center, Bronx, United States,* [2]*Albert Einstein College of Medicine & Montefiore Medical Center, Perfusion, Bronx, United States*

Background: Survival of patients on ECMO has remained stable in every population.
Aims: Laboratory values predictors of survival are required to improve patient care.
Methods: Clinical Looking Glass software was used to assess Electronic Medical Records (EMRs) of patients at Albert Einstein College of Medicine, Montefiore Medical Center (2007-2014).
Results: Our population comprises of 166 adults and was divided in survivors and non-survivors, within 30 days. Indications for ECMO were cardiac (65%), respiratory (25%) and infectious diseases (< 10%). Eighty six patients (51.8%) survived the procedure. Gender, body weight, ejection fraction, diastolic blood pressure, and socio-economic status did not differ among survivors and non-survivors. In contrast, younger patients (45 yo *vs* 55 yo, p=0.0001) and higher systolic blood pressure (115 mmHg *vs* 103 mmHg, p=0.025) have favorable outcome. Univariate analysis shows that pre-cannulation values for creatinine (p=0.019), chloride (p=0.0026), and bicarbonate (p=0.026) have prognostic value. Post-cannulation aPTT, pH, platelet and lymphocyte counts also have discriminative power. Notably, multiple logistic regressions for Multivariate Analysis identified chloride (OR 1.07; 95% CI 1.02-1.13; p=0.004), pH (OR 3.35; 95% CI 1.89-5.9; p< 0.0001) and aPTT (OR 0.98; 95% CI 0.976-0.998; p=0.024) as independent risk factors for 30-day mortality. These results imply that pre-existing renal conditions and hemostatic dysregulation contribute to poor outcome. Finally, patients on VV-ECMO have increase odds of survival (OR 1.88; 95% CI 1.06-3.34; p=0.029).
Conclusions: The aPTT and other laboratory markers identified herein may guide the management of patients on ECMO.

PB 605 | Sensitivity of Spatial Thrombin Generation and Fibrin Clot Growth to Clotting Factors Deficiency

A. Kuprash[1,2], A. Balandina[1,2], R. Vijay[3], S. Nair[3], F. Ataullakhanov[1,2,4], A. Srivastava[3], M. Panteleev[1,2,4]

[1]*Center for Theoretical Problems of Physicochemical Pharmacology RAS, Moscow, Russian Federation,* [2]*Dmitry Rogachev National Research and Clinical Center of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation,* [3]*Christian Medical College& Hospital, Vellore, India,* [4]*Lomonosov Moscow State University, Biophysics Department, Moscow, Russian Federation*

Background: Blood coagulation is a space- and time-dependent process of plasma coagulation that leads to formation of a clot which prevents blood loss in the case of vascular injury.

Aims: To investigate the effect of tissue factor (TF) distribution in space on blood coagulation in normal and coagulation factors deficient plasmas and to identify the underlying molecular mechanisms.

Methods: We employed an in vitro reaction-diffusion experimental model of coagulation with a Thrombodynamics Analyzer device. Clotting in platelet free plasma supplemented with phospholipids (2 μm) was activated with TF homogeneously distributed in plasma volume (5 pM) or localized on surface (100 pmoles/m^2). Fibrin clot growth was registered via light scattering; clotting time or clot growth velocity was calculated. Spatial and homogeneous thrombin generation was determined using the registration of the fluorescence of thrombin-activated fluorogenic substrate; the amplitude of thrombin peak or thrombin wave was calculated.

Results: The comparison of clot formation and thrombin generation parameters in FII-, V-, VII-, VIII-, IX-, X- and XI-deficient plasmas of patients (37 samples total) demonstrated that in the case of spatially localized TF plasma clotted in all samples, while in the case of uniformly distributed standard TF concentration (5 pM) clotting was not observed in FV-, FVII- and FX-deficient plasma. When we increased uniformly distributed TF concentration up to 50-200 pM, clotting occurred in all deficient plasmas. In the case of spatially localized TF clotting parameters were normal (difference between measured parameters and baseline was less than 30%) when factor concentration was higher than 5%, while in the case of uniformly distributed standard TF concentration clotting parameters normalization occurred when factor concentration was higher than 30-70%.

Conclusions: We found that TF localization on surface could decrease coagulation system sensitivity to clotting factors deficiency.

PB 606 | In-cardiome: A Knowledgebase Integrating Molecular and Clinical Worlds for Translational Research and Drug Development in Coronary Artery Disease

A. Sharma[1,2], V. Deshpande[3], M. Ghatge[2,3], R.K. Vangala[3]

[1]Thrombosis Research Institute, Bioinformatics and Biostatistics unit, Bangalore, India, [2]Manipal University, Manipal, India, [3]Thrombosis Research Institute, Bangalore, India

Background: Coronary artery disease (CAD) is a leading cause of death and major hurdle in the improvement of diagnosis and treatment is the lack of integration of knowledge from different areas research.

Aims: Our aim was to create "Integrated Cardiome - In-Cardiome" a knowledgebase integrating molecular and clinical worlds.

Methods: We used PolySerarch datamining tool along with manual curation for genes associated with CAD. Other data such as genetic, gene, expressions, pathway modulations, functional, phenotype, knockout gene etc, and clinical information such as clinical trials, drugs and their target networks, patient data from Indian population (Indian Atherosclerosis Research Study-IARS) were integrated. We have implemented network graphics for visualization of results and the backend integration was performed using MYSQL and PHP, JavaScript, D3 script and cytoscape.js in the web platform.

Results: In-Cardiome (http://tri-incardiome.org/) contains 995 highly curated genes, 1204 completed clinical trials, 12 drug classes with 138 drug targets. In-Cardiome provides 4 different kinds of search criteria i.e. Therapy based, Function based, Risk factors based and direct link to "Search genes".Therapy based criteria gives information on 12 different drug classes according to American Heart Association classification where each class has individual page of drugs, drug targets and their interactome are included. The 13 functional categories showing the disease progression is represented in a hierarchical system integrated with all the other clinical and molecular information. In the Risk factor categorization analysis we have selected 10,217 Patient data from IARS for 3 risk factors; hypertension, diabetes and obesity. Demographics, distribution and association data for each and combinations of risk factors can be accessed.

Conclusions: In-Cardiome is one of its kind novel knowledgebase which can enable better translational research and drug development for CAD.

PB 607 | Addressing Reproducibility Concerns for Mechanistic Models of Clot Formation

M. Anand, M. Susree

Indian Institute of Technology Hyderabad, Chemical Engineering, Sangareddy, India

Background: Coagulation and Fibrinolysis are complex phenomena including hundreds of biochemical interactions, and a few biophysical processes. Mechanistic models have become established as tools to simulate the quantitative behaviour of these phenomena, and to elucidate their design principles. However, the reliability of results from such models is complicated due to concerns about reproducibility.

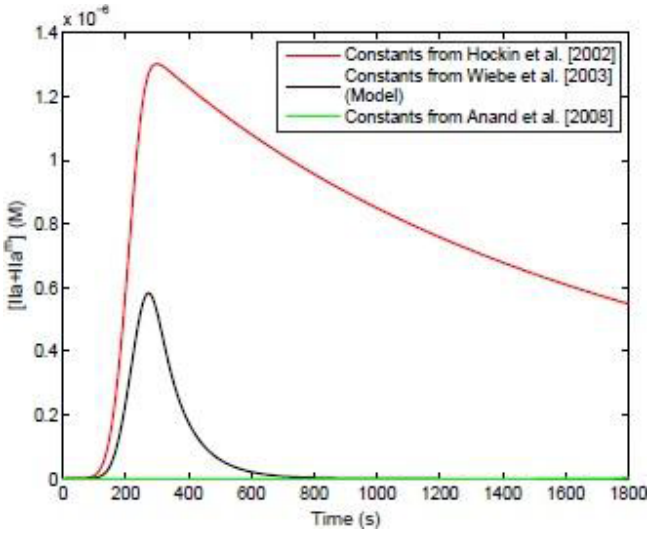

FIGURE 1 Variation of total thrombin for ATIII inhibition constants from different sources

Aims: The large number of parameters that are used in mechanistic models of hemostasis pose a challenge in terms of reproducibility as well as possible utility in patient-specific simulations. We address the challenge of reproducibility by shaping a consensus on the parameters that can be used in mechanistic models.

Methods: We show, using simulations of a sample model, that model predictions vary significantly with the use of different values available in the literature for the same kinetic constant. We thus highlight the importance of having consensus of kinetic constants used in mechanistic models for coagulation. The literature is then reviewed to document values of each kinetic constant corresponding to different reaction conditions (namely synthetic, in vitro, or in vivo).

Results: The variation in model predictions due to different literature values of a given kinetic constant can be as high as ±100% (see Fig 1). A table is proposed that documents values of kinetic constants that can be used in mechanistic models of coagulation. A portion of the table, which is available in Susree and Anand, (MMNP 2016), is given for illustration purposes in Table 1.

TABLE 1 Illustrative table depicting consensus kinetic constants for reactions of coagulation

Binding of TF and VII	**k1 = 3.2x10^-3 nM-1s-1**	**OBrien et al 1994 Krishnaswamy 1992**	**synthetic, in vitro**
Dissociation of TF-VII	k2 = 3.1x10^-3 s-1	OBrien et al 1994 Krishnaswamy 1992	synthetic, in vitro
Binding of TF and VIIa	k3 = 0.023 nM-1s-1	OBrien et al 1994 Shobe et al 1999	synthetic, in vitro
Dissociation of TF-VIIa	k4 = 3.1x10^-3 s-1	OBrien et al 1994 Shobe et al 1999	synthetic, in vitro

Conclusions: The proposed table of kinetic constants are the consensus values for the reactions in a particular reaction network. Other reaction networks could throw up different reaction mechanisms for which a separate literature review needs to be performed.

PB 608 | Epigenetic Regulation of PAR-4-mediated Platelet Activation Underlies Smoking-related Cardiovascular Disease

C.M. Williams[1], L.J. Corbin[2], S.J. White[3,4], M. Van Den Bosch[1], A. Taylor[5], M.T. Harper[1,6], M.L. Jones[3], M. Bond[3], G. Davey Smith[2], C.L. Relton[2], L. Falk[2], A. Groom[2], B.G. Nordestgaard[7], A. Tybjaerg-Hansen[8], S. Egil Bojesen[8], A.D. Mumford[3], A.W. Poole[1], N.J. Timpson[2]

[1]University of Bristol, School of Physiology, Pharmacology and Neuroscience, Bristol, United Kingdom, [2]University of Bristol, School of Social and Community Medicine, Bristol, United Kingdom, [3]University of Bristol, School of Clinical Sciences, Bristol, United Kingdom, [4]Manchester Metropolitan University, School of Healthcare Science, Manchester, United Kingdom, [5]University of Bristol, School of Experimental Psychology, Bristol, United Kingdom, [6]University of Cambridge, Department of Pharmacology, Cambridge, United Kingdom, [7]Copenhagen University Hospital, Clinical Biochemistry, Copenhagen, Denmark, [8]University of Copenhagen, Department of Clinical Medicine, Copenhagen, United Kingdom

Background: Smoking is a known risk factor for cardiovascular disease, with nearly 10% of cases worldwide attributed to tobacco use. The underlying mechanisms for this association remain largely unknown; however, increasing evidence has arisen suggesting epigenetic modifications may play a role. Several methylation loci have emerged as robust indicators of smoking, including within *F2RL3*, where methylation is reduced. *F2RL3* codes for Protease-Activated Receptor 4 (PAR-4), a GPCR expressed on the surface of platelets that stimulates platelet activation and thrombus formation in response to thrombin.

Aims: To determine whether the methylation status of *F2RL3* influences platelet function.

Methods: Pyrosequencing was used to assess methylation at four CpG sites in *F2RL3*. For *F2RL3* epidemiology, participants from the Copenhagen City Heart Study had methylation status determined and were classified based on smoking status. For platelet function analysis, participants from the Avon Longitudinal Study of Parents and Children (ALSPAC) cohort were recruited based on methylation of *F2RL3*. Activation of platelet $a_{IIb}b_3$ integrin and surface exposure of P-selectin in response to PAR-1 and PAR-4-specific peptides were determined by flow cytometry. Experiments were conducted in a double-blind manner. For *F2RL3* methylation cell model, human coronary endothelial cells (HCAEC) were exposed to cigarette smoke extract (CSE) in culture and assayed for methylation status and cell response.

Results: Low *F2RL3* methylation corresponds to higher platelet responsiveness to PAR4 activator peptide.

Conclusions: Epigenetic regulation of PAR-4-mediated platelet activation underlies smoking-related cardiovascular disease.

PB 609 | Polymorphic Variation in Glutathione-S-transferase Genes among Chronic Myeloid Leukemia Patients in Pakistan

A. Shahni[1], S.N. Mukry[2], T. Farzana[1], M. Nadeem[1], T.S. Shamsi[1]

[1]National Institute of Blood Disease and Bone Marrow Transplantation, Hematology, Karachi, Pakistan, [2]National Institute of Blood Disease and Bone Marrow Transplantation, Hematology and Applied Microbiology, Karachi, Pakistan

Background: Glutathione S Transferases are Phase II drug metabolizing enzymes which help in detoxification carcinogens of catalyses of conjugation of glutathione with reactive electrophiles. Human GSTs: GSTM1 and GSTT1 are two genes which detoxify or protect against reactive oxygen species and xenobiotics. Reduced individual ability in drug detoxification activity may leads to cancers upon prolonged exposure to xenobiotics. It is known that polymorphism of GSTs genes affects the detoxification of xenobiotics which leads to genetic susceptibility of chronic myeloid leukemia (CML).

Aims: To determine the polymorphism of GSTs enzymes in CML patients.

Methods: *Multiplex PCR of GSTM1* and *GSTT1* genotypes of 60 DNA samples of CML were performed.

Results: A total of confirmed 60 cases (7 females and 53 males) of CML with mean age of 35 (median) range (9-64) and 63 normal healthy individuals of same sex and age as control were analyzed. GSTM1 null deletion was significantly more frequent in controls (41%) as compared to CML patients (31%). CML patients (14%) have low frequency of GSTT1 null deletion as compared controls (21%). Double deletion was present in CML (7%) and has double frequency in controls (14%) and these differences were statistically significant (p= 0.025).

Conclusions: This study has allowed determining the frequency of GSTM1 and GSTT1 polymorphism in a sample of our patients. A significant increase has also been observed in control group which suggest they might be susceptible to disease occurrence. Further studies with large sample size are required to draw a valid conclusion.

PB 610 | Gene Expression Profile of Schistosoma Mansoni Adult Worms after Treatment with an Anti-schistosomicidal Drug that Inhibits Lysine Demethylase LSD1

H. Asif[1], D.D.S. Pires[1], E.J.R. Vasconcelos[1], M.S. Amaral[1], V. Coutinho[2], J.C. Setubal[3], M. Fantappié[1], S. Verjovski-Almeida[1]

[1]Butantan Institute, Sao Paulo, Brazil, [2]Instituto de Bioquímica Médica Leopoldo DeMeis, Universidade Federal do Rio de Janeiro,, Rio de Janeiro, Brazil, [3]Institute of Chemistry, University of Sao Paulo, Sao Paulo, Brazil

Background: Schistosomiasis is ranked as the second most common human parasitic disease in the developing world after malaria. *Schistosoma mansoni*, the most widespread blood parasite moves through the intestinal veins by means of the host circulatory system. To date no vaccine is available for schistosomiasis, and the treatment is done by long-term application of a single drug, praziquante (PZQ).

Aims: The aim of this project is to check how the parasites respond to different drugs developed by our partners in the project "Anti-Parasitic Drug Discovery in Epigenetics" (A-ParaDDisE) that target histone-modifying enzymes. The drugs are tested at sub lethal doses and we identify the genes that are differentially expressed (DEGs) using high-throughput RNA sequencing technology. In the present work, we treated the adult parasites with compound A, a potential lysine demethylase (LSD1) inhibitor and compared transcriptomic profiles of drug treated and untreated parasites.

Methods: An in-house bioinformatics pipeline involving up-to-date software is used to carry out the analysis. The various components of pipeline include quality control filtering, read mapping, transcript quantification, differential expression analysis and gene ontology (GO) enrichment.

Results: We found 938 significantly differentially expressed genes (629 down and 309 up regulated genes) in female and 2709 genes in males (1312 down and 1397 up) respectively. Based on GO classification, the genes were divided into three major functional categories (biological, molecular and cellular), of these the dominant terms were ion transport, regulation of cellular and metabolic process, chromatin modification, drug transport and glycoprotein metabolic process.

Conclusions: We hope this comprehensive differential gene expression profile of drug-treated adult parasites will provide useful information to the community in search of anti-schistosomicidal drug targets and new therapeutics for the control of schistosomiasis.

PB 611 | Nanoscale Measurement of Force Generation during Platelet-driven Clot Formation in Platelet Rich Plasma

T. Feller[1], J. Harsfalvi[1], G. Domján[2], K. Gado[2], K. Varnai[2], M. Kellermayer[1]

[1]Semmelweis University, Biophysics and Radiation Biology, Budapest, Hungary, [2]Semmelweis University, 1st Department of Medicine, Budapest, Hungary

Background: We developed a nano-thrombelastographic (nTEG) method based on atomic force microscopy (AFM) that gives information about the viscoelasticity and contractility of fibrin network during clot formation and degradation in human plasma.

Aims: Our aim was to follow platelet-driven clot formation in platelet-rich plasma (PRP) by using nTEG.

Methods: Blood was collected into Vacuette tube (sodium citrate 3.2%) from five untreated and eight coumarine-treated individuals. PRP was prepared by centrifuging citrated blood with 150g at room temperature for 10 minutes. An AFM cantilever was submerged in a 300-µL sample and cyclically moved up and down with an amplitude of 1 µm and a speed of 1 µm/s. The sample contained PRP and Ca^{2+} 10 mM, and clotting was initiated with thrombin or collagen (at 1 IU or 5 µg/ml). A silicon shield surrounding the droplet prevented evaporation. As the sample clotted the cantilever increasingly deflected during its vertical travel.

Results: The peak-to-peak force amplitude, measured as the difference between the maximal upwards and downwards cantilever deflections, gradually increased during the formation of the elastic, platelet-rich fibrin network. The time delay until the initial rise of the force amplitude was 100-200 s and became prolonged three-fold in lieu of thrombin activation. Force hysteresis, measured as the difference between the areas under the upwards and downwards force-displacement curves, started to increase prior to that of the force amplitude, suggesting that the viscous response preceded the elastic one. Upon activation the platelets contracted the clot, leading to a permanent cantilever deflection the magnitude of which scaled with platelet number.

Conclusions: The presence of coumarine apparently did not influence the above nTEG parameters. In sum, by a quantitative monitoring of the time-dependent nanoscale changes of an AFM cantilever the nTEG method provides a unique insight into the microscopic mechanisms of clot formation and contraction.

PB 612 | Analysis of Platelet Activation by Stable Isotope-resolved Metabolomics (SIRM)

S. Joshi[1], M. Banerjee[1], Z. Qi[2], P. Lin[3], M.O. Warmoes[3], Q. Sun[3], H.N.B. Moseley[1,3], R.M. Higashi[2,3], A.N. Lane[2,3], T.W.M. Fan[2,3], S.W. Whiteheart[1], Q.J. Wang[4]

[1]University of Kentucky, Department of Molecular and Cellular Biochemistry, Lexington, United States, [2]University of Kentucky, Department of Toxicology and Cancer Biology, Lexington, United States, [3]University of Kentucky, Center for Environmental Systems Biochemistry, Lexington, United States, [4]University of Kentucky, Department of Ophthalmology and Visual Sciences, Lexington, United States

Background: In response to vessel damage, platelets activate, aggregate, and pull against each other (*i.e.*, clot retraction), to form a stable clot. These processes require energy. Patients with metabolic diseases are particularly at risk of thrombosis, in part, due to hyperglycemia-linked platelet hyper-reactivity. Thus platelet metabolism is critical for modulating normal hemostasis and controlling pathogenic thrombosis. Early studies showed that platelet activation increases glycolysis and lactate production; however, these studies relied on crude analytics and inhibitors, so details are still ill-defined.

Aims: We sought to delineate platelet metabolism in both resting and activated states, utilizing state-of-the-art, stable isotope-resolved metabolomics (SIRM).

Methods: Human platelets were labeled with [U-$^{13}C_6$]-glucose and then treated with or without thrombin. Platelet pellets and releasates were separated by centrifugation and pellets were further extracted for polar and non-polar fractions. Metabolites in pellet fractions and releasates were analyzed by high-resolution nuclear magnetic resonance spectroscopy (NMR) and mass spectrometry (MS).

Results: Both NMR and MS analyses showed release of AXP (ATP, ADP and AMP) upon activation. AXP production clearly occurred in platelets, as the ribose-rings were synthesized from [U-$^{13}C_6$]-glucose *via* the pentose phosphate pathway. We noted increased production and excretion of [$^{13}C_3$]-lactate, indicating enhanced glycolysis and lactic fermentation, during activation. We directly monitored activation-dependent changes in a large panel of metabolites in glycolysis, the tricarboxylic acid (TCA) cycle, and glycogen, lipid, and nucleic acid metabolism.

Conclusions: Using SIRM, a more complete picture of platelet metabolism is emerging, leading to a better understanding of platelet energy utilization. Our work will yield critical insights into the causes of platelet dysfunction in metabolic disorders and uncover novel therapeutic strategies *via* modulating platelet metabolism.

PB 613 | Metabolites Associated with Massive versus Submassive Pulmonary Embolism - A Pilot Study

O. Zeleznik[1,2], E. Poole[1,2], S. Lindstrom[3], P. Kraft[4], A. Van Hylckama Vlieg[5], B. Parry[6], N. Giordano[6], C. Kabrhel[1,6,7]

[1]Brigham and Women's Hospital, Channing Network Medicine, Boston, United States, [2]Harvard Medical School, Medicine, Boston, United States, [3]University of Washington, Epidemiology, Seattle, United States, [4]Harvard T.H. Chan School of Public Health, Epidemiology, Boston, United States, [5]Leiden University Medical Center, Clinical Epidemiology, Leiden, The Netherlands, [6]Massachusetts General Hospital, Center for Vascular Emergencies, Department of Emergency Medicine, Boston, United States, [7]Harvard Medical School, Boston, United States

Background: Outcomes after acute pulmonary embolism (PE) vary greatly. To improve our understanding and ability to risk-stratify PE patients, we performed the first-ever global metabolomic study comparing hemodynamicaly stable, "submassive" PE to unstable, "massive" PE.

Aims: To identify metabolites associated with massive vs. submassive PE.

Methods: We enrolled consecutive patients with acute PE in an academic emergency department from 2009-2012. We compared 28 submassive PE patients with 18 massive PE patients. All PE were lobar or more proximal with right heart strain or a positive troponin. Massive PE patients were hypotensive, required life support or thrombolysis within 5 days or died within 30 days. Blood samples were drawn within 24 hrs of diagnosis and processed within 60 min. We performed global metabolomic analysis using the Metabolon® DiscoveryHD4™ platform. We used Welch's two-sample *t*-test to identify biochemicals that differed across groups and Fisher's Exact Test for Metabolite Set Enrichment Analysis (MSEA) to determine pathways/metabolite categories driving differences. We calculated false discovery rates (FDR) to account for multiple comparisons.

Results: 42 metabolites differed between submassive and massive PE, at a nominal p value ≤0.05, with N-acetyl-beta-alanine, N-stearoyl-sphingosine and docosahexaenoylcholine the top hits. We performed a first MSEA at a global level, identifying the category Lipid to be significantly enriched with a nominal p value =0.03. A second MSEA, focused on sub-categories, identified ceramides to be significantly enriched with a nominal p value ≤0.05. Additionally, Xanthine Metabolism, Tyrosine Metabolism and Urea cycle; Arginine and Proline Metabolism had a nominal p value ≤0.2. However, the small sample size made it difficult to identify significant results after multiple testing correction.

Conclusions: While the small sample size did not allow firm conclusions, several metabolites, including lipids and ceramides, may differentiate massive from submassive PE.

PB 1133 | A Single Analysis for Simultaneous Measurement of All 4 DOACs

J. Emmerechts, S. Ameye, V. Engelrelst, D. Borrey

AZ Sint-Jan, Brugge, Belgium

Background: Commercial kits are available for functional measurements of the direct oral anticoagulants (DOAC) dabigatran, rivaroxaban, apixaban and edoxaban by coagulation assays. However, as each DOAC requires its own assay with separate kit, calibrators and quality controls, laboratories are confronted with high reagent costs and a cumbersome work load for a limited number of clinical samples.

Aims: To develop a single in-house method for measurement of all 4 DOACs.

Methods: A liquid chromatography-tandem mass spectrometry (*LC-MS/MS*) analysis was set up using a single extraction procedure for the simultaneous measurement of all 4 DOACs. A single in-house calibrator series was prepared for dabigatran, rivaroxaban and apixaban by spiking normal pooled plasma. For edoxaban, a commercial calibrator (Stago, France) was used. Different optimization steps led to a final LC-MS/MS protocol including sample extraction in acid phosphate buffer pH2, dabigatran dissolution in DMSO HCl5% and the use of an analytical precolumn backflush system. HemosIL Liquid Anti-Xa assay (Werfen, USA) and Hemoclot Thrombin Inhibitors assay (Hyphen Biomed, France) were used for functional measurements.

Results: Results for commercial quality control material where within the manufacturer's range for all 4 DOAC's. Within and between run imprecision CV's were < 9%, limit of quantitation was < 10 ng/mL and correlation coefficients of linearity studies were >0.999 for all 4 DOACs. Passing-Bablock analysis revealed excellent correlations with the respective functional measurements using patient samples, spiked samples and commercial quality controls. LC-MS/MS analysis could be performed on a high number of samples in less than one hour. Commercial kits are not required, although commercial control material can be used when desired.

Conclusions: A single LC-MS/MS assay measures all 4 DOACs in a sensitive, accurate, rapid and a cost-effective way, even when the type of DOAC is unknown to the laboratory or when a mixture of anticoagulants is present.

PB 1134 | Interest of PERC Rule (Pulmonary Embolism Rule-out Criteria) to Exclude Pulmonary Embolism in European Patients with Low Implicit Clinical Probability: PERCEPIC Study

A. Penaloza[1], C. Soulie-Chavignon[2], A. Ghuysen[3], D. El Kouri[4], C. Brice[5], N.S. Marjanovic[6], A. Trinh-Duc[7], T. Moumneh[2], Q. Delmez[1], P.-M. Roy[2]

[1]*Cliniques Universitaires Saint Luc, Bruxelles, Belgium,* [2]*Université et Faculté de Médecine d'Angers, EA 3860 ,Cardioprotection, Remodelage et Thrombose', Institut de Recherche MITOVASC, Département de Médecine d'Urgence, Angers, France,* [3]*Université de Liège, Liège, Belgium,* [4]*Urgences Medecines et Soins Critiques - Hotel Dieu, Nantes, France,* [5]*Service d'Urgences Adultes, CH Saint Brieuc, Saint Brieuc, France,* [6]*Service des Urgences, SAMU 86 Centre 15 - CHU de Poitiers Faculté de Médecine - Université de Poitiers, Poitiers, France,* [7]*Service d'Accueil des Urgences CH Agen, Agen, France*

Background: Pulmonary Embolism Rule-out Criteria (PERC) is a clinical rule designed to exclude pulmonary embolism (PE) without further testing including D-dimer. Its accuracy has not been confirmed when it was retrospectively applied to European populations with relatively high overall PE prevalence. Nevertheless, one study suggests PERC reliability in patients with low clinical probability (CP) assessed by implicit judgment.

Aims: To prospectively assess the reliability of a negative PERC rule among European patients with low implicit CP to rule out PE.

Methods: Multicenter observational prospective study (9 French and 3 Belgian centers) of patients suspected of PE. The study received the approval of ethic committee. The main outcome was the rate of thromboembolic events (TEE) among patients with low implicit CP and a negative PERC rule: PE diagnosed during the initial admission, TEE and unexplained sudden deaths occurring during the 3 month follow-up. To consider PERC rule as reliable, the upper limit of the 95% confidence interval (CI) of TEE rate had to be less or equal to 3 %. The sample size of patients with low implicit CP and negative PERC has been calculated as 300 patients (NCT02360540).

Results: 1757 suspected PE patients were included, 201 had PE and/or TEE during follow-up leading to an overall prevalence of 11.4% (CI:10.0-13.0%): 4.7% (CI:3.5-6.1%) in patients with a low CP (n=1052), 16.1% (CI:13.3-19.4%) in patients with moderate CP(n=558) and 41.5% (CI:33.7-49.6%) in patients with high CP (n=147). Among patients with a low implicit CP, 336 had a negative PERC rule (32%). In this group, 4 PE were diagnosed: 1.2% (CI: 0.5-2.8%), including 1 isolated subsegmental PE. The tests performed in this group included 322 D-Dimer tests, 46 CTPA, 3 V/Q scan and 1 leg ultrasonography.

Conclusions: In European patients with low implicit CP of PE, PERC rule may exclude PE with a low rate of false negative and could avoid a substantial number of exams.

PB 1135 | Validation of STA-Liatest D-Di Assay for Exclusion of Deep Vein Thrombosis According to the Latest Clinical and Laboratory Standard Institute/Food and Drug Administration Guideline. Results of a Multicenter Management Study

C. Aguilar[1], M. Sartori[2], A. D'Angelo[3], D. Richardson[4], C. Kabrhel[5], J. Groce[6], E. Demaistre[7], S. Rathbun[8], J. Kassis[9], J. Lazarchick[10], C. Kaide[11], P. Marco Vera[12], J. Kline[13], M. Courtney[14], M. Sharafuddin[15], A. Rubin[16], G. Pernod[17]

Orsola Malpighi, Bologna, Italy,* [3]*Ospedale San Raffaele, Milan, Italy,* [4]*Lehigh Valley Health Network Hospital, Allentown, United States,* [5]*Massachusetts General Hospital, Boston, United States,* [6]*The Moses H Cone Memorial, Greensboro, United States,* [7]*CHU Dijon, Dijon, France,* [8]*OKC VAMS Pathology a,d Laboratory Services, Oklahoma City, United States,* [9]*Hopital Maisonneuve Rosemont, Montreal, Canada,* [10]*Medical University of South Carolina, Columbuss, United States,* [11]*Ohio State University Medical Center, Columbus, United States,* [12]*Hospital General Universitario de Alicante, Alicante, Spain,* [13]*Indiana University Health Methodis Hospital, Indianapolis, United States,* [14]*NothWestern University Hospital, Chicago, United States,* [15]*University of Iowa Hospitals and Clinics, Iowa City, United States,* [16]*Texas Health Fort Worth Hospital, Fort Worth, United States,* [17]*University Hospital Grenoble-Alpes, Grenoble, France*

Background: Diagnosis of venous thromboembolism (VTE) is challenging. Objective confirmation is needed: failure to treat due to missed diagnoses can be life-threatening, while anticoagulation carries risk. Imaging studies are considered the most reliable diagnostic tool although time-consuming and expensive. Using assays with high negative predictive value (NPV), a negative D-dimer (DD) excludes clinically relevant VTE when used in conjunction with a pre-test

probability (PTP) score. In 2011, the Clinical and Laboratory Standards Institute (CLSI) issued a guideline on the use of DD in VTE exclusion and, with the US FDA, recommendations for testing patients with low/moderate VTE PTP.

Aims: Demonstrate the performance of STA®- Liatest® D-Di assay used in combination with a PTP score for deep vein thrombosis (DVT) exclusion according to CLSI guideline.

Methods: International, multicenter, prospective non-randomized, noninterventional clinical outcome management study conducted in standard of care setting. DD (STA®- Liatest® D-Di, Stago) measured in consecutive, ambulatory outpatients suspected of DVT, with low/moderate PTP, and without medical conditions known to alter DD values regardless of thrombosis presence using a 0.5 µg/mL (FEU) threshold for DVT exclusion.

Results: 1234 patients signed informed consent, of which 1031 underwent DD testing. 980 (mean age: 55y) had valid results (494 negative DD) and completed the study as planned. DVT prevalence was 8.4%. STA® - Liatest® DDi assay performance exceeded the CLSI/FDA guidance requirements: sensitivity: 100% (95% confidence interval [CI]: 95.8-100%), specificity: 55.2% (CI: 51.9-58.5%) NPV: 100% (CI: 99.3100%).

Conclusions: STA® - Liatest® DDi used in combination with PTP score has an excellent performance in relevant patients for DVT exclusion. Similar assay performances were recently demonstrated for PE. Altogether, the assay allows safe VTE exclusion, while avoiding unnecessary and expensive imaging tests.

(CI: 99.3100%).

PB 1136 | Variation in Practice for FVIII and FIX Inhibitor Investigations - Results from a UK NEQAS (Blood Coagulation) and UK HCDO Multicentre Exercise

I. Jennings[1], D. Kitchen[1], S. Kitchen[1], A. Riddell[2], D. Hart[3], T. Woods[1], I. Walker[1]

[1]UK NEQAS (Blood Coagulation), Sheffield, United Kingdom, [2]Royal Free Hospital, Haemophilia Centre, London, United Kingdom, [3]Barts and the London School of Medicine and Dentistry, Queen Mary University of London, The Royal London Haemophilia Centre, London, United Kingdom

Background: Detection and accurate measurement of FVIII and IX inhibitors is important in the management of patients with haemophilia. Previous studies by UK NEQAS (BC) have shown variability in approaches to performing inhibitor assays, and variability in results obtained on samples with FVIII inhibitors.

Aims: In this study, we sought further information on inhibitor assay performance, including adoption of heat inactivation to improve inhibitor accuracy, and the precision of laboratory testing for FIX inhibitors.

Methods: Samples from a patient with an acquired FVIII inhibitor and a patient with haemophilia B with a FIX inhibitor were distributed to 95 centres. Participants were asked to perform FVIII and IX inhibitor assays, and to complete a questionnaire on assay methodology and the laboratory approach to inhibitor investigation. Results were obtained from 74 centres.

Results: Variation in practice for inhibitor assays was observed. For example, only 25 centres report use of a heat inactivation step prior to assay - 8 of which carry this out before all assays, whilst 17 do so only if FVIII or IX is above a certain level (from >0.01IU/ml to >0.2IU/ml). Temperatures for heat inactivation ranged from 56-60oC and incubation times from 56-90min. The effect such variation has on inhibitor assay results is unknown. For the sample from a patient with an acquired FVIII inhibitor, the median titre reported was 3BU, range 0.7-7BU, CV 43%, excluding one outlying result of 15.4BU. For the sample from a patient with a FIX inhibitor, the median titre reported was 18BU, range 0-43.8BU, CV 33%, excluding one outlying result of 117.54BU. The outlying centre was the same in each assay. For the FVIII assay, several labs reported a non-linear dilution effect.

Conclusions: Variation in practice may contribute to the lack of precision in FVIII and IX inhibitor assays. Further standardisation is required to improve detection and quantification of these inhibitors.

PB 1137 | Improving aPTT Test and Resource Utilisation in Manitoba, Canada - A Successful Provincial Experience

C.T. Musuka[1,2], P. Sun[1,2], C. Mc Mahon[1], C. Morales[1,2]

[1]Diagnostic Services Manitoba, Haematology, Winnipeg, Canada, [2]University of Manitoba, Pathology, Winnipeg, Canada

Background: aPTT is one commonly performed test that is non-sensitive in predicting bleeding risk. An abnormal aPTT may lead to cancellation or unnecessary delays in surgical procedures, and haemostasis work-ups. The bleeding score is recommended in assessing patients' bleeding risk. Manitoba has been advocating evidence-based practice in all facets of medicine.

Aims: To improve test utilisation, we reviewed our practice, and the evidence of routine aPTT testing.

Methods: We audited aPTT ordering in all Manitoban hospitals. We found aPTT frequently being requested in situations where it was not evidence-based. After extensive consultations with various stakeholders, we decided to restrict the test availability and provided a consensus recommendation for proper utilization of aPTT.

Requests for indications other than unfractionated heparin monitoring and a selected number of specialty settings were processed after approval by hematopathologist or haematologist. In addition, the aPTT tick box was moved away from the INR/PT box on the requisitions and a reason for the test had to be specified. The laboratory staff enforced the initiative with 24/7 support from hematopathologists. The planning process lasted 6 months. The initiative commenced in June 2015. Data collected included test numbers, indications and clinical feedback. Some initial resistance required further education along with involvement of the province's senior medical leadership.

Results: Prior to June 2015, the use for aPTT was 16277 tests/month, with an 82% reduction to 2816 tests/month in 2016. The change did not impact patient care. Savings were realised in the following categories: 1) replacement of conventional coagulation analysers with point of care INR devices in small-medium sized sites: $462,000; 2) service contracts: $105,950 (33%) yearly and 3) annual reduction of reagents and consumables: $245,500 (21%).

Conclusions: Our local policy in restricting aPTT has successfully resulted in proper use, resource savings without impacting patient care.

PB 1138 | Prediction of Coagulation Testing in Underfilled Patient Samples

A. Cloe, K. Mikrut, G. Wool, J. Miller

University of Chicago Hospitals, Chicago, United States

Background: The common practice of rejecting blood samples for coagulation testing that are underfilled to < 90% of optimal volume, due to improper ratios of blood to anticoagulant, delays reporting of results and requires an additional blood draw.

Aims: This IRB-approved study was designed to determine the effect of addition of a standardized buffer solution to bring the underfilled specimen up to intended volume, thereby restoring proper blood to anticoagulant ratio, upon determinations of PT, aPTT, and fibrinogen.

Methods: Initially from eight healthy volunteers, citrated tubes were drawn to 50, 60, 70, 80, 90, and 100% of full volume. Imidazole-buffered Saline (IBS) was then added to each of the underfilled tubes to bring them to full volume, following which coagulation testing was performed. The results were well fit for PT (Fig. 1) and aPTT by exponential, and for fibrinogen by polynomial, models to create standard curves.

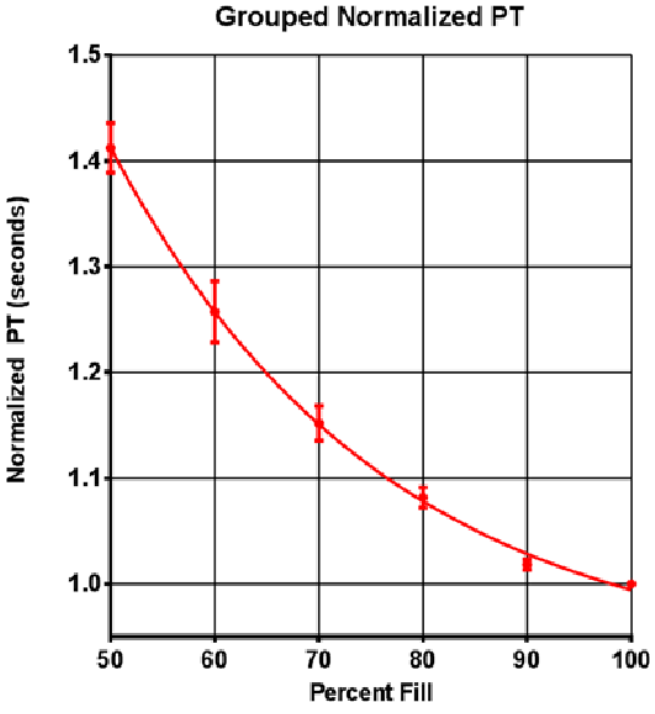

FIGURE 1 Prothrombin time curve from healthy volunteers

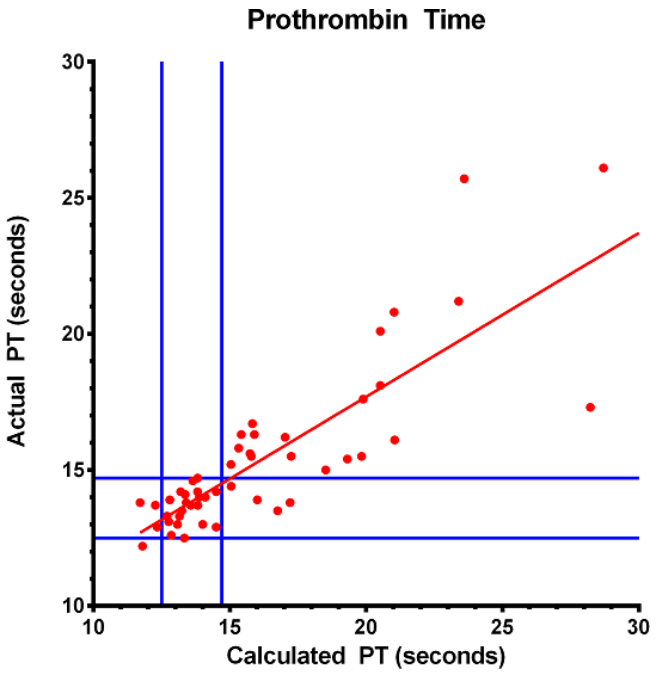

FIGURE 2 Comparison of calculated vs. actual prothrombin time

We next studied patients for whom underfilled samples were received by the coagulation laboratory. The underfilled tubes were brought to 100% volume with IBS, testing performed, and predictions of true values made based on the respective models. These predictions were then compared with actual values obtained on full volume patient tubes subsequently received.

Results: In the context of testing for exclusion of hemorrhagic tendency, where a false negative abnormality would pose the greatest clinical risk, no false negative misclassifications were made for PT (Fig 2) and aPTT, and in the case of fibrinogen, only one false negative misclassification in which the actual value was found to be only minimally below the lower normal limit.

Conclusions: While clearly obtaining a properly filled tube promptly would always be preferred, the approach employed in this study is encouraging, particularly in situations where additional delay of test results could have highly deleterious effects on patients, such as in the determination as to whether a stroke patient may be a candidate for tPA administration.

PB 1139 | Thrombin Generation Based Factor VIII Assay is Sensitive to Low FVIII Levels in Hemophilia

R. Kremers[1,2], C. Bai[3], J. Remijn[4], I. van Moort[5], D. Huskens[1,2], M. Ninivaggi[1], B. de Laat[1,2], M. de Maat[5]

[1]CARIM, Maastricht University, Synapse Research Institute, Maastricht, The Netherlands, [2]CARIM, Maastricht University, Department of Biochemistry,

Maastricht, The Netherlands, [3]Synapse Research Institute, Synapse Research Institute, Maastricht, The Netherlands, [4]Gelre Hospital, Department of Clinical Chemistry and Hematology, Apeldoorn, The Netherlands, [5]Erasmus Medical Center, Department of Hematology, Rotterdam, The Netherlands

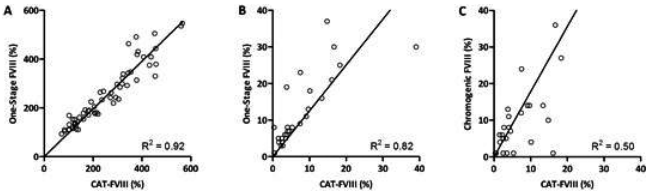

FIGURE 1 Correlation of FVIII-CAT and one-stage FVIII assay in healthy subjects (A) and hemophiliacs (B), and chromogenic FVIII assay in hemophiliacs (C).

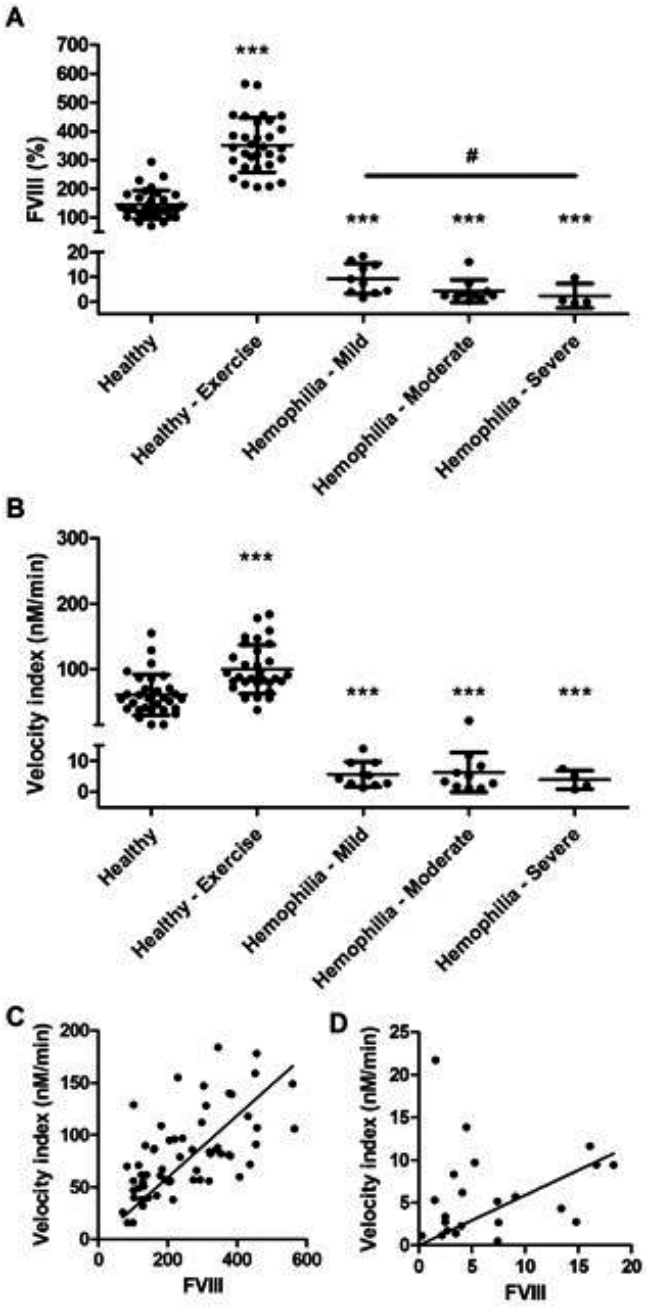

FIGURE 2 FVIII and velocity index in healthy subjects before and after exercise (A) and hemophiliacs (B) and their correlation (C-D).

Background: The adequate assessment of FVIII level is essential for treatment and monitoring of hemophilia A patients. Current tests include the one-stage assay and chromogenic assay. However, discrepancies have been reported between various assay results and both assays are not sensitive to detect FVIII level below 1%. Thrombin generation (TG) has previously been shown to be predictive of bleeding in hemophilia and a TG-based test for FVIII may be sensitive to FVIII levels below 1%.

Aims: To develop and validate a highly sensitive TG-based FVIII assay.

Methods: TG was triggered with 2 nM factor IXa in FVIII deficient plasma containing 12.5% standard plasma (containing 0-20% FVIII) or sample plasma and a linear calibration curve was constructed using the velocity index (FVIII-CAT). The test was validated in plasma samples with normal FVIII (healthy subjects, n=30), high FVIII (healthy subjects after strenuous exercise, n=30) and low FVIII (haemophiliacs, n=31) by comparing to the one-stage assay results. Samples were collected after informed consent.

Results: The intra- and inter-assay CVs of the FVIII-CAT were 3.1% and 7.4%. The FVIII-CAT correlated well with the one-stage FVIII determination in healthy subjects and hemophilia patients, but less with the chromogenic FVIII determination in hemophiliacs (figure 1).

FVIII levels were significantly elevated in healthy subjects after exercise and decreased in hemophiliacs (figure 2). Regular TG was measured at 1 pM tissue factor to assess the overall hemostatic potential of the subjects and the velocity index (VI) was elevated after exercise (+63%, p< 0.001) and reduced in hemophiliacs (-91%, p< 0.001). The FVIII level was significantly correlated to the VI in healthy subjects and hemophiliacs.

Conclusions: The FVIII-CAT can quantify FVIII in normal and hemophilia plasma, correlates well with the current golden standard (one-stage assay) and is sensitive to FVIII levels as low as 0.2 %. Global hemostasis in hemophiliacs is only partially determined by the FVIII level.

PB 1140 | Novel Biochip Detects Drug Effects in Patients with Cardiovascular Disease in a Near Patient Setting

A. Hall[1], M. Somers[1], J. Cowman[2], P. McCluskey[1], D. Kenny[2], N. Kent[1,3], N. Gilmartin[1,3]

[1]Dublin City University, Biomedical Diagnostics Institute, Dublin, Ireland, [2]Royal College of Surgeons in Ireland, Dublin, Ireland, [3]Dublin Institute of Technology, Dublin, Ireland

Background: Antiplatelet agents are used to prevent major events such as myocardial infarction in patients with cardiovascular disease (CVD), with over 50 million people in the US currently on anti-platelet therapy. Despite their proven benefit, major events still occur in CVD patients taking antiplatelet agents. Up to 30% of patients on anti-platelet drugs are non-responsive to the therapy and are at increased risk of adverse cardiovascular events. Consequently, a rapid, accurate assay of antiplatelet drug effect is needed.

Aims: To demonstrate the ability of a novel biochip to measure the effects of anti-platelet agents *in vitro* and *ex vivo*.

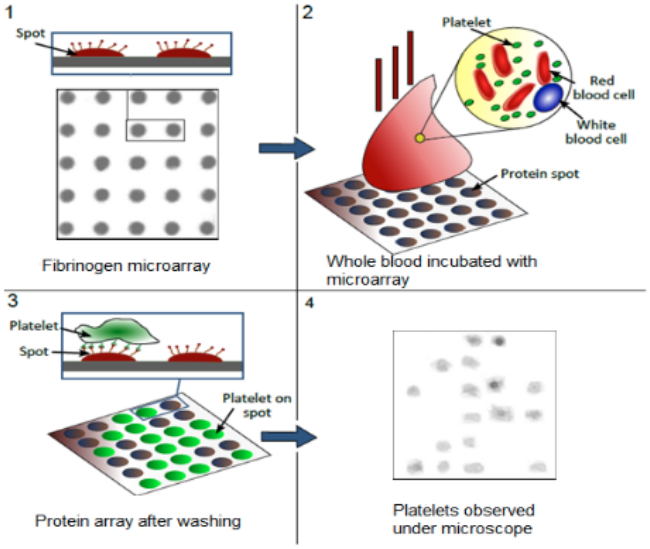

Figure 1 Assay principle. In the assay, unactivated platelets adhere to 6 µm fibrinogen spots. The addition of platelet agonists decreases platelet adhesion to fibrinogen spots by promoting platelet activation and aggregation. However, in the presence of an agonist-specific inhibitor, this decrease in platelet adhesion does not occur. Hence, the assay measures the inability of agonists to decrease adhesion in the presence of antiplatelet agents.

FIGURE 1 Assay principle

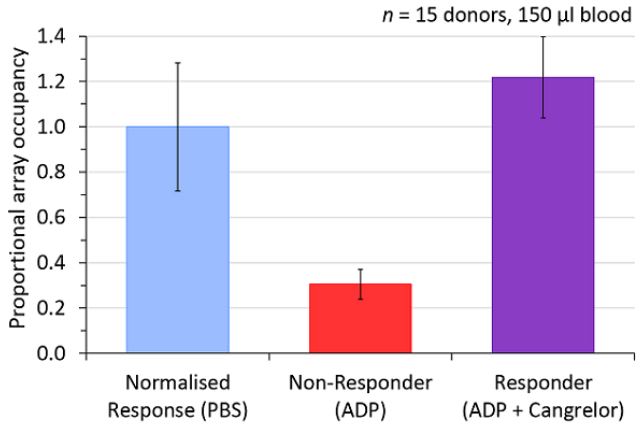

Figure 2. Cangrelor effect on platelet adhesion in vitro. In healthy volunteers, platelet adhesion is 72 ± 13 % (mean ± SD, Normalised response). The platelet agonist adenosine diphosphate (ADP, 20 mM) causes a significant decrease in platelet adhesion (non-responder). Cangrelor (10 mM) inhibits this ADP induced decrease in platelet adhesion (responder), demonstrating the ability of the assay to detect antiplatelet effects in vitro.

FIGURE 2 Cangrelor effect on platelet adhesion in vitro

Methods: We have developed a simple biochip-based approach to assess platelet function by measuring the specific adhesion of individual platelets from small volumes of whole blood to fibrinogen-patterned surfaces (Fig. 1). This biochip is capable of accurately measuring the effect of antiplatelet agents.

Results: The biochip can detect antiplatelet effects *in vitro* (Fig. 2). In CVD patients taking P2Y12 inhibitors such as Plavix, platelet adhesion in untreated and ADP treated blood samples is comparable, demonstrating the ability of the assay to detect antiplatelet effects *ex vivo*. The assay has also been optimised to detect the effect of other clinically relevant antiplatelet agents, including aspirin.

Conclusions: In conclusion, we have developed a simple, sensitive biochip that can accurately detect the effect of antiplatelet therapies *in vitro* and *ex vivo*. Due to its simplicity and sensitivity, the assay has potential for widespread use in the monitoring and tailoring of antiplatelet therapies in CVD patients.

Work was co-funded by Enterprise Ireland and the European Regional Development Fund under Ireland's European Structural and Investment Funds Programmes 2014-2020, grant no. CF/2015/0009. It was approved by the RCSI ethics committee and informed consent was obtained.

PB 1141 | Microfluidic Systems with Vascular Biomimetic Surfaces for Assessment of Platelets and Fibrin Components of Hemostasis: Comparison with a Classic Annular Device in the Evaluation of the Antithrombotic Effects of Apixaban

I. Lopez-Vilchez[1], E. Mir-Fuertes[1,2], J. Casals-Terre[3], M. Pegueroles[4], E. Arellano-Rodrigo[1], M. Diaz-Ricart[1], G. Escolar[1]

[1]Hospital Clinic of Barcelona, Centre of Biomedical Diagnosis (CDB), Institute of Biomedical Research August Pi i Sunyer (IDIBAPS), University of Barcelona, Department of Hemotherapy and Hemostasis, Barcelona, Spain, [2]Josep Carreras Leukemia Research Institute, Barcelona, Spain, [3]MicroTech Laboratory, Department of Mechanical Engineering, Technical University of Catalonia (UPC), Barcelona, Spain, [4]Biomaterials, Biomechanics and Tissue Engineering Group, Department of Materials Science and Metallurgical Engineering. Technical University of Catalonia (UPC), Barcelona East School of Engineering (EEBE), Barcelona, Spain

Background: Blood flow devices have improved our understanding on the mechanisms of bleeding and thrombotic disorders. The main inconvenient is that use of the classic devices is not standardized between different laboratories. New microfluidic technologies have been widespread implemented by reducing blood volumes and simplifying the evaluation process. Studies comparing the performance of microfluidic and classic devices are needed.

Aims: Compare the results of a microfluidic model using a biomimetic vascular surface vs. a classic annular device exposing genuine subendothelial components. Validate their performance evaluating the *in vitro* antithrombotic effects of apixaban (APIX).

Methods: Microfluididic studies were carried out with a commercial slide-based chamber (µ-Slide^{VI} 0.4, IBIDI). Citrated-recalcified blood aliquots were perfused through channels coated with fibrillar collagen type I and tissue factor, for 5 min at 800/s. We tested the effect of different APIX concentrations (0, 10, 40 and 160 ng/mL) and evaluated platelet and fibrin deposition onto the biomimetic surface by dual immunofluorescence. Parallel studies were performed in annular perfusion chambers exposing damaged vascular segments in which platelets and fibrin were morphometrically evaluated in histological sections.

Results: APIX caused a dose-dependent reduction in platelet and fibrin interactions onto the different thrombogenic surfaces, with similar results and statistical trends in both flow devices. APIX at 40 ng/mL statistically reduced platelet coverage; this effect was further increased at 160 ng/mL, also affecting the fibrin deposition.

TABLE 1 Percentage of surface coverage by platelet aggregates and fibrin nets

[APIX]	Annular chamber		Microfluidic chamber	
ng/mL	Platelets	Fibrin	Platelets	Fibrin
0	46.6 ± 3.5	53.8 ± 7.4	23.0 ± 3.0	43.4 ± 4.8
10	42.1 ± 2.5	51.2 ± 3.5	17.9 ± 0.9	42.1 ± 1.9
40	35.5 ± 4.8 *	46.9 ± 6.3	14.0 ± 5.3 *	23.4 ± 7.7
160	21.0 ± 2.8 *#	19.3 ± 4.4 *#	5.4 ± 2.2 *#	14.1 ± 4.9 *#

Mean ± S.E.M. *p<0.05 vs. absence of APIX; #p<0.05 vs. APIX 10 ng/mL

Conclusions: Results of the evaluation of platelets and fibrin in the microfluidic model using biomimetic vascular components showed a high level of correspondence with those observed in the classic annular device. The microfluidic model explored offers an alternative to classical flow based systems and may be useful in the evaluation of drugs that interfere with hemostasis.

Grant: DTS16/00133

PB 1142 | Automated CH50-like Assays for Assessment of the Complement System and Complement Inhibitor Drugs

I. Mackie[1], C. Gardiner[1], P. Lane[1], A. Chitolie[1], H. Kurono[2], M. Nunn[3,4], S. Machin[5]

[1]University College London, Haemostasis Research Unit, London, United Kingdom, [2]Sysmex Corporation, Kobe, Japan, [3]University College London, Haemosastsi Research Unit, London, United Kingdom, [4]Akari Therapeutics, London, United Kingdom, [5]University College London, Haeostasis Research Unit, London, United Kingdom

Background: Complement dysfunction plays a role in many diseases including: PNH and thrombotic microangiopathies; a variety of pharmaceutical complement inhibitors are in development. Complement is assessed by lytic CH50 assays or commercial Elisa, which are cumbersome and time consuming.

Aims: We have automated a CH50-like test on a coagulation analyser, to provide a global complement test for hospital laboratories.

Methods: We initially established a CH50-like assay (auto CH50) on the CS-2100i (Sysmex) coagulometer using reagents from Siemens, but later developed a high sensitivity method using in-house sheep erythrocytes (SE) and hemolysin. The time taken until 50% SE lysis was measured at 660nm and standardized against dilutions of pooled normal serum (PNS). CH50 ELISA (Quidel Corp) and manual, in-house, lytic CH50 were reference methods.

Results: The auto CH50 was linear over a wide range of dilutions, detection limit 1.6%; intra- & inter-assay cv: 2.5 & 7.0%. Serum was stable for 4hr at RT. Good correlations were obtained with both manual lytic CH50 and CH50 ELISA (r=0.50 & 0.57, respectively, p< 0.001) in sera from normals (n=36), patients with liver disease (n=7), antiphospholipid syndrome (n=48) and their disease controls (n=25). In vitro spiking of PNS with C5 inhibitor coversin, showed dose responsiveness, but a difference in inhibition between auto CH50 and ELISA methods (IC50: 6 v 3ug/ml); weaker inhibition was observed with the C5 monoclonal antibody eculizumab (IC50: 32 v 10ug/ml). Phase I & II (PNH) coversin studies gave similar inhibition by all assays at peak dose, but faster normalisation by auto CH50. Using in-house reagent (more dilute SE), the auto CH50 gave good agreement with Elisa and manual CH50 for both complement inhibitor drugs in vitro and ex vivo.

Conclusions: The auto CH50 potentially allows routine assessment of complement activity in a standardized manner. The more sensitive in-house automated assay may allow pre-treatment screening and efficacy monitoring of C5 inhibitor drugs.

PB 1143 | Prenatal diagnosis for Inherited Bleeding Disorders in India

E.S. Edison[1], R.V. Shaji[1], G. Sankari Devi[1], S.V. Rajkumar[1], M. Kamath[2], T.K. Aleyamma[2], N.A. Fouzia[1], A. Korula[1], A. Abraham[1], B. George[1], S.C. Nair[3], V. Mathews[1], A. Srivastava[1]

[1]Christian Medical College, Haematology, Vellore, India, [2]Christian Medical College, Reproductive Medicine, Vellore, India, [3]Christian Medical College, Transfusion Medicine and Immunohaematology, Vellore, India

Background: Inherited bleeding disorders are a group of heterogeneous disorders which includes quantitative and qualitative defects in the coagulation proteins and platelets. Although phenotypic assays still remain the first line in diagnostic testing, molecular diagnosis provides carrier detection and prenatal diagnostic opportunities. The latter is particularly significant where therapeutic options are limited. This is particularly relevant in southern India where such disorders are more common given the high level of consanguinity in the community. We have therefore established methods for genetic diagnosis for a wide range of bleeding disorders.

Aims: This report reflects our experience with prenatal diagnosis for inherited bleeding disorders carried out between 2002 and 2016 at our institution.

Methods: Prenatal diagnosis (PND) is carried out on DNA extracted from chorionic villous samples obtained at 10-12 weeks of pregnancy. Mutations were detected by a range of techniques including CSGE and Sanger sequencing. Maternal cell contamination was ruled out by analyzing STR markers. Diagnostic methods are established for Haemophilia (A&B), other factor deficiencies (II, V, VII, X, XI, XIII), platelet disorders (Glanzmann Thrombasthenia, Bernard Soulier Syndrome), von willebrand disease and Wiskott Aldrich syndrome.

Results: PND was offered to 303 couples with different bleeding disorders. Most of the PND done was for Haemophilia A (n= 240, 78%) followed by haemophilia B (n=37, 12%). Other disorders were Glanzmann Thrombasthenia (n=8), Wiskott Aldrich Syndrome (n=8), F13 deficiency (n=4), F7 deficiency (n=3), Von willebrand disease Type-3 (n=3) and F10 deficiency (n=1). Of these 143 fetuses were found to be normal, 78 were identified as carriers and 84 were affected.

Conclusions: Genetic counselling aided families with inherited bleeding disorders to make an informed decision. Prenatal diagnosis provides an important tool in the control and management of a wide range of inherited bleeding disorders in India.

PB 1144 | Availability of Age-specific Coagulation Laboratory Values in Pediatric Hospitals vs. Combined Pediatric/Adult Hospitals: An International Perspective

Z. Solh[1,2], R. Rajagopal[3], J. Thachil[4], A. Chan[1], N. Heddle[1], P. Monagle[3]

[1]McMaster University, Hamilton, Canada, [2]Canadian Blood Services, Hamilton, Canada, [3]Royal Children's Hospital, Melbourne, Australia, [4]Manchester Royal Infirmary, Manchester, United Kingdom

Background: The diagnostic scoring system for disseminated intravascular coagulation (DIC) was developed by ISTH for adult medicine. Pediatric DIC care may be suboptimal if pediatric DIC diagnosis and management are guided by adult reference ranges.

Aims: To explore age-specific issues in DIC diagnosis including the availability of age-appropriate reference ranges worldwide.

Methods: A web-based questionnaire was developed using LimeSurvey software; 3 sections: Respondent Demographics; DIC Diagnosis; and DIC Management. International dissemination was done via pediatric and neonatal professional societies. Study coordinated by sites in Hamilton (Canada) and Melbourne (Australia) in collaboration with Manchester (England) and members of ISTH Pediatric and DIC SSC. Data were collected from January to September 2016.

Results: A total of 211 responses were obtained: 160 full and 51 partial. There were 133 (63%) respondents from pediatric hem/onc, 45 (21%) from NICU, and 23 (11%) from PICU. Geographic distribution of responses was: 96 (46%) from North America, 56 (27%) from Asia, 25 from Australia (12%) and 24 from Europe (11%). Overall, 25% reported that age-appropriate laboratory values for PT, INR, aPTT, fibrinogen, and platelet count were not available; 20% for protein C, S, anti-thrombin and thromboelastography. Lack of access to age-appropriate values varied by location: Asia 35%, North America 25%, Europe 14% and Australia < 10%. A lack of access to age-appropriate values was reported in 20% of respondents in pediatric-only hospitals and 35% in combined pediatric/adult hospitals.

Conclusions: Despite ISTH position statements emphasizing the importance of reporting age-appropriate data from diagnostic labs, a substantial proportion of respondents report that labs offering services to pediatric patients are still not compliant with this concept. Future studies should assess the impact of this finding on pediatric quality of care and research outcomes from centres that are not using age-appropriate reference values.

PB 1145 | The Use of the ADJUST (Age Adjusted) D-dimer Cut-off in Screening Patients Aged over 50 Years Presenting with Suspected DVTs Can Decrease the Need for Compression Ultrasonography

A. Hughes[1], B. Hall[1], C. Smith[1], J. King[1], G. Page[1], K. Jennings[1], S. Macdonald[1], V. Webb[1], F. Charova[2]

[1]North East London Foundation Trust, Community Haematology, Brentwood, United Kingdom, [2]Mid Essex Hospitals, Radiology Department, Chelmsford, United Kingdom

Background: In patients with suspected DVT, D-dimer levels below the conventional cut-off of 500ug/l (CDD) can rule out DVT in patients with a non-high clinical probability score. As DD levels rise with age a higher proportion of older patients with suspected DVT may have a DD >conventional cut-off resulting in a greater need for unnecessary compression ultrasonography (CUS), as many will be normal. It has been suggested that the use of an age-adjusted DD cut-off, age x10ug/l, (AADD) in individuals of >50 years can improve specificity without significant loss of sensitivity, decreasing the need for unnecessary imaging.

Aims: To determine, in a primary care setting, whether the use of an AADD could safely decrease the number of CUS required in patients >50 years presenting with suspected DVT and a non-high Wells score (WS).

Methods: We analysed retrospectively data from two cohorts of patients presenting with suspected DVTs to a single community clinic. One, previously reported, from Sept 2012 to Sept 2014, and a second, new, cohort from Jan 2015 to Mar 2016. All patients were screened with a WS and a quantitative Point of Care DD. CUS was carried out on site as per standard protocols. All patients discharged with DVT excluded had a 90-day follow (90dFU) to determine the subsequent incidence of venous thromboembolism (VTE).

Results: 1411 patients were reviewed. 1173 (83%) were >50 years. Of these, 305 (26%) had non-high WS and a raised CDD but 127 (42%) had a normal AADD. 113 of these 127 either had a normal CUS and/or a 90dFU without recurrent VTE. 14 were lost to follow up but were not re-referred with suspected VTE within 90 days.

Conclusions: In patients >50 years with suspected DVT, a non-high WS and a raised CDD, the use of an AADD cut-off can safely exclude a DVT without the need for CUS. This could decrease the need for CUS in this group by 40%, improving the efficiency and cost effectiveness of a DVT service, especially in primary care, decreasing the need to refer to secondary care for CUS.

PB 1146 | Is the Application of a Single Conversion Factor Suitable for the Laboratory Monitoring of Single Chain rFVIII by One-stage FVIII:C Assay?

A.E. Bowyer[1], S. Kitchen[1], D. Dalton[2], N.S. Key[2], M. Makris[1]

[1]Sheffield Haemophilia and Thrombosis Centre, Department of Coagulation, Sheffield, United Kingdom, [2]University of North Carolina at Chapel Hill, Division of Hematology-Oncology, Department of Medicine, Chapel Hill, United States

Background: A novel single chain, recombinant factor VIII (SCrFVIII) for the treatment of haemophilia A has recently been licensed. The manufacturer recommends that either a chromogenic (FVIII:CR) or one-stage assay (FVIII:C1) is used to monitor levels but that a conversion factor of 2 be applied to all FVIII:C1 results regardless of APTT reagent used in the assay.

TABLE 1 Recovery of SCrFVIII using converted FVIII:C1 and six APTT reagents

Labelled Potency (IU/ml)	Converted Synthasil (IU/ml)	Converted APTT SP (IU/ml)	Converted Synthafax (IU/ml)	Converted Actin FSL (IU/ml)	Converted Actin FS (IU/ml)	Converted Pathromtin SL (IU/ml)
2.39	2.02	2.28	2.48	2.48	2.46	2.04
1.59	1.38	1.62	1.76	1.70	1.82	1.36
1.19	0.92	1.24	1.38	1.36	1.34	0.98
0.60	0.48	0.68	0.74	0.72	0.72	0.54
0.24	0.20	0.30	0.36	0.28	0.28	0.22
0.12	0.12	0.16	0.20	0.16	0.18	0.12
0.06	0.06	0.08	0.14	0.08	0.10	0.08
0.02	0.04	0.04	0.08	0.04	0.06	0.04

Aims: The aim was to assess whether a universal conversion factor for the FVIII:C1 is suitable for a range of APTT reagents used in the routine monitoring of SCrFVIII.

Methods: SCrFVIII was reconstituted in water then serially diluted using the labelled potency to 2.39-0.02 IU/ml in 0% FVIII. FVIII:C1 was assayed with Synthasil, APTT SP and Synthafax (all Werfen), Actin FLS, Actin FS and Pathromtin SL (all Siemens). All FVIII:C1 results were multiplied by a factor of 2. FVIII:CR was measured by Hyphen Biomed assay. All assays were performed on Sysmex CS5100i instrumentation at multiple dilutions.

Results: At higher FVIII:C1, >0.60 IU/ml, up to 23.3% difference was demonstrated between labelled potency and converted FVIII:C1. 43.3% difference was seen between highest and lowest results at the same potency with different APTT reagents. The greatest variation was at the 0.02 IU/ml dilution which was 100-300% higher than target with all APTT reagents (see table 1). The FVIII:CR overestimated the FVIII:C by 13-50% depending on the target dilution.

Conclusions: The application of a conversion factor improved the results but underestimation was still observed with some reagents and overestimation with others. At very low FVIII:C, similar to patient trough levels, a gross overestimation of converted FVIII:C1 was observed with all APTT reagents which may lead to under-dosing of patients. FVIII:CR demonstrated less dose dependant variation and was more accurate at very low FVIII:C. Clinicians should exercise caution when using the FDA and EMA approved single conversion factor in FVIII:C1 for all APTT reagents especially when measuring and interpreting trough levels.

PB 1147 | Impact of Pneumatic Tube System Transportation for the Monitoring of Heparin Therapy

A. Lebreton, A. Casini, O. Bulla, P. Fontana

University Hospitals of Geneva, Division of Angiology and Haemostasis and Haemostasis Laboratory, Geneva, Switzerland

Background: Transport by pneumatic tube system (PTS) is a rapid and widely spread mode of transport for biological samples in laboratories. It allows reduced turnaround time but its impact on haemostasis assay results is unclear. PTS transport did not seem to have a major impact on several haemostasis parameters including aPTT in healthy subjects but there is no data regarding samples of patients anticoagulated with heparin.

Aims: To evaluate the impact of PTS transport on aPTT and anti-Xa assays of samples collected in patients treated with heparin.

Methods: Citrated blood samples of 156 patients treated with unfractionated heparin (UFH, n=126) or low molecular weight heparin (LMWH, n=30) were divided in two identical tubes. For each patient, one tube was hand-delivered to the laboratory and one tube was transported by PTS. Both tubes were then simultaneously centrifuged at 2500 *g* for 15 min and aPTT and anti-Xa assays were performed on a BCS XP automate (Siemens) during the same run.

Results: Compared to the hand-delivered samples, aPTT and anti-Xa assays were lower on samples transported by PTS (median difference of 2.8 sec, interquartile range [IQR]: 0.4-7.5, p< 0.001 and 0.03 UI/ml, IQR 0.0-0.09, p< 0.001 respectively). For patients with UFH, the difference was more obvious for aPTT (4.5 sec, IQR:1.3-9.0, p< 0.001) and for anti-Xa assay (0.04 UI/ml, IQR:0.03-0.07, p< 0.001), while there was no difference of anti-Xa results in patients with LMWH (0.0 UI/ml, IQR: 0.0-0.01, p=0.52). Bland&Altman plots showed that the difference of both parameters increased with the heparin concentration in patients treated with UFH. Among the 58 patients with UFH and with anti-Xa assay in therapeutic range as measured on hand-delivery samples, 12 (21%) would have been classified as infra-therapeutic if the samples had been transported by PTS.

Conclusions: PTS transport significantly impacts the results of aPTT and anti-Xa assays for UFH monitoring.

PB 1148 | Comparison of von Willebrand Factor Collagen Binding Activity (VWF:CB) Determined by a Chemiluminescent Assay on AcustarTM to an ELISA Kit

E. Jousselme[1], L. Rugeri[2], C. Nougier[1]

[1]*Hospices Civils de Lyon, Service d'Hématologie Biologique, Groupement Hospitalier*

Est, Bron, France, [2]Hospices Civils de Lyon, Centre Régional de Traitement des Hémophiles, Groupement Hospitalier Est, Bron, France

Background: VWF collagen binding (VWF:CB) activity assay is a second-laboratory level test used to explore and phenotype Von Willebrand Disease (VWD). This assay is particularly sensitive to high molecular weight (HMW) of Von Willebrand Factor (VWF) and helps to differentiate VWF variants.

Aims: The aim of the study was to evaluate performance characteristics of a new chemiluminescent technology for the diagnosis of VWD. Results of VWF:CB were compared between the classical assay (ELISA method) and this new technology.

Methods: In this retrospective study, VWF:CB was measured by chemiluminescent assay (Acustar™, Werfen) and ELISA (Asserachrom® VWF:CB, STAGO) in samples from 53 patients. All patients were well-defined by phenotype evaluations and genetic reports: VWD type 2-2A (n=13), VWD type 2-2M (n=7), VWD type 2-2B (n=11) and VWD type 1 (n=22). We also analysed normal plasmas (n=15). By measuring antigen of VWF (VWF:Ag) on the same sample, we calculated VWF:CB/VWF:Ag ratio. The concordance of the ratio obtained with the two methods (> or < to 0.6) have been interpreted in relation to the genetic reports.

Results: We found adequate diagnostic performance (within-run, between-run, reference range), highly correlated results (r^2=0.9564) and a minimal bias (+4.7%) with the chemiluminescent assay. Evaluation of VWF:CB/VWF:Ag ratio on VWD plasmas (n=53) were concordant between the two assays for almost all subtypes and almost all mutations. We obtained 4 different results for the 5 patients with VWD 2M-2A like. For these samples, VWF:CB/VWF:Ag ratios with chemiluminescent assay were lower and more concordant to the genetic report: p.(R1374C) and p.(R1374H) mutations.

Conclusions: Automatized of VWF:CB assay is benefit for laboratories: better analytical performance and more sensibility to HMW of VWF. This phenotype assay based on chemiluminescent technology is also well correlated to genetic results of VWD patients.

PB 1149 | Validation of a Flow Cytometric Platelet Function Test in a Cohort of Patients with a Suspected Platelet Function Disorder

I. van Asten[1], M. Baaij[1], J. Zandstra[1], A. Huisman[1], G. Pasterkamp[1], R. Schutgens[2], S. Korporaal[1], R. Urbanus[1]

[1]University Medical Center Utrecht, Department of Clinical Chemistry and Haematology, Utrecht, The Netherlands, [2]University Medical Center Utrecht, Van Creveld Clinic, Utrecht, The Netherlands

Background: Light transmission aggregometry (LTA) is the most commonly used test for the diagnosis of platelet function disorders (PFDs). However, LTA is labor-intensive, requires a large blood volume, is poorly reproducible and has only moderate sensitivity for the detection of mild PFDs. Flow cytometry has been recommended for additional diagnostics of PFDs, but is hard to standardize and not readily applicable in diagnostic laboratories. We developed a standardized protocol for flow cytometric analysis of platelet function (FCAP) that measures fibrinogen binding to integrin αIIbβ3 and P-selectin expression as markers of platelet activation in response to stimulation with agonists.

Aims: To determine the additional value of FCAP with a panel of agonists in a cross sectional cohort of patients suspected of a PFD.

Methods: Platelet function was assessed with LTA and FCAP in 60 healthy controls and 108 patients suspected of a PFD in whom Von Willebrand disease and coagulation factor deficiencies were excluded. Bleeding scores (BS) of patients were determined with the ISTH bleeding assessment tool. Performance of both tests was analyzed with an Area Under a Receiver Operating Curve (AUC).

Results: Out of 108 patients, 81 patients had a BS>3. 42 out of 81 patients (51.9%) had abnormal platelet function measured with FCAP and 40 out of 81 patients (49.4%) were abnormal based on LTA. 25 patients (30.9%) had poor platelet function based on both tests and 24 patients (29.6%) had normal platelet function in both LTA and FCAP. Agreement between LTA and FCAP was poor to moderate (κ=0.29). The discriminative ability of FCAP was good (AUC 0.74), but moderate for LTA (AUC 0.68). Both tests combined had a better discriminative ability (AUC 0.82, p< 0.05) than LTA alone, but performed similar to FCAP (p=0.27).

Conclusions: Flow cytometric analysis of platelet function can be used to discriminate between healthy controls and patients with a PFD, especially combined with LTA.

PB 1150 | Comparison of light transmission aggregometry and multiple electrode aggregometry for the evaluation of platelet aggregation in patients with mucocutaneous bleeding

S.J. Israels[1,2], E. McMillan-Ward[2], R. Mian[3], D. Murariu[3], P. Sun[4,5]

[1]University of Manitoba, Department of Pediatrics and Child Health, Winnipeg, Canada, [2]Research Institute in Oncology and Hematology, Winnipeg, Canada, [3]CancerCare Manitoba, Department of Epidemiology, Winnipeg, Canada, [4]University of Manitoba, Department of Pathology, Winnipeg, Canada, [5]Diagnostic Services Manitoba, Winnipeg, Canada

Background: Light transmission aggregometry (LTA) is the "gold standard" diagnostic test for platelet aggregation, although required blood volumes can limit its use. Whole blood or multiple electrode aggregometry (MEA) using the Multiplate® analyzer requires much smaller blood volumes, but has not been directly compared to LTA for evaluation of patients with mucocutaneous bleeding.

Aims: To compare results of LTA and MEA for patients referred for platelet function analysis.

Methods: Blood samples were collected following informed consent; the study was approved by the Research Ethics Board. LTA and MEA assays were performed using threshold concentrations of ADP, arachidonate (AA), collagen and thrombin receptor activating peptide (TRAP). Concordance of LTA and MEA for each platelet agonist was calculated using the McNemar Chi-square test. Using LTA as the standard, the sensitivity and specificity for each MEA agonist were determined.

Results: 44 patients (30F/14M) were studied: median age 18 (range 2.2-84) years; mean platelet count 250±94 x 10^9/L. 6 patients had at least 1 abnormal agonist response with LTA; 8 had at least 1 abnormal agonist response with MEA. The two methods were concordant based on the McNemar Chi-square test: p > 0.6 for all agonists. Sensitivities of MEA relative to LTA were: ADP, 0.33; AA, 0.5; collagen, 0 [the small numbers of patients with abnormal results contributed to the low sensitivities]. Specificities of MEA relative to LTA were: ADP, 0.9; AA, 0.95; collagen, 0.93. Negative predictive values (NPVs) for MEA relative to LTA were: ADP, 0.95; AA, 0.98; collagen, 0.95. Values for TRAP could not be determined as no patient had an abnormal LTA result.

Conclusions: The two methods provided concordant results for responses to ADP, AA and collagen. MEA results showed good specificities and NPVs in relation to LTA; i.e., MEA performed well in identifying the patients who had no abnormal aggregation results by LTA. Comparison of additional patient samples is required for validation of results.

PB 1151 | Clot Waveform Analysis Has the Potential to Detect Fibrinogen Abnormalities

A. Suzuki[1], N. Suzuki[2], M. Kishimoto[3], T. Kanematsu[3], T. Matsushita[2,3]

[1]Nagoya University Hospital, Department of Medical Technique, Clinical Laboratory, Nagoya, Japan, [2]Nagoya University Hospital, Department of Transfusion Medicine, Nagoya, Japan, [3]Nagoya University Hospital, Department of Laboratory Medicine, Nagoya, Japan

Background: Fibrinogen abnormalities comprise two classes of plasma fibrinogen defects: quantitative and qualitative deficiencies. The Clauss fibrinogen assay, which has been used for an initial screening test, provides only fibrinogen clottable activity; however, we cannot distinguish between qualitative and quantitative defect of fibrinogen.

Aims: Automated coagulation analyzers can provide the additional information in conventional clotting tests. Clot waveform analysis (CWA) has been applied to evaluate coagulability in patients with bleeding disorders such as hemophilia. CWA is also available in Clauss fibrinogen assay determined by light transmittance, and in this study we investigated the CWA in fibrinogen analysis to detect fibrinogen abnormalities.

Methods: Citrated plasma samples were obtained from healthy volunteers and patients with dysfibrinogenemia. We performed both Clauss fibrinogen assay and latex agglutination assay to measure fibrinogen antigen. We compared fibrinogen activity, antigen, and CWA parameters; clotting time, changes in absorbance (dOD), |min1| value from 1st derivative curve, |min2| and |max2| values from 2nd derivative curve.

Results: The results showed that fibrinogen activity and antigen were strongly correlated in normal plasma, the discrepancies between activity and antigen were observed in dysfibrinogenemia plasma. The CWA parameters: dOD and |min1| were also highly correlated to fibrinogen antigen in normal plasma. The clotting time was prolonged due to low fibrinogen activities, and the dOD values were high as compared with normal low fibrinogen level in dysfibrinogenemia plasma. The |min1| values in dysfibrinogenemia were low, that indicated impaired fibrin polymerization of abnormal fibrinogen.

Conclusions: The CWA in Clauss fibrinogen assay had the potential and could be helpful to detect abnormal fibrinogen using |min1| values, with no additional costs in standard laboratory tests.

PB 1152 | Effect of Anticoagulant Adjustment on Prothrombin Time Test Using 2 Different Thromboplastins in Patients with Elevated Hematocrit

V.M. Silva[1], C. Cavalheiro-Filho[2], D.C. Rezende[3], C.C. Strunz[1]

[1]Heart Institute of the University of São Paulo, Clinical Laboratory, São Paulo, Brazil, [2]Heart Institute of the University of São Paulo, Haemostais, São Paulo, Brazil, [3]University of Sao Paulo, Hematology, São Paulo, Brazil

Background: An elevated hematocrit(Ht) value changes the ratio of citrate anticoagulant concentration/volume of blood collected and the excess of the anticoagulant increases the prothrombin time (PT) results.The adjustment of sodium citrate volume is important on samples of patients with high hematocrit(HT>55%) since unadjusted citrate volume in these situations can lead to errors in the treatment.

Aims: The aim of this study was to compare the effect of adjusted and unadjusted citrate volume using two different thromboplastin on patients with Ht>55% and under anticoagulation therapy.

Methods: Paired citrate-adjusted and non-citrate-adjusted blood specimens were obtained from 179 patients with high Ht values on use of warfarin.Two different thromboplastins were used: one is a recombinant human tissue factor (PT-RTF) and the other is extracted from rabbit brain

(PT- Rabbit).Results are expressed as *international normalized ratio* (INR).

Results: The PT- RTF results from the citrate adjusted and citrate-unadjusted blood specimens did not differ significantly and presented a strong correlation (R^2=0.8226,p< 0.0001).The median of PT-RTF for citrate adjusted samples was 2.10(CI95% 2.06 to 2.38)and for citrate-unadjusted was 2.00 (CI95%2.10 to 2.41).From the 179 samples analyzed seventeen (9.5%) exceeded the Allowable Total Error for this test (>15%) and all of them presented hematocrit >62%.Already, the results using PT- Rabbit presented a moderate correlation between samples (R^2 =0.4267,p< 0.0001).The median of the results was 2.30 (CI95%:2.34 to 2.67) for citrate adjusted and 2.70(CI95%:3.11 to 3.81) for citrate-unadjusted. From the 179 samples analyzed seventy nine (44.1%) were above the Total Error and had Ht values between 56% and 72%.

Conclusions: Our data demonstrate that using PT-RTF reagent, samples with hematocrit up to 62% may be safely performed and interpreted with confidence without anticoagulant adjustment.Unlike for PT-Rabbit it will be necessary to adjust the citrate volume according to Ht.

PB 1153 | Methodology of Thrombogenicity Assessment Intended for Biomaterials Utilized in Blood Pumps

M. Gawlikowski, K. Janiczak, B. Zawidlak-Wegrzynska, R. Kustosz

Foundation of Cardiac Surgery Development, Artificial Heart, Zabrze, Poland

Background: Construction of blood contacting devices (particularly blood pumps) requires materials which high biocompatibility and low thrombogenic potential. Platelet (PLT) activation followed by coagulation pathway and complementary system induction leads to thrombus formation and increases risk of thromboembolic complications.

Aims: The aim of study was to develop the set of examinations in order to in-vitro evaluation of thrombogenicity of various biomaterials.

Methods: Samples of biomaterials were prepared in form of discs. Surface roughness was measured optically. Samples were sterilized in a way appropriate for biomaterial (ETO, radiation). Citrated or anticoagulated by R-hirudin human blood was used.

First the PLT aggregation under ADP was measured. Static thrombogenicity test was as follow: samples incubation in human PRP (60min, 37°C), washing in PBS, fixing in formalin. Afterwards the qualitative surface assessment (number and morphology of PLT) was performed by means of AFM or SEM.

Thrombogenicity test under shear stress was evaluated utilizing Impact-R analyser. Our modification of method consisted in placing a disc of tested biomaterial into a polystyrene cell. The assessment of biomaterial thrombogenicity consisted of:

· platelet activation and aggregation (CD61, CD62P, CD45, CD14) in blood circulating above the examined biomaterial by means of flow cytometry,

· cells adhesion to the surface of biomaterial (CD62P, CD45) by means of fluorescent microscopy.

Depending on biomaterial the references were: polystyrene,Ti6Al7Nb or PU (Bionate2) -without any surface modification.

Results: Described methodology was applied to evaluate the thrombogenicity of bionanocellulose, Ti alloys, PU, PEEK, PET/DLA copolymers and their surface modifications (TiN, DLC). The comparison of obtained results to reference allowed to quantitative assessment of thrombogenicity of investigated biomaterials.

Conclusions: The proposed method allows to in-vitro, quantitative assessment of biomaterials in terms of thrombogenicity.

PB 1154 | LC-MS/MS Nonradioactive Serotonin Release Assay for Platelet Function Analysis in Whole Blood

S.L. Chan[1], X. Yi[2], E. Wysocki[1], R. Bridgman[1], K. Mikrut[1], J. Gutierrez[1], E.K.-Y. Leung[1], K.-T.J. Yeo[1], J. Miller[1]

[1]*University of Chicago, Pathology, Chicago, United States,* [2]*Houston Methodist Hospital and Research Institute, Department of Pathology and Genomic Medicine, Houston, United States*

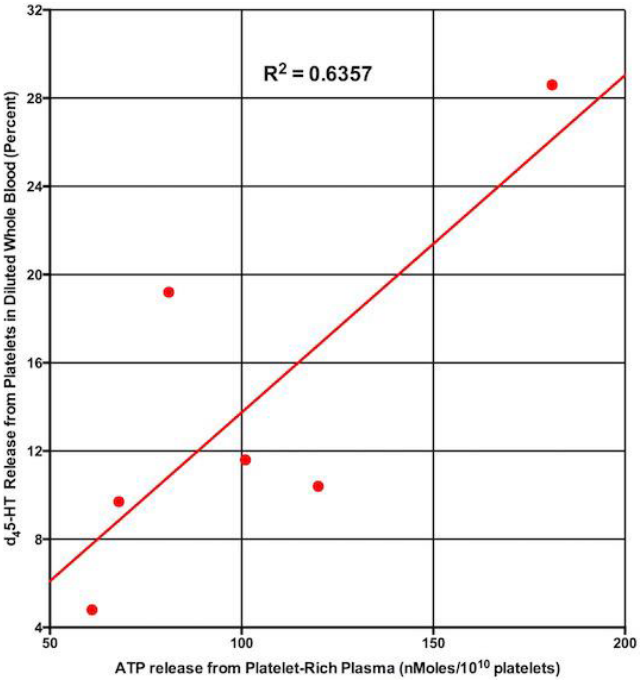

FIGURE 1 ADP-Induced Dense Granule Release: Comparison of d5-HT Release in Whole Blood and ATP Release in Platelet-Rich Plasma

Background: Assay of dense granule secretion as part of an evaluation of platelet function is presently most typically performed by study of ATP release in a lumi-aggregometer. Sensitivity of this approach limits its applicability both for very young patients and for adult patients with a significant degree of thrombocytopenia.

Aims: The aim of this IRB-approved study is the development of a highly sensitive, non-radioactive assay of dense granule secretion that could be performed using very small numbers of platelets in whole blood.

Methods: From a single pediatric size citrate tube, 200 µL of whole blood was incubated with exogenous deuterated serotonin ($d_4$5-HT). Following $d_4$5-HT uptake, the blood was diluted and then incubated with a variety of platelet stimuli. Following stimulation, specimens were centrifuged to obtain releasate. A platelet lysate was used to assess total $d_4$5-HT uptake and calculation of percent release. For sample preparation, methylated-5HT was used as internal standard. Calibrators were prepared by spiking $d_4$5-HT into a matrix of modified Tyrode buffer. Samples were precipitated by perchloric acid and centrifugation. Analytes were detected using a Sciex QTrap 6500 mass spectrometer with an ESI source.

Results: Platelet stimuli being evaluated in this study include ADP, epinephrine, arachidonic acid, U46619, TRAP, and convulxin. The degree of correlation with the release of platelet ATP from stirred platelet-rich plasma varied by agonist. An example of such correlation, in this case following stimulation of platelets from normal volunteers with 10 µM ADP, is shown in Fig. 1.

Conclusions: The deuterated serotonin LC-MS/MS assay developed in this study permits extensive study of platelet dense granule secretion using extremely small blood volumes. This approach offers

promise as a means to overcome serious limitations of current platelet function testing by expanding the availability of such testing both to pediatric patients and to adult or pediatric patients with decreased platelet counts.

PB 1155 | Thromboelastometry can Generate Significant Disagreement in the Management of Patients after Cardiopulmonary Bypass due to Analytical Variability

B. Bachellerie[1], H. Charbonneau[2], S. Voisin[3], F. Labaste[1], A. Caussanel[4], F. Guerrero[5]

[1]CHU de Toulouse, Anesthesia, Toulouse, France, [2]Clinique Pasteur, Toulouse, France, [3]CHU de Toulouse, Toulouse, France, [4]CEDIBIO UNILABS, Toulouse, France, [5]CHU de Toulouse, Hematology Laboratory, Toulouse, France

Background: Thromboelastometry is widely used after cardiac surgery in patients presenting with bleeding complications. However the role of this test in the management strategy is still subject to debate. One possible explanation for this controversy is that excessive analytical variability modifies the conclusions of the management strategy.

Aims: To test if within-patient variability of ROTEM® results increases the variability in the management of patients.

Methods: We included 85 cardiac surgery patients after cardiopulmonary bypass, during 4 different periods between July 2014 and April 2016. Inclusions were consecutive for each period. The periods reflect different conditions for performing the tests (ROTEM®): point of care, re-localization to lab, single or multiple operators. Measurements were performed within 30 to 60 minutes after blood sampling on two samples obtained from the same patient at the same time and in identical conditions. The primary endpoint was any discrepancy in the conclusion of a standard algorithm applied to both results. The factors influencing the risk of discrepancy were studied using multivariate logistic regression. Odds ratios and 95% confidence intervals (95CI) were verified by bootstrapping. The study was approved by a local research ethics committee (n°13-0215).

Results: The main results are presented in figure 1.

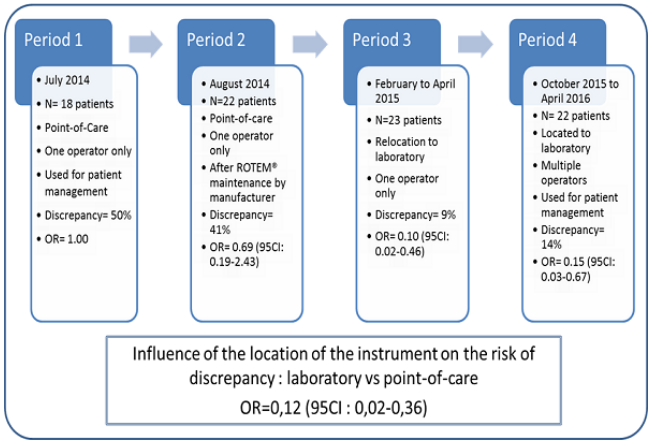

FIGURE 1 Changes in the risk of discrepancy according to study periods

The main factor that reduced discrepancy was location of the ROTEM® to the lab. When measurements were performed by multiple operators, the risk of discrepancy increased by 50% but remained 70% below the risk observed in POC. The model's AUC-ROC was 0.79 (95CI:0.66-0.89).

Conclusions: Significant variability in the management strategy resulting from thromboelastometry can be observed when the ROTEM® is located as point-of-care. Re-localization to the lab considerably reduces this variability. We recommend that within-patient variability of thromboelastometry be assessed in each institution to reduce variability in the management of these patients.

PB 1156 | Establishing of Therapeutic Range for Unfractionated Heparin Therapy: Activated Partial Thromboplastin Time vs. Anti-Xa Measurement

L. Zhang[1], P. Toulon[2], X. Zheng[3], J. Yang[1], Q. Fan[1], C. Liu[4], Z. Zhang[1]

[1]Wuhan Asia Heart Hospital, Wuhan University, Department of Clinical Laboratory and Pathology, Wuhan, China, [2]Université Nice Sophia Antipolis, Laboratoire d'Hématologie, Nice, France, [3]Wuhan Asia Heart Hospital, Wuhan University, Laboratory of Molecular Cardiology, Wuhan, China, [4]Wuhan Asia Heart Hospital, Wuhan University, Heart Center, Wuhan, China

Background: Activated partial thromboplastin time (aPTT) and anti-Xa activity are currently used to monitor unfractionated heparin (UFH) therapy. However, the aPTT heparin therapeutic range (HTR) is highly dependent on the reagent and analyzer used. So, it is recommended by Guidelines for each laboratory to define its own aPTT HTR using its technical conditions, to correlate with heparin levels between 0.30 and 0.70 IU/mL (anti-Xa).

Aims: To establish the aPTT HTR accordingly in a large cohort of inpatients receiving full dose of UFH, and to compare to the historical aPTT HTR at our institution (ratio=1.5 to 2.5 times the control).

Methods: We retrospectively reviewed the charts of inpatients aged over 18 years who were treated with continuous intravenous infusion of UFH for acute coronary syndrome, venous thromboembolism or other diseases, in Wuhan Asia Heart Hospital between 01/15 and 12/16. Both aPTT and anti-Xa assays were performed simultaneously using HemosIL APTT SynthASil and HemosIL Liquid Anti-Xa reagents respectively. The correlation between aPTT and anti-Xa was analyzed by linear regression, and HTR calculated by best data-fit equation.

Results: A total of 15,311 samples from 4,280 patients were included in our study. aPTT and anti-Xa showed the best data-fit in exponential linear regression analysis (R^2=0.65). The prolongation of aPTT, which corresponded to anti-Xa activity between 0.30 and 0.70 IU/mL, was between 51 and 91 seconds (ratio=1.6-2.9). Historical aPTT HTR between 1.5 and 2.5 times the control corresponded to lower anti-Xa activities between 0.25 and 0.60 IU/mL.

Conclusions: A strong correlation between aPTT and anti-Xa assays was observed in our laboratory. Historical aPTT HTR was lower than that calculated from the correlation curve with anti-Xa activity

between 0.30 and 0.70 IU/mL, further researches are needed to define the optimal HTR in clinical practice.

PB 1157 | Impact of Rivaroxaban and Dabigatran on Clotting Screens as Performed Using the Roche Cobas t 711 Analyser

A. Lowe[1], R. Jones[2], A. Stankiewicz[3], S. Kitchen[2]

[1]Sheffield Haemophilia and Thrombosis Centre, Sheffield, United Kingdom, [2]Sheffield Haemophilia and Thrombosis centre, Sheffield, United Kingdom, [3]Roche Diagnostics, Indianapolis, United States

Background: Direct Oral Anticoagulants (DOACs) including Rivaroxaban and Dabigatran can cause method specific prolongation of some clotting tests. The cobas t 711 analyser is a new platform likely to be used for analysis of samples from patients taking these drugs. Data on the impact of these drugs on clotting screens performed with this system are therefore needed to facilitate interpretation of such test results in the presence of DOACs.

Aims: To assess the impact of Rivaroxaban and Dabigatran on clotting screens performed using cobas t 711 analyser in comparison to a previously studied instrument/reagent system.

Methods: Pooled normal plasma was spiked with varying amounts of Rivaroxaban or Dabigatran to achieve 6 different concentrations in the range 0-1250 ng/ml. Prothrombin Time (PT) and Activated Partial Thromboplastin Time (APTT) were performed on all samples using 2 different methods, Roche cobas t 711 analyser/Roche reagents and Sysmex® CS5100/Siemens reagents. In addition, Clauss Fibrinogen (CFbg) and Thrombin Time (TT) were determined on samples containing Dabigatran.

Results: Results are shown in the table. PT and APTT were prolonged above baseline at >217ng/ml Dabigatran respectively for cobas t 711 analyser and for Sysmex® CS5100. Clauss fibrinogen was unaffected by Dabigatran for the concentrations studied. Thrombin times were unclottable in all samples containing Dabigatran. PT and APTT were prolonged above baseline at concentrations >249ng/ml Rivaroxaban respectively for cobas t 711 analyser and for Sysmex® CS5100.

Conclusions: There was a dose dependent prolongation of PT and APTT as determined using the cobas t 711 analyser by either Rivaroxaban or Dabigatran. The sensitivity of these tests to presence of drug was similar to that observed for a previously studied comparator method. Clauss fibrinogen was unaffected by Dabigatran up to 1250 ng/ml.

PB 1158 | Genotypic Characteristics of Polish Patients with Antithrombin, Protein C and Protein S Deficiency

E. Odnoczko[1], E. Stefanska-Windyga[1], A. Buczma[1], B. Baran[1], J. Oldenburg[2], A. Pavlova[2], V. Ivaskevicius[2], J. Windyga[1]

[1]Institute of Haematology and Transfusion Medicine, Warsaw, Poland, [2]University Clinic Bonn, Institute of Experimental Haematology and Transfusion Medicine, Bonn, Germany

Background: Diagnosis of congenital deficiency of antithrombin (AT), protein C (PC), protein S (PS) is hampered by various factors affecting determination of their plasma activity/antigen concentration. The only definite confirmation of congenital deficiency of these proteins is through identification of causative mutations in the encoding genes (*SERPINC1*, *PROC*, *PROS1*, respectively).

Aims: To identify the causative mutations in *SERPINC1*, *PROC1* and *PROS1* in patients with AT, PC or PS deficiency recognized in plasma studies.

Methods: The study comprised 106 Polish patients registered in the local database: 21 with reduced AT activity, 12 with reduced PC activity and 73 with reduced levels of free PS antigen. Patients with clinical and laboratory findings indicative of liver damage were not qualified. *SERPINC1*, *PROC1* and *PROS1* genes analyses were performed by Sanger sequencing of all coding regions and exon/intron splicing sites on ABI 3130XL Genetic Analyzer.

Results: Sequencing data outcome: 11 different mutations in the *SERPINC1* (3 as yet undescribed), 9 in *PROC* (2 not described), 12 in *PROS1* (7 not described). Causative mutations were detected in 44/106 (42%) studied cases, which confirmed the congenital defect in 17/21 (81%) with reduced AT (range 39-66 IU/dl; n.75-125IU/dl); in 10/12 (83%) with reduced PC (range 32-66 IU/dl; n.70-140IU/dl); in 17/73 (23%) with reduced PS (range 15-60 IU/dl; n.70-130 IU/dl). Free PS antigen plasma level (39.9±21.2 IU/dl) was lower in the group of 17/73 patients with identified mutations in the *PROS1* than in 56/73 patients (54.2±10.5 IU/dl) with undetected causative mutations in the *PROS1*.

TABLE 1 Effects of Dabigatran and Rivaroxaban on PT and APTT

	PT	PT	APTT	APTT		PT	PT	APTT	APTT
Dabigatran (ng/ml)	t711 PT Rec (Sec)	CS5100 Innovin (Sec)	T711 APTT L (Sec)	CS5100 AFS (Sec)	Rivaroxaban (ng/ml)	t711 PT Rec (Sec)	CS5100 Innovin (Sec)	T711 APTT L (Sec)	CS5100 AFS (Sec)
0	9.0	10.9	27.3	24.9	0	8.9	10.9	27.8	25.2
217	11.4	12.8	54.0	47.8	249	10.4	12.4	36.4	33.5
522	15.0	15.6	70.0	61.6	488	12.1	14.0	43.4	40.6
732	27.9	20.3	79.7	71.6	639	13.6	15.6	50.6	47.7
1080	31.6	32.3	99.4	83.2	1012	15.4	17.7	56.3	53.7
1248	40.3	44.5	90.1	89.8	1245	17.0	19.2	65.5	59.9

Conclusions: Despite relatively small populations of patients with AT and PC deficiency, we believe that the search for causative mutations in *SERPINC1* and *PROC* is justified even in those symptomatic patients with minimal reduction of AT or PC plasma activity. In contrast, the search for causative mutations in *PROS1* is justified only in patients with significantly reduced levels of free PS antigen.

PB 1159 | Assessment of Overall Coagulation and Fibrinolytic Activity in Hemophilia A Patients by Using Global Hemostatic Laboratory Methods: Overall Hemostasis Potential, aPTT-waveform Analysis and Endogenous Thrombin Potential

M. Milos[1], D. Coen Herak[1], S. Zupancic-Salek[2], J. Pavic[3], N. Mahmoud Hourani Soutari[4], J.P. Antovic[4], R. Zadro[1,5]

[1]University Hospital Centre Zagreb, Department of Laboratory Diagnostics, Zagreb, Croatia, [2]University Hospital Centre Zagreb, Department of Medicine, Zagreb, Croatia, [3]General County Hospital Livno, Department of Medical Biochemistry and Hematology Laboratory, Livno, Bosnia and Herzegovina, [4]Institute for Molecular Medicine and Surgery, Karolinska Institutet, & Department of Clinical Chemistry, Karolinska University Hospital, Department of Coagulation Research, Stockholm, Sweden, [5]Faculty of Pharmacy and Biochemistry, Zagreb, Croatia

Background: Measurement of FVIII activity allows diagnosis of hemophilia A and categorization of disease severity, but has poor correlation with clinical phenotype. New laboratory methods that assess global hemostasis have been developed, with intention to better diagnose and monitor hemophilia A patients.

Aims: To assess overall coagulation and fibrinolytic activity in hemophilia A patients using non-standard laboratory methods: overall hemostasis potential (OHP), aPTT-waveform analysis (aPTT-WA) and endogenous thrombin potential (ETP).

Methods: Total of 63 hemophilia A patients (30 severe and 33 non-severe) and 27 healthy male subjects as control group were tested. OHP method, based on repeated spectrophotometric registration of the fibrin-aggregation in plasma, after addition of small amounts of exogenous thrombin, tissue-type plasminogen activator and calcium, provides besides OHP parameter (area under the fibrin aggregation curve) 3 supplemetary parameters: overall coagulation potential (OCP), overall fibrinolytic potential (OFP) and clot lysis time (CLT). In-house aPTT-WA was performed on BCS with Actin FS (Siemens Healthcare Diagnostics, Germany), obtaining 3 quantitative waveform parameters from 2 different evaluation modes, drifting baseline (DB) and point of inflexion (PI): DELTA (aPTT-PI minus aPTT-DB), RATIO1 (aPTT-PI/aPTT-DB) and RATIO2 (DELTA/aPTT-DB). ETP method, setting C was performed on BCS-XP (Siemens), giving 4 parameters: area under the thrombin generation curve (AUC), peak thrombin concentration (Cmax), time to peak thrombin concentration (t-max) and time to signal beginning (t-lag).

Results: Obtained results revealed statistically significant difference ($P < 0.05$) for all parameters between analyzed groups, except for CLT between severe and non-severe group (Table 1).

Conclusions: Global assays can serve as a useful laboratory tool for assessing overall coagulation and fibrinolysis activity, providing at the same time additional information about hemophilia A patients.

PB 1160 | Thrombin Generation in Patients with Systemic Lupus Erythematosus (SLE)

N.K. Tóth[1], T. Tarr[2], P. Soltész[2], L. Muszbek[1], Z. Bagoly[1]

[1]University of Debrecen, Faculty of Medicine, Division of Clinical Laboratory Sciences, Debrecen, Hungary, [2]University of Debrecen, Faculty of Medicine, Department of Clinical Immunology, Debrecen, Hungary

Background: Patients with systemic lupus erythematosus (SLE) are subject to significant morbidity and mortality due to atherosclerotic diseases, which cannot be fully explained by traditional risk factors. Thrombin generation test (TGT) is a global hemostasis test providing information about the speed and amount of generated thrombin in plasma.

Aims: Our aim was to find out whether results of this test might differ in patients with SLE as compared to healthy individuals and to see

TABLE 1 Results of overall hemostasis potential, aPTT-waveform analysis and endogenous thrombin potential in analyzed groups of patients and controls

	Overall hemostasis potential				aPTT-waveform analysis			Endogenous thrombin potential	
	OHP	OCP	OFP %	CLT min	DELTA s	RATIO1	RATIO2	AUC mA	C-max mA/min

whether TGT parameters are associated with thrombotic episodes in SLE patients.

Methods: Forty-six patients with SLE not taking anticoagulants and 70 age and sex-matched healthy controls were enrolled. TGT was performed on platelet poor plasma and results were evaluated by the Thrombinoscope software. Lagtime, endogen thrombin potential (ETP), peak thrombin, time-to-peak and velocity index were calculated. Clinical parameters including age, sex, BMI, smoking habit, traditional risk factors, thrombotic history and disease activity were registered.

Results: In SLE patients lagtime and time-to-peak parameters were significantly elevated, while ETP was significantly reduced as compared to controls ($p< 0.0001$). TGT parameters showed significant positive correlation with BMI and CRP in patients and in controls, as well. The presence of lupus anticoagulant increased lagtime and time-to-peak parameters significantly, while the presence of anticardiolipin antibodies was associated with significantly lower ETP. SLE patients with history of thrombotic events had significantly higher ETP values, pregnancy morbidity was associated with elevated peak thrombin levels.

Conclusions: In patients with SLE, the extent of TG was significantly lower as compared to controls, which might be associated with the presence of antiphospholipid antibodies. The history of thrombosis or pregnancy morbidity was associated with increased TG, indicating that the test might be suitable for identifying those with elevated thrombotic risk in this patient population.

PB 1161 | Comparison of Three Different Anti-Xa Assays in Major Orthopedic Surgery Patients Treated with Edoxaban

H. Wada

Mie University School of Medicine, Molecular and Laboratory Medicine, Tsu, Japan

Background: The levels of anti-Xa drug cannot be monitored by routine assays; therefore, drug-specific anti-Xa assays use a chromogenic substrate to measure the concentration of anticoagulants that inhibit factor Xa in patients being treated with anti-Xa.

Aims: Measurement of edoxaban plasma concentration in major orthopedic surgery patients receiving edoxaban for the prevention of venous thromboembolism (VTE).

Methods: The anti-Xa activity was measured one hour after edoxaban intake using 3 different assays in 200 patients at three different time points Day 1, Day 4 and Day 8 after major orthopedic surgery.

Results: The anti-Xa activities on Day 8 were significantly higher than those on Day 4 and those on Day 4 were significantly higher than those on Day 1. The anti-Xa activities in assay A closely correlated with those in assay B, but the correlations between assays A and C and assays B and C were not close. The anti-Xa activities as detected in the three Xa assays were significantly higher in the patients without deep vein thrombosis (DVT) than in those with DVT on Day 4. Additionally, there were no significant differences in the anti-Xa activities of assays A, B and C between patients with and without MB on Days 1, 4, 8 and 15.

Conclusions: The three anti-Xa assay kits tested are appropriate for measuring edoxaban plasma concentration in orthopedic surgery patients. The results of this study additionally suggests that anti-Xa level could be predictive of the risk of VTE, but not of the risk of massive bleeding.

PB 1162 | Assessment of Two Chromogenic FVIII Assays In Haemophilia A Patients Infused with B-domain Truncated or Deleted Products: Results from a French Multicentric Study

Nuwiq (n=24/25)®	Mean(SD) IU/dL Bias (all/>30IU/dL)	41.4 (37.8)	58.8 (52.7) 17.5/29.7%	62.7 (55.1) 21.4/35.4%	60.2 (42.2)	71.2 (52) 11/16.7%	77.3 (50.7) 17.1/23.3%
All patients (n=71/71)	Bias		14%	18.8%		6.8%	13.2%
Normal samples (n=56/51)	Mean(SD) IU/dL	89 (24)	88 (24)	97 (24)	107 (21)	100 (23)	96 (19)

Background: The measurement of FVIII activity may be achieved using one-stage clotting (OSA) or chromogenic (CSA) assay. The latter is the reference method for the European Medicine Agency. Discrepant results using both methods in post-infusion samples have been widely reported, especially when B-domain deleted products are used.

Aims: The aim of this French multicentric study was to compare FVIII activity using OSA and CSA on post-infusion plasma samples from haemophilia patients treated by recombinant FVIII B-truncated or deleted products.

Methods: One hundred forty two samples originating from patients receiving ReFacto AF®(Pfizer, n=53), NovoEight® (NovoNordisk, n=40), Nuwiq®(Octapharma, n=49) were gathered by 10 centers, anonymized and randomly distributed to 4 centers for measurement of FVIII activity. OSA was determined using APTT reagent Siemens Actin® FS, CSA was determined using Siemens® Chromogenic FVIII (CSA-I) , and Biophen® FVIII, Hyphen BioMed (CSA-II) on Siemens BCS®XP (2), Sysmex® CS2100 (1), Sysmex®CS2500 (1). Samples from non-haemophiliacs were also tested in each center.

Results:]Based o the good interlaboratory agreement, results of FVIII activity were pooled according to Siemens BCS®XP or Sysmex®CS instrument. Calculation of the bias as difference between CSA and OSA level showed that discrepancies were lower on BCS®XP than on Sysmex®CS whatever the CSA reagent, and more pronounced on both instruments for FVIII levels higher than 30 IU/dL.

Conclusions: Discrepancies between CSA and OSA are confirmed but seem depend on the instrument and on the CSA reagent: they are less extended on BCS®XP with Siemens reagent while wider on Sysmex®CS instruments with Hyphen reagent. Differences between assays may be more acceptable in the Siemens configuration i.e instrument and OSA/CSA reagent.

PB 1163 | Effects of Interfering Substances on Factor Assays Performed Using Q Smart Analyser and DG-PT RecombiLIQ or DG-APTT Synth Reagents

A. Woolley, S. Kitchen

Sheffield Haemophilia and Thrombosis Centre, Sheffield, United Kingdom

Background: Guidelines for assay of clotting factors including FVIII consistently recommend analysis of patient samples using at least 3 dilutions of sample to improve both precision and accuracy of results. There are few publications describing the degree of agreement between the 3 results for different dilutions that might be expected in the presence and absence of interfering substances results that would be obtained. We decided to study this using Q Smart analyser which includes assay protocols for analysis of multiple test sample dilutions.

Aims: To assess the effects of interfering substances on intrinsic and extrinsic clotting factor assays.

TABLE 1 Effects of DOACs on FVIII assay results

Patient/Group		FVIII on 1 dilution	FVIII :Mean of 3 dilutions	CV of FVIII results on 3 dilutions	r value for 3 dilutions
Hospital patients	mean of 21 cases	190 IU/dL	183 IU/dL	7% (range 2- 18%)	0.998 (0.994-1.0)
patients with deficiency of FVIII,FIX or FV	mean of 10 cases with different defects	78 IU/dL	73 IU/dL	8% (range 4-19%)	0.998 (0.993-1.0)
Normal plasma	before addition of apixaban	77 IU/dL	76 IU/dL	3%	0.999
same plasma as above with Apixaban added	Apixaban 164 ng/ml	34 IU/dL	48 IU/dL	29%	0.998
Normal plasma	before addition of dabigatran	53 IU/dL	60 IU/dL	11%	0.995
same plasma as above with Dabigatran added	Dabigatran 155 ng/ml	13 IU/dL	21 IU/dL	40%	0.986
Normal plasma	before rivaroxaban added	63 IU/dL	67 IU/dL	7%	1.000
Same plasma as above with Rivaroxaban added	Rivaroxaban 121 ng/ml	26 IU/dL	34 IU/dL	23%	0.988

TABLE 2 Effects of some interfering substances on FVIII assay results

Sample	Relevant test results	FVIII on 1 dilution	FVIII:mean of 3 dilutions	CV of FVIII results on 3 dilutions	r value for 3 dilutions
Lupus anticoagulant	DRVVT >5.0	42 IU/dL	55 IU/dL	20%	0.965
Patient on heparin	Anti Xa- 1.7 IU/ml	23 IU/dL	66 IU/dL	66%	0.5
Patient on Heparin	Anti Xa- 0.87 IU/ml	25 IU/dl	58 IU/dL	55%	0.465
FVIII inhibitor	>120 BU/ml	6 IU/dL	9 IU/dL	29%	0.996

Methods: Factor VIII, FIX and FV assays were performed on 21 samples from hospital cases; 10 subjects with isolated deficiency of either FVIII, FIX or FV; Lupus anticoagulant (n=10); patients on unfractionated heparin therapy (n=10); patients with FVIII inhibitors; and normal plasma before and after addition of apixaban, dabigatran or rivaroxaban. FVIII, FIX and FV assays were performed using 1 or 3 test dilutions using DG-PT RecombiLIQ (liquid human thromboplastin) for FV or DG-APTT Synth (ellagic acid/synthetic phospholipids) for FVIII and FIX in combination with the Q Smart analyser (Diagnostic Grifols) which determines the r value for the line through test sample dilutions and the CV of results on the 3 dilutions.

Results: Factor VIII results of selected cases are shown in tables below. For FIX and FV assays in hospital patients all r values were > 0.994 and the mean and range of CVs for results on 3 different dilutions were 4.7 % (1-11%) and 7.6% (2-16%).

Conclusions: Unfractionated heparin, apixaban, rivaroxaban, dabigatran and lupus anticoagulant can all interfere in factor assays confirming the importance of testing multiple test sample dilutions for accurate results. When 3 dilutions are analysed using the Q Smart analyser protocols a CV of 20% or more for the 3 results indicates that results are inaccurate at some test sample dilutions.

PB 1164 | Comparison of Point-of-Care Instruments I-STAT, ACTPlus and Hemochron Signature Plus for Measurement of Activated Clotting Time (ACT)

S. Vandendriessche, H. Laverge, K. Devreese

University Hospital Ghent, Clinical Biology, Ghent, Belgium

Background: Activated clotting time (ACT) point-of-care testing is frequently used to monitor high-dose heparin therapy.

Aims: We evaluated the performance characteristics of I-STAT (Abott), ACTPlus (Medtronic) and Hemochron Signature Plus (Archiva Diagnostics) point-of care instruments for ACT measurement.

Methods: Three ACTPlus, two I-Stat and two Hemochron Signature Plus were validated. Within-run and between-run imprecision was determined using quality controls of normal (low) and abnormal (high) range. For ACTPlus, intra-assay reproducibility was determined by comparing duplicate channel results for blood samples per instrument, whereas for I-STAT and Hemochron measurements of the same sample performed in parallel on two instruments were evaluated (duplicate measurements). Instruments were compared per type by evaluating measurements simultaneously performed on all instruments (parallel measurements). Acceptance criteria for duplicate (intra-assay) and parallel (inter-assay) measurement were set as < 12% spread error. Linearity (0 - 5IU/ml heparin) in spiked blood samples was evaluated.

Results: Detailed results are displayed in Table 1. Overall, all instrument types performed equally when using normal and high range quality control materials. However, when using real blood samples, I-STAT performed better than Hemochron Plus, which in turn performed better than ACTPlus. On ACTPlus, a significant proportion of duplicate and parallel measurements of real blood samples did not fulfill the acceptance criteria. Linearity was good on all instrument types. Heparin concentrations gave comparable ACT-values on all instruments types in the low range, but values differed in the high range.

Conclusions: This study illustrates that correct evaluation of point-of-care ACT-instruments should not be limited to quality control material, but should also include real blood samples. Overall, I-STAT performed better than Hemochron Signature Plus and ACTPlus.

PB 1165 | Extracellular Proteases of Micromicetes as New Agents for Protein C, Factor X and Plasma Prekallikrein Diagnostics

A.A. Osmolovskiy, A.V. Orechova , E.S. Zvonareva , V.G. Kreyer , N.A. Baranova , N.S. Egorov

Lomonosov Moscow State University, Biology, Moscow, Russian Federation

Background: Many patients deficient in such hemostatic factors as protein C, factor X and prekallikrein have been described and have an associated thrombotic tendency. Some snake venom proteases are

TABLE 1 Comparison of I-STAT, ACTPlus and Hemochron Signature Plus for measurement of ACT

	ACTPlus 1	ACTPlus 2	ACTPlus 3	I-Stat 1	I-Stat 2	Hemochron 1	Hemochron 2
QC - CV% low range (within-run)	2.2	6.7	2.4	1.9	1.5	4.1	7.2
QC - CV% high range (within-run)	3.0	4.9	3.5	2.2	3.0	1.3	2.0
QC - CV% low range (between-run)	4.0	3.2	8.6	1.8	1.8	8.1	12.5
QC - CV% high range (between-run)	5.6	8.3	10.2	3.2	4.9	1.5	3.2
Blood - duplicate samples (intra-assay reproducibility)							
Measurements that fulfill <12% criteria	7/17	11/17	12/17	30/30		27/30	
Blood - parallel samples (inter-assay reproducibility)							
Measurements that fulfill <12% criteria	12/34	10/34	16/34	30/30		27/30	
Linearity (correlation coefficient)	0.9823			0.9639		0.9409	

used in diagnostics of them. At this time, there are some fungal proteases with activator activity to protein C, factor X and prekallikrein produced by *Aspergillus ochraceus* and *Aspergillus terreus*.

Aims: Study of applicability of proteases of *A. ochraceus* and *A. terreus* for protein C, factor X and prekallikrein determination.

Methods: Proteases were obtained from cultural fluids by FPLC. Activity was studied with the chromogenic peptide substrates after preincubation of proteases with human plasma.

Results: It was demonstrated the same results with specific activity proteinases of *A. ochraceus* with commercial diagnostic preparations Protac® (protein C activator from venom of South American copperhead) and RVV-X® (factor X activator from venom of Russell's viper). Similar experiments were conducted in the presence of factor X deficient plasma and protein C deficient plasma. It was found that concentration of protein C is identical with Protac® (32,7% ± 5%) diagnostic system and specific activity proteinases of *A. ochraceus* (31,5% ± 5%). Uniform diagnostics interval was detected with RVV-X® diagnostic system (36,6% ± 4%) and proteinases of *A. ochraceus* (37,4% ± 4%). *A. ochraceus* protease did not show any activator activity with human plasma, deficient by prothrombin complex factors and plasma deficient by prothrombin complex factors and by contact phase of coagulation factors. *A. terreus* protease retained activator activities with chromogenic substrates of protein C and factor Xa with both of these deficient plasmas. Activity of the *A. terreus* with kallikrein chromogenic substrate showed after preincubation with both plasmas is not reduced.

Conclusions: Proteases of *A. ochraceus* are very perspective for protein C and X factor diagnostics and proteases of *A. terreus* may be useful for prekallikrein determination.

PB 1166 | Laboratory Expert System in the Field of Hemostasis and Thrombosis: A Pilot Project for the Diagnosis of von Willebrand Disease

H. Seidel[1], B. Pötzsch[2], U. Budde[3], R. Dittmer[3], S. Schneppenheim[3], D. Peetz[4], P. Lodemann[4], M. Hägele[5], M.-O. Link[5], M. Takla[5], R. Groh[5], W.A. Scherbaum[6], F. Strasding[7], P. Westhofen[1], J.P. Kruppenbacher[1]

[1]*Centrum für Blutgerinnungsstörungen und Transfusionsmedizin, Bonn, Germany,* [2]*Institute for Experimental Haematology and Transfusion Medicine, University Clinic Bonn, Bonn, Germany,* [3]*Asklepios MVZ Nord GmbH, Haemostaseology, Hamburg, Germany,* [4]*Helios Klinikum Berlin-Buch, Institut für Labormedizin, Berlin-Buch, Germany,* [5]*Qonsilus GmbH, Mainz, Germany,* [6]*Heinrich-Heine-University, University Hospital, Düsseldorf, Germany,* [7]*Ludwig-Maximilians-University, Medizinische Klinik und Poliklinik IV, München, Germany*

Background: A laboratory expert system (LES) in the field of ‚gynecological endocrinology' was recently developed by the Qonsilus company, Germany. The software supports medical doctors in their decision-making process by linking sets of laboratory analyses with data from medical history, signs and symptoms in order to provide individual treatment recommendations. In the field of hemostasis and thrombosis the major parameters in clinical chemistry comprise alterations of hemostatic parameters as well as clinical parameters and specific risk factors.

Aims: The present pilot project aimed to extend the above mentioned LES to the field of ‚hemostasis and thrombosis', specifically to the diagnosis of von Willebrand disease (VWD).

Methods: An iterative process was used to digitize medical expert knowledge into actionable rules with a continuous review of patient cases. Each finding of a knowledge model evaluation had a certainty factor that represents the scoring value reached. Evaluation of the knowledge model was performed by comparing the diagnostic accuracy in 79 patients with suspected or confirmed VWD, with the diagnosis either made by LES or by an expert in the field (EIF).

Results: In 61 (77%) cases we found no differences in the diagnosis assessed by LES versus EIF and 73 (92%) cases evaluated by two different EIF, respectively. Among the deviations there were 6 (8%) non-relevant, 9 (11%) relevant and 3 (4%) critical cases for the evaluation by LES versus EIF and 1 (1%), 3 (4%) and 2 (3%) for EIF versus EIF, respectively.

Conclusions: The automated LES here described may be a promising useful tool for the diagnostic workup of a non-expert in the field of VWD. However, clinical data are essential for detailed diagnostic and therapeutic recommendations. At this stage LES cannot substitute the EIF of hemostasis, but may support the non-specialist to come closer to the diagnosis.

PB 1167 | A New and Improved Euglobulin Clot Lysis Time Assay (iECLT)

A. Ilich[1,2], N. Key[1]

[1]*University of North Carolina at Chapel Hill, Department of Medicine, Division of Hematology/Oncology, Chapel Hill, United States,* [2]*First Moscow State Medical University n.a. I. M. Sechenov, Department of Medicine, Division of Internal Medicine 1, Moscow, Russian Federation*

TABLE 1 a) Correlations of iECLT with fibrinolysis proteins in PFP and EF. b) Concentration reduction in the EF compared to PFP

a) CORRELATION WITH iECLT									
	PAI1		tPA		α2antiplasmin		α2macroglobulin		Plasminogen
	PFP	EF	PFP	EF	PFP	EF	PFP	EF	PFP ___ EF
n	17	17	16	16	16	15	15	15	15 _____ 15
Spearman r	0.82	0.72	0.15	-0.68	0.11	0.56	-0.11	-0.03	0.3 ___ 0.29
p value(two-tailed)	0.0001	0.0016	0.58	0.0047	0.68	0.026	0.69	0.90	0.27 ___ 0.3
b) REDUCTION IN EF									
(%, mean±SEM)	97.84±1.24		12.79±29.64		95.25±0.75		99.82±0.06		28.39±3.89

Background: Alterations in balance between coagulation and fibrinolysis may lead to thrombosis or bleeding. Many methods have been proposed for fibrinolytic activity measurement, however the majority have used tPA to initiate fibrinolysis. To assess endogenous fibrinolysis, an assay without tPA addition is desirable. Utilization of the plasma euglobulin fraction (EF) could be a solution. The EF contains significantly reduced amounts of PAI-1 with relatively preserved levels of tPA. This allows intrinsic fibrinolytic activity to be measured without addition of tPA. The original ECLT described 6 decades ago is rarely used now, due to high variability of results and low throughput. We propose a modified ECLT with spectrophotometric readout to address some of these limitations.

Aims: Characterize the iECLT.

Methods: Citrated platelet free plasma (PFP) from 42 healthy individuals was collected after obtaining informed consent.

A] In the iECLT assay, EF was mixed with fibrinogen, ovalbumin and clotted with thrombin. OD changes were read spectrophotometrically for 25 hours. The time needed for half lysis of the clot was measured.

B] ELISA - free PAI-1, free t-PA, plasminogen, α2macroglobulin (α2MG) and α2antiplasmin (α2AP).

Results: iECLT values showed a non-parametric bimodal distribution, with normal range from 11.06 to 21.56 hours. iECLT intra-assay and inter-assay variabilities were 2.45% and 9.85%, respectively.

A strong correlation was found between iECLT and PAI-1 (both in PFP and EF), tPA (in EF) and α2AP (in EF) (Table 1a).

In addition, we have confirmed that levels of endogenous inhibitors are significantly reduced, while activators are partially preserved in EF (Table 1b).

Conclusions: iECLT allows global analysis of fibrinolysis without addition of exogenous plasminogen activators. iECLT has low variability of results and high throughput, compared with the original ECLT.

PB 1168 | Platelet Estimation from Peripheral Blood Smear: Does it Really Works?

I. Bachiri, Z.Yahiaoui , N.Fenni

Algiers University, Algiers, Algeria

Background: Assessment of platelet count is an important diagnostic parameter in haematology. Platelet counts can be done manually or with an automated analyzer. Counts can also be estimated during blood smear examination.

Aims: The objective of our study is to compare 03 manual methods using peripheral blood smear with the automatic method and to determine their effectiveness in the estimation of platelet count.

Methods: Blood samples were obtained from 220 patients.

Automated method : Sysmex XT4000i

Manual methods :

1st methode : blood smears were stained and examined under light microscopy. The red cell: platelet ratio was calculated : The number of erythrocytes observed in a quarter of the oil-immersion field was multiplied by four. Then all the platelets in the same field were counted. Other fields were examined until we reached a number of 1000 erythrocytes. The number of platelets per 1000 erythrocytes was multiplied by the automated Red Blood Count to give an approximate count.

2nd method :we counted the numbers of platelets per 10 oil immersion fields and divided by 10 to find the average number of platelets per field and then multiply by 14 (field factor)

3rd method: we multiply the average number of platelets per 10 fields by the patient's hemoglobin and then by 1,000 mm3 to obtain the number of platelets/mm3.

Results: The results showed positive correlation between the fours methods .The ICC was calculated in order to identify the reliability of the manual techniques in comparison to the automated method. In our study, the ICC was equal to 0.946 ,0.937 ,0.888 for method 1, 2 and 3 respectively. The paired t-test showed no significant difference between the four methods ($p>0.05$).

Conclusions: We conclude there is a no difference between the automatic method and the manual methods.The results of our study proove that manual estimation is a reliable method and can be used in rural areas where automatic methods are not available and when there is discordance between clinical and biological results.

PB 1169 | Comparison of Rotational Thromboelastometry Reference Ranges with Normative Ranges across Trimesters in Pregnancy

A.A. Shamshirsaz[1], K.A. Fox[1], H. Erfani[1], K. Brudozski[2], V. Kostousov[2], H. Rocky[2], J. Teruya[2]

[1]Baylor College of Medicine/Texas Childrens Hospital, Obstetrics and Gynecology, Houston, United States, [2]Baylor College of Medicine/Texas Childrens Hospital, Pathology, Houston, United States

Background: In pregnancy and postpartum, women exhibit hypercoagulability and physiologic changes of coagulation factors Rotational thromboelastometry (ROTEM) is increasingly used as a point of care coagulation monitoring device in patients with massive haemorrhage; however, there are limited data on reference ranges in pregnancy across different gestational age.

Aims: We hypothesized that normative ranges of rotational thromboelastometry (ROTEM) may differ across trimesters of pregnancy and differ in compare to the non-pregnant values recommended by the manufacture.

Methods: After IRB approval, citrated blood was collected from 72 healthy pregnant women and grouped by trimester: 1st (11±3 weeks gestation, n= 20), 2nd (21±5, n=23), and 3rd (33+3, n= 29). EXTEM, INTEM, and FIBTEM were performed on ROTEM (IL, USA) to establish reference ranges. Reference ranges defined by the 5th and 95th percentiles, and were compared to the manufacturer's recommended ranges. ANOVA with Tukey test were used (SPSS v23, 2016, IBM, USA; significance = $P < 0.05$).

Results: After excluding outliers, only maximum lysis (ML) in INTEM, EXTEM, and FIBTEM differed significantly across trimesters (Table 1)

TABLE 1 Maximum Lysis (ML) difference across the trimesters

Table-1	1st trimester, range	2nd trimester, range	3rd trimester, range
ML INTEM	3-16%	3-18%	2-9%
ML EXTEM	3-16%	2-16%	3-11%
ML FIBTEM	0-16%	0-4%	0-2%

Our population reference ranges overlap with those from the manufacturer, however all variables showed a narrower range in pregnancy, especially in 3rd trimester. (Table 2).

TABLE 2 reference ranges in different trimester and comparing to reference ranges provided by manufacture

Table-2	Manufacture	1st trimester	2nd trimester	3rd trimester
INTEM CT(sec)	122-208	176-187	169-183	163-177
INTEM CFT(sec)	44-110	62-73	62-72	61-69
INTEM MCF(mm)	51-71	64-68	64-68	67-71
EXTEM CT(sec)	43-82	58-65	56-59	53-59
EXTEM CFT(sec)	48-127	63-74	64-73	59-70
EXTEM MCF(mm)	52-70	67-70	67-70	69-72
FIBTEM MCF(mm)	7-24	21-25	21-25	24-28

Conclusions: Majority of ROTEM reference ranges remain similar across pregnancy, with the exception of ML. Normal ranges in all trimesters are significantly narrower than those suggested by the manufacturer. Upper limits of CT and CFT are significantly shorter, consistent with physiologic hypercoagulability. Use of pregnancy and trimester-specific ranges may prevent clinical over- or underestimation of function of coagulation function.

PB 1170 | Enhanced Coagulation Decreases Probability of Positive Outcome during in vitro Fertilization

A. Balandina[1,2], E. Koltsova[1], T. Teterina[3], A. Yakovenko[3], E. Simonenko[4], A. Poletaev[1], I. Zorina[3], S. Yakovenko[4], F. Ataullakhanov[1,2,4]

[1]*Dmitry Rogachev National Research and Clinical Center of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation,* [2]*Center for Theoretical Problems of Physicochemical Pharmacology RAS, Moscow, Russian Federation,* [3]*"AltraVita" IVF Clinic, Moscow, Russian Federation,* [4]*Lomonosov Moscow State University, Biophysics Department, Moscow, Russian Federation*

Background: Infertility in women is often accompanied with hypercoagulable state such as thrombophilia, antiphospholipid syndrome and etc. In vitro fertilization (IVF), which is widely used for infertile women, increases the coagulation potential futher due to controlled ovarian stimulation (COS).

Aims: To investigate the coagulation system state with standard assays (clotting times, fibrinogen and D-dimers levels) and global coagulation assay (thrombodynamics) in women with infertility prior to the IVF cycle and during the treatment to reveal the association between coagulation imbalance and outcome of the IVF procedure.

Methods: A total of 114 patients undergone fresh IVF cycles were included in the prospective cohort study. All gave their written informed consent. Blood samples for monitoring of coagulation were collected before IVF, one week after COS starting, on the day of follicles puncture, on the day of embryo transfer and one week after embryo transfer. The main outcome was clinical pregnancy rate.

Results: In total, 28 women (24.6%) became pregnant after IVF. Women with higher platelet count (>260x10^9/L) and higher clot growth rate (>29.9 μm/min, detected with thrombodynamics) before IVF demonstrated a higher percentage of unsuccessful IVF outcomes (odds ratio (OR) 5.98, 95% confidence interval (CI) 1.64-21.73, p=0.007 and OR 4.47, 95% CI 0.98-20.38, p=0.053, respectively). Clotting times, fibrinogen and D-dimers levels before and during IVF did not differ significantly between groups with successful/unsuccessful outcomes. Hemostasis assays demonstrated shift towards hypercoagulation in response to COS with subsequent normalization in response to low molecular weight heparin prophylaxis after the embryo transfer.

Conclusions: High platelets level and hypercoagulation detected with thrombodynamics in infertile women independently predict higher risk of unsuccessful IVF outcomes. The results of current research may be of relevance in counseling and monitoring women undergoing IVF.

PB 1171 | Development and Implementation of a Coagulation Factor Testing Method Utilizing Autoverification in a High Volume Clinical Reference Laboratory Environment

P. Riley[1], A. Valcour[2], B. Gallea[3]

[1]*Diagnostica Stago, Parsippany, United States,* [2]*Laboratory Corporation of America Holdings, Center for Esoteric Testing (CET), Burlington, United States,* [3]*Diagnostica Stago SAS, Asnières-sur-Seine, France*

Background: Testing coagulation factor activities requires that multiple dilutions be assayed and analyzed to produce a single result. The slope of the line created by plotting measured factor concentration against sample dilution is evaluated to discern the presence of inhibitors giving rise to nonparallelism. Moreover, samples that produce results on initial dilution that fall outside the analytic measurement range of the assay must be tested at additional dilutions to produce reportable results.

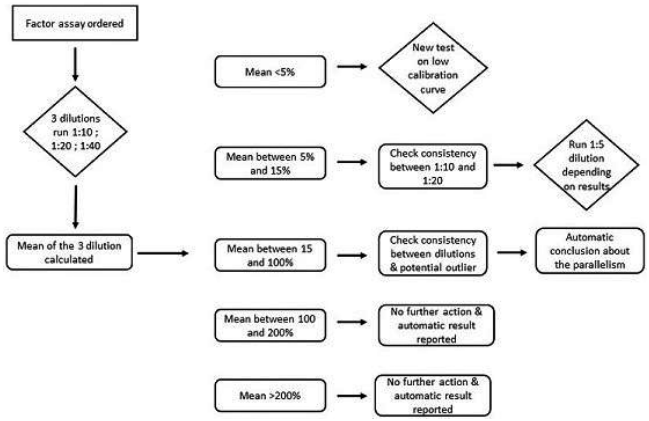

FIGURE 1 Factor Testing Expert Rules Flow Chart

Aims: The complexity of the coagulation factor testing process motivated a large clinical reference laboratory to develop advanced computer algorithms with automated reflex testing rules to complete coagulation factor analysis.

Methods: Prospective validation of the expert rules was accomplished using 552 different anonymized FVIII deficient plasma samples each tested at 1:10, 1:20, and 1:40 dilutions giving a total of 1,656 individual results on an automated coagulation analyzer using the using the STA Coag Expert data manager system (Diagnostica Stago Inc., Parsippany, NJ).

Results: The testing cascade and rules for factor activity assays programmed into the STA Coag Expert data manager are displayed in the figure included. Starting from the top left point of the flow chart, where the test is ordered through the LIS (Factor assay ordered); initial testing at three different dilutions (1:10, 1:20 and 1:40) is performed. The mean of these three dilutions is used to determine the next step, followed by subsequent steps as shown.

Conclusions: Expert rules utilizing autoverification procedures can be applied on the instrument, in the data manager software, or in the LIS. When properly implemented, the expert rules can

1) handle the mundane and error prone task of result verification, allowing medical technologists to focus on the true problem samples,

2) improve the consistency in the quality of test results, and

3) reduce staff fatigue, improving the work environment in the process.

PB 1172 | Factors VII and VIII Assays: Analytical Performance and Reference Ranges for Argentinian Population

R. Raimondi, V. Monserrat, S. Aguirre, L. Herrera, S. Pons, A. Grinspon, A. Scazziota

Universidad de Buenos Aires. Facultad de Farmacia y Bioquimica, Bioquímica Clinica, Buenos Aires, Argentina

Background: Laboratory scientists are responsible for providing both accurate and precise test results as well as valid reference intervals (RI) in order to allow clinicians to differentiate between health and disease to properly manage patients.

Aims: To verify the analytical performance of one stage determination of Factor VII (FVII) and Factor VIII (FVIII) and to determine the RI for local population.

Methods: FVII and FVIII activity were determined on a STA®-Compact Max analyzer using STA® Deficient FVII and FVIII. Precision and trueness were determined with the CLSI EP15-A3 Protocol with STA®-System Control N+P. Linearity was determined using CLSI EP6-A protocol with serial dilutions of a patient sample, covering the working range of products (15-150% for FVII and 5-150% for FVIII). RI was determined with 65 blood donors plasma (ages between 24 and 64). Informed consent was obtained prior to blood being drawn. Outliers were eliminated using Tukey´s method.

Results: Precision was evaluated at normal (N) and Patological (P) levels: intra-assay coefficient of variation (CV) was 4.42% (N) and 3.95% (P) for FVII; 4.17% (N) and 5.20% (P) for FVIII. Inter-assay CV was 5.79% (N) and 5.93% (P) for FVII; 6.60% (N) and 9.87% (P) for FVIII. With respect to trueness, FVII average was 95.5% (77.5-104.5) and 44.7% (37-49); FVIII average 101.1% (82.4-115.6) and 49.4% (34.4-57.6) for N and P respectively. Both factors showed a Gaussian distribution and proved to be linear in the working range. The RI for FVII was 51 % (43-60) to 142% (134-150) and 67% (54-80) to 206 % (193-218) for FVIII. FVIII was 18% lower in O blood carriers compared with non O blood group.

Conclusions: The performance for measuring both factors showed accuracy and trueness according to manufacter‘s report. The RI obtained in our laboratory was quite different from the manufacture‘s information, so it´s important to establish local RI to better classify the patients at risk of bleeding or thrombosis.

PB 1173 | Can Thromboelastography Accurately Assess Coagulation in Anemic Patients?

A.A. Kuperman[1,2], E. Shaoul[3], R. Pollack[3], A. Braester[3,4]

[1]Galilee Medical Center, Blood Coagulation Service and Pediatric Hematology, Naharia, Israel, [2]Bar-Ilan University, Faculty of Medicine in the Galilee, Safed, Israel, [3]Galilee Medical Center, Hematology, Naharia, Israel, [4]Bar Ilan University, Faculty of Medicine in the Galilee, Safed, Israel

Background: Thromelastography (TEG) is a method performed on whole blood, examining the physical properties of blood clots. TEG is often performed in bleeding patients so it is essentially important to examine its significance when hematocrit (Hct) decreases.

Aims: Assessing the effect of ex-vivo Hct reduction (by erythrocyte removal) on TEG parameters in healthy volunteers.

Methods: Fifty one healthy volunteers aged 18-50 years, were studied. Blood drawn into EDTA tube served as a baseline measure. Four citrate tubes were used for measuring TEG, PT, PTT and derived fibrinogen. Two of the citrate tubes retained Hct of 35-55%, and served as reference. The other tubes were used to produce a variable Hct around 20-25% by removal of red blood cells pellet. Two methods of TEG were used: citrate kaolin TEG on all 51 blood samples, and FFR (functional fibrinogen reagent) TEG used to determine the functional

fibrinogen contribution on the TEG MA (maximal amplitude) of 38 blood samples.

Results: Using the citrate kaolin TEG, there was a significant elevation of MA correlated with Hct reduction (Pearson correlation, R = -0.551, p< 0.001, n=51), which may imply a pattern of hypercoagulation. Using the FFR TEG there was a statistically significant correlation between Hct reduction and elevation of functional fibrinogen levels (Spearman correlation, R = -0.390, p=0.016, n=38), indicating its contribution to the MA changes. Fibrinogen levels measured in all tubes were not significantly changed by Hct reduction. The changes in platelet numbers were in all cases in normal range, and no statistical correlation was found between platelets number changes and the Hct changes (Spearman correlation, R = 0.027, p=0.850, n=51).

Conclusions:

1. Ex-vivo reduction of Hct is strongly associated with MA elevation.
2. The high MA is explained by elevation of functional fibrinogen levels.
3. It is not clear whether these findings reflect physiology or an artifact of the method, and further in-vivo studies are needed.

PB 1174 | Standardization of a Cytometry Test to Measure the von Willebrand Factor Collagen Binding Activity

L. Maira Moura de Oliveira, M.V. de Almeida Amorim, D. Gonçalves Chaves

Fundação Hemominas, Belo Horizonte, Brazil

Background: von Willebrand disease (VWD) is the most common inherited bleeding disorder characterized by von Willebrand factor (VWF) deficiency. Diagnoses of different types and subtypes of the disease require expensive tests based on immune and functional assays.

Aims: This study aimed to standardize a cytometry test to measure the VWF binding to collagen.

Methods: Plasma samples from VWD patients (n=27) were tested for collagen binding assay using a commercial vWF:CBA ELISA kit. A cytometry assay based on collagen-coated beads was developed and all samples were tested. Median Fluorescence Intensity (MFI) obtained in cytometry for tested samples was transformed in percentage based on normal control MFI. Pooled plasma collected from six healthy blood donors constituted the normal control. Spearman test was used to compare the results of the two tests. ROC curve analysis was generated to test to define a cut-off point (distinction between low and normal binding to collagen) for cytometry assay. This study was approved by Brazilian ethics committees and patients signed an informed consent.

Results: Collected samples presented a wide range of results in vWF:CBA kit (median of 0.34 U/mL; range of 0.01-0.89 U/mL; normal range: 0.4-2.5 U/mL). Results from cytometry test also presented a wide range of results (median of 59.8%; range of 17.1-99.4%). Spearman test revealed a strong correlation between the two tests (r=0.93; p< 0.01; 95% CI 0.85-0.97). The ROC curve defined (AUC=0.97; 95% CI 0.92-1.02; p< 0.01) identified 59.2% as the best cut-off point for cytometry test (sensitivity=0.92, 95% CI 0.64-0.99; specificity=0.86, 95% CI 0.57-0.98).

Conclusions: We initiate to standardize a low cost method based on flow cytometry that can be useful in VWD treatment centers. This is an ongoing study and additional molecular defects and clinical aspects will be reported upon completion of the work. Financial support: FAPEMIG and HEMOMINAS.

PB 1175 | Implementing Autoverification of Coagulation Screen Tests in Universitary Hospital Laboratory in Brazil

M.L. Pereira Gonçalves, P. Orlandi Mourão

Universidade Federal de Minas Gerais, Propedeutica Complementar/Hematology, Belo Horizonte, Brazil

Background: Autoverification (AV) has been widely used on clinical laboratories. However, few studies related to AV of coagulation tests (CT) were published.

Aims: Implementing AV of coagulation screen tests: prothrombin time (PT), activated partial thromboplastin time (aPTT), fribrinogen (FIB) aiming: reduce turnaround time (TAT) and technician intervention, report more than 80,0% of CT in an interval shorter than 2 hours (general laboratory goal).

Methods:

1) Definition AV limits: Were calculated using percentile 90 from CT between 2011 and 2015. Intervals defined: for PT: 10,5 - 31,5 seconds; aPTT: 23,0 - 45,0 sec; FIB: 1,15 - 6,00 g/L.

2)Delta check (DC) calculation: From coefficient of variation analytical (CVa) and coefficient of variation individual (CVi, biological variation), using the Reference Change Values formula :

RCV=2(1/2) x Z x(CV(A)(2) +CV(I)(2))(1/2), where Z is the number of standard deviations appropriate to the probability. In our study, Z= 2, 58 (corresponding 99,0%). DC PT:18.9% (35 days); DC aPTT: 12.6% (1 day); DC FIB: 47.0% (1 day).

3) Evaluation ofTAT 3 months before (25.933 tests) and after (25.066 tests) AV implementation, using Wilcoxon test.

Results:

1) TAT reduction: PT (median before and after AV: 114 to 50 minutes, p< 0,001), aPTT (median before and after AV: 111 to 49 minutes, p< 0,001), FIB (median before and after AV: 101 to 44 minutes, p< 0,001).

2) Passing rate results < 2 hours before and after AV (median, 95% CI):PT= 53,0% (52,2-53,8%) to 91,0% (90,5-91,5%); aPTT= 54,9% (54,0- 55,9%) to 92,0% (91,4- 94,6%); FIB= 60,9% (56,8- 64,9%) to 92,7% (90,1- 94,6%).

Conclusions:

1) The general **turnaround time** of coagulation screen tests was shortened by 56,0% (109 minutes to 48 minutes).

2) Incorrect results were not reported by clinicians neither laboratory supervisors, since autoverification implementation.

3) Our laboratory reached passing rate >90,0% of coagulation screen tests in less than 2 hours.

PB 1176 | Assessment of a Pre-analytical Check System on ACL TOP 750 CTS®

K. Kanouchi[1], T. Sakata[2], Y. Takahama[1], R. Ohta[1], M. Sato[1], A. Suzuki[1], K. Morikane[1]

[1]Yamagata University Hospital, Laboratory Center for Clinical Investigation, Yamagata, Japan, [2]IL Japan Co., Ltd., Coagulaton Scientific Support, Minato-ku, Japan

Background: ISO15189 requires us to indicate in the report whether the quality of the primary sample is unsuitable for examination or not. ACL TOP 750 CTS® has a pre-analytical check system that detects incorrect tube filling volumes and clog-clot, and identifies optical interferences (Hemoglobin, Icterus, Lipemia ; HIL) by means of a new multi-wavelength module.

Aims: We assessed the pre-analytical check system on the detection accuracy of ACL TOP 750 CTS® (Instrumentation laboratory, Bedford, MA, USA) by comparing with visual inspection.

Methods: We measured general coagulation parameters including PT, APTT, fibrinogen, antithrombin, FDP, and D-dimer on ACL TOP 750 CTS® in 2,360 blood samples collected in the Yamagata University Hospital from June to July 2016. Then we compared the prevalence of rejection between ACL TOP 750 CTS® and visual inspection.

Results: Seventeen of 2,360 samples were rejected on ACL TOP 750 CTS® by the reason of HIL, incorrect tube filling volumes, or clog-clot (Table 1). Eleven of these 17 samples were not rejected in visual inspection, even if they should have been rejected as they consisted of 8 incorrectly filled tubes and 3 samples with clots. There was no significant difference in the incidence of rejection between the two groups (0.72% vs 0.64%, *P*= 0.86). In the analysis using only HIL, the prevalence of rejection in visual inspection was significantly higher than that in ACL TOP 750 CTS® (0.47% vs 0.09%, *P*= 0.02).

Conclusions: We compared the prevalence of rejection in the ACL TOP 750 CTS® with visual inspection to assess the pre-analytical check system on ACL TOP 750 CTS®. This system might be useful not only for detection of the incorrect tube filling volumes and clog-clot, but also for decrease of the number of rejection limited in HIL.

TABLE 1 Statistical analysis between ACL TOP 750 CTS® and visual inspection

HIT+clog-clot+tube-filling		Visual inspection			P value
		rejcted	good		
ACL TOP 750 CTS	rejcted	6	11	17	0.8596
	good	9	2,334	2,343	
		15	2,345	2,360	
HIL		Visual inspection			P value
		rejcted	good		
ACL TOP 750 CTS	rejcted	2	0	2	0.0223
	good	9	2,334	2,343	
		11	2,334	2,345	

PB 1177 | Results of Implemented Postanalytical Quality Indicator - Turnaround Time (TAT) Monitoring for Urgent Coagulation Tests

S. Margetic[1], I. Vukasovic[2], N. Vrkic[2]

[1]Medical School University Hospital ´Sestre Milosrdnice´, Laboratory Haematology and Coagulation, Zagreb, Croatia, [2]Medical School University Hospital ´Sestre Milosrdnice´, Clinical Institute of Chemistry, Zagreb, Croatia

Background: Turnaround time (TAT) represents an important postanalytical quality indicator of laboratory service.

Aims: The aim was to present the results of TAT monitoring for urgent coagulation tests during the year 2016.

Methods: As accredited to ISO15189 norm, our laboratory has implemented daily TAT monitoring for urgent tests measured as the difference between sample receipt time and the result sending time.

For the purpose of long term TAT monitoring, we defined two measures: ratio (%) of reports delivered outside the specified time (60 mins) with sigma metric evaluation included (minimal acceptable sigma 3.0; desirable sigma 5.0) and time (mins) for International Normalized Ratio (INR) value reporting at 90th percentile with predefined eligibility criteria (minimal 67.5 mins, desirable 54.0 mins and optimal 40.5 mins). The results of TAT monitoring data were compared between the six-month periods.

Results: Total ratios (%) of reports with exceeded TAT were 1328/26946 (4.9%) for the first six months and 1150/26501 (4.4%) for the second six months with almost equal and minimal acceptable sigma values for both periods i.e. 3.2 and 3.3, respectively. In the first 6 months 90th percentile for urgent INR deviated from 3.4 to 7.4% (range for monthly obtained values was 56 to 58 mins) of the desired criteria (54.0 mins) and only a minimum criterion (67.5 mins) of eligibility was obtained. For the second six months 90th percentile for urgent INR deviated from -7.4 to + 5.6% (range for monthly obtained values was 50-57 mins) and desirable criteria was obtained.

Conclusions: Our results showed the minimal acceptable rather than desirable values of both TAT measures for urgent coagulation tests during the observed period. The implemented system for TAT monitoring is useful tool and we assumed that auto-validation implementation could be the key factor for further TAT improvement.

PB 1178 | Is it Helpful for Physicians the Laboratory Post Analytical Comments on a Prolonged APTT?

M.D.V. Arias, R.E. Sueldo, M. Avalos, M. Gurfinkiel

Unidad Asistencial por mas Salud Dr. Cesar Milstein, Hematology Laboratory, Ciudad Autonoma de Buenos Aires, Argentina

Background: Partial Activated Thromboplastin Time (APTT) evaluates globally the intrinsic and common pathway of coagulation. When an APTT is prolonged, Thrombin Time (TT) is normal, and APTT fail to correct in mixtures with pooled normal plasma (NP), it is suggestive of

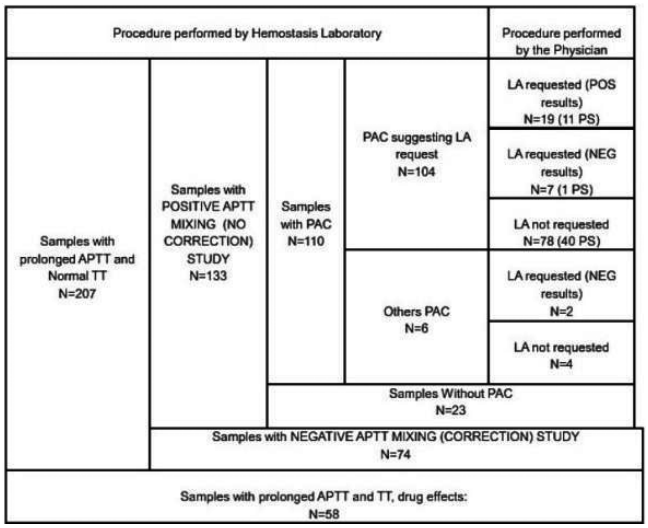

FIGURE 1 Results of the procedure performed by the laboratory and by the physician

the presence of a lupus anticoagulant (LA), particularly in the absence of bleeding manifestations. The prevalence of LA in elderly patients is increased.

Aims: To analyze the samples of elderly patients with prolonged APTT in routine laboratory setting, like presurgery evaluation (PS), and to evaluate the request for LA testing in those patients with prolonged APTT without correction with NP in which a post analytical comment (PAC) suggesting LA search was made by laboratory (lab).

Methods: 265 samples of asymptomatic patients (60-93 years) with normal prothrombin time and prolonged APTT were analyzed during a period of 15 months. APTT-SP IL (reference range 24 - 38 sec) in an ACL TOP300 was performed, and mixing studies were performed in 1: 1 mixtures with NP. Samples were divided in groups according to mixing studies results and post analytical comment (PAC) or suggestion made by lab. AL was performed according to the ISTH guidelines.

Results: See figure1

Conclusions: The physician´s response to the laboratory´s PAC suggesting LA request was only 25% (26/104). Of these studies, 19 had results compatible with the presence of LA (73%). Even when more than 50% of APTT studies were in the setting of a PS evaluation, the physician response to PAC suggestion was surprisingly low. Although the search for LA in asymptomatic patients is questioned, the prevalence of LA positive results in the study was high, probable related to the population age. It seems to be important to do PAC suggesting for LA searching to avoid postponements or additional treatments in elderly PS patients.

PB 1179 | Sensitive Method for Determination of Blood Hypercoagulation

V. Sukhanov[1], O. Petrova[2]

[1]*Regional Hospital #1, ICU, Ekaterinsburg, Russian Federation,* [2]*Regional Oncology Center, Ekaterinsburg, Russian Federation*

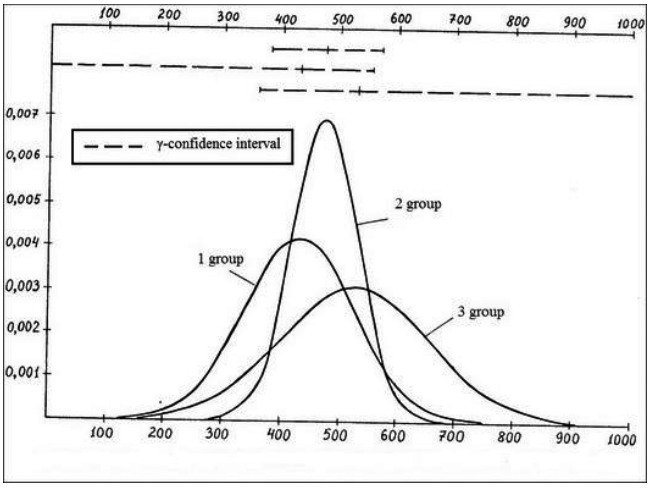

FIGURE 1 The probability density function of blood clotting time, sec. (after recalcification 0.98 mg/0.66 ml blood)

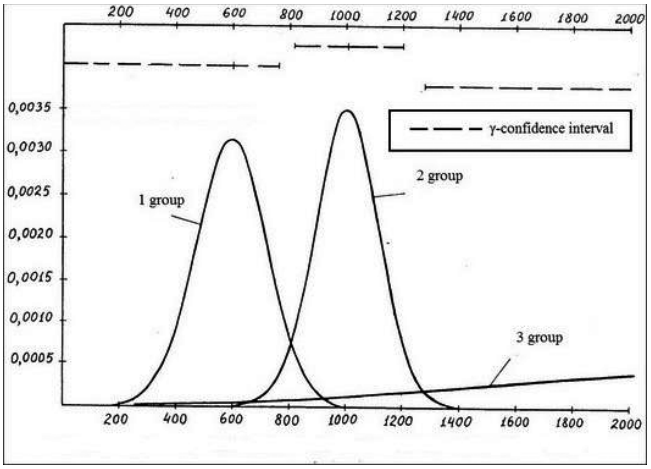

FIGURE 2 The probability d*ensity function of blood clotting time, sec. (after recalcification 0.55 mg/0.66 ml blood)*

Background: Hypercoagulation of blood (HPRB) is one of the main predictors of thrombosis. One of the methods of diagnosis of HPRB is recalcification technique. The principle of this method is the recovery of ionized calcium initial concentration in citrated blood (balanced recalcification technique - BRT).

Aims: The aim of our study was to investigate the influence of lesser amounts of calcium (LBRT) than in BRT.

Methods: We investigated the influence of different concentrations of ionized calcium (less than in BRT) on recalcification time. As a basis for our investigation we selected instructions for thromboelastograph ROTEM, where the final concentration of calcium in the mixture with blood after recalcification was 0.98 mg/0.66 ml blood. We chose the reaction time of thromboelastography as the end of obtained results. Empirically we determined that the most convenient final concentration of calcium in the mixture with blood was ~0.55 mg/0.66 ml blood. We selected 3 groups for the study: 1 group - 350 patients (pts) with thrombosis, 2 group - 60 healthy donors and 3 group - 215 pts from the 1st group during anticoagulant therapy (the blood was

investigated after 3-4 hours after injection of therapeutic dose of low molecular weight heparin (LMWH)).

Results: The results of our study are shown on Figure 1 and 2. BRT coincided with the shortest time of blood coagulation. When we used BRT, the γ-confidence intervals of all three groups were essentially surpassed each other for any confidence coefficient that didn't allow pattern recognition (Fig. 1). In contrast, in LBRT confidence intervals were separated from each other (Fig. 2).

Conclusions: Use of LBRT in patients' study has demonstrated its higher diagnostic potential in the determination of HPRB and possibly monitoring of anticoagulant therapy with LMWH.

PB 1180 | Variants of FVII Deficiency at an Elderly Care Hospital

R.E. Sueldo[1], G. Guerrero[1], P. Do Nascimento[1], A. Baques[1], A. Girolami[2], G. Scoles[1], M.D.V. Arias[1]

[1]*Unidad Asistencial por mas Salud Dr. Cesar Milstein, Ciudad Autónoma de Buenos Aires, Argentina,* [2]*University of Padua Medical School Department of Medicine, Padua, Italy*

Background: FVII deficiency (FVIId) is an autosomal recessive disorder. There are two types: Type I (FVII-T1) with decreased FVII:C activity and antigen (FVII:Ag) and Type II (FVII-T2), with decreased FVII:C, variable with different thromboplastin (THR) origin, and normal FVII:Ag.

Aims: To report 5 cases of FVIId at an Elderly care Hospital.

Methods: Patients (P) and initial diagnosis (ID) performed with rabbit brain THR (rBT):

P 1: woman age 64, severe (S) FVIId

P 2: daughter of P1 age 44

P 3: woman age 71, S FVIId

P 4: man age 78, S FVIId

P 5: man age 75, mild FVIId

PT and FVII:C were performed with at least two THR of different origin:

* rBT: PT-Fibrinogen HS Plus; Instrumentation Laboratory (IL), THR S; Hemo Medica, STA Neoplastin Plus; Diagnostica Stago.

* Recombinant human: Dade Innovin; Siemens, Recombiplastin 2G; IL

* Human placental: Thromborel; Siemens

* Ox Brain: Thrombotest; Nyagaard Laboratories.

APTT (APTT-SP, IL), Factor deficient plasmas (IL), Coagulometer ACL TOP 300 (IL). Genetic Analysis (GA): ABI PRISM BigDye and ABI3130 Genetic Analyzer (Applied Biosystems, Foster City, Ca, U.S.A.)

Results: PT and FVII:C results are in tables 1 and 2

APTT and factors within the reference range.

P1, P2 and P4 presented lower PT % of activity and levels of FVII:C when tested with rBT compared to THR from human origin, possible FVII-T2.

GA of P1 and P2 reveled Homozygous Mother, Heterozygous Daughter for p.Arg364Gln mutation in exon 8 of FVII gene.

Conclusions: P1, P2 and P4 showed variable results with different THR. P1 and P2 confirmation of FVII Padua variant by GA became the first report of the mutation in Argentina. GA of P4 is pending. P3 and P5 did not show significant results variation with different THR (possible FVII-T1), maintaining the ID. It is important to study patients with at least two THR of different origin to determine which type of variant is present, because this could have therapeutic implications.

TABLE 1 PT (% of activity) with different THRs - (reference range: 70 - 120%)

PB 1181 | Towards Harmonization of Critical International Normalized Ratio Values Reporting: The Croatian Survey

A. Bronic[1,2], D. Coen Herak[2,3], S. Margetić[2,4], M. Milic Gall[2,5,6]

[1]Medical School University Hospital´Sestre Milosrdnice´, Clinical Institute for Chemistry, Zagreb, Croatia, [2]Working Group for Laboratory Coagulation, Committee for the Scientific Professional Development, Croatian Society of Medical Biochemistry and Laboratory Medicine, Zagreb, Croatia, [3]University Hospital Centre Zagreb, Department of Laboratory Diagnostics, Zagreb, Croatia, [4]Medical School University Hospital´Sestre Milosrdnice´ Zagreb, Clinical Institute of Chemistry, Zagreb, Croatia, [5]Osijek University Hospital, Department of Clinical Laboratory Diagnostics, Osijek, Croatia, [6]Faculty of Medicine, University of Osijek, Osijek, Croatia

Background: Development and implementation of international normalized ratio (INR), reflecting patient´s prothrombin time (PT) adjusted for the reagent/instrument combination, corrected by International Sensitivity Index (ISI) and Mean Normal Prothrombin Time (MNPT), has clearly improved oral anticoagulation therapy (OAT) monitoring. However, critical INR values are variable due to lack of published guidelines for appropriate critical value usage.

Aims: The study aimed to determine how laboratories obtain and report critical INR values.

Methods: Responses related to obtaining and reporting INR results received from 104 hospital and outpatient laboratories participating in a survey conducted in 2015, were analyzed.

Results: An estimated 56.7% respondents use PT reagents from human placenta and rabbit brain, whereas 39.4% respondents use recombinant reagents. ISI value of reagent in use provided 90.4% laboratories (median:0.99, range: 0.84-1.40). Majority of laboratories (72.1%) determine INR values from a direct INR calibration curve, while 26.9% laboratories calculate INR using manufacturer-provided ISI values.Only 12/28 respondents stated how they determine MNPT, mostly using plasma pool from healthy individuals (9/12), and only 1 participant stated how MNPT is calculated (the arithmetic mean). Of all respondents, 50% report INR as a numerical value, regardless the obtained result, whereas 48% report INR as a numerical value greater than certain critical limit (4.0 to 13.0: median >6.7).

Conclusions: Laboratory policies and procedures for obtaining and reporting INR results are highly variable, although almost all laboratories follow recommendation provided by the Croatian Chamber of Medical Biochemists, related to the use of PT reagents with desireable ISI value. As reporting of obtained critical INR value could be confusing to physicians, further efforts should be directed towards harmonization and development of national and international recommendations.

PB 1182 | Improving Laboratory Operational Efficiency with the Implementation of a Specialized Hemostasis Lab Automation

V. Cortina[1], A. Marín[2], F. Bosch[2], A. Santamaría[2]

[1]Hospital "Universitario Vall d´Hebrón, Laboratory Core - Hematology, Barcelona, Spain, [2]Hospital "Universitario Vall d´Hebrón, Barcelona, Spain

Background: In 2013 Vall d'Hebron University Hospital Laboratories (VHLabs) merged its operations with two primary care hospital laboratories: Manso and Bon Pastor. In the case of hemostasis, this resulted in an increase in the number of samples in VHLabs while they had to maintain specialization as a reference center and meet demanding turnaround time (TAT) goals.

Aims: To evaluate the impact of a specialized hemostasis lab automation on the hemostasis testing efficiency in the recently consolidated VHLabs.

Methods: The study is a comparison of the operational data from pre-merger VHLabs in 2013 versus data from one consolidated VHLabs following implementation of HemoCell specialized lab automation (Instrumentation Laboratory) from 2013-16. Data was extracted from the LIS and complemented with inputs from the personnel involved in the laboratory. Information was gathered on number of samples analyzed, TAT of each sample, number of analyzers, number of personnel involved in testing, analyzers' maintenance activities and reagent efficiency.

Results: Three years after implementation of specialized hemostasis lab automation (integrated specialty, routine and stat testing), the total number of samples analyzed in VHLabs increased by 47% while TAT decreased by 40%.

In the network, automation also led to a 36% decrease in hemostasis personnel, who were reallocated to other areas of the lab. This led to a 72% increase in samples analyzed/hemostasis laboratorian. In addition, the total number of hemostasis instruments reduced from 8 on different platforms to 3 on one platform, which led to an increase of 206% in samples analyzed/instrument, an estimated 25% increase in reagent efficiency and 89% decrease in maintenance hours/year.

Conclusions: With the installation of the a specialized hemostasis lab automation system, VHLabs was able to absorb the increase in workload due to the merger of three laboratories, meet the TAT goals and maintain specialization as a reference center.

PB 1183 | In Search of a Sensitive and Reliable Laboratory Tool to Assess Hypercoagulability

D. Bertaggia Calderara[1], D. Kröll[2], P. Nett[2], A. Aliotta[1], D. Pratte[3], N. Weiland-Jäggi[3], G. Stirnimann[2], L. Alberio[1]

[1]CHUV, University Hospital and Univeristy of Lausanne, Department of Hematology, Lausanne, Switzerland, [2]Inselspital, Bern University Hospital, and University of Bern, Department of Visceral Surgery and Medicine, Bern, Switzerland, [3]Endotell, Allschwil, Switzerland

Background: Obesity is considered a prothrombotic state, which would increase the risk for thrombotic events: stroke (VTE) and myocardial infarction (MI). The ability of conventional coagulation assays to detect hypercoagulation and to evaluate thrombotic risk is poor. Additionally, traditional coagulation tests give only a partial picture of coagulation. A promising strategy to assess hypercoagulation could be the use of global hemostasis tests.

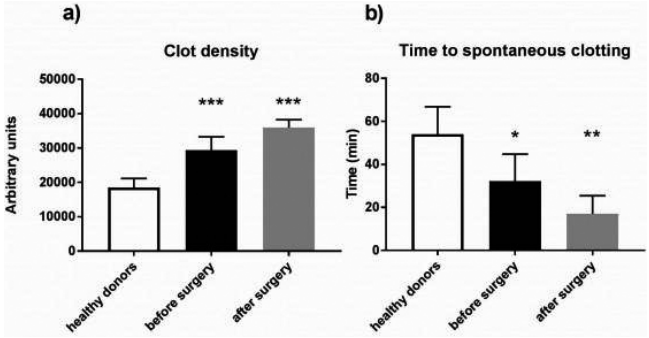

FIGURE 1A and 1b Clot density and time to spontaneous clotting in obese patients versus healthy donors.

Aims: The aim of this study was, using two different global hemostasis tests, to assess the hypercoagulable state of obese patients, before and after bariatric surgery (early postsurgical phase), and to compare it to healthy individuals.

Methods: Whole blood was collected from 12 obese patients with a body mass index ≥ 35 kg/m^2 before and after bariatric surgery and from 5 healthy donors. Propagation of clot growth from a tissue factor (TF)-coated surface and TG were monitored in platelet-poor-plasma (PPP) with a Thrombodynamics analyzer. TF induced thrombin generation (TG) was measured with calibrated automated thrombogram (CAT) in PPP.

Results: All Thrombodynamics parameters describing clot growth formation were significantly increased in obese individuals already at baseline compared to controls, and they further increased after surgery. Clot density increase in obese patients was particularly significant compared to healthy controls ($p < 0.001$); time to the appearance of spontaneous clot was significantly faster in obese patient (Figure 1a and 1b).

Maximum concentration of TG (peak) was significantly increased in obese patients compared to controls. Peak and velocity index were higher post-surgery with both systems tested.

Conclusions: Our preliminary results show that Thrombodynamics has a promising potential as a tool to evaluate hypercoagulability and thrombotic risk. CAT assay confirmed TG Thrombodynamics results in patients before and after surgery. Further investigations are needed in order to correlate assays parameters with clinical phenotypes.

PB 1184 | HIL Interferences in Coagulation Testing: Evaluation of Automatic Check with the New ACL TOP 550 CTS Analyzer

A. Skibowska-Bielińska, E. Wierszyło, E. Czajkowska, K. Lewandowski

University Clinical Center, Clinical Laboratory, Gdansk, Poland

Background: Preanalytical issues are the most common part of errors in coagulation testing. Spurious hemolysis, lipemia or icterus can jeopardize the quality of results in coagulation testing.

Aims: This study was to evaluate automatic check for HIL interferences offered by pre-analytical module of ACL TOP 550 CTS analyzer (Instrumentation Laboratory, Bedford, USA) in comparison to standard visual inspection of samples.

Methods: 5293 samples were examined during 2 months of routine laboratory work . All samples prior to analysis were visually inspected and noticeable abnormalities in sample color (due to excessive HIL interferences) were recorded. Based on the inspection samples were classified as “rejected” - questionable due to HIL issues or “accepted” - suitable for testing. Samples with clots were not included in the study. Assays included: PT, APTT, Fib, D-Dimer, AT, FVIII, LMWH. Whole set of samples was analyzed with ACL TOP 550 CTS which detected and flagged samples with HIL interferences. Configuration of the analyzer was with HIL limits (reagent and parameter specific) provided by producer.

Results: Of the 5293 samples analyzed 162 were rejected because of HIL visual inspection only. In 43 samples HIL interferences were confirmed by automatic check. Of the 5131 samples qualified visually as acceptable 5 were flagged by analyzer as having HIL interferences for at least one of the assay´s tested. ACL TOP 550 CTS system reduced sample rejection rate because of HIL issues by 70,3% (% of total samples rejected by visual inspection 3.06% (2.6% - 3.6%) vs automatic inspection 0.91% (0.7% - 1.2%);CI95%;p< 0,0001 Fisher X^2 test). Moreover analyzer detected some samples and tests with HIL issues which were not noticed visually.

Conclusions: Automatic check for plasma indices provided by ACL TOP 550 CTS system is objective tool which helps to improve the accuracy of HIL interferences management. It significantly reduces the number of HIL questionable results, unnecessary sample redraws saving both costs and staff time.

PB 1185 | Comparison of Clot Waveform Analysis from Sepsis Patients and Healthy Control Group

N. Zamalek

Dr Hasan Sadikin General Hospital, Clinical Pathology, Bandung, Indonesia

Background: PT and aPTT are parameters mostly asked by physicians for patient management. But in these measurements, the results only show time of plasma to clot. No information about how the clot is form. Clot Waveform Analysis (CWA) will gives us information about the clot formation include the acceleration and deceleration of clotting which may can be used to predict patient‘s condition in severely ill such as sepsis.

Aims: To compare CWA from patients with sepsis and healthy control group.

Methods: Subjects include in control groups are people without signs and symptoms of hemostasis disorders, no drugs consumed include vitamins and contraceptive within last 10 days, and female not in perimenstrual periode. All control subjects should showed normal CBC, ALT, AST, negative CRP and normal hemostasis measured with thrombelastography. Measurement of PT, aPTT and CWA were using

TABLE 1 PT, aPTT and CWA results

	Normal Subjects	Normal Subjects	Sepsis Subjects	Sepsis Subjects	Mann-Whitney p
	Median	Range	Median	Range	
PT(sec)	10.4	9.3 - 11.3	13	10.4 - 30.5	<0,001
Min1	1.62 (mean)	0.342 (SD)	2.19 (mean)	1.15 (SD)	0.0477 *t-test
Max2	0.3	0,2 - 0,4	0.373	0.04 - 0.90	0.018
APTT(sec)	24.3	21.5 - 35.8	33.9	23.4 - 82.1	<0.001
Min1	4.18 (mean)	0.786 (SD)	4.22 (mean)	1.63 (SD)	0.928 *t-test
Min2	0.7	0.5 - 1.0	0.621	0.07 - 1.18	0.234
Max2	0.6	0.4 - 0.9	0.471	0.05 - 0.92	0.004

automated coagulation analyzer CS 2100i. Statistical methods used: normality test, independent t-test, or Mann-Whitney U test. Study was done in Dr Hasan Sadikin Bandung during August until November 2016. This study approved by ethical committee.

Results: There are 33 healthy people recruit for this study and 18 patients diagnosis as sepsis. PT, aPTT and CWA results can be seen in Table 1.

For PT: max coagulation velocity and maximum coagulation deceleration in sepsis significantly longer compare to normal subjects; while for aPTT: maximum coagulation velocity is not significantly different, and for maximum coagulation acceleration and maximum deceleration in normal subjects significantly longer compare to sepsis.

Conclusions: This study showed that from CWA we can observed that PT (extrinsic pathway) is more affected in sepsis patients.

PB 1186 | Impact of New Oral Anticoagulants on Routine Coagulation Assays

A. Bronic, M. Pavic, L. Milevoj Kopcinovic

Medical School University Hospital ´Sestre Milosrdnice´, Clinical Institute for Chemistry, Zagreb, Croatia

Background: New oral anticoagulants (NOAC), like dabigatran and rivaroxaban, have been recently approved in many countries for primary and secondary prophylaxis of thromboembolic conditions. Monitoring of coagulation function is not routinely required with these drugs but may be useful in emergencies. Routine coagulation tests do not provide enough information on the anticoagulant effect of NOAC and the interpretation of the results obtained in everyday practice is still unsolved.

Aims: The aim of this study was to assess the effect of dabigatran and rivaroxaban on routine coagulation assays: Prothrombin Time (PT), Activated Partial Thromboplastin Time (aPTT) and the Fibrinogen assay.

Methods: Samples collected at Traumatology Clinic from 43 patients treated with dabigatran (N = 24) and rivaroxaban (N=19) during 2015 were analysed and obtained results on PT, aPTT and fibrinogen were reviewed.

Results: In 24 patients on dabigatran treatment, PT and aPTT values ranged from 0.29-1.11 and 21.9-67.8 s, respectively. A prolonged PT was obtained in 9 (median 0.64; range 0.36-0.66) and aPTT in 12 patients (median 38.3 s range 30.4-67.8). Obtained median INR in patients with prolonged PT was 1.2 (range 1.0-1.8). Low levels of fibrinogen (< 1.8 g/L) were obtained in 4 patients. In 19 patients treated with rivaroxaban PT and aPTT values ranged from 0.45-1.28 and 21.9-39.9 s, respectively. A prolonged PT was obtained in 8 (median 0.53, range 0.36-0.66,) and aPTT in 11 patients (median 34.5s, range 30.4-67.8) whereas low levels of fibrinogen were not obtained in these patients. Obtained INR median value in patients with prolonged PT was 1.1, range 1.0-1.3.

Conclusions: Most of the routine coagulation assays are affected by the application of dabigatran and rivaroxaban, which makes their interpretation a challenge. As an increasing number of patients who use NOACs could be expected, appropriate educational strategies and policies to avoid misinterpretation of routine coagulation test results should be established.

PB 1384 | Evaluation of a New D-dimer Concept for Venous Thrombosis Exclusion: A Prospective Study (FSET Study) ClinicalTrials.gov ID: NCT02523937

I. Mahé[1], E. Peynaud-Debayle[2], H. Helfer[3], J. Chidiac[3], B. Dumont[4], R. Omezzine[3], M. Pinson[3], N. Javaud[5]

[1]Paris7 University, EA 7334, APHP Louis Mourier Hospital, Internal Medicine Department, Colombes, France, [2]APHP, Louis Mourier Hospital, Hematologie Biologique Department, Colombes, France, [3]APHP, Louis Mourier Hospital, Internal Medicine Department, Colombes, France, [4]APHP, Louis Mourier Hospital, Hématologie Biologique Department, Colombes, France, [5]Paris7 University, APHP Louis Mourier Hospital, Emergency Department, Colombes, France

Background: D-dimer (DDi) is the reference test to rule out venous thromboembolism (VTE) in patients with a low or medium probability, due to its high negative predictive value (NPV). However, it cannot be used for its positive predictive value (PPV) since it is also detected in patients with inflammation and hypercoagulability. A new DDi-based assay insensitive to these processes was described to improve VTE diagnosis specificity (ISTH 2017 submitted).

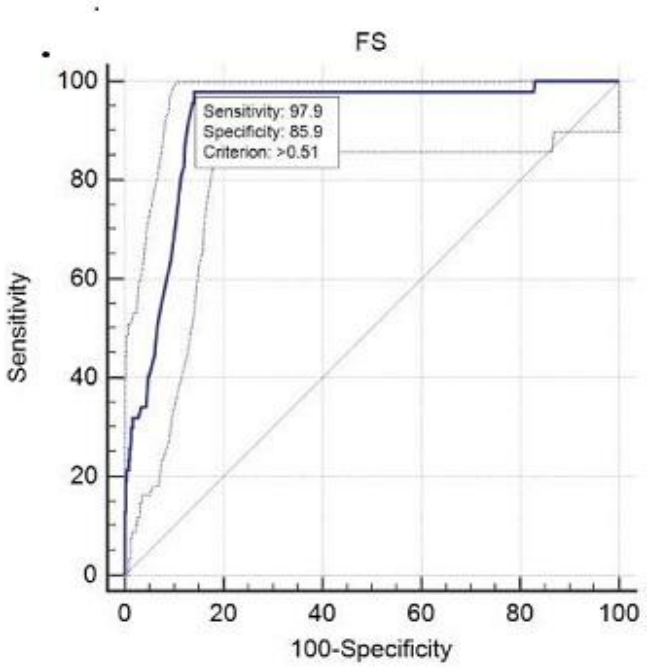

FIGURE 1 ROC curve of the new assay in FSET study

Aims: Evaluate in patients with clinically suspected VTE the diagnostic performances of this assay (sensitivity (Se), specificity (Sp), NPV and PPV) from calculation of the area under the curve in comparison with DDi. Determine the cut off.

Methods: Patients with suspected VTE were prospectively included in Emergency and Internal Medicine Units of one center. VTE was excluded by DDi test in patients with a non-high clinical probability, and confirmed or excluded on the basis of imaging tests and follow up. Blood was taken in patients with no anticoagulant treatment. Citrated plasma was frozen until use. The assay was blindly performed with regard to the diagnosis. An algorithm based on DDi and Fibrin polymerization curve variables was used for calculation and result. Receiver operating characteristic (ROC) curves were used to determine the performances and the cut-off value according to VTE diagnosis.

Results: 628 patients were enrolled (48%>50 years, 19%>75 and 7.5% with cancer). VTE was confirmed in 47 (7.5%). One false negative case was observed in a patient with an isolated subsegmental pulmonary embolism. Test clinical performances from ROC analysis (Se 100%, Sp 85.9%, NPV 99.8% vs 100% for DDi, PPV 35.8% vs 15.6% for DDi at 0.51 µg/mL FEU) are compared to DDi and age-adjusted DDi ones.

Conclusions: In this prospective study in patients with suspected VTE, the new assay demonstrated an increased specificity and PPV with a similar sensitivity and NPV as DDi, resulting in excluding more VTE than DDi and reducing imaging testing.

PB 1385 | A New D-dimer concept for More Specific Detection of Venous Thromboembolism

G. Contant[1], S.S. Mirshahi[2], F. Depasse[3], J. Soria[2,4]

[1]*STAGO, Prospective Research Dept, Gennevilliers, France,* [2]*UMR INSERM U 965, Translational Research Hopital Lariboisière, Paris, France,* [3]*STAGO, Clinical Development Dept, Asnières-sur-Seine, France,* [4]*Hotel Dieu, Clinical Research in Oncology, Paris, France*

Background: D-dimer (DDi) used with pretest probability score (PTP) has excellent negative predictive value to rule out venous thromboembolism (VTE). However due to low specificity, many VTE-suspected patients undergo imaging tests, mainly because of inflammation or hypercoagulability.

We designed a new assay insensitive to inflammation and hypercoagulability to improve VTE diagnosis.

Aims: Evaluate method analytical (reproducibility, sensitivity (Se), specificity (Sp)) and clinical performances without PTP, compared with DDi in a preliminary prospective study on patients with suspected VTE.

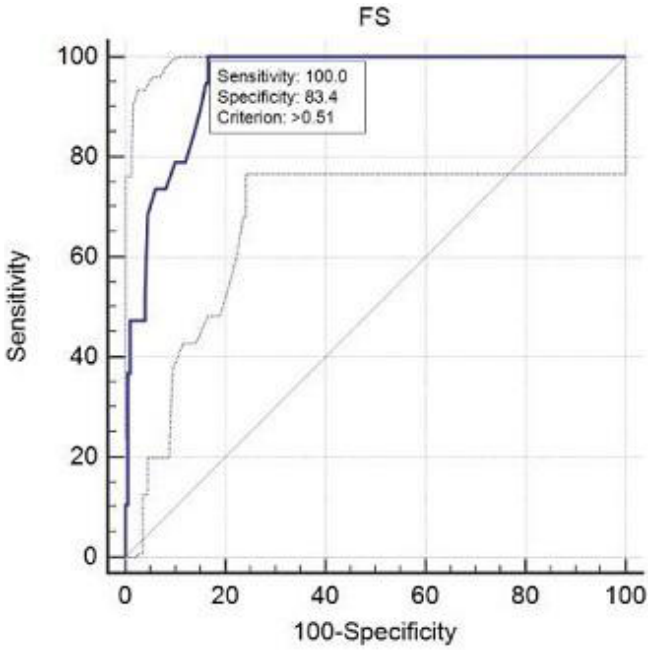

FIGURE 1 New assay ROC curve

TABLE I Clinical performances of the new assay in FSET study (*1 isolated SSPE)

N=628	Number of patients excluded for VTE diagnosis	Sensitivity % [95% CI]	Specificity % [95% CI]	Positive likelihood ratio	Negative likelihood ratio
New assay	500/628 (79.6%)	97.9%* [88.7 - 99.9%]	85.9% [82.8 - 88.6%]	6.93	0.025
D-dimer	329/628 (52.4%)	100% [92.5 - 100%]	56.6% [52.5 - 60.7%]	2.31	0.00
Age-adjusted D-dimer	366/628 (58.3%)	100% [92.5 - 100%]	63.0% [58.9 - 66.9%]	2.70	0.00

TABLE I Clinical performances of the new assay versus regular D-dimer cut-off or D-dimer with age-adjusted cut-off

N=218	Number of patients excluded for VTE diagnosis	Sensitivity % [95% CI]	Specificity % [95% CI]	Positive likelihood ratio	Negative likelihood ratio
New assay	166/218 (76.2%)	100% [82.4 - 100%]	83.2% [77.5 - 88.3%]	6.03	0.00
D-dimer	115/218 (52.8%)	100% [82.4 - 100%]	57.8% [50.6 - 64.7%]	2.37	0.00
Age-adjusted D-dimer	123/218 (56.4%)	100% [82.4 - 100%]	61.8% [54.7 - 68.6%]	2.62	0.00

Methods: Patients with suspected VTE were included prospectively in one center. VTE was excluded by D-dimer testing and confirmed or excluded by compression ultrasonography, lung scanning or spiral computed tomography angiography. The assay, run using frozen citrated plasma on STA® prototypes, combines use of DDi and fibrin polymerization curve variables: Fibrin Formation Time (FFT), Time to reach fibrin polymerization Plateau (TP), Clot Polymerization Rate (CPR), Optical Density variation (OD). Assay result was calculated by an algorithm built in partnership with clinicians using assay parameters that were faced with clinical data in an open clinical pre-study.

Intra/inter-assay reproducibility was studied using normal and hypercoagulable control plasmas (3 prototypes, 5 consecutive days). Receiver operating characteristic (ROC) curves were used to define cut-off value according to VTE status.

Results: 218 patients with VTE suspicion (47% > 50 years, 17% > 75 and 15% with cancer) were tested. VTE was confirmed in 19 (9.4%). Result is available in 10 min. Coefficients of variation (CV) for FFT, TP and CPR were below 6% and below 3% for OD; inter-instrument CV was below 2.5 %. Test clinical performances (Se 100%, Sp 83.4%) are in Fig 1 and Table I.

Conclusions: In this preliminary study, proof of concept was demonstrated. The test looks promising with improved VTE diagnosis specificity leading to imaging testing reduction.

PB 1386 | GDF-15 Alters the expression of Actin Associated Protein, Increases Migration and the Phosphorylation of Smad2 is Mediated via TGFβRII

L. Kask[1], K. Hörneaus[2], M. Åberg[1], A. Jorsback[3], J. Bergquist[2], A. Siegbahn[1]

[1]Uppsala University, Department of Medical Sciences, Uppsala, Sweden, [2]Uppsala University, Department of Chemistry, Uppsala, Sweden, [3]Ge Healthcare, Uppsala, Sweden

Background: The stress induced cytokine GDF-15 is strongly associated with cardiovascular disease.

Aims: Our aim was to investigate GDF-15´s function and the more precise identity of the receptor.

Methods: We have performed a proteomic array, 2-D DIGE, with purified human monocytes after GDF-15 stimulation. GDF-15´s function was investigated with a transwell migration assay. Protein regulation was verified by using Western blot and for receptor studies we used inhibitory chemicals and siRNA together with Western blot.

Results: When human monocytes were stimulated with GDF-15 and oxidative stress the expression of several actin associated proteins but also chaperones and glycolysis proteins were affected. We could confirm the upregulation of WD repeat 1 (WDR1, actin regulator) and T complex protein 1 (TCP-1 ε, chaperone) by Western blot. When performing a migration assay we found an increased migration when THP-1 cells are stimulated with GDF-15 alone, together with oxidative stress and oxidative stress alone. The oxidative stress in itself increases the expression of GDF-15, shown by Western blot, which in turn amplifies the migration. We detected an increased phosphorylation of Smad2 after 15 minutes of GDF-15 stimulation in human monocytes, which was blocked in THP-1 cells with the inhibitors ITD 1 and A 83-01 and by siRNA treatment, indicating that TGFβRII is involved in the binding of GDF-15. When analyzing migration after ITD 1 and A 83-01 treatment the increasing effect seen by GDF-15 is prohibited. The phosphorylation of Smad2 was decreased when stimulating monocytes with the natural existing variant of GDF-15 (H6D).

Conclusions: GDF-15 upregulates the actin associated protein WDR1, the chaperone TCP-1 ε and affects migration. The GDF-15 initiated Smad2 phosphorylation transmits via TGFβRII as shown by inhibitor studies. The natural existing variant of GDF-15 (H6D) decreased the phosphorylation of Smad2 indicating that this mutation would give GDF-15 less potency.

PB 1387 | Validation of Plasma Marker Candidates for VTE Using Affinity and Mass Spectrometry-based Proteomics Indicate a Link to Alternative Complement Pathway

L. Sanchez-Rivera[1], M.J. Iglesias[1], M. Bruzelius[2,3], M.-G. Hong[4], L. Butler[5,6], J. Schwenk[4], P. Morange[7,8], D.-A. Trégouët[9,10], J. Odeberg[1,2,3]

Paris 06, INSERM, UMR_S 1166, Paris, France, [10]Institute for Cardiometabolism and Nutrition, ICAN, Paris, France

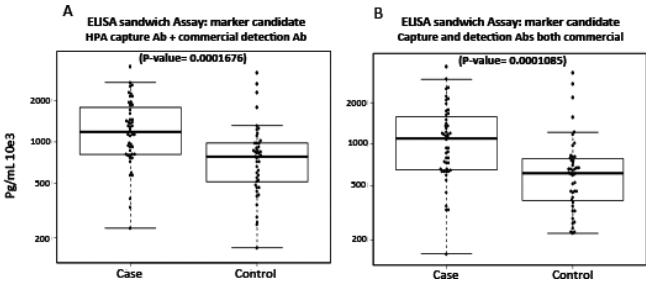

FIGURE 1 Quantitative ELISA-sandwich assay (in-house developed) for the marker candidate using Human Protein Atlas and commercial antibodies

Background: Venous thromboembolism (VTE), has an incidence of 1-2/1,000 year, high mortality and 25% recurrence rate. There is a clear need for improvement in the clinical tools for diagnosis and risk prediction of VTE; D-Dimer, the only plasma marker currently used, has low specificity.

Aims: To identify novel plasma markers for diagnosis and risk prediction of incident and recurrent VTE and to study their relevance to disease development.

Methods: The project is based on the VEBIOS study that includes both patients with acute VTE and patients sampled after discontinuation of anticoagulant treatment following a first-time thrombosis. Plasma samples (n=270) were screened for 760 proteins, using multiplex suspension bead arrays with antibody (Ab) reagents from the Human Protein Atlas Project (HPA). Immunocapture-mass spectrometry (IC-MS) and ELISA-sandwich assays were used to verify and validate the selected targets with significant association with VTE.

Results: 29 proteins were found to be significantly associated with VTE in the cohort that included the patients sampled after discontinuation of anticoagulants (P< 0.01); and 3 proteins in the acute-VTE cohort (P< 0.01). One of these proteins was found to overlap both cohorts. By IC-MS we verified the binding of this target candidate to the Ab used in the discovery. IC-MS analysis also revealed a component of the alternative complement pathway. In plasma the latter protein was found to be associated with acute VTE when measured using two independent quantitative ELISA sandwich assays (48 cases vs 48 controls P=0.0001, Figure1).

Conclusions: This study may yield clinically relevant markers for VTE diagnosis and risk prediction. The results suggest a possible role of the alternative complement pathway in VTE pathobiology.

PB 1388 | Proteomic Profiling to Find Candidate Biomarkers Associated with the Risk of First and Recurrent Venous Thrombosis

A. van Hylckama Vlieg[1], C. Kabrhel[2], S.C. Cannegieter[1], F.R. Rosendaal[1]

FIGURE 1

Background: Large-scale proteomic profiling has the potential to identify novel biomarkers that can aid in the assessment of venous thrombosis risk.

Aims: To assess the role of proteomic profiling to find candidate biomarkers associated with the risk of first and recurrent venous thrombosis.

Methods: As a proof-of-principle study, we analysed a sample of THE VTE case-control study on risk factors for venous thrombosis. We selected 27 random control subjects and 27 patients with a first idiopathic venous thrombosis, i.e., no surgery, plaster cast, injury, immobilisation, hormone use, pregnancy, or post-partum period in the three months prior to the event. Furthermore, individuals had no active cancer, normal levels of protein C, protein S and antithrombin (>80 U/dL), and no factor V Leiden or prothrombin 20210A mutation. Citrated plasma samples were obtained 2-3 months after discontinuation of anticoagulation therapy in the cases. Out of the 27 patients, 11 had a recurrent event during subsequent follow-up. We applied an aptamer-based proteomic profiling platform (SOMAscan) that currently measures 1310 proteins.

Results: 119 Proteins were associated with a first venous thrombosis at a significance level of p< 0.05 but due to the small sample size, no tests were significant after correction for multiple testing. Four

proteins were associated with a q-value of 0.05: Immunoglobulin superfamily containing leucine-rich repeat protein 2 (ISLR2), tissue factor pathway inhibitor (TFPI), antithrombin, and Histone-lysine N-methyltransferase EHMT2. Using principal component analysis (PCA) using the top proteins (p< 0.05), we were able to separate the patients and controls and also patients with and without a recurrent event (figure).

Conclusions: This pilot study shows the potential value of using large-scale proteomic profiling to find candidate biomarkers associated with the risk of first and recurrent venous thrombosis.

Background: The tendency of a plasma sample to generate thrombin, a central enzyme in blood coagulation, might be an important indicator of prothrombotic and haemorrhagic risk.

Aims: To investigate the clinical and laboratory determinants of thrombin generation (TG), measured in platelet rich plasma (PRP) and platelet free plasma (PFP), in individuals from the adult population-based Gutenberg Health Study (GHS).

Methods: Clinical data, standard laboratory markers and TG, investigated in both PRP and PFP at 1pM TF, were available in 407 individuals from the GHS. Endogenous thrombin potential (ETP) and TG_peak were the investigated parameters of a TG curve.

Results: No differences were observed in TG parameters both in PRP and PFP between males and females. The multivariable linear regression analysis, adjusted for age, sex, laboratory markers and antithrombotic treatment, showed that ETP_{PRP} was positively associated to C-reactive protein (CRP,β:64.6[28.2;101],p=0.00056) and negatively to leukocyte count (β:-15.0[-27.0;-3.01],p=0.015). The TG_peak_{PRP} was positively associated to mean platelet volume, MPV, (β:4.97[0.529;9.41],p=0.029) and platelet count (β:0.106[0.04;0.17],p=0.0017). Further, ETP_{PFP} was positively associated to erythrocyte count (β:88.7[13.9;164],p=0.021) and CRP (β:31.5[4.96;58.1], p=0.021) and negatively to cholesterol (p=0.021). TG_peak_{PFP} was negatively associated to cholesterol only (β:-0.182[-0.299;-0.065],p=0.0024). Of traditional cardiovascular risk factors (CVRFs) obesity only was positively associated to ETP_{PRP} (β:218;44.3]131],p=0.0033) in a fully adjusted multivariable model. Antithrombotic agents were strongly and negatively associated to TG in both PRP and PFP (p< 0.0001).

Conclusions: This is the first adult population-based study comprehensively investigating TG from both PRP and PFP samples. Our findings support that TG, particularly in PRP, relates to cardiovascular risk in an apparently healthy population.

PB 1390 | Metabolomic Study in Plasma Samples to Identify a Metabolite Profile Associated to Venous Thromboembolism

A. Fernández-Pardo[1], L. Martos[1], D. Hervas[2], L.A. Ramón[1], J. Oto[1], A.R. Cid[3], S. Haya[3], S. Bonanad[3], Y. Pico[4], P. Medina[1], F. España[1], S. Navarro[1]

[1]Medical Research Center IIS La Fe, Research Group in Haemostasis, Thrombosis, Atherosclerosis and Vascular Biology, Valencia, Spain, [2]Medical Research Center IIS La Fe, Bioestatistics Unit, Valencia, Spain, [3]University and Polytechnic La Fe Hospital, Service of Hematology, Valencia, Spain, [4]University of Valencia, Food and Environmental Research Group, Valencia, Spain

Background: Current laboratory techniques do not identify all individuals at high risk of venous thromboembolism (VTE), therefore there must be unknown thrombotic risk factors that interact with those already known. Metabolomics could be a good method for detecting these new molecules.

Aims: To identify a characteristic metabolomic profile of patients diagnosed with VTE.

Methods: Citrated plasma samples from 20 VTE patients and 20 healthy volunteers from our VTE cohort were selected. Informed consent was obtained from all subjects. Four methods, based on acetonitrile protein precipitation, were compared to establish which of them were able to extract the highest number of metabolites. Metabolites were analyzed by UHPLC-QqTOF-MS/MS, since it offers high separation power and high sensitivity for metabolomic research. In addition, a homemade MS/MS Library was developed to improve the identification of the metabolites. The results were analyzed using an elastic net penalized logistic regression model (R version 3.3.1), to focus the study in the variables that have the discriminant information.

Results: We obtained a list of 33 variables able to distinguish between patients and controls. A prediction graph of class probability including these variables was drawn. This graph showed how both populations are perfectly classified. We identified each variable using our

homemade library. The results showed that various metabolites, such as L-carnitine, are responsible for distinguishing between patients and controls. Consistently, previous studies associated plasma levels of acylcarnitines and the risk of VTE.

Conclusions: Our results suggest that untargeted metabolomic analyses may be useful for identifying new molecules involved in VTE. Further studies in larger cohorts are needed to corroborate these results and to elucidate the implication of these metabolites in the blood clotting system. ISCIII-FEDER (PI14/00512, PI12/00027, RD12/0042/0029, PI14/00079, FI14/00269, CPII15/00002), GVA (PROMETEOII/2015/017), IIS La Fe.

PB 1391 | Prevalence of Deep Vein Thrombosis and Wells Score Accuracy for Inpatient with Suspected Deep Vein Thrombosis

M. Sartori, F. Gabrielli, E. Favaretto, M. Filippini, E. Conti, B. Cosmi

Azienda Ospedaliera di Bologna Policlinico Sant'Orsola Malpighi, Angiology and Haemostasis Unit, Bologna, Italy

Background: The Wells score to determine the pretest probability of deep vein thrombosis (DVT) was validated in outpatient settings, but its utility for risk stratification of inpatients it is unclear.

Aims: To establish the prevalence of DVT in inpatients and whether the Wells score applies for risk stratification in inpatients with suspected DVT

Methods: A single centre cross-sectional study has been performed. All the patients from our academic hospital with suspected lower-extremity DVT were evaluated using Wells score and underwent whole leg ultrasound to confirm the presence of DVT. Padua score was also calculated for patients in medical wards.

Results: We enrolled 402 inpatients (males 40%): 302 (75.1%) were hospitalized in medical wards, 100 (24.9%) in surgical wards. Age was 76.9±14.4 y and mean duration of hospitalization was 5.6 days. We found 82 (20.4%) DVTs: 31 proximal DVTs (7.7%) and 51 (12.7%) isolated distal DVTs. DVT incidence in low, moderate, and high pretest probability groups was 10.1%, 24.1%, and 37.7%, respectively (P≤0.001). The area under the receiver operating characteristics curve (AUC) for the discriminatory accuracy of the Wells score for risk of DVT identified on whole leg ultrasound ultrasound was 0.65±0.03. When only proximal DVTs were considered the AUC was 0.69±0.05. The percentage of subjects receiving heparin thromboprophylaxis was similar in patients with a high and a low Padua score (53.4% vs. 58.9% p=0.526). DVT incidence in low and high probability groups according to Padua score was 10.2% and 27.3%, respectively (P≤0.001), and did not change after excluding patients receiving thromboprophylaxis (9.1% vs. 31.4%, respectively, p=0.001).

Conclusions: The accuracy of the Wells score for inpatients was lower compared with that reported in the outpatient literature. Therefore, the Wells score risk stratification is not sufficient to rule out DVT in the inpatient setting. In our series, DVT incidence was not negligible in patients with low Padua Score.

PB 1392 | Impact of Chronic Inflammation, Assessed by C-reactive Protein, on the Association between Red Cell Distribution Width and Risk of Incident Venous Thromboembolism

T.S. Ellingsen[1], J. Lappegård[1], S.K. Brækkan[1,2], P. Aukrust[1,3,4], T. Ueland[1,3,4], J.-B. Hansen[1,2]

[1]K.G. Jebsen TREC - Trombosis Research and Expertice Center, Department of Clinical Medicine, UiT The Arctic University of Tromsø, Tromsø, Norway, [2]Division of Internal Medicine, University Hospital of North Norway, Tromsø, Norway, [3]Research Institute for Internal Medicine, Oslo University Hospital Rikshospitalet, Oslo, Norway, [4]Institute of Clinical Medicine, Oslo University Hospital Rikshospitalet, Oslo, Norway

Background: Red cell distribution width (RDW), a quantitative measure of variability in size of erythrocytes, is associated with risk of venous thromboembolism (VTE). The mechanism(s) underlying the association remains unsettled. RDW is a marker of pro-inflammatory conditions, and it is suggested that the association between RDW and VTE risk is mediated by inflammation.

Aims: To investigate whether inflammation, assessed by C-reactive protein (CRP), is the underlying link between RDW and VTE in a nested case-control study.

Methods: The study included 202 cases with incident VTE and 496 age- and sex-matched controls sampled from a general population-based study (the Tromsø Study 1994-2012). Baseline information, including RDW, was obtained in 1994/95. The plasma concentration of high-sensitivity CRP was determined by ELISA. RDW was categorized into tertiles (≤12.5, 12.6-13.1 and ≥13.2%), and CRP levels were categorized as low (< 1 ml/L), intermediate (1-3 mg/L) or high (≥3 mg/L). Multivariable logistic regression was performed to calculate odds ratios (ORs) with 95% confidence intervals (CIs) for VTE by categories of RDW and CRP, and for combined exposures (high RDW and high CRP).

Results: RDW was associated with VTE, and the OR was 1.58 (95% CI 1.02-2.45) for the highest versus the lowest tertile of RDW. The risk estimate remained unchanged after adjustment for CRP. CRP correlated with RDW (Pearson's correlation coefficient: 0.15, p< 0.001), and subjects with a high CRP-concentration (≥3 mg/L) had a greater risk of VTE than subjects with low CRP-concentration (< 1 ml/L) (OR 1.46, 95% CI 0.92-2.29). The risk of VTE increased further for subjects with both high RDW and CRP (OR 3.06, 95% CI 1.48-6.30) when compared to those with low RDW and CRP. The combined estimate did not exceed the sum of the individual components.

Conclusions: Our findings suggest that chronic inflammation is not a mediator of the association between RDW and VTE risk. A combination of high RDW and CRP had an additive effect on VTE risk.

PB 1393 | Improved Exclusion of the Pulmonary Embolism Diagnosis in the Emergency Department Using a New D-dimer-Based Assay

B. Planquette[1,2], S. Jumel[3], J. Pastre[1], P. Aelion[3], H. Pereria[4], J. Marey[1], A. Roche[1], G. Chatelier[4], O. Sanchez[1,2], G. Meyer[1]

[1]Hôpital Européen Georges Pompidou, Service de Pneumologie et de Soins Intensifs, Paris, France, [2]Université Paris Descartes / Sorbonne Paris Cité, Unité INSERM 1140, Paris, France, [3]Hôpital Européen Georges Pompidou, Service d'Accueil des Urgences, Paris, France, [4]Hopital Européen Georges Pompidou, Unité de Recherche Clinique, Paris, France

Background: D-dimer (DDi) testing excludes pulmonary embolism (PE) in patients with non-high clinical probability but its specificity is limited. A new assay is proposed with improved specificity (ISTH 2017 submitted).

Aims: To assess diagnostic performances of a new DDi-based concept in patients with suspected PE.

Methods: Consecutive outpatients admitted to the emergency department of a single center for a clinically suspected PE were included provided they did not receive anticoagulant treatment. The reference test was performed as follows. PE was excluded on the basis of a negative DDi test or of a negative computed tomography pulmonary angiography (CTPA) according to clinical probability and a 3-month follow-up without venous thromboembolism (VTE). PE was diagnosed on the basis of a positive CTPA or of an objectively confirmed VTE during follow-up. The new test was performed on citrated frozen plasma from blood taken on admission. Test diagnostic value was evaluated based on the 0.51 µg/mL cut-off value determined in another patients´ sample. The assay was performed blindly from clinical context, results of diagnostic tests and follow-up data. Patients were managed without knowledge of the new test result.

Results: As of January 27th 2017, 448 of the 500 planned patients were included: 186 men (41.5%), mean age 53.3 ± 19.3 years. Clinical probability was low in 43.3%, intermediate in 54.1% and high in 2.6%. PE was confirmed in 41 (9.8%) patients. Results of the assay were available for 387 patients. Sensitivity was 100% (95% confidence interval (CI): 90.6-100.0), specificity, 82.9% (78.6 - 86.4%), positive predictive value, 38.1% (29.1 - 48.1%) and negative predictive value, 100% (98.7 - 100.0%). Results among the 500 planned patients will be presented at the meeting.

Conclusions: If these results are confirmed in a multicenter setting, this assay could help to safely exclude PE in a large number of patients.

PB 1394 | Plasma Leptin is Not a Mediator of the Association between Obesity and Risk of Venous Thromboembolism

L.D. Horvei[1,2], T. Sovershaev[1], N. Latysheva[1], L. Wilsgård[1], S.K. Brækkan[1,2], P. Aukrust[1,3,4], T. Ueland[1,3,4], J.-B. Hansen[1,2]

[1]UiT - The Arctic University of Norway, KG Jebsen TREC, Department of Clinical Medicine, Tromsø, Norway, [2]University Hospital of North Norway, Division of Internal Medicine, Tromsø, Norway, [3]Oslo University Hospital Rikshospitalet, Research Institute for Internal Medicine, Oslo, Norway, [4]Oslo University Hospital Rikshospitalet, Institute of Clinical Medicine, Oslo, Norway

Background: The underlying mechanism(s) for the strong and consistent association between obesity and risk of venous thromboembolism (VTE) is unknown. Leptin, a hormone synthesized and released by adipose tissue, is increased in obesity and demonstrated to have prothrombotic properties. No previous study has investigated whether plasma leptin is associated with future VTE risk or modulates the VTE risk by obesity.

Aims: To investigate whether plasma leptin is associated with future risk of VTE or a mediator of VTE risk by obesity in a nested case-control study recruited from the general population.

Methods: We performed a nested case-control study of 205 VTE cases and 502 age- and sex-matched controls recruited from a general population-based study (The Tromsø study). Body mass index (BMI) was measured at baseline, and leptin concentration was measured in thawed samples using ELISA. Logistic regression models were used to calculate ORs according to tertiles of leptin (< 10.6, 10.6-23.5, >23.5 ng/mL) and BMI (< 24.2, 24.2-27.2, >27.2 kg/m^2).

Results: Leptin levels correlated significantly with BMI (r=0.59, p< 0.001), but were not associated with risk of VTE (OR upper versus lower tertile: 1.22, 95% CI 0.73-2.06). Subjects with BMI in the upper tertile had a 1.9-fold (95% CI 1.2-2.9) higher risk of VTE than those in the lower tertile. This risk estimate increased to 2.1 (95% 1.3-3.5) after adjustment for leptin levels. A combination of high BMI and low leptin levels was associated with the highest risk of VTE. Subjects within the upper tertile of BMI and low- or mid-tertiles of leptin had a 2.7-fold (95% CI 1.2-6.1) and 3.1-fold (95% CI 1.6-6.0) increased risk of VTE, respectively, when compared to those within the lowest tertiles of BMI and leptin.

TABLE 1 Odds ratios with 95 % CIs for VTE according to tertiles of BMI and plasma leptin

BMI (tertiles, kg/m2)	Leptin (tertiles, ng/mL)	Controls	Cases	OR (95% CI)
<24.2	<10.6	87	21	Reference
<24.2	10.6-23.5	59	23	1.59 (0.76-3.34)
<24.2	>23.5	16	3	0.75 (0.20-2.93)
24.2-27.2	<10.6	55	21	1.59 (0.79-3.20)
24.2-27.2	10.6-23.5	68	29	1.73 (0.89-3.34)
24.2-27.2	>23.5	44	13	1.19 (0.51-2.74)
>27.2	<10.6	23	15	2.71 (1.20-6.08)
>27.2	10.6-23.5	44	33	3.08 (1.59-5.96)
>27.2	>23.5	104	46	1.76 (0.91-3.41)

TABLE 2 Odds ratios for VTE according to the presence of obesity (yes/no) and plasma leption below/above the median

Obesity (BMI> 30 kg/m2)	Leptin (>15.2 ng/mL)	Controls	Cases	OR (95% CI)
No	No	246	88	Reference
No	Yes	193	71	1.15 (0.74-1.81)
Yes	No	5	9	5.04 (1.64-15.46)
Yes	Yes	56	36	1.99 (1.15-3.42)

Conclusions: Our findings suggest that plasma levels of leptin neither was associated with VTE, nor mediated the VTE risk by obesity. However, subjects with dysregulation of leptin, i.e. high BMI and low leptin levels, appeared to have the highest VTE risk.

PB 1395 | Identifying a Common Biochemical Background for Thrombotic Events in Patients with Deep Vein Thrombosis (DVT) and Peripheral Artery Disease (PAD)

A.J. ten Cate-Hoek[1], S. Birocchi[2], R. van Oerle[3], S. Zeerleder[4], H. Spronk[5], B. Luken[6], H. ten Cate[7]

[1]MUMC, Thrombosis Expertise Center, Maastricht, The Netherlands, [2]Ospedale San Paolo, Internal Medicine, Milan, Italy, [3]MUMC, Laboratory of Clinical Thrombosis and Hemostasis, Maastricht, The Netherlands, [4]Academic Medical Center, University of Amsterdam, Haematology, Amsterdam, The Netherlands, [5]Maastricht University / Cardivascular Research Institute Maastricht (CARIM), Laboratory of Clinical Thrombosis and Hemostasis, Maastricht, The Netherlands, [6]Sanguine Research, Immunopathology, Amsterdam, The Netherlands, [7]MUMC, Internal Medicine, Maastricht, The Netherlands

Background: There is an increased risk for atherothrombosis following DVT. The role of neutrophil activation as contributor to arterial thrombosis in non-acute DVT is unknown.

Aims: Elucidate the role of neutrophils in patients with non-acute DVT in comparison with patients with PAD, a high risk population for atherothrombosis .

Methods: We studied 115 patients from two cohorts (75 DVT, 40 PAD). For PAD 20 patients with progressive disease, for DVT 25 patients with recurrence and 25 with Post thrombotic syndrome (PTS). Control patients were age and sex matched. Markers of neutrophil recruitment (P-selectin), activation (nucleosomes,human neutrophil elastase- **α1**anti-trypsin (HNE-AT)) and anti-inflammation (Lipoxin A4)

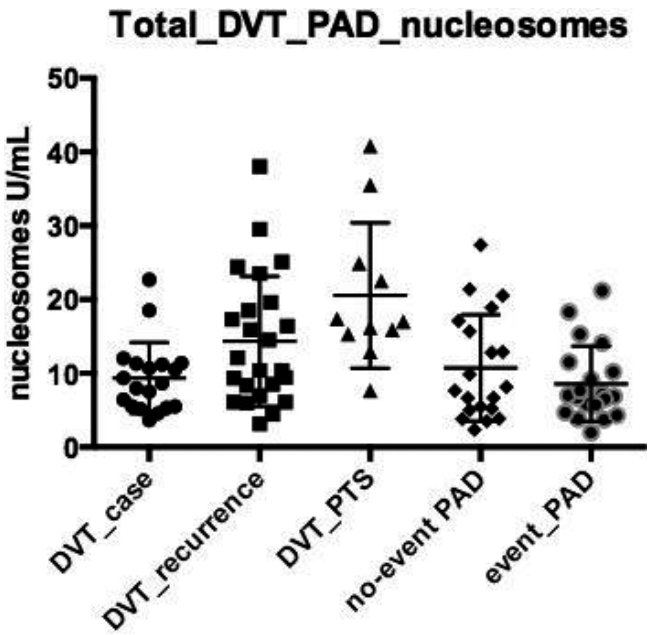

FIGURE 1 Nucleosomes

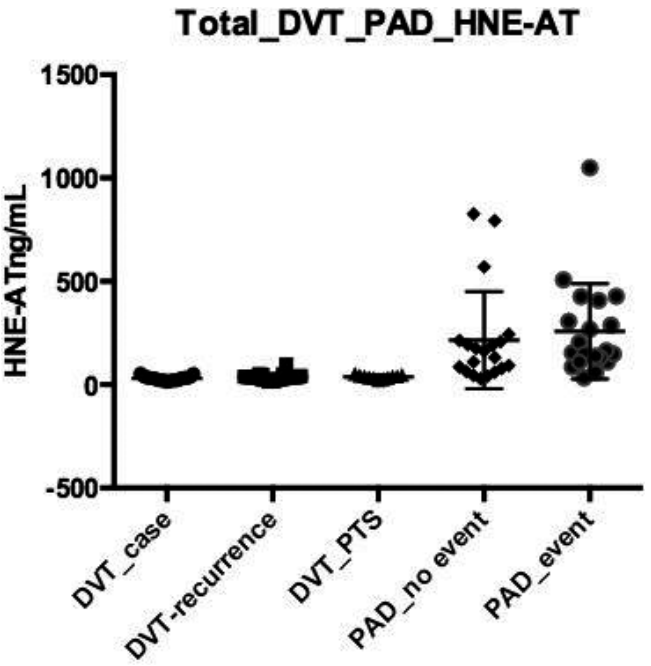

FIGURE 2 HNE-AT

were measured with ELISA. Coagulation was analysed by thrombin generation (CAT method) and D-dimer.

Results: P selectin was not different in PAD vs.DVT (p0.08). Nucleosomes differed between PAD and DVT: 7.1 (5.1-13.8) vs. 11.3 (7.4-17.7), p0.008, and were borderline significant in recurrent DVT (11.3 (7.3-19.3) vs. no recurrence 8.7(5.5-11.3), p0.07 and higher in PTS 17(15.3-14.9), p0.0002. HNE-AT was higher in PAD compared to DVT: 158(88.1-283) vs. 33.4(23.5-40.5), p< 0.0001; in PTS levels were higher: 40.4(31.3-44.6) vs. DVT without recurrence 31.1 (20.6-35.9), p=0.046. Lipoxin A4 was higher in PAD vs DVT: 35.6 (16.6-80.1) vs. 2.4(1.7-4.8), p< 0.001, but not different within DVT. TG was significantly higher for PAD compared to DVT: p=0.003. TG peak was higher in recurrent DVT: 174.5±26.0 vs. 259.6±35.3, p0.059. D-dimer levels were higher in PAD vs. DVT 550 (369-959) vs. 330 (220-550), p0.003. D-dimer was higher in both recurrent DVT (580(330-1950), p 0.008 and PTS (380(257-500), p0.0013 vs DVT without recurrence 225(199-297). D-dimer was not correlated with nucleosomes or HNE-AT.

Conclusions: Neutrophil activity is 5-fold higher in PAD and is hardly detectable in DVT. This suggests that mechanisms for atherothrombosis in DVT are unlikely to depend on neutrophil activity.

PB 1396 | Plasma Levels of miRNAs Are Associated with Risk of Cancer-related Venous Thromboembolism

I. Starikova[1,2], K. Hindberg[1], J. Oto[3], F. España[3], S. Navarro[3], S. Brækkan[1,2], P. Medina Badenes[3], J.-B. Hansen[1,2]

[1]UiT - The Arctic University of Norway, K. G. Jebsen - Thrombosis Research and Expertise Center (TREC), Department of Clinical Medicine, Tromsø, Norway, [2]University Hospital of North Norway, Division of Internal Medicine, Tromsø, Norway, [3]La Fe Sanitary Research Institute, Haemostasis, Thrombosis, Atherosclerosis and Vascular Biology Research Group, Valencia, Spain

Background: Venous thromboembolism (VTE) is a serious complication in patients with malignancies. Current markers do not allow accurate prediction of the majority of VTEs in cancer patients. Thus, there is a need to identify novel biomarkers for the risk of cancer-associated VTE.

Aims: To investigate whether the plasma miRNAs are differentially expressed in subjects who develop cancer with or without concurrent VTE during follow-up.

Methods: Participants were recruited from the Tromsø VI study. We performed a pilot nested case-control study including six subjects who developed cancer and eight subjects who developed both cancer and VTE within the first year after blood sampling. Total RNA was extracted from plasma using the miRNeasy Mini kit (Qiagen, USA) with modifications. Profiling of 179 miRNAs was conducted on the Serum/Plasma Focus MicroRNA PCR Panel (Exiqon, Denmark). miRNAs expression levels were normalized by the expression of miR-425-5p as suggested by BestRef. Statistical analyses were performed using R software (v3.2.3). Logistic regression analysis with backward selection was used to build a predictive model of risk of cancer-related VTE. The study was approved by the regional ethical committee and all participants gave their informed written consent.

Results: High quality signals of 90 miRNAs were found in all samples in both study groups. We determined three microRNAs (miR-133a-3p, miR-324-3p, and miR-421) as possible predictors of VTE in patients with malignancies. We identified the target proteins of these miRNAs.

Conclusions: In this pilot nested case-control study, we found that three plasma miRNAs could be promising markers of future risk of VTE in cancer patients. Our findings will be validated in a larger cohort.

PB 1397 | A Global Metabolomic Analysis Comparing Low-risk and High-Risk Pulmonary Embolism

O. Zeleznik[1,2], E. Poole[1,2], S. Lindstrom[3], P. Kraft[4], A. Van Hylckama Vlieg[5], B. Parry[6], N. Giordano[6], C. Kabrhel[1,6,7]

[1]Brigham and Women's Hospital, Channing Network Medicine, Boston, United States, [2]Harvard Medical School, Medicine, Boston, United States, [3]University of Washington, Epidemiology, Seattle, United States, [4]Harvard T.H. Chan School of Public Health, Epidemiology, Boston, United States, [5]Leiden University Medical Center, Clinical Epidemiology, Leiden, The Netherlands, [6]Massachusetts General Hospital, Center for Vascular Emergencies, Department of Emergency Medicine, Boston, United States, [7]Harvard Medical School, Emergency Medicine, Boston, United States

Background: To improve our understanding of the physiology of PE, we performed the first-ever global metabolomic study comparing low- and high-risk PE.

Aims: To identify metabolomic markers associated with high risk PE.

Methods: We studied 92 patients diagnosed with acute PE in an academic emergency department from 2009-12. We compared 46 high-risk PE patients with 46 age, sex and cancer-status matched low-risk PE patients. High-risk PE were lobar or more proximal, with right heart strain or a positive troponin. Low-risk PE had segmental or smaller PE, no right heart strain, negative troponin, no clinical deterioration within 5 days and no 30-day death. Blood samples were drawn within 24 hrs of PE diagnosis and processed within 60 min. We performed global metabolomic analysis using the Metabolon® DiscoveryHD4™ platform. We used Welch's two-sample *t*-test to identify biochemicals that differed across groups and Fisher's Exact Test for Metabolite Set Enrichment Analysis (MSEA) to determine pathways/metabolite categories driving differences. We calculated false discovery rates (FDR) to account for multiple comparisons.

Results: 42 metabolites differed significantly between low- and high-risk PE at p-values ≤0.05, after FDR correction. The top three are: picolinate, xanthosine and alpha-ketoglutarate. We performed a first MSEA at a global level, identifying the categories Nucleotide and Energy to be significantly enriched (FDR ≤0.05). The Amino Acid category had an FDR = 0.1. A second MSEA, focused on sub-categories, identified Fatty Acid Metabolism (Acyl Carnitine), Purine Metabolism, (Hypo)Xanthine/Inosine containing and TCA cycle at FDR ≤0.05. Methionine, Cysteine, SAM and Taurine Metabolism and Polyamine Metabolism had a FDR = 0.09.

Conclusions: Our results are the first to show that metabolites linked to energy homeostasis, polyamine synthesis, purine turnover, transsulfuration, and protein turnover differ between low- and high-risk PE patients. These findings may be useful in risk-stratifying PE.

PB 1398 | Changes in the Fibrinolytic Status and Cardiovascular Profile in Obese Patients Undergoing Bariatric Surgery

A. Marco, P. Marco

General University Hospital, Haematology Service, Alicante, Spain

Background: Obesity is characterized by chronic inflammation, impaired fibrinolysis and the presence of cardiovascular risk factors (CVRF). Proinflammatory cytokines contribute to endothelial dysfunction and an increase in the expression of plasminogen activator inhibitor-1 (PAI-1) and thrombin activatable fibrinolysis inhibitor (TAFI). Bariatric surgery induces and improvement in the haemostasis and the CVRF. However, it is not well-known how these markers are modified after the bariatric surgery.

Aims:

- To assess the changes in PAI-1 and functional TAFI once completing the fasting phase and after the bariatric surgery
- To evaluate the impact in the prothrombotic state induced by the obesity.

Methods: We designed a prospective study including obese patients undergoing bariatric surgery in our institution from May 2014 to July 2015. All patients have signed the informed consent and the study was approved by the local ethics committee. We have obtained blood samples for PAI-1 and TAFI study at enrolment, once completing the fasting phase, 1 month and 6 months after the bariatric surgery. In addition, we have evaluated the main CVRF at inclusion and 6 months after the surgery. All the patients received antithrombotic prophylaxis with pneumatic compression and enoxaparin 60 mg once daily

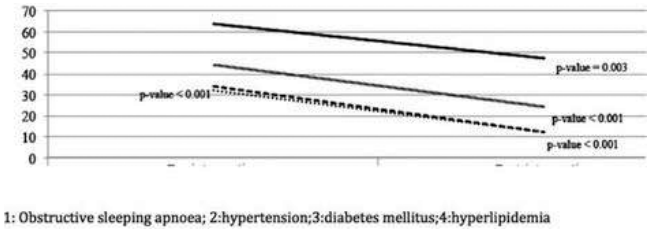

FIGURE 1 Changes in CVRF after the bariatric surgery

for 1 month following the operation. A p value< 0.05 had statistical significance.

Results: We studied 91 patients with a mean age of 45±10.7 years (72% women). The mean body mass index was 49.7 ±7.2kg/m^2. We have observed a reduction in PAI-1 along the visits (p=0.009). In the same way, a TAFI reduction not only after the fasting phase but after the surgery has been detected (p< 0.001). No thrombosis has been documented. The CVRF strongly improved after the surgery (p< 0,001) (see figure).

Conclusions: The massive loose weight implies an improvement in the fibrinolytic balance and a correction of CVRF in a high number of patients. These changes contribute to a reduction in the thrombotic risk development.

PB 1399 | Evaluation of Risk Factors for Postpartum Hemorrhage after Vaginal Delivery in Uncomplicated Pregnancy

K. Nishioka[1], N. Furukawa[2], K. Horie[1]

[1]*Yamatotakada Municipal Hospital, Nara, Japan,* [2]*Nara Prefecture Western Medical Center, Obstetrics and Gynecology, Nara, Japan*

Background: Postpartum hemorrhage (PPH) is the leading cause of maternal morbidity after a vaginal delivery. As most coagulation factors increase during normal pregnancy, the prothrombin time (PT) and the activated partial thromboplastin time may be decreased, but the association between PPH and the coagulation profile is unclear.

Aims: The present study aimed to identify risk factors for PPH in uncomplicated pregnancies.

Methods: Our retrospective cohort study included 396 pregnant women without complications from two institutions between Jan 1, 2015 and Dec 31, 2016. The logistic regression model was used to evaluate univariate and independent multivariate associations of the clinical parameters with PPH
(blood loss >800 ml).

Results: The incidence of PPH > 800ml was 11.6% (46/396). Univariate analysis using the logistic regression model revealed that PT/INR at 36-37 weeks of gestation, multipara, birth weight > 3000g, and episiotomy or laceration were significantly associated with PPH. Multivariate analysis revealed that independent risk factors for PPH were PT/INR, episiotomy or laceration, and birth weight (p= 0.0022, 0.0032, and 0.0132, respectively). Based on receiver operating characteristic analysis, the cut-off value of PT/INR level to predict PPH >800ml was 1.03.

Conclusions: The findings of the present study indicated that risk factors for PPH > 800ml were PT/INR at 36-37 weeks of gestation, episiotomy or laceration, and birth weight > 3000 g. A PT/INR value at 36-37gestational weeks > 1.03 is an independent predictor of severe PPH.

PB 1400 | Analysis of the Substrate Specificity of Factor VII Activating Protease (FSAP) and Design of a Specific and Sensitive Peptide Substrate

E. Kara[1], D. Manna[1], G. Åge Løset[1], E. Schneider[2], C. Craik[2], S. Kanse[1]

[1]*University of Oslo, Oslo, Norway,* [2]*University of California San Francisco, San Francisco, United States*

Background: Factor VII (FVII) activating protease (FSAP) is a circulating serine protease which is likely to be involved in a number of disease conditions such as stroke, atherosclerosis, liver fibrosis, thrombosis and cancer. To date, no systematic information is available about the substrate specificity of FSAP.

Aims: To characterize the substrate specificity of FSAP using multiple approaches and to design specific and sensitive FSAP probes to measure its activity in plasma.

Methods: We have characterized the specificity of FSAP towards small peptides using phage display and positional scanning substrate combinatorial library (PS-SCL) approach. Results were compared with known protein substrates and molecular modelling of the peptides in the active site of FSAP was performed. Novel fluorescent substrates were tested for sensitivity, specificity and suitability for the measurement of endogenous FSAP activity in plasma.

Results: The representative FSAP-cleaved sequence obtained from the phage display method was Val-Leu-Lys-Arg-Ser (P4-P1'). The sequence X-Lys-Nle-Arg (P4-P1) was derived from the PS-SCL method. These results show a predilection for cleavage at a cluster of basic amino acids on the nonprime side. Molecular modelling studies showed a preference for Arg over Lys at the P1 site. Based on these data a fluorescent substrate (Ala-Lys-Nle-Arg-AMC) was synthesized with a 10-fold higher selectivity for FSAP compared to other proteases from hemostasis. This substrate could be used to measure FSAP activity in plasma. In histone-treated plasma FSAP was strongly activated as validated by the use of an inhibitory antibody.

Conclusions: Natural FSAP substrates as well as small peptide substrates are preferentially cleaved in regions rich in basic amino acids. Development of FSAP activity probes shows a specific activation by histones that may contribute to the latter's hemostasis-related effects. These novel data will help to elucidate the role of FSAP in vivo.

PB 1401 | Von Willebrand Factor Propeptide May Identify the Patients Susceptible for Renal Dysfunction in Collagen Disease

N. Yada[1], M. Matsumoto[2], K. Sakai[2], M. Hayakawa[2], T. Fujimura[3], T. Fujimoto[3], S. Ono[1], K. Yoshimoto[1], Y. Urizono[4], K. Nishio[1]

[1]Nara Medical University, Department of General Medicine, Kashihara, Japan, [2]Nara Medical University, Department of Transfusion Medicine, Kashihara, Japan, [3]Nara Medical University, Department of Rheumatology, Kashihara, Japan, [4]Nara Medical University, Department of Emergency and Critical Care Medicine, Kashihara, Japan

Background: VWF propeptide（VWF pp）is cleaved from mature von Willebrand factor (VWF) just before secretion and released from endothelial cell. Since VWF pp has a shorter half-life and is less involved in maintaining physiological homeostasis than VWF, it has been proposed to be a better predictor of acute vascular endothelial dysfunction.

Aims: To investigate whether VWF pp levels discriminate among collagen diseases and predict subsequent renal dysfunction.

Methods: The patients diagnosed as collagen disease from January 2007 to March 2015 were investigated. We evaluated the plasma levels of VWF pp, VWF antigen (VWF), ADAMTS13 antigen (ADAMTS13) at diagnosis using ELISA, and subsequent renal function including eGFR and urine findings (protein and hematuria).

Results: Sixty eight patients were diagnosed as collagen diseased; systemic lupus erythematosus (SLE, n=10), Systemic scleroderma (SSc, n=12), Sjögren´s syndrome (SS, n=19), rheumatoid arthritis (RA, n=27). Mean value of VWF pp was 329±85% (mean ± SD) in SLE, 195±63% in SSc, 179±60% in SS, 186±120% in RA. VWF pp in SLE was significantly higher than that in others, but there were no differences among groups in VWF and ADAMTS13. Also, higher levels of VWF pp were observed in patients who developed renal dysfunction including reduced eGFR by over 25%, proteinuria, or hematuria.

Conclusions: We speculated that increased plasma VWF pp levels in SLE may reflect vascular endothelial dysfunction due to vasculitis, and found that VWF pp may be a more sensitive early indicator of renal dysfunction than VWF and ADAMTS13. VWF pp may identify the patients with vasculitis and susceptible for renal dysfunction in collagen disease.

PB 1402 | Age-related Diagnostic Value of D-dimer Testing and the Role of Inflammation in Patients with Suspected Deep Vein Thrombosis - Results from the VTEval Study

J. Prochaska[1], B. Frank[2], M. Nagler[2], H. Lamparter[2], G. Weißer[3], A. Schulz[4], L. Eggebrecht[4], S. Göbel[5], N. Arnold[3], M. Panova-Noeva[2], I. Hermanns[6], A. Pinto[4], S. Konstantinides[7], H. ten Cate[7,8], K. Lackner[9], T. Münzel[10], C. Espinola-Klein[3], P. Wild[11]

Background: While previous reports have focused on the impact of age on D-Dimer testing in elderly individuals with suspected deep vein thrombosis (DVT), data on the age-related diagnostic value of D-dimer in a sample covering a broad age range are limited.

Aims: To assess the age-dependent diagnostic performance of D-dimer in patients with suspected DVT.

Methods: In the VTEval project (NCT02156401), patients ≥18 years with suspected DVT underwent a standardized investigation plan including assessment of biomarker concentrations and compression duplex ultrasound. In the present study, the diagnostic accuracy of D-dimer was investigated in young and elderly patients and compared to C-reactive protein (CRP).

Results: In 231 of 500 patients, proximal DVT (N=111) and isolated distal DVT (N=120) were diagnosed. Sensitivity of D-dimer was lower in patients < 60 years in comparison to patients ≥60 years (Δ-16.8%), whereas specificity was 27.9% higher. In patients < 60, lowest sensitivity was detected for female sex (69.0%, 95% confidence interval (CI) 52.9%/82.4%), unprovoked DVT (69.0%, 95%CI 52.9%/82.4%) and low thrombotic burden (61.1%, 95%CI 46.9%/74.1%), and distal DVT (60.9%, 95%CI 45.4%/74.9%). In contrast to the established cut-off (0.5mg/L FEU) and an age-dependent threshold (age/100mg/L FEU), a fixed D-dimer threshold of 0.25mg/L FEU resulted in elevated sensitivity for patients < 60 with a reduction of false negatives by 40.0% for proximal DVT and by 50.0% for distal DVT. D-dimer and CRP demonstrated comparable diagnostic performance for proximal ($AUC_{D\text{-}dimer}$=0.843 vs. AUC_{CRP}=0.832) and distal DVT ($AUC_{D\text{-}dimer}$=0.674 vs. AUC_{CRP}=0.667) in patients < 60 years.

Conclusions: This study highlights clinically-relevant limitations of D-dimer testing in young patients with suspected DVT and the role of inflammation in venous thrombosis.

PB 1404 | Characterization of a Transient Procoagulant Phenotype Induced by Recombinant Activated Factor VII (rFVIIa)

H. Rühl, C. Berens, F.I. Winterhagen, J. Müller, J. Oldenburg, B. Pötzsch

University Hospital Bonn, Experimental Hematology and Transfusion Medicine, Bonn, Germany

Background: In a significant proportion of patients with unprovoked venous thromboembolism (VTE) no laboratory risk factors are found. Monitoring a standardized and limited activation of coagulation in these patients could presumably help to identify intermediary phenotypes in VTE. Promising biomarkers to detect subclinical changes of the hemostatic activation status are plasma levels of active enzymes including thrombin and activated protein C (APC).

Aims: To characterize a physiological phenotype of coagulation activation in healthy individuals as a prerequisite for the characterization of a thrombophilic phenotype.

Methods: Limited activation of extrinsic hemostasis was induced by i.v. injection of rFVIIa (15 µg/kg) into 12 healthy volunteers (6 males). rFVIIa-induced hemostatic activation was monitored by measuring plasma levels of free thrombin and APC at baseline and repeatedly during a 24 h lasting follow-up period using oligonucleotide-based enzyme capture assays (OECA). In addition, prothrombin fragment F1+2 (F1+2), thrombin-antithrombin complex, plasmin-α2-antiplasmin complex, soluble fibrin monomer (sFM), and D-dimer were determined.

Results: rFVIIa was well tolerated, and its elimination kinetics showed an expected course in all probands. Median APC plasma levels of 35 (IQR: 28-68) pg/ml were measured at baseline. Following rFVIIa injection, a consistent and highly significant increase of APC was observed in samples taken between t=10 min and t=5h with a peak of 164 (139-194) pg/ml at t=1h (p=0.0003). Among the other biomarkers, only F1+2 showed an increase from baseline (125, 87-188 pmol/l) that became statistically significant (p=0.03) at t=2h (179, 111-200 pmol/l). Levels of D-dimer and sFM remained unchanged and within normal ranges at all sampling points.

Conclusions: APC appears to be a promising candidate to discriminate between a physiological and a thrombophilic response to rFVIIa-induced hemostatic activation, which we currently evaluate in carriers of thrombophilic mutations.

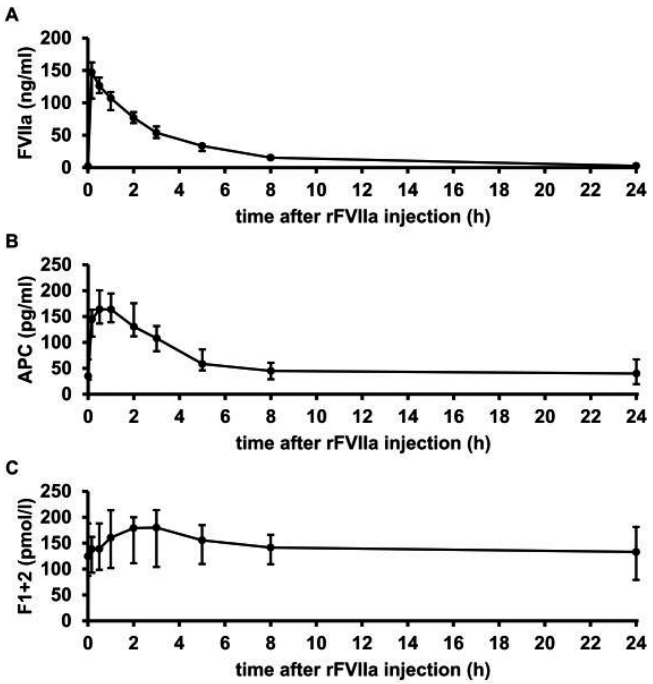

Fig.1: Plasma levels (median, IQR) of (**A**) FVIIa, (**B**) APC, and (**C**) F1+2 in 12 healthy subjects before (t = 0) and after injection of 15 µg/kg rFVIIa.

FIGURE 1 Plasma levels of FVIIa, APC, and F1+2 in healthy subjects before and after injection of rFVIIa

PB 1405 | The Effects of Shear Stress on Platelet Activation and Incipient Clot Characteristics: Exploring the Mechanisms of Shear Induced Clot Formation

R. Hambly, B. Thomas, C. Thornton, P.R. Williams, K. Hawkins

Swansea University, Swansea, United Kingdom

Background: Shear flow is known to modulate the kinetics of fibrin polymerization leading to changes in clot microstructure. It has been widely reported that clot microstructure plays a pivotal role in a variety of diseased states and dictates susceptibility to fibrinolysis. A possible mechanism for altered clot microstructure as a consequence of shearing is its direct effect on individual platelets that provide a surface for enhanced thrombin generation.

Aims: The objective of the study was to investigate the links between platelet activation and resultant clot microstructure in blood that has been exposed (in vitro) to shear stresses, the latter being assessed by a novel rheological biomarker. This aims to provide insight into the mechanisms of clotting during its earliest stage of formation.

Methods: Samples of human blood, Platelet Rich Plasma and Platelet Poor Plasma were subjected to different levels of shear stress for fixed periods using an AR-G2 Rheometer. Flow cytometry was used to measure platelet activation. Rheometry was further utilised to measure incipient clot formation, in terms of a fractal dimension (a biomarker of clot complexity) in order to quantify the microstructural characteristics of the underlying fibrin network.

Results: The results show that subjecting blood to relatively high levels of shear rate (>1000 s-1) leads to a decrease in the time to incipient clot formation, an increase in fractal dimension and an increase in platelet activation. However, at intermediate levels of shear rate (*ca* 100 s-1 to 1000 s-1), an increase in fractal dimension is observed in the absence of any increase in platelet activation.

Conclusions: Alternative mechanisms other than enhanced activation of platelets may be responsible for differences in incipient clot formation as a result of exposure of blood to shear. The results have importance for understanding clotting in blood that has been subjected to elevated levels of shear such as in diseased states associated with atherosclerosis and in stenotic vessels.

PB 1406 | VWF and ADAMTS13 Levels in Early Onset Preeclampsia: Prothrombotic Mechanisms in Mothers with Elevated Risk of Venous Thromboembolism

T. McKinnon[1], K. Egan[2], L. Ghribi[1], P. Henne[1], R. Griffin[1], H. O'Conner[3], J. Donnelly[3], C. Monteith[3], P. Maguire[4], P. Szklanna[5], S. Allen[2], F. Ní Áinle[2]

[1]Imperial College London - Hammersmith Hospital Campus, London, United Kingdom, [2]University College Dublin/School of Medicine and Medical Science, Dublin, Ireland, [3]Rotunda Hospital, Dublin, Ireland, [4]UCD Conway Institute, School of Biomolecular and Biomedical Science, University College Dublin, Dublin, Ireland, [5]UCD Conway Institute, UCD School of Medicine, University College Dublin, Dublin, Ireland

Background: Preeclampsia (PE) is a serious complication of pregnancy with potentially life-threatening consequences for both mother and baby. Early onset preeclampsia (EOPE; onset < 34 gestational weeks), is associated with higher maternal and fetal risks than late onset PE. The risk of venous thromboembolism is increased, particularly in severe PE. Consequently, mothers may be considered for thromboprophylaxis. However, risk assessment may be challenging due to complicated by competing bleeding risks such as placental abruption, post-partum haemorrhage, or renal impairment.

Aims: To characterise the relationship between VWF and ADAMTS13 levels in EOPE patients in order to better understand parameters that may modulate thrombotic and bleeding risk.

Methods: Plasma samples obtained from healthy pregnancy (HP) or PE were compared to healthy control (HC) females. Plasma VWF and ADAMTS13 levels were determined by VWF and ADAMTS13 ELISA. ADAMTS13 activity was measured using FRETS73.

Results: Mean plasma VWF levels were significantly (p=0.0001) elevated in pregnancy and further significantly (p=0.0008) increased in PE (HC = 110%, HP = 240%, PE = 380%). In contrast, plasma ADAMTS13 levels were significantly decreased in pregnancy (p=0.0019) and PE (p=0.05) when compared to HCs. (HC = 100%, HP = 36%, PE = 20%). While severity of PE did not correlate with VWF levels, the lowest ADAMTS13 levels and activity was observed in patients with severe PE. Moreover the VWF/ADAMTS13 was calculated to be lowest in patients with severe PE.

Conclusions: PE is associated with highly elevated plasma VWF and decreased ADAMTS13 levels and activity. In combination with other parameters including thrombin generation and platelet function, these data are of relevance to understanding overall haemostatic balance in high-risk pregnant mothers with EOPE.

PB 1407 | Changes in Thrombin Generation in Obese Patients Undergoing Bariatric Surgery: Improvement in the Hypercoagulable Status

A. Marco, P. Marco

General University Hospital, Haematology Service, Alicante, Spain

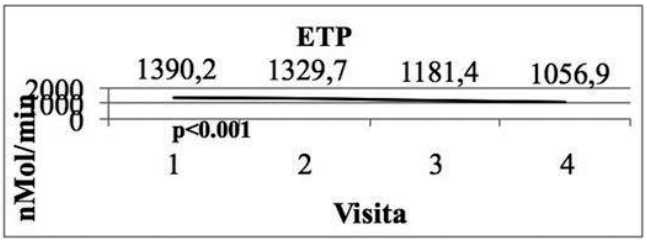

FIGURE 1 Changes in ETP

Background: Obesity modifies the haemostasis, leading to a hypercoagulable state. Bariatric surgery induces a massive loose weight, improves cardiovascular risk factors and the haemostatic parameters. These changes imply an improvement in the inflammation status, and haemodinamic parameters as well, reducing the cardiovascular events.

Aims: The aim of this study is to evaluate the changes in the thrombin generation parameters and F1+2 prothrombin fragment once completing the fasting phase and after the bariatric surgery.

Methods: We have designed a prospective study including obese patients candidates to bariatric surgery enrolled in our institution from May 2014 to July 2015. All patients have signed the informed consent and the study was approved by the local ethics committee. The following parameters were measured: 1) F1+2 (µmol/l), 2) Lag time (LT, seconds), 3) Peak of thrombin (PMAX, nmol), 4) Time to peak (TPEAK, seconds), 5) Endogenous thrombin potential (ETP, nmol x minute), 6) Start tale (ST, seconds). All the patients received antithrombotic prophylaxis with pneumatic compression and enoxaparin 60 mg once daily for 1 month following the operation. A p value< 0.05 had statistical significance.

Results: We have studied 91 patients with a mean age of 45±10.7 years, 72% of them were women. The mean body mass index was 49.7 ±7.2 kg/m^2. We have observed a reduction in ETP, PMAX, TPEAK and ST throughout the scheduled visits (p< 0.001). However, no LT reduction has been documented, but it had no clinical impact (p:0.412). Regarding F1+2, in the same way, we have also documented a progressive reduction not only following the bariatric surgery but also once completing the fasting phase.

Conclusions: The weight loose induced by bariatric surgery has evidenced a clear reduction in thrombin generation. These changes contribute to an improvement of the hypercoagulable status of the obesity. This improvement together with a favourable cardiovascular risk profile minimizes the thrombus development.

PB 1408 | Combined Detection of Factor XIII and D-Dimer Is Helpful for Differential Diagnosis in Patients with Suspected Pulmonary Embolism

N. Tang

Tongji Hospital, Clinical Laboratory, Wuhan, China

Background: D-dimer has been used to rule out pulmonary embolism (PE). Previous authors have reported decreased concentration

of coagulation factor XIII (FXIII) in venous thromboembolism, and no change in the FXIII concentration in patients with acute cardiovascular disease. we speculated that combined detection of the FXIII and D-dimer concentrations might be useful to distinguish PE from cardiovascular disease, such as acute coronary syndrome (ACS) and aortic dissection (AD).

Aims: We evaluated the contribution of measurement of the combination of the D-dimer and FXIII concentrations to the diagnosis of PE.

Methods: In this prospective single-center study, 209 patients initially suspected to have PE were enrolled, D-dimer and FXIII concentrations of each patient were detected. Forty-oneof them were diagnosed with PE and 168 with other final diagnoses, including ACS; AD; spontaneous pneumothorax (SP); other respiratory, heart, digestive and nervous diseases; and uncertain diagnoses.

Results: Patients with PE had significantly higher D-dimer and lower FXIII concentrations than patients without PE. At the best-fit cut-off value of 65.0%, the sensitivity and specificity of FXIII concentrations for PE were 88.2% and 81.9%, respectively. Specifically, patients with AD or ACS showed a higher FXIII concentration and mean platelet volume than did patients with PE or SP, and patients with PE and AD had higher D-dimer concentrations than did other patients. At the thresholds of 69% for FXIII and 1.10 μg/mL for D-Dimer, 123 of 151 patients (81.5%) with serious diseases (PE, AD, ACS and SP) were correctly distinguished.

Conclusions: The combination of D-dimer and FXIII measurement seems to be helpful in distinguishing PE from serious diseases with similar symptoms, likely because of increased FXIII release from active platelets in cardiovascular disease.

PB 1409 | Clinical Significance of Circulating Endothelial-derived Microparticles and Coagulation Profiles in Patients with Advanced Solid Tumors

S. Der Sheng[1], H.K. Lee[2], Y. Kim[2], H.S. Won[1], Y.H. Ko[1], H. Kim[2]

[1]Uijeongbu St. Mary's Hospital, the Catholic University of Korea, Medical Oncology, Department of Internal Medicine, Uijeongbu, Korea, Republic of, [2]Uijeongbu St. Mary's Hospital, the Catholic University of Korea, Laboratory Medicine, Uijeongbu, Korea, Republic of

Background: Venous thromboembolism (VTE) is a frequent and clinically important issue in patients with cancer. Early and proper risk estimation and diagnosis are important for the prevention and treatment of VTE. Circulating microparticles (MP) are known to provide a catalytic surface for the assembly of blood coagulation factors, and are therefore associated with thrombotic conditions.

Aims: This study was aimed to investigate the clinical significance of endothelial-derived MP (EMP) and platelet-derived MP (PMP) in patients with advanced cancer.

Methods: Patients newly diagnosed with cancer, who were scheduled to receive chemotherapy, were enrolled in this study. D-dimer, fibrinogen, fibrin degradation product (FDP), prothrombin time (PT), activated partial thromboplastin time (aPTT), protein C, and protein S levels were defined as CD41+/Annexin V+ and CD31+/Annexin V+ particles, respectively. Development of VTE was monitored for one year after diagnosis.

Results: 67 cancer patients were enrolled. In the cancer stages, 2 were stage II , 8 were stage III and 57 were stage IV of enrolled population. 10 of 67 (14.9%) patients developed VTE during the first year period after diagnosis. D-dimer levels were significantly higher in cancer with VTE (7.1±10.4 mg/L) than those of cancer without DVT (2.4±2.7 mg/L), (P=0.005). EMP (%) were significantly higher in cancer with VTE (33.1±17.2%) than in cancer without VTE (22.3±15.4%), (p=0.04). PMP (%) were higher in cancer with VTE (36.6±15.3%) than in cancer without VTE (31.3±17.9%); however, statistical significance was not shown (p=0.38). Both EMP and PMP were significantly associated with levels of D-dimer (p=0.002 and p=0.04) and FDP (p=0.0007 and p=0.03), respectively.

Conclusions: EMP are increased in cancer with VTE. Both EMP and PMP were significantly associated with levels of D-dimer and FDP. EMP and PMP are procoagulant markers and may help to predict VTE in patients with tumors.

PB 1410 | Markers of Neutrophil Extracellular Traps in Patients with Thrombosis and Sepsis

L. Cavanaugh[1], K. Lee[1,2], H. Leung[2], F. Yan[2], Z. Ahmadi[2], B. Chong[1,2], F. Passam[2]

[1]St George Hospital, Haematology, Sydney, Australia, [2]University of New South Wales, Medicine, St George Clinical School, Sydney, Australia

Background: Neutrophil extracellular traps (NETs) are networks of extracellular fibres produced from neutrophil DNA with a pathogenic role in infection and thrombosis. Reliable assays for measuring NETs are desirable as novel treatments targeting NETs are being explored for the treatment of these conditions.

Aims: To quantitate serum markers of NETs in septic and thrombotic patients for potential diagnostic and monitoring purposes.

Methods: Serum markers were measured in 21 healthy controls, 18 patients fulfilling the sepsis criteria and 23 patients with radiologically confirmed thrombosis within 3 days of the diagnosis. Informed consent was received from all participants and the study was approved by local Research Ethics.

Serum double stranded (ds) DNA and DNAse were measured by fluorometric assay. Myeloperoxidase, myeloid-related protein (MRP), nucleosomes and elastase were measured by ELISA. Production of reactive oxygen species (ROS) by donor platelets incubated with patient serum was quantified by the 2',7'dichlorofluorescein diacetate fluorometric assay. Serum markers were compared by Mann-Whitney test.

Results: There is a significant increase in dsDNA, MRP, DNase and ROS production in patients with sepsis and thrombosis compared with healthy controls (p< 0.005). Serum myeloperoxidase is significantly increased in patients with thrombosis compared with healthy controls

but not in sepsis patients. Neutrophil elastase is significantly increased in patients with sepsis (545 +/- 141 ng/mL) compared with healthy controls (198 +/- 37 ng/mL) but not in thrombosis (291 +/- 59 ng/mL). Serum nucleosomes did not show a difference between patient groups and controls.

Conclusions: Serum markers of NET are a simple method of quantifying NETotic burden in patients with thrombosis and sepsis. The differential expression of myeloperoxidase in thrombosis patients and neutrophil elastase in sepsis patients may reflect the difference in pathogenesis of NETs in these two conditions.

PB 1411 | A Quantitative Clot-based Assay for Antithrombin Activity

B. Woodhams[1], S. Gavasso[2], W. Calhoon[3], L. Spiezia[2], E. Campello[2], M. Morris[4], P. Simioni[2]

[1]Haemacon Ltd, Hawkinge, Folkestone, United Kingdom, [2]University of Padua Medical School, Department of Medicine, Padua, Italy, [3]R2 Diagnostics, R&D, South Bend, United States, [4]R2 Diagnostics, South Bend, United States

Background: Antithrombin (AT) is the primary physiologic inhibitor of the active coagulation enzymes thrombin and activated Factor X (FXa). The inhibitory effect of AT is enhanced in the presence of glycosoaminoglycans such as heparin. To date assays for AT are chromogenic based on the use of either a FXa or thrombin specific chromogen.

Aims: We report here on a simple clot based assay that involves both FXa and thrombin.

Methods: Test plasma is diluted with buffer, mixed with antithrombin deficient plasma and a silica based activated partial thromboplastin time reagent with added exogenous heparin, and incubated at 37C. The reaction is initiated with 0.025 M calcium chloride, and the time to clot formation is recorded. The time to clot formation is proportional to the amount of AT in the patient sample.

Results: The reagents are stable for 24hr at 2-8°C. The assay is linear from 0% AT to 150% AT with all r^2 greater than 0.990. The limit of detection is 11%. No interference was seen in icteric, lipaemic or haemolysed samples up to 20mg/dl of unconjugated bilirubin, 2,000 mg/dl of triglyceride or 500mg/dl of bilirubin. Unfractionated heparin in the patient sample up to 1IU/mL showed no interference in the assay. Samples from a normal patient (n=40) and samples from patients suspected of having an AT deficiency (n=50) were assayed using this assay and the results were compared with results obtained using a commercial AT assay. Good comparison was obtained with this assay (y=1.054x + 0.886). No deviation in result was observed with any of the samples tested.

Conclusions: We conclude that we have a sensitive clot based assay that can be used for AT assays. The assay can be performed on any coagulation instrument even the simplest clot only instruments. We have successfully performed the assay on a range of instruments of different complexity. We can conclude that this assay can be performed in even the most basic of coagulation laboratories.

PB 1412 | Identification of microRNAs as Biomarkers for Predicting the Risk of Venous Thromboembolism

J. Gabler, O. Steinbrecher, M. Kollars, P. Kyrle, S. Eichinger

Medical University of Vienna, Department of Medicine I, Vienna, Austria

Background: Venous thromboembolism (VTE) is a multicausal disease with a high risk of recurrence. Currently available risk models are not predictive enough to assess either the risk of a first or a recurrent VTE in an individual patient. To improve risk assessment of VTE, more appropriate biomarkers are needed. Recently, circulating microRNAs (miRs) have attracted attention in their disease predictive value and emerged as a promising class of biomarkers.

Aims: Up to now, information on VTE-related miRs is limited which hampers our understanding of the role of these short RNAs and options to use them as tools in the management of patients with VTE. Therefore, our purpose was to identify miRs which are clinically useful biomarkers of VTE.

Methods: To generate an important and convincing miR database, a plasma pool from 20 patients with a high thrombotic risk (male, history of two unprovoked VTE, mean age 48) and one pool of age-matched healthy men were subjected to miR expression analysis. The Affymetrix miRNA Microarray includes 2.578 human miR samples, which cover the majority of all thus far known human miRs

Results: By miR expression analysis we identified 5 miRs which were exclusively detected in the plasma pool of VTE patients and 23 in the control pool, whereas 55 miRs were detected in all samples (Fig. 1). miRs which were exclusively detected in the plasma pool of VTE patients or the controls were just moderately expressed. The miR expression analysis also showed that the levels of miR-3613-3p and miR-6126 of VTE patients were higher (≥2-fold) than those of controls, whereas nine miRs showed lower levels (≤2-fold).

Conclusions: Plasma miRs could be reliable candidates for the development of minimally invasive biomarkers for predicting the risk of VTE. Moreover, these VTE-related miRs could provide a basis for further research of the molecular mechanism underlying the pathomechanism of VTE.

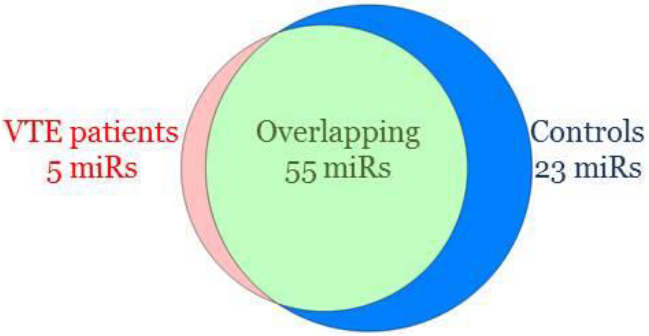

FIGURE 1 Venn diagram of differential and overlapping expression of miRs in patients with a high thrombotic risk and matched controls

PB 1413 | Platelet Counts and Plateletcrit are Associated with an Increased Risk of Venous Thrombosis in Females. Results from the RETROVE Study

M. Vázquez-Santiago[1,2], N. Vilalta[1], A. Ziyatdinov[2], B. Cuevas[1], R. Macho[1], N. Pujol-Moix[1], M. Carrasco[1], J. Mateo[1], J. Fontcuberta[1], J.M. Soria[2], J.C. Souto[1]

[1]Hospital de la Santa Creu i Sant Pau, Unitat d'Hemostàsia i Trombosis, Barcelona, Spain, [2]Sant Pau Institute of Biomedical Research (IIB-Sant Pau), Unit of Genomics of Complex Diseases, Barcelona, Spain

Background: Platelets play a role in the pathophysiology of arterial and venous thrombosis (VTE). Several studies have associated cardiovascular risk with high platelet counts. However, the association of these platelet parameters with VTE remains unclear.

Aims: The aim of our study was to evaluate the thrombotic risk in patients with VTE related to the platelet counts (PLT, PLTOP) and plateletcrit (PCT).

Methods: RETROVE (Riesgo de Enfermedad TROmboembólica VEnosa) is a Spanish case-control study which include 400 adult patients (over 18 years old) with VTE and 400 healthy volunteers. The platelet parameters were determined with an analyser Sysmex XE-2100® (Roche Diagnostics, Switzerland). The Mann-Whitney and Chi-square tests were used to evaluate differences. The platelet values over the 90th percentile were considered risk factors. To evaluate the *odds ratio* (OR) and 95% confidence interval (CI) for the risk of VTE, we used an unconditional logistic regression analysis for the platelet parameters (over 90th percentile). We analysed three OR models: not adjusted model (model 1); age and gender adjusted model (model 2) and; age, gender, BMI, hypertension and the risk factor VIII and von Willebrand factor (over 215.6% and 183%) levels (model 3).

Results: We did not find any significant difference between patients and controls for the platelet parmeters. However, in females, the platelet counts over 326·10^{9}/L showed an OR of 2.27 (95% CI, 1.22–4.29). Plateletcrit over 0.34% showed an OR of 2.24 (95% CI, 1.22–4.16).

Notably, no risk of VTE was found for elevated the platelet counts in males.

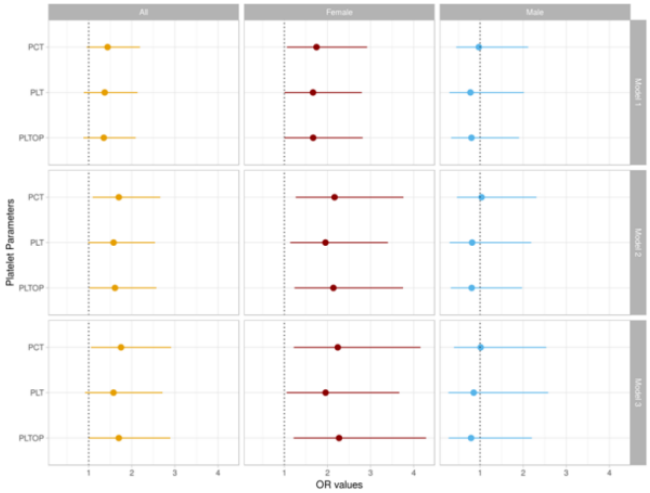

FIGURE 1 Risk of venous thromboembolism (VTE) for 3 platelet parameters in the sample, females and males following the three models.

Conclusions: In females, high platelet counts and plateletcrit (even within the reference clinical range) were associated with a double risk of VTE.

We believe that our results provide a firm foundation for additional studies which might be confirm our observations that high platelet counts are predictors of VTE risk in females.

Grants: FIS PI12/00612, RIC RD12/0042/0032 and FIS PI 15/0269.

PB 1414 | Plasma Levels of miRNAs Are Associated with Future Risk of Incident Venous Thromboembolism

Background: Circulating miRNAs are emerging as a prominent class of biomarkers in many diseases. Previous studies reported differential expression patterns of certain miRNAs in venous thromboembolism (VTE). In these reports, differentially expressed miRNAs could be a consequence of the disease rather than a cause. No study has prospectively evaluated the association between the expression of plasma miRNAs and risk of future VTE.

Aims: To investigate whether plasma levels of miRNAs are differentially expressed in subjects with and without incident VTE during follow-up.

Methods: We conducted a pilot nested case-control study including 19 subjects who developed VTE within 3 years after blood sampling and 19 age- and sex-matched healthy controls recruited from the general population (Tromsø VI survey). Total RNA was extracted from plasma using the miRNeasy Mini kit (Qiagen, USA) with modifications. Screening of 179 miRNAs was performed on a Serum/Plasma Focus microRNA PCR panel (Exiqon, Denmark). miRNAs expression levels were normalized by the expression of miR-425-5p as suggested by BestRef. Statistical analyses were performed in R software (v3.2.3). We used logistic regression with backward selection to build a predictive model of incident VTE. The study was approved by the regional ethical committee and all participants gave their informed written consent.

Results: High quality signals from 61 miRNAs were identified in all 38 plasma samples. Plasma levels of nine miRNAs, namely, miR-328-3p, miR-208a-3p, miR-629-5p, miR-15a-5p, miR-451a, miR-199a-3p, miR-363-3p, miR-20b-5p, miR-223-5p were found to be associated with future risk of incident VTE.

Conclusions: In this pilot nested case-control study, we found nine plasma miRNAs that could be important markers of future risk of incident VTE in the general population. Currently, these miRNAs are included in a larger-scale validation study.

PB 1415 | The Blood Components Strongly Affect Thrombus Structure Formed in a Novel Microfluidic Device

N. Sugita[1], H. Hirakata[2], K. Inoue[2], K. Tatsumi[3], S. Ii[4], H. Niioka[4], S. Wada[4], K. Koike[2]

[1]Kyoto University Hospital, Psychiatry, Kyoto City, Japan, [2]Kyoto University Hospital, Emergency Medicine, Kyoto City, Japan, [3]Kyoto University, Engineering, Kyoto City, Japan, [4]Osaka University, Mechanical Science and Bioengineering, Toyonaka, Japan

Background: Venous thromboembolism (VTE) is a major cause of sudden death. Prevention is still hard for lacking understanding of mechanical property of thrombus, that should be important because fatal VTE is caused by breakdown of thrombus. We reported that shear rate strongly affects thrombus structures in the ISTH SSC 2016 Meeting (BR06). In this study, we tried to clarified the effect of some kinds of blood cell on thrombus structure.

Aims: Our aim is to extract mechanical property of venous thrombus to predict the breakdown of venous thrombus preemptively, using multiscale mechanics simulation model and mathematical model of biological structure.

Methods: Human venous blood was obtained from healthy volunteers. We separated red blood cells (RBCs), washed platelets and platelet free plasma by centrifugation. We mixed them with various ratios of platelets or RBCs. Plasma was fluorescently-stained with FITC-conjugated dextran to visualize RBCs. Platelets were fluorescently-stained with quinacrine. Alexa fluor 546-conjugated fibrinogen was added to visualize fibrin formation.

The blood sample was introduced to a home build microfluidic channels that ware fully siliconized and partly coated with collagen. The thrombus imaged was observed by a fluorescence microscope.

Results: The structures of thrombus with various ratios of blood components were much different from each other.

1. Thrombus formed by platelet poor blood traps more RBCs compared with control.

2. Fibrin fibers of thrombus formed using very low hematocrit blood appeared to anisotropic in orientation and also fibers are thinner and unclear than control.

3. The size of platelet clusters adhered on collagen surface formed by very low hematocrit blood is much bigger compared with that of normal hematocrit blood.

Conclusions: RBCs and platelets play pivotal roles to determine thrombus structure. Our findings are very informative to construct mathematical model of venous thrombus to elucidate mechanical property of thrombus in various conditions.

PB 1416 | D-dimer in Acute Medically Ill Adults: A Multicenter Observational Study Evaluating the Prevalence of Elevated D-dimer in Acute Medically Ill, Hospitalized Adults: The DAMIACT Study, Initial Results

C.L. Clark[1], A.H. Shams[1], W.F. Peacock[2], G.J. Fermann[3], B. Kea[4], A.M. Chang[5], S.E. Mace[6], B.C. Hiestand[7], J.A. Welker[8], R.A. Swor[1], K.N. Sawyer[1,9], A. Bastani[10], on behalf of the DAMIACT Study Investigators

[1]Beaumont Health System-Royal Oak, Emergency Medicine, Royal Oak, United States, [2]Baylor College of Medicine/Texas Childrens Hospital, Emergency Medicine, Houston, United States, [3]University of Cincinatti, Emergency Medicine, Cincinatti, United States, [4]Oregon Health and Science University School of Medicine, Emergency Medicine, Portland, United States, [5]Thomas Jefferson University, EmergencyMedicine, Philadelphia, United States, [6]Cleveland Clinic, Emergency Medicine, Cleveland, United States, [7]Wake Forest School of Medicine, Emergency Medicine, Winston-Salem, United States, [8]Anne Arundel Health System, Internal Medicine, Baltimore, United States, [9]University of Pittsburgh, Emergency Medicine, Pittsburgh, United States, [10]Beaumnt Health System-Troy, Emergency Medicine, Troy, United States

Background: Recent guidelines for the diagnosis of venous thromboembolism (VTE) in hospitalized non-surgical patients use D-dimer for risk stratification. The prevalence of an elevated D-dimer at the time of hospitalization in this cohort is unknown.

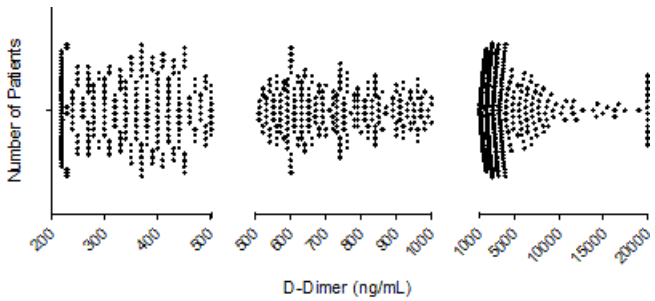
Aims: We aimed to evaluate the prevalence of an elevated D-dimer in older, hospitalized, acute medically ill patients.

Methods: This was a prospective observational study of acute medically ill patients admitted Feb 14-Nov 15, 2016, across 9 US hospitals. Patients were eligible if they were ≥60 y and admitted for an acute medical illness; excluded if they were admitted for suspected or diagnosed VTE, were anticoagulated prior to enrollment, or had surgery within 30 d of presentation. After consent, a single D-dimer sample was drawn within 24 h of admission and before receiving anticoagulation. Samples were analyzed at a central laboratory using the STA®Compact, Diagnostica Stago analyzer (range 0.22-0.50 µg/mL). Results were stratified using 3 cut-offs: 1) ≥the upper limit of normal (ULN) ng/mL; 2) ≥2xULN; 3) ≥age x 10. Data were analyzed using SAS for Windows®, v9.3.

Results: There were 995 patients included; mean age was 70±8 y; 491(49.3%) were male; 707(72%) were Caucasian, 260(26%) African American, 61(6.1%) Hispanic. Elevated D-dimer was found in 74.4% of patients (Table 1). D-dimer values ranged from < 220 ng/mL to >20,000 ng/mL (Figure 1). The most common diagnoses were chest pain [127(12.8%)], pneumonia [91(9.2%)], and CHF [88(8.8%)]. ICU admissions were 10%, mortality 1%. The median D-dimer level in patients with VTE (n=15) was 1100 ng/mL (IQR 600-3210). VTEs included deep venous thrombus (n=9), pulmonary embolus (n=3), superficial thrombus (n=2), and cardiac thrombus (n=1).

TABLE 1 The prevalence of an elevated D-dimer in acute medically ill patients

	Number of Patients (N=995)
D-dimer ≥ULN (500 ng/mL)	740 (74.4%)
D-dimer ≥2xULN (1000 ng/mL)	486 (48.8%)
D-dimer ≥the age adjusted D-dimer (≥age x 10)	619 (62.2%)



*33 patients had D-dimer levels <220 ng/mL, and 12 patients had D-dimer levels >20,000 ng/mL

FIGURE 1 Distribution of D-dimer values*

Conclusions: D-dimer above both the ULN and the age adjusted D-dimer were found in the majority of older acute medically ill patients, with almost half of the patients with levels ≥2xULN. This may have important implications for clinical risk assessment and research studies.

PB 1417 | Down-regulation of Protein C Pathway Associated with Increased Inflammation in Patients with Implanted Ventricular Assist Devices as a Potential Cause of Pump Thrombosis

T. Torres[1], J. Walenga[1], W. Jeske[1], V. Escalante[1], E. Coglianese[2], J. Schwartz[1], M. Bakhos[1]

[1]Loyola University Medical Center, Thoracic and Cardiovascular Surgery, Maywood, United States, [2]Loyola University Medical Center, Heart Failure Section of Cardiology, Maywood, United States

Background: Left ventricular assist devices (LVADs), increasingly common for heart failure management, have associated thrombosis as a major cause of mortality. We hypothesize that inflammation in LVAD patients dysregulates the protein C pathway, creating a hypercoagulable state leading to thrombosis.

Aims: To identify changes in the protein C pathway in LVAD implanted patients who experienced a thrombotic event.

Methods: Citrated plasma samples, collected from patients implanted with a Thoratec HeartMate II LVAD, were analyzed by commercial ELISAs. Retrospective sample selection included near time of adverse event and 1-3 months prior. LVAD-associated thrombosis (n = 51 samples, 17 patients) was characterized as cerebrovascular accident, rise in LDH or plasma free hemoglobin, pump dysfunction identified by pump parameters, clot imaging or surgical pump exchange. A comparator group consisted of patients with LVAD-associated bleeding (n = 20 samples, 6 patients) characterized as anemia or bleeding.

Results: The median level of C-reactive protein (CRP) was higher and total and free protein S (PrS) was lower in patients with thrombosis compared to bleeding. Median levels of protein C (PrC) and soluble thrombomodulin (TM) were comparable in patients with thrombosis or bleeding. Total PrS, free PrS, and PrC (but not TM or CRP) were further decreased at time of thrombosis. No changes were observed in these parameters at time of bleeding. Pre-event levels of PrC and PrS were consistent with low-dose warfarin (INR 1.5-2.0); TM levels were near normal (2.8 ng/mL). Soluble endothelial cell protein C receptor (EPCR) level was lower than normal (828 ng/mL) in all groups with no change at time of event. Compared to normal (0.8 µg/mL) CRP levels were more elevated in thrombosis than bleeding patients.

TABLE 1

	Median Levels			
	Pre-Bleeding	Bleeding	Pre-Thrombosis	Thrombosis
Total PrS; %	47.5	55.6	40.0	34.3
Free PrS; %	50.3	47.3	42.9	34.7
PrC; %	51.5	56.8	57.5	50.5
CRP; ug/mL	8.0	9.9	27.5	25.4
TM; ng/mL	3.3	3.3	3.5	2.9
EPCR; ng/mL	444	496	513	437

Conclusions: This study suggests that protein S, influenced by the inflammatory state, is a gatekeeper for the function of protein C in patients with LVAD-associated thrombosis.

PB 1418 | Impact of Iron Status, Assessed by Ferritin Light Chain and Soluble Transferrin Receptor, on the Association between Red Cell Distribution Width and VTE. The Tromsø Study

J. Lappegård[1], T.S. Ellingsen[1], S.K. Brækkan[1,2], P. Aukrust[1,3,4], T. Ueland[1,3,4], J.-B. Hansen[1,2]

[1]*K.G. Jebsen Thrombosis Research and Expertise Center (TREC), Department of Clinical Medicine, UiT The Arctic University of Norway, Tromsø, Norway,* [2]*University Hospital of North Norway, Division of Internal Medicine, Tromsø, Norway,* [3]*Research Institute for Internal Medicine, Oslo University Hospital Rikshospitalet, Oslo, Norway,* [4]*Institute of Clinical Medicine, Oslo University Hospital Rikshospitalet, Oslo, Norway*

Background: Red cell distribution width (RDW), a measure of the variability in size of circulating erythrocytes, is associated with incident venous thromboembolism (VTE). The mechanism underlying the association remains unclear, but iron deficiency has been proposed as a potential mediator.

Aims: To investigate whether markers of iron deficiency may explain the relationship between RDW and VTE.

Methods: A nested case-control study was performed with 202 VTE cases and 496 age- and sex-matched controls randomly selected from a general population-based study (The Tromsø Study 1994-2012). Baseline characteristics, including RDW, and blood samples were collected in 1994/95. To assess iron status, plasma samples were thawed and analyzed for levels of ferritin light chain (FtL) and soluble transferrin receptor (sTfR). Logistic regression models were used to calculate odds ratios (OR) with 95% confidence intervals (CI) for VTE by tertiles of RDW (≤12.5, 12.6-13.1 and ≥13.2%), FtL (≤4.8, 4.9-9.9 and ≥10.0 ng/mL), sTfR (≤407, 407.5-565.5 and ≥567 ng/mL), and for the combined exposures of RDW and FtL.

Results: Subjects with RDW in the upper tertile had a 54% increased risk of VTE compared to subjects in the lower tertile (OR 1.54, 95% CI: 1.00-2.38). After adjustments for FtL and sTfR, the risk estimate increased to 61% (OR 1.61, 95% CI: 1.04-2.50). Moreover, the risk of VTE increased across tertiles of FtL (OR for upper vs. lower tertile: 1.39, 95% CI: 0.90-2.13). No relationship was observed between sTfR and VTE. For subjects with upper tertile of both RDW and FtL the OR was 3.32 (95% CI: 1.43-7.70) when compared to those with lowest tertile for both variables. The relative excess risk caused by interaction was 0.59, indicating a modest synergistic effect.

Conclusions: Our findings suggest that the link between RDW and VTE is not explained by iron status. However, there was a modest synergistic effect of high RDW and high FtL on the risk of VTE.

PB 1419 | Utility of Novel Biomarkers of DIC—TAT (Thrombin-antithrombinIII Complex), PIC (alpha2plasmin Inhibitor-plasmin Complex), tPAIc (Tissue Plasminogen Activator-plasminogen Activator Inhibitor Complex) and TM (Thrombomodulin) in Predicting the Worsening of Coagulopathy and/or Mortality in Acute Promyelocytic Leukaemia (APL) and Sepsis: A Prospective Observational Study

A. Janaki Krishnamoorthi[1], S.C. Nair[1], S. David[2], A.M. Varghese[3], V. Mathews[2], P. John Victor[3], P. Tavkar[4], J. Matsui[4], M. Baliwag[4], J.J. Mammen[1]

[1]*Christian Medical College & Hospital, Department of Transfusion Medicine and Immunohematology, Vellore, India,* [2]*Christian Medical College & Hospital, Department of Clinical Haematology, Vellore, India,* [3]*Christian Medical College & Hospital, Department of Medical Intensive Care Unit, Vellore, India,* [4]*Sysmex Corporation, Kobe, Japan*

Background: DIC characterised by consumptive coagulopathy with initial thrombotic phase in sepsis patients and predominantly fibrinolysis in APL patients.

Aims: To test the significance of novel biomarkers in predicting worsening of DIC and/or mortality.

Methods: Study was conducted from May 2014-September 2015. Patients were recruited based on clinical suspicion of DIC in Sepsis and lab diagnosis of APL. ISTH DIC score was calculated daily and serial sampling done. Endpoints studied were worsening of DIC score and death.

Novel Markers were analysed using HISCL5000(CLEIA tech.,Sysmex,Kobe,Japan). Differences in biomarkers between the outcome groups were analysed using Wilcoxon rank sum test. Kruskal-Wallis test was used to study the statistical difference between DIC types(APL, sepsis and control). AUROC was computed for different biomarkers at baseline.

Results: Of 24 and 36 patients with Sepsis and APL respectively 15 and 5 died. 15 of sepsis and 27 of APL patients had worsening DIC. Comparison of biomarkers between the DIC types and control is depicted in Fig1.

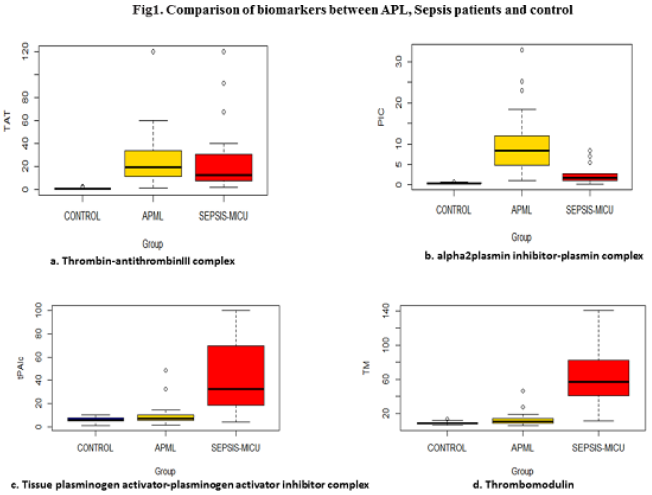


FIGURE 1 Comparison of novel biomarkers in APL, sepsis-induced DIC and controls

APL

TAT, PIC and TM(p=0.003,0.01,0.001 respectively) were showing significant difference between worsening and recovery groups. There was a significant difference in t-PAIc and TM(p=0.002,0.001 respectively) between the two outcome groups-Alive and Dead.

Sepsis

Among the sepsis patients, none of the novel biomarkers or the routine parameters were significantly different between worsening and recovery groups. TM and t-PAIc had comparatively better AUROC. Between the alive and dead, only ATIII was significantly different(p=0.011).

AUROCs are shown in Tab1. Combined ROC was not done because there were very less number of patients in each group.

Conclusions: The main findings of this study are - the patients of APL in whom DIC worsened had a higher PIC while it was a higher tPAIc in sepsis type. This study helps us in predicting worsening DIC with novel biomarkers using a method with potentially short turnaround time.

PB 1420 | Measurement of Thrombin Generation in Conditions of Low Antithrombin

P. Giesen[1], R. van Oerle[2], A. Sehgal[3], A. Akinc[3], H.M.H. Spronk[2]

[1]Thrombinoscope BV, Maastricht, The Netherlands, [2]Cardiovascular Research Institute Maastricht, Maastricht University, Laboratory for Clinical Thrombosis and Haemostasis, Departments of Biochemistry and Internal Medicine, Cardiovascular Research Institute Maastricht, Maastricht, The Netherlands, [3]Alnylam Pharmaceuticals, Cambridge, United States

Background: As a global assay Thrombin Generation (TG) has proven useful in evaluating the coagulation system. The Calibrated Automated Thrombography (CAT) method allows for the measurement of thrombin generation in clotting plasma using a fluorogenic substrate and a thrombin calibrator. Fitusiran is an investigational RNAi therapeutic targeting antithrombin (AT), designed to promote thrombin generation, and therefore hemostasis, in persons with hemophilia and other rare bleeding disorders. The CAT assay has the potential to be a useful tool for demonstrating the effect of fitusiran on coagulation parameters. AT is the main inhibitor of thrombin, and conditions of low AT can potentially result in substrate consumption prior to completion of the assay run. Therefore, it is important to recognize conditions in which the Thrombogram can be properly calculated.

Aims: To demonstrate the ability to accurately measure thrombin generation in plasma samples with low AT levels.

Methods: The CAT assay was run on samples from patients with hemophilia A and B, with and without inhibitors, from the Phase 1 and open label extension study with fitusiran (NCT02035605, NCT02554773).

Results: Under standardized conditions (platelet poor plasma, 1 pM tissue factor, 4 µM phospholipids), the CAT assay demonstrated an average increase in peak thrombin by 290% at AT lowering ≥75%, approaching the lower end of the normal range in healthy volunteers in the Phase 1 study. The CAT analysis software was used to ensure absence of substrate consumption in the analyzed values. The addition of thrombomodulin to activate the Protein C system, a second anticoagulant pathway, was tested as an approach to modify the CAT assay for low AT conditions. Addition of thrombomodulin (0.5-5 nM) led to dose dependent reductions in peak thrombin levels up to 75%.

TABLE 1 AUROCs for DIC worsening and Mortality in APL and Sepsis induced DIC patients

Biomarkers (Day 1)	DIC Worsening: Cut-off values	DIC Worsening: AUC	DIC Worsening: Sensitivity/ Specificity(%)	DIC Worsening: PPV/NPV(%)	Mortality: Cut-off values	Mortality: AUC	Mortality: Sensitivity/ Specificity(%)	Mortality: PPV/NPV(%)
APL: TAT	18	0.84	76.9/77.8	90.9/53.8	20	0.70	80.0/56.7	23.5/94.4
APL: PIC	6.5	0.79	76.9/77.8	90.9/5.38	11	0.61	60.0/70.0	25.0/91.3
APL: tPAIc	6.5	0.71	69.2/66.7	85.7/42.9	12.5	0.94	80.0/93.3	66.7/96.6
APL: TM	13	0.87	50.0/100.0	100.0/40.9	14	0.96	100.0/83.3	50.0/100.0
Sepsis: TAT	11.5	0.63	60.0/55.6	69.2/45.5	11.5	0.66	60.0/55.6	69.2/45.5
Sepsis: PIC	1.5	0.49	60.0/33.3	40.0/33.3	1.5	0.36	53.3/22.2	53.3/22.2
Sepsis: tPAIc	24	0.66	80.0/55.6	75.0/62.5	28	0.58	66.7/55.6	71.4/50.0
Sepsis: TM	58.5	0.69	66.7/77.8	83.3/58.3	55	0.64	66.7/66.7	76.9/54.5

Conclusions: The CAT assay may be a method to reliably measure thrombin generation in hemophilia patients treated with fitusiran; modified conditions may be used to further optimize the assay for low AT.

PB 1421 | Sensitivity of Different D-dimer Cut-off Levels In Unselected Patients with Confirmed Acute Pulmonary Embolism: FOCUS, a Prospective Multicenter Cohort Study

Background: The ongoing multicenter ´Follow-up after acute pulmonary embolism´ (FOCUS) observational study has set out to prospectively follow, over a 2-year period at predetermined intervals with standardized follow-up (FUP) protocols, the clinical and hemodynamic course of 1,000 unselected patients with confirmed acute symptomatic pulmonary embolism (PE).

Aims: To estimate the sensitivity of D-dimer levels at PE diagnosis and evaluate the course of D-dimer levels over FUP.

Methods: Quantitative D-dimer measurement was performed at each recruiting site as part of the PE diagnostic algorithm. For this analysis, a negative D-dimer test was defined by using a fixed (500 ng/mL), or an age-adjusted (age*10 ng/mL in patients >50 years) cut-off. We calculated the diagnostic sensitivity (95% Confidence Interval [CI]) of D-dimer testing measured upon admission and also began to determine the proportion of patients with negative values at 3-month FUP visit. FOCUS was approved by ethics committee and patient informed consent obtained.

Results: A total of 611 consecutive acute PE patients were included in FOCUS as of December 2016. Mean age was 62.0 years, 323 (52.9%) were males, 103 (16.7%) had symptoms of concomitant deep vein thrombosis, and 58 (9.5%) had active cancer. A negative D-dimer was demonstrated in 12 (1.96%) and in 14 (2.29%) patients using the fixed or age-adjusted cutoff, respectively, leading to calculated maximum sensitivities of 98.0 (95% CI: 96.6-99.0) and 97.7 (95% CI: 96.2-98.7) (*Table 1*).

TABLE 1 Sensitivity of D-dimer at different cutoffs measured at the time of pulmonary embolism diagnosis

	Fixed cutoff of 500 ng/mL	Age-adjusted cutoff (age*10 ng/mL) in patients >50 years
Negative D-dimer, n	12	14
Whole study population (n=611)	98.0 (95% CI: 96.6-99.0)	97.7 (95% CI: 96.2-98.7)
Patients tested (n=499)	97.6 (95% CI: 95.8-98.8)	97.2 (95% CI: 95.3-98.5)

A total of 383 patients was retested for D-dimer at 3 months and values remained higher than 500 ng/mL in more than 20% (*Table 2*).

TABLE 2 Course of D-dimer measurements over early follow-up

Visit number	Timepoint	D-dimer >0.500, n (%)	D-dimer ≤0.500, n (%)	Total
Visit 1	PE diagnosis	487 (97.6)	12 (2.4)	499
Visit 2	Discharge	51 (96.2)	2 (3.8)	53
Visit 3	Month 3	85 (22.2)	298 (77.8)	383

Conclusions: The sensitivity of D-dimer test measured at presentation appears lower than previously described in patients with suspected acute PE and low clinical probability, but consistent with that observed in patients with high clinical probability.

PB 1422 | Assessment of Endothelial and Inflammatory Markers in Brazilian Renal Transplant Recipients

S.R. Martins[1], K.B. Gomes[1], I.F.O. Silva[1], P.N. Alpoim[1], C.X. Lima[2], A.C. Simões e Silva[2], L.S. Dusse[1], A.P. Mota[1]

[1]Federal University of Minas Gerais, Faculty of Pharmacy, Belo Horizonte, Brazil, [2]Federal University of Minas Gerais, Faculty of Medicine, Belo Horizonte, Brazil

Background: Chronic kidney disease (CKD) and kidney transplantation(KTx) are associated to endothelial dysfunction, which contributes to a hypercoagulable state, with a consequent increase cardiovascular risk. Hypertension and diabetes mellitus, common causes of CKD, can result in endothelial dysfunction, vascular fragility and hypoxia, contributing to cardiovascular mortality in KTx

Aims: The aim of this study was to evaluate endothelial markers, thrombomodulin (TM) and vWF, in KTx and correlate them to the primary cause of pre-transplantation CKD. Additionally, the correlation of these parameters with the pro-inflammatory cytokine interleukin-6(IL-6) was also investigated

Methods: One hundred and sixty KTx were studied. Patients were distributed into 4 groups, according to the primary cause of pre-transplantation CKD, G1: glomerulopathies -N=27, G2: hypertensive nephrosclerosis -N=38, G3: diabetic nephropathy -N=18 and G4: other causes /unknown etiology -N=76. The patients were also assessed according to creatinine levels (C1≤1.4; C2>1.4mg/dL) and estimated glomerular filtration rate(eGFR, R1≤60; R2< 60 mL/min/1.73m$^{2)}$. TM and vWF levels were determined by ELISA and IL-6 was performed by Flow Cytometry.

Results: The median TM levels were significantly higher (8.38ng/mL; P=0.001) in G1 group compared to the others (G2: 5.51ng/mL; G3: 5.88ng/mL; G4:6.33ng/mL).(Fig.1A) There was no difference among the groups comparing vWF and IL-6 levels (Fig.1A and B). TM levels were significantly higher (P=0.028) in patients with low eGFR(R2) compared to patients with eGFR>60 (Fig.1C). In subsequent correlation analysis, the levels of TM were positively correlated with IL-6 (r=0.23, P=0.012), serum creatinine (r=0.20; P=0.012) and negatively with eGFR (r=-0.17; P=0.028). IL-6 levels were positively correlated with vWF(r=0.23; P=0.012). However, these correlations were weak.

Conclusions: Our data showed that TM was the most promising endothelial marker in Brazilian KTx with glomerulopathies and low eGFR.

Support: Capes, CNPq, FAPEMIG

PB 1423 | Remote Platelet Function Testing Using Platelet-Bound P-selectin as a Marker of Platelet Activation

S. Heptinstall

University of Nottingham, Clinical Neuroscience, Nottingham, United Kingdom

Background: Platelet function is often limited by access to specialist equipment and expertise. Measurement of P-selectin on activated platelets by flow cytometry following fixation of blood from a patient offers the opportunity of testing in remote locations, with samples transferred to a central laboratory for analysis.

Aims: To describe our experience of the use of P-selectin in several patient groups.

Methods: Kits are provided to enable platelet activation in whole blood from patients in remote locations. Activating agents include arachidonic acid (AA), adenosine diphosphate (ADP) and thrombin receptor activation peptide. The fixing agent is PAMFix (Platelet Solutions, Nottingham, UK). Activated/fixed samples are stable for up to 9 days. Platelet P-selectin is measured using flow cytometry.

Results: Studies in patients with acute coronary syndromes (ACS), acute stroke and other neurological syndromes, and enhanced bruising and bleeding are either complete or on-going. Studies to assess platelet viability prior to using platelet-rich plasma in wound healing are ongoing. Successful outcomes include: 1) demonstration of a significant relation between high platelet reactivity to ADP in patients with ACS taking clopidogrel who go on to experience a further thrombotic event; 2) demonstration of good inhibition of AA-induced platelet reactivity in patients with acute stroke taking aspirin, but variable ADP-induced platelet reactivity in the same patients taking clopidogrel; 3) detection of drug non-compliance and/or reduced effectiveness in patients scheduled for a neurological stent insertion; 4) identification of secretory defects in patients who bleed; 5) reassurance on platelet viability during wound healing procedures.

Conclusions: Measurements of platelet-bound P-selectin as an approach to platelet function testing without access to specialist equipment or expertise is proving of value in a variety of patient groups.

PB 1424 | Endothelial Microparticles, Thrombomodulin and D dimer in Women with Systemic Lupus Erythematosus under treatment

F. Campos[1], W. Cicarini[1], K. Ferreira[1], C. Loures[1], L. Alves[1], T. Guimarães[1], V. Toledo[1], R. Consoli[2], C. Neiva[2], P. Pádua[2], E. Reis[3], M.G. Carvalho[1]

[1]*Faculdade de Farmácia da Universidade Federal de Minas Gerais, Análises Clínicas e Toxicológicas, Belo Horizonte, Brazil,* [2]*Santa Casa de Misericórdia, Belo Horizonte, Brazil,* [3]*Universidade Federal de Minas Gerais, Instituto de Ciências Exatas, Departamento de Estatística, Belo Horizonte, Brazil*

Background: Systemic Lupus Erythematosus (SLE) is an inflammatory and autoimmune multisystem disease. Microparticles (MPs) are cell

TABLE 1 Endothelial Microparticles, Thrombomodulin and D Dimer expressed as medians in women with Systemic Lupus Erythematosus under treatment

Parameter	Controls (n=30)	Patients with SLE (n=60)	SLE Patients with Low Activity (n=30)	SLE Patients with Moderate/ High Activity (n=30)	P value
EMPs(EMPs/μL)	a,b,c 7.40	a 12.13	b,d 10.33	c,d 10.70	a0.019 b0.088 c0.0056 d0.2732
TM(ng/mL)	a,b,c 0.21	a 0.29	b,d 0.25	c,d 0.34	a0.0341 b0.0001 c0.0007 d0.0002
DDi(ng/mL)	a,b,c 374	a 1155	b,d 930	c,d 1563	a0.0133 b0.0001 c0.0198 d0.0004

membrane-shedded fragments released during apoptosis and cell activation. Endothelial microparticles (EMPs) are derived from activated endothelial cells and may reflect endothelial dysfunction in response to the inflammatory process. As EMPs can stimulate coagulation by exposure of negatively charged phospholipids and tissue factor can be hypothesized that the higher the number of EMPs the greater the state of hypercoagulability.

Aims: This study has evaluated EMPs, endothelial lesion, and hypercoagulable status, and their relationship to disease activity in SLE women under treatment, compared to controls.

Methods: Disease activity was defined by Systemic Lupus Erythematosus Disease Activity Index (SLEDAI 2K). This study included women with similar age distributed into 3 groups: Group 1: healthy women (control, n=30); Group 2: SLE women with low disease activity (SLEDAI 2K ≤ 4, n=30); Group 3: SLE patients with / moderate high disease activity (SLEDAI 2K > 4, n=30). EMPs were purified by ultracentrifugation, labeled with antibody anti-CD51 / 61 and annexin V and then analysed flow cytometry. Endothelial lesion was assessed by thrombomodulin and hypercoagulable status by D-dimermeasurements in citrated plasma samples. The results were analyzed with Mini Tab program and median values were compared.

Results: The results are shown in Table 1.

Conclusions: The data from this study suggest that increasing the number of EMPs may partially support the state of hypercoagulability found in patients with SLE, particularly those with active disease, which is reinforced by increased plasma levels of thrombomodulin and D-dimer. These tools may be useful in stratifying and monitoring patients.

Support: CNPq,CAPES and FAPEMIG

PB 1425 | Chronic Lymphocytic Leukemia: Is there a Role for Circulating Microparticles or Trombin Generation in Clinical Heterogeneity?

M.G. Carvalho[1], A. Ferrão[1], F. Evangelista[1], F. Campos[1], R. Duarte[1], T. Braga[1], L. Gomes[1], M. Santiago[1], W. Cicarini[1], S. Araújo[2], A. Sabino[1]

[1]*Faculdade de Farmácia da Universidade Federal de Minas Gerais, Análises Clínicas e Toxicológicas, Belo Horizonte, Brazil,* [2]*Hospital das Clinicas, UFMG, Belo Horizonte, Brazil*

Background: CLL prognosis is variable and some patients progress with short survival. It is unclear whether hemostatic changes, variable by tumor type, play a role in clinical heterogeneity in patients with CLL.

Aims: To evaluate parameters of the hemostatic profile in patients with CLL, compared to controls and their correlation with the progression of the disease.

Methods: Thirty-five CLL patients classified according to the BINET criteria of Hospital das Clínicas-UFMG-Brazil and 35 apparently healthy individuals (Controls) were evaluated, from whom informed consent was obtained. Hemostatic profile was evaluated by quantification of MPs derived from endothelial cells (EMP), B lymphocytes (LMP) and platelets (PMP) using flow cytometry and by Thrombin Generation Test using CAT® method.

Results: Significantly increased levels (/μL) of EMPs were observed in patients with CLL, [132.1 (78.6 to 199.1)] compared with the control group [81.6 (53.1 to 121, 0), p = 0.002]. The same was observed for LMP [142.1 (93.7 to 203.1)] compared to controls [85.2 (63.4 to 115.9), p < 0.001] and PMPs [134.8 (85.7 to 183.1)], control group = [81.2 (52.8 to 118.9), p = 0.003]. When patients were stratified according to Binet staging, significant differences were observed (p < 0.05) between groups Binet A versus controls for EMPs [149.8 (75.3 to 212.5)] LMP [145.2 (91.9 to 235.6)] and PMPs [148.1 (82.2 to 202.1)]. No significant difference was observed between Binet A and Binet B+C. On the other hand, endogen thrombin potential (ETP) was lower in CLL patients [1453.00 (1176.33 to 1602.57)] compared to control group [1577.38 (1326.20 to 1816.95), p = 0.031] especially in severe cases classified as Binet B + C [1216.54 (1130.47 to 1540.15), p = 0.009].

Conclusions: Increased number of MPs in CLL and decreased thrombin generation are not necessarily related to disease progression. So, it seems that such variables do not play a role in clinical heterogeneity in patients with CLL.

Supported by Brazilian agencies CAPES, CNPq and FAPEMIG

PB 1426 | Determinants of Clot Strength in Polycythemia Vera and Primary Myelofibrosis using Rotational Thromboelastometry

N. Nytofte[1], O. Pedersen[2], H. Hasselbalch[3]

[1]*Næstved Sygehus, Center for Trombose og Hæmostase, Næstved, Denmark,* [2]*Næstved Sygehus, Klinisk Immunologisk Afdeling, Næstved, Denmark,* [3]*Sjællands Universitetshospital, Hæmatologisk Afdeling, Roskilde, Denmark*

Background: The Myeloproliferative Neoplasias (MPNs) Polycythemia Vera (PV) and Primary Myelofibrosis (PMF) are clonal disorders of hematopoietic stem cells associated with thrombosis. Rotational

Thromboelastometry (ROTEM) is a point of care global coagulation assay, which has showed a hypercoagulable state in MPNs. Little is known about the contribution of platelets to clot strength in MPN.

Aims: We aimed to identify determinants of whole blood clot strength in PV and PMF using ROTEM and to assess the contribution of platelets to clot strength.

Methods: Venous blood samples were collected from 23 PV and 17 PMF patients. ROTEM analysis was performed using EXTEM reagents, which provides a measure of extrinsic activation of coagulation and FIBTEM reagents where platelet contribution to clot strength is inhibited. Maximum Clot Firmness (MCF, [mm]) was obtained, and Shear Modulus (G, [dyne/cm^2]) and the platelet component of clot strength were calculated. The local medical ethics committee approved the study and informed consent was obtained from all patients.

Results: For PV and PMF EXTEM MCF was 69±5 and 69±6 (reference range 50-72) and FIBTEM MCF was 25±10 and 26±9 (reference range 9-25). For PV EXTEM MCF correlated with platelets, r=0.61 (0.27-0.82, p=0.002) and fibrinogen, r=0.48 (0.09-0.75, p=0.02) and FIBTEM MCF correlated with platelets, r=0.72 (0.43-0.87, p=0.0001) and fibrinogen, r=0.52 (0.13-0.77, p=0.01). For PMF EXTEM MCF correlated with platelets, r=0.49 (0.01-0.78, p=0.04) and FIBTEM MCF correlated with fibrinogen, r=0.64 (0.23-0.86, p=0.01). For PV and PMF platelet contribution to clot strength was 0.85±0.06 and 0.84±0.05.

Conclusions: ROTEM analysis confirmed hypercoagulability in PV and PMF. The contribution of platelets to clot strength was comparable to what others have reported for pregnancy, which is also a hypercoagulable state with increased fibrinogen concentration and lower than reported for patients undergoing cardiac surgery.

PB 1427 | Identification & Characterization of Novel Hemostatic Biomarkers of Adverse Clinical Events in Patients with Continuous Flow Left Ventricular Assist Device Implants

N. Mcclane[1], W. Jeske[1], J. Walenga[1], V. Escalante[1], E. Coglianese[2], D. Hoppensteadt[3], J. Schwartz[1], M. Bakhos[1]

[1]Loyola University Medical Center, Thoracic and Cardiovascular Surgery, Maywood, United States, [2]Loyola University Medical Center, Heart Failure Section of Cardiology, Maywood, United States, [3]Loyola University Medical Center, Pathology, Maywood, United States

Background: Increased incidence of heart failure and lack of donor hearts has led to increased use of continuous flow left ventricular assist devices (CF-VAD). CF-VAD patients are at risk for non-surgical bleeding and thrombotic complications.

Aims: To identify biomarkers to improve risk assessment for CF-VAD patients.

Methods: Blood samples collected from 16 patients implanted with a Thoratec HeartMate II CF-VAD (25 normal individuals as controls) were analyzed by commercial ELISAs and SELDI mass spectrometry. Patients experienced 12 thrombotic, 8 hemorrhagic and 2 septic events. CF-VAD thrombosis included: cerebrovascular accident, rise in LDH or plasma free hemoglobin, hemolysis, pump dysfunction consistent with thrombus, evidence of clot upon imaging or pump exchange. CF-VAD bleeding events included anemia or overt bleeding.

Results: Annexin V levels increased 3-fold compared to normal (9.2±0.9 *vs.* 2.8±0.2 nM). Levels of C-reactive protein (CRP) (14.5±2.7 *vs.* 2.2±0.6 µg/ml; p=0.034) and TF(+)microparticles (3.7±1.1 *vs.* 0.5±0.1 pg/ml; p=0.038) were significantly higher in CF-VAD patients. SELDI-MS analysis indicated distinct peaks, not found in normals, at 8.1, 11.7 and 15.2/16.2 kDa in CF-VAD patients. The 8.1 kDa biomarker was found in 10/12 patients with thrombosis, 2/6 patients with bleeding, 0/2 patients with sepsis and 0/2 event-free patients. The 8.1 kDa peak was associated with elevated annexin V (p=0.01) and the presence of annexin V(+) microparticles (p=0.005); the 11.7 kDa peak was associated with elevated CRP (p=0.01); the 15.2/16.2 kDa peaks were associated with the presence of TF(+)microparticles (p=0.002), annexin V(+) microparticles (p<0.001) and elevated annexin V (p=0.03).

Conclusions: Despite treatment with low-dose aspirin and warfarin, CF-VAD patients exhibit signs of hemostatic activation. The SELDI-MS identified biomarkers of CF-VAD-associated adverse events may provide a feasible approach to facilitate management of this patient population.

PB 1428 | Haemostasis in Children with Acute Lymphoblastic Leukemia

E. Seregina[1,2], L. Zharikova[1], M. Gracheva[1], N. Trubina[1], M. Korsantya[1], H. Sepoyan[1], D. Rokhoeva[1], A. Poletaev[1], T. Vuimo[1], F. Ataullakhanov[1,2,3]

[1]Dmitry Rogachev National Research Center of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation, [2]Center for Theoretical Problems of Physicochemical Pharmacology, Moscow, Russian Federation, [3]Moscow State University, Department of Physics, Moscow, Russian Federation

Background: The incidence of thrombosis in children with Acute Lymphoblastic Leukemia(ALL) is nearly 40%. Fast and accurate assessment of the haemostasis in children with ALL is still important and actual problem.

Aims: To investigate the haemostatic state in children with ALL using global and standard hemostasis assays.

Methods: Seventy patients aged 1 to 17 years with ALL before the first consolidation phase in ALL-MB-2015 protocol were enrolled in this study. Standard coagulation tests (APPT, TT, PT, fibrinogen, ATIII, D-dimer concentrations), Thromboelastography(TEG), Thrombodynamics(TD) and Thrombomodulin concentration were used to assess coagulation status in patients during the treatment.

Results: TEG parameters and standard tests were in normal(89%) or in hypocoagulation(11%) area during the treatment. The concentrations of fibrinogen and ATIII lowered during the treatment in 87% of patients. Thrombosis occurred in 36 patients (51%). TD revealed hypercoagulation in 89%. We‘ve divided patients in two groups, 1st with low ATIII concentration and 2nd with normal ATIII concentration. There was 45% of thrombosis in 1st group in patients with hypercoagulation

by TD and normal D-dimer levels and only 3% with high D-dimer levels. Even there was 42% of thrombosis in 2nd group in patients with hypercoagulation by TD and low D-dimer levels and 13% with high D-dimer levels despite normal ATIII concentration. There was no thrombosis in both groups with TD parameters in normal area. This is confirmed by threefold increase in free thrombomodulin concentration in patients with thrombosis($p < 0.001$). Similar hypercoagulation by TD parameters but lower ATIII and D-dimer levels revealed reducing lysis potential in patients with ALL.

Conclusions: Thrombodynamics revealed significant hypercoagulability in patients with ALL. The reduced lysis potential confirmed by low ATIII, normal D-dimer levels and hypercoagulation confirmed by TD is the hypothetic group of parameters to predict thrombotic complication in children with ALL.

PB 1429 | Association between FTO rs9939609 Polymorphism and Risk of Recurrent Venous Thromboembolism

A. Ahmad[1], K. Sundquist[1,2], B. Zöller[1], P.J. Svensson[3], J. Sundquist[1], A.A. Memon[1]

[1]*Lund University, Skåne University Hospital, Clinical Sciences, Malmö, Sweden,* [2]*Icahn School of Medicine, Department of Family Medicine and Community Health, New York, United States,* [3]*Lund University, Skåne University Hospital, Haematology and Coagulation Disorders, Malmö, Sweden*

Background: Multiple genetic variations have been identified in *FTO* (fat mass and obesity-associated) gene, among them, *FTO* rs9939609 polymorphism has been shown to be associated with the risk of primary venous thromboembolism (VTE). However, its role in recurrent VTE is not known.

Aims: The aim of our study was to investigate the association between *FTO* rs9939609 polymorphism and the risk of VTE recurrence in a prospective follow up study.

Methods: *FTO* rs9939609 polymorphism was analyzed in Malmö thrombophilia study (MATS, followed for ~10 years) by using TaqMan PCR.

Results: MATS patients (n=1,050) were followed from the discontinuation of anticoagulant treatment until diagnosis of VTE recurrence or the end of the study. One hundred twenty-six patients (12 %) had VTE recurrence during follow up. Cox regression analyses showed no evidence of an association between *FTO* rs9939609 polymorphism and the risk of VTE recurrence in the study population as a whole. However, by including an interaction term in the analysis we found that gender modified the effect of *FTO* rs9939609 polymorphism: male patients with *FTO* polymorphism had significantly higher risk of VTE recurrence (Hazard ratio [HR] = 2.05, 95% confidence interval [CI] = 1.2-3.5, P= 0.009 and HR=2.03, CI= 1.2-3.6, P=0.013) as compared to females on uni- and multi-variate Cox regression analysis (after adjusting for BMI, family history, acquired risk factors for VTE and risk of thrombophilia) respectively.

Conclusions: Our results show that *FTO* rs9939609 polymorphism is associated with higher risk of VTE recurrence in males but not in females independent of other well-known risk factors for VTE.

PB 1430 | The Protein Z System Dynamic in Patients Undergoing Off-pump Coronary Artery Bypass Surgery

E. Żekanowska[1], A. Słomka[1], A. Piekuś[2], M. Kowalewski[2], W. Pawliszak[2], L. Anisimowicz[2]

[1]*Nicolaus Copernicus University in Toruń, Ludwik Rydygier Collegium Medicum in Bydgoszcz, Department of Pathophysiology, Bydgoszcz, Poland,* [2]*Dr Antoni Jurasz Memorial University Hospital in Bydgoszcz, Department of Cardiac Surgery, Bydgoszcz, Poland*

Background: A large number of studies has evaluated multiple markers of coagulation in patients undergoing cardiac surgery. Nonetheless, evidence regarding the protein Z (PZ) system in patients scheduled for off-pump coronary artery bypass surgery (OPCAB) so far is lacking.

Aims: In this pilot study, we evaluated the effect of OPCAB surgery on the protein Z system by measuring the levels of PZ, protein Z-dependent protease inhibitor (ZPI) and factor X (FX) before surgery and one week after surgery.

Methods: The sample consisted of 30 men aged between 45 and 77 years who underwent elective first-time isolated OPCAB surgery. Ethical approval for the study was obtained from the Ethics Committee of Collegium Medicum. Written informed consent was received from all of the study subjects. Fasting blood samples were obtained from the participants before surgery and one week after surgery. PZ, ZPI and FX in plasma were measured by ELISA kits.

Results: The Wilcoxon test was used to compare the levels of PZ, ZPI and FX at the two measurement time points. Of note, both plasma PZ and FX levels were significantly higher one week after surgery than before surgery (median, 3.95 μg/mL versus 3.38 μg/mL, p=0.02; 122.27% versus 111.71%, p=0.002, respectively). In contrast, the levels of ZPI were significantly lower one week after surgery; that is, the median value was 5.96 μg/mL compared with 7.11 μg/mL (p=0.004).

Conclusions: We demonstrated the impact of OPCAB surgery on the plasma levels of PZ, ZPI and FX. However, further studies are necessary to elucidate the exact role of the protein Z system in patients undergoing this surgical procedure.

PB 1431 | Relevance of Co Morbidities, D-Dimer, Red Cell Distribution Width and Factor VIII Levels in Thrombosis

A. Kurien[1], S. Badagubettu[2], A.S. Babu[3], P. Ramachandran[4]

[1]*Melaka Manipal Medical College, Manipal University, Pathology, Udupi, India,* [2]*Manipal College of Nursing, Manipal University, Udupi, India,* [3]*School of Allied Health Sciences, Manipal University, Physiotherapy, Udupi, India,* [4]*Kasturba Medical College, Manipal University, Cardiology, Udupi, India*

Background: Arterial or venous thrombosis is a leading cause of mortality worldwide accounting for 1-2 deaths/ 1000 population per year. The interest in recent years have been in identifying comorbidities as risk factors and the usefulness of D- Dimer and red cell distribution width (RDW)in of thrombosis.

Aims: To compare the relevance of co morbidities, factor VIII, D-Dimer levels and RDW in patients with thrombosis.

Methods: 68 patients who attended thrombosis screening programme in a tertiary care hospital in India were included in this study after informed consent and ethical clearance. The clinical history, comorbidities (hypertension, diabetes), D-Dimer(Normal < 250 ng/ml),RDW(Normal range11.5- 15.5%) and Factor VIII assay (Normal range 50 -150%)levels were noted in patients with history of thrombosis. The data was analyzed.

Results: The 68 patients included 9 (13%) subjects with stroke, 26 (38%) subjects with deep vein thrombosis, 10 (15%) with heart diseases and 10 (15%) subjects with other conditions like recurrent abortions and chronic kidney disease. 13 patients (19%) had comorbid conditions without an event while 81% had thrombosis.51% of patients with thrombosis had elevated factor VIII levels of which 69% were seen in venous thrombosis .D Dimer levels were elevated in 33% and RDW in 15% cases respectively. In venous thrombosis all 3 parameters were elevated in 4 patients and either of 2 parameters in 10 patients. However there was no statistically significant difference for D-dimer (F=1.167, p=0.331), RDW (F=0.419, p=0.740) and Factor VIII (F=1.305, p=0.283) values for the various clinical conditions of thrombosis.

Conclusions: Comorbidities may or may not be associated with an event. Factor VIII levels followed by D Dimer and RDW were elevated . Elevation of two or more markers were seen in complications like pulmonary embolism , inferior vena cava / portal vein thrombosis or polycythemia. These simple test combinations can help to predict outcome and risks in thrombosis especially venous thrombosis.

PB 1432 | Longitudinal Assessment of Coagulation and Fibrinolysis in Pregnant Women with Risk Factors for Preeclampsia

L. Dusse[1], F. Lucena[1], P. Alpoim[1], A. Barbosa[2], A. Cabral[2], R. Diniz[3], E. Lage[2], P. Teixeira[2]

[1]Federal University of Minas Gerais-Brazil, Department of Clinical and Toxicological Analysis, Belo Horizonte, Brazil, [2]Federal University of Minas Gerais-Brazil, Department of Gynecology and Obstetric, Belo Horizonte, Brazil, [3]Federal University of Minas Gerais-Brazil, Department of Epidemiology, Belo Horizonte, Brazil

Background: Preeclampsia-PE is a multifactorial disease whose pathophysiology was not fully elucidated. No laboratory marker to present favorable cost-effectiveness ratio was proposed for PE diagnosis, which is primarily done based on blood pressure and proteinuria determination and clinical symptoms.

Aims: To assess coagulation and fibrinolysis markers in pregnant women with risk factors for PE.

Methods: Women were selected and followed throughout pregnancy. D-Di and PAI-1 plasma levels were determined by ELISA in 23 samples from 11 pregnant women who developed PE and 55 from 17 women who did not develop the disease in the following gestational periods 12-19,20-29,30-34 and 35-40 weeks.

Results: There was no significant difference in D-Di and PAI-1 levels in pregnant women who developed PE compared to those who did not develop the disease, in each of the 4 gestational periods evaluated. However, a significant increase in D-Di levels in pregnant that developed PE was observed when comparing the 12-19x30-34 gestational periods(P=0.045), 12-19x35-40(P< 0.001), 20-29x30-34(P=0.048), 29x35-40 weeks(P=0.030). Similar results were found in the ones that did not develop the disease: 12-19x30-34 periods(P=0.001), 12-19x35-40(P=0.000), 20-29x30-34(P=0.003), 29x35-40 weeks(P=0.001). A significant increase in PAI-1 levels was also obtained in pregnant women who developed PE, comparing the periods 35-40x12-19(P=0.001), 35-40x20-29(P< 0.001) and 35-40x30-34 weeks(P< 0.001) and in women who did not develop the disease in 12-19x20-29(P=0.004), 12-19x30-34(P< 0.001), 12-19x35-40(P=0.001), 20-29x35-40(P=0.009) and 30-34x35-40 weeks(P=0.002).

Conclusions: There was a trend of increase in D-Di and PAI-1 levels throughout gestation in pregnant women who developed and who did not develop PE. This increase was more evident in those who developed the disease, which allow inferring that D-Di and PAI-1 are promising candidates to integrate a diagnostic algorithm for PE, to be applied after a clinical score and associated with imaging tests

PB 1433 | Role of Oxidized High-density Lipoprotein (oxHDL) on Coagulation and Platelet Adhesion Modulation

L. Pérez[1,2], F. Simón[1,2]

[1]Universidad Andrés Bello, Facultad de Ciencias Biológicas, Santiago, Chile, [2]Millennium Institute of Immunology and Immunotherapy, Santiago, Chile

Background: High density lipoprotein (HDL) exerts some antithrombotic properties by inhibiting coagulation and modulating platelet reactivity. Nevertheless, when oxidative modification of HDL takes place due to pathological condition, subsequent generation of oxHDL occur and unknown detrimental properties emerge.

Aims: To determine the effects of oxHDL on coagulation function and platelet adhesion.

Methods: Primary rat mesenteric endothelial cells (RMEC) were isolated from SD rats (180 g approximately). In addition, an endothelial cell line was obtained form ATCC. Endothelial cells were stimulated with HDL or oxHDL (50 µg/mL) and alteration of coagulation and thrombosis-related protein expression was determined. Furthermore, blood serum from vehicle- and oxHDL-treated rats was subjected to coagulation and thrombosis-related protein expression analysis and coagulation activity measurements. The investigation conforms to the principles outlined in the Declaration of Helsinki.

Results: TF and P-selectin protein expression in RMEC increased significantly in response to oxHDL treatment, compared to control condition. Also, we observed a significant increase in platelet adhesion in response to oxHDL treatment, when compared to control. (Preliminary)

Conclusions: Our results provides evidence which suggests that oxHDL modulates coagulation and promotes platelet adhesion.

PB 1434 | Inter-individual Variability and Normal Ranges of Whole Blood and Plasma Thrombin Generation and Correlation with Clotting Factor Levels in a Large Healthy Control Population

S. Bloemen[1,2], D. Huskens[1,2], J. Konings[1,2], R. Kremers[1,2], A. Miszta[1,2], B. de Laat[1,2], H. Kelchtermans[1,2]

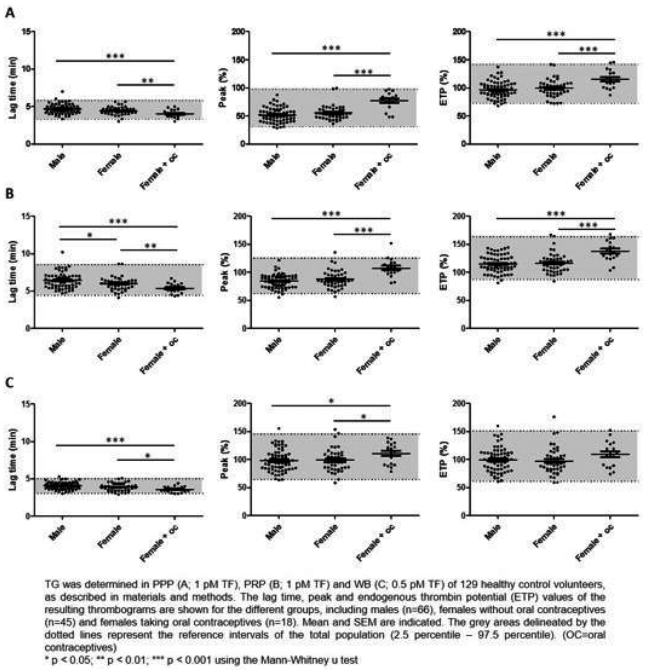
[1]CARIM, Maastricht University, Synapse Research Institute, Maastricht, The Netherlands, [2]CARIM, Maastricht University, Department of Biochemistry, Maastricht, The Netherlands

Background: Global assays measuring thrombin generation (TG) in plasma increasingly gained attention in the field of thrombosis and hemostasis. Adaptation of the method enabled the measurement of TG in whole blood (WB). Despite their potential, TG assays did not yet reach the stage of universal clinical application, partly due to the absence of normal ranges.

Aims: To accurately determine normal ranges/inter-individual variability of TG and correlate results with coagulation factor levels, sex and oral contraceptive (OC) usage.

Methods: The study protocol was evaluated by the local medical ethical board. 129 healthy volunteers gave full informed consent. Clotting factors were determined with STA-R technology; normal ranges of TG in platelet-poor/platelet-rich plasma (PPP/PRP) and WB according to CLSI guidelines.

Results: Our study is the first to measure normal ranges of TG in PPP, PRP and WB in a large healthy cohort. Significant correlations were found between TG in plasma and WB. Inter-individual variability of TG in WB was comparable to that of plasma (10 to 27% for all parameters). OC use increased TG in PPP/PRP/WB (figure).



TG was determined in PPP (A; 1 pM TF), PRP (B; 1 pM TF) and WB (C; 0.5 pM TF) of 129 healthy control volunteers, as described in materials and methods. The lag time, peak and endogenous thrombin potential (ETP) values of the resulting thrombograms are shown for the different groups, including males (n=66), females without oral contraceptives (n=45) and females taking oral contraceptives (n=18). Mean and SEM are indicated. The grey areas delineated by the dotted lines represent the reference intervals of the total population (2.5 percentile – 97.5 percentile). (OC=oral contraceptives)
* p < 0.05; ** p < 0.01; *** p < 0.001 using the Mann-Whitney u test

FIGURE 1 Effect of sex and oral contraceptive use on TG parameters determined in PPP, PRP and WB

The inhibitory effect of thrombomodulin on TG was significantly lower in females compared to males and this effect was more pronounced upon OC use. Main clotting factor determinants for TG parameters depended on the TF concentration but were similar in WB/PRP/PPP.

Conclusions: Establishing normal ranges for TG brings us one step closer to clinical use. Good correlations between plasma and WB (also regarding clotting factor determinants for TG) suggest that also WB TG can be reliably used in clinic. The relatively high inter-individual variability in TG is important to consider. Previously, inhibition of TG by a fixed concentration of anticoagulant -also direct FXa/thrombin inhibitors- proved to be highly variable from one individual to another. These data may argue against the idea that one standard dose of new oral anticoagulants fits for all.

PB 1435 | Venous Thromboembolism Events over Five Years Presenting with a Normal D-Dimer

H. Rowswell, T. Nokes

Plymouth Hospitals NHS Trust, Haematology, Plymouth, United Kingdom

Background: Failure of the d-dimer level in its negative predictive capability to rule out VTE, can be a real concern. To address this problem in a large hospital, data has been collated on d-dimer levels between 2012 and 2016, in PE and DVT diagnoses. Community acquired thrombosis (CAT) is by far the main source of this data, with an aim to determine patterns in VTE diagnosed in the context of a negative d-dimer.

Aims: To identify all VTE events presenting with normal d-dimer levels over five years. Determine whether there are specific risk factors, medical history or presentation in those VTE events, compared to patients presenting with elevated d-dimer levels.

Methods: Observational cohort study reviewing CAT events, associated with a d-dimer test, Liatest D-I plus, from January 1st 2012 to December 31st 2016. VTE diagnosis is determined from radiology records, with demographic information and VTE risk factors obtained from patient notes. The mean age and standard deviation was calculated for all VTE events. The student's t-test was used to detect significance between positive and negative d-dimer groups.

Results: 3079 VTE events (1366 DVT & 1713 PE) associated with a d-dimer test were identified. 72 events (38 DVT 34 PE), having a normal d-dimer (< 0.50 ug FEU/ml). Normal d-dimer patients had a mean age of 47.34 (SD ± 16.30) significantly lower than the mean age of all VTE patients being 62.70 (SD± 18.230) (p< 0.0001). Patients with a previous VTE and normal d-dimer comprised 25/72 (35%) compared with 680/3079 and raised d-dimer (22%) (p=0.011).

Conclusions: Over 5 years, patients presenting with a VTE event and a normal d-dimer were significantly younger and more likely to have had a previous thrombosis than those with a raised d-dimer. The younger age at presentation may be explained by the age-related association with d-dimer levels.

PB 1436 | Biomarkers for the Diagnosis of Venous Thromboembolism: D-dimers, Thrombin Generation, and Phospholipid-dependent Clotting Time

N. Riva[1], K. Vella[2], D. Zammit[2], S. Spiteri[2], K. Hickey[3], S. Kitchen[3], M. Makris[3], W. Ageno[4], A. Gatt[1,2]

[1]University of Malta, Department of Pathology, Msida, Malta, [2]Mater Dei Hospital, Coagulation Medicine Laboratory, Department of Pathology, Msida, Malta, [3]University of Sheffield, Sheffield Haemophilia and Thrombosis Centre, Sheffield, United Kingdom, [4]University of Insubria, Department of Clinical and Experimental Medicine, Varese, Italy

Background: The diagnostic algorithms for venous thromboembolism (VTE) currently involve a composite of clinical pre-test probability, laboratory D-dimer (DD) and specific imaging techniques. However, different DD assays show differences in sensitivity and specificity, and other research tests might assist in the identification of VTE patients.

Aims: To assess the accuracy of different laboratory tests (DD, thrombin generation and phospholipid-dependent clotting time) as biomarkers of acute VTE.

Methods: Samples arriving at the Coagulation Laboratory at Mater Dei Hospital (Msida, Malta) from the Accident and Emergency Department with a request for DD measurement were collected. The following tests were performed: Innovance DD (Siemens Healthcare Diagnostics), HemosIL DD HS (Instrumentation Laboratory), Thrombin Generation (using the CAT), STA Procoag PPL (Diagnostica Stago). According to Innovance DD, samples were divided in 3 groups: negative DD (group 1), positive DD without VTE (group 2), positive DD with VTE confirmed by lower limb compression ultrasonography or computed tomography pulmonary angiography (group 3).

Results: These are preliminary data of 38 out of 75 samples planned for this study (13 in group 1, 13 in group 2, 12 in group 3). The agreement between Innovance and HemosIL DD in the categorization of patients was 95%, since 2 patients with positive Innovance DD but no evidence of VTE, were classified as negative by HemosIL DD. The phospholipid-dependent clotting time was slightly shorter in VTE patients vs non-VTE patients (median 32.2 sec in Group 3 vs 35.5 in Groups 1 and 2 joined, p=0.34).

On the thrombin generation curve, lag time was prolonged (5.25 vs 4.33 min, p=0.18), peak thrombin concentration increased (303 vs 279 nM, p=0.23) and velocity index increased (118.4 vs 96.9 nM/min, p=0.07).

Conclusions: The results of this study suggest that some laboratory research tests might have the potential to support the diagnosis of VTE. However, this data should be confirmed on a larger sample size.

PB 1437 | Risk Factors and Clinical Characteristics Favoring Pulmonary Embolism Vs DVT in Hormonal Therapy (HT) Associated Thromboembolism. Retrospective Analysis of 73 Cases from a Single Hemostasis Unit

E. Papadakis[1], D. Theocharidou[2], A. Banti[2], S. Efremidou[1], A. Kioumi[1]

[1]Papageorgiou Hospital, Hematology, Thessaloniki, Greece, [2]Papageorgiou Hospital, Hemostasis Unit, Thessaloniki, Greece

Background: In women who use combined oral contraceptives (COC) the risk of Thromboembolism (TE) is increased 3-6 fold compared to non- users. Inherited thrombophilias synergize to an excess risk of thrombosis among users of OC. Age and family history constitute risk factors for VTE among women on hormonal treatment. However, limited data exist regarding risk factors and clinical characteristics leading either to HRT induced PE or DVT.

Aims: Our objectives were to analyze the baseline characteristics of women who suffered VTE during the use of COC and to investigate possible risk factors favoring the development of PE or DVT.

Methods: We studied 73 COC users, who suffered TE, with a median age of 28 years, which received COC for a median period of 2 months. Among them, 4 (5.5%) suffered ischemic strokes while 69 VTE. Lower limbs were the predominant site of VTE n=42(60.9%), followed by Pulmonary Embolism (PE) n=17(27.5%), Upper limbs n=7(10.1%), CNS n=7(10,1%) and Abdomen n=4(5.8%). 17/73 (23,3%) presented TE recurrence, while in total 19/73 (26,0%) suffered PE either as 1st episode or during recurrence. We analyzed, patients age, duration of hormonal treatment intake, smoking, family history, thrombophilia profile and assess their impact on the development of PE or DVT. For that purpose we used SPSS 20.0 package with lower limit of sensitivity set at 0,05.

Results: Median age of women that developed PE was 33,6 years contrasting the median age of the non-PE population which was 28,7 years p= 0,034. 9/21(42.9%) of women that reported family history of thrombosis presented PE, while 10/52 (19.2%) with negative family history manifested PE p= 0,037.PE was not associated with duration of hormonal treatment, smoking, and thrombophilia profile. Elevated plasma homocysteine was encountered more often, albeit not significantly (p= 0.07).

Conclusions: In HRT-VTE increased age and positive family history seem to favor PE phenotype. Although small and retrospective, our study is the first to demonstrate the above.

PB 1438 | The Influence of Ethnicity on Thrombin Generation

C.W. Tan[1], W.H. Wong[1], C.K. Tan[1], Y.H. Chan[2], H. Kaur[1], L.H. Lee[1], H.J. Ng[1]

[1]Singapore General Hospital, Singapore, Singapore, [2]National University of Singapore, Singapore, Singapore

Background: Ethnicity is touted as an independent risk factor for venous thromboembolism (VTE) although the basis for this is varied and contentious. Comparison of plasma thrombin generation using calibrated automated thrombogram (CAT) across ethnic groups offers a modality that objectively measures global haemostatic function to evaluate this influence. Direct comparative data across ethnic groups is currently not available.

Aims: To establish the influence of ethnicity on plasma thrombin generation.

Methods: 60 normal subjects, matched for age and gender, equally representing 4 ethnic groups - Caucasian, Chinese, Indian and Malay,

were recruited. TG parameters {lag time, time to peak, peak and endogenous thrombin potential (ETP)} in platelet-poor plasma were measured using CAT.

Results: Mean ETP±SD for the different ethnic groups were as follows: Caucasians - 1338.18±194.19nM.min, Chinese - 1318.91±108.90nM.min, Indians - 1389.81±182.61nM.min and Malays - 1436.21±184.24. Caucasian subjects have the longest mean lag time - 2.59±0.37s; Indian subjects had the highest mean peak - 284.22±30.74nM and Malay subjects had the longest mean time to peak - 5.47±0.59s apart from the highest mean ETP. Statistical analysis based on ethnicity however did not demonstrate any significant difference for all thrombin generation parameters.

Conclusions: In a population of healthy subjects, thrombin generation mediated by plasma factors is not influenced by ethnicity and does not explain the reported racial differences in VTE incidence. In view of the absence of significant difference, the use of separate normal ranges according to ethnic groups for plasma thrombin generation is not essential.

PB 1439 | Is Platelets - Bound C4d a Marker for Active Disease and Correlates with Hypercoagulability in Patients with Systemic Eritematosus Lupus?

K. Ferreira[1], W. Cicarini[1], C. Loures[1], F. Campos[1], R. Consoli[2], C. Neiva[2], P. Pádua[2], L. Alves[1], E. Reis[3], T. Guimarães[1], V. Toledo[1], M.G. Carvalho[1]

[1]*Faculdade de Farmácia da Universidade Federal de Minas Gerais, Análises Clínicas e Toxicológicas, Belo Horizonte, Brazil,* [2]*Santa Casa de Misericórdia, Belo Horizonte, Brazil,* [3]*Universidade Federal de Minas Gerais, Instituto de Ciências Exatas, Departamento de Estatística, Belo Horizonte, Brazil*

Background: Platelets - bound C4d (P-C4d) is a potential biomarker of active disease and hypercoagulability in patients with systemic lupus erythematosus (SLE). Patients positive for P-C4d have shown disease activity related to a higher frequency of cardiovascular events associated with thrombosis than patients negative for P-C4d. In fact, considering the biological role of platelets in hemostasis and coagulation, it is believed that high levels of P-C4d may be related to the thrombotic tendency in patients with SLE. By other side, Thrombomodulin (TM) and D dimer (DDi) are recognized biomarkers for endothelial lesion and hypercoagulability status, respectively.

Aims: This study has evaluated P-C4d, TM and DDi levels and their relationship to disease activity in SLE women under treatment, compared to controls.

Methods: Disease activity was defined by Systemic Lupus Erythematosus Disease Activity Index (SLEDAI- 2K). This study included 90 women with similar age distributed into 3 groups: 1) Healthy women (control, n=30); 2) SLE women with low disease activity (SLEDAI 2K ≤ 4, n=30), and 3) SLE patients with /moderate high disease activity (SLEDAI 2K > 4, n=30). Analysis of P-C4d was performed by flow cytometry using anti-CD42a antibody to identify platelet population and antibody specific for C4d. Endothelial lesion and hypercoagulable status were assessed by thrombomodulin and D-dimer measurements in citrated plasma samples, respectively. Data analysis was performed by Mann Withney using GraphPad Prism software 6™.

Results: The results are shown in Table 1.

Conclusions: Increased levels of P-C4d, TM and DDi, compared to controls, are directly linked to disease activity defined by SLEDAI-2K index and may indicate a thrombotic potential associated with the SLE inflammatory process. Support: CNPq,CAPES and FAPEMIG

PB 1440 | Profiling of Thrombotic and Inflammatory Mediators in Synovial Fluid from Patients Undergoing Primary Total Joint Arthroplasty

E. Finkler[1], C. Wanderling[2], C. Thorson[2], K. Galicia[2], R. McMillan[3], A. Otto[2], S. Statz[2], J. Fareed[2], W. Hopkinson[1]

[1]*Loyola University Medical Center, Orthopedics, Maywood, United States,* [2]*Loyola University Medical Center, Pathology, Maywood, United States,* [3]*Loyola University Chicago, Department of Pathology, Maywood, United States*

Background: Synovial fluid is an intra-articular fluid whose main function is to lubricate joints and decrease the coefficient of friction. The role of inflammatory and thrombotic mediators in degenerative joint disease (DJD) has been well established. Previous reports have suggested that increased plasma levels of biomarkers such as IL-1b, CRP, and (MP-TF) play a role in the DJD. It is hypothesized that the levels of these biomarkers in synovial fluid may provide additional information on the pathogenesis of DJD.

Aims: This study is designed to profile synovial fluid samples for various inflammatory biomarkers and to demonstrate their relevance to the progression of DJD.

Methods: This study consisted of 25 patients undergoing primary total joint arthroplasty (TJA) of the hip or knee for DJD. Patients were consented prior to surgery in accordance with LUMC IRB. At the time of arthrotomy, a sample of synovial fluid was obtained using a syringe and

TABLE 1 *P-c4d, Thrombomodulin and D dimer levels expressed as medians in women with Systemic Lupus Erythematosus under treatment*

	Controls (n=30)	Patients with SLE (n=60)	SLE Patients with Low Activity (n=30)	SLE Patients with Moderate/ High Activity (n=30)	P value*
P-C4d(P-C4d/μL)	a,b,c5.080	a 42.47	b,d 12.70	c,d 69.45	a0,0000 b0,0003 c0,0000 d0,0000
TM(ng/mL)	a,b,c 0.21	a 0.29	b,d 0.25	c,d0.34	a0,0341 b0,0000 c0,0007 d0,0002
DDi(ng/mL)	a,b,c 374	a 1155	b,d 930	c,d 1563	a0,0133 b0,0000 c0,0198 d0,0004

placed into a tube containing calcium citrate for preservation and analysis. Biomarkers including IL-1b, MP-TF and CRP were measured using commercially available ELISA methods from R&D laboratories (Minneapolis, MN). Total protein levels were measured by nantrope technology.

Results: Total protein levels ranged from 5-65 mg/ml (mean 18 mg/ml +/- standard deviation 13 mg/ml). IL-1b levels ranged from 0.04-0.96 pg/ml (0.19pg/ml +/-0.18pg/ml). MP-TF levels ranged from 0-55 pg/ml (14pg/ml+/-19pg/ml). CRP levels ranged from 0-7 ug/ml (1.5 ug/ml +/- 1.9ug/ml).

Conclusions: The presence of IL-1b and CRP in synovial fluid is highly suggestive of an ongoing inflammatory process, whereas MP-TF represent is a thrombotic biomarker which is a complex of microparticles with tissue factor. The wide variation in the levels of these markers may suggest differing degrees of degenerative and inflammatory processes in DJD. These levels can be quantified to provide more insight into the role of these mediators in the pathogenesis of DJD.

PB 1441 | The Proteins with Prothrombine Origine in Blood Plasma of Ischemic Stroke Patients as a Markers of Hipercoagulation

T. Katrii, T. Vovk, O. Savchuk

Taras Shevchenko National University of Kyiv, Educational and Scientific Centre ‚Institute of Biology and Medicine', Kyiv, Ukraine

Background: Shifts of the balance between coagulation and fibrinolysis play a crucial role in pathogenesis and treatment of cerebral ischemia.

Aims: In this study, we characterized the main markers of hipercoagulations as proteins with prothrombin origin in patients in acute as well as post acute phase of ischemic stroke.

Methods: Blood plasma samples were taken from 35 healthy donors as well as 66 patients with atherothrombotic ischemic stroke (AIS) and 56 patients with cardioembolic ischemic stroke (CIS) during the acute phase of disease; 56 patients with AIS and 56 patients with CIS one year past acute phase. Vitamin K-dependent plasma proteins fraction was obtained by sorption on barium sulfate. Systemic generation of the proteins with prothrombin origin at the vitamin K-dependent fractions was done by ELISA. Fraction composition was described throuhg size-exclusion chromatography on Healthcare „HiLoad 16/60 Superdex 200 pg" column.

Results: Increased concentration of hipercoagulation marker in blood plasma of acute ischemic stroke patients was showed. Concentrations become more close to physiological one year past. Results of chromatographic separation of fraction obtained from the patients with ischemic stroke in acute and post acute phase suggests the presence of proteins with Mr from 70 to higher 200 kDa. Mostly all peaks were presented in each tested fractions. Just the high of peaks was different for each tested fraction. The fact is that just one vitamin K-dependent protein - prothrombin with Mr 70 kDa is in bloodstream of healthy donors in the highest amount and its level become lover during the acute stroke. In this frame we could assume important role of prothrombin in the pathological process of the ischemic stroke development.

Conclusions: The first characterization of the coagulation marker in acute and post acute period was done. The difference in quantity and quality composition of the fractions could be used as a potential target for the prevention of the stroke repetition.

PB 2085 | Molecular Genetic Investigations in Hereditary Hemorrhagic Telangiectasia in Hungary; Identification of a Founder Mutation

R. Gindele[1], T. Major[2], Z. Szabó[1], K.B. Kovács[1], G. Pfliegler[3], Z. Bereczky[1]

[1]University of Debrecen, Faculty of Medicine, Division of Clinical Laboratory Science, Department of Laboratory Medicine, Debrecen, Hungary, [2]Markhot Ferenc Hospital, Department of Otorhinolaryngology, Eger, Hungary, [3]University of Debrecen, Faculty of Medicine, Division of Rare Diseases, Department of Internal Medicine, Debrecen, Hungary

Background: Hereditary hemorrhagic telangiectasia (HHT; Osler-Rendu-Weber syndrome) is an autosomal dominant vascular disease characterized by the presence of epistaxis, mucocutaneous telangiectases and visceral arteriovenous malformations (AVMs). Mutations in the genes for endoglin (*ENG*), the activin receptor-like kinase 1 (*ACVRL1*) and *SMAD4*, which encode proteins of the transforming growth factor-beta superfamily are responsible for the disease. Approximately 85 % of HHT cases have heterozygous family-specific mutations either in the *ENG* or *ACVRL1* genes, causing HHT type 1 and 2, respectively. Clinical diagnosis of the disease is based on the four Curacao criteria.

Aims: Our aims were to identify causative mutations of HHT in Hungary and to examine if common mutations exist.

Methods: Genetic analysis was performed in HHT index patients and their relatives (total n=85) between 2012 and January 2017. All exons and flanking intronic regions of *ENG*, *ACVRL1* and *SMAD4* were determined by direct fluorescent sequencing. Genotyping of markers D12S1677, D12S85, D12S2196, D12S1712, D12S270, rs2071219, rs706815 and rs706816 around *ACVRL1* gene was performed in 14 carriers of the *ACVRL1* c.625+1 G>C and 50 healthy controls to ascertain the possibility of a founder effect.

Results: The mutation detection rate was 75% among the 41 HHT index patients, 46% were detected with ENG (11 known and 6 novel), 29% with *ACVRL1* (3 known and 4 novel) mutations and no *SMAD4* mutations were found. A novel *ACVRL1* c.625+1 G>C mutation was detected in 6 apparently unrelated HHT families. Haplotype analysis of the above-mentioned genetic markers suggested a founder effect. The genealogical analysis revealed that the possible common ancestors were married in 1779.

Conclusions: The identification of a founder mutation in HHT is helpful, since the clinical presentation of the disease becomes more predictable and it might simplify the molecular genetic diagnosis algorithm.

PB 2086 | How Well can Laboratories Make a Diagnosis of Type 3 VWD? Results from a UK NEQAS (Blood Coagulation) Diagnostic Challenge Exercise

I. Jennings, L. Brown, D. Kitchen, S. Kitchen, T. Woods, I. Walker

UK NEQAS Blood Coagulation, Sheffield, United Kingdom

Background: Proficiency testing (PT) in the Haemostasis laboratory usually involves assay of a specified factor assay or screening test on a single sample, as directed by the PT provider. However, this does not reflect "real life" in laboratories where a panel of tests on the same sample is often required to make a diagnosis for a patient with a bleeding history.

Aims: We describe here an exercise where laboratories were provided with plasma and brief clinical details and asked to perform whichever tests they deemed necessary to make a diagnosis.

Methods: 73 centres took part in this exercise. The history given was a 10 year old male with a history of bleeding into joints, with a prolonged APTT. No details were available on the parents. The sample was from a patient previously diagnosed with type 3 VWD.

Results: 41/73 centres correctly identified type 3 VWD in this exercise, with 5 reporting VWD requiring subtyping, and 1 reporting haemophilia or VWD, with further investigation required. 17/73 centres reported haemophilia A, all these centres failed to perform a VWF assay (11 of these centres are registered for VWF assays in the UK NEQAS BC programme, so probably have this assay available, 5 of these centres do not perform VWF assays but did not suggest referral for this investigation). One centre diagnosed a lupus anticoagulant in this sample, and did not perform either FVIII or VWF assays.

The number and pattern of tests employed in this exercise varied markedly - 40/73 centres did not confirm the reported APTT, and 7 performed only a FVIII assay. Mixing studies were carried out in 46 centres, with 14 performing incubated mixes to exclude an inhibitor.

Conclusions: The failure of 18/73 centres to perform sufficient assays to correctly diagnose severe VWD highlights the need for expertise within departments to fully investigate bleeding disorders, and also highlights the value of proficiency testing exercises such as this.

PB 2087 | Rivaroxaban but Not Apixaban Causes False-positive Results in Lupus Anticoagulant Testing that Can Be Overcome with Andexanet Alfa

R.I. Baker[1,2], G. Gilmore[1,2], J. Tiao[1,2], S.R. McGregor[1,2]

[1]Murdoch University, Western Australian Centre for Thrombosis and Haemostasis, Perth, Australia, [2]Perth Blood Institute, Perth, Australia

Background: Direct Factor Xa (FXa) inhibitors are capable of inducing false-positive lupus anticoagulant (LA) dRVVT results, however information on inter-patient variability and dose response is limited. Andexanet alfa is a recombinant FXa decoy protein, and its incorporation *in-vitro* during LA testing may overcome FXa inhibitor-induced false-positive LA results.

Aims: To determine inter-individual variability and dose-dependent effects of rivaroxaban and apixaban on LA testing and whether andexanet alfa can overcome this interference.

Methods: After informed consent, plasma from 8 healthy volunteers and 12 patients on therapeutic doses of rivaroxaban (n=6) or apixaban (n=6) with known LA status (3/6 LA positive in each group) were collected. Normal pooled plasma, known concentrations of rivaroxaban, apixaban, andexanet alfa and affinity purified LA+ and control IgG were used in experiments. dRVVT and anti-FXa assays were performed on the Sysmex CS5100 analyser.

Results: Plasma from healthy volunteers yielded false-positive dRVVTs when spiked with 200ng/mL rivaroxaban, but not apixaban (100% and 0% of samples, respectively). In pooled normal plasma, rivaroxaban caused more dose-dependent prolongation of the dRVVT Screen relative to the Confirm, leading to a false-positive LA ratio at concentrations ≥100ng/mL. In contrast apixaban proportionately prolonged the dRVVT Screen and Confirm, and even at high concentrations (>1,200ng/mL) the LA ratio remained negative. The addition of andexanet alfa abolished the rivaroxaban-induced false-positive LA results in LA-negative patient plasma without compromising the interpretation of true LA-positive patient results; this was replicated in LA-positive IgG spiking experiments.

Conclusions: Rivaroxaban but not apixaban causes an exaggerated dose-dependent prolongation of the dRVVT Screen, yielding a false-positive LA test interpretation. Andexanet alfa corrects the false-positive LA ratio in patients on rivaroxaban but may not be required for patients on apixaban.

PB 2088 | The Feasibility of Heparin Neutralization Assay to Replace Serotonin Release Assay in the Diagnosis of Heparin-induced Thrombocytopenia

G. Zheng, M. Streiff, C. Takemoto, J. Bynum, E. Gelwan, J. Jani, D. Judge, T. Kickler

Johns Hopkins University, Baltimore, United States

Background: Heparin-induced thrombocytopenia (HIT) remains diagnostically challenging. Nearly all patients with HIT produce antibodies that recognize the PF4-heparin complex that can be detected by immunoassays. However, these assays are also positive in many heparin-treated patients who do not have HIT. In these cases, functional assays such as the serotonin release assay (SRA) are useful for identifying pathogenic HIT antibodies. However, the SRA is labor intensive and not widely available.

Aims: We assessed the clinical utility of heparin neutralization assay (HNA) and evaluated whether it improves the diagnostic specificity for HIT.

Methods: We implemented a heparin neutralization assay (HNA) in conjunction with PF4/heparin enzyme-linked immunosorbent assay (ELISA) over a one year period. 1194 patient samples were submitted to the laboratory for HIT testing from December 2015 to November 2016.

Results: Using SRA as the "gold standard", the positive predictive value of a positive ELISA (Opitical Density, or OD≥0.4) is only 25%. In fact, ELISA OD < 0.9 or HNA %inhibition < 70% essentially exclude HIT. HNA significant improves the diagnostic specificity in conjunction with ELISA. With ELISA OD≥1.4 and HNA %inhibition ≥70%, the sensitivity of the test combination is 94%, and the specificity 93%. With a more stringent diagnostic criteria for HIT using 4T score and ELISA OD, ELISA/HNA has similar diagnostic accuracy to SRA.

Conclusions: HNA is a much easier procedure than SRA, and it has the potential to facilitate more timely and accurate HIT diagnosis. Based on our data, we propose a new diagnostic algorithm for HIT, which mostly eliminates the need for SRA.

PB 2089 | One Stage and Chromogenic FVIII Assays in Spiked and Post Infusion Samples Containing rFVIIIFc or Recombinant FVIII: Data from a UK NEQAS for Blood Coagulation Survey

S. Kitchen[1], I. Jennings[1], M. Makris[2], D. Kitchen[1], T. Woods[1], I. Walker[1]

[1]UK NEQAS (Blood Coagulation), Sheffield, United Kingdom, [2]University of Sheffield, Sheffield, United Kingdom

Background: Variability in FVIII:C measurement is a recognised problem although there are few data for samples containing recombinant Factor VIII Fc fusion protein (rFVIIIFc) . Many studies use samples for which factor concentrate has been spiked into FVIII deficient plasma in vitro. This approach should be validated by comparison to samples obtained from patients after infusion of product.

Aims: To assess one stage and chromogenic FVIII assay results in spiked and post infusion samples.

Methods: Four samples were distributed in a UK National External Quality Assessment Scheme for Blood Coagulation (NEQAS) survey. One was constructed by adding Advate, a recombinant FVIII

TABLE 1 One stage FVIII assay results obtained with different APTT reagents

		Post Advate Infusion	Post Advate Infusion	Sample Spiked with Advate	Sample Spiked with Advate	Post rFVIIIC Infusion	Post rFVIIIC Infusion	Sample Spiked with rFVIIIFc	Sample Spiked with rFVIIIFc

(rFVIII) concentrate to FVIII deficient plasma, one was from a severe Haemophilia A patient after infusion of Advate, one was prepared by addition of rFVIIIFc (trade name Elocta or Eloctate) to FVIII deficient plasma and the 4th was collected from a severe Haemophilia A patient following rFVIIIFc infusion. Fifty-three haemophilia centres in the UK and Scandinavia performed FVIII assays using one stage methods and 27 performed chromogenic FVIII assays. Centres calibrated assays with their local plasma standard.

Results: One stage assay results were lower than chromogenic by 7% and 15% for the two Advate samples, and by 29% and 31% for the 2 rFVIIIFc samples. The inter-laboratory variation was similar for all samples with CVs of 12-16% for chromogenic assays and 10-13% for one stage assay results. Results according to different reagents are shown in table 1 and 2. For both materials there was a highly significant correlation between results obtained on spiked and post infusion samples for both one stage and chromogenic assays.

Conclusions: In this study inter lab variability was similar for rFVIII and rFVIIIFC, and the data indicate that either can be safely monitored by one stage or chromogenic assay. Spiked samples behaved in a similar way to post infusion samples for both products and are therefore suitable for use in proficiency testing exercises.

PB 2090 | Epitope Mapping of Anti-FVIII Antibodies in Hemophilia A Patients Using LumiTope, a FVIII Domain-specific Multiplex Microsphere Based Immunoassay

B. Pezeshkpoor, A.-C. Berkemeier, J. Müller, T. Albert, J. Oldenburg

University Clinic Bonn, Institute of Experimental Hematology and Transfusion Medicine, Bonn, Germany

Background: FVIII neutralizing antibodies develop in response to replacement treatment in 30% of patients with severe hemophilia A. Such inhibitory antibodies represent a serious complication in the treatment of these patients.

Aims: The aim of the present study was investigation of domain specificity of anti-FVIII antibodies in hemophilia A patients in a time-frame of two years using a multiplex microsphere-based immunoassay on the Luminex™ system.

Methods: FVIII protein was expressed and purified in several single and multi-domain fragments using a baculovirus expression system in insect cells. The domains were purified (>80%) and individually coupled to colored-coded magnetic microspheres. Commercially available full length (FL-FVIII) and B-domain deleted (BDD-FVIII) FVIII proteins were immobilized accordingly. The coupled target proteins were used to establish the Luminex™ based assay, termed *LumiTope*.

Results: In total 765 samples from 266 hemophilia A patients (20 mild, 43 moderate and 203 severe) were analyzed. Among these 200 patients were without and 66 patients were with inhibitor. For all samples domain and isotype specificity of the anti-FVIII antibodies was determined. Our results show that *LumiTope* is a sensitive test for detection of anti-FVIII antibodies. The test revealed positive results against FL-FVIII beads for all patients with antibody titers> 0.6 BU/ml and positive results on FVIIII-ELISA antibody test. Moreover, we were able to identify several monoclonal and polyclonal antibodies against A2a2, a3A3, LC, C1, C2 and C1C2 domains. Detected antibodies were predominantly directed against the A2a2 and C2 domains of FVIII. The IgG1 and IgG4 subclasses contributed to the majority of anti-FVIII IgG response.

Conclusions: Our new immunoassay, *LumiTope*, provides a sensitive and fast method for characterization of inhibitory anti-FVIII-antibodies in hemophilia A patients. The characterization of the binding regions of these antibodies may provide the basis for understanding of inhibitory mechanisms.

PB 2091 | Investigation of an Incidental Finding of Factor 8 Gene Duplication Detected by Chromosomal Microarray Analysis

R. Dardik, E. Avishai, N. Rosenberg, D. Eli, G. Kenet

Sheba Medical Center, National Hemophilia Center, Ramat Gan, Israel

Background: A 32 year old female patient (YL) with recurrent pregnancy loss (X4) was referred to the National Hemophilia Center for investigation of an incidental finding of a duplication involving a part of the Factor 8 (F8) gene, which was observed in chromosomal microarray (CMA) analysis performed in her 4th miscarried male fetus.

Aims: To confirm or exclude the involvement of F8 gene in the above duplication with the aim of establishing hemophilia A carrier status for YL.

Methods:

1. Multiplex ligation-dependent probe amplification (MLPA) was used to detect duplication of F8 gene exons.
2. Genotyping based on STR markers was used to establish the grandparental origin of the fetal F8 gene copy involved in the duplication.

Results:

1. The duplicated region indicated by CMA, Xq28 (154,225,507-154,285,587; GRCh37/hg19 genome build), includes F8 exons 1-3. MLPA analysis demonstrated duplication of F8 exons 1-3 in both the miscarried fetus and in YL.
2. Based on STR analysis, YL´s mother was found to be negative for the above duplication, and the fetus was found to carry the haplotype of YL´s father, who was not available for DNA or FVIII level analysis.

Conclusions: Using MLPA, we confirmed the involvement of F8 gene in duplication of a chromosome X segment containing a part of the F8 gene, which was incidentally detected in a miscarried fetus. Furthermore, we detected the same duplication in the mother, suggesting that she may be a hemophilia A carrier. In her future pregnancy, we will be able to offer prenatal diagnosis based on MLPA. In view of the uncertainty regarding the association of the duplication of F8 exons 1-3

with hemophilia A, we will offer fetal blood sampling to measure fetal FVIII level if such duplication is detected in a male fetus in the future.

PB 2092 | Thromboxane Formation Assay to Identify High on-treatment Platelet Reactivity to Aspirin

L. Dannenberg[1], A. Mohring[1], C. Helten[1], K. Bartkowski[2], T. Zeus[1], M. Kelm[1], T. Hohlfeld[2], A. Polzin[1]

[1]*Heinrich Heine University Medical Center Düsseldorf, Division of Cardiology, Pulmonology, and Vascular Medicine, Düsseldorf, Germany,* [2]*Heinrich Heine University, Institute for Pharmacology and Clinical Pharmacology, Düsseldorf, Germany*

Background: Platelet inhibition by aspirin is indispensable in secondary prevention of cardiovascular events. Nevertheless impaired aspirin antiplatelet effects (high on-treatment platelet reactivity [HTPR]) are frequent. This is associated with an enhanced risk of cardiovascular events. The current gold standard to evaluate aspirin induced platelet inhibition is the light-transmittance aggregometry (LTA). However, the pharmacologically most specific test is measurement of arachidonic acid (AA) induced thromboxane (TX) formation. TX is the specific product of the transformation of AA by cyclooxygenase-1 (COX-1). By now, the optimal cut-off to define HTPR to aspirin by inhibition of TX formation is not known.

Aims: We aimed to compare the results of LTA with the TX ELISA assay and calculate a cut-off level for detecting HTPR by TX ELISA assay.

Methods: We measured platelet function in 2507 samples. Arachidonic acid (AA) induced TX formation by ELISA assay and AA induced LTA was used to measure aspirin antiplatelet effects and to detect aspirin specific HTPR.

Results: TX formation correlated nonlinear with the maximum of aggregation in the AA induced LTA (Spearman's rho R=0.7396; confidence interval [CI] 0.7208 - 0.7573, p< 0.0001). Receiver operating characteristic (ROC) analysis revealed 209.8 ng/ml as the optimal cut-off value to detect HTPR to aspirin with the TX ELISA assay (area under the curve: 0.92, P< 0.00001, sensitivity of 82.7 %, specificity of 90.3 %).

Conclusions: TX formation ELISA is reliable in detecting HTPR to aspirin. The calculated cut-off level needs to be tested in trials with clinical end points.

PB 2093 | Prospective Multicenter Validation of Standard and Age-adjusted D-Dimer Testing in Patients with Suspected Pulmonary Embolism (PE) and Deep Venous Thrombosis (DVT)

Background: D-dimer testing, with or without age-adjustment, is the standard of care for ruling out pulmonary embolism (PE) or deep vein thrombosis (DVT).

Aims: To determine the test characteristics of an automated D-dimer assay for the exclusion of PE and DVT in emergency department (ED) patients using standard and age-adjusted cutoff formulas.

Methods: Prospective observational study of consecutive ED patients with suspected DVT or PE in 24 centers (18 USA, 6 Europe). All patients had low or intermediate Wells scores for PE or DVT. We evaluated the INNOVANCE D-dimer assay on the CS-5100 platform. For the standard cutoff, we considered a D-dimer result < 0.50 mg/L negative. For the age adjusted cutoff, we adjusted cutoff in patients > 50 years old to consider a result negative if D-dimer (in mg/L) was < Age * 10 (years). The diagnostic standard was imaging demonstrating PE (excluding subsegmental PE) or DVT (excluding calf vein DVT, including recurrent and chronic DVT) within 3 months. Patients without 3-month follow up data were excluded. We calculated test characteristics using standard methods. We also explored modifications of the age adjustment formula.

Results: Among 3,586 patients, those evaluated for PE (n=1834) had mean age of 48 ± 16 years, 676 (37%) were male, 1081 (59%) were white and PE prevalence was 5.5% (101/1834). Among those evaluated for DVT (n=1752) the mean age was 53 ± 16 years, 710 (41%) were male, 1172 (67%) were white, and DVT prevalence was 6.4%

TABLE 1 Test Characteristics INNOVANCE D-dimer

	PE (%)				DVT (%)			
Method	Sens.	Spec.	NPV	PPV	Sens.	Spec.	NPV	PPV
Standard cutoff (0.5)	98.02	54.54	99.73	13.75	92.04	45.77	98.61	12.08
Age-adjusted cutoff (Age (if >50)*10)	97.03	59.00	99.63	14.89	92.04	52.51	98.79	13.56

(113/1752). Test characteristics using standard and age-adjusted cut-offs are reported in Table 1. Altering the age adjustment formula did not improve specificity but did increase false negatives.

Conclusions: The INNOVANCE D-dimer assay is highly sensitive and has reasonably high specificity. Age-adjustment allows slightly more patients to be safely excluded, without increasing false negatives. Further modification of this formula does not appear to be beneficial.

PB 2095 | The Detection of Cross-reactive Antibodies to Recombinant Porcine FVIII

A.E. Bowyer, M.F. Shepherd, S. Kitchen, M. Makris

Sheffield Haemophilia and Thrombosis Centre, Coagulation, Sheffield, United Kingdom

Background: Recombinant porcine FVIII (rpFVIII) is licensed for the treatment of bleeding in adults with acquired haemophilia A (AHA). Its safety and efficacy have not been established in patients with >20 Bethesda units (BU) of cross-reactive antibodies to rpFVIII.

Aims: The aim was to determine the stability, sensitivity of FVIII:C assay and baseline inhibitor titre to rpFVIII in patients with AHA.

Methods: rpFVIII was reconstituted in water then diluted to 1IU/ml of labelled potency in 0% FVIII plasma containing VWF (George King). One-stage FVIII:C (FVIII:C1) using Actin FS (AFS) and 0% FVIII (Siemens) was measured at times 0, 1 and 2 hours post reconstitution against human plasma standard (SHP, Siemens). rpFVIII was serially diluted, 1.25 to 0.06 IU/ml, in 0% FVIII and FVIII:C1, using a single batch of AFS and Synthasil (Werfen), or Chromogenic FVIII (FVIII:CR, Siemens) was assayed against SHP or rpFVIII standard. The Nijmegen modified Bethesda assays (BA) of 9 patients with AHA were performed with rpFVIII used as the source of FVIII. Residual FVIII was measured by FVIII:C1 with AFS. All assays were performed with Sysmex CS5100i instrumentation.

Results: There was no difference in FVIII:C1 between t0 and t2 hours post reconstitution of rpFVIII (t0 was 1.63 IU/ml and t2 was 1.62 IU/ml). rpFVIII measured against SHP was underestimated by FVIII:CR (67% of target) and overestimated by FVIII:C1 (45% with AFS, 20% with Synthasil). The recovery of FVIII:C1 was improved by the use of rpFVIII as the standard however further investigation is required.

Cross-reactive antibodies to rpFVIII were detected in 6 patients with AHA. Porcine titres ranged from 0.83-52.0 BU. 3 of these patients demonstrated non-linear assays common in AHA. 3 patients with antibodies to human FVIII did not have antibodies to rpFVIII (table1).

TABLE 1 Human and porcine inhibitor titre in patients with AHA

Patient ID	FVIII:C1 (IU/ml)	rpFVIII BA (BU)	Linearity	Human FVIII BA (BU)
P1	<0.01	52	linear	>360
P2	0.02	0		8.2
P3	0.03	0		2.5
P4	0.02	0.83	linear	>74
P5	0.03	0		>9
P6	0.04	>5.3	non-linear	>200
P7	0.11	>42	non-linear	>530
P8	0.02	2.0	linear	>380
P9	<0.01	>0.98	non-linear	>102

Conclusions: Not all individuals with AHA have antibodies to rpFVIII. The antibody kinetics varied between patients. The assessment of antibodies to rpFVIII may be useful prior to treatment of patients with AHA.

PB 2096 | Mixing Test to Discriminate between Lupus Anticoagulant and Direct Oral Anticoagulant in Diluted Russell's Viper Venom Time Test

O. Kumano, Y. Komiyama

Sysmex Corporation, Hemostasis Product Engineering, Kobe, Japan

Background: Lupus anticoagulants (LA) are associated with an increased risk of thrombosis and laboratory detection is major importance. One of the recently developed anticoagulants is rivaroxaban, a direct Xa inhibitor. The false positive results of LA tests were reported in the samples with rivaroxaban.

Aims: The aim of this study is to discriminate between LA and rivaroxaban in LA tests, and distinguish the true positive.

Methods: Thirteen samples positive for LA in APTT and dRVVT reagents were assayed. Ten LA negative samples with rivaroxaban were also used in this study. dRVVT screen and confirm tests were performed in undiluted and 1:1 mix with normal pooled plasma. Screen / confirm normalized ratio was calculated in all samples including the mixing plasmas. Index of circulating anticoagulant (ICA) was used to show the mixing test results in not only screen but also confirm

reagent. ICA = (b - c) / a X 100 where a, b and c are the clotting times of the patient's plasma, the 1:1 mixture, and normal plasma respectively.
Results: The means of screen / confirm ratios in LA and rivaroxaban samples were 1.6, 1.6 for undiluted and 1.3, 1.3 for 1:1 mixing, respectively. The means of ICA values in screen reagent were 18.9 and 24.2 in LA and rivaroxaban samples, respectively. There were no significant differences in these indexes. The means of ICA values in confirm reagent were 2.2 and 19.4, respectively and showed significant difference.
Conclusions: There was a large difference between LA and rivaroxaban group in ICA of confirm. The clotting times were not prolonged in LA samples due to the high phospholipid concentration, but rivaroxaban samples prolonged because of a direct Xa inhibitor in both undiluted and 1:1 mix plasmas. When screen / confirm ratio shows more than cut-off value in rivaroxaban suspicious samples, ICA of confirm could be useful to interpret the ratio results. The mixing test of confirm reagent can discriminate between LA and rivaroxaban samples.

PB 2097 | Assessment of Three Contact Activation Reagents for the Diagnosis of Factor XI Deficiency

S. Salloum-Asfar[1], M.E. de la Morena-Barrio[1,2], J. Esteban[3], A. Miñano[1], C. Aroca[1], J. Padilla[1], V. Vicente[1,2], V. Roldán[1], J. Corral[1,2]

[1]*Servicio de Hematología y Oncología Médica, Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, Murcia, Spain,* [2]*CIBERER, Madrid, Spain,* [3]*Servicio de Hematología. Hospital Virgen del Castillo de Yecla, Murcia, Spain*

Background: FXI deficiency is usually diagnosed by prolonged aPTT (ratio>1.3) and confirmed by coagulation assays (FXI:C< 70%). The low bleeding risk of carriers and the limitations of current diagnostic methods suggest that FXI deficiency might be underestimated. Sensitive and reliable methods are required.
Aims: To assess 3 contact activation commercial reagents in subjects with congenital FXI deficiency.
Methods: Plasma of 140 cases with FXI deficiency (9 homozygous or compound heterozygous and 131 heterozygous for 12 mutations) were collected. Under identical conditions, samples were evaluated in ACL TOP 500 coagulometer with the following reagents:
1) SynthASil (SS; silica-based),
2) SynthAFax (SF; ellagic acid-based), both from Instrumentation Laboratory, and
3) EA-DG-APTT (EA; ellagic acid-based) from Grifols. *F12* rs1801020 was genotyped usingTaqman probes.
Results: Severe FXI deficiency prolonged aPTT with all reagents. However, a high proportion of mild deficiencies would not be detected using aPTT, with false negatives of 77% for EA, 22% for SS and 12% for SF. 42-46% of false negatives corresponded to cases with qualitative deficiency (CRM+). The common *F12* SNP significantly prolonged aPTT when activated by silica. FXI:C values obtained with ellagic acid were higher than those with silica (SF: 47.7±12.7%, EA: 46.3±10.9% *vs.* SS: 40.4±14.9%). Thus, silica gave 2-3-fold lower rate of false negatives (2.1%) than ellagic acid; most of them were CRM+. Noteworthy, FXI:C levels were not determined by current adjustments with ellagic acid in cases with severe deficiency.
Conclusions: Mild FXI deficiency, particularly CRM+, might be underestimated due to the high rate of false-negative results that render aPTT assays. Other elements of the contact phase, as *F12* SNP, and the strength of the activation may explain the high rate of false negatives. Our results suggest that the best method to detect and quantify FXI deficiency is FXI:C using silica.

PB 2098 | Platelet Reactivity in a Large Population with the Bruneck Cohort

M.V. Chan[1], T. Barwari[2], J.E. Huffman[3], P.C. Armstrong[1], P. Santer[4], S. Kiechl[5], J. Willeit[5], M. Mayr[2], A.D. Johnson[3], T.D. Warner[1]

[1]*The William Harvey Research Institute, Barts and The London School of Medicine & Dentistry, Queen Mary University of London, London, United Kingdom,* [2]*King's British Heart Foundation Centre, King's College London, London, United Kingdom,* [3]*The National Heart, Lung, and Blood Institute's Framingham Heart Study, Framingham, Massachusetts, United States,* [4]*Bruneck Hospital, Department of Laboratory Medicine, Bruneck, Italy,* [5]*Medical University Innsbruck, Department of Neurology, Innsbruck, Austria*

Background: The Bruneck Study began in 1990 as a population-based study in 1000 people on the epidemiology and pathogenesis of cardiovascular disease with a follow-up every 5 years. Extensive platelet reactivity using multiple concentrations of agonists has rarely been studied in large cohorts due to constraints of blood volume, time and expertise. We have developed a high throughput plate-based (Optimul) assay requiring a relatively small amount of blood and minimal technical skill.
Aims: To provide in-depth platelet reactivity phenotyping in a large population.
Methods: Fasting blood was taken from 338 people (age 55-98, 51% male) in citrate (0.105M) vacutainers and platelet rich (PRP) and poor (PPP) plasma was obtained by centrifugation. Light transmission aggregometry (LTA; AA 1mM; ADP 5 & 20μM; collagen 0.4, 4 & 10μg/ml; TRAP-6 amide 25μM; U46619 10μM) and Optimul aggregometry (AA 0.3-1.5mM; ADP 1-30μM; collagen 0.4-30μg/ml; epinephrine 0.6-10μM; ristocetin 0.1-1.5mg/ml; TRAP-6 0.1-25μM; U46619 0.01-10μM) were performed within 2 hours of blood draw. % aggregation was calculated and data were analyzed using R with the nlpr package. Data is reported as mean±s.d.
Results: Mean % aggregation to AA (30±33%), ADP 5μM (58±14%) and 20μM (62±12%), collagen 0.4μg/ml (35±27%), 4μg/ml (60±14 %), 10μg/ml (60±15%), TRAP-6 (64±12%) and U46619 (65±11%) was generated by LTA. Additionally, maximum % aggregation to agonists were calculated from the Optimul assay for AA (78±17%), ADP (85±6%), collagen (87±8%), epinephrine (76±19%), ristocetin (89±6%), TRAP-6 (88±5%) and U46619 (87.9±3.7%).
Conclusions: This is the first complete study of platelet reactivity using LTA and the Optimul assay in a large population. We are

currently interrogating the platelet reactivity data according to clinical characteristics such as sex, age and smoking status. The potential of our assay in gathering data easily in large cohorts is unprecedented and can only advance the field of platelet reactivity testing.

PB 2099 | Evaluation of IgG4 Anti-FVIII as Strategy to Improve the Diagnosis of Factor VIII Inhibitor in Association with Modified-Bethesda Assay

S.A.L. Montalvao[1], L.B. Rosa[2], A.A. Oliveira[2], P.S. Elídio[2], H.J. Aguiari[2], A.A.L. Sambo[2], M.M.T. Hosokawa[2], M.C. Della-Piazza[2], C.S. Costa-Lima[2], S.S. Medina[2], M.C. Ozelo[2,3]

[1]IHTC, University of Campinas, Campinas, Brazil, [2]IHTC ‚Cláudio L P Corrêa', INCT do Sangue Hemocentro Unicamp, University of Campinas, Campinas, Brazil, [3]Department of Internal Medicine, Faculty of Medical Sciences, University of Campinas, Campinas, Brazil

Background: Alternative methods for better evaluate the presence of factor(F) VIII inhibitor have been assessed during the last years.

Aims: The aim of this study was evaluate the use of FVIII-IgG4 in order to improve the inhibitor testing, currently based on modified-Bethesda assay (MBA).

Methods: Samples from 47 hemophilia A patients, and 4 acquired FVIII inhibitor patients were assessed. Each plasma sample was tested to MBA and FVIII-IgG4 by ELISA.

Results: In total 269 plasma samples, divided into 3 groups, were analyzed. The correlation of all samples for MBA and FVIII-IgG4 were 0.70 (p< 0.0001). Group A: 44 samples with MBA negative (< 0.6BU), with median MBA of 0.11BU (0-0.56), had median FVIII-IgG4 not detectable (ND) (ND-1:640). Group B: 94 samples with MBA 0.6-5BU, and median of 1.32BU, with median FVIII-IgG4 titer of 1:80 (ND-1:2560), being ND in 19% of samples. Group C: 55 samples with MBA >5BU and median of 32.58BU (5.2-1254BU) with median FVIII-IgG4 titers of 1:1280 (1:20-1:81920). Interestingly, one patient who developed inhibitor, showed first 3 consecutives MBA negative results with high titers of FVIII-IgG4 (1:320-1:640). When MBA became positive the levels of FVIII-IgG4 were maintained. Patients with similar MBA results showed different FVIII-IgG4 titers, suggesting a higher sensitivity of FVIII-IgG4 compared with MBA. For 76 samples, from 11 patients under ITI, the MBA was performed using both coagulometric and chromogenic methods. Samples from 6 patients had concordance in all 3 tests. However, for 3 patients with both chromogenic MBA and FVIII-IgG4 negative, the coagulometric MBA was 0.6-6.4BU.

Conclusions: The classification of inhibitor in high and low titer is an important clinical information. This study suggests that FVIII-IgG4 was able to improve the specificity of inhibitor detection in comparison to MBA assay.

PB 2100 | Comparison of Age-adjusted D-dimer and Clinical Probability-adjusted D-dimer for Diagnosing Pulmonary Embolism

S. Sharif[1], C. Kearon[2], M. Li[3], M. Eventov[3], R. Jiang[3], P. Sneath[3], R. Leung[3], K. de Wit[1]

[1]McMaster University, Medicine, Division of Emergency Medicine, Hamilton, Canada, [2]McMaster University, Medicine, Sub-Department of Respirology/Hematology and Thromboembolism, Hamilton, Canada, [3]McMaster University, Hamilton, Canada

Background: Diagnosing pulmonary embolism (PE) in the emergency department can be challenging and often results in the over-utilization of CT pulmonary angiography (CT-PA). Age-adjusted D-dimer has been shown to decrease CT utilization rates. Recently, clinical probability-adjusted D-dimer has been promoted as an alternative strategy to reduce CT scanning.

Aims: To compare the safety and efficacy of the age-adjusted D-dimer and clinical probability-adjusted D-dimer rules in Canadian ED patients tested for PE.

Methods: This was a retrospective chart review of ED patients investigated for PE at two hospitals from April 2013 to March 2015. Inclusion criteria were ED physician ordered CT-PA, Ventilation-Perfusion (VQ) scan or D-dimer for investigation of PE. Patients under the age of 18 were excluded. PE was defined as CT/VQ diagnosis of acute PE or acute PE/DVT in 30-day follow-up. Trained researchers extracted anonymized data. The age-adjusted D-dimer and clinical probability-adjusted D-dimer rules were applied retrospectively. The rate of CT/VQ imaging and false negative rates were calculated.

Results: In total, 1,189 patients were tested for PE. 1,129 patients had a D-dimer and a Wells score less than 4.0, or a Wells score greater than 4.0 with or without a D-dimer. 364/1,129 patients (32.3%, 95%CI 29.6-35.0%) would have imaging for PE if the age-adjusted D-dimer rule was used. 1,120 patients had a D-dimer and a Wells score less than 6.0, or a Wells score greater than 6.0 with or without a D-dimer. 217/1,120 patients (19.4%, 95%CI 17.2-21.2%) would have imaging for PE if the clinical probability-adjusted D-dimer rule was used. The false-negative rate was 0.3% (95%CI 0.1-0.9%) for the age-adjusted D-dimer and 1.0% (95%CI 0.5-1.9%) for the clinical probability-adjusted D-dimer.

Conclusions: The false-negative rates for the age-adjusted D-dimer and clinical probability-adjusted D-dimer are low. The clinical probability-adjusted D-dimer results in a 13% absolute reduction in CT scanning compared to age-adjusted D-dimer.

PB 2101 | The Screening aPTT Mixing Test Is Not Sufficient to Rule Out the Presence of Inhibitor

S.A.L. Montalvao[1], A.A. Oliveira[1], L.B. Rosa[1], H.J. Aguiari[1], P.S. Elídio[1], A.L.A. Sambo[1], M.M.T. Hosokawa[1], M.C. Della-Piazza[1], C.S. Costa-Lima[1], S.S. Medina[1], M.C. Ozelo[1,2]

[1]IHTC ‚Cláudio L P Corrêa', INCT do Sangue Hemocentro Unicamp, University of Campinas, Campinas, Brazil, [2]Department of Internal Medicine, Faculty of Medical Sciences, University of Campinas, Campinas, Brazil

Background: Many laboratories routinely perform screening aPTT mixing test to evaluate the presence of inhibitors, which if positive triggers the investigation with the modified-Bethesda assay (MBA).

Aims: The aim of this study was evaluate the sensitivity/specificity of screening aPTT mixing test to identify factor (F) VIII inhibitors.

Methods: This study had 2 phases. Phase 1: Evaluation of 15 laboratories for their capacity to assess FVIII inhibitors presence using aPTT mixing test. Each laboratory received 3 lyophilized plasma samples from patients with hemophilia A (HA), acquired HA and health individuals (controls), with 3.45, 5.67 and 0.4BU, respectively. Phase 2: According to the results the central lab evaluated each step of the procedure, including FVIII source and different mathematical approaches.

Results: 4/15 (27%) laboratories showed inadequate results for aPTT mixing test in at least one sample, including false positive or negative results. In the phase 2, the central lab analyzed 59 samples from 44 HA and 6 acquired HA patients. These samples were tested in parallel to MBA and aPTT mixing test, with previous incubation at 37°C for 2h. In MBA assay, 38 samples were negative for inhibitor (< 0.6BU) and 21 positive. No correlation between aPTT mixing test and MBA results was observed. aPTT mixing test was false positive in 12/59 (25%) samples using not buffered in house pool, and 4/59 (7%) using commercial plasma. For the mathematical approach, classical aPTT reference range correction and Rosner index had 5% of false negative results, and using WFH previous recommendation 14%. The sensitivity/specificity was calculated for 10 procedures combinations. The range of sensibility to inhibitor detection was from 70 to 100% and the specificity 64 to 93%.

Conclusions: Although, aPTT mixing test is simple with low cost, it is not enough to rule out the presence of FVIII inhibitor. This suggests that aPTT mixing test should not be recommended as screening test, due to the occurrence of false negative results.

PB 2102 | Quantitation of Dabigatran by Global and Specific Coagulation Assays

J. Lozier[1], K. Nghiem[1], A. Cullinane[1], R. Alfaro[2], L. Gordon[3], C. Hadigan[4], P. Kumar[2]

[1]NIH Clinical Center, Department of Laboratory Medicine, Bethesda, United States, [2]NIH Clinical Center, Pharmacy Department, Bethesda, United States, [3]Xavier University of Louisiana, College of Pharmacy, New Orleans, United States, [4]National Institutes of Allergy and Infectious Disease, Laboratory of Immunoregulation, Bethesda, United States

Background: The direct oral thrombin inhibitor dabigatran offers the advantage of fixed dosing without the need for laboratory monitoring, in contrast to warfarin. Therapeutic ranges for dabigatran have not been established and no assay for its activity is approved by the US FDA; the EMEA has approved a thrombin time test with dabigatran calibrators (HYPHEN), available in the EU.

Aims: We sought to assess the ability of common tests such as the thrombin time (TT), global hemostasis assays such as thromboelastography (TEG), and a specific ecarin clotting time (ECT) activity assay to quantify dabigatran.

Methods: 110 plasma samples from 11 healthy volunteers who underwent testing of dabigatran pharmacokinetics in IRB-approved research (Circulation 2016 134:1909-1911) were tested with the thrombin time (TT), an ECT dabigatran assay (Stago Diagnostica), and TEG (Haemonetics) assays. Dabigatran levels for each sample were determined by liquid chromatography tandem mass spectroscopy (LCMS).

Results: Samples with 0- 221 ng/ml dabigatran (by LCMS) were tested. Table 1 lists the correlation between each test parameter and LCMS dabigatran level. The TT was highly correlated with dabigatran LCMS values. A normal TT (< 20.5 seconds) excluded dabigatran values of > 3.4 ng/ml. An ECT dabigatran assay likewise was highly correlated with dabigatran MS values. TEG R times obtained without kaolin activator ("native" TEG) demonstrated variable correlation with LCMS dabigatran levels. R times obtained by TEG with kaolin activator ("kaolin" TEG) similarly had poor correlations with, and sensitivity to dabigatran.

TABLE 1 Correlation of Various Assay Parameters with LCMS Dabigatran Level.

	Thrombin Time	ECT	R (native) TEG	R (kaolin) TEG
Correlation Range for 11 Individual Subjects (r)	0.93-1.0	0.86-0.99	0.55-0.94	0.51-0.90
Mean of 11 Subject Correlations (r)	0.98	0.95	0.74	0.73
Correlation for All Samples Combined (r)	0.86	0.91	0.56	0.43

Conclusions: The TT was extremely sensitive to, and highly correlated with dabigatran levels from 3.4 ng/ml to 131 ng/ml. The ECT assay was likewise highly correlated with dabigatran LCMS between 0 and 221 ng/ml. TEG R times (native or kaolin) showed poor sensitivity to, and inferior correlations with dabigatran LCMS levels, and were limited by high inter-subject variability.

PB 2104 | Influence of the Statistical Approach on Cut-off Values of IgG/IgM Anticardiolipin and Anti-β2 Glycoprotein I Antibodies in Classification of Antiphospholipid Syndrome

L. Vanoverschelde[1], H. Kelchtermans[2,3], J. Musial[4], B. de Laat[2,3], K. Devreese[1]

[1]Ghent University Hospital, Coagulation Laboratory, Department of Laboratory Medicine, Ghent, Belgium, [2]Maastricht University / Cardivascular Research Institute Maastricht (CARIM), Synapse Research Institute, Maastricht, The Netherlands, [3]Maastricht University / Cardivascular Research Institute Maastricht (CARIM), Department of Biochemistry, Maastricht, The Netherlands, [4]Jagiellonian University Medical College, Department of Medicine, Krakow, Poland

Background: IgG/IgM anticardiolipin (aCL) and anti-β2 glycoprotein I (aβ2GPI) antibodies are laboratory criteria for classification of antiphospholipid syndrome (APS). Recommendations published in 2014 by the SSC-ISTH state that threshold for positivity should be determined by the 99th percentile (p) of at least 120 healthy subjects.

However, no specific recommendations regarding statistical methods are indicated.

Aims: To determine the impact of statistical methods on the calculated 99thp for aCL and aβ2GPI.

Methods: 99thp was calculated on 120 and 200 healthy subjects using a non-parametric percentile method (NPP) with different tests identifying outliers (Tukey/Reed). Specificity (spec), sensitivity (sens) and odds ratio (OR) were calculated in a patient cohort applying different

cut-offs. We included 114 patients with thrombotic APS, 138 with non-APS thrombosis, 138 with auto-immune disease and 183 healthy controls (no clinical criteria for APS). IgG/IgM aCL and aβ2GPI were determined by a chemiluminescent immunoassay (HemosIL®AcuStar).

Results: Results of the normal population were not Gaussian distributed; Box-Cox/logarithmic transformations did not normalize the data. The manufacturer's cut-off was valid according to the transference principle (NCCLS-C28-A3). The calculated 99thp and their confidence intervals (CI) are shown in table 1 and 2.

Tukey classified more subjects as outliers lowering the 99thp by up to 93%. Large CI were observed.

Conclusions: The choice of the statistical method influences the calculated cut-off. We recommend the use of conservative methods to detect outliers. Nonetheless, excluding outliers by Reed hardly influences the performance characteristics. CI illustrate that larger sample sizes (n>200) are needed for a reliable calculation of the 99thp. Although guidelines recommend a local cut-off calculation, a multicenter approach to collect a large number of normals may be a good alternative, as well as transference of the manufacturer's cut-off if populations are comparable.

PB 2105 | Reference Interval Mean Clotting Times Should Not Be Used to Calculate Lupus Anticoagulant Mixing Test Ratios Unless They Match the Normal Pooled Plasma Clotting Time

G.W. Moore, J.C. Maloney, N. de Jager, C. Dunsmore, D.K. Gorman, R.F. Polgrean

Viapath Analytics at Guy's & St. Thomas' Hospitals, Haemostasis & Thrombosis, London, United Kingdom

Background: Lupus anticoagulant (LA) testing can be enhanced if clotting times (CT) are converted to ratios via normal pooled plasma (NPP) or reference interval mean (RIM) CT as denominator. The advantage of NPP is that it reflects immediate assay system performance but NPPs with CTs distant from RIMs can systematically bias towards false-positive or -negative results. There are no data on how applying RIM CTs to mixing tests that mix test plasma with NPP of RIM-distant CTs affects interpretation.

Aims: To assess mixing test interpretations in one assay with similar NPP and RIM CTs and another where they are discordant.

Methods: Diagnostic data on 311 samples from non-anticoagulated patients positive for LA by dilute Russell's viper venom time (dRVVT) and/or dilute activated partial thromboplastin time (dAPTT) using RIM CTs for screen, confirm and 1:1 mix ratios were further evaluated using NPP CTs as mix test ratio denominators. 104 of the patients had antiphospholipid syndrome (APS), 34 had systemic lupus erythematosus (SLE) and persistent LA, 27 had SLE and first LA positive testing, and 146 were clinically appropriate patients being investigated for APS.

Results: All were LA-positive in undiluted plasma, 92 in dRVVT only, 156 in dAPTT only and 63 in both. RIM CTs (s) for dRVVT and dAPTT screen were 43.8/41.4 respectively, mean NPP CTs (n=38) 44.0/36.0 respectively. Locally established mix ratio cut-offs derived from RIM CT and NPP CT were >1.07/>1.13 respectively for dRVVT, and >1.10/>1.15 respectively for dAPTT. Mixing test interpretations are in Table 1.

TABLE 1 dRVVT and dAPTT mixing test ratio interpretations derived from reference interval mean or normal pool plasma clotting time denominators

Mixing test interpretations from ratios derived from RIM CT or NPP CT as denominator	RIM + NPP +	RIM - NPP -	RIM + NPP -	RIM - NPP +
dRVVT (n=155)	96 (61.9%)	42 (27.1%)	10 (6.5%)	7 (4.5%)
dAPTT (n=219)	55 (25.1%)	111 (50.7%)	0 (0%)	53 (24.2%)

Conclusions: Most dRVVT mix interpretations (89%) agreed, doubly negative samples arising from the dilution effect. 17 discordant results arose from slightly different cut-offs. dAPTT mix was less sensitive as 50.7% were doubly negative. The lower NPP than RIM CT elevated a further 24.2% of dAPTT mix ratios above the cut-off as they reflected LA's effect on plasma in which they were mixed. If NPP and RIM CTs are discordant, NPP CT should be used for mix ratios.

PB 2106 | Lupus Anticoagulant-hypoprothrombinemia Syndrome (LAHPS): Report of 4 Cases

L. Remotti, M.L. Romero, S.H. Grosso, M.F. Ingratti, M.P. Vera Morandini, A. Sánchez-Luceros, A.N. Blanco

Academia Nacional de Medicina, Hemostasia y Trombosis, Ciudad Autónoma de Buenos Aires, Argentina

Background: LAHPS, the association of acquired FII deficiency and lupus anticoagulant (LA), is a rare disorder caused by aFII antibodies. It is drastically different from antiphospholipid syndrome (APS); it may cause predisposition to severe bleeding, in addition or not to thrombosis.

Aims: We report and discuss 4 cases of LAHPS.

Methods: LA was detected using a sensitive APTT and DRVVT, according to the ISTH guidelines. Hypoprothrombinemia was defined as FII under reference value (< 70IU/dL); abnormal PT and FII, were corrected by normal plasma (NP). Coagulation factors were determined by one-stage methods; those tests based on APTT were interfered by LA.

Results: Table 1 summarises laboratory results and clinical features. All cases showed abnormal PT, corrected by NP, and prolonged APTT, not corrected by NP. Cofactor effect on APTT was observed when FII was ≤25IU/dL. No time-temperature dependent inhibition was detected. Cases showed APTT and DRVVT tests compatible with LA, as well as low FII (8-52IU/dL) corrected by NP. In 3/4 cases, low FVIII (1.2-50IU/dL) and FIX (2-40IU/dL) and increased apparent activity on progressive dilutions of sample were observed. Acetic acid

TABLE 1 Laboratory results and clinical features

CASE (sex/ age)	Platelet count (plat/µL)	PT(%)/ Mixing test	FII (IU/ dL)	APTT(sec)/ Mixing test/ Confirmatory test (RV: 37-48)	DRVVT/ Mixing test/ Confirmatory test	TT (ratio) (RV:0.75-1.25)	Other coagulation factors (IU/dL)	Clinical features
1 (M/27)	70000	50/C	25	138/NC/+	Prolonged/NC/+	0.95	FV:70; FVII:96; FVIII:4; FIX:2; FX:100; abnormal CST	Intracerebral haematoma
2 (F/34)	216000	47/C	8	94/NC/+	Prolonged/NC/+	1	FV:80; FVII:80; FVIII:1.2; FIX:8; X:82	Severe bleeding, requiring blood transfusion, after caesarean section
3 (M/57)	154000	58/C	38	57/NC/+	Prolonged/NC/+	1.12	FV:80; FVII:90; FVIII:50; FIX:40; X:88	Asymptomatic
4 (M/59)	172000	65/C	52	62/NC/+	Prolonged/NC/+	1.05	FV:70; FVII:110; FVIII:60; FIX:60; X:100	Severe bleeding, requiring blood transfusion, after tooth extractions and plastic surgery

M: male; F: female; C: corrected by normal plasma; NC: not corrected by normal plasma; (+): positive confirmatory test; CST: acetic acid clot solubility test

clot solubility test was abnormal, suggesting low FXIII in 1 patient; he also showed thrombocytopenia. Other tests, like those to study von Willebrand disease and platelet function, were normal. One case was asymptomatic, the rest had suffered from bleeding. No other associated condition was found.

Conclusions: LAHPS has a heterogeneous spectrum of appearance. While it has been reported associated with other clinical conditions (primary APS, infections, drugs, systemic lupus erythematosus), in any of cases presented here, an associated condition was found; all except one, referred bleeding symptoms. LAHPS diagnosis is challenging; it should be suspected when abnormal PT+positive LA results were observed, mainly in the context of bleeding complications. A careful analysis should be done in order to achieve accurate diagnosis.

PB 2107 | Fibrinogen Prothrombin Time Derived Method Is Not Useful in Anticoagulated Patients by LMWH or Rivaroxaban

C. Duboscq[1], M. Martinuzzo[2], J. Ceresetto[1], M. Lopez[2], L. Barrera[2], J. Oyhamburu[2], G. Stemmelin[1]

[1]*Hospital Británico de Buenos Aires, Servicio de Hematología y Hemoterapia, Buenos Aires, Argentina,* [2]*Hospital Italiano de Buenos Aires - Instituto Universitario del Hospital Italiano, Grupo Bioquímico,Laboratorio Central, Buenos Aires, Argentina*

Background: Fibrinogen prothrombin time derived method (FibPT-d) is an easily available and economic method in laboratories with automated cogulometers. There are few reports on the behavior of this test in anticoagulated patients with DOACs or LMWH.

Aims: Compare Fibrinogen results obtained by Clauss method (FIBC) and FibPT-d with two thromboplastins in anticoagulated patients.

Methods: Population: 285 consecutive patients with a normal PT and APTT before initiating anticoagulation:102 with vitamin -K antagonist (VKA), 50 with unfractioned heparin (UFH), 35 with LMWH, 50 with rivaroxaban (RIVA) and 48 with dabigatran (DABI) and 100 healthy controls (NC).

Methods: Fib C by HemosiL Fibrinogen C (FIBC) or reagent with 100 NHI thrombin U/mL for DAB samples (HemosiL Q:F:A or TriniCLOT Fibrinogen); Fib PT-d with rabbit brain (HemosiL PT Fibrinogen HS plus, Fib PT HS) and with human recombinant (HemosiL Recombiplastin 2 G, FibPTRP) thromboplastins; heparin level by HemosiL Liq anti Xa; RIVA level by Liq Anti Xa with specific calibrators (HemosiL Rivaroxaban calibrators) and DABI level by HemosiL Direct Thrombin Inhibitor Assay. All FIB assays were calibrated with Calibration Plasma and performed on ACL TOP platform.

Data Analysis: BIAS % between FibC and FibPT-d with each thromboplastin were calculated. Comparisons between methods was performed by Bland Altman plots.

Results: The table shows the BIAS % between FIBC and Fib PT-d with each trhomboplastins. Bland Altman analysis shows that there is a positive bias ($p < 0.001$) for FibPT-d in either NC or anticoagulated samples, but BIAS was significantly higher compared to NC for RIV and VKA samples with FIB PT HS in a concentration dependent manner. LMWH samples present a higher bias compared with NC with both thromboplastins used.

TABKE 1 % BIAS FIB C vs FIbPT-d with both thromboplastin. (p vs NC)

Group	BIAS (%) Fib-PTHS	BIAS (%) Fib-PTRP
Normal controls n=100	13,19 ±10.93	16,38±9.45

UFH anticoagulated pts n=50 (0,16-1,08 anti Xa/mL)	19.54±15.18 p=0.068	22.86±9.80 p=0.017
LMWH anticoagulated pts n=35 (0.10-1.27 anti Xa /mL)	24.62±16.54 p<0.0001	26.86±13.63 p<0.0001
Rivaroxaban anticoagulated pts n=50 (13.94 - 845 ng/mL)	34.52±17.41 p<0.0001	16.38±12.05 p=0.47
Dabigatran amticoagulated pts n=48 (25-995 ng/mL)	18.04±13.14 p=0.0368	17.83±9.60 p=0.49

Conclusions: Although the FibPT-d is an economic and rapid method, it should not be used in all situations because of the FIB PT- d mathematical algorithm is only validated in normal subjects without anticoagulation.

PB 2108 | Development of Novel Assays for Factor VIII Potency Determination

M. Kusch, S. Rosenkranz, A. Schroda, C. Grundmann, S. Keitel, A. Hunfeld, R. Seitz, G.J.K. Praefcke

Paul-Ehrlich-Institut, Federal Institute for Vaccines and Biomedicines, Haematology / Transfusion Medicine, Langen, Germany

Background: The determination of factor VIII (FVIII) plasma levels is widely used for diagnosis of patients and monitoring of their treatment with clotting factor concentrates. Furthermore, the potency determination of plasma-derived and recombinant FVIII concentrates is used during manufacturing and batch release. Several assays have been established for the determination of FVIII but the one-stage clotting assay and the chromogenic assay are predominantly used. For potency measurements of FVIII concentrates, the European Medicines Agency (EMA) requires the chromogenic method in accordance with the European Pharmacopoeia, while the US FDA requires the one-stage clotting assay. However, modified recombinant FVIII products such as B-domain deleted as well as fusion proteins yield different potencies with these two assays and also with different reagent kits.

Aims: We want to improve fluorogenic and clotting-based FVIII assays in order to reduce discrepancies in potency determination of different types of FVIII products.

Methods: Based on previous studies we have further developed our fluorogenic assay using low amounts of FIXa as trigger and by addition of corn trypsin inhibitor (CTI) to prevent spontaneous activation of the intrinsic pathway. The conditions of this assay were transferred to a clotting assay with optical readout.

Results: By addition of CTI to commercially available FVIII-deficient plasma we achieved a significant improvement and simplification compared to previous assays. With both readouts the assays displayed a large measurement range and high reproducibility. The optical clotting assay could be adapted to an automated analyser.

Conclusions: The adaptations of our FVIII assays may help to resolve assay discrepancies between FVIII products while offering a simple and automated format for the processing of clinical samples as well as concentrates.

PB 2109 | Evaluations of Automated Chromogenic Assays for the Diagnosis and Monitoring of Haemophilic Patients

C. Novembrino, M. Boscolo Anzoletti, E. Biguzzi, M.R. Fasulo, F. Peyvandi

Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy

Background: One-stage clotting assay is still the most widely used method for measuring both FVIII and FIX activities in haemophilic patients. Chromogenic assay is increasingly diffusing, in particular for monitoring the recovery of the novel longer acting concentrates.

Aims: To evaluate the analytical performance of newly developed applications of BIOPHEN FVIII:C and BIOPHEN Factor IX (HYPHEN BioMed, France) on Sysmex CS 2400 (Sysmex, Kobe, Japan) analyzer and their diagnostic accuracy evaluating possible discrepancies between one-stage and chromogenic assays.

Methods: Sixty patients with haemophilia A and 40 with haemophilia B (severe, moderate and mild), were enrolled together with 40 healthy Italian subjects (aged 20-62 years). The clotting tests were performed on citrate platelet poor plasmas stored at -80°C. BIOPHEN FVIII:C was compared with another chromogenic automated assay (COAMATIC Factor VIII, CROMOGENIX on ACL TOP analyzer; Instrumentation Laboratory, Italy).

Analytical performance and method comparison analysis were performed according to the Clinical & Laboratory Standards Institute (CLSI) guidelines.

Results: Imprecision analysis results are reported in Tables 1 and 2. Linearity was good up to 1/128 dilution for both assays (r=0.99); mean recovery was 91.74 % for BIOPHEN FVIII:C and 97.28% for BIOPHEN Factor IX.

Generally, a good correlation was found between one-stage and chromogenic assays for both FVIII:C and FIX:C (Spearmen's Rank correlation: 0.983 and 0.994, respectively) and between the two FVIII chromogenic assays (Spearmen's Rank correlation: 0.991).

TABLE 1 BIOPHEN FVIII:C imprecision

		Mean ± SD (IU/dL)	CV%
Intra-assay (repeatability)	Normal Control 87 (70-104) IU/dL	91.26±1.45	1.59
	Pathologic Control 28 (21-35) IU/dL	30.27±0.51	1.68
	Pool A	121.61±6.28	5.16
Inter-assay (reproducibility)	Normal Control 87 (70-104) IU/dL	90.96±1.48	1.63
	Pathologic Control 8 (21-35) IU/dL	31.09±0.41	1.32
	Pool B	140.04±3.81	2.72

TABLE 2 BIOPHEN Factor IX imprecision

		Mean ± SD (IU/dL)	CV%
Intra-assay (repeatability)	Normal Control 109 (87-131) IU/dL	97.50±2.05	2.11
	Pathologic Control 34 (25-43) IU/dL	30.70±0.89	2.89
	Pool A	87.50±1.45	1.66
Inter-assay (reproducibility)	Normal Control 109 (87-131) IU/dL	104.33±7.72	7.40
	Pathologic Control 34 (25-43) IU/dL	35.56±2.42	6.81
	Pool B	98.69±7.22	7.32

Conclusions: Our results showed a good analytical performance of both the assays. The introduction of chromogenic FVIII and FIX tests as part of routine analytical panel could help to determine the most suitable functional haemostatic assay for the diagnosis and the monitoring of haemophilic patients treatment, particularly using new longer acting products.

PB 2110 | Evaluation of Utility of ISTH Scoring System and its Modifications in Diagnosis of Disseminated Intravascular Coagulation in a Tertiary Care Centre in Southern India

P.S. Muddana[1], R. Kar[2], S.S. Kar[3]

[1]*Jawaharlal Institute of Post Graduate Medical Education and Research, Puducherry, India,* [2]*Jawaharlal Institute of Post Graduate Medical Education and Research, Pathology, Puducherry, India,* [3]*Jawaharlal Institute of Post Graduate Medical Education and Research, Preventive and Social Medicine, Puducherry, India*

Background: DIC is an acute emergency whose diagnosis is based on clinico-pathologic picture. In our setup routine diagnosis is based on clinical profile along with microangiopathic haemolysis and FDP positivity. However in contrast to a scoring system, this lacks objectivity.

Aims: To evaluate the

1. ISTH scoring system and its modifications in patients suspected with DIC
2. agreement among routine method, ISTH scoring system and its modifications.

Methods: Blood samples were collected in EDTA and Citrate for cell count with peripheral smear and coagulation assays respectively. Scoring was done and analysis of agreement between the scores considering ISTH score as reference standard was done by kappa analysis. Various scoring algorithms are given in Table 1.

TABLE 1 Components of ISTH score, Fibrinogen exclusion score (Modified ISTH score) and Modified ISTH score with schistocytes

Parameter involved	ISTH score	Fibrinogen exclusion score	Modified ISTH Score with Schistocytes
Platelet count	>1,00,000 =0 51,000-1,00,000 =1 <50,000 =2	>1,00,000 =0 51,000-1,00,000 =1 <50,000 =2	>1,00,000 =0 51,000-1,00,000 =1 <50,000 =2
D - Dimer / FDP	No increase=0 Moderate increase=2 Strong increase=3	No increase=0 Moderate increase=2 Strong increase=3	No increase=0 Moderate increase=2 Strong increase=3
Prolongation of PT	<3 sec=0 >3 sec - <6 sec=1 >6 sec=2	<3 sec=0 >3 sec - <6 sec=1 >6 sec=2	<3 sec=0 >3 sec - <6 sec=1 >6 sec=2
Fibrinogen (g/l)	≥1 =0 <1 =1	Not included	Not included
Schistocytes	Not included	Not included	Absent=0 Present=1
Diagnostic of DIC	5/8	4/7	5/8
Considered diagnostic score (Since FDP quantification not done)	5/7	4/6	5/7

FDP quantification could not be performed in our lab, hence FDP positive was taken as moderate increase for scoring. Approval from Institute Ethics Committee and informed consent from participants were obtained.

Results: Among the total of 56 cases, 36 (64.28%), 9 (out of 52 - 17.3%), 22 (39.3%) and 17 (30.4%) were diagnosed positive by routine diagnosis, ISTH score, Fibrinogen exclusion score (Modified ISTH score) and Modified ISTH score with schistocytes respectively. Fibrinogen assay was not performed in 4 cases. Frequency of derangement in various parameters among cases diagnosed positive by scoring systems are mentioned in Table 2.

The agreement between routine diagnosis, Fibrinogen exclusion score (Modified ISTH score) and Modified ISTH Score with schistocytes with ISTH DIC score was fair (κ = 0.215, p = 0.012); moderate (κ = 0.502, p = 0.000) and substantial (κ = 0.681, p = 0.000) respectively.

TABLE 2 Frequency of deranged parameters in positive cases according to diagnostic modalities under consideration

Parameter	All cases (n=56)	Routine diagnosis (n=36)	Fibrinogen Exclusion score (n=22)	Modified ISTH score with Schistocytes (n=17)	ISTH score (n=9) (out of 52 cases)
Thrombocytopenia (≤10000/μL)	47 (83.92%)	33 (91.66%)	20 (90.90%)	16 (94.11%)	9 (100%)
PT prolongation (>3 sec)	26 (46.42%)	17 (47.22%)	19 (86.36%)	14 (82.35%)	9 (100%)
Fibrinogen (< 100 mg/dl)	2 (3.85%) (not done in 4 cases)	2 (6.06%) (not done in 3 cases)	2 (10%) (not done in 2 cases)	2 (13.33%) (not done in 2 cases)	2 (22.22%)
FDP / D-Dimer (present)	26 (46.42%)	23 (63.88%)	16 (72.72%)	14 (82.35%)	7 (77.77%)
Schistocytes (present)	39 (69.64%)	33 (91.66%)	15 (68.18%)	15 (88.23%)	7 (77.77%)

Conclusions: The best agreement was observed between Modified ISTH score with schistocytes and ISTH score. A considerable number of cases were under diagnosed by ISTH score and Fibrinogen assay in every case is difficult in a resource constraint setup. Hence in cases where ISTH score is difficult to assess Modified ISTH score with schistocytes can be considered.

PB 2111 | Method Comparison of the Atellica COAG 360 System* with Sysmex CS-2000i System and BCS XP System

E. Knoch[1], O. Bätz[2], C. Haas[3], M. Haddad[4,5], Y. Henskens[6], T. Renné[5]

[1]Siemens Healthcare Diagnostics Products GmbH, Marburg, Germany, [2]LADR GmbH Medizinisches Versorgungszentrum, Geesthacht, Germany, [3]MVZ Clotten, Freiburg, Germany, [4]Labor Lademannbogen, Hamburg, Germany, [5]Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany, [6]Academisch Ziekenhuis Maastricht (AZM), Maastricht, The Netherlands

Background: The Atellica COAG 360 System* is a novel, fully automated random-access blood coagulation analyzer. The system includes coagulometric, chromogenic, immunological, aggregation, and high-sensitivity LOCI®-based immunoassay technology. Cap-piercing and advanced preanalytical sample integrity (PSI™) checks provide fill-volume checks for primary tubes and assay-specific warning levels for HIL interferences.

Aims: The aim was to compare suitability and efficiency in coagulation testing of the new Atellica™ COAG 360 System* (Siemens Healthcare Diagnostics Products GmbH, Marburg, Germany) with other coagulation analyzers in a multicenter validation study.

Methods: Method validation and comparisons were performed for selected parameters including PT, APTT, fibrinogen, Ddimer, antithrombin, and vWF activity using >60,000 routine samples from various sources, including general physicians and intensive-care centers.

Results: Atellica COAG 360 System* based analysis is highly consistent with BCS® XP System and Sysmex® CS-2000*i* System results (>100 samples/parameter), leading to high correlation coefficients: r > 0.975 for all assays tested. The Atellica COAG 360 System* provided robust and reliable results. Atellica COAG 360 System* software and hardware features, including speed of diagnostics, result flagging, continuous reloading of reagents and consumables, high onboard reagent stability, graphical display of reaction curves, and ability to import assigned values for controls via file transfer, were appreciated by the users.

Conclusions: Coagulation analyses with the novel Atellica COAG 360 System* are comparable and non-inferior to those performed with the established BCS XP and Sysmex CS-2000*i* systems. Considering the various novel functionalities provided by the Atellica COAG 360 System*, the system is expected to be well-suited for routine and specialty testing requirements in coagulation laboratories.

*Not available for sale in the U.S. Product availability varies by country.

PB 2112 | Evaluation of an Automated Chemiluminescent Assay and two ELISA's for Detection of Heparin Induced IgG Antibodies in the Diagnosis of Heparin Induced Thrombocytopenia (HIT)

L. De Cooman, K. Devreese

University Hospital Ghent, Coagulation Laboratory, Department of Clinical Chemistry, Microbiology and Immunology, Ghent, Belgium

Background: Heparin Induced Thrombocytopenia (HIT) is an adverse drug reaction to heparin in which the patient forms platelet factor 4 (PF4) antibodies (PF4Ab). The antibodies form PF4-Ab/heparin complexes binding FcγIIa receptors on platelets activating them, with formation of microparticles and clots. Correct and rapid diagnosis is crucial because of high risk of thrombosis and death. Diagnosis based solely on clinical symptoms is not straightforward. Confirmation with a rapid and reliable assay is therefore of the utmost importance.

Aims: Performance characteristics of an automated chemiluminescent assay (HemosIL® AcuStar HIT IgG, Instrumentation Laboratory, Bedford, MA, USA) and two enzyme linked immunosorbent assays (ELISA) (Asserachrom® HPIA HIT-IgG, Diagnostica Stago, S.A.S. France and Zymutest HIA IgG, Hyphen Biomed, Neuville-sur-Oise, France) for detection of heparin induced IgG antibodies in the diagnosis of HIT were evaluated.

Methods: Citrated plasmas from 153 patients with clinical suspicion of HIT were evaluated with all assays and confirmed with a functional, flowcytometric assay. Manufacturers's cut-off and optimized cut-off calculated by receiver operating curve (ROC) were evaluated.

TABLE 1

Pre- and post-test probability for Zymutest HIA IgG, HemosIL® AcuStar HIT IgG and Asserachrom® HPIA HIT –IgG with cut-off calculated per run as recommended by the manufacturer, per 4T score class.

			Post-test probability (%)					
			Zymutest HIA IgG		HemosIL® AcuStar HIT IgG		Asserachrom® HPIA HIT–IgG	
		Pre-test probability (%)	Negative	Positive	Negative	Positive	Negative	Positive
4T score	Low R (2/54)	3.57 [0.98-12.12]	0.00 [0.0-7.87]	18.18 [2.28-51.78]	3.7 [0.45-12.75]	0.00 [0.00-84.19]	0.00 [0.00-7.71]	20.00 [2.52-55.61]
	Intermediate R (9/58)	13.43 [7.23-23.60]	0.00 [0.00-8.41]	36.00 [17.97-57.48]	0.00 [0.00-6.38]	81.82 [48.22-97.72]	0.00 [0.00-7.71]	42.86 [21.82-65.98]
	High R (9/21)	30.00 [16.66-47.88]	0.00 [0.00-23.16]	56.25 [29.88-80.25]	0.00 [0.00-20.59]	64.29 [35.14-87.24]	0.00 [0.00-21.8]	71.43 [47.82-88.72]

Cut-off for AcuStar: 1.00 U/mL, ELISA: mean for all batches (Zymutest: 0.34 OD, Asserachrom: 0.24 OD)

TABLE 2

Pre- and post-test probability for Zymutest HIA IgG, HemosIL® AcuStar HIT IgG and Asserachrom® HPIA HIT –IgG with ideal cut-off calculated with ROC, per 4T score class.

			Post-test probability (%)					
			Zymutest HIA IgG		HemosIL® AcuStar HIT IgG		Asserachrom® HPIA HIT–IgG	
		Pre-test probability	Negative	Positive	Negative	Positive	Negative	Positive
4T score	Low R (2/54)	3.57 [0.98-12.12]	0.00 [0.00-6.85]	50.00 [6.67-93.24]	0.00 [0.00-7.71]	20.00 [2.52-55.61]	0.00 [0.00-6.98]	40.00 [5.27-85.34]
	Intermediate R (9/58)	13.43 [7.23-23.60]	0.00 [0.006.60]	69.23 [38.57-90.91]	0.00 [0.00-7.71]	20.00 [2.52-55.61]	0.00 [0.00-6.72]	64.29 [35.14-87.24]
	High R (9/21)	30.00 [16.66-47.88]	0.00 [0.00-21.80]	60.00 [32.29-83.66]	0.00 [0.00-7.55]	45.00 [23.06-68.47]	0.00 [0.00-19.51]	69.23 [38.57-90.91]

* 95% CI between []; number of HIT positive/HIT negative samples between ()

Cut-off for AcuStar: 0.22 U/mL, Zymutest: 0.71 OD, Asserachrom: 0.59 OD

Results: 20 out of 153 patients were confirmed positive. Sensitivity for Asserachrom® and Zymutest was 100.00% with specificity of 81.20% and 75.94%, respectively. Altering the cut-off, improved specificity to 91.00% for Asserachrom® HPIA HIT-IgG and 90.90% for Zymutest HIA IgG, without loss of sensitivity. With the insert cut-off, sensitivity for AcuStar was 90.00 % with a specificity of 93.23 %. Given that already two cases were missed, no higher cut-off was considered.Pre- and post-test probability was calculated for different cut-offs (table 1 and 2).

Conclusions: This study showed excellent performance of Asserachrom® HPIA IgG and Zymutest HIA IgG, but specificity varies with the selected cut-off. Although less sensitive,HemosIL® AcuStar HIT IgG had best specificity.

PB 2113 | The Influence of a High Fat Meal, Smoking, Coffee, Exercise and Sample Storage on Light Transmission and Impedance Aggregometry in Healthy Volunteers

Y. Henskens, J. Krekels, D. van den Kerkhof, R. Wetzels, P. Verhezen

Maastricht University Medical Centre+, Central Diagnostic Laboratory, Maastricht, The Netherlands

Background: Platelet function testing (PFT) is an important part of the workup of patients with a bleeding tendency. Logistic and pre-analytical aspects in PFT are crucial since platelets are viable cells and samples cannot be frozen and analyzed on a later moment in time. Guidelines give recommendations on pre-analysis in PFT but not all advices are evidence based. Some of the recommendations are troubling patient's logistics or are patient unfriendly.

Aims: The aim of this study was to investigate sample storage temperature (4°C, room temperature (RT) and 37°C) and storage time (3, 6, 24 hours), high fat meal, smoking, exercise and coffee drinking on the most used methods for platelet function testing: light transmission aggregometry (LTA) and multiple electrode impedance aggregometry (MEIA).

Methods: Per test condition 5 to 10 healthy volunteers were included. Informed consent was obtained. Citrated/hirudin whole blood and platelet rich citrated (PRP) plasma was used for testing. Platelet aggregation was measured using Chronolog LTA and Multiplate® analyzer. LTA was executed using 1mM arachidonic acid, 5µM ADP, 2µg/ml collagen and 5µM epinephrine as agonists. The Multiplate® was executed with 0.5mM arachidonic acid, 6.4µM ADP, 3.2µg/ml collagen and 32µM thrombin receptor activating peptide as agonists. Statistical analysis were performed using Wilcoxon signed rank test.

Results: No significant differences in platelet aggregation results (LTA and MEIA) could be detected in healthy subjects before and after smoking, high fat meal, exercise and coffee consumption. Citrated whole blood for LTA could be stored for 6 hours on RT. Storage of citrated PRP was agonist dependent possible for 3 or 6 hours. Multiplate results were stable after storage of hirudin whole blood for 6 hours at RT for all agonists.

Conclusions: These results are a first step for improvement of the patient friendliness and logistics in platelet function diagnostics. Prolongation of storage time beyond 6 hours needs new sample stabilizators.

PB 2114 | Automated Data Management for Thrombin Generation

K.G. Guria[1,2], H. Elsinga[1], P.W. Hemker[1], H.C. Hemker[1]

[1]Cardiovascular Research Institute Maastricht (CARIM), Maastricht University, Maastricht, The Netherlands, [2]Moscow Institute of Physics and Technology, Moscow, Russian Federation

Background: The thrombin generation (TG) test is widely used nowadays in both fundamental and clinical research. The test itself can easily be adapted to meet specific needs of the investigator. However the use of currently available software for the calculation of TG parameters restricts its flexibility for the development of new applications. Moreover the use of “black box” software might restrict the interpretation of results that are obtained under experimental conditions that are not foreseen by such software.

Aims: The aim of this work was to develop a fully automated and „transparent“ algorithm for the calculation of thrombin generation data and to compare it to the existing black box software.

Methods: Two fully automated algorithms for the calculation of TG parameters were developed. One, written in C, performed a five-parameter fit to obtain ETP, peak, lag time and time to peak and can be used on batches of hundreds of fluorescence curves. The other was designed in Wolfram Mathematica and in addition compensated for temperature irregularities during the course of the experiments.

The performance of both programs was tested in comparison with the standard software on a data set of approximately 5000 raw TG curves.

Results: The data calculated by the two new algorithms were consistent with the data calculated by the standard software for the TG curves obtained in normal pool plasma and plasma of healthy donors (correlation coefficient > 0.97), except for the measurement of the lag time which consistently was longer with the standard program. Discrepancies were observed in the sets of TG data of patients on anticoagulants (both VKA´s & NOACs) and for hemophiliacs. The differences appeared to be mainly due to the algorithms used for the subtraction of α2macroglobulin-thrombin activity.

Conclusions: Both developed algorithms showed itself robust and reliable. The open code in the easily accessible Mathematica programming language makes it a flexible tool for research purposes.

PB 2115 | The Laboratory Control of Anticoagulant Thromboprophylaxis during Early Postpartum Period after the Caesarean Delivery

E. Koltsova[1], A. Balandina[1,2], K. Grischuk[3], M. Shpilyuk[3], E. Seregina[1], N. Dashkevich[2,4], A. Poletaev[1], A. Pyregov[3], G. Sukhih[3], I. Serebriyskiy[5], F. Ataullakhanov[1,2,6]

[1]Dmitry Rogachev National Research and Clinical Center of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation, [2]Center for Theoretical Problems of Physicochemical Pharmacology RAS, Moscow, Russian Federation, [3]Kulakov Research Center for Obstetrics, Gynecology and Perinatology, Moscow, Russian Federation, [4]HemaCore Labs LLC, Moscow, Russian Federation, [5]Laboratory Medicine Federation, Moscow, Russian Federation, [6]Lomonosov Moscow State University, Moscow, Russian Federation

Background: The incidence of VTE after caesarean section reaches 0.6% and the widespread use of it draws attention to this group. The dosage and duration of low molecular weight heparin (LMWH) prophylaxis is estimated by anamnestic risk-scales, which predictive potency can be low in case of individual patient's risk estimation. The laboratory hemostasis assays are supposed to solve this problem.

Aims: The aim of this study was to estimate a potency of tests to reflect the coagulation state of patients, receiving prophylactic doses of LMWH in early postpartum.

Methods: We conducted an observational study in 97 women undergoing caesarean section (CS). All gave their written informed consent. The protocol was approved by ethics committee. Blood samples were collected 3-5 hours after the CS (P1) and 2 days after the CS (P2). Standard tests (Fg, APTT, prothrombin, D-dimer), anti-Xa assay, ROTEM and thrombodynamics/thrombodynamics-4D were performed. ROC-analysis, Wilcoxon signed rank test and Mann-Whitney U-test were used for statistical analysis of the data.

Results: At P1 fibrinogen (Median[5-95%]: 5.7[3.3-7.3]; reference range: 2.0-4.7 g/l) and D-dimer concentrations (5118[1532-9999]; 0-550 μg/l), CFT (156[93-292]; 164-430 sec) and α (61[46-73]; 32-60°) in ROTEM, Vi (63[54-70]; 38-56 μm/min), V (39[32-57]; 20-29 μm/min), Vst (38[32-46]; 20-29 μm/min) in thrombodynamics and Ast (206[97-344]; 40-100 AU/l) in thrombodynamics-4D were shifted to hypercoagulation and had the tendency to normalization at P2. Coagulation parameters were compared in groups formed in presence or absence of LMWH for estimation of laboratory assays sensitivity to LMWH influence. Vs had maximal AUC in ROC-analysis (AUC=0.76), Ast had AUC=0.75. For all other tests AUC varied from 0.45 to 0.55.

Conclusions: Coagulation assays reveal hypercoagulation after the delivery and tendency to normalization of coagulation during early postpartum. Parameters of thrombodynamics/thrombodynamics-4D had the highest sensitivity to the presence of LMWH-prophylaxis.

PB 2116 | Forty Years of Riddle Solving to Decipher Puzzling Test Results in the Coagulation Laboratory

A. Zivelin

Sheba Medical Center, Coagulation Laboratory, Ramat Gan, Israel

Background: The coagulation laboratory is responsible for performing all the routine and specialized tests in the coagulation field. Occasionally the laboratory activity is "spiced up" by puzzling results requiring out of the box thinking, and solving those issues contributes to enhancement of the professional level of the laboratory, expands clinicians´ expertise and provides great benefit to the patients.

Aims: This abstract illustrates my personal experience accumulated over 4 decades of work, starting as a young technician and stepping up to become the laboratory manager.

Methods: Various coagulation and molecular biology methods have been used to evaluate puzzling test results.

Results: The following cases will be presented:

- Ten possible reasons for very prolonged INR of 5-10.
- Pitfalls in measurements of fibrinogen levels.
- Distinguishing between high D-Dimer levels occurring in vitro or present in vivo.
- Severe bleeding due to rare acquired inhibitor to factor X.
- Thrombosis due to acquired non-neutralizing inhibitor of Protein S.
- How to establish Hemophilia A carriership in women randomly found to have low factor VIII levels.
- Severe thrombosis due to "smart" inhibitor that distinguishes between native Protein C and activated protein C (APC).
- Requirements for antibodies development in factor XI deficiency.
- Infusion of disguised factor XI can cause inhibitor development in factor XI deficiency.
- Bleeding due to exposure to animal's clotting factors.

Conclusions: Each of those ten cases will be presented including a short description, path of laboratory investigation and conclusions. References to published data will be provided. It should be noted that my experience represents collaboration and team work with laboratory personnel and clinicians, to whom I thank from the bottom of my heart.

PB 2117 | "Function over Form"? Low Dose V/Q SPECT is Superior to Planar V/Q and Has a Diagnostic Yield Approaching that of CTPA in the Diagnosis of Acute Pulmonary Thromboembolic Disease

L. Stephens[1], I. Niematallah[2], M. Memmott[2], R. Sajjan[2], J. Thachil[3], S. Muthu[2]

[1]Central Manchester University Hospital NHS Foundation Trust - Manchester Royal Infirmary, Department of Radiology, Manchester, United Kingdom, [2]Central Manchester University Hospital NHS Foundation Trust - Manchester Royal Infirmary, Department of Nuclear Medicine, Manchester, United Kingdom, [3]Central Manchester University Hospital NHS Foundation Trust - Manchester Royal Infirmary, Department of Haematology, Manchester, United Kingdom

Background: Since revision of the guidelines for Ventilation/Perfusion (V/Q) scintigraphy by the European Association of Nuclear Medicine (EANM) in 2009, it was suggested that V/Q Single Photon emission computed tomography (SPECT) should be more readily available due to its high sensitivity and specificity for the diagnosis of pulmonary embolism (PE) and low radiation burden.

Aims: To assess diagnostic yield and rate of indeterminate scans when performing low dose V/Q SPECT with holistic interpretation in the diagnosis of acute pulmonary thromboembolic disease and to compare this with published rates.

Methods: All patients that underwent V/Q SPECT (using 100 MBq Tc99m MAA and 20 MBq Technegas) over one year were included in the study. Pregnant patients were excluded. Scans positive and negative for PE and indeterminate scans were recorded. Rates were compared with those published in the literature.

Results: 343 patients were included in the analysis. 14.9% of scans were positive and 76.4% excluded PE. Rate of indeterminate scans was 8.7%, higher than published rates of 3% (Leblanc et al). However, only 19 of 30 patients with indeterminate scans went on to have Computed Tomography of the Pulmonary Arteries (CTPA), (5.5%). This suggests SPECT is superior to planar V/Q, as it has been shown to yield a rate of indeterminate scans requiring CTPA of 20% in the literature. A dichotomous report confirming or excluding PE was provided in 91.3% of cases. This gave a non-diagnostic scan rate of 8.7%, comparable to CTPA similar to Bajc et al where CTPA was non-diagnostic in 6%.

Conclusions: Low dose V/Q SPECT with holistic interpretation is feasible, superior to Planar V/Q and has a diagnostic yield approaching that of CTPA. Given the low radiation burden, and the constant increasing demand on CT services, we believe V/Q SPECT to be an underutilized investigation. It is suggested that this functional test could become a more prominent tool in the assessment of patients with suspected acute pulmonary thromboembolic disease.

PB 2118 | Point-of-care INR with CoaguChek XS Pro is comparable to laboratory INR in a hospital setting

A.K. Stroobants, B.S. van der Veen, A. Sturk

Academic Medical Center, Amsterdam, The Netherlands

Background: Point-of-care-testing (POCT) of International Normalized Ratio (INR) to monitor vitamin K antagonist (VKA) anticoagulant therapy is fast, easy and minimal invasive. POCT INR with CoaguChek XS Pro is widely used in patients on stable long-term VKA therapy in outpatient and home settings. However, it is unclear whether POCT INR methods are reliable in clinical practice with patients who undergo changes in anticoagulant treatment.

Aims: To investigate whether POCT INR using CoaguChek XS Pro is comparable to laboratory INR in a clinical patient population.

Methods: POCT INR measurements were performed in patients admitted to the cardiology ward and compared to the reference INR method (manual tilt-tube using HepatoQuick thromboplastin) and the routine INR method (automated method using Innovin reagent). In addition, five other laboratory INR methods were compared. Analytical and clinical agreement was estimated using error grids.

Results: Analytical comparisons of CoaguChek XS Pro and laboratory INR methods with the reference INR method showed a substantial number of deviating INR results in several INR methods. Comparison of CoaguChek XS Pro with the routine INR method revealed an analytical agreement of 79% and a clinical agreement of 83%. The median analytical agreement of all laboratory INR methods compared to the routine INR method was 73% (range 41%-94%) and the median clinical agreement 80% (range 70%-87%).

Conclusions: The analytical and clinical agreement of CoaguChek XS Pro with the routine laboratory method for VKA monitoring in a clinical patient population is acceptable in the context of the observed differences between INR methods.

PB 2119 | Evaluation of Assay Performance Monitoring Edoxaban Plasma Concentration with Technoview® Edoxaban and Technochrom® Anti-Xa

S. Geiter[1], M. Unterberger[1], M. Llusa[1], M. Griffiths[1], L. Wagner[1], L. He[2], N. Binder[1]

[1]Technoclone Herstellung von Diagnostika und Arzneimitteln GmbH, Vienna, Austria, [2]Daichii-Sankyo Pharma Development, Edison, United States

Background: The increasing use of the new oral anticoagulant edoxaban creates the need of it's measurement in clinical routine in some special clinical settings such as urgent invasive procedures or in cases of bleeding.

Aims: The aim of this study was to evaluate the performance of measurement of edoxaban with a system composed of an anti-Xa assay using lyophilized calibrators and controls, as well as correlation of patients sample results with those measured with Mass Spectrometry Liquid Chromatography (LC-MS).

Methods: The one stage chromogenic assay for the determination of Xa inhibitor activity in human citrated plasma, Technochrom® anti-Xa, is used for edoxaban measurement on Ceveron® alpha. Lyophilzed calibrators with assigned edoxaban values are used for assay calibration. Controls with assigned edoxaban values as well as in vitro spiked

plasma are measured to calculate assay performance parameters. Anti-Xa assay results of patient samples are compared to those obtained with LC-MS reference method to evaluate assay correlation.

Results: Calibration curves in low range 0-150ng/mL and in high range 0-500ng/mL are made using two adjusted analyzer settings. All calibration curves has a linearity of R^2=1.0±0.1. LLoQ is determined at 25ng/mL. The recovery of control is within 100% ± 10% of target value for all concentrations and precision is very good with intra-assay and inter-assay variations of < 15%. For method comparison the correlation of spiked samples as well as patient samples shows a Passing and Bablock regression with a Slope of 1.0 +/- 0.1, an Intercept < 15ng/mL and r >0.95.

Conclusions: Our data demonstrate that using the lyophilized calibrator set Technoview® Edoxaban for calibration of Technochrom® anti-Xa assay in optimized settings on Ceveron alpha the determination of edoxaban plasma concentrations in patient samples can be performed with very good performance, patient sample results correlating with the LC-MS results.

PB 2120 | Evaluation of Platelet Response by Whole Blood Multiple Electrode Aggregometry Method in Patients Using Antiplatelet Therapy

M. Matos, E. Taniguchi, C. Finazzo, E. Sanches, A. Maia

Hospital do Coração, Laboratory, São Paulo, Brazil

Background: Platelets play a key role in both hemostasis and thrombosis. Platelet function tests are used for monitoring the efficacy of antiplatelet drugs, with the aim of predicting the adverse events such as bleeding or thrombosis in arterial thrombotic diseases.

Aims: To evaluate results of platelet response by multiple electrode aggregometry in patients using antiplatelet drugs (Aspirin and/or Clopidogrel).

Methods: Platelet aggregation by multiple electrode aggregometry was performed in 650 patients using antiplatelet therapy (Aspirin n=400; Clopidogrel n=47; Aspirin and Clopidogrel n=203). Additionally the test was performed in normal controls (n=59). The blood was collected in hirudin tubes and the platelet aggregation studies were performed in whole blood using Multiplate® Analyser (Roche) equipament. The agonists used were: Adenosine Diphosphate (ADP) final concentration: 6.5 µM and Arachidonic Acid (AA) final concentration: 0.5 mM. The normal range used to compare the response to antiplatelet therapy was 57-113 U for ADP and 71-115 U for AA.

Results: 92%of patients using Aspirin were poor responsive for AA (mean=20U) and 8% were normal responsive for AA (mean= 90U).

In patients using only Clopidogrel, 76.6% were poor responsive with ADP (mean=26U) and 23.4% patients were normal responsive for ADP (mean= 75U).

Regarding patients using combined therapy (Aspirin and Clopidogrel), 91.1% were poor responsive with AA (mean=15U) and 8.9% were normal responsive with AA (mean=92U); 84.2% of patients were poor responsive with ADP (mean=27.7U) and 15.8% were normal responsive with ADP (mean=75U).

Normal controls were 100% responsive to AA (mean 100U) and ADP (mean= 90U).

Conclusions: The use of whole blood multiple electrode aggregometry method is an important tool to evaluate platelet response in patient's using antiplatelet drugs and permits to distinguish patients with normal platelet activity despite a positive history of antiplatelet medication intake.

PB 2121 | Evaluation and Comparison of the Productivity of the Atellica COAG 360 System* and the BCS XP System in Daily Routine Setting

S. Echternacht[1], K.-P. Kienle[2], I. Hoberg[3], M. Haddad[3,4]

[1]Siemens Healthcare Diagnostics GmbH, Marburg, Germany, [2]Siemens Healthcare GmbH, Germany, Erlangen, Germany, [3]Labor Lademannbogen MVZ GmbH, Hamburg, Germany, [4]Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany

Background: The Atellica™ COAG 360 System* is a fully automated, high-volume coagulation analyzer. The system includes novel elements to extend system availability time and reduce technician hands-on time.

Aims: The purpose of this study was to evaluate and compare the performance of the Atellica COAG 360 System* and the BCS® XP System, specifically evaluating instrument availability time and technician hands-on time in daily laboratory setting with equal conditions.

Methods: One Atellica COAG 360 System* and three BCS XP Systems (routine devices) were included in this study. Plasma samples (n = 1775) were analyzed routinely over 5 days on one of the BCS XP Systems and on the Atellica COAG 360 System* at Labor Lademannbogen.

Results: The results show extended system availability for the Atellica COAG 360 System*, with an average increase of 54% compared to the BCS XP System. Hands-on technician time was examined at two levels. First, the overall time savings for device preparation using the Atellica COAG 360 System* compared to one BCS XP System was 5 hours 21 minutes over the course of the study week (51% reduction in technician hands-on time). Second, there was an 83% reduction (1 hour 40 minutes vs. 17 minutes per 1000 samples) in technician hands-on time required for sample management and a 41% reduction (3 hours 1 minute vs. 1 hour 46 minutes) for reagent management.

Conclusions: In this study, the Atellica COAG 360 System* performed with increased system availability and reduced technician hands-on time, resulting in the same productivity on one Atellica COAG 360 System* as three of the BCS XP Systems. This advantage over the standard equipment has the potential to affect the overall efficacy and productivity of a high-volume coagulation laboratory.

*Not available for sale in the U.S. Product availability varies by country.

PB 2122 | Rotational Thromboelastometry Parameters Have Variable Correlation with Plasma-based Assays of Coagulation across Trimesters of Pregnancy: A Cross-sectional Study

K. Fox[1], A. Shamshirsaz[2], H. Erfani[2], V. Kostousov[3], K. Bruzdoski[3], S.-K. Hui[3], J. Teruya[3]

[1]Baylor College of Medicine/Texas Childrens Hospital, Obstetrics and Gynecology, Houston, United States, [2]Baylor College of Medicine/Texas Childrens Hospital, Obstetrcis and Gynecology, Houston, United States, [3]Baylor College of Medicine/Texas Childrens Hospital, Pathology/Transfusion Medicine, Houston, United States

Background: In pregnancy and postpartum, women exhibit hypercoagulability and physiologic changes in of coagulation factors. We hypothesized that normative ranges of rotational thromboelastometry (ROTEM) across trimesters of pregnancy correlate with changes in plama-based assays of coagulation

Aims: To compare ROTEM with plasma-based assays in pregnancy.

Methods: After IRB approval, citrated blood was collected from 72 healthy pregnant women and grouped by trimester: 1st (11±3 weeks gestation, n= 20), 2nd (21±5, n=23), and 3rd (33±3, n= 29). EXTEM, INTEM, and FIBTEM were performed on ROTEM (IL, USA) to establish reference ranges. Routine, plasma-based coagulation tests, i.e., activated partial thromboplastin time (PTT), prothrombin time (PT), and Fibrinogen were performed on a STA-R Evolution analyzer (Stago, USA). Data analysis was performed Pearson correlation (SPSS v23, 2016, IBM, USA, significance = P< 0.05).

Results: Fibrinogen showed highest correlations with MCF FIBTEM ($r = 0.92$, $p < 0.001$) and A10 FIBTEM ($r = 0.90$, $p < 0.001$), while CT INTEM correlated modestly with PTT ($r = 0.51$, $p < 0.001$.) Interestingly, CT EXTEM did not correlate with PT ($r = 0.11$, $p = 0.35$,) but rather did correlate with PTT ($r = 0.48$, $p < 0.001$). Fibrinogen level showed a significant contribution to CFT, α-angle, and MCF for both INTEM and EXTEM (Table).

TABLE Correlation of Fibrinogen with INTEM and EXTEM values

Fibrinogen correlation with:	CFT	α-angle	MCF
INTEM	r = -0.67, p < 0.001	r = 0.70, p < 0.001	r = 0.81, p < 0.001
EXTEM	r = -0.71, p < 0.001	r = 0.73, p < 0.001	r = 0.87, p < 0.001

Conclusions: The high correlation of MCF FIBTEM with fibrinogen suggests that FIBTEM can be reliably used to guide clinical management. A10 values can be used similar precision and more rapid results (10-14 min) over MCF or plasma-based fibrinogen testing. As CT INTEM correlates only modestly with PTT values, clinical correlation studies in pregnancy are needed. Elevated fibrinogen levels during pregnancy substantially contribute to shortening of CFT and increasing α-angle and MCF on INTEM and EXTEM tracings that should be interpreted as physiological changes rather than pathologic hypercoagulability.

PB 2123 | Thrombin Generation Assay CANNOT Identify Antithrombin Resistance During Anticoagulant Therapy

Y. Takagi[1,2], S. Suzuki[1], N. Kawamura[1], A. Makiyama[1], H. Sakane[1], E. Hashimoto[1], A. Fujioka[1], S. Tamura[1], A. Takagi[1], V. Djordjevic[3], T. Kojima[1]

[1]Nagoya University Graduate School of Medicine, Pathophysiological Laboratory Sciences, Nagoya, Japan, [2]Japan Society for the Promotion of Science, Tokyo, Japan, [3]Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Belgrade, Serbia

Background: Variant thrombins derived from missense mutant prothrombins at Arg596 codon are resistant to inactivation by antithrombin (AT), causing susceptibility to venous thromboembolism (VTE). Prothrombin mutations associated with AT resistance (ATR) have been identified in VTE patients worldwide (e.g., Japan, Serbia, India, Italy). There is no simple laboratory test that can detect ATR, although we have reported a clinical test detecting ATR, which is not widespread.

Aims: We examined whether thrombin generation assay (TGA), a widely used blood coagulation function test, can identify ATR.

Methods: We tested TGA for plasma samples from ATR patients with or without anticoagulant therapy (warfarin or heparin) and non-ATR VTE patients taking warfarin. TGA was performed with tissue factor trigger at a final concentration of 5 pM using Calibrated automated thrombography.

Results: In the ATR patients without anticoagulant therapy (N=10), the average of total thrombin generation (ETP) and the duration of thrombin generation (StartTail) were 3,733 nM and 65 sec, whereas those in the non-ATR VTE patients with warfarin therapy (N=3) were 531 nM and 37 sec, respectively. In the healthy subjects (N=3), those were 1,600 nM and 24 sec, respectively. ETP of the ATR patients with anticoagulant therapy (N=6) ranged from 702 to 2,055 nM, similar to those of healthy subjects. On the other hand, StartTail of the ATR patients with anticoagulant therapy apparently prolonged, ranging from 45 to 66 sec. Thus, it seemed that a prolongation of StartTail was one of the characters of ATR, although StartTail of the non-ATR VTE patients with warfarin therapy and the AT deficiency patients without anticoagulant therapy were prolonged.

Conclusions: TGA may be useful as an ATR screening test only in the patients without anticoagulant therapy. To efficiently identify the ATR of VTE patients with or without anticoagulant therapy, we hope that the ATR detection method reported by us will be widely spread.

PB 2124 | Clot Wave Form Parameters of Prolonged APTT in Different Situations: Is There Any Difference between Them?

M.E. Martinuzzo[1,2], E. Sueldo[3], R. Porsella[3], M.A. D´Adamo[4], M.S. Lopez[1], L.H. Barrera[1,2], M.G. Gurfinkiel[3], M. Arias[3], J. Oyhamburu[1,2]

[1]Hospital Italiano de Buenos Aires, Laboratorio Central, Grupo Bioquímico, Buenos Aires, Argentina, [2]Instituto Universitario del Hospital Italiano, Bioquímica, Buenos Aires, Argentina, [3]Unidad Asistencial Por más Salud Dr. Cesar Milstein, Laboratorio de Hemostasia, Buenos Aires, Argentina, [4]Hospital Italiano de Buenos Aires, Laboratorio Central, Buenos Aires, Argentina

Background: ACL TOP coagulometers give APTT clot reaction parameters: Clotting time (CT), Maximum first derivative of Absorbance= Velocity (Max 1), Maximum and minimum second derivative= Acceleration (Max 2) and deacceleration (Min 2). There is not much information of them in other causes of APTT prolongation than hemophiliacs.

Aims: To evaluate APTT parameters, APTT SP in ACL TOP, in Unfractioned Heparin (UFH), Dabigatran (DABI), Lupus anticoagulant (LA), anti-Vitamin K antagonists (AVK) and single factor deficiencies (SFD) of factor XII, XI, IX, V, and VIII (HA and vWD).

Methods: 222 curves from 61 normal controls (NC), 31 LA, 41 UFH, 20 DABI, 34 AVK and 33 SFD were analyzed. Parameters: CT, Max 1, Max 2 and Min 2. Second derivative curve morphology (SDM): single peak (SP), double peak (DP), peak with shoulder (PSH) and wide peak (WP). Parameters differences between groups and SDM were analyzed by ANOVA test with post HOC Bonferroni. Statistics was performed by SPSS 23 software.

Results: Max 1 was lower in all groups compared to NC ($p< 0.0001$), but UFH and Dabi tended to be higher than others. Max 2 was lower than NC in all groups, without differences between them, except Dabi higher than LA ($p= 0.011$). Min 2 expressed as absolute value was lower in all groups compared to NC, but in LA, AVK and SFD was lower than UFH and DABI ($p< 0.001$),

Samples with DP had significantly lower Max 1 and Max 2 than SP ($p< 0.001$ and $p=0.005$), but similar to PSH and WP. However, Min 2 of DP was significantly lower than SP, PSH and WP, table 2.

TABLE 2 APTT reaction curve parameters according different second derivative morphology (SDM) in patietns with prolonged APTT

SDM	CT Mean (SD)	Max 1 Mean (SD)	Max 2 Mean (SD)	Min 2 Mean (SD)
SP (N:74)	75,6 (47.2)	219,4 (109.6)	318,4 (217.4)	-160,6 (99.3)
DP (N: 50)	69,3 (30.3)	153,0 (63.7)	207,9 (135.2)	-39,5 (62.0)
PSH (N: 30)	62,8 (29.0)	179,0 (50.9)	236,7 (138.7)	-67,5 (82.7)
WP (N: 7)	80,2 (42.5)	156,6 (70.3)	159,7 (132.3)	-36,7 (30.7)

Conclusions: SDM of UFH and DABI is like NC (SP), but different to LA, AVK and SFD which present higher prevalence of DP and PSH. Max 1 and Max 2 are lower in all patients´ groups compared to NC, but similar between them. Min 2 was lower in LA, AVK or SFD compared to UFH and DABI. Looking at SDM and Min 2 could be useful to discriminate prolongations of APTT by UFH or DABI to those secondary to factor deficiencies or LA in low complexity laboratories.

PB 2125 | Hereditary Angioedema: Role of Genetic Test in Diagnosis

P. Martinez[1,2], P. Rozenfeld[3]

[1]Hospital Penna de Bahia Blanca, Hematologia, Bahia Blanca, Argentina, [2]Universidad Nacional del Sur, Bahia Blanca, Argentina, [3]Universidad Nacional de la Plata. CONICET, La Plata, Argentina

Background:

- Laboratory tests for the diagnosis of HAE in Argentina are underdeveloped. Most patients are diagnosed with C1-INH tests, but for patients with high clinical suspicion of HAE and normal test for C1-INH, testing for mutations in the Factor XII (FXII) gene may allow diagnosis in some patients.

Aims:

- To show the outcomes of patients diagnosed in Argentina with hereditary angioedema (HAE) and the utility of genetic tests results.

Methods:

- Patients and samples: A total of 587 patients with clinical suspicion of HAE were studied.
- Quantification of complement factors: serum samples are collected to measure C3, C4 and C1-INH levels using a turbidimetric method.

TABLE 1 APTT clot reaction curve parameters in different group of patients

GROUP	CT Mean (SD)	Max 1 Mean (SD)	Max 2 Mean (SD)	Min 2 Mean (SD)	SP (% cases)	DP (% cases)	PSH (% cases)	WP (% cases)
NC	28.5 (3.2)	292.9 (51.2)	818.4 (187.3)	-332.5 (74.9)	100	0	0	0
LA	73.7 (36.5)	164.9 (89.7)	203.3 (195.1)	-79.4 (91.0)	6.5	35.5	54.8	3.2
UFH	88.8 (53.9)	219.0 (126.6)	248.6 (174.7)	-149.7 (95.4)	100	0	0	0
DABI	63.6 (19.1)	232.7 (46.7)	383.0 (189.8)	-195.6 (75.0)	100	0	0	0
AVK	61.4 (26.7)	157.4 (52.6)	266.5 (173.1)	-51.5 (41.6)	19.4	55.5	8.3	16.7
SFD	63.4 (28.5)	180.1 (73.2	255.4 (174.7)	-53.9 (111.1)	12.1	57.6	30.3	0

Spectrophotometric assays are used to measure the functional activity of C1-INH.

- SERPING1 genetic test: involves isolation of patients' DNA and sequencing of PCR-amplified exons 1-8 and the underlying intronic regions.
- FXII genetic test: the most common mutation c.983C>A in exon 9.

Results: A total of 587 samples were received and 144 (24.5%) patients were diagnosed,125 (21.3%) patients with HAE type 1 (HAE 1), 15 (2.5%) type 2 (HAE II) and 4 (0.7%) with normal C1 inhibitor (HAE-nC1). SERPING1 genetic test: A genetic test was performed in 23 families and confirmed HAE I/II. Forty-two percent mutations were consistent with the common mutation c.1031-20a>g. No mutation was found in the coding region in 2 cases.

FXII genetic test: This test was only performed in patients with strongly clinically suspected HAE, but functional C1-INH was normal. Four out of the 14 tested patients had the FXII mutation (28%), thereby confirming HAE diagnosis based on mutations in FXII gene.

Conclusions: A total of 587 samples were received and 144 patients were diagnosed. Mutations of the SERPING1 gene were found in 91% of patients. HAE-nC1 was diagnosed based on the FXII mutation gene in 28% of patients with normal C1-INH function, being important in the diagnostic algorithm.

PB 2126 | Alterations in the Parameters of Classic, Global and Innovative Assays of Hemostasis Caused by Sample Transport via a Pneumatic Tube System

A. Poletaev[1], A. Ignatova[1], E. Koltsova[1], A. Kuprash[1], P. Gitelson[2], H. Sepoyan[1], A. Balandina[1], G. Novichkova[1], M. Panteleev[1]

[1]Dmitry Rogachev National Scientific and Practical Center of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation, [2]Pirogov Russian National Research Medical University of Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

Background: Pneumatic tube system(PTS) is presently an integral part of blood sample transport in large medical facilities. However, pre-analytical effects of PTS use on different hemostasis assays are only partially characterized.

Aims: To evaluate the effect of PTS on haemostasis using a large array of laboratory assays.

Methods: Blood was collected from 9 healthy donors. All gave their written informed consent, and the study protocol was approved by the institutional ethics committee. TEG, Thrombodynamics(TD), Thrombodynamics-4D(TD-4D), TGA, LTA with 4 inductors, and routine tests(APTT, PT, TT, Fib) were determined. Platelet function(levels of CD42b, CD61, CD62P, PAC1, annexin V binding, and mepacrine release) was determined using flow cytometry with/without stimulation by collagen-related peptide plus SFLLRN.

Results: PTS significantly increased collagen-indused LTA(84 vs 72%,p< 0.05) and decreased epinephrine-induced one(64 vs 72%, p< 0.05). Flow cytometry revealed significant platelet pre-activation in PTS samples: procoagulant platelets were increased from 0.5 to 1.8%(p< 0.05), while mepacrine accumulation was impaired by 10%(p< 0.05). Activation markers were also higher in the stimulated platelets. Significant changes were registered in all global hemostasis tests: TD, TEG, TGT, TD-4D. TD showed increased clot growth velocity: Vi and Vst were 68 vs 58 µm/min and 42 vs 32 µm/min(p< 0.05), respectively. In all tube-delivered samples there was spontaneous clotting. TEG parameters R and K were significantly decreased(13.8 vs 20.8 min and 4 vs 7.6 min(p< 0.05)), angle was increased (42.3 vs 26.8,p< 0.05). TGA increase parameters ETP and Amax were changed: 1372 vs 1056nM*min and 103 vs 89nM(p< 0.05), respectively. TD-4D showed increased parameter Ast: 72.8 vs 53.9nM(p< 0.05). In routine tests no significant difference was revealed.

Conclusions: The results indicate that the PTS does no affect routine assays, moderately affects platelet activation, and induces significant procoagulant deviation in global haemostasis tests.

PB 2127 | Productivity Evaluation of a Novel Blood Coagulation Analyzer in the 24/7 Clinical Coagulation Laboratory Environment

S. Echternacht[1], A. Patapovas[2], S. Kuehn[3], E. Langer[4], K. Hegel[3]

[1]Siemens Healthcare Diagnostics GmbH, Global Marketing Hemostasis, Marburg, Germany, [2]Siemens Healthcare GmbH, Germany, Enterprise Services & Solutions, Erlangen, Germany, [3]Labor Berlin - Charité Vivantes Services GmbH, Berlin, Germany, [4]Labor Berlin - Charité Vivantes GmbH, Berlin, Germany

Background: The Atellica™ COAG 360 System* is a fully automated random-access blood coagulation analyzer with cap-piercing technology. Its novel elements include a refrigerated chamber and anti-evaporation caps, which prolong onboard reagent stability, as well as continuous management of reagents and consumables.

Aims: The study aimed to compare the productivity of the Atellica COAG 360 System* with a routine laboratory setup.

Methods: Hands-on/walkaway time managing samples, reagents, and consumables were assessed over 5 days in the coagulation laboratory at Labor Berlin. A total of 1732 plasma samples (492 manually loaded) were collected from the routine laboratory setup (two blood coagulation analyzers, one connected to the 24/7 laboratory automation track, the other used stand-alone for specialty hemostasis assays) prior to archiving and additionally analyzed on the Atellica COAG 360 System* (off-track).

Results: In comparison with the routine laboratory setup, we observed a reduction in hands-on time with the use of one Atellica COAG 360. For reagent and consumables (cuvettes/cleaning solution) management the total hands-on time per day was reduced by 90% and 70% respectively (Mean 90.1%, SD ±4.2% and Mean 69.9%, SD±11.9%). In addition, the prolonged reagent stability feature was noted to save up to 31min 15s in average for un/freezing of specialty assays daily. The sample analysis was interrupted during the week in total 33min on the Atellica COAG 360 compared to 6h 42min on both Stago STA R Max analyzers. Total hands-on time per day on

manual plasma samples loading was reduced by 89% (Mean 88.5%, SD ±4.3%).

Conclusions: In terms of overall time savings, especially hands-on time and, importantly, reduction in time needed for active sample and reagent management, the Atellica COAG 360 System* is well-suited for routine and specialty testing in high-volume coagulation laboratories. *Not available for sale in the U.S. Product availability varies by Country.

PB 2128 | Mutation Screening for the C677T Variant in the MTHFR Gene by Melting Point Analysis with the Real Time PCR: Detection of a Rare Variant Val225Ile

I. Tirado Garcia[1], L. Romero Roman[1], A. Oliver Samper[2], N. Vilalta Seto[1], I. Coll Torrents[1], E. Martínez-Sánchez[1], J. Mateo Arranz[1], J.C. Souto Andrés[1], J. Fontcuberta Boj[1]

[1]Hospital de la Santa Creu i Sant Pau, Servei d'Hematologia Unitat d'Hemostàsia i Trombosi, Barcelona, Spain, [2]Fundació Puigvert, Servei d'Hematologia, Barcelona, Spain

Background: The genetic determinant affecting plasma homocysteine levels is a polymorphism *C677T* (rs1801133) in the 5,10-methlylene-tetrahydrofolate reductase (*MTHFR*) gene substitutes Ala222Val. The "T "variant produces a thermolabile and less efficient enzyme. As a result, T/T homozygote produces a small increase in plasma homocysteine levels. This is a risk factor for venous thromboembolism. We used a melting peak analysis with fluorescence hybridization probes Real Time PCR.

Aims: We describe the results that showed atypical melting curves in the analysis of *C677T*.

Methods: The patient was a 49-year-old man who presented with an idiopathic thrombosis in the right renal vein. The thrombophilia study included the analysis of phospholipids antibodies, antithrombin, Protein S, Protein C and Factor V Leiden, *F2G20210A*, *F12C46T*, *C677T* in the *MTHFR* gene mutations. The *C677T* was analyzed by Real Time PCR with fluorescence probes for the specific allele. The sequencing was performed with Sanger method.

Results: Genetic analysis by Real Time PCR of the patient's results showed atypical melting curves in the analysis of *C677T*. Subsequent sequencing of the corresponding PCR fragment reveals a very rare polymorphism that was heterozygous, rs200100285 A/G that substitutes Val225Ile amino acid. This variant is listed in the genetic public databases by the 1000 Genomes Project. Its prevalence is very low in Caucasian populations. This variant was not detected in 500 analysis of *C677T* with Real Time PCR over a period of 10 years in our centre.

Conclusions: The Real Time PCR with specific fluorescence probes is an efficient, accurate and robust technique to study variations that may have clinical application.

Spanish grant RD12/0042/0032.

PB 2129 | Evaluation of Potential Sources of Variation in 1-stage Factor IX Assays

J. Needham[1], H. Lewis[2], M. Stringer[2], S. Mangles[2], S. Rangarajan[2]

[1]Hampshire Hospitals NHS Foundation Trust, Haemophilia Haemostasis and Thrombosis Centre, Basingstoke, United Kingdom, [2]Hampshire Hospitals NHS Foundation Trust, Haemophilia Haemostasis & Thrombosis Centre, Basingstoke, United Kingdom

Background: Monitoring of effective replacement therapy in Haemophilia B patients is routinely measured using a 1-stage clotting factor assay. Recent pharmaceutical advances have delivered new products for the management of bleeding in Haemophilia B and movement towards pharmacokinetic based personalised dosing requires laboratory assays to accurately reflect in vivo activity.

Aims:

1. To evaluate on a single platform using the Tcoag Destiny Max analyser variation in resulting factor IX levels applying a 1-stage factor IX assay (1-st FIX assay) using either optical or mechanical end-point detection mechanisms.
2. To evaluate resulting factor IX levels associated with various combinations of manufactures reference material and reagents.

Methods: 1-st FIX optical and mechanical assays using all reagent combinations were performed on the Destiny Max analyser using aPTT HS (Tcoag), APTT-SP (Werfen), Actin FS (Dade-Behring), factor IX deficient plasma (Tcoag, Technoclone, Werfen), reference plasma (Tcoag and Technoclone) and quality control TriniCHECK 1 and abnormal control (Tcoag).

Results: Overall reagents combinations and reference sources generated 36 reference curves. Based on normal and abnormal quality control results there was no statistically significant difference between optical (range p = 0.41 - 0.93) and mechanical FIX levels (range p = 0.65 - 0.85) across all reagent and reference combinations. Reference curves were run at nine points from 1/5 to 1/100 dilutions, with Actin FS giving statistically significant shorter clotting times (p = 0.002). Linearity r values ranged from 0.999 - 0.987 with Werfen FIX deficient plasma curves linear over dilutions 1/5 to 1/25.

Conclusions: No major variation was detected in levels of FIX quality control results across detection systems or reagent and reference plasma combinations investigated. However, linearity findings could have an impact on calculation of results particularly at low levels. Further work is in progress to include chromogenic assay and clinical samples.

PB 2130 | The Calibrated Automated Thrombography in Normal Pregnancy

N. Silina[1], O. Smirnova[1], A. Nikolaeva[2], O. Golovina[1], L. Papayan[1], O. Matvienko[1]

[1]Russian Research Institute of Haematology and Transfusiology, Laboratory of Blood Coagulation, Saint Petersburg, Russian Federation, [2]Antenatal Clinic №22, Saint Petersburg, Russian Federation

Background: Normal pregnancy is associated with hypercoagulable state. It manifests by high level of coagulation factors VII, VIII, IX and

TABLE. 1 Parameters of CAT in normal pregnancy (Me, 90% (CI) (* - p<0.05 compare to controls)

Parameters of CAT	I trimester (n=18)	II trimester (n=36)	III trimester (n=18)	Controls (n=20)
LT, min (TM-)	2.30 (1.70-2.60)	2.60 (1.90-3.60)	2.55 (1.70-3.20)	2.33 (1.68-2.67)
LT, min (TM+)	2.30* (2.00-2.80)	2.60* (2.30-3.60)	2.60* (1.70-3.00)	2.33 (1.69-2.67)
ETP, nM*min (TM-)	2354.60* (1883.60-2850.10)	2110.45* (1656.50-3118.50)	2257.10* (1697.50-2805.50)	1577.75 (1344.53-1871.10)
ETP, nM*min (TM+)	1838.05* (1377.70-2253.10)	1660.45* (1244.00-2682.00)	1676.35* (1498.00-2346.00)	714.58 (480.95-947.80)
Peak, nM (TM-)	368.00* (284.20-447.30)	383.80* (257.60-579.70)	350.35* (251.70-536.60)	285.61 (241.98-336.68)
Peak, nM (TM+)	327.20* (252.10-402.50)	329.35* (222.20-546.30)	329.10* (247.40-498.00)	159.16 (107.25-199.60)
TTP, min (TM-)	5.23 (4.50-6.00)	5.00 (4.30-7.00)	5.20 (4.30-7.60)	5.03 (4.01-5.55)
TTP, min (TM+)	5.00* (4.30-5.50)	5.00* (4.30-6.50)	5.00* (4.30-6.30)	4.33 (3.97-4.86)

Von Willebrand. At the same time anticoagulation system factors change too. The Calibrated Automated Thrombography (CAT) can be useful in the functional testing of coagulation system of pregnant women. When thrombomodulin (TM) is used thrombin generation (TG) becomes sensitive to the disorders of the protein C system.

Aims: The aim of this study was to estimate normal parameters of CAT for all trimesters of physiological pregnancy.

Methods: The study involved 74 healthy pregnant women (19 - 40 years, I, II and III trimester - 18, 36 and 18 respectively) and 20 non-pregnant controls. TG was measured according to Hemker et al. at 5pM TF and 4 μM phospholipids platelet poor plasma (PPP) with PPP plasma +/- TM reagent (Thrombinoscope BV, Maastricht, The Netherlands). Such parameters were assessed: lag time (LT, min), endogenous thrombin potential (ETP, nM*min), peak thrombin (Peak, nM) and time to peak (TTP, min). STATISTICA 6.0 was used. Results are given as median (Me) with 90% confidence intervals (CI) for each gestational period. P< 0.05 was considered statistically significant.

Results: Data are shown in the table. All parameters of CAT were markedly reduced in the presence of TM. ETP and Peak in the absence and presence of TM were significant increased during pregnancy. LT and TTP were significantly higher with TM vs. without it. This fact can indicate the hypercoagulation in healthy pregnant women.

Conclusions: Calibrated Automated Thrombography with and without TM allows the effectively detecting of hypercoagulability that is very important for clinical practice. Extremely high levels of CAT parameters can indicate some complications of normal pregnancy and delivery.

PB 2131 | The Impact of Pre-analytical Variables and Reagents on the Results of Thrombin Generation - Lessons Learned from the Generation of Normal Reference Ranges

E. Fosbury

Royal Free London NHS Foundation Trust, Katharine Dormandy Haemophilia and Thrombosis Centre, London, United Kingdom

Background: Haemostasis is a complex interplay between coagulation factors, platelets and vascular endothelium. Clinicians often rely on routine clotting assays that assess a small part of the haemostatic process. Global haemostatic assays such as thrombin generation provide an important means of eliciting dynamic information about coagulopathic or thrombotic states.

Aims: The objective was to generate data for normal reference ranges using an in house normal plasma pool (NPP) as a quality and normalisation control. The data were analysed to detect any significant difference between use of reagents and differences in sample processing.

Methods: Ethical approval and informed consent for samples from healthy volunteers was obtained via the KD Coagulation Research Plasma Bank. Individuals with a known coagulation defect or on antiplatelet or anticoagulant medication were excluded. Table 1 gives the details of the different sample processing and tissue factor (TF) reagents used. Thrombin generation (TGA) was performed as per Hemker et al.

TABLE 1 TGA assay conditions for normal reference ranges; Platelet count adjusted to 150 x 10^9/L.

PRP (with CTI)	Unadjusted platelet count	Adjusted platelet count
	PRP reagent	PRP reagent
	Innovin 0.5 pM	Innovin 0.5 pM
	Innovin 1 pM	Innovin 1 pM
PPP (with CTI)	Double spun	Triple spun
	PPP low	PPP low
	Innovin 1 pM	Innovin 1 pM & 2 pM
PPP (no CTI)	Double spun	
	PPP reagent	
	Innovin 5 pM	

Results: 21 male and 20 female volunteers were recruited to the study. Data were collected for the in house NPP and the coefficients of variation (CVs) were found to differ between in-house and ready-made TF reagents, with the latter being closer to 10% (acceptable for a diagnostic assay).

Results from PRP samples with unadjusted and adjusted platelet counts were compared and found to be significantly different (see Table 2). Results of PPP samples processed on the same day or after thawing of frozen aliquots were also compared. Significant differences were seen in the results,

(see Table 2).

TABLE 2 Results of paired t tests for adjusted vs unadjusted platelet count and fresh vs frozen PPP samples; p values (< 0.05 significant)

PRP Adjusted vs unadjusted platelet count	PRP reagent p value	Innovin 0.5 pM p value	Innovin 1 pM p value		
LT	0.032	0.219	0.752		
ETP	0.132	0.014	0.259		
Peak	0.005	0.004	0.008		
ttPeak	<0.0005	<0.0005	<0.0005		
Fresh vs frozen PPP samples	PPP Low (CTI) p value	Innovin 1 pM (CTI) p value	Innovin 2 pM (CTI) p value	PPP reagent p value	Innovin 5 pM p value
LT	0.146	0.113	0.045	0.171	0.015
ETP	0.883	0.255	0.053	0.006	0.613
Peak	0.976	0.122	0.001	0.290	0.003
ttPeak	0.267	0.257	0.064	0.145	0.007

Conclusions: The findings of this study underline the potential impact of different methods of sample processing and TF reagents on results from thrombin generation. This is a highly useful test, but in order to maximise use of the output and to minimise variability, each part of the protocol should be carefully considered.

PB 2132 | High Level of Concordance for Routine Assays between Results Obtained with Two Automated Coagulation Analyzers

S. Just[1], D. Zebeljan[1], L. Smith[2], J. Loats[3], K. Hill[3], G. Lakos[2]

[1]*Sydney South West Pathology Service (SSWPS), Haematology, Sydney, Australia,* [2]*Abbott Laboratories, Santa Clara, United States,* [3]*Abbott Diagnostics, Sydney, Australia*

Background: The Sekisui CP3000 coagulation system was reviewed.
Aims: The analytical performance characteristics of the Sekisui CP3000 Coagulation System were assessed in comparison with STAGO STA-R Evolution for several haemostasis assays.
Methods: Testing was performed using remnant samples for PT and APTT (n=215), TT (n=30), fibrinogen (n=74), D-dimer (DD)(n=40), antithrombin (AT)(n=47) and Protein C (PC)activity (n=33). Anti-Xa (heparin) activity was determined in 34 and 10 samples from patients on LMWH and UFH, respectively. Results were compared between the two analysers using regression statistics, Pearson correlation and qualitative agreement methods. Time to first result was studied and user experience was assessed with a weighted scoring survey.
Results: Within-run and within-laboratory %CVs were < 5%, except for abnormal level PT and AT and normal level fibrinogen, but all were clinically acceptable. Significantly better imprecision results (1.1% and 4.2%, respectively) were obtained for DD at normal level than the manufacturer's claim. Correlation coefficients (r) ranged from 0.86 (APTT) to 1.0 (INR) in comparison with STA-R Evolution. Qualitative agreement results were 79.0% and 97% for APTT and TT when the STAGO-recommended reference ranges were used. Total agreement for PT results was 90%. Reference ranges were successfully verified for APTT, PT/INR, TT and AT, results indicated need for adjustment for fibrinogen, DD and PC. The average time to result was 133 seconds for PT, and 327 seconds for the panel of PT, APTT and fibrinogen. CP3000 scored significantly higher in the user experience survey than the STAR-Evolution for size, QC monitoring, weekly maintenance and troubleshooting, but lower for calibration, QC processing, start-up, and noise.
Conclusions: CP3000 showed high level of repeatability, reproducibility, and strong correlation with the STA-R Evolution results. Time to first result was rapid, and the analyzer was rated favorably for its size, QC monitoring, maintenance and troubleshooting.

PB 2133 | Current Practice Related to D-dimer Testing in Croatia

S. Margetić[1,2], A. Bronić[2,3], D. Coen Herak[2,4], M. Milic Gall[2,5,6]

[1]*Medical School University Hospital´Sestre Milosrdnice´, Clinical Institute for Chemistry, Zagreb, Croatia,* [2]*Working Group for Laboratory Coagulation, Committee for the Scientific Professional Development, Croatian Society of Medical Biochemistry and Laboratory Medicine, Zagreb, Croatia,* [3]*Clinical Institute of Chemistry, Medical School University Hospital´Sestre Milosrdnice´ Zagreb, Clinical Institute for Chemistry, Zagreb, Croatia,* [4]*University Hospital Centre Zagreb, Department of Laboratory Diagnostics, Zagreb, Croatia,* [5]*Osijek University Hospital, Department of Clinical Laboratory Diagnostics, Osijek, Croatia,* [6]*Faculty of Medicine, University of Osijek, Osijek, Croatia*

Background: D-dimer assay provides an important contribution to the venous thromboembolism diagnostic workup. However, the lack of standardization among different assays and laboratories is the main aspect that still complicates its diagnostic use.
Aims: The aim of this study was to present current practice related to D-dimer testing in Croatia.
Methods: The results are based on a review of data obtained in a national survey related to overall haemostasis testing in the form of a questionnaire,conducted between June and September 2015.
Results: Among all respondents to the questionnaire (104/170; 61.2%), 42/104 (40.4%) of laboratories declared to perform the D-dimer assay. More than half of them reported to use Siemens Innovance D-dimer assay (25/42), while other commercial D-dimer reagents were represented as followed: bioMerieuxVidas D-dimer (5/42), Roche Cardiac D-dimer (3/42), Roche immunoturbidimetric assay (3/42), Olympus

D-dimer reagent (2/42), Nycocard D-dimer (2/42), IL-Dimer HS500 (1/42) and Abbott D-dimer (1/42). Among them, 24/42 indicated to use fibrinogen equivalent unit (FEU) and 18/42 declared to use D-dimer unit (DDU) reporting units for expressing D-dimer results. Survey results showed a number of different measurement units currently in use: mg/L (19/42), mg/L FEU (12/42), µg/L (5/42), µg/L FEU (4/42), µg/mL (1/42), ng/mL (1/42) and ng/mL FEU (1/42). All 42 laboratories declared to use fixed cut-off value and no one laboratory declared to use age-adjusted cut-off values. The most commonly used cut-off values were 0.5 mg/L DDU (15/42) and 0.5 mg/L FEU (10/42).
Conclusions: Results of our survey showed that different combinations of measurement and reported units are currently used for reporting D-dimer results. These results confirm and underline the need for further standardization in D-dimer results reporting at national level. Obviously, an effort should be directed towards harmonization of available commercial D-dimer methods.

PB 2134 | Usefulness of APTT Reagents for LA Detection and Frequency of LA Positive Patients in APTT Prolonged Patients

S. Anun[1], A. Pirunsarn[2], K. Boonyoung[1], P. Mitreejit[1]

[1]*Bhuddasothorn Hospital, Laboratory Department, Muang, Thailand,* [2]*Bhuddasothorn Hospital, Hematologist, Muang, Thailand*

Background: Lupus anti-coagulant (LA) is an antibody that inhibits phospholipid-dependent coagulation reactions and of the several tests to detect LA, APTT is among the most accessible. However, APTT test sensitivity to LA varies depending on the reagent, with poor sensitivity in some cases resulting in false negatives.
Aims: The aim of this study was to verify the usefulness of the two types of APTT reagents used in our hospital for LA detection.
Methods: 3.2% sodium citrate blood samples from 26 patients were analysed using the APTT test on both the CP 2000 with the Coagpia APTT-N reagent (APTT-N) and the CS 2100i with the Actin FS reagent (ACTIN). The samples were also used for mixing tests, dRVVT and factor assays.
Results: In the APTT-N prolonged/ACTIN normal group (N=8),there was a significant difference between the mean values for APTT-N and ACTIN of 72.9 vs 28.7 sec respectively (P< 0.01). In this group,various bleeding or thrombogenic factors were identified in all specimens. In the LA positive (LA+) group (N=9), the mean value for APTT-N of 87.7 sec was significantly longer than that for ACTIN, 36.0 sec (P< 0.01). Among the APTT prolonged specimens, the LA+ rate was 50% (9/18). Furthermore, in the LA+ group, the abnormality rate for APTT results was 100% with APTT-N (9/9) and 55.5% with ACTIN (5/9).
Conclusions: APTT-N was able to detect all instances of APTT prolongation in LA+ patients, with mean values for LA+ specimens also showing significantly higher prolongation times compared to ACTIN. As such, it was considered that the sensitivity of APTT-N to LA and its utility are high. Even within the results of this study, which tested at random a number of APTT-prolonged specimens, the number of LA+ patients reached 50%. Based on this, predisposition to thrombophilia maybe more common among patients than is conventionally thought, and as such use of an APTT reagent with high LA sensitivity should be given due consideration for its benefit to patients.

PB 2135 | An Evaluation of the Activated Partial Thromboplastin Time Waveform in Various Diseases

T. Matsumoto[1], H. Wada[2], K. Ohishi[1], N. Katayama[3]

[1]*Mie Univ Hospital, Blood Transfusion Service, Tsu, Japan,* [2]*Mie University Graduate School of Medicine, Lavoratory Medicine, Tsu, Japan,* [3]*Mie University Graduate School of Medicine, Hematology and Oncology, Tsu, Japan*

Background: The activated partial thromboplastin time (APTT) waveform includes several parameters relating to various underlying diseases.Another benefit of optical endpoint coagulation analyzers is the ability to visualize the clot reaction curve as the prothrombin time (PT) and APTT. Previous reports have highlighted the usefulness of the visual inspection of the APTT clot reaction curves, and abnormal biphasic clot reaction curves have been reported to be associated with the early detection of disseminated intravascular coagulation (DIC).
Aims: In this study, we measured and analyzed the APTT wave form in patients with various diseases, and examined the relationship between the disease and the parameters of the APTT waveform.
Methods: The APTT waveform was examined in various diseases.
Results: Regarding the pattern of APTT waveform, a biphasic pattern of acceleration or velocity curve is observed in patients with hemophilia and those positive for antiphospholipid antibody (aPL) or inhibitor for coagulation factor VIII (FVIII). The time of acceleration, velocity and fibrin formation at 1/2 height are prolonged in patients with hemophilia, those with an inhibitor, those positive for aPL, those treated with an anti-Xa agent and those with DIC, and those all tend to become shorten in pregnant women. The height of the acceleration peak 1 is significantly lower in patients with hemophilia, those with an inhibitor, those positive for aPL, those treated with an anti-Xa agent and those with DIC, and that it tend to be significantly higher in pregnant women. The height of velocity is significantly lower in patients positive for FVIII inhibitor and it is also significantly higher in patients treated with an anti-Xa agent and in pregnant women. The width of acceleration peak 1 and peak 2 and the velocity were significantly longer in almost all diseases.
Conclusions: An analysis of the APTT waveforms was thus found to provide us with useful information.

PB 2136 | Identification of Rare Inherited Diseases by Next Generation Sequencing

S. Shahid, S. Ahmed, S. Munzir, T. Shamsi

National Institute of Blood Disease & Bone Marrow Transplantation, Karachi, Pakistan

Background: Genomic studies on rare inherited diseases in recent years have revolutionized molecular diagnosis for inherited disease.

Recent whole genome and targeted gene studies have found novel somatic mutations with pathological importance in inherited diseases. We performed mutational screening to reach accurate diagnosis of diseases and want to apply a targeted gene panel for the detection of possible mutation in a diagnostic molecular pathology laboratory.

Aims: To implement an NGS panel for genetic diagnosis of more than 100 inherited diseases. The gene panels targets 552 regions known to haven pathogenic mutations in genes with potential involvement in severe recessive, pediatric onset diseases.

Methods: We performed next generation sequencing (NGS) using Trusight Inherited disease panel which included 552 genes covered 110 inherited rare diseases. Research protocol was approved by the Institutional Review Board (ERC/IRB) and conformed to the tenets of the Declaration of Helsinki. We extracted genomic DNA of apparently undiagnosed eight cases from peripheral blood by QIAamp® Blood mini kit, Qiagen. DNA quality/quantity was checked by Qubit® 2.0 flurometer (life technology®) and then used TruSight™ DNA Amplicon Sequencing chemistry for library preparation and normalization. Sample was run on Next generation sequencer MiSeq Illumina™.

Results: In total 10509 variants were detected, after excluding intronic and synonymous variants, 1851 missense variants were found in eight undiagnosed patients. We identified p.Q96* mutation in *FERMT3* gene in homozygous state which is responsible for rare inherited bleeding disorder Leukocyte adhesion molecule III Deficiency. A most frequent mutation p.A177T found in *RNASEH2B* gene that cause Aicardi-Goutières syndrome type 2 (AGS-2).

Conclusions: Targeted gene panel testing by NGS was applicable for accurate detection of inherited diseases. We are able to provide correct diagnosis with respect to individualize genetic pattern in the clinical setting.

PB 2137 | Type and Frequency of Hemoglobinopathies, Diagnosed in the Area of Karachi, in Pakistan

S. Shabbir

National Institute of Blood Disease and Bone Marrow Transplantation, Karachi, Pakistan

Background: Hb comprises four subunits, each having one polypeptide chain and one heme group.The polypeptide chains of adult Hb themselves are of two kinds, known as alpha and beta chains, similar in length but differing in amino acid sequence. The alpha chain of all human Hb, embryonic and adult, is the same. The non-alpha chains include the beta chain of normal adult Hb ($\alpha 2\beta 2$), the gamma chain of fetal Hb ($\alpha 2\beta 2$), and the delta chain of HbA2.

Aims: Aim was to know the frequency distribution of hemoglobinopathies in the Karachi,which will help in formulating various strategies for the effective control and prevention of these disorders.

Methods: The blood samples were collected from the patients of low Hb,for testing of parameters like, CBC, peripheral smear, Hb analysis by electrophoresis (at alkaline pH),high-performance liquid chromatographyand sickling test. CBCs were done by Sysmex XN 1000 analyzer, peripheral blood smears were stained with Leishman's stain, grading of hypochromia, anisocytosis, microcytosis, macrocytosis, and polychromasia was done according to the standard criteria. Hb electrophoresis at alkaline pH was performed on Genio analyzer.

Results: Out of total 2731, 935 (34.2%) patients had hemoglobinopathies. Out of these 935 patients who had hemoglobinopathies, beta thalassemia minor 51.8%, beta thalassemia major 24.1%, HbD trait 6.7, sickle/beta thalassemia 4.5%, sickle cell disease 3.9%, HbE trait 1.9%, and sickle cell trait 1.7% were most common hemoglobinopathies. Less prevalent were delta/beta thalassemia, HbE homozygous, HbD homozygous, and HbH disease.

Conclusions: Our study is an attempt to determine the type and frequency of various hemoglobinopathies in Karachi region that can be useful in prevention and management of various hemoglobinopathies, which may play a vital role in the hospital blood bank as well as in the formulation of transfusion policies.

FIBRINOLYSIS & PROTEOLYSIS

PB 161 | Affimers for Modulation of Fibrinolysis: An Alternative Approach for Bleeding Disorders

K. Kearney[1], C. Tiede[2], K. Smith[1], F. Phoenix[1], N. Oxley[1], R. Ariëns[1], N. Pechlivani[1], D. Tomlinson[2], R. Ajjan[1]

[1]University of Leeds, Division of Cardiovascular and Diabetes Research, Leeds Institute of Cardiovascular and Metabolic Medicine, Leeds, United Kingdom, [2]University of Leeds, Astbury Centre for Structural and Molecular Biology, School of Molecular & Cellular Biology, Leeds, United Kingdom

Background: Restance of a fibrin clot to lysis can determine clot stability and has implications for bleeding disorders. We hypothesised that fibrinogen-targeting affinity proteins, termed Affimers, represent a tool to manipulate fibrin network characteristics and the potential to identify novel therapeutic targets for conditions characterised by excessive bleeding.

Aims: Modulate fibrin clot properties and enhance resistance to fibrinolysis using fibrinogen-specific Affimers.

Methods: A phage display system was used to screen a large library ($n=10^{10}$) of random Affimers for fibrinogen binding. Effects of Affimers on fibrin clot properties were assessed by turbidimetric assays, confocal microscopy and ROTEM. Mass spectrometry (MS) was used to elucidate interaction sites.

Results: 112 fibrinogen-binding Affimers were isolated from two independent screens, of which 14 demonstrated distinct sequences. Two of these, F5 and B9, prolonged plasma clot lysis time from 42.2±12.3 mins (mean±SD) to 234.4±7.4 and 102.3±8.0 mins respectively at 20:1 Affimer:fibrinogen molar ratio ($p< 0.01$ for both). A dose response curve showed the lowest molar ratio to have an effect was 5:1 and 10:1 for F5 and B9, respectively. In whole blood ROTEM, B9 reached maximum clot lysis after 75 minutes, compared to control at 54 minutes, F5 only reached 22.3±6.1% ($p< 0.01$) lysis by the 2 hour endpoint. F5 caused a decrease in maximum clot firmness

(MCF) from 45.7±1.5mm to 35.3±2.1mm (p< 0.01), while B9 did not influence MCF. F5 and B9 had no significant effect on clot structure when assessed by confocal microscopy. MS analysis of trypsin digest products of Affimer-fibrinogen complexes suggested that F5 binds 2 regions on the fibrinogen α chain, while B9 binds to the fibrinopeptide B region.

Conclusions: Our data show that Affimers can modulate fibrinolysis while maintaining clot structure, in plasma and whole blood. This novel approach may help to develop new antifibrinolytic therapeutic agents for use in bleeding disorders.

PB 162 | A Novel Tick Salivary Protein Modulates Fibrinolysis by Interacting with Plasminogen and Tissue Plasminogen Activator, and Prevents Arterial Thrombosis in vivo

I. Francischetti[1,2], T. Assumpcao[1], D. Mizurini[3], D. Ma[1], R. Monteiro[3], H. Kaneku[2], M. Reyes[2], M. Kotsyfakis[4], J. Andersen[1], J. Lukszo[1], J. Ribeiro[1]

[1]National Institutes of Health, Bethesda, United States, [2]Albert Einstein College of Medicine & Montefiore Medical Center, Bronx, United States, [3]Institute of Medical Biochemistry, Rio de Janeiro, Brazil, [4]Institute of Parasitology, Biology Center, Czech Academy of Sciences, České Budějovice, Czech Republic

Background: Tick saliva is a rich source of anti-hemostatics, including inhibitors of platelet aggregation and blood coagulation. Here, we have characterized a novel family of salivary proteins named Tick Salivary Fibrinolysis Modulator (TSFM) from the vector of Lyme Disease, *Ixodes scapularis*. TSFM is among the most abundant transcripts and proteins expressed in the salivary gland.Molecularly, TSFM is a basic 10 Kda non-enzymatic protein which contains 6 disulfide bonds and a C-terminal domain rich in lysine residues.

Aims: Identify the function of TSFM which has been elusive for more than a decade.

Methods: TSFM was generated by chemical synthesis. *In vitro* assays for fibrinolysis and arterial thrombosis model in mice have been employed to study the mechanism of action of TSFM.

Results: Assays with chromogenic substrate (S-2251) demonstrate that synthetic TSFM accelerates plasminogen activation by tissue-type Plasminogen Activator (TPA), with a *Km* of 20 nM. This activity is inhibited by lysine analogue, e-aminocaproic acid. Additionally, Surface Plasmon Resonance (BIAcore) results show that TSFM exhibits high-affinity binding to TPA, and to plasminogen (K_D 5-10 nM), but not to Urokinase. Conceivably, lysine residues mediate interaction of TSFM with components of the fibrinolytic cascade, providing a scaffold for formation of a productive TSFM/plasminogen/TPA ternary complex. TEG experiments with whole blood show that TSFM decreases the α angle, suggesting interference in the rate of fibrin formation. *In vivo*, TSFM inhibits $FeCl_3$-induced thrombosis in mice.

Conclusions: TSFM emerges as a novel modulator of vascular biology from tick saliva.

PB 163 | Comparison and Characterization of Two Assays (TAFIa/ai ELISA vs. Activity Based Selective CPU Assay) for the Monitoring of Carboxypeptidase U (CPU, TAFIa, CPB2) Levels in Patients

J.C. Mertens[1], D. Leenaerts[1], L. Yperzeele[2], Y. Sim[1], P. Van Der Veken[3], D. Hendriks[1]

[1]University of Antwerp, Laboratory of Medical Biochemistry, Wilrijk, Antwerp, Belgium, [2]University Hospital Antwerp, Department of Neurology, Edegem, Belgium, [3]University of Antwerp, Laboratory of Medicinal Chemistry, Wilrijk, Antwerp, Belgium

Background: The influence of the procarboxypeptidase U (proCPU, TAFI, proCPB2) system in thrombotic disorders has been investigated elaborately. As a consequence, interest in the potential of CPU inhibitors is rising. Nevertheless, the measurement of CPU (TAFIa, CPB2) is challenging, with both critical pre-analytical and analytical factors. Well characterized assays to monitor plasma CPU levels in (pre)clinical studies are indispensable.

Aims: This research focuses on the comparison of two assays that can be used for the monitoring of CPU plasma levels in patients.

Methods: An *in-house* activity based CPU assay using the selective and specific substrate Bz-*o*-cyano-Phe-Arg was compared with a commercially available TAFIa/ai ELISA, both for monitoring of CPU plasma levels in patients and with regard to the influence of *in vitro* added CPU inhibitors. The performance of the assays was compared both using spiked CPU standards and control plasma samples (n=10). Additionally, CPU levels were measured in plasma samples of a selected number of thrombolyzed patients.

Results: Analysis of spiked CPU standards before and after thermal inactivation shows a lower reactivity of the ELISA antibody against thermally inactivated CPU compared to active CPU. Addition of a CPU inhibitor influences the reactivity as well. In thrombolyzed stroke patients, a clear increase in CPU plasma levels was demonstrated with both assays, but marked differences in kinetics were observed.

Conclusions: Both assays measure different aspects of CPU generation in patients. The differences in kinetic profiles provide additional information. Although the ELISA is able to detect the overall activation of the CPU system, it cannot accurately show the time-dependent inactivation of CPU. On the contrary, our activity based assay detects peak CPU levels more accurately if enough time points during thrombolysis are available and also detects both the increase and decrease of CPU plasma levels. It seems advantageous to combine both assays in (pre)clinical trials.

PB 164 | Optimising the Degradation of NETs to Destabilise Fibrin Clot Structure and Promote Fibrinolysis

M. Locke, C. Longstaff

NIBSC, Biotherapeutics, Potters Bar, United Kingdom

Background: Neutrophils release DNA and histones as Neutrophil Extracellular Traps (NETs), to kill invading pathogens. NETs also

promote thrombosis by activating coagulation and inhibiting fibrinolysis, causing thrombotic disease.

Aims: To understand regulation of fibrinolysis by NETs and identify strategies to enhance thrombolysis by NET destabilisation.

Methods: Precise methods are available to monitor effects of DNA and histones on clotting and lysis, to determine binding constants for histones and heparinoids, and the effects of histone post-translational modifications, proteases and DNase.

Results: Although histones stimulated plasminogen activation by tPA or streptokinase in solution they delayed fibrinolysis by altering clot structure, producing thicker fibres with a higher mass/length ratio. Histone subtype separation by heparin chromatography identified histone core (H2, H3, H4) as more significant than H1 linker. Histones were digested by neutrophil elastase>plasmin>>activated protein C, but were protected by DNA. Fragmentation of histones reversed their effect on clot structure, but still impeded fibrinolysis. Only brief treatment with DNase is required to promote clot lysis, indicating large DNA fragments in NETs are needed to influence clotting and lysis rates.

Therapeutic concentrations of unfractionated heparin (UFH) and low molecular weight heparin (LMWH) bind tightly to histones: the IC50 for 0.2 IU/ml UFH is 1.1 and 2.7 µg/ml for lysine-rich (H1) and arginine-rich fractions (H3), respectively. Citrullination of histones by PAD4 weakened the IC50 with UFH around 3-fold.

Conclusions: Arginine-rich core histones regulate fibrinolysis more than lysine-rich H1 and citrullination reduces effects on clot structure. Though heparin neutralisation remains effective there is a need to develop non-anticoagulant heparinoids. Susceptibility of NETs to proteolysis is variable and modulated by DNA. DNases offer most immediate promise to improving thrombolysis by degrading NETs.

PB 165 | Extracellular Histones Enhance Fibrin Degradation by Prourokinase in a Factor Seven Activating Protease (FSAP)-dependent Manner

F. Semeraro, M. Colucci, N. Semeraro, C.T. Ammollo

Aldo Moro University of Bari, Dept. Biomedical Sciences and Human Oncology, Bari, Italy

Background: Histones have been described to inhibit fibrinolysis by modifying fibrin structure and rheological properties. This observation, however, was restricted to tissue plasminogen activator (tPA)-mediated fibrinolysis.

Aims: To evaluate the effect of histones on fibrinolysis by other plasminogen activators.

Methods: Plasma or purified fibrinogen, supplemented with calf thymus histones or vehicle, was clotted with tissue factor in the presence of either tPA (40 ng/ml), urokinase (uPA, 100 U/ml) or prouPA (10 µg/ml), and fibrinolysis was assessed by a turbidimetric method as clot lysis time.

Results: In plasma, histones (≥ 50 µg/mL) inhibited tPA or uPA-mediated fibrinolysis. On the contrary, histones dose-dependently potentiated prouPA-driven fibrinolysis, with a significant effect at 2.5 µg/ml and maximal stimulation at 40 µg/mL (23±4.3 min vs 111±24 min in controls). Recombinant histone subtypes, particularly H4, H3 and H2A, recapitulated the effect of the mixture. Binding of histones to negatively charged molecules (DNA, unfractionated heparin or de-N-sulfated heparin), as well as cleavage of histones by activated protein C did not abolish but rather potentiated the effect on prouPA-induced lysis. Stimulation of fibrinolysis by histones was independent of thrombin (similar results with reptilase-clotted plasma) and progressively declined by incubation of histones in plasma. In purified system, histones dose-dependently impaired prouPA (40 ng/ml) fibrinolytic activity, indicating that a plasma factor was required for stimulation. In plasma, indeed, histones generated a proteolytic activity towards p-Glu-Pro-Arg-MNA that was quenched by a neutralizing antibody against FSAP. In the clot lysis assay, inhibition of FSAP abolished the effect of histones on prouPA-mediated fibrinolysis.

Conclusions: While inhibition of tPA-mediated fibrinolysis by histones can be relevant to thrombogenesis, enhancement of prouPA activity may contribute to extravascular proteolysis and tissue damage.

PB 166 | Localization of the C-terminal Cleavage Site of Human Alpha-2-antiplasmin

S. Abdul[1], D.H. Dekkers[2], J.J. Demmers[2], R.A. Ariëns[3], F.W. Leebeek[1], D.C. Rijken[1], S. Uitte de Willige[1]

[1]Erasmus University Medical Center, Hematology, Rotterdam, The Netherlands, [2]Erasmus University Medical Center, Center for Proteomics, Rotterdam, The Netherlands, [3]Leeds Institute of Cardiovascular and Metabolic Medicine, School of Medicine, University of Leeds, Thrombosis and Tissue Repair Group, Leeds, United Kingdom

Background: Native alpha-2-antiplasmin (a2AP), the main natural inhibitor of plasmin, consists of 464 amino acids. The C-terminus of a2AP is crucial for the initial interaction with plasmin(ogen) and the rapid inhibitory mechanism. Circulating a2AP exists in different molecular forms: ~65% is C-terminally intact and can bind to plasmin(ogen) (plasminogen-binding a2AP/PB-a2AP), whereas due to proteolytic cleavage, ~35% has lost its C-terminus (non-plasminogen binding a2AP/NPB-a2AP) and thereby its rapid inhibitory capacity. To date, the exact C-terminal cleavage site of PB-a2AP is unknown. It is known that a commercially available monoclonal antibody (mAb) against a2AP (TC 3AP, Technoclone) detects PB-a2AP but not NPB-a2AP, indicating that the epitope of this mAb should be located C-terminally from the C-terminal cleavage site.

Aims: To determine the epitope of TC 3AP and to localize the C-terminal cleavage site of a2AP.

Methods: Epitope mapping of TC 3AP was performed using commercially available a2AP (Calbiochem). After enzymatic digestion, peptide fragments were immunoprecipitated using TC 3AP-loaded Dynabeads® Protein G. Bound peptide fragments were eluted and analyzed by mass spectrometry (MS). To localize the C-terminal cleavage site, PB- and NPB-a2AP were purified from plasma by affinity chromatography using a polyclonal anti-a2AP antibody and analyzed by MS after enzymatic digestion.

Results: We found that the epitope of TC 3AP is located between Phe429 and Asp439. The first MS data from plasma-purified a2AP showed that NPB-a2AP likely results from cleavage between Glu421 and Asp422. This fits with the epitope of TC 3AP being C-terminal of the cleavage site.

Conclusions: We mapped the epitope of TC 3AP and preliminarily localized the C-terminal cleavage site of plasma-purified a2AP. This knowledge will be used to identify the protease responsible for C-terminal cleavage of a2AP, a potential regulator of a2AP activity.

PB 167 | PAI-1 Inhibition with MDI-2001: Towards a Safer and More Effective Treatment for Deep Vein Thrombosis

M.E. Shaydakov[1], M. Warnock[2], D.A. Lawrence[2,3], J.A. Diaz[1]

[1]*University of Michigan, Surgery, Vascular Surgery, Ann Arbor, United States,* [2]*University of Michigan, Internal Medicine, Ann Arbor, United States,* [3]*MedigenixBio, Novi, United States*

Background: Anticoagulation as treatment of deep vein thrombosis (VT) carries a significant risk of bleeding. The 33% mortality rate, 30-50% incidence of post thrombotic syndrome, and 10-30% recurrence emphasize the need for improved therapeutic options. Stimulation of the fibrinolytic system is a potentially safer option for thrombosis treatment, with plasminogen activator inhibitor-1 (PAI-1) considered a key therapeutic target. However, efforts to develop PAI-1 inhibitors have been unsuccessful due in part to complex formation of PAI-1 with its stabilizing cofactor vitronectin.

Aims: Using a proprietary screening method, we identified a first-in-class small molecule, MDI-2001, that inhibited the PAI-1 vitronectin complex. Our aim was to profile its efficacy in a murine model of VT.

Methods: VT was induced via the electrolytic inferior vena cava model in 12 week-old C57BL/6 mice. After induction, mice received either 3 mg/Kg/ MDI-2001 or Low Molecular Weight Heparin (LMWH), or vehicle IP 3x/day. Thrombi were harvested 2 days following VT induction, and thrombus weight (TW) was recorded. Bleeding risk was assessed in another cohort of mice for the same treatment groups.

Results: All mice survived until harvest and no bleeding complications or behavioral changes were observed. MDI-2001 was associated with 62% decrease in TW compared to controls ($p < 0.05$). The reduction TW on LMWH was identical compared to MDI-2001 (62% vs 62%). Importantly, MDI-2001 did not change the bleeding time, whereas LMWH demonstrated significantly prolonged bleeding times compared to the other groups.

Conclusions: This work demonstrated that MDI-2001 represents a first-in-class PAI-1 inhibitor that is as effective as LMWH in reducing TW, however without any increase in bleeding risk. Ongoing investigations will evaluate synergism between the standard of care and stimulation of the fibrinolytic system with MDI-2001. Our data suggests that fibrinolytic stimulation with MDI-2001 is a promising avenue for improving VT treatment.

PB 168 | A Phase 2/3, Open-label, Repeat-Dose Study of the Pharmacokinetics, Efficacy, and Safety of Prometic Plasminogen Intravenous Infusion in Subjects with Hypoplasminogenemia (HPLG)

C. Nakar[1], B. Hardesty[1], N. Thurkal[1], G. Albert[2], M. Rubinacci[2], K. Thibaudeau[3], J. Parker[2], J. Moran[2], A. Shapiro[1]

[1]*Indiana Hemophilia and Thrombosis Center, Indianapolis, United States,* [2]*ProMetic BioTherapeutics, Rockville, United States,* [3]*ProMetic Life Sciences Inc, Laval, Canada*

Background: Plasminogen (PLG) is converted to form plasmin, which is responsible for the lysis of clots and clearance of extravasated fibrin (Collen 1991). Type 1 plasminogen deficiency caused by mutations in the *PLG* gene is a rare disorder (HPLG) that leads to clinical manifestations due to extravascular fibrinous deposits on mucous membranes with disruption of organ function (Tefs 2006; Mehta 2008). ProMetic has developed an intravenous (IV) PLG product (Glu-PLG) derived from human plasma (ProMetic's PLG) to treat HPLG.

Aims: To determine whether ProMetic's PLG is safe and effective in subjects with HPLG.

Methods: Fourteen subjects aged 2 to 80 years with HPLG were enrolled in an open-label study to receive multiple IV doses of 6.6 mg/kg ProMetic's PLG for 48 weeks. An interim analysis was performed after 10 subjects completed 12 weeks of treatment. Subjects were dosed every 2, 3, or 4 days based upon a pharmacokinetic (PK) profile to maintain target PLG activity trough levels $\geq$ 10% (absolute) above baseline values. Trough levels were measured every 2 weeks for 12 weeks. Primary endpoint success was defined as $\geq$80% of subjects achieving target PLG trough levels for at least 3 measurements over 12 weeks; efficacy and safety were also assessed.

Results: Subject baseline characteristics are included in Table 1. Target PLG trough activity levels were achieved in 10 subjects (100%) after 12 weeks (Table 2). Baseline pharmacokinetic parameters were unchanged at 12 weeks. Six of 10 subjects had 11 visible lesions. After 8 weeks, 10 of 11 lesions (90.9%) completely resolved; the remaining lesion shrank to an unmeasurable size after 12 weeks (Table 2). There were no deaths, serious adverse events (AEs), or AEs resulting in study drug discontinuation. The most frequent AE was nasopharyngitis.

Conclusions: Repeated doses of 6.6 mg/kg ProMetic's PLG achieved target PLG activity trough levels in subjects with HPLG and demonstrated excellent efficacy after 12 weeks of treatment, with no safety concerns.

TABLE 1 Demographics and Baseline Characteristics

Baseline Characteristics	Total (N=10)

PB 169 | Colistin Dampens Fibrinolysis and Endothelial Activation during Endotoxemia: A Randomized, Double Blind Trial

C. Schoergenhofer[1], P. Matzneller[1], M. Mußbacher[2], J. Schmid[2], P. Jilma-Stohlawetz[3], B. Jilma[1]

[1]Medical University of Vienna, Clinical Pharmacology, Vienna, Austria, [2]Medical University of Vienna, Department of Vascular Biology and Thrombosis Research, Center for Physiology and Pharmacology, Medical University of Vienna, Austria, Vienna, Austria, [3]Medical University of Vienna, Laboratory Medicine, Vienna, Austria

Background: Colistin electrostatically interacts with lipopolysaccharides (LPS) located at the outer membrane of bacterial membranes. Pre-clinical studies demonstrated beneficial effects of colistin on LPS-induced coagulation and fibrinolysis.

Aims: The objective of this trial was to investigate the effects of colistin during experimental endotoxemia.

Methods: A randomized, double-blind, placebo-controlled, crossover trial in healthy volunteers was conducted. Healthy volunteers received a 2ng/kg LPS bolus after infusion of 2.5 million IU colistin or placebo. Plasma levels of F1+2 prothrombin fragments, thrombin-antithrombin complexes (TAT), von Willebrand factor antigen levels (vWF), E-selectin, plasmin-antiplasmin complexes (PAP), tissue-type plasminogen activator (tPA) antigen and activity, plasminogen activator inhibitor-1 (PAI-1) were measured.

Results: Infusion of colistin significantly reduced peak concentrations of PAP complexes by 70%, t-PA antigen levels by 63%, t-PA activity by 48% and PAI-1 levels by 63%. Two hours after the LPS bolus F1+2 levels and TAT complexes were slightly reduced in the colistin period, but peak concentrations were similar in both periods. Colistin blunted the LPS induced four-fold increase in soluble E-Selectin levels by ~50% and the two-fold increase in vWF antigen levels by ~70%.

Conclusions: The LPS-scavenging actions of colistin significantly reduce endothelial activation and fibrinolytic response in the human endotoxemia model, while the activation of the coagulation system remains largely unaffected. Thus, in patients with gram-negative sepsis colistin may exert beneficial effects, by endothelial protection in patients with overshooting immune response, independent of its antimicrobial activity.

PB 170 | A Novel Fluorescent Assay for the Measurement of Activated Thrombin-activatable Fibrinolysis Inhibitor (TAFIa) Activity

T. Marar[1], K. Picco[2], M. Boffa[1]

[1]University of Western Ontario, Biochemistry, London, Canada, [2]University of Windsor, Chemistry & Biochemistry, Windsor, Canada

Background: Thrombin-activatable fibrinolysis inhibitor (TAFI) is a procarboxypeptidase present in plasma that acts as a molecular connection between the coagulation and fibrinolysis pathways. TAFI is activated to form TAFIa through proteolytic cleavage by thrombin, thrombin in complex with thrombomodulin, or plasmin. Several assays are available to measure the carboxypeptidase activity of TAFIa; however, these methods suffer one or more disadvantages including low sensitivity, labour intensivity and complexity.

Aims: To develop a novel fluorescence-based assay for the measurement of the basic carboxypeptidase activity of TAFIa.

Methods: A synthetic peptide substrate was designed composed of four amino acids (Gly-Ala-Gly-Arg) modified with an amino-terminal tetramethylrhodamine (TAMRA) fluorophore. An anionic quencher interacts electrostatically with the positively charged carboxyl-terminal arginine side chain in the substrate allowing quenching of the TAMRA fluorescence. The cleavage of the carboxyl-terminal arginine by TAFIa results in the release of the substrate causing an increase in fluorescence.

Results: The fluorescent quencher dye Evans Blue was determined to be the optimal quencher for the TAMRA-GAGR synthetic peptide substrate. The interaction between the substrate and quencher was unaffected by salt concentration. The sensitivity of the TAMRA-GAGR substrate is superior to that of commonly employed direct carboxypeptidase B substrates, with a detection limit for TAFIa of 100 pM. Interestingly, pancreatic carboxypeptidase B was even more active against the substrate, with a detection limit of 6.1 pM. The assay is capable of monitoring the rate of activation of TAFI *in vitro* in a single-stage assay.

Conclusions: The assay could be used to measure TAFIa activity and TAFI activation in situ in turbid or high-protein solutions, potentially including plasma and fibrin clots, in a manner analogous to how the endogenous thrombin potential is determined.

PB 171 | Global Assay of Fibrinolysis in Sickle Cell Disease: Contrasting Results in Plasma and Whole Blood

A. Ilich[1,2], M. Piegore[1], R. Pawlinski[1], N. Key[1]

[1]University of North Carolina at Chapel Hill, Department of Medicine, Division of Hematology/Oncology, Chapel Hill, United States, [2]First Moscow State Medical University n.a. I. M. Sechenov, Department of Medicine, Division of Internal Medicine 1, Moscow, Russian Federation

Background: Sickle cell disease (SCD) is caused by a $Glu_6 \rightarrow Val$ mutation in the β-globin gene that results in hemoglobin polymerization in hypoxic erythrocytes. Few studies have evaluated fibrinolysis in SCD, or its contribution to vascular complications, such as the increased risk of venous thromboembolism.

Aims: To evaluate resistance to t-PA-mediated fibrinolysis in platelet-free plasma (PFP) and whole blood (WB) of patients with SCD.

Methods: A] *Global Assay in PFP*. Tissue factor (TF, 1pM), $CaCl_2$ and t-PA (2.5, 1.25 or 0.625nM) were added to citrated PFP from 13 patients with SCD at baseline and 9 race-, sex- and age-matched controls. Turbidity was read spectrophotometrically, and clot lysis time (CLT-the time from half clotting to half lysis) was used to evaluate fibrinolysis.

B] *Global Assay in WB*. TF, $CaCl_2$ and t-PA (0.625, 1.25, 2.5, 5 and 10nM) were added to citrated whole blood in transparent tubes from 15 patients with SCD and 11 matched controls. When the clot was formed, a steel ball (d=2mm, w=0.13g) was placed on its surface. The time from coagulation/fibrinolysis activation to the ball reaching the bottom of the tube was measured by capturing time-lapse video.

Sample collection was approved by IRB. Informed consents were obtained.

Results: In the t-PA challenged turbidity assay in PFP, CLT in SCD samples was significantly shorter than the AA group at all three t-PA concentrations.

TABLE 1 Clot Lysis in PFP

t-PA concentration (nM)	CLT mean±SEM (min)		p value
	SS	AA	
2.5	60.7±2.7	136.7±12.3	p<0.00001
1.25	92.9±5.9	182.7±9.2	p<0.00001
0.625	138.5±12.9	226.7±0.7	p<0.0001

In the WB ball sedimentation assay, no significant difference was noted between AA and SS clots at high t-PA concentrations (2.5-10nM). However, SS clots challenged with lower t-PA concentrations (0.6-1.2nM) were more resistant to fibrinolysis.

TABLE 2 Clot Lysis in WB

t-PA concentration (nM)	CLT mean±SEM (min)		p value
	SS	AA	
10	21.4±1.2	22.4±1.7	p=0.63
5	34.9±2.0	33.8±2.0	p=0.71
2.5	157.1±59.4	51.0±2.3	p=0.14
1.25	402.0±59.3	157.9±57.9	p=0.0085
0.625	651.5±33.9	369.8±75.4	p=0.001

Conclusions: Plasma clots from SCD patients are more susceptible to t-PA challenge compared to healthy controls. In contrast, SCD whole blood samples are more resistant to fibrinolysis at low t-PA concentrations. These findings imply an important role for the cellular components of blood in resisting t-PA mediated fibrinolysis in SCD.

PB 174 | Generation and Characterization of Monoclonal Antibodies against the N-terminus of Alpha-2-antiplasmin

S. Abdul[1], M. Peeters[2], E. Brouwers[2], J.J. Malfliet[1], F.W. Leebeek[1], P.J. Declerck[2], D.C. Rijken[1], S. Uitte de Willige[1]

[1]Erasmus University Medical Center, Hematology, Rotterdam, The Netherlands, [2]KU Leuven, Laboratory for Therapeutic and Diagnostic Antibodies, Department of Pharmaceutical and Pharmacological Sciences, Leuven, Belgium

Background: ~70% of circulating alpha-2-antiplasmin (a2AP), the main natural inhibitor of plasmin, is N-terminally cleaved by antiplasmin-cleaving enzyme between residues Pro12 and Asn13, converting native Met-a2AP into the more potent fibrinolysis inhibitor Asn-a2AP. The Arg6Trp (R6W) polymorphism affects the N-terminal cleavage rate of Met-a2AP, with ~8-fold faster conversion of Met(R6)-a2AP (R6-a2AP) compared to Met(W6)-a2AP (W6-a2AP). To date, methods to determine N-terminal variation of a2AP in plasma have been limited to ELISAs that can only measure R6-a2AP.

Aims: To generate and characterize monoclonal antibodies (mAbs) towards R6-a2AP, W6-a2AP, and one towards all a2AP forms (total-a2AP), and to develop specific R6-a2AP and W6-a2AP ELISAs.

Methods: R6-a2AP, W6-a2AP and Asn-a2AP were recombinantly expressed in Drosophila S2 cells. Using hybridoma technology, a panel of 25 mAbs was generated towards a mixture of recombinant R6-a2AP plus W6-a2AP. All mAbs were evaluated for their specific reactivity using purified native a2AP and the three recombinant a2APs in one-site noncompetitive ELISAs. Three selected mAbs (one for R6-a2AP, one for W6-a2AP and one for total-a2AP) were further evaluated in sandwich-type ELISAs. The mAb towards total-a2AP was HRP-conjugated to function as detection antibody.

Results: Two mAbs were selected, MA-AP37E2 and MA-AP34C4 (both IgG1 kappa isotype), that showed selective reactivities towards R6-a2AP and W6-a2AP respectively (cross-reactivities were 0.6% and 0.05%, respectively). MA-AP15D7 (IgG2b kappa isotype) was selected for its reactivity towards total-a2AP. MA-AP37E2 strongly

responded to pooled plasma of R6 homozygotes, but did not respond to pooled plasma of W6 homozygotes, whereas MA-AP34C4 strongly responded to pooled plasma of W6 homozygotes, but did not respond significantly to pooled plasma of R6 homozygotes.

Conclusions: We developed two specific ELISAs for R6-a2AP and W6-a2AP in plasma. This will enable us to determine N-terminal cleavage of a2AP in plasma samples.

PB 175 | Stretching Fibrin Fibers Hampers their Lysis

M. Guthold[1], W. Li[1], T. Lucioni[1], R. Li[1,2], S. Cho[1,2]

[1]*Wake Forest University, Physics, Winston-Salem, United States,* [2]*Wake Forest University, Computer Science, Winston-Salem, United States*

Background: Fibrinolysis is controlled by numerous chemical and enzymatic factors, and it is also influenced by the fibrin network architecture and fibrin fiber structure. It may also be affected by mechanical strain exerted on fibrin fibers by blood flow and clot retraction forces.

Aims: Our goal was to test the hypothesis that straining single fibrin fibers affects their lysis.

Methods: We developed a transparent, striated and highly stretchable substrate to investigate how strain affects lysis of single, suspended fibrin fibers. Lysis was observed by optical microscopy.

Results: In this suspended fiber assay, lysis manifested itself by considerable fiber elongation (up to 25%), fraying and collapse. Stretching single fibrin fibers significantly hampered their lysis. This effect was seen in uncrosslinked and crosslinked fibers. Crosslinking (without stretching) also hampered single fiber lysis.

Conclusions: Our data suggest that strain is a novel mechanosensitive factor that regulates blood clot dissolution (fibrinolysis) at the single fiber level. At the molecular level of single fibrin molecules, strain may distort, or hinder access to, plasmin cleavage sites and thereby hamper lysis.

PB 176 | Performance and Determinants of whole Blood and Plasma Fibrinolysis Assays in Patients with Mild Bleeding Symptoms

M.J.A. Vries[1], F. Macrae[2], P.J. Nelemans[3], G.J.A.J.M. Kuiper[4], R.J.H. Wetzels[5], P. Bowman[2], P.W.M. Verhezen[5], H. ten Cate[1,6], R.A.S. Ariens[2], Y.M.C. Henskens[1,5]

[1]*Maastricht University, Biochemistry, Maastricht, The Netherlands,* [2]*University of Leeds, Division of Cardiovascular and Diabetes Research, Leeds Institute for Genetics, Health and Therapeutics, Multidisciplinary Cardiovascular Research Centre, Leeds, United Kingdom,* [3]*Maastricht University Medical Centre +, Epidemiology, Maastricht, The Netherlands,* [4]*Maastricht University Medical Centre +, Anaesthesiology, Maastricht, The Netherlands,* [5]*Maastricht University Medical Centre +, Central Diagnostic Laboratory, Maastricht, The Netherlands,* [6]*Maastricht University Medical Centre +, Internal Medicine, Maastricht, The Netherlands*

Background: Clot stability and resistance to fibrinolysis are important for adequate haemostasis. Although enhanced clot lysis is associated with bleeding, a reliable functional lysis assay is not yet available.

Aims: We assessed whether the tissue Plasminogen Activator-Thromboelastometry (tPA-ROTEM), the Turbidity lysis assay and the Euglobulin lysis time (ELT) could find enhanced lysis capacity in patients who report bleeding symptoms, but are not diagnosed with bleeding disorders. We also gained insight in determinants of the lysis assays in these patients.

Methods: In this study, 240 patients with and 95 patients without reported bleeding symptoms on a preoperative questionnaire were included. The whole blood tPA-ROTEM (35 pM tissue factor) and plasma Turbidity assay (0.5 U/ml thrombin) were performed with addition of 125 ng/mL and 85 ng/ml tPA, respectively, and lysis times and speed were recorded. Blood count, coagulation and fibrinolysis factor activity levels were determined. Data were analysed with multiple linear regression models. Informed consent was obtained and the ethics committee approved the study.

Results: The median ELT did not differ between patients with and without reported bleeding symptoms (105 (IQR 85-120) vs. 105 (IQR 80-120) min, p=0.58), but surprisingly, the former group showed signs of *prolonged* and *slower* lysis in the tPA-ROTEM and Turbidity lysis assays (Tables 1, 2). In patients reporting bleeding symptoms, FII, plasminogen, antiplasmin, plasminogen activator inhibitor and thrombin activatable fibrinolysis inhibitor (TAFI) levels were independent

TABLE 1 tPA-ROTEM lysis in patients reporting bleeding symptoms vs. patients not reporting bleeding symptoms (subjects with all data available)

	tPA-ROTEM: Time from start to 90% lysis (n=327), Beta in SD (95%CI)	p	tPA-ROTEM: Lysis speed (%/min from 15% to 90% clot lysis) (n=320), Beta in SD (95%CI)	p

Age (SD)	0.15 (0.039 to 0.26)	0.008	-0.083 (-0.19 to 0.027)	0.14
Body Mass Index (BMI) (SD)	0.18 (0.074 to 0.29)	0.001	-0.16 (-0.27 to -0.044)	0.006

TABLE 2 Turbidity lysis in patients reporting bleeding symptoms vs. patients not reporting bleeding symptoms (subjects with all data available)

	Time from Max Optical Density to 90% lysis (n=326), Beta in SD (95%CI)	p	Lysis speed (%/min from 15% to 90% clot lysis) (n=326), Beta in SD (95%CI)	p
Patients reporting bleeding symptoms (vs. patients without bleeding symptoms)	0.23 (-0.014 to 0.46)	0.065	-0.15 (-0.40 to 0.11)	0.26
Male	0.17 (-0.048 to 0.40)	0.12	-0.24 (-0.47 to -0.005)	0.045
Age (SD)	0.15 (0.041 to 0.25)	0.007	-0.049 (-0.16 to 0.062)	0.39
Body Mass Index (BMI) (SD)	0.30 (0.20 to 0.40)	<0.001	-0.15 (-0.26 to -0.042)	0.007

determinants of the tPA-ROTEM results, while fibrinogen, antiplasmin, TAFI, gender and BMI independently influenced Turbidity lysis.

Conclusions: Patients reporting bleeding symptoms showed signs of *diminished* fibrinolysis in the tPA-ROTEM and Turbidity lysis assays compared to those without bleeding symptoms. This might be a compensation mechanism for impaired clot formation; once a clot is formed, slower lysis could help to maintain it.

PB 177 | Characterisation of the Different Pathways of Neutrophil Extracellular Trap (NET) Formation Triggered by Treatment with phorbol-12-myristate-13-acetate (PMA) or Calcium Ionophores

M. Locke[1], R. Francis[2], C. Longstaff[1]

[1]*NIBSC, Biotherapeutics, Potters Bar, United Kingdom,* [2]*NIBSC, Analytical Sciences, Potters Bar, United Kingdom*

Background: Neutrophils (PML) are pivotal players in host immune defence and deploy a number of mechanisms to combat invading pathogens including extrusion of chromatin and enzymes, termed NETosis. In vitro, PMA or Ca^{2+} ionophores (e.g. ionomycin) initiate NETosis. PML also respond to soluble ligands of the promiscuous receptor Mac-1 (alpha M beta 2).

Aims: We investigated differences between PMA and ionomycin as NET triggers and modulation by Mac-1 ligands fibrinogen (Fg) and fibrin.

Methods: NET formation by human PML was followed by confocal video microscopy after treatment with PMA or ionomycin, in the presence of Fg or multivalent, cross-linked fibrin degradation products (FDP). Observations were supported by biochemical studies.

Results: PMA and ionomycin both trigger chromatin release from 90 min under our conditions, but with morphological differences. Using blue Syto41 to follow intracellular DNA, green Fluo4 for intracellular Ca^{2+} and red propidium iodide to stain emerging extracellular DNA, we observed different patterns of intracellular Ca^{2+} accumulation and of nuclear DNA breakdown and release. The average area of NET DNA per NETosed cell was 1.9-fold higher with PMA than ionomycin. Adding Alexa fluor488 labelled-Fg slowed NET formation. With ionomycin, but not PMA, almost all PML bound Fg with surface clustering. In contrast, FDP bound to PML after PMA treatment, but not ionomycin. Quantitative Sytox Green staining confirmed that Fg reduced release of DNA after ionomycin treatment by more than 50%. Ionomycin also resulted in more proteolysis of cell associated Fg (alpha and gamma chains) than PMA.

Conclusions: PMA and ionomycin are not interchangeable and mimic different natural responses to pathogens, which are further modulated by cell environment. By studying triggers and regulation of NET formation we can understand how NETs switch from microbial defence into a risk factor for thrombotic and inflammatory disease and identify opportunities for therapeutic interventions.

PB 178 | Effect of Alpha-2 Plasmin Inhibitor p.Arg6Trp Polymorphism and Antigen Level on the Risk of Myocardial Infarction in Young Patients

É. Katona[1], A. Orosz[1], Z. Mezei[1], L. Balogh[2], R. Bogáti[1], I. Édes[2], L. Muszbek[1]

[1]*University of Debrecen, Faculty of Medicine, Department of Laboratory Medicine, Division of Clinical Laboratory Science, Debrecen, Hungary,* [2]*University of Debrecen, Faculty of Medicine, Department of Cardiology, Debrecen, Hungary*

Background: Alpha2-plasmin inhibitor (a2-PI) is the primary inhibitor of plasmin. Its increased levels have been associated with increased thrombotic risk. A2-PI in the plasma undergoes both N- and C-terminal cleavages, which significantly modify its activities. About 70% of circulating a2-PI is amino-terminally shortened (by 12 amino acids) by antiplasmin cleaving enzyme (APCE). This isoform is cross-linked more effectively to fibrin alpha-chain by activated factor XIII; thereby the ratio of N-terminal isoforms may influence the fibrinolytic resistance of the fibrin clot. The p.Arg6Trp polymorphism affects the rate of this cleavage as APCE cleaves the Arg6 form 8-fold faster than the Trp6 form.

Aims: In this case-control study we investigated the effect of a2-PI p.Arg6Trp polymorphism and a2-PI antigen concentration on the risk of myocardial infarction (MI) in young patients.

Methods: 116 patients who had ST elevation MI below 40 years of age (MI) and age-matched healthy controls (HC, n=120) were recruited into the study. Total a2-PI antigen levels were determined by

a sandwich type ELISA, a2-PI Arg6Trp genotype was determined by RT-PCR using LightCycler® 480.

Results: Genotype distribution was consistent with the Hardy-Weinberg distribution in both study groups. The minor allele frequency did not differ significantly between HC and AMI (0.20 and 0.22 respectively; p=0.225). Possession of the Trp allele did not influence the risk for MI (OR: 1.104, 95% CI: 0.595-2.046). Total a2-PI antigen levels were significantly elevated in MI patients compared to HC (MI: 74.2±6.0 mg/L versus HC: 67.1±8.5 mg/L). Elevated a2-PI level (above 71.0 mg/L) increased the risk of MI (OR: 4.923, 95%CI: 2.72-8.909, p< 0.0001), which remained significant after adjustment to other cardiovascular risk factors.

Conclusions: In our study, the a2-PI p.Arg6Trp polymorphism had no effect on the risk of MI in young patients, however a2-PI levels in the upper tertile resulted in a significant risk enhancement.

PB 179 | Effect of PAI-1 on Vascular Smooth Muscle Cells Phenotype

X. Deng, M. Luo, J. Wu

Southwest Medical University, Luzhou, China

Background: Pharmacological administration of recombinant plasminogen activator inhibitor-1 (PAI-1) blocks vascular smooth muscle cell (VSMC) proliferation and migration in cell culture and neointimal formation following vascular injury in vivo. However, the role of PAI-1 in VSMC phenotype transitions remain unclear.

Aims: The purpose of this study was to determine molecular effects of PAI-1 on VSMCs.

Methods: Primary cultured human umbilical artery smooth muscle cells (HUASMC) were treated with recombinant PAI-1 mutants, and real-time reverse transcription-PCR was used to detect the gene expression.

Results: We show that PAI-1(10μg/mL) up-regulated the expression of serum response factor (*SRF*), a transcription factor in regulating VSMCs phenotypic modulation. Both the VSMCs differentiation marker genes smooth muscle α-actin (*SMA*), smoothelin (*SMTN*) and synthetic markers genes cyclin D1, 2 are all up-regulated by PAI-1 in VSMCs, whereas using other recombinant PAI-1 mutants with selective loss-of-function mutation we demonstrated that binding of PAI-1 to VN down-regulates the VSMCs synthetic markers genes (cyclin D1, 2, p< 0.05), and has no effect on the VSMC differentiation marker genes(SMA, SMTN). PAI-1 mutant with markedly reduced binding capacity for LDL receptor family members abrogate the effects of PAI-1 in the regulation VSMCs phenotype. Furthermore, pretreatment of RAP (receptor associated protein) and anti-LRP1 (LDL receptor-related protein 1) inhibited the *phenotypic* modulation *effects* of PAI-1, suggesting receptor family is required for PAI-1 regulation of VSMCs modulation.

Conclusions: Altogether, these data show diverse roles of PAI-1-VN binding and LDL receptor family in the control of the differentiated properties of VSMCs and suggest that the binding of VN is a key process for PAI-1 regulating phenotypic switch of VSMCs.

PB 180 | Study of Fibrinolytic Factors along with Thrombophilia Screening Gives a Comprehensive Picture of the Cause of Venous Thrombosis in Indian Patients

A. Prabhudesai[1], S. Shetty[1], K. Ghosh[2], B. Kulkarni[1]

[1]National Institute of Immunohaematology, Haemostasis and Thrombosis, Mumbai, India, [2]Surat Raktadan Kendra & Research Centre, Surat, India

Background: Many venous thrombosis cases, irrespective of a strong family history, recurrence or unusual site of thrombosis, remain unexplained as thrombophilia account for only about 1/3rd cases. Hypofibrinolysis is being reported to increase risk of thrombosis.

Aims: To study the fibrinolytic pathway defects along with conventional thrombophilia in venous thrombosis patients.

Methods: Study: 224 venous thrombosis cases; 104 CVT, 95 DVT, 17 PVT & 8 RVO. Protein C, Protein S, Antithrombin, Tissue plasminogen activator, Plasminogen activator inhibitor-1, Plasminogen & α-2-antiplasmin were measured by ELISA. Factor V Leiden mutation & PAI-1 4G/5G promoter polymorphism were studied by PCR-RFLP & ASA-PCR.

Results: 7.6% cases were FVL heterozygous. 4.9% cases had PC deficiency. 2.2% cases had PS deficiency. 0.9% cases had a combined PC & PS deficiency. 0.4% cases had AT deficiency. Conventional thrombophilia accounted for 16% cases. 16.5% cases had high PAI-1 levels (170.7±89.9ng/ml) against 2% in controls (p=0.0268, OR=9.6952). High PAI-1 level was significantly associated with CVT (p=0.0182, OR=11.67) & DVT (p=0.0344, OR=9.19). PAI-1 4G/5G polymorphism was associated with PAI-1 level (p=0.0065). 4G/4G (104.5±97.6ng/ml) had significantly high PAI-1 levels against 4G/5G (63±41.6ng/ml) & 5G/5G (55.9±42.5ng/ml). 23.6% cases had 4G/4G against 16.2% in controls (p=0.0953) with no significant difference in CVT (22.2%), DVT (22%), RVO (25%) cases. 4G/4G genotype had strong association (53%) (p=0.0015,OR=5.82) with PVT. Reduced TPA levels were observed in 3.1% cases (0.65±0.08ng/ml). PLG deficiency (237.5±32.7μg/ml) was observed in 1.3% cases. High AP levels (273.4±39.1ng/ml) were observed in 2.7% cases. 5.8% (13 cases) had both thrombophilia & fibrinolytic markers. Thus, 33% (74 cases) had at least one of these markers.

Conclusions: Hypofibrinolysis has significant role in venous thrombosis, and its investigation along with thrombophilia will facilitate in a comprehensive explanation of the cause of venous thrombosis.

TABLE 1 Thrombophilia and fibrinolysis markers in venous thrombosis

	Cerebral Vein Thrombosis (CVT=104)	Deep Vein Thrombosis (DVT=95)	Portal Vein Thrombosis (PVT=17)	Retinal Vein Occlusion (RVO=8)	Venous thrombosis cases (Total=224)
Protein C (PC) deficiency	2 (1.9%)	6 (6.3%)	3 (17.6%)	-	11 (4.9%)
Protein S (PS) deficiency	2 (1.9%)	3 (3.2%)	-	-	5 (2.2%)
Combined PS+PS deficiency	-	2 (2.1%)	-	-	2 (0.9%)
Antithrombin (AT) deficiency	-	1 (1%)	-	-	1 (0.4%)
Factor V Leiden (FVL) mutation	5 (4.8%)	11 (11.6%)	-	1 (12.5%)	17 (7.6%)
High Plasminogen activator inhibitor-1 (PAI-1) levels	20 (19.2%)	15 (15.8%)	2 (11.8%)	-	37 (16.5%)
Reduced Tissue Plasminogen activator (TPA) levels	2 (1.9%)	3 (3.2%)	-	2 (25%)	7 (3.1%)
Plasminogen (PLG) deficiency	1 (0.4%)	1 (1%)	1 (5.9%)	-	3 (1.3%)
High Antiplasmin (AP) levels	3 (2.9%)	3 (3.2%)	-	-	6 (2.7%)

PB 181 | Impaired Plasminogen Binding in Patients with Venous Thromboembolism: Association with Protein Carbonylation

J. Siudut[1,2], J. Natorska[1,2], M. Zabczyk[1], D. Zajac[3], K. Seweryn[3], M. Rapala-Kozik[3], A. Undas[1,2]

[1]Jagiellonian University Medical College, Cracow, Poland, [2]John Paul II Hospital, Cracow, Poland, [3]Jagiellonian University, Cracow, Poland

Background: Venous thromboembolism (VTE) is associated with hypofibrinolysis. Its mechanisms are poorly understood.

Aims: The aim of the current study was to investigate plasminogen-fibrin interaction and its impact on plasmin generation, fibrinolysis and the extent of protein oxidation/carbonylation in VTE patients.

Methods: Plasma-purified plasmin(ogen) functional activity was evaluated together with surface plasmon resonance employed for fibrin-plasminogen interactions individually in healthy controls and patients following VTE. We also assessed plasma fibrin clot permeability (K_s), clot lysis time (CLT), activators and inhibitors of fibrinolysis together with oxidation/carbonylation markers, including thiobarbituric acid reactive substances (TBARS), total antioxidant capacity (TAC), and total protein carbonyl (total PC).

Results: VTE patients had impaired plasminogen binding to fibrin compared with controls (Kd, +265%, p=0.006), mainly related to reduced plasmin protease activity (-20.5%, p=0.04). VTE patients had longer CLT (+17%, p=0.002) but K_s remained unaffected when compared to controls. Of note, CLT was associated with Kd (r=0.44, p=0.03), while Kd correlated with plasmin activity (r=-0.65, p=0.002), PAI-1 (r=0.43, p=0.046), and tPA-PAI-1 complex (r=0.52, p=0.03). Among oxidation/carbonylation markers, VTE patients presented higher TBARS (+50%, P< 0.001) and total PC (+49%, p< 0.001), but lower TAC (-25%, p< 0.001) compared with healthy controls. TBARS (r=0.61, p=0.003), TAC (r=-0.47, p=0.03), and total PC (r=0.56, p=0.009) correlated with CLT. Moreover, associations between Kd and TBARS (r=0.44, p=0.04) or PC (r=0.45, p=0.03) were observed in the whole group.

Conclusions: The fibrin-plasminogen binding affinity as well as plasmin activity are impaired in VTE patients. We showed for the first time an increased carbonylation of plasma proteins in VTE patients and its association with prolonged clot lysis indicating novel antifibrinolytic mechanisms in VTE.

PB 182 | Ligneous Gingivitis due to Severe Plasminogen Deficiency: Results of a Prophylactic Protocol for Dental Care

M.T. Sartori, S. Sivolella, I. Di Pasquale, G. Saggiorato, F. Boscaro, M. De Biagi

University of Padua, Padua, Italy

Background: Severe plasminogen (PLG) deficiency causes a rare disease, known as ligneous conjunctivitis, characterized by the growth of fibrin rich pseudomembranes on mucosal surfaces. Besides of conjunctiva, gums are often involved, leading to ligneous gingivitis (LG). Specific therapy for LG is not established.

Aims: We describe a prophylactic protocol with enoxaparin and fresh frozen plasma (FFP) for dental invasive procedures in a patient with LG due to PLG deficiency.

Methods: A 43 years old female with LG was referred to us in 2009. She had ligneous conjunctivitis in childhood and ligneous cervicitis refractory to conization. PLG antigen and activity levels, and PLG genetic analysis were carried out. In order to prevent LG recurrence after dental invasive procedures, a prophylactic treatment including 10 ml/kg bw FFP before and the day after the intervention and enoxaparin 100 U/kg bw od for 20 days was given in addition to proper mini-invasive dentistry techniques and implant surgery.

Results: The patient's PLG antigen and activity levels were 25 ug/ml and 27%, respectively, and genetic analysis showed a c.112A>G p.K38E mutation in exon 2 and c.1256+1G>A substitution at donor site of exon 10, each in heterozygous level. Right tooth root extraction with gum suture was performed in 2009, left molar tooth extraction

and contralateral implant positioning in 2012, and right molar tooth extraction in 2015. PLG activity levels raised to about 46% two hours after FFP transfusion and returned to baseline after 48 hours. Small gingival pseudomembranes developed soon after interventions and disappeared within one week; no bleeding complications were seen. The patient denied FFP transfusion in 2015.

Conclusions: In our patient with LG, the adoption of combined hematological and dentistry protocols appeared to be safe and effective in preventing abnormal gingival pseudomembranes growth after dental interventions, maintaining a good parodontal condition.

PB 183 | Effect of Polyamidoamine (PAMAM) Dendrimers on the Activity of the Fibrinolytic System in vitro

R. Aisina[1], L. Mukhametova[1,2], E. Ivanova[1], K. Gerchkovich[3], E. Zakharyan[1], S. Varfolomeyev[3]

[1]Lomonosov Moscow State University, Chemical Department, Moscow, Russian Federation, [2]Bauman Moscow State Technical University, Moscow, Russian Federation, [3]Emanuel Institute of Biochemical Physics of RAS, Moscow, Russian Federation

Background: Due to their tree-like structure, the presence of internal cavities and the multitude of surface groups, dendrimers are used in medicine as drug delivery, imaging, antiviral and transfecting agents. PAMAM dendrimers with different surface charges interact with blood components and can affect the activity of enzymes.

Aims: Studying the effect of the surface charge density and concentration of anionic and cationic PAMAM dendrimers on activity of fibrinolytic system *in vitro*.

Methods: The effect of concentration of amine-terminated (G1, G2 and G3) and carboxy-terminated (G1.5, G2.5 and G3.5) PAMAM dendrimers on amidolytic, plasminogen(Pg)-activator and thrombolytic activities of tPA and uPA was studied.

Results: Cationic dendrimers G1, G2 and G3 (0.4 mM) increased in tPA activity against S-2228 by 10-30% and have not affect on uPA activity against S-2444. Anionic dendrimers G1.5, G2.5 and G3.5 (0.4 mM) reduced amidolytic activity of tPA by 5-15% and uPA by 30, 40 and 100%, respectively. The sharp decline in Pg-activator activity of tPA was observed with increasing concentrations of both cationic and anionic dendrimers. In the case of uPA, anionic dendrimers strongly reduced, while cationic dendrimers significantly increased the Pg activation rate. Nonetheless, anionic, and, to a lesser extent, cationic dendrimers lowered the lysis rate of plasma clot induced by tPA and uPA. The thrombolytic activity of tPA and uPA reduced stronger with increasing concentration and generation of dendrimers. The possible sites of binding of cationic and anionic PAMAM dendrimers to plasminogen, tPA, uPA and fibrin surface explaining the observed effects were considered.

Conclusions: Anionic PAMAM dendrimers stronger lower the activity of the fibrinolytic system than cationic dendrimers and this effect enhanced with increasing the surface charge density and concentration of dendrimers. This should be considered when using higher generations of PAMAM dendrimers for drug delivery.

PB 184 | Fibrinolytic Markers in Patients Undergoing Total Hip Replacement with and without Administration of Tranexamic Acid

I.P. Antropova[1,2], T.A. Zhirova[1,2], A.N. Varaksin[3], B.G. Yushkov[4,5]

[1]Ural State Medical University, Ekaterinburg, Russian Federation, [2]Ural Institute of Traumatology and Orthopedics named after V.D. Chaklin, Ekaterinburg, Russian Federation, [3]Institute of Industrial Ecology, the Urals Branch of the Russian Academy of Sciences, Ekaterinburg, Russian Federation, [4]Institute of Immunology and Physiology, the Urals Branch of the Russian Academy of Sciences, Ekaterinburg, Russian Federation, [5]Ural Federal University named after the first President of Russia B.N.Yeltsin, Ekaterinburg, Russian Federation

Background: Tranexamic acid (TA) inhibits plasminogen activation and interferes with fibrinolysis. TA administration is effective in decreasing blood loss without increasing complications in surgery.

Aims: To evaluate the effect of TA on the fibrinolysis markers plasminogen (Pg) and plasminogen activator inhibitor type 1 (PAI-1) after total hip replacement (THR).

Methods: Ninety-four patients admitted for THR were enrolled in a sequential series study. The no-TA group comprised 48 patients (51±10 years, 26 men) and the TA group had 46 patients (53±13 years, 20 men). TA was administered intravenously at 30 min prior to the THR and at 6 hours after the first dose. Pg and PAI-1 were measured before the THR, and at 30 min, 1, 3, 7, and 14 days after. Total blood loss and number of symptomatic deep vein thromboses (DVT) were determined. Statistical differences between groups were analyzed by the Mann Whitney U test. All participants gave written informed consent. The study was approved by the local research ethics committee.

Results: Blood loss in the TA group was 780±293 mL and 1337±490 mL in the no-TA group. After surgery Pg was lower in the TA compared to the no-TA group: 30 min (median [interquartile range]) (65.5 [55.4, 79.1] and 72.0 [63.7, 88.5]%, $p< 0.05$), day 1 (64.3 [56.3, 75.4] and 73.3 [64.0, 85.8]%, $p< 0.01$), day 7 (111.3 [104.6, 118.7] and 123.2 [108.2, 133.9]%, $p< 0.05$), respectively. PAI-1 was higher in the TA compared to the no-TA group: 30 min, (5.4 [3.0, 8.8] and 1.55 [0.40, 5.0] U/ml, $p< 0.05$), day 1 (14.7 [8.8, 28.5] and 6.2 [2.5, 14.8] U/ml, $p< 0.01$), day 3 (10.1 [3.7, 18.7] and 5.2 [2.5, 9.6] U/ml, $p< 0.05$), respectively. Symptomatic DVT was detected in 2 patients in the TA group and in 3 patients in the no-TA group.

Conclusions: Administering TA before and after THR reduced Pg and increased PAI-1 levels in the blood serum. Blood loss was reduced by TA. Symptomatic DVT remained unchanged.

PB 185 | Hyperfibrinolysis during Liver Transplantation Detected by Classical Parameters and Thromboelastometry

S. Maggiolo[1], E. Campello[1], L. Spiezia[2], A. Tredese[3], G. Saggiorato[4], S. Gavasso[2], P. Feltracco[5], P. Simioni[2]

[1]Università degli Studi di Padova, Dipartimento di Medicinam unità di Malattie Trombotiche ed Emorragiche, Padova, Italy, [2]Università degli Studi di Padova, Dipartimento di Medicina, Unità di Malattie Trombotiche ed Emorragiche, Padova, Italy, [3]Università degli Studi di Padova, Padova, Italy, [4]Università degli Studi di Padova, Dipartimento di Medicina Unità di Malattie Trombotiche ed Emorragiche, Padova, Italy, [5]Università degli Studi di Padova, Dipartimento di Anestesia e Rianimazione, Padova, Italy

Background: Low coagulation and hyperfibrinolysis are the major causes of excessive bleeding during orthotopic liver transplantation (OLT). However, the impact of hyperfibrinolysis in haemorrhagic complications complicating OLT remains a matter of debate.

Aims: To dynamically evaluate the presence of hyperfibrinolysis during OLT and the role of thromboelastometry to detect hyperfibrinolysis and to predict bleeding loss.

Methods: Thirty consecutive liver-transplanted recipients (M/F 22/8, mean(±SD) age 56(±12) years) who underwent OLT were included. Blood samples were drawn at serial time points: T0, preoperatively; T1, anhepatic phase; T2, 15 min after the reperfusion of the graft; T3, postoperatively. Fibrinolysis parameters (plasminogen, α2- antiplasmin, tissue plasminogen activator (tPA), thrombin-activatable *fibrinolysis* inhibitor, factor XIII, D-dimer, plasminogen activator inhibitor antigen) and thromboelastometry parameters (by ROTEM) were measured.

Results: Mean levels of antifibrinolytic factors were significantly lower during T1 than T0 and T2/T3, and higher in T2 than T3. TPA was significantly higher during T1 than T0 and T2/T3. Fibrinolysis ROTEM parameters (maximum lysis (ML) and lysis at 30 min (LI30) exactly mirrored these findings; in particular ML and LI were significantly higher in T1 compared to the other time-points both in the intrinsic-INTEM and in the extrinsic-EXTEM assays. Fourteen (46%) patients had blood loss >2,000 mL during OLT. Those patients showed significantly higher ML (53%) than patients with blood loss < 2,000 mL (ML 12%, p=0.018) both in INTEM and in EXTEM assay in T1.

Conclusions: Hyperfibrinolysis seemed to be related only to the anhepatic phase of the OLT and it was mainly determined by a significant reduction of antifibrinolytic proteins and increased tPa. Thromboelastometry parameters of fibrinolysis could identify patients with hyperfibrinolysis. Hyperfinrinolysis detected by ROTEM during the anhepatic phase could identify patients at higher risk of bleeding.

PB 186 | The Use of Antiplasmin-Specific Affimer as a Tool to Modulate Fibrin Clot Properties and Thrombosis Risk

M. Almutairi[1], C. Tiede[2], K. Kearney[1], N. Pechlivani[1], F. Phoenix[1], N. Oxley[1], D. Tomlinson[2], R. Ajjan[1]

[1]*University of Leeds, Division of Cardiovascular and Diabetes Research, Leeds Institute of Cardiovascular and Metabolic Medicine, Leeds, United Kingdom,* [2]*University of Leeds, Astbury Centre for Structural Molecular Biology, School of Molecular and Cellular Biology, Leeds, United Kingdom*

Background: Fibrin clot lysis, which limits thrombus formation, is controlled by various factors including incorporation of anti-fibrinolytic proteins into the clot, most importantly Plasmin Inhibitor (PI). Affimers are small proteins composed of a scaffold constraining two random conformational 9AA peptides that are easily produced in *E. coli*.

Aims: Identify the role of Affimers in modulating PI-specific prolongation in clot lysis.

Methods: A library of Affimers, containing $3x10^{10}$ different combinations of random peptides, was screened for PI binding using a phage display system. After 3 rounds of panning, high affinity PI-binding Affimers were tested for modulation of fibrin clot lysis. Validated turbidimetric assays were employed to assess fibrin clot structure/lysis, using both purified and plasma systems.

Results: A total of 167 high affinity PI-binding Affimers were isolated, of which 22 had distinct sequences and these were subsequently expressed in *E. coli*. One Affimer (termed A68) consistently inhibited the prolongation of PI-induced clot lysis in a purified system in a dose dependent manner with an effect observed at Affimer/PI molar concentration of 2/1. Clots formed from pooled plasma showed a reduction in lysis time from 650±23 sec with the addition of scaffold only Affimer to 420±21 sec in the presence of A68 (35% reduction in lysis time, p< 0.001). Addition of A68 or scaffold showed no effect on clot final turbidity (0.211 and 0.213 AU respectively, p>0.1), suggesting that A68 has no significant effect on clot structure. Tested in plasma from patients with diabetes, A68 reduced clot lysis time in 11 of the 12 samples analysed by an average of 25% (range 7-47%; p< 0.01).

Conclusions: The work so far provides proof of concept that PI-binding Affimers represent a viable tool to modulate fibrin clot lysis and may help to identify novel therapeutic targets to reduce thrombosis risk.

PB 187 | Application of the CloFAL Assay, a Global Assay which Evaluates Coagulation and Fibrinolysis in a Cohort of Venous Thromboembolism (VTE)

B.M. Martinelli, S. Montalvao, S.C. Huber, J.L. Cunha, M.P. Collela, F.A. Orsi, E.V. de Paula, J.M. Annichino-Bizzacchi

University of Campinas - UNICAMP, Hematology and Hemotherapy Center, Campinas, Brazil

Background: The Clot Formation and Lysis (CloFAL) assay, that simultaneously measures coagulation and fibrinolysis, appears as an interesting method, easy to standardize with a low cost.

Aims: To evaluate the CloFAL assay in patients with VTE and evaluate alterations associated to the hypercoagulable state and rethrombosis.

Methods: A hundred-eight patients (median age of 46 years; 22-80 years; 71 female/37male) who were attended at the outpatient clinic of Hemocentro de Campinas, UNICAMP, from January 2013 to November 2016, were enrolled. Fifty-five (50.9%) patients presented spontaneous DVT. The median time after the first VTE was 3 years. The history of recurrent thrombosis was present in 12 (11.1%) patients. The control group included 20 healthy individuals with a median age of 28.85 years (13 female/7 male). In the CloFAL assay, a buffered reactant solution containing trace amounts of calcium, tissue factor and tissue-type plasminogen activator were added to plasma samples on a 96-well microplate in a spectrophotometer at 37°C. The coagulation index (CI) and various fibrinolytic index (FI) were calculated.

Results: The CI showed similar results when patients and controls were compared, with a median of 90% (49-235%) and 80% (4-892%), respectively. FI median was markedly decreased in patients (98%, 47-313%) in comparison to controls (144.5%, 69-296%), p< 0.001. No correlation was found between CI and FI. Patients who presented

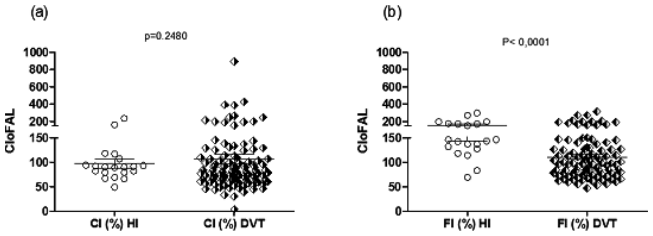

FIGURE 1 CloFAL analyses from healthy individuals (HI) and patients with Deep Venous Trombosis (DVT)

provoked DVT showed lower FI when compared with those with spontaneous DVT (98% *vs.* 76%, P= 0,0031).

Conclusions: The CloFAL global assay appears to be analytically sensitive to several key components of the coagulation and fibrinolytic systems, as well as to physiologic alterations in hemostasis. A study with a higher number of patients with DVT would be important to validate these results, and to investigate which fibrinolytic parameters are involved in the observed hypofibrinolysis. These results highlights that other fibrinolytic pathways can play a role on venous thrombotic disease.

PB 188 | Simultaneous Thrombin Plasmin Generation Assay in Haemorragic and Non Haemorragic Caesarean Section: Pilot Study

E. Jeanpierre[1], I. Saidi[1], A.-S. Ducloy-Bouthors[2], B. Hennart[3], A.-S. Baptiste[2], S. Giovannoni[1], E. Simon[4], D. Lannoy[4], D. Allorge[3], A. Duhamel[5], S. Susen[1,6]

[1]CHU Lille, Hematology Transfusion, Lille, France, [2]CHU Lille, Anesthesia, Lille, France, [3]CHU Lille, Toxicology, Lille, France, [4]CHU Lille, Pharmacy, Lille, France, [5]CHU Lille, Biostatistics, Lille, France, [6]Inserm, U 1011, Lille, France

Background: TRACES-trial is a multicenter randomized double-blind placebo-controlled therapeutic and pharmaco-biological dose-ranging study supported by French ministry of health (NCT02797119). Simultaneous Thrombin and Plasmin Generation Assay (STPGA) described by Van Geffen has been developed and validated in a preliminary study.

Aims: To evaluate interest of STPGA for the follow-up of patients undergoing either haemorragic (>800ml) (H) or non-haemorragic (< 800ml) (NH) ceasarean section (CS) compared to non-pregnant woman (NP).

Methods: The pilot study included 15, 10 and 9 patients in H, NH and NP group respectively. Eleven patients from H group were treated by Tranexamic Acid (TXA). For the 3 groups, STPGA was realized at baseline. A kinetic study was realized, after CS, for NH and H treated by TXA. Thrombin and plasmin AUCs at T0 in NH and H were compared

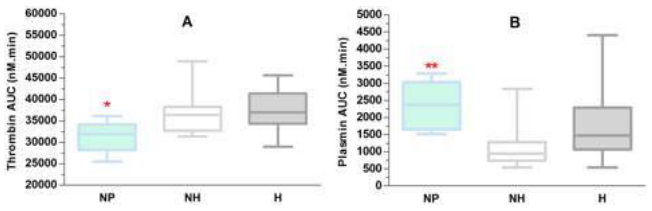

FIGURE 1 Thrombin (A) and plasmin (B) AUCs measured in STPGA at T0 on NH and H groups compared to NP group

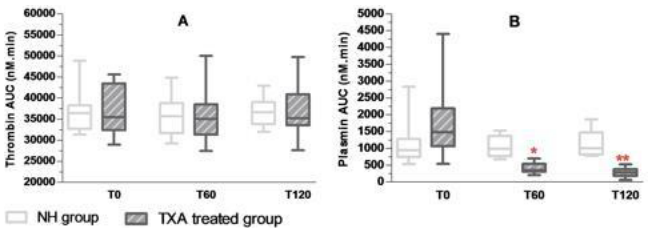

FIGURE 2 Thrombin and plasmin (B) AUCs measured in STPGA at T0 T60 and T120 in NH and TXA-treated groups

to NP group. Thrombin and plasmin AUCs were compared at T0 T60 and T120 (after CS) between NH and H treated by TXA.

Results: At T0, thrombin AUC (figure 1A) is lower in NP than in NH and H group whereas plasmin AUC (figure 1B) is higher in NP group than in NH and H group. During the follow-up, for NH and H treated by TXA, no statistical difference was noted at any time in thrombine AUC (figure 2 A). Plasmin AUC were statistically lower in the TXA-treated group at T60 (p=0.0002) and T120 (p< 0.0001) (Figure 2 B) *(*Thrombin AUC in NP vs NH group: p=0.02; **Plasmin AUC in NP vs NH group: p=0.002).*

*(Plasmin AUC in TXA-treated vs NH group at *T60: p=0.0002 and **T120: p< 0.0001).*

Conclusions: STPGA shows hypercoagulable state in late pregnancy and fibrinolysis capacity following placental separation, and is able to evaluate fibrinolysis inhibition by TXA during haemorragic CS. These primilarly results must be confirmed in the TRACES-study.

PB 189 | Simultaneous Thrombin Plasmin Generation Assay: Effect of Tranexamic Acid Concentration in vitro

E. Jeanpierre[1], I. Saidi[1], A.-S. Ducloy-Bouthors[2], B. Hennart[3], A.-S. Baptiste[2], S. Giovannoni[1], E. Simon[4], D. Lannoy[4], D. Allorge[3], A. Duhamel[5], S. Susen[1,6]

[1]CHU Lille, Hematology Transfusion, Lille, France, [2]CHU Lille, Anesthesia, Lille, France, [3]CHU Lille, Toxicology, Lille, France, [4]CHU Lille, Pharmacy, Lille, France, [5]CHU Lille, Biostatistics, Lille, France, [6]Inserm, U1011, Lille, France

Background: In order to explore coagulation, fibrinolysis and interplay, a Simultaneous Thrombin-Plasmin Generation Assay (STPGA) has been developed recently in our laboratory.

Aims: To evaluate the sensivity of the STPGA to in vitro effect of Tranexamic Acid (TXA) , spiking of different concentration of TXA was realized in a normal pooled plasma.

Methods: Successive dilutions from a tranexamic acid (TA) solution for injection (tranexamic acid concentration :100 mg/mL) were realized , in order to obtain a final TA plasmatic concentration in each well ranged from 0 to 8 mg/L, to assess the effect of different TA concentrations *in vitro* on STPGA in a normal pooled plasma. Briefly, STPGA is realized with 2 non-interfering fluorogenic thrombin and plasmin specific substrates. In a black microtiter well, were added 80 µl plasma, 2µl cephalin, 2 µl TF (0.28pM approximately), 4µ µl fluorogenic thrombin substrate, 2µl fluorogenic plasmin substrate

and TBS. After adding starting reagent (Cacl2 and t-PA), fluorescence was measured and convert to thrombin and plasmin concentration.

Results: The STPGA profiles of differents TA concentration are presented separately for thrombin (figure 1) and plasmin (figure 2).

As expected, plasmin generation decreased with rising TA concentrations, whereas thrombin generation was unaffected by the TA concentration variations.

Conclusions: *In vitro*, STPGA permitted to show the dose effect relationship between TA and plasmin generation. The next step will be the *in vivo* evaluation of TA treated patient.

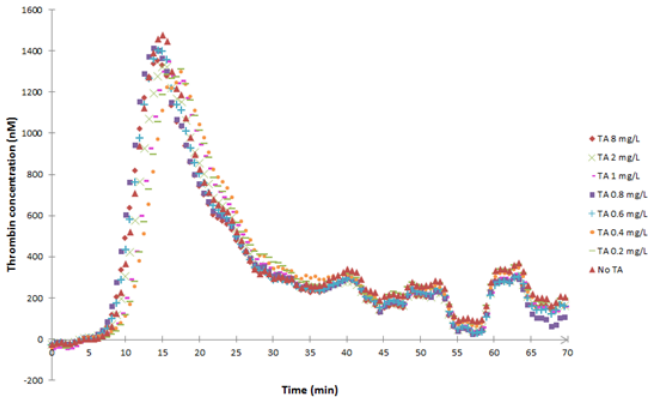

FIGURE 1 Thrombin generation profile in the STPGA of different tranexamic plasmatic concentrations

PB 190 | Association of Fibrinolytic Parameters with Coagulation Activity and Fibrin Clot Permeability in Patients with Hemophilia A

M. Milos[1], D. Coen Herak[1], S. Zupancic-Salek[2], J. Pavic[3], N. Mahmoud Hourani Soutari[4], J.P. Antovic[4], R. Zadro[1,5]

[1]*University Hospital Centre Zagreb, Department of Laboratory Diagnostics, Zagreb, Croatia,* [2]*University Hospital Centre Zagreb, Department of Medicine, Zagreb, Croatia,* [3]*General County Hospital Livno, Department of Medical Biochemistry and Hematology Laboratory, Livno, Bosnia and Herzegovina,* [4]*Institute for Molecular Medicine and Surgery, Karolinska Institutet, & Department of Clinical Chemistry, Karolinska University Hospital, Department of Coagulation Research, Stockholm, Sweden,* [5]*Faculty of Pharmacy and Biochemistry, Zagreb, Croatia*

Background: Hemophilia A has been considered as a bleeding disorder that is not only a consequence of the defect in the coagulation system, but also of the impaired down-regulation of the fibrinolytic system.

Aims: To examine correlation between activities and/or concentrations of most important fibrinolytic parameters with overall hemostasis potential (OHP) and fibrin clot permeability (FCP) in hemophilia A patients.

Methods: Activities of FXIII, plasminogen, plasmin inhibitor, plasminogen activator inhibitor-1 (PAI-1) (Siemens Healthcare Diagnostics, Germany) and thrombin-activatable fibrinolysis inhibitor (TAFI) (Diagnostica Stago, France), as well as activated/inactivated TAFI antigen (TAFIa/ai) (Diagnostica Stago) and prothrombin fragment F1+2 concentrations (PF1+2) (Siemens) were tested in plasma samples of 63 hemophilia A patients (30 severe, 33 non-severe). OHP method,

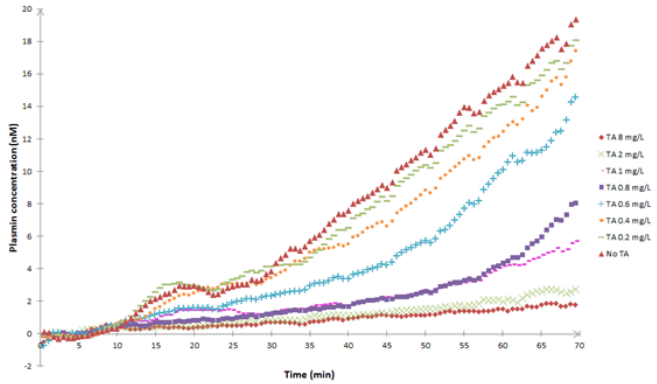

FIGURE 2 Plasmin generation profilein the STGPA of different tranexamic plasmatic concentrations

based on repeated spectrophotometric registration of fibrin-aggregation in plasma, after addition of small amounts of exogenous thrombin, tissue plasminogen activator and calcium, gave beside OHP parameter (area under the fibrin aggregation curve) 3 supplementary parameters: overall coagulation potential (OCP), overall fibrinolytic potential (OFP) and clot lysis time (CLT). Permeability coefficients (Ks), providing information on fibrin network porosity, were obtained by FCP method, flow measurement technique along with visualisation by electron microscopy scanning.

Results: Among fibrinolytic and OHP parameters significant but weak correlation (P< 0.05) was found only for OCP with TAFI and PF1+2 (r=0.252 and 0.266, respectively). Regarding FCP, significant correlation of Ks was found with FXIII, plasmin inhibitor and PF1+2 (r=-0.466, -0.432 and -0.599, respectively). There was no correlation between Ks and OHP parameters.

Conclusions: Obtained correlation between fibrinolytic parameters and parameters that assess coagulation activity and fibrin network porosity confirmed the association between these two processes in patients with hemophilia A.

PB 191 | Consequences of Tranexamic Acid on Fibrinolysis in Patients with Hereditary Bleeding Disorders Compared with Healthy Controls

I. Goncalves[1], D. Draxler[2], B. Niego[2], V. Sonia[2], R. Medcalf[2], H. Tran[1]

[1]*Alfred Hospital, Clinical Haematology, Melbourne, Australia,* [2]*Monash University, Australian Centre for Blood Diseases, Melbourne, Australia*

Background: Tranexamic acid (TXA) is an anti-fibrinolytic used to prevent bleeding in haemophilia patients who undergo minor procedures such as dental extractions. Despite a number of studies reporting avoidance of additional factor replacement using this strategy, the impact of TXA on fibrinolysis in this setting is yet to be elucidated.

Aims: To use the clot lysis assay to evaluate the impact of TXA on fibrinolysis in haemophilia patients undergoing dental procedures.

Methods: Ten healthy volunteers and ten patients with haemophilia were recruited after approval by the hospital research ethics board. Blood was

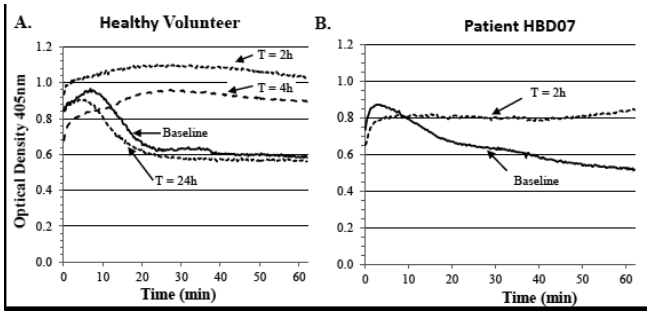

FIGURE 1 Represenative Clot lysis profiles. A. Healthy Volunteer, B. Patient HBD07

TABLE 1 Patient Demographics

Patient	Age	Bleeding Disorder	Factor Level (%)	Dental Procedure	Post-procedural Bleeding and Management
HBD01	57	Haemophilia A	15	1x Tooth extraction	Severe: Hospital admission for factor replacement
HBD02	29	Haemophilia A	4	1x Tooth extraction	Nil
HBD03	41	Haemophilia A	<1	1x Tooth extraction	Nil
HBD04	53	Haemophilia A	3	1x Tooth extraction	Nil
HBD05	56	Haemophilia A	10	1x Tooth extraction	Nil
HBD06	77	Haemophilia A	33	1x Tooth extraction	Nil
HBD07	59	Haemophilia A	28	1x Tooth extraction	Nil
HBD08	49	Haemophilia A	11	1x Tooth extraction	Nil
HBD09	80	Haemophilia B	15	1x Tooth extraction	Moderate: Extended treatment with TxA
HBD10	68	Haemophilia B	3	3x Tooth extraction	Nil

taken from the healthy volunteers at baseline, then at 2, 4 and 24 hours after ingestion of 1 gram of TXA. Haemophilia patients had blood collected on the day of their procedure, at baseline and 2-4 hours post ingestion of TXA. The Clot lysis assay was performed as described (Niego et al 2008 Blood Coag Fibrinol 19:322-324). Any procedural bleeding was retrospectively evaluated by accessing patient medical records.

Results: In the healthy volunteers, typical normal clot formation and lysis profiles were observed at baseline and TXA showed complete blockade of fibrinolysis at 2 and 4 hours but returned back to normal at 24hours (Figure 1A: representative profile of one volunteer). Ten haemophilia patients underwent tooth extractions under local anaesthetic. Patient details are outlined in Table 1. Six patients had comparable clot formation and lysis profiles at baseline and all patients had completely inhibited fibrinolysis at 2-4 hours post TXA ingestion (Figure 1B: representative profile of one patient). Unexpectedly, one patient with mild haemophilia experienced post-procedural bleeding requiring factor replacement.

Conclusions: Similar to healthy volunteers, TXA is effective at blocking t-PA mediated fibrinolysis in patients with haemophilia undergoing dental procedures and further supports its use as prophylaxis in the absence of factor concentrate.

PB 192 | Association of TAFI Polymorphisms and Fibrinolytic Status with Obesity in Subjects Suspected for Coronary Artery Disease

C. Rattanawan[1,2], N. Komanasin[2,3], N. Settasatian[2,4], C. Settasatian[2,5], U. Kukongviriyapan[2,6], P. Intharapetch[2,7], V. Senthong[2,8]

[1]Khon Kaen University, PhD Candidate in Biomedical Sciences Program, Graduate School, Khon Kaen, Thailand, [2]Cardiovascular Research Group, Khon Kaen University, Khon Kaen, Thailand, [3]Khon Kaen University, Faculty of Associated Medical Sciences, Department of Clinical Microscopy, Khon Kaen, Thailand, [4]Khon Kaen University, Faculty of Associated Medical Sciences, Department of Clinical Chemistry, Khon Kaen, Thailand, [5]Khon Kaen University, Faculty of Medicine, Department of Pathology, Khon Kaen, Thailand, [6]Khon Kaen University, Faculty of Medicine, Department of Physiology, Khon Kaen, Thailand, [7]Queen Sirikit Heart Center of the Northeast, Khon Kaen University, Khon Kaen, Thailand, [8]Khon Kaen University, Faculty of Medicine, Department of Medicine, Khon Kaen, Thailand

Background: Obesity is a risk factor for coronary artery disease (CAD), which is associated with impaired fibrinolysis. Plasminogen activator inhibitor-1 (PAI-1) and thrombin-activatable fibrinolysis inhibitor (TAFI) are inhibitors in fibrinolysis. Their levels were genetically controlled by gene polymorphisms.

Aims: This study aimed to assess the association of *PAI-1* and *TAFI* polymorphisms with obesity and fibrinolysis status in subjects suspected for CAD.

Methods: A of total of 327 subjects suspected for CAD and underwent coronary angiogram were recruited and individuals with body mass index ≥25 kg/m^2 were classified as obesity. The studied polymorphisms included *PAI-1* -675 4G/5G, *TAFI* 505G/A, 1040C/T, +1542C/G and +1583T/A. All polymorphisms were genotyped by allele-specific polymerase chain reaction (ASPCR) except for *TAFI* 1040C/T which was genotyped by PCR-restriction fragment length polymorphism. The global fibrinolytic activity was measured by euglobulin clot lysis assay while PAI-1 antigen was investigated by enzyme-linked immunosorbent assay.

Results: There was no difference in genotype distribution of -675 4G/5G in obesity compared to non-obesity group. Significantly increased level of PAI-1 was found in obesity compared to non-obesity group (7.8±2.1 vs 5.7±2.3, p=0.018). The T allele carrier of 1040C/T and G allele carrier of +1542C/G were associated with obesity after adjustment for age and sex [adjusted OR (95% CI) 0.62 (0.40, 0.97), and 0.57 (0.36, 0.89), respectively]. Global fibrinolytic activity was not significantly different among genotypes of the studied polymorphisms. Moreover, the polymorphisms were not associated with CAD.

Conclusions: This study suggested that the *TAFI* 1040C/T, +1542C/G may affect fibrinolysis in obesity. The tendency of hypofibrinolysis in subjects suspected CAD may in part due to increased PAI-1. However, TAFI level was not determined in this study, thus it should be further measured to clarify these results.

PB 193 | Nattokinase Easily Hydrolyzed Fish Elastin and Collagen, and Produced Anti-platelet Aggregation Activity

H. Sumi[1], M. Maruyama[2], T. Ito[3], N. Toki[4]

[1]Kurashiki University of Science and the Arts, Kurashiki, Japan, [2]University of Miyazaki, Miyazaki, Japan, [3]Organo Food Tech Corporation, Saitama, Japan, [4]Japan Organization of Clinical Dermatologists, Tokyo, Japan

Background: *Bacillus subtilis natto* is well known as one of the safest bacteria in the world. Nattokinase has a single-stranded polypeptide structure with 275 amino acid residues linked together, at pI 8.7 with a molecular weight of 27,274.

This enzyme also hydrolyzes elastin (Sumi *et al*., XXIII Congress of ISTH, P-TU-269, Kyoto, 2011).

Aims: There were two aims to this study: first, to hydrolyze fish elastin and collagen, and, second, to show each anti-platelet aggregation activity.
Methods: Nattokinase was supplied by Organo Foodteck Co. Ltd. and lumbrokinase was supplied by Well Stone Ltd.. Elastin, trypsin, chymotrypsin and synthetic substrates were purchased from Sigma-Aldrich Co. Ltd.. Several fish elastins were kindly supplied Hayashikane Sangyo Co. Ltd., and fish collagen was kindly supplied by Yamaki Co. Ltd..
The fibrin plate method (Sumi *et al*., *Experientia* 43:1110, 1987), elastin plate method (Sbarra *et al*., *Nature*, 188:322, 1960) and platelet aggregation activity (Sumi, *J. Home Econ. Jpn*., 50:683, 1999) was tested elsewhere.
Results: It was observed that nattokinase has strong lysis activity for elastin (< 2.5mg/ml, elastin plate method), which is a characteristic not observed at all under the same conditions for trypsin (10mg/ml), chymotrypsin (10mg/ml), or lumbrokinase (50mg/ml).
Nattokinase also easily hydrolyzed fish elastin (sea jack and sea bream). The addition of fish collagen rather than fish elastin, resulted in the same anti-platelet aggregation activity.
Conclusions: Nattokinase easily hydrolyzed fish elastin and collagen, and each anti-platelet aggregation activity was produced.

PB 195 | A New Functional Food "Coix-Natto" for Fibrinolysis

H. Sumi, S. Naito, C. Yatagai, T. Ohsugi, E. Yoshida
Kurashiki University of Science and the Arts, Kurashiki, Japan

Background: Coix (*Coix lacryma-jobi var. ma-yuen*) is a well known Chinese medicine which increases peripheral cytotoxic T and natural killer cells (Hidaka *et al*., *Biotherapy*, 5:2013, 1992). On the other hand, natto is a common Japanese food made of fermented soybeans, and nattokinase (NK) is a fibrinolytic enzyme generated from *Bacillus subtilis natto*. NK (M.W. 27,724, pI. 8.7) has been determined as a single polypeptide molecular structure linking 275 amino acid residues (Sumi *et al*., *Experientia*, 43:1110, 1987; Sumi *et al*., 22nd ISFP, P8, Marseille, 2014). NK has t-PA releasing activity from human endotherial cells (Yatagai *et al*., *Pathophysiol. Haemost. Thromb*., 36:227, 2009).
Aims: Coix (*Coicis Semen*) and Bacillus (*Bacillus subtilis* (*natto*)) were first conjugated. This study compared Coix-Natto and normal natto products by employing an evaluation method.
Methods: *Bacillus subtilis natto* (A and B) and *Bacillus subtilis* (C) were used in solid culture. Determinations of fibrinolysis (Sumi *et al*., *Experientia*, 43:1110), polyamine (Saito *et al*., *Anal. Sci*., 8: 675, 1992), vitamin K_2(Sumi, *Food Sci. Technol. Res*., 5, 48, 1999) and synthetic substrate hydrolysis were reported elsewhere. Double immnodiffusion was performed using anti-serum against highly purified NK (Sumi *et al*., 23rd ISTH, P-TU-268, Kyoto, 2011).
Results: The maximal fibirinolysis "B" (>1,000mm^2/30µl) was detected in the presence of glycerol (1.0-5.0%) at 37°C for 90hr culture. The "B" hydrolyzed synthetic substrate II (Suc-Ala-Ala-Pro-Phe-*p*NA) at a rate less than half of synthetic substrate I (Bz-Ile-Glu-(OR)-Gly-Arg-*p*NA). The "B and C" also produced high concentration of vitamin K_2 (1,400-1,530µg/100g wet wt.) and polyamine (4.81-5.01mg/100g wet wt.). All NK and NK-like activities were very stable in dry powder conditions.
Conclusions: Coix-Natto was not sticky and offered a good taste. The vitamin K_2 concentration was no less than that of general soybean natto (Sumi *et al*., 25th ISTH, PO462-TUE, Toront, 2015; *New Food Industry*, 59:23, 2017).

PB 197 | Fibrinolytic Effects of Regulatory Leucine-containing Peptides in the Organism

L. Lyapina, T. Obergan
Lomonosov Moscow State University, Biology, Lab. Blood Coagulation, Moscow, Russian Federation

Background: Previously it is established that the products of hydrolysis of structural proteins -collagen and elastin- proline-containing peptides have the ability to inhibit the polymerization of fibrin . It is shown the interaction of amino acid leucine with fibrinogen.
Aims: The aim of this work was to study the effects of two leucine-containing peptides Leu-Pro-Gly-Pro(LPGP) and Pro-Gly-Pro-Leu (PGPL) on the parameters of enzymatic fibrinolysis and polymerization of fibrin, in the blood of animals in vivo.
Methods: Experiments were conducted on more than 50 white laboratory rats weighing 200-230 g in accordance with the ethical principles of the Helsinki Declaration. Experienced rats intranasally daily for 5-7 days injected each peptide in a volume of 20 µl (dose: 200 µ/kg of the rat body weight), a control - 0.85% saline. In blood plasma the level of fibrinogen, fibrindepolymerizing activity (FDPA), total enzymatic fibrinolytic activity (TEFA) and activity of tissue plasminogen activator (t-PA) was determined by the standard methods 20 hours after the last administration of peptides.
Results: It was found that the peptides LPGP and PGPL increased TEFA on 55 - 90%, t-PA on 120-140%, FDPA on 70- 110%, respectively. Fibrinogen concentration decreased under the action of both peptides by 12%. The highest fibrinolytic and fibrindepolymerizing effects has been installed after the introduction of the PGPL.
Conclusions: We showed that addition of leucine to the C - or N-ends of the peptide Pro-Gly-Pro increased fibrinolytic activity of blood plasma. Thus, leucine-containing glyprolines introduced into the organism promoted depolymerization of fibrin, increased the enzymatic properties of blood plasma, reduced the concentration of fibrinogen. Therefore they can be considered effective fibrinolytic factors, which prevented the polymerization of fibrin in the organism.

PB 198 | Very High Production of Nattokinase by D-amino Acids

Y. Yanagisawa[1], T. Ito[2], H. Sumi[3]
[1]Chiba Institute of Science, Pharmacy, Choshi, Japan, [2]Organo Food Tech Corporation, Tokyo, Japan, [3]Kurashiki University of Science and the Arts, Kurashiki, Japan

Background: Nattokinase (NK) is a single-stranded polypeptide structure with 275 amino acid residues linked together at pI 8.7 with

a molecular weight of 27,274. NK has also t-PA releasing effect on human endotherial cells (Yatagai *et al*., *Pathophysiol. Haemost. Throm*b., 36:227, 2009).

NK production is controlled by dipicolic acid (Ohsugi *et al*., *J. Food. Biochem*., 35:370, 2011) and isoflavone (genistein) (Yatagai *et al*., *Pathophysiol. Haemost. Thromb*., 36:298, 2009).

Aims: Relation of D-amino acid NK production was first reported.

Methods: D-amino acids and synthetic substrates were purchased from Sigma-Aldrich Co Ltd.. Additional amino acid test was performed for 7days at 41°C (2% High- polypeptone S-3% glycerol).

Determinations of fibrinolysis (Sumi *et al*., *Experientia*, 43:1110), polyamine (Saito *et al*., *Anal. Sci*., 8: 675, 1992), vitamin K_2(Sumi, *Food Sci. Technol. Res*., 5, 48, 1999) and synthetic substrate hydrolysis were reported elsewhere. Double immnodiffusion was performed using anti-serum against highly purified NK (Sumi *et al*., 23rd ISTH, P-TU-268, Kyoto, 2011).

Results: Addition of 1% D-amino acids (D-Phe, D-Lys, D-Pro, D-Asp etc.) in *Bacillus subtilis natto* (Miyagino) culture system produced very high NK activity 8 times more than the control (which contained no amino acid).

An increase of NK at 3.5 times higher than the control was also confirmed using synthetic substrate (Bz-Ile-Glu-(OR)-Gly-Arg-*p*NA) hydrolysis.

Production of vitamin K_2 was confirmed to be like that of NK.

Conclusions: It was proven that very high production of NK occurred with the addition of several D-amino acids.

PB 906 | Thrombin-activable Fibrinolysis Inhibitor (Procarboxypeptidase B2) Deficiency Protects from Carbon Tetrachloride-induced Liver Fibrosis

T. Totoki[1], C.N. D'Alessandro-Gabazza[2], R. Mifuji-Moroka[1], K. Nishihama[3], A. Takeshita[3], T. Yasuma[2], Y. Takahashi[4], K. Fujiwara[4], M. Toda[2], M. Nakamura[1], N. Horiki[1], M. Iwasa[1], T. Kobayashi[4], Y. Takei[1], E.C. Gabazza[2]

[1]*Mie University School of Medicine, Gastroenterology and Hepatology, Tsu, Japan,* [2]*Mie University School of Medicine, Immunology, Tsu, Japan,* [3]*Mie University School of Medicine, Diabetes, Metabolism and Endocrinology, Tsu, Japan,* [4]*Mie University School of Medicine, Pulmonary and Critical Care Medicine, Tsu, Japan*

Background: Thrombin-activatable fibrinolysis inhibitor (TAFI; procarboxypeptidase B2, [proCPB2]) is produced by several cells including hepatocytes, macrophages, and megakaryocytes. Activated TAFI induces inactivation of proteins or peptides by removing the arginine and lysine residues from the carboxy-terminus. TAFI can be activated by the thrombin/thrombomodulin complex on the surface of endothelial cells leading to inhibition of fibrinolysis and inflammation. TAFI gene deficiency was reported to ameliorate bleomycin-induced lung fibrosis in a murine model but contrarily it was reported that TAFI gene deficiency worsens liver damage in a carbon tetrachloride (CCl4)-induced liver failure in mice.

Aims: In this study, we examined the effect of TAFI gene deficiency in a murine model of CCl4-induced liver fibrosis.

Methods: To induce liver fibrosis CCl4 was injected intraperitoneally twice a week for eight weeks in wild type and TAFI deficient mice both under C57BL/6 background. The experimental protocol was approved by the Institutional Committee for Animal Investigation and followed approved international guidelines.

Results: Liver damage was ameliorated in TAFI deficient mice after chronic CCl4 administration. TAFI deficient mice showed decreased plasma levels of aspartate aminotransferase and alanine aminotransferase compared to wild type mice. Hepatic fibrosis was also ameliorated in TAFI deficient mice. Collagen deposition assessed by Sirius Red staining and hydroxyproline content in the liver was significantly lower in TAFI deficient mice.

Conclusions: These data suggest that TAF play a detrimental role in the fibrotic phase of liver injury.

PB 907 | Transcriptional Regulation of the Tissue Factor Gene is Mediated by the Androgen Receptor

B. Hoesel[1], M. Mussbacher[1], M. Salzmann[1], H. Paar[1], A. Assinger[1], N. Mackman[2], J. Schmid[1]

[1]*Medical University of Vienna, Vascular Biology and Thrombosis Research, Vienna, Austria,* [2]*University of North Carolina at Chapel Hill, Chapel Hill, United States*

Background: Prostate cancer is one of the leading causes of cancer death in men. Advanced prostate cancer is usually treated by androgen deprivation therapy (ADT), which aims at diminishing circulating testosterone to reduce cancer growth. There is growing evidence that ADT increases the rate of VTE in prostate cancer patients, suggesting that low levels of testosterone can induce a hypercoagulable state. One of the most important mediators of extrinsic coagulation is tissue factor (TF). Despite a potential role for TF in ADT, an analysis of androgen receptor (AR) mediated regulation of TF has not been performed.

Aims: To characterize androgen receptor mediated regulation of tissue factor expression.

Methods: We stimulated two AR dependent prostate cancer cell lines with dihydrotestosterone (DHT) and analysed TF expression by qPCR and FACS. Furthermore, we cloned the TF promoter into a luciferase reporter vector and created serial deletions of known transcription factor binding sites. In addition, we use castration experiments in mice to characterize AR mediated TF regulation *in vivo*.

Results: We show that TF expression is regulated by DHT in two androgen dependent prostate cancer cell lines LNCAP and VCAP. This DHT mediated TF regulation is AR dependent as it could be blocked by the addition of the AR antagonist bicalutamide. Using luciferase reporter assays, we show that TF regulation is mediated through the NF-κB and EGR1 in LNCAP as well as the AP-1 and EGR1 binding site(s) in VCAP cells, respectively. Finally, we provide evidence that TF expression is also regulated through AR *in vivo*.

Conclusions: In summary, we provide evidence that TF expression in prostate epithelial cells is mediated through AR *in vitro* and *in vivo*. These findings are especially important in the context of ADT. We

provide a molecular basis for the underlying signaling events, which could contribute to better treatment options for androgen deprived patients.

PB 908 | Factor V Expression in Aggressive Breast Cancer Modifies Patient Survival, Tumor Cell Growth and Response to Treatment

M. Tinholt[1,2], M. Sletten[1], Ø. Garred[3], K.K. Sahlberg[4,5], P.M. Sandset[6,7], N. Iversen[1]

[1]Oslo University Hospital, Dep. of Medical Genetics, Oslo, Norway, [2]Oslo University Hospital, Dep. of Haematology, Oslo, Norway, [3]Oslo University Hospital, Dep. of Pathology, Oslo, Norway, [4]Oslo University Hospital, Dep. of Genetics, Institute for Cancer Research, Oslo, Norway, [5]Vestre Viken, Dep. of Research, Drammen, Norway, [6]Oslo University Hospital, Dep. of Haematology and Research Institute of Internal Medicine, Oslo, Norway, [7]Oslo University Hospital, Institute of Clinical Medicine, Oslo, Norway

Background: The hypercoagulable state in cancer patients contributes to tumor progression. Coagulation factor V (FV) is an essential co-factor of the tissue factor pathway. We have shown that genetic variants in *F5* are associated with breast cancer, yet, it is unknown how FV affects cancer processes.

Aims: To clinically and functionally characterize the role of *F5* expression in cancer pathogenesis and response to therapy.

Methods: The endogenous and doxorubicin-responsive expression of *F5* was characterized in breast, ovarian, colon and liver cancer cell lines. Tumor-expressed *F5* was related to clinical data, survival and biological function in a Scandinavian breast cancer material (n=152) and a merged breast cancer dataset (n=1881). *F5* was overexpressed *in vitro* in breast cancer cells and growth (WST-1), apoptosis (DNA fragmentation), and cancer signaling pathways (Cignal Finder Rep. Array) were assessed. Gene/protein expression was determined by qRT-PCR/ELISA. CRISPR-Cas9 will be used to activate/repress endogenous *F5* cell expression.

Results: *F5* was expressed in all cancer cell lines tested, and the expression was further induced by doxorubicin in *TP53* wt cells. In breast cancer patients, tumor-expressed *F5* was increased in aggressive subtypes; estrogen receptor negative, human epidermal growth factor receptor 2 positive and basal tumors. High *F5* expression was associated with improved survival in these patient groups. Consistently, *F5* overexpression reduced *in vitro* cell growth and induced apoptosis, likely through a p53-dependent mechanism. *F5* correlated with the expression of immune response genes in the tumors, and *in vitroF5* overexpression induced the gene and protein expression of multiple cytokines.

Conclusions: *F5* expression in aggressive breast tumors was a positive predictor of survival. FV was shown to inhibit cancer growth and to be a possible mediator of treatment response. In conclusion, we demonstrate a novel function of FV as a possible tumor suppressor gene.

PB 909 | Low Phosphatase Activity Mediates L-selectin Shedding in B-CLL

I. Beke Debreceni[1], R. Szász[2], Z. Kónya[3], F. Erdődi[3], G. Vereb[4], J. Kappelmayer[1]

[1]University of Debrecen, Faculty of Medicine, Department of Laboratory Medicine, Debrecen, Hungary, [2]University of Debrecen, Faculty of Medicine, Institute of Internal Medicine, Debrecen, Hungary, [3]University of Debrecen, Faculty of Medicine, Department of Medical Chemistry, Debrecen, Hungary, [4]University of Debrecen, Faculty of Medicine, Department of Biophysics and Cell Biology, Debrecen, Hungary

Background: Chronic lymphocytic leukemia (CLL) is the most common form of leukemia in adults and has a variable clinical outcome that is dependent on several factors including cellular trafficking.

Aims: We investigated L-selectin surface expression on CLL cells from untreated patients and explored the mechanism that lead to L-selectin shedding.

Methods: In 51 untreated CLL patients, surface and soluble L-selectin expression was investigated by flow cytometry and ELISA respectively. Magnetically isolated B-cells from 33 untreated CLL patients and 20 healthy subjects were included in our study. Protein phosphatase activity was determined both for total and PP2 activity (PP2A) by using a ^{32}P-labeled substrate. Flow cytometry was utilized for the determination of intracellular phosphorylated p38MAPK and surface ADAM17 expression as well as to study the effect of specific inhibitors on ADAM17 and L-selectin expression.

Results: In CLL cells, both total and PP2 activities were significantly lower (p< 0,0001 and p=0,009), conversely intracellular phosphorylated p38MAPK level was higher (p=0,023) compared to normal B-cells. In case of CLL patients, increased soluble L-selectin levels were detected with decreased surface L-selectin and ADAM-17 expression. During in vitro experiments, normal and CLL-B cells were treated by the phosphatase inhibitor Calyculin A (CLA). Malignant B cells showed an elevated phosphorylated p38MAPK level and reduced surface L-selectin and ADAM17 expression compared to normal B-cells. When normal B-cells were preincubated with the p38MAPK inhibitor (SB203580) before CLA treatment, p38MAPK phosphorylation was blocked and CLA-induced L-selectin shedding was also attenuated.

Conclusions: The decreased phosphatase activity detectable in CLL, results in a downstream signaling cascade with subsequent reduction of surface L-selectin expression and we suggest that this effect is mediated by enhanced phosphorylation of p38MAPK and altered ADAM17 expression.

PB 910 | Platelet-dependent von Willebrand Factor Activity in Acute Myeloid Leukemia Patients: Role in Haemostatic Alterations

B. Farweez[1], H. Abaza[2], S. Samaan[1]

[1]Ain Shams University, Clinical Pathology, Cairo, Egypt, [2]Ain Shams University, Clinical Pathology-Hematology Unit, Cairo, Egypt

Background: Acute myeloid leukemia (AML) patients may suffer from bleeding complication which occurs mainly due to thrombocytopenia,

disseminated coagulopathy (DIC) and platelet dysfunction. von Willebrand Factor (VWF) defects have been implicated as contributor in bleeding complication.

Aims: The study aimed to investigate the vWF-Ristocetin cofactor (vWF-RCO) activity pattern in newly diagnosed AML patients and its relation to therapy, to explore its potential role in the prevalent phenomenon of bleeding in AML patients, to correlate between vWF-RCO activity and other hemostatic parameters and known prognostic factors in AML.

Methods: Thirty newly diagnosed patients with AML and twenty healthy age and sex-matched subjects (control group) were studied. The vWF-RCO activity using platelet agglutination method was performed on plasma samples of both patients and controls.

Results: Our results showed a significantly reduced vWF-RCO activity in AML patients at diagnosis compared to control group (mean value of 80.5%±12.6% and 99.5%±10.5% respectively) ($p< 0.001$), meanwhile, vWF-RCO activity significantly increased after two weeks post-treatment. In addition, vWF-RCO activity showed a statistically significant lower mean value among patients presenting with bleeding manifestations (76.0 ±11.7%) in relation to those without bleeding (86.5±11.4%)($p=0.02$). Also, on grading the bleeding manifestation, patients with grade (3) had the lowest mean value of vWF-RCO activity (61.1% ±5.2%), Our study proposes the following cut-offs for vWF-RCO :"≤ 85.2%" for predicting the AML patients prone to bleeding manifestations and „≤82.6%" for the prediction of bad outcome.

Conclusions: In AML, vWF-RCO activity at diagnosis, represents a valuable prognostic marker for predicting bleeding complication and bad outcome, and the provided cut-offs for vWF-RCO activity represent first steps for its use as a bleeding predictor and prognostic marker.

PB 911 | Fibronectin Supports Glioma Invasion and Colonization of Fibrin in Co-operation with Slug/Snail2

L.M. Knowles, C. Wolter, A. Burkardt, S. Urbschat, R. Ketter, D. Lessig, I. Müller, H. Eichler, J. Pilch

Saarland University Medical Center, Homburg/Saar, Germany

Background: High grade gliomas are brain tumors that are characterized by diffuse growth and resistance to most if not all therapies. Typically, these aggressive tumors possess high angiogenic activity, which causes vascular leakage and fibrin-rich edema.

Aims: To determine if fibrin promotes invasion and colonization of malignant brain tumors and whether this process is supported by factors of epithelial to mesenchymal transition (EMT) such as fibronectin and Slug/Snail2.

Methods: Primary tumor cells from patients with high-grade glioma (WHO grade III-IV) or benign meningioma (grade I-II) were embedded in a 3-dimensional matrix of clotted plasma, fibrin, fibrin-fibronectin or Matrigel™ and scored for invadopodia formation as well as proliferation using phase contrast microscopy. Expression of fibronectin and Slug/Snail2 was analyzed using quantitative PCR, western blotting and fluorescence microscopy. The role of fibronectin and Slug/Snail2 for invasion/proliferation in 3D matrices was further assessed by transfecting U87MG glioma cells with siRNA.

Results: Glioma cells invaded extensively in clotted plasma and fibrin while lagging behind in matrigel. Benign meningioma cells, on the other hand, were considerably less clot invasive. Glioma invasion was associated with strong expression of the transcription factor Slug/Snail2 and the adhesion protein fibronectin, which worked together to promote invadopodia formation in fibrin as well as matrigel. Moreover, knocking down Slug/Snail2 or fibronectin reduced colonization of gliomas in 3D, suggesting that both proteins are involved in the self-renewal of tumor-initiating cells.

Conclusions: Our data show that clotted plasma, which is present in the fibrin-rich edema of the tumor extracellular matrix, strongly promotes invasion as well as colonization of high-grade glioma. Mechanistically, we found that this process is promoted by the EMT factors fibronectin and Slug/Snail2, which both are upregulated in aggressive glioma.

PB 912 | Altered Fibrin Clot Properties in Advanced Lung Cancer: Impact of Chemotherapy

M. Zabczyk[1], G. Krolczyk[2,3], G. Czyzewicz[2], A. Undas[1,2]

[1]Jagiellonian University Medical College, Institute of Cardiology, Cracow, Poland, [2]John Paul II Hospital, Cracow, Poland, [3]Jagiellonian University Medical College, Cracow, Poland

Background: The impact of cancer, a well-established risk factor for thromboembolism, on clot properties remains unclear. Faster formation of dense and poorly lysable fibrin networks has been previously reported in patients with gastrointestinal cancer.

Aims: To investigate alterations of plasma fibrin clot features in lung cancer patients before and after chemotherapy.

Methods: Plasma fibrin clot permeability (K_s), clot formation (lag phase and maximum absorbance at 405 nm, ΔAbs), and lysability (clot lysis time, CLT) were investigated before chemotherapy and during the third or fourth cycle of standard chemotherapy adjusted to the histopathological type of cancer and co-morbidities in a cohort of 150 consecutive patients aged 46-82 years with advanced inoperable lung cancer, including 61 subjects with the small-cell lung carcinoma (SCLC) and 89 with the non-small-cell lung carcinoma (NSCLC). Healthy subjects (n=90) matched for age and sex served as controls.

Results: At baseline lung cancer patients had 27.9% higher fibrinogen, 27.2% lower K_s, 8.1% shorter lag time, and 26.5% longer CLT than healthy controls. ΔAbs did not differ between both groups. Chemotherapy was associated with increased K_s and lag phase (+7.5% and +9.5%, respectively; both $p< 0.05$), shorter CLT (-4.8%, $p=0.053$), and unaltered fibrinogen and ΔAbs. Differences in clot properties remained significant after adjustment for fibrinogen. No differences in fibrin characteristics were found between lung cancer stages as well as between SCLC and NSCLC at baseline and after chemotherapy. As few as 19 (12.7%) patients survived during a median follow-up of 10.4 (5.8-18.6) months. The Kaplan-Meier analysis showed that the lag phase ≤37s (1st quartile) was the predictor for death (log-rank test, $p=0.039$).

Conclusions: Advanced lung cancer unfavorably alters plasma clot properties, including faster formation of more compact clots displaying impaired lysability regardless of cancer histology and disease stage but chemotherapy improves these properties.

PB 913 | The Effect of Neoadjuvant Chemotherapy on the Activated Protein C (aPC) Pathway in High Grade Serous Ovarian Cancer Patients

M.P. Ward[1], F.A. Saadeh[2], J.J. O'Leary[3], N. Gleeson[1,4], S.A. O'Toole[1,3], L.A. Norris[1]

[1]*Trinity College Dublin, Obstetrics and Gynaecology, Dublin, Ireland,* [2]*St James's Hospital, Gynaecology-Oncology, Dublin, Ireland,* [3]*Trinity College Dublin, Histopathology, Dublin, Ireland,* [4]*St Jame's Hospital, Gynaecology-Oncology, Dublin, Ireland*

Background: Ovarian cancer and chemotherapy treatment are risk factors for cancer-associated thrombosis. However, the mechanisms are not understood. We have previously shown that the aPC pathway is dysregulated in ovarian cancer.
Aims: To determine the effect of chemotherapy on the aPC pathway in ovarian cancer and to elucidate the role of aPC in increased thrombin generation in ovarian cancer patients.
Methods: Ovarian cancer patients (benign n=23, chemotherapy naïve n = 23, neoadjuvant treated n=23) gave full and informed consent. Venous blood samples were obtained prior to surgery. Thrombin generation was determined +/- thrombomodulin (TM) (10 nM). Plasma levels of sTM and soluble Endothelial protein C receptor (EPCR) were determined by ELISA. OAW42 (ovarian) and EA.hy926 (endothelial) cells were treated with paclitaxel or carboplatin for 24 h. mRNA expression of TM and EPCR were determined by TaqMan PCR.
Results: Neoadjuvant patients had lower endogenous thrombin potential (ETP) compared with the benign and chemo naïve groups($p< 0.001$). Lag time and peak thrombin were increased compared with benign and neoadjuvant groups($p< 0.001$). Following addition of TM, neoadjuvant chemotherapy increased ETP, peak thrombin and decreased lag time compared with benign and chemo naïve groups($p< 0.01$). Neoadjuvant patients also had decreased levels of sEPCR in plasma compared with benign and chemo naïve groups($p< 0.01$). sTM levels were unchanged. Neither paclitaxel nor carboplatin altered TM or EPCR mRNA expression in EA.hy926. Conversely, carboplatin exposure decreased TM expression in OAW42 cells($p< 0.008$), while paclitaxel exposure decreased EPCR expression($p< 0.009$).
Conclusions: Neoadjuvant chemotherapy alters thrombin production in ovarian cancer patients. The increased resistance to the aPC pathway maybe mediated by reduced levels of sEPCR which may originate from the tumour. This data highlights that neoadjuvant chemotherapy alters tumour expression of aPC proteins which may impact the increased VTE risk in these patients.

PB 914 | Inhibition of Tumour Cell-induced Platelet Aggregation by a Novel Stat3 Inhibitor in Podoplanin Positive Cancer Cells

K.-Y. Chong[1], P.-S. Lu[1], P.-Y. Lin[1], Y.-W. Chang[2], T.-T. Huang[3]

[1]*Chang Gung University, Department of Medical Biotechnology and Laboratory Science, College of Medicine, Gui-Shan, Taiwan, Republic of China,* [2]*Chang Gung University, Graduate Institute of Biomedical Science, College of Medicine, Gui-Shan, Taiwan, Republic of China,* [3]*Chang Gung University, Center for Molecular and Clinical Immunology, Gui-Shan, Taiwan, Republic of China*

Background: Cancer cells acquire the ability to penetrate the walls of lymphatic and/or blood vessels for escape from the primary site. Podopalanin (PDPN) was involved in cancer development, lymphatic metastasis and poor prognosis in a wide variety of cancer types. By binding to platelet C-type lectin-like receptor 2 (CLEC-2), PDPN stimulates tumor cell-induced platelet aggregation (TCIPA) and facilitates cancer cell metastasis. Furthermore, the Signal Transducer and Activator of Transcription 3 (STAT3) plays an important role in megakaryopoiesis and serves as a transcription factor activated by cytokine-induced intracellular signals. Recent study indicated that stat3 inhibitors selectively inhibited collagen-induced aggregation of human platelets.
Aims: To investigate a novel stat3 inhibitor whether elicit functional blockage of PDPN-stimulated CLEC-2 activation and TCIPA.
Methods: TCIPA was induced in human platelets by mixing with two PDPN-overexpressed osteosarcoma cancer cells, MG63 and HOS cells.
Results: Our results shown that the a novel stat3 inhibitor consistently inhibited tumour cell-induced platelet aggregation (TCIPA) in response to all two PDPN-overexpressed osteosarcoma cancer cells, MG63 and HOS cell lines. The PDPN- or collagen-induced platelet aggregation was significantly decreased in a dose-dependent manner of the novel stat3 inhibitor treatment. The Western blot analysis shown that treatment with PDPN produced marked Syk phosphorylation and treatment with collagen produced PLCγ2 and Syk phosphorylation. We noted that a novel stat3 inhibitor inhibited PDPN-induced Syk phosphorylation, collagen-induced PLCγ2 and Syk phosphorylation.
Conclusions: Our results show that a novel stat3 inhibitor was an effective inhibitor of TCIPA and inhibited PDPN- or collagen-induced Syk and PLCγ2 phosphorylation. The findings are valuable for future application of novel stat3 inhibitor in the prevention and treatment of cancer metastasis.

PB 915 | Cancer Stromal Targeting Therapy Using MMAE Conjugated Anti-insoluble Fibrin Antibody

H. Fuchigami[1,2], S. Manabe[3], T. Obonai[1], M. Yasunaga[1], Y. Matsumura[1]

[1]*National Cancer Center Hospital East, Division of Developmental Therapeutics, Kashiwa, Japan,* [2]*University of Tokyo, Graduate School of Frontier Science, Kashiwa, Japan,* [3]*RIKEN Advanced Science Institute, Wako, Japan*

Background: Most invasive cancers including pancreatic cancer possess abundant stroma that hinders the distribution of high molecular

weight agents including antibody drug conjugate (ADC). We report here a successful new strategy that overcomes the above drawbacks by ADC against particular components of tumor stroma.

The fibrin clot (Fbn) formation in cancer stroma lasts for as long as the cancer cells survive in the body, unlike non-malignant conditions such as cardiac infarction. Anti-human monoclonal antibody (mAb) against insoluble fibrin recognizes an unexplored hole that is uncovered only when a fibrin clot forms.

Aims: In this study, we show a new concept of ADC that conjugated anti-insoluble fibrin mAb to monomethyl auristatin E (MMAE) for targeting stroma.

Methods: Antibody and ADCs: Anti-insoluble fibrin IgG (Fbn-ADC) and Control (Control-ADC) were prepared in our laboratory.

In vivo experiments: Bulb/c nude mice were subcutaneously inoculated with 5×10^5 5-11 cells on the back and used in the experiments when the tumor volume reached approximately 200 mm^3. Mice received PBS, 0.3 mg/kg MMAE, 20mg/kg ADCs (0.3 mg/kg, MMAE equivalent) twice a week, 12 times in total.

8 weeks-old spontaneous pancreatic tumor-bearing KPC mice were treated with PBS and ADCs at same regimen of subcutaneous model.

Results: In the subcutaneous tumor model, Fbn-ADC significantly inhibited tumor growth compared with PBS, MMAE and Control-ADC ($P< 0.01$). In the KPC mice, Fbn-ADC significantly improved survival compared with PBS and Control-ADC ($P< 0.05$).

Conclusions: Our strategic concept of cancer stromal targeting (CAST) therapy is unique as follows.

1) The ADC can extravasate from the leaky tumor vessels selectively, and forms a scaffold as it is captured by tumor stromal network.

2) The ADC allows the effective sustained release of anti-cancer agent from the scaffold, and the released payload is distributed throughout the tumor resulting in high antitumor effect by damaging tumor cells and tumor vessels.

PB 916 | A Linkage between ERBB2 Expression and the Pro-coagulant Properties of Breast Cancer Cells is Mediated by the PI3k/Akt Signaling Pathways

C. Yunliang[1], M. Scully[1], A. Kakkar[1,2]

[1]Thrombosis Research Institute, London, United Kingdom, [2]University College London, London, United Kingdom

Background: The overexpression of ERBB2 in primary tumours and corresponding metastases are associated with certain aggressive types of breast cancer. As regards cancer, the occurrence of thrombosis is often the first indicator of an underlying malignancy and a close association has been established between tumour progression and the development of a procoagulant profile, suggesting that the activation of the blood coagulation system contributes to tumour biology.

Aims: To investigate a possible modulatory role of ERBB2 in the procoagulant status of breast cancer cells.

Methods: A line of ERBB2 overexpressing human breast cancer MCF-7 cells (MCF-7 ERBB2+) and human normal mammary MCF-12a cells (MCF-12a ERBB2+) respectively, were established by transfection with an ERBB22 plasmid. The effect of ERBB overexpression on the synthesis and activities of selected blood coagulation proteins were analysed as well as relevant signalling pathways.

Results: Overexpression of ERBB2 induced by gene transfection was associated with a significant increase in the levels of p-ERK / p-Akt - central components of key signalling pathways for tumorigenesis - as well as enhanced expression of pro-tumorigenic proteins. In addition, Western Blot showed that the expression levels of the majority of the coagulation proteins corresponded with the level of ERBB2 when tested in three native breast cancer cell lines. The overexpression of ERBB also altered the level of each of these blood coagulation proteins in MCF-7-ERBB2+ and MCF-12a-ERBB2+ cells. The modulation of coagulation proteins, as mediated by the level of ERBB2 in breast cancer cells, was dependent on the PI3k/Akt pathway. ERBB2 also modulated the procoagulant activity including tissue factor and thrombomodulin, again, in a PI3K/Akt pathway manner.

Conclusions: The level of ERBB2 correlates positively with the procoagulant properties of breast cancer cells, an effect which is mediated by PI3k/Akt pathways.

PB 917 | Exosomes from Heparin-treated Cancer Cells Exhibit Transferable Anti-tumorigenic Activity

C. Yunliang[1], M. Scully[1], A. Kakkar[1,2]

[1]Thrombosis Research Institute, London, United Kingdom, [2]University College London, London, United Kingdom

Background: We have shown previously that heparin treatment of human breast cancer cells induces a less tumorigenic genotype and phenotype. Recently, interest has been engendered in the role of exosomes, extracellular vesicles released from cells, which are stable concentrated carriers of genetic and proteomic information, capable of altering the properties of target cells and thereby acting as intercellular messengers.

Aims: To investigate *whether* the exosomes released from heparin treated cells exhibit a similar anti-tumorigenic effect as heparin, itself.

Methods: The anti-tumorigenic properties of exosomes prepared from heparin treated breast cancer cells (Exo-HT) were compared to those from untreated cells (Exo-Ctrl) as well as to those separated from conditioned medium following the termination of treatment (heparin discontinued, Exo-HD) in terms of the profile of pro-tumorigenic proteins and cytological characteristics. Also, confocal microscopy and flow cytometry were used to determine if heparin was bound to the purified exosomes.

Results:

1) The numerous anti-tumorigenic effects of heparin treatment on human breast cancer cells were reversed after heparin was removed from the cultures.

2) Similar anti-tumorigenic effects, in terms of *pro-tumorigenic and* cell cycle regulatory proteins as well as signalling *activities were observed* in breast cancer cells treated with Exo-HT and Exo-HD.

3) A less tumorigenic cytological profile was also observed following treatment of MCF-7 and MDA-MB231 cells with Exo-HT and Exo-HD.

4) Heparin was observed to be bound to exosomes and heparin-loaded exosomes could, therefore, act as a longer lived reservoir of heparin activity in the circulation.

Conclusions: The anti-tumorigenic effect of heparin treatment on cancer cells was also observed in treatment with heparin derived exosomes - whether the occurrence of such heparin derived exosomes in the circulation is of clinical significance awaits investigation.

PB 918 | Sonic Estimation of Elasticity via Resonance (SEER) Sonorheometry to Identify Hypercoagulability in Patients with Cancer

E. McLoughlin[1], E. Ferrante[2], F. Viola[2], H. Maitland[1]

[1]*University of Virginia, Hematology/Oncology, Charlottesville, United States,* [2]*HemoSonics LLC, Charlottesville, United States*

Background: Venous thromboembolic (VTE) disease is associated with significant morbidity and mortality and is one of the leading causes of death in patients with cancer. The actual reported incidence of VTE in patients with cancer varies greatly and depends on the type and stage of cancer, type of treatment, and patient-specific factors. Currently no specific biomarkers have been shown to reliably predict VTE risk.

Aims: To assess the efficacy of Sonic Estimation of Elasticity via Resonance (SEER) Sonorheometry in identifying hypercoagulability in cancer patients.

Methods: SEER Sonorheometry was implemented in an earlier research version of the Quantra, (HemoSonics) a novel cartridge-based viscoelastic analyzer. Twelve cancer patients and 30 controls were enrolled in this study. Treatment naïve patients with a new diagnosis of a solid tumor were eligible for inclusion. Baseline conventional measures of hemostasis (D-Dimer, Fibrinogen, Thrombin time, PT, PTT, and Platelet count) were measured within the first cycle of chemotherapy and at 6 months for all patients. Quantra measurements were simultaneously obtained and included Clot Time (CT), Clot Stiffness (CS), Fibrinogen (FCS) and Platelet (PCS) Contributions to clot stiffness.

Results: Seven patients with lung cancer, 4 patients with squamous cell carcinoma of the head and neck, and 1 patient with gastric adenocarcinoma were included in the analysis. A summary of Quantra parameters is shown in Figure 1. CS, FCS, and PCS increased by over 80% from baseline to follow-up, indicating a higher than normal state as compared to normal healthy subjects. At the initial and follow-up time points, the mean values for PT, PTT, Thrombin time, and Platelet count were normal. The mean D-Dimer and mean Fibrinogen were elevated at both time points. The D-Dimer decreased by 7.1% over the 6 months while Fibrinogen increased by 7.7% over the same period.

Conclusions: SEER measurements showed a trend towards increasing coagulation, suggesting a potential hypercoagulable state.

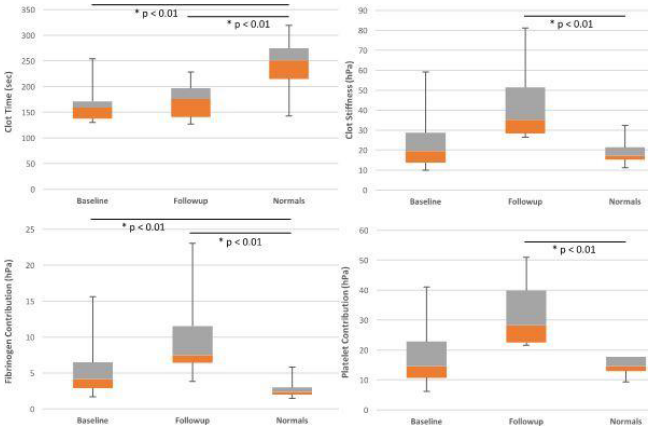

FIGURE 1 Box and whiskers plots of Quantra parameters: cancer patients at baseline, cancer patients at 6 month follow up, and normal controls

PB 920 | Direct Oral Anticoagulants Do Not Inhibit Growth and Metastasis of Orthotopically Growing Claudin-low MDA-MB-231 Human Breast Cancer Cells in Immunodeficient mice

J.T. Buijs[1], C. Tieken[1], K. van der Molen[1], J. Crooijmans[1], C. Kroone[1], N. Swier[1], E.H. Laghmani[1], R.F.P. van der Akker[1], G. van der Pluijm[2], S.E. le Dévédec[3], H.H. Versteeg[1]

[1]*Leiden University Medical Center, Internal Medicine, Leiden, The Netherlands,* [2]*Leiden University Medical Center, Urology, Leiden, The Netherlands,* [3]*Leiden University, Leiden Academic Centre for Drug Research, Leiden, The Netherlands*

Background: Cancer is associated with a 4-6-fold increased risk for venous thromboembolism (VTE). It has recently been suggested that coagulation could drive cancer progression as well. However, beneficial effects of prophylactic treatment with Low Molecular Weight Heparin on survival in cancer patients were not consistently found. Recently, direct oral anticoagulants (DOACs) have shown a superior safety profile and are at least as efficient in inhibiting VTE recurrence in patients without cancer.

Aims: We tested whether the DOACs dabigatran and rivaroxaban exert anti-tumorigenic effects in claudin-low breast cancer cells *in vivo* as well as *in vitro*, as powerful anticancer strategies for claudin-low breast cancer are lacking.

Methods: Seven-week-old NOD/SCID/$\gamma_C^{-/-}$ (NSG) mice were continuously (day-2 onwards) fed a custom-made chow diet, which included dabigatran etexilate (DE) (10mg/g) or rivaroxaban (0.4mg/g). All mice were orthotopically inoculated with 500,000 MDA-MB-231 claudin-low breast cancer cells and tumor size was weekly measured with a caliper. Human-specific qPCR allowed for sensitive detection of metastatic cells in the liver and lungs at the end (11 weeks) of the experiment.

Results: DE and rivaroxaban increased significantly the coagulation time when compared to vehicle mice as measured by aPTT and PT assay, respectively. In addition, FXa activitiy was inhibited in the rivaroxaban mice using a chromogenic assay. However, both DE and

rivaroxaban did not result in significant inhibition of tumor growth at primary or metastastic site.

Furthermore, the coagulant factors thrombin (10-50nM) and FXa (2-20nM) did not induce migration, proliferation or stemness in the MDA-MB-231 cells *in vitro*.

Conclusions: This study showed that DOACs could not inhibit cancer progression in claudin-low breast cancer. However, it remains to be investigated whether DOACs exert anti-tumorigenic effects in other types of breast cancer, as well as other malignancies such as pancreatic cancer.

PB 921 | Does Remote Ischemic Preconditioning Increase Fibr inolysis in Head and Neck Cancer Surgery? Preliminary Results from a Randomized Controlled Trial

A.E. Krag[1,2], B.J. Kiil[2], C.L. Hvas[3], A.-M. Hvas[1]

[1]Aarhus University Hospital, Center for Hemophilia and Thrombosis, Department of Clinical Biochemistry, Aarhus, Denmark, [2]Aarhus University Hospital, Department of Plastic Surgery and Breast Surgery, Aarhus, Denmark, [3]Aarhus University Hospital, Department of Anesthesiology and Intensive Care, Aarhus, Denmark

Background: Cancer induces abnormal coagulation and fibrinolysis leading to an increased risk of thromboembolism. Large head and neck tumors are primarily treated by surgical resection and reconstruction of the defect by transfer of the patient's own tissue. Thrombosis in the transferred tissue or the patient's circulation is a life-threatening complication in head and neck cancer surgery. Remote ischemic preconditioning (RIPC) attenuates ischemia-reperfusion injury and reduces subsequent thrombotic events in cardiovascular procedures.

Aims: The aim of the trial is to investigate if RIPC increases fibrinolysis in head and neck cancer patients undergoing surgery.

Methods: The local Ethics Committee has approved this trial, and informed consent is obtained before study inclusion. We aim to randomize 60 patients undergoing head and neck cancer surgery to RIPC or sham intervention. RIPC is induced with an inflatable tourniquet and administered intraoperatively by four 5-minute cycles of upper extremity ischemia and reperfusion. Blood samples are collected preoperatively, intraoperatively, and in the postoperative phase. An in-house clot lysis assay, tissue plasminogen activator (tPA), plasminogen activator inhibitor-1 (PAI-1), and fibrin D-dimer will be measured.

Results: Until now, 35 patients have been included in the trial. Preliminary results show reduced clot lysis area under the curve and 50% lysis time, reduced PAI-1, and increased tPA measured postoperatively in the RIPC group. No difference is found in postoperative fibrin D-dimer between the groups.

Conclusions: Preliminary results indicate that RIPC increases fibrinolysis in head and neck cancer patients undergoing surgery, which may reduce the risk of postoperative thromboembolism. Despite increased fibrinolysis, postoperative fibrin D-dimer was similar in the two groups.

We expect to present data from at least 40 patients at the congress.

PB 922 | The Role of asTF in Glioblastoma Multiforme

M.Y. Kapteijn, B. Ünlü, H.H. Versteeg

Leiden University Medical Center, Einthoven Laboratory for Vascular and Regenerative Medicine, Leiden, The Netherlands

Background: Full-length Tissue Factor (flTF) in complex with its ligand, protease FVIIa, is the initiator of the coagulation cascade and a signaling receptor involved in inflammation and angiogenesis. It is also known to be overexpressed in Glioblastoma Multiforme (GBM). This aberrant expression results in microenvironmental changes including recruitment of proinflammatory cells that affect the cancer cell genome and epigenome . Alternatively spliced Tissue Factor (asTF), the soluble isoform of flTF, has been reported to contribute to cell proliferation, angiogenesis and tumor growth in vivo. However, the exact role of asTF in GBM has not been determined.

Aims: Here we aim to unravel the influence of asTF in GBM and to distinguish between the functions of flTF and asTF.

Methods: Stable cell lines expressing flTF or asTF, and control cells that express neither isoform, were generated through lentiviral transduction of low TF expressing U373 human glioma cells. These cell lines were used to characterize the role of asTF in GBM by examining cell proliferation, migration, invasion and gene expression levels.

Results: Interestingly, no differences in proliferation were found in U373 flTF and asTF cells compared to control cells. flTF cells, unlike asTF cells, showed upregulation of the typical TF-dependent pro-inflammatory gene CCL-2 in response to FVIIa. In contrast, migration and invasion rates were found to be increased in asTF cells in comparison to control and flTF glioma cells.

Conclusions: flTF in GBM is associated with pro-inflammatory signaling, while asTF is associated with cell movement and invasion.

PB 923 | Tumoral Factor VII Expression Changes TGF-β-mediated Intercellular Communication in Breast Cancer

M. Paauwe, R. Hikmet, E.H. Laghmani, H.H. Versteeg

Leiden University Medical Center, Thrombosis and Haemostasis, Leiden, The Netherlands

Background: It is known that cancer patients have an increased risk for developing thromboembolic events compared to healthy people. The incidence of venous thrombosis in cancer patients is even further enhanced upon metastatic disease, suggesting a correlation between tumor cell spread and coagulation. Recently, our group found that a subset of breast tumors expresses coagulation factor VII (fVII), a protein normally solely produced by the liver. In an orthotopic mouse model for breast cancer, MDA-MB-231 cells expressing fVII proved to be more metastatic, when compared to the control cell line. One of the major regulators of tumor metastasis is the tumor

stroma, which consists of endothelial and immune cells, extracellular matrix and cancer-associated fibroblasts (CAFs). Previously, we have shown that interactions between CAFs and tumor cells are of crucial importance for tumor invasion and metastasis and that Transforming Growth Factor-β (TGF-β) is a key player in this process.

Aims: The aim of this study was to assess the effect of tumoral fVII expression on TGF-β-mediated cell-cell interactions in breast cancer.

Methods: In order to assess the effects of cell-cell interactions on TGF-β-mediated signaling we used RNA expression analysis by qPCR and western blot for protein regulation and modification. Moreover, direct and indirect co-culture experiments were performed to allow for bidirectional paracrine interactions and their effects.

Results: Preliminary data showed that the TGF-β signaling route is activated in breast cancer CAFs upon stimulation with conditioned medium (CM) from either fVII-expressing or control MDA-MB-231 cells. Additionally, various TGF-β receptors appeared to be upregulated to a higher extent after stimulation with fVII CM than after control CM.

Conclusions: Based on these data, we conclude that the TGF-β-mediated interactions between CAFs and tumor cells are altered when tumor cells express fVII.

PB 924 | Chemotherapy as a Factor in the Pathogenesis of Thrombosis in Patients with Ovarian Cancer

A. Vorobev, A. Makatsariya, A. Solopova

I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

Background: Patients with ovarian cancer represent group of the highest risk of thrombotic and hemorrhage complications, especially during chemotherapy. Chemotherapy stipulates for endothelium damage, direct platelet activation and reduction of fibrinolytic activity.

Aims: To determine necessary range of laboratory tests for a high-grade estimation of haemostasis state in ovarian cancer patients undergoing chemotherapy.

Methods: 209 patients with ovarian cancer undergoing chemotherapy were divides at random on 2 groups: **Igroup** 109 has received LMWH 0,4 ml (4000 IU) before each chemotherapy curse and **II group** 100 has not received any anticoagulant prophylaxis during chemotherapy.

Laboratory tests: Platelet aggregation tests with different stimulators: Adrenaline, Ristocetin and ADP in various concentrations, platelet factor 4 (PF4). DIC and thrombophilia marker tests: D-dimer, TAT complexes, F1+2 prothrombin fragments. Fibrinolytic activity tests: determine PAI level, Protein C and S levels.

Results: We have detected the sign of thrombofilia and DIC in more than 90% patient during chemotherapy. The rate of the sub-compensated forms of DIC was 30%, decompensated 23%. It was observed damage of fibrinolytic activity due to iatrogenic effects of chemotherapy: reduction in proteins C and S levels, increase PAI concentration, platelets hyperaggregation in ristotetin presence.

In **I group** normalization of lab test results was detected during 2-3 days after chemotherapy course in comparison with **II group** normalisation was in 5-7 days in 22% and in 7-12 day in 58%, in 20% was not registered spontaneous normalisation.

Conclusions: Due to endothelium protection activity LMWH in ovarian cancer patients during chemotherapy significantly reduce intensity of thrombofilia and DIC. 85-90% patients with ovarian cancer required permanent preventive anticoagulant prophylaxis.

PB 925 | Preoperative Panel Scores of CA 19-9, FVIII and D-dimer Predict Postoperative Survival in Pancreatic Ductal Adenocarcinoma

N. Mattila[1], H. Seppänen[2], C. Haglund[2], R. Lassila[1]

[1]Helsinki University Central Hospital Comprehensive Cancer Center, Department of Hematology, Coagulation Disorders Unit, Helsinki, Finland, [2]Helsinki University Hospital, Department of Surgery, Helsinki, Finland

Background: Pancreatic ductal adenocarcinoma (PDAC) is one of the leading causes of cancer-associated deaths worldwide. It is often diagnosed at a late incurable stage, and survival after surgery even with local PDAC is poor. CA 19-9 is the most used tumor marker for PDAC, however its sensitivity and specificity are not optimal. PDAC is associated with signs of increased coagulation activity.

Aims: The aim of this study was to find out whether a preoperative panel of CA 19-9, FVIII, D-dimer and thrombin time (TT) predicts cancer diagnosis and survival outcomes after pancreatic surgery.

Methods: Patients (n=121) were operated during 2010-2015 for PDAC in Helsinki. CA 19-9, FVIII, TT and D-dimer were analyzed 1-3 days preoperatively. Patients were divided into groups based on the disease stage: local (n=92) and metastasized (n=29). Neo-adjuvant treatments (NT) were recorded. The results were analyzed with a 10-point preoperative panel score. The median (range) follow-up for was 1.62 (0.01-1) years for local and 0.81 (0.16-2.29) years for metastasized PDAC. Survival data was gathered for each patient. A Kaplan-Meier survival analysis was made.

Results: Of the 92 local PDAC patients, 48 were alive at follow-up. All patients with a metastasized disease were deceased at follow-up. The median (range) panel score was 7 (4-10) for local and 8 (6-10) for metastasized PDAC. In local PDAC 75% had values of 7 or higher and it predicted worse survival in local PDAC vs lower scores ($p< 0.01$), regardless of NT. CA 19-9 alone associated with worse survival when over 340 kU/L (n=31, $p< 0.05$). When CA 19-9 was below 340 kU/L, panel scores of 7 or more predicted worse survival in local PDAC ($p< 0.05$). Panel score values did not predict survival in metastasized disease.

Conclusions: Preoperative screening of CA 19-9 combined with FVIII, D-dimer and TT associates with survival after PDAC surgery in local disease. A larger study is needed to verify whether the panel could assist in the determination of surgical suitability.

PB 926 | Expression of Coagulation Proteases from the Activated Protein C Pathway in Ovarian Tumours

C. Spourquet[1], M.P. Ward[1], F.A. Saadeh[2], J.J. O'Leary[3], N. Gleeson[1,2], S.A. O'Toole[1,3], L.A. Norris[1]

[1]Trinity College Dublin, Obstetrics and Gynaecology, Dublin, Ireland, [2]St James's Hospital, Gynaecology-Oncology, Dublin, Ireland, [3]Trinity College Dublin, Histopathology, Dublin, Ireland

Background: Ovarian cancer is the leading cause of death from gynaecological malignancy. Coagulation proteases have been implicated in the pathogenesis of ovarian cancer. Previous studies by our group have shown that ovarian cancer is associated with altered gene expression of coagulation proteases particularly those associated with the anticoagulant activated protein C pathway (aPC).

Aims: The aims of this study were to characterise the expression of the aPC pathway in ovarian cancers using cell line models and ovarian cancer tissue.

Methods: mRNA expression of 15 coagulation genes was measured in ovarian cancer cells lines (HIO-80 (benign characteristics), OAW42, SKOV3 and 59M). Protein expression of thrombomodulin(TM) was determined by Western blot and ELISA. TM and Factor V(FV) expression was localised in benign, high grade serous (HGS), clear cell and endometrioid tumour tissue using immunohistochemistry.

Results: OAW42 had the most similar pattern of expression to that found in our previous study of tumour tissue with reduced expression of Protein S(PS), TM and Factor VIII, and a slight reduction in EPCR. Factor V and Protein C were not expressed. TaqMan PCR confirmed the reduced TM mRNA expression in OAW42 cell lines compared to HIO-80(benign model)($p < 0.001$). Weak to moderate staining of TM expression was observed in tumour cells from malignant biopsies compared with strong staining in cells from benign serous tumours. Strong staining for FV was also found in HGS tumours compared with benign tissue which was localised to tumour cells.

Conclusions: OAW42 cell line showed reduced levels of expression of genes and proteins involved in the activation of protein C compared with the benign cell line which concurs with previous findings in tumour tissue. To the author's knowledge, this is the first report of FV expression in ovarian cancer tissue. As the plasticity of the tumour milieu is crucial for ovarian cancer, components of the aPC may be responsible not only regulating coagulation but also driving oncogenesis.

PB 927 | Mucin1 Acts as a Potential Mediator of the Pro-coagulant Properties of Breast Cancer Cells by Altering the Activity of Key Phosphokinase Pathways

C. Yunliang[1], M. Scully[1], A. Kakkar[1,2]

[1]Thrombosis Research Institute, London, United Kingdom, [2]University College London, London, United Kingdom

Background: An aberrantly glycosylated form of cell membrane tethered Mucin 1 (MUC1) is overexpressed in a variety of epithelial cancers in which it participates in intracellular signalling thereby regulating the expression of a wide range of genes. Likewise, clinical data indicate that the activation of the blood coagulation system contributes to tumour aggressiveness and vice versa. Whether there is a link between the level of expression of the cancer biomarker MUC1 and the procoagulant activity of cancer cells is unknown.

Aims: To investigate if there is a link between the level of MUC1 in breast cancer cells and procoagulant activity.

Methods: A *shRNA-mediated MUC1 gene knockdown* was carried out in human breast cancer cell line MCF-7 establishing the shMUC1-MCF7 cell line which was investigated antigenically by WB for the level of kinase activity in selected key signalling pathways and compared to cells treated with a blank shRNA and to untreated MCF-7 cells. The level of phosphorylated proteins on the cell surface was also analysed by flow cytometry. The effect of MUC1 knockdown on the procoagulant properties was investigated by activity assays and the expression of selected coagulation factors was determined by WB.

Results: Compared to shCtrol-MCF7 cells, the phosphokinase activity of the MAPK, PI3K/Akt, TGFβ receptor, ERBB, and PKC signalling pathways were significantly reduced in shMUC1-MCF7 cells. Clotting activity and tissue factor activity were also reduced in shMUC1-MCF7 cell as well as levels of factors Xa and XIa as determined by WB.

Conclusions: MUC1 gene knockdown in breast cancer cells diminishes the activities of wide range of phosphokinase pathways as well as procoagulant activity and coagulation factor expression. Aberrantly glycosylated MUC1 in breast cancer cells may act as a potential mediator for pro-coagulant properties via the intensification of signalling activity.

PB 928 | Coagulation Factor Xa Promotes Melanoma Metastasis

M. Arce[1], M. Galleguillos[1], C. Ramirez[1], R. Erices[1], L. Lobos[2], L. Leyton[3], A. Quest[3], G. Owen[4]

[1]Pontificia Universidad Catolica de Chile, Facultad Ciencias Biológicas, Santiago, Chile, [2]Fundacion Ciencia y Vida, Santiago, Chile, [3]Universidad de Chile, Facultad de Medicina, Santiago, Chile, [4]Pontificia Universidad Catolica de Chile, Biological Science, Santiago, Chile

Background: A hypercoagulable state and complications from metastasis are the principal reasons for cancer-related mortality. Accumulate evidence suggest that the coagulation system plays a role in metastasis, and anticoagulants have been reported to be beneficial in prolonging cancer patient survival. However, the contribution of distinct proteins of coagulation cascade to cancer progression is still understood. The coagulation factor Xa (FXa), an effector protease of coagulation cascade, has a pivotal role among distinct cells types, such as: endothelial cells, fibroblast, mesangial cells and vascular smooth muscle cells. Nevertheless, the contribution of FXa to cancer cell biology and tumor progression is poorly described.

Aims: The principal aim of this study is to elucidate the contribution of FXa to cancer cell proliferation, migration, invasion (*in vitro*), and the contribution to cancer cell metastasis (*in vivo*)

Methods: The potential role of FXa upon metastasis was assessed using tail-vein injections of melanoma in the B16F10-C57BL/6 metastasis model. The effect of FXa upon the biological properties of cancer cells was assessed *in vitro*, using boyden chamber (invasion assay), scratch assay (migration) and flow cytometry (cell cycle analysis).

Results: FXa significantly increased B16F10 melanoma lung metastasis in mice, but FXa did not alter melanoma cell proliferation, migration or invasion capabilities in *in vitro* assays

Conclusions: Despite having no detectable effect upon the melanoma cells in culture, FXa can notably increase metastasis foci. FXa may promote metastasis by modulating the microenvironment of the metastatic niche. Preliminary data suggest that FXa promote the adhesion of melanoma cells to endothelial cells monolayer. Furthermore, FXa change Vascular endothelial cadherin (VE-cad) levels and distribution, suggesting an increase of endothelial permeability. These data support the idea that FXa may promote metastasis through changes in the tumor microenvironment, specifically the endothelium.

PB 929 | Identification of Novel Molecular Targets of the Kunitz-type Molecule Amblyomin-X Using Immuno-fishing Interactomics Approach

A.M. Chudzinski-Tavassi[1,2,3], A. Iqbal[1,3], K.L.P. Morais[1,2,3], M.B. Goldfeder[1,3]

[1]*Butantan Institute, Biochemistry and Biophysics Laboratory, Sao Paulo, Brazil,*
[2]*Federal University of São Paulo, Department of Biochemistry, Sao Paulo, Brazil,*
[3]*Butantan Institute, Centre of Excellence in New Target Discovery, Sao Paulo, Brazil*

Background: Amblyomin-X is a Kunitz-type protein, identified from a cDNA library of the salivary glands from the tick *Amblyomma cajennense* that has shown great potential to combat variety of cancer cells including skin melanoma, murine renal cell carcinoma and pancreatic cancer. In contrast, Amblyomin-X has not showed any cytotoxic effects on normal human fibroblasts.

Aims: The aim of the work was the identification of novel molecular targets inside cells and deducing mechanism of action of Amblyomin-X.

Methods: Proteins that bind to Amblyomin-X was identified using Amblyomin-X- Immuno-fishing column followed by mass spectrometry. For identification and evaluation of the pathways, we employed STRINGS, METACORE, flow cytometry and confocal microscopy.

Results: Proteins from several pathways such as endocytosis, apoptosis, cell cycle, blood coagulation and proteasomal degradation were found to interact with Amblyomin-X. Amblyomin-X was confirmed to enter the tumor cells via endocytoses and induced death in tumor cells via those pathways from which the proteins were identified to interact with this molecule.

Conclusions: The interactomics profile and mechanism of action was construed for Amblyomin-X. This is extremely effective model of interactomics, which can provide valuable clues for the pathways that could be effected by a particular protein/peptide drug.

PB 930 | Dissolution of Platelet-rich Thrombus by Perfusion of N-acetyl Cysteine

S.M. Hastings, D.N. Ku

Georgia Institute of Technology, Mechanical Engineering, Atlanta, United States

Background: Both stroke and heart attack arise from thrombotic occlusion of an artery. These thrombi can be either fibrinous or platelet-rich depending on the mechanism of formation. Current thrombolytics typically target clots composed of fibrin. The effects of these agents on platelet-rich arterial thrombi are not known.

Aims: We have developed an *in vitro* system to study the efficacy of known and proposed thrombolytic agents on platelet-rich thrombi under flow. Specifically, we test anti-vWF agents as an alternative to tPA.

Methods: Whole porcine blood was perfused through a collagen-coated glass stenosis at a shear rate of 3500 s^{-1} to create platelet-rich thrombus. Then an agent was perfused at 1 mL/min for an hour. The agents tested include tissue plasminogen activator (tPA) (n=5), N-acetyl cysteine (NAC) (n=5), ADAMTS-13 (n=2) and abciximab (n=2). Saline was used as a negative control (n=3).

Results: Larger concentrations of NAC completely dissolved platelet thrombi within 10 min (Fig 1). Lower doses of NAC also showed dissolution within 1 hr perfusion, with average reduction in surface area of 96.8% ± 6.0% (avg ± s.d.). This was significantly different than tPA and the control ($p << 0.001$). TPA perfusion reduced thrombus surface

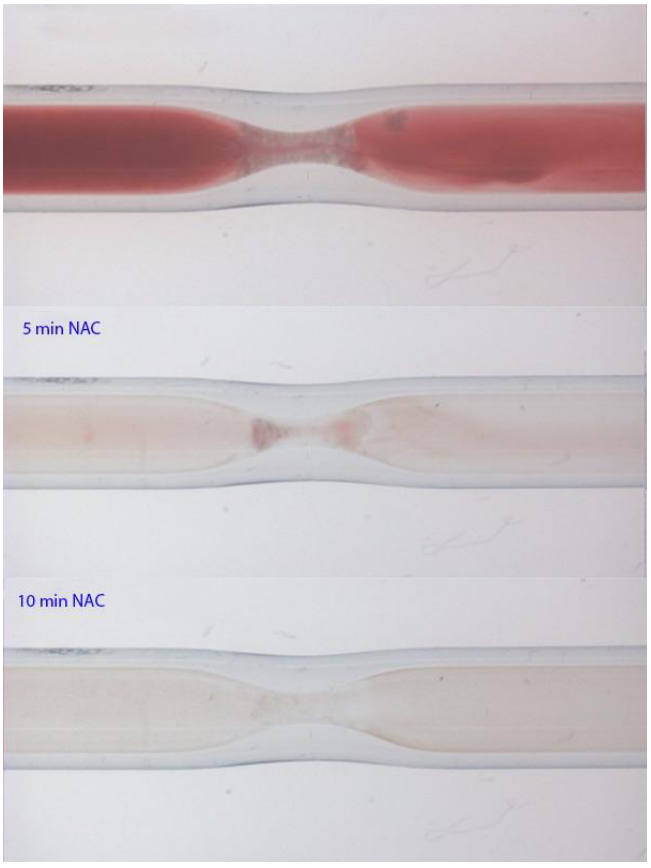

FIGURE 1 Platelet thrombus created under high shear conditions dissolves before 10 mins of perfusion with NAC.

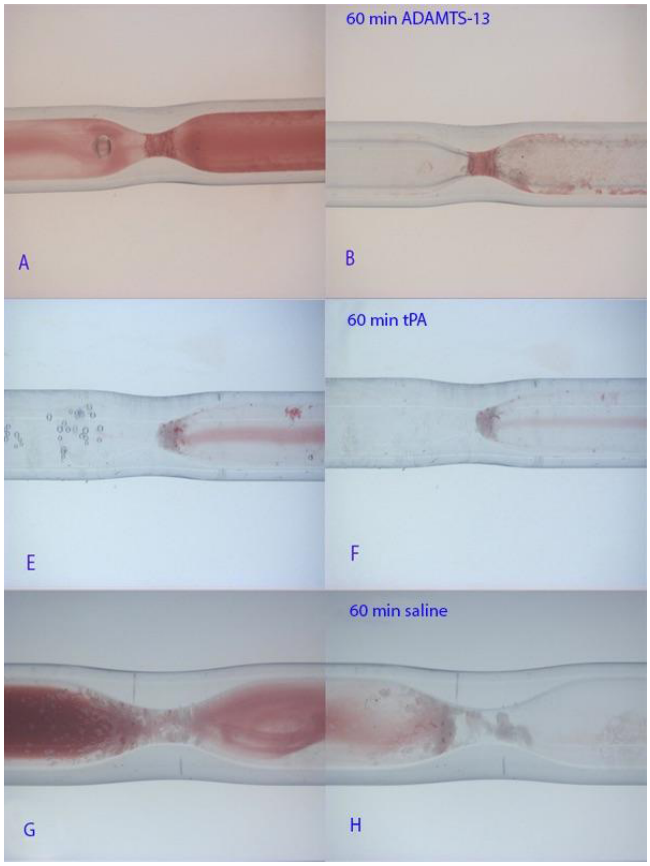

FIGURE 2 Platelet thrombus after A,B: perfusion of ADAMTS-13; E,F: perfusion of tPA; and G,H: perfusion of saline.

area by 25.2% ± 8.6%, and control by 7.4% ± 0.8%, and these were significantly different (p=0.008). ADAMTS-13 perfusion reduced thrombus surface area by 14.0% ± 12%, and abciximab by 13.9% ± 6.1%, which are significantly different than NAC (p<< 0.001 for both agents). ADAMTS-13, tPA, and saline post-perfusion thrombi are shown in Fig 2.

Conclusions: NAC demonstrated the ability to completely dissolve a platelet-rich thrombus under flow. Other agents such as tPA and ADAMSTS-13 demonstrated limited ability to achieve platelet thrombus dissolution. These results lead to a novel use for NAC as an effective thrombolytic agent against platelet-rich arterial occlusions.

PB 931 | Thrombolysis by rt-PA Combinated with Anticoagulant and Antiaggregant Molecules under Flow Conditions

S. Loyau[1], Y. Boulaftali[1], N. Ajzenberg[2], B. Ho Tin Noe[1], M. Jandrot-Perrus[1]

[1]*INSERM U 1148, LVTS, Paris, France,* [2]*HUPNVS, Hematology and immunology Department, Paris, France*

Background: We have developed a flow chamber model to study fibrinolysis under arterial flow conditions allowing to evaluate the thrombolytic efficacy of rt-PA.

Aims: To compare in whole blood the efficacy of rt-PA alone or in association with anticoagulant or antiplatelet drugs on thrombolysis.

Methods: Fluorescent fibrin-rich thrombi were obtained by perfusing recalcified citrated whole blood containing A467-coupled fibrinogen inside collagen- and tissue factor-coated flow chambers. Next step consisted in the perfusion of whole blood in which platelets were labeled by DIOC6 and supplemented with rt-PA (15 µg/mL) associated or not with anticoagulants [Heparin or Hirudin (20 U/mL), Argatroban
(1 µg/mL)], or with antiplatelets [Abciximab (3 µg/mL), Ticagrelor or a blocking anti-GPVI Fab (50 µg/mL)] over selected preformed fibrin rich thrombi. Real-time measurement of the fluorescence associated to fibrin and platelets permited quantifying fibrinolysis and platelet accumulation.

Results: A progressive lysis of the fibrin network was observed in the presence of rt-PA alone reaching up to 70% in 10 min as compared to the control in absence of rt-PA (p = 0.0026). However, and unexpectedly, a persistant accumulation of new platelets on the thombi was observed during lysis with an up to 500 fold increase in the platelet associated fluorescence. Combining anticoagulants with rt-PA did not modify the recruitment of platelets, but Hirudin increased the rate of fibrinolysis as well as its extent (+ 50%). All antiplatelet molecules combined to rt-PA, decreased the recruitment of platelets by up to 50%; additionaly the anti-GPVI Fab accelerated fibrinolysis.

Conclusions: These results strongly suggest that platelet accumulation by a thrombus during lysis could limit the therapeutic efficacy of rt-PA and evidence the relevance to associate rt-PA with antiplatelet molecules to optimize the thrombolysis efficacy.

PB 932 | Systematic Review and Meta-analysis of Treatments for Massive and Submassive Pulmonary Embolism

L.A. Castellucci[1], S. Gupta[2], M. Carrier[1]

[1]*University of Ottawa, Ottawa Hospital Research Institute, Ottawa, Canada,* [2]*University of Ottawa, Ottawa, Canada*

Background: The standard treatment for acute pulmonary embolism (PE) is anticoagulation. Patients with massive or submassive PE may require other interventions including systemic thrombolysis (STL) or catheter-directed thrombolysis (CDT). In the absence of randomized trials comparing STL and CDT, the benefits and harms of these therapies are unclear.

Aims: To evaluate the risks and benefits of STL and CDT in patients with massive and submassive PE.

Methods: Systematic literature search of MEDLINE, Embase, Cochrane Central Register of Controlled Trials was performed. Pooled proportions and 95% confidence intervals (CI) for recurrent PE, fatal PE, major bleeding, intracranial hemorrhage (ICH), and mortality were calculated.

Results: 62 studies were included for analysis: 28 evaluated STL; 19 used CDT; 5 used the Angiojet system; and 10 studies used ultrasound-assisted CDT.

TABLE 1 Pooled Proportions for Outcomes

Outcome % (95% CI)	Heparin Therapies (16 Trials)	All Systemic thrombolytics (28 Trials)	Catheter directed thrombolytics (19 Studies)	AngioJet System (5 Studies)	Ultrasound assisted CDT (10 Studies)
Recurrent PE	6.91 (3.06 - 12.16)	3.15 (1.95 - 4.63)	2.68 (1.33 - 4.47)	5.57 (1.84 - 11.15)	1.35 (0.46 - 2.68)
Fatal recurrent PE	2.28 (0.97 - 4.14)	0.63 (0.34 - 1.02)	1.54 (0.54 - 3.04)	5.57 (1.84 - 11.15)	1.16 (0.34 - 2.47)
Major Bleeding	4.90 (2.55 - 7.95)	9.74 (7.15 - 12.70)	5.46 (2.47 - 9.53)	11.26 (1.03 - 30.27)	4.56 (2.19 - 7.74)
ICH	0.48 (0.15 - 0.98)	1.17 (0.76 - 1.68)	1.29 (0.49 - 2.45)	2.44 (0.30 - 6.56)	0.61 (0.10 - 1.55)
Mortality	5.48 (3.60 - 7.73)	4.16 (3.21 - 5.23)	9.47 (5.95 - 13.70)	12.62 (5.32 - 22.45)	4.48 (1.80 - 8.29)

TABLE 2 Pooled Proportions for Outcomes according to Systemic Thrombolytic Agent

Outcome % (95% CI)	Low-dose t-PA (5 Trials)	Standard-dose t-PA (12 Trials)	Streptokinase (8 Trials)	Urokinase (8 Trials)	Tenecteplase (3 Trials)
Recurrent PE	2.16 (0.21 - 6.10)	3.45 (1.69 - 5.81)	4.31 (2.11 - 7.25)	3.65 (1.19 - 7.38)	1.75 (0.015 - 6.26)
Fatal recurrent PE	0 (0 - 1.94)	1.48 (0.58 - 2.80)	0.98 (0.13 - 2.62)	0.84 (0.26 - 1.74)	0 (0 - 0.50)
Major Bleeding	3.29 (0.57 - 8.13)	10.74 (5.92 - 16.77)	14.25 (5.38 - 26.45)	10.55 (5.91 - 16.34)	8.67 (4.08 - 14.78)
ICH	0 (0 - 2.02)	1.23 (0.44 - 2.49)	0 (0 - 2.15)	0.73 (0.21 - 1.57)	2.28 (1.23 - 3.66)
Mortality	2.54 (0.85 - 5.11)	4.70 (2.59 - 7.39)	4.54 (2.21 - 7.65)	5.48 (3.80 - 7.45)	2.44 (1.34- 3.85)

Recurrent PE rates were lowest with STL [3.15% (95% CI: 1.95-4.63%)] and ultrasound assisted CDT [1.35% (0.46-2.68%)] (Table 1). Major bleeding rates were highest in the STL treated group: 9.74% (7.15-12.70%); however, mortality in the STL group was lowest at 4.16% (3.21-5.23%). Rates of ICH were lowest in the heparin group [0.48% (0.15-0.98)] and ultrasound assisted CDT [0.61% (0.10-1.55%)].

Outcomes according to systemic thrombolytic agent used are provided in Table 2. Low-dose t-PA was associated with the lowest major bleeding rates [3.29% (95% CI: 0.57-8.13%)] and ICHs [0% (0-2.02%)]. Mortality rates were lowest in the low-dose t-PA [2.54% (0.85-5.11%)] and tenecteplase groups [2.44% (1.34-3.85%)].

Conclusions: In patients with massive or submassive PE, mortality rates are similar between STL and ultrasound-assisted CDT, and lower than other therapies. Major bleeding rates were lowest with heparins and CDT options, with the exception of the Angiojet device. Low-dose t-PA was associated with the safest risk profile. Randomized trials comparing STL and CDT are needed to determine the optimal therapies in patients with massive and submassive PE.

PB 933 | Structure and Function of Trypsin-loaded Fibrinolytic Liposomes

A. Tanka-Salamon[1], A. Bóta[2], A. Wacha[2], L. Szabó[2], J. Mihály[2], M. Lovas[1], K. Kolev[1]

[1]*Semmelweis University, Institute of Medical Biochemistry, Budapest, Hungary,* [2]*Research Centre for Natural Sciences, Hungarian Academy of Sciences, Institute of Materials and Environmental Chemistry, Budapest, Hungary*

Background: Protease encapsulation and its local release in thrombi by external targeting may contribute to the reduction of haemorrhagic complications of thrombolysis.

Aims: To prepare sterically stabilized trypsin-loaded liposomes (SSL_T) and characterize their structure and in vitro fibrinolytic efficiency.

Methods: Hydrogenated soybean phosphatidylcholine-based SSL_T was prepared and their structure was studied by transmission electron microscopy combined with freeze fracture (FF-TEM), Fourier transform infrared spectroscopy (FT-IR) and small angle X-ray scattering (SAXS). Fibrinolytic activity of SSL_T was examined at 45 and 37 or 24°C on fibrin or plasma clots under static conditions with turbidimetric assay and in a dynamic, permeation-driven lysis assay measuring the soluble protein content released from the permeated clots. The stability of the construct was monitored daily by measuring the activity of the encapsulated trypsin on a small peptide substrate.

Results: Trypsin is attached to the inner surface of vesicles (according to SAXS and FF-TEM) close to the lipid hydrophilic/hydrophobic interface (as revealed by FT-IR). According to the trypsin activity measurements, following an initial drop of 30% during the first 3 days, enzymatic activity of the SSL_T preparation remained unchanged for more than one week. Thermosensitivity of SSL_T was observed by enhanced fibrinolysis at 45˚C:

(i) time to reduce the maximal turbidity to 20% decreased by 8.6% compared to 37˚C and

(ii) the soluble fibrin degradation products in the early stage of the permeation lysis assay was 7-fold higher than at 24˚C. SSL_T exerted its fibrinolytic action on fibrin clots under both static and dynamic conditions, whereas plasma clot dissolution was observed only in the permeation-driven assay.

Conclusions: The improved fibrinolytic efficiency of SSL_T under dynamic conditions suggests that they may serve as a novel therapeutic candidate for dissolution of intravascular thrombi, which are always exposed to permeation forces.

PB 934 | Changes in Treatments and Outcomes after Creation of a Pulmonary Embolism Response Team (PERT)

R. Rosovsky[1], Y. Chang[2], K. Rosenfield[3], R. Channick[4], M. Jaff[5], I. Weinberg[3], T. Sundt[6], A. Witkin[4], J. Rodriguez-Lopez[4], B. Parry[7], S. Harshbarger[7], P. Hariharan[7], C. Kabrhel[7]

[1]Massachusetts General Hospital, Division of Hematology and Oncology, Department of Medicine, Boston, United States, [2]Massachusetts General Hospital, Division of Internal Medicine, Boston, United States, [3]Massachusetts General Hospital, Division of Cardiology, Department of Medicine, Boston, United States, [4]Massachusetts General Hospital, Division of Pulmonary and Critical Care, Department of Medicine, Boston, United States, [5]Newton Wellesley Hospital, Department of Medicine, Newton, United States, [6]Massachusetts General Hospital, Division of Cardiac Surgery, Department of Surgery, Boston, United States, [7]Massachusetts General Hospital, Center for Vascular Emergencies, Department of Emergency Medicine, Boston, United States

Background: Multidisciplinary pulmonary embolism response teams (PERTs) are being implemented to improve care of patients (pts) with life-threatening PE.

Aims: To determine how creation of PERT affects treatment and outcomes of PE pts.

Methods: Study compared PE patients before and after implementation of PERT. Consecutive sample of ER patients with PE and one high-risk feature were included in pre-PERT group. Activations from ED were included in post-PERT group. Primary outcomes included types of treatment, major bleeding and 30-day mortality. Means were used to summarize continuous variables; percentages summarized categorical variables. T-tests, Chi-square tests and logistic regression compared outcomes. To further control for differences, matched subgroups of pts pre- and post-PERT were analyzed. Data were divided into mutually exclusive six-month time periods and an interrupted time-series design examined slopes and change points pre- and post-PERT. SAS® was used for analysis and two-sided p-value < 0.05 was considered significant.

Results: Total of 212 pre-PERT pts and 228 post-PERT pts were analyzed. Patient demographics were generally similar, though pre-PERT, PE were more likely to be low-risk (37% vs. 19%) while post-PERT, PE were more likely to be submassive (32% vs. 49%), p< 0.0001. After adjusting for severity, more pts underwent catheter directed thrombolysis (1% vs. 14%, p=< 0.0001) post-PERT and there was trend towards use of any advanced therapy post-PERT (9% vs. 19%, p=0.011). Results of matched analysis were similar. There were no differences in major bleeding or mortality pre- and post-PERT. However, the interrupted time-series analysis suggested a downtrend in both bleeding and death post-PERT.

Conclusions: Creation of PERT affects treatment and outcomes of pts with life-threatening PE. Advanced therapies, particularly catheter-directed thrombolysis, increased after creation of PERT, especially in pts with submassive PE. In contrast, PERT appears to be associated with lower bleeding and mortality.

PB 935 | Comparing Emergency Department Patients to Inpatients Receiving a Pulmonary Embolism Response Team (PERT) Activation

E. Deadmon[1], N. Giordano[1], K. Rosenfield[2,3], R. Rosovsky[3,4], B. Parry[1], R. Al-Bawardi[2,3], C. Kabrhel[1,3]

[1]Massachusetts General Hospital, Center for Vascular Emergencies, Department of Emergency Medicine, Boston, United States, [2]Massachusetts General Hospital, Vascular Medicine, Boston, United States, [3]Harvard Medical School, Boston, United States, [4]Massachusetts General Hospital, Hematology, Boston, United States

Background: Pulmonary Embolism Response Teams (PERTs) that provide multidisciplinary care to patients with severe PE are increasingly common. Most PERT activations originate from the Emergency Department (ED).

Aims: To describe how PERT activations originating from the ED differ from those originating from inpatient floors or intensive care units (ICU).

Methods: We enrolled a consecutive cohort of patients for whom PERT was activated at an urban teaching hospital. We compared PERT activations based on whether the activation originated from the ED, ICU or an inpatient floor. We compared groups in terms of the proportion of PERT activations that occurred during day, evening or weekend hours, and the proportion of confirmed PE. We compared PE severity, treatment and outcomes across locations. We tested differences using Fisher exact tests, with a two-tailed p-value < .05 considered significant.

Results: We enrolled 565 patients; including 449 (79%) with confirmed PE. The mean age was 61±16 years, and 241 (54%) were male. Activations from the ED (n=286, 89%) or floor (n=100, 75%) were more likely to be for confirmed PE than activations from the ICU (n=63, 58%), p< 0.0001. There were no statistical differences in the time of day of PERT activation based on location. Most activations for massive PE originated from the ICU (n=41, 65.1%), followed by the ED (n=82, 28.7%) and inpatient floors (n=22, 22.0%), p< 0.0001. Most activations from the ED (n=157, 54.9%) and floors (n=55, 55.0%) were for submassive PE. The use of thrombolysis or thrombectomy was most common among ICU patients (n=18, 31.6%), and more common among ED patients (n=52, 18.4%) than floor patients (n=6, 6.0%). Mortality and major bleeding events were most common among ICU patients, and similar among ED and floor patients.

Conclusions: PERT activations from different clinical locations differ in terms of patient presentation, PE confirmation, treatments and outcomes. PERTs should be designed and prepared to support the different needs of each clinical area.

PB 936 | Indications and Results of Treatment with Ultrasound Assisted Cathether Thrombolysis in Patients with Pulmonary Embolism

S. Obradovic[1], B. Subotic[1], B. Dzudovic[1], M. Stavric[2], V. Subota[2], N. Antonijevic[3]

[1]Military Medical Academy, School of Medicine, University of Defense, Clinic of Emergency Medicine, Belgrade, Serbia, [2]Military Medical Academy, School of Medicine, University of Defense, Institute of Biochemistry, Belgrade, Serbia, [3]Clinical Center of Serbia, Clinic of Cardiology, Belgrade, Serbia

Background: The precise role of ultrasound assisted thrombolysis (USAT) in the treatment of pulmonary embolism (PE) is not defined.
Aims: To investigate safety and efficacy of USAT in special subgroups of PE patients.
Methods: During the period of 3 years, 163 patients with PE were treated in the tertiary emergency clinic. Among 75 patients categorized as intermediate-risk, 17 patients were eligible for USAT-EkoSonic endovascular system (age 58±12 y, 14 men) and 58 patients (age 59±16 y, 30 men) were treated with slow systemic thrombolysis. The indications for USAT were: 2 patients had severe refractory pneumonia in the irrigation of the occluded pulmonary artery, 10 had high risk for bleeding (recent major surgery or major bleeding) and 5 were in NYHA-3 stage of heart failure (HF) between 7-45 days from the onset of PE symptoms. All of them received infusion of 2 mg/h tissue plasminogen activator (t-PA) via EKOS with the total dose of 50 mg. Intrahospital mortality, major bleeding, right ventricle dysfunction improvement measured by the change of right ventricle systolic pressure (RSVP) by echocardiography and duration of hospitalization were compared between two groups.
Results: The inserting of EkoSonic endovascular device was successful in all patients without complications. Intrahospital mortality were 12.1% vs 0% and major bleeding were 13.8% vs 11.8%, in systemic thrombolysis and USAT group, respectively. The median duration of hospitalisation was 8 days for both groups. There were no significant differences between admission (53.7 vs 58.4 mmHg, p=0.39) and discharge (28.3 vs 36.7mmHg, p=0.08) RVSP between two groups. Only two patients with the duration of PE symptoms between 30-45 days treated with USAT because of the NYHA-3 stage HF had no significant reduction of RVSP during follow-up.
Conclusions: USAT therapy is efficious and safe in intermediate-high risk PE patients with high risk for bleeding, severe pneumonia behind the occluded artery and less efficious in patients with longer duration of symptoms.

PB 937 | In vitro Thrombolytic Action of New Fibrinolytic Enzyme Complexes - Strictoliase and Lilasyn

E.I. Kornienko, A.A. Bobrovskaya , N.S. Fokichev, A.A. Osmolovskiy, T.S. Sharkova

Lomonosov Moscow State University, Biology, Moscow, Russian Federation

Background: Modern medicine has made its choice in a favor of thrombolytic agents - plasminogen activators. Such preparations implement the lysis of blood clots by activating the patient's own system of thrombolysis and greatly reduce the number of conventional medical treatment complications: bleeding and rethrombosis. A very promising source for finding new therapeutic thrombolytic agents are new plasminogen activating proteinases, produced by microspore fungi.
Aims: Studying the properties of thrombolytic enzyme complexes strictoliase and lilasyn with fibrinolytic activity.
Methods: Strictoliase and lilasyn were obtained from the culture fluid of *Sarocladium strictum* and *Purpureocillum lilacinum*, respectively. Fibrinolytic activity was determined by Atrup- Müllertz method, destruction of a thrombus *in vitro*, and with the chromogenic peptide substrates (CPS).
Results: The test on the fibrin plates demonstrated the presence of fibrinolytic activity in both studied preparations. For the strictoliase the value of the fibrinolytic activity was 651 U/ml and plasminogen activator activity 674,3 U/ml, but for the lilasyn these values were significantly lower and were 36,1 and 9,4 U/ml respectively. Nevertheless, both preparations demonstrated the high possibility to thrombolysis. The adding of the preparation of a single active purified protein from the lilasyn complex resulted in the thrombus weight reduction of 25% after 30-minutes incubation at 37°C, %94 after 45 minutes and whole reduction after 1 hour. The thrombolytic activity of the four purified protein fractions of the strictoliase preparation after 90 minutes was 57.1 ,36.8 ,25.6 ,38 %, respectively. Activity determination with CPS showed that, strictolyase has urokinase activity and lilasyn has tissue plasminogen activator-like activity.
Conclusions: Thus, was demonstrated the trombolytic and plasminogen activator activity of the obtained enzyme complexes, thanks to which may be possible their use for treatment of thrombophlebitis and phlebothrombosis.

PB 938 | A Case Series of Low Dose Alteplase for Submassive Pulmonary Embolism (PE)

J. Lozier[1], A. Suffredini[2], D. Rosing[3], J. Elinoff[2], R. Danner[2], R. Sherry[4], A. Metwalli[5], R. Chang[6]

[1]NIH Clinical Center, Department of Laboratory Medicine, Bethesda, United States, [2]NIH Clinical Center, Department of Critical Care Medicine, Bethesda, United States, [3]National Heart Lung Blood Institute, Department of Cardiology, Bethesda, United States, [4]National Cancer Institute, Center for Cancer Research, Surgery Branch, Bethesda, United States, [5]National Cancer Institute, Center for Cancer Research, Urologic Oncology Branch, Bethesda, United States, [6]NIH Clinical Center, Department of Radiologic Diagnostics, Bethesda, United States

Background: Anticoagulation is standard therapy for PE. Fibrinolytic therapy with alteplase is reserved for massive PE with hemodynamic collapse, by administering 100 mg over < 1 hr (AHA/AT9 grade 2C recommendations). Alteplase doses of 50 mg to 100 mg have been studied for submassive PE, but the benefits of clot lysis are offset by increased bleeding risk. We have previously shown that lysis of massive deep venous thrombi can be achieved with catheter-directed alteplase using daily doses of ≤10 mg. We describe treatment of 9

TABLE 1 Clinical Summary of Patients Treated with Low Dose Alteplase for Submassive PE

Case	Alteplase Rx	Outcome
42 y/o with thymoma, s/p pneumonectomy	6 mg/6 hr, daily, x 2	Filling defect of R PA improved on CTA at 72 hr.
86 y/o with heparin-induced thrombocytopenia	6 mg/6 hr, daily, x 3	Improved perfusion RUL and LPIL on V/Q at 72 hr.
75 y/o with metastatic endometrial cancer	6 mg/6 hr, daily, x 2	Left PA and smaller clots improved on CTA at 72 hr.
41 y/o sickle cell anemia, chronic PE	6 mg/6 hr, daily, x 2	No improvement on CT at 72 hr.
46 y/o von Hippel Lindau s/p VP shunt surgery	2 mg each PA, then 6 mg/6 hr x 1	Improved RV function on echocardiogram at 24 hr.
78 y/o prostate cancer	2 mg each PA, then 6 mg/6 hr daily x 1; subsequent low dose tPA of leg DVT	Marked decrease right PA thrombus and decrease in L PA thrombus on CTA at 72 hr.
65 y/o with sickle cell anemia, chronic PE	6 mg/6 hr, daily, x 3	Bilateral decreased perfusion abnormalities on V/Q at 72 hr.
52 y/o with Cushing´s disease, s/p adrenalectomy	2 mg each PA, then 6 mg/6 hr x 1; subsequent low dose tPA of leg DVT	Improved RV function and decreased PA pressures on echocardiogram at 24 hr.
29 y/o s/p nephrectomy & retroperitoneal lymph node dissection for renal cancer	2 mg in R PA, then 4 mg/4 hr, x 1, then 6 mg/6 hrs x 1	Hemorrhage into operative field requiring re-exploration. Improved PA pressures and RV function on echocardiogram at 24 hr.

patients with submassive PE with low dose alteplase infused through central venous catheters.

Aims: To inform the design of randomized clinical trials to test the safety and efficacy of low dose alteplase for submassive PE.

Methods: Nine patients (29-86 yrs) enrolled in clinical research studies at the NIH Clinical Center under IRB-approved protocols were treated with one to three alteplase infusions (1 mg/hr for 6 hours daily) via central venous catheters; four were treated with 2 mg boluses of alteplase into the affected pulmonary arteries before the continuous infusion. All patients received concomitant anticoagulation.

Results: Eight patients had evidence of clot lysis within 72 hours by CT angiogram, V/Q scan and/or echocardiogram; one without immediate lysis had normalization of the CT angiogram after one month. One patient with recent abdominal surgery developed bleeding that required re-exploration.

Conclusions: Low dose (≤10 mg/day) alteplase may provide benefit compared with anticoagulation alone in the setting of submassive PE, particularly in patients that merit more aggressive therapy than anticoagulation alone. A randomized trial comparing anticoagulation with and without low dose alteplase could determine the relative risks and benefits. Patients with recent invasive procedures involving non-compressible structures should be excluded from any such trial.

PB 939 | Successful Thrombolysis of Huge Right Atrial Thrombus in a Patient with Primary Repair of Atrial Septal Defect

B. Shakerian[1], N. Razavi[2]

[1]*Shahrekord University of Medical Sciences, Cardiovascular Surgery, Shahrekord, Iran, Islamic Republic of,* [2]*Azad University of Shahrekord, Genetic, Shahrekord, Iran, Islamic Republic of*

Background: Surgical repair of an atrial septal defect (ASD) is a standard procedure with very low morbidity and mortality. Thrombus formation after patch-based repair, albeit a recognized complication, is very rare after the primary repair of an ASD.

Aims: Herein, we report a case of huge right atrial thrombous formation 6 months after repairs of ASD which treated nonsurgically.

Methods: A 23-year-old man underwent primary surgical closure of an ASD via a right lateral minithoracotomy. Defect was closed directly by 4-0 polypropylene. Six months postoperatively, however, although he was asymptomatic, routine follow-up echocardiography revealed a partially mobile mass (measuring 45 mm × 32 mm) in the right atrium. Intravenous infusion of low dose of Streptokinase (250,000 U bolus followed by 10,000 U/ hour) for 48 hours resulted in complete resolution of the thrombus. Heparin treatment was continued after fibrinolytic therapy. Follow-up at 3 month, 6 month, 1 year, 2 year, and 3 year after treatment of the clot demonstrated no evidence of intra-cardiac thrombus recurrence.

Results: Fibrinolysis is generally efficient but exposes the patient to risk of migration of the intra-cavity thrombus. Between surgery and thrombolysis, we tend to opt for thrombolytic therapy because of the association of surgery with high rates of morbidity and mortality.

Conclusions: We recommend periodic follow-up echocardiography and short-term (three months) of postoperative anticoagulation administration in patients undergoing primary ASD closure.

PB 940 | Thrombolytic Properties of Longolytin - Proteinase Complex from Impertfect Fungi Arthrobotrys Longa - in Dependence on its Fibrinolytic Activity

T. Sharkova, L. Podorolskaya, I. Pavlova

Moscow State University, Biolodical Faculty, Moscow, Russian Federation

Background: Proteinase complex from imperfect fungi Arthrobotrys longa -longolytin- possesses of high fibrinolytic and thrombolytic activities, has significant affinity to thrombi, and is studied as perspective thrombolytic preparation. Longolytin fibrinolytic activity (F.A.) is very sensitive to rather variable fungi cultivation conditions. It is noted, the preparations with more high plasminogen activator activity (P.A.A.) as part of its general F.A. have more essential thrombolytic activity.

Aims: The aim- retrospectively to evaluate thrombolytic properties of different longolytin preparations in dependence of its P.A.A. in model of thrombi dissolving in thrombosis of marginal rabbit's ear vein.

Methods: There were analyzed 3 groups of longolytin preparations with different P.A.A.:25-32%-9 rabbits, 39-42%-8 rabbits, 44-48%-13 rabbits, compared to control group, containing correspondingly 5-4-7 rabbits. There were compared velocity of thrombi dissolving by longolytin in dependence on different P.A.A. of its general F.A.

Results: Velocity of thrombi dissolution was greater in experimental thrombi - 0,04-0.28 mm^2/min, where thrombi dissolved by longolytin, compared to control 0,02-0,12 mm^2/min.with glycerol as dissolving material. It depended on thrombi size and was greater in large thrombi, compared to small ones as in experiment and in control. However large thrombi (20-40 mm^2) in most big experimental group with P.A.A. 44-48% were dissolved with velocity 0,05-0,34 mm^2/min, and in group wth P.A.A.25-32 % with velocity 0,02-0,17 mm^2/min. ($p< 0,05$) This difference was significantly less in control:0,03-0,16 mm^2/min. -P.A.A. 44-48%, 0,02-0,14 mm^2/min -P.A.A. 25-32%.

Conclusions: Longolytin thrombolytic activity depended on level of P.A.A. in structure of general F.A. of preparation. It is necessary to create such cultivation conditions, which stimulated greater level of P.A.A. in synthesized longolytin.

PB 941 | Sub-massive PE - A Role for Low Dose Thrombolysis?

M.P. Crowley[1], T. Mason[2], K.A. Breen[1], B.J. Hunt[1], N. Karunanithy[3], B. Lams[2], A. West[2]

[1]Guy's and St Thomas' NHS Foundation Trust, Thrombosis, London, United Kingdom, [2]Guys'and St Thomas' NHS Foundation Trust, Respiratory Medicine, London, United Kingdom, [3]Guy's and St Thomas' NHS Foundation Trust, Interventional Radiology, London, United Kingdom

Background: The use of thrombolysis in sub-massive PE is controversial (1). Studies to date have been heterogeneous, making it difficult to draw conclusions (2). The MOPETT trial (3) showed that an intermediate dose of t-PA was safe and effective and resulted in a significant reduction in pulmonary artery pressure but not in death and recurrent PE. The PEITHO study (4) found that fibrinolytic therapy reduced haemodynamic decompensation but increased the risk of major haemorrhage and stroke. The American College of Chest Physicians suggest consideration of systemic thrombolysis in selected patients with acute PE who deteriorate after starting anticoagulant therapy but have yet to develop hypotension and who have a low bleeding risk (5).

Aims: To review the outcomes of patients with sub-massive PE who presented to a tertiary referral centre.

Methods: A retrospective review of the records of patients between January 2014 and December 2016.

Results: 24 patients were included, their characteristic are shown in table 1. They underwent either low dose systemic thrombolytic therapy using t-PA (10mg in 1 minute followed by 40mg over 2 hours) - six patients or catheter-directed thrombolysis - nine patients, or standard therapy with close observation, following multidisciplinary review (respiratory/radiology/critical care/haematology). Indications for thrombolysis included progression on anticoagulation (6), large clot burden (5) and unwell at presentation (but not meeting criteria for massive PE) (4). The group that received thrombolytic therapy had more severe disease (higher BNP, echo features of pulmonary hypertension, higher PESI scores). No major bleeding was seen.

Conclusions: Low -dose thrombolysis is an option for a selected cohort of patients with sub-massive PE. It should be considered when a patient is significantly compromised by a PE or has progressed on anticoagulation, in a clinical setting where experienced clinicians are available to guide treatment.

TABLE 1 Characteristics of patients with sub-massive PE

Table 1. Characteristics of patients with sub-massive PE

	Sub-massive PEs thrombolysed	Sub-massive PEs not thrombolysed
N	15	9
Median (IQR) age in years	51 (43-67)	50 (46-70)
Provoked/Unprovoked	13/2	5/4
DVTs	5 /11 (4 had no doppler)	3/9
Baseline echo features of pulmonary hypertension	14/15	5/9
Right heart strain on CTPA	13/15 (2 had extensive clot burden but no right ventricular strain)	8/9 (1 had V/Q scan only – with extensive clot burden)
Median (IQR) BNP (ng/L)	2553 (672-4504) (14/15 had BNP measured)	410 (120-1746)
Median (IQR) Troponin (ng/L)	28 (17-93)	86 (45-131)
Median (IQR) lowest SBP (mmHg)	118 (95-121)	109.5 (106-113)
Median (IQR) PESI	102 (97-130)	75 (70-96.5)
Systemic thrombolysis/Catheter-directed thrombolysis	6/9	Not applicable
Median (IQR) Length of hospital Stay (days)	16 (6-22.5)	5 (5-9)
Median (IQR) Length of critical care admission (days)	5 (2-12)	0 (0-0)
Bleeding risk factors	3 (menorrhagia, pregnancy, recent surgery)	4 menorrhagia, pregnancy, recent fracture, recent surgery)
Complications of thrombolysis	5 (bleeding at puncture sites)	Not applicable
Deceased at time of data censure	4 (2 catheter directed, 2 systemic thrombolysis)	0

PB 942 | A Complex Non-invasive Assessment of the Effect of Hirudotherapy on Structural and Functional State of Vascular Bed

I. Pavlova[1,2], Pavlova I.B., Parfenov A.S.

[1]M.V. Lomonosov Moscow State University, Moscow, Russian Federation, [2]Lomonosov Moscow State University; Pirogov Russian National Research Medical University, Moscow, Russian Federation

Background: A successfully curable dysfunction of vascular endothelium is an initial stage of atherosclerotic vascular lesions that underlies the majority of cardiovascular diseases. The use of hirudotherapy (HT) was considered helpful in this case.

Aims: A non-invasive assessment of the HT effect on the various levels of vascular bed is topical, and it was the aim of the present work.

Methods: Patients with arterial hypertension, dysfunction in micro- and macrocirculation in endothelium and practically healthy people underwent a course HT (8 sessions). To this end, 7 leeches were stated to them once a week. The vasoactive function of vascular endothelium was measured using a certified device of «Angioscan-01» at various diagnostic regimes. A contour analysis of volume pulse waves parameters before and after the sublingual introduction of trinitroglycerol (0.5 mg) was performed. The state of artherial capillaries was observed using videocapillaroscopy (VC).

Results: The vasodilating effect of HT was partly preserved in time, and it increased with each session. The volume pulse waves parameters that are a function of the vasoactive NO-dependant endothelium activity equally differed from their pathologically changed initial values after a course of HT and a single dose of nitroglycerol. Those parameters approached (either increasing or reducing) the parameters characteristic of healthy people. The VC showed that the HT increased the number of functioning capillaries, improved the rate of blood circulation in them and increased the size of perifocal zone (vessel-tissue).

Conclusions: For the first time, using the non-invasive method of photoplethysmography, it was established in vivo and confirmed by VC that the course of HT reliably improved the values of structural and functional characteristics of various vascular bed levels in patients with cardiovascular diseases even making a few of those characteristics approach the normal values.

PB 1742 | FXIII and EACA Increase Thrombus Stability and Decrease Pulmonary Embolism in an in vivo Mouse Model of Venous Thromboembolism, but EACA Increases Thrombus Size

S.A. Shaya[1], J.I. Weitz[1,2,3], P.L. Gross[1,2]

[1]McMaster University and Thrombosis and Atherosclerosis Research Institute, Medical Sciences, Hamilton, Canada, [2]McMaster University and Thrombosis and Atherosclerosis Research Institute, Medicine, Hamilton, Canada, [3]McMaster University and Thrombosis and Atherosclerosis Research Institute, Biochemistry, Hamilton, Canada

Background: Clinical factors determine if a patient presents with deep vein thrombosis (DVT) or pulmonary embolism (PE). Thus, the mechanisms underlying DVT stability and the progression of DVT to PE are unknown. Anticoagulation is contraindicated in patients with DVT and severe bleeding. Inferior vena cava filters are used but are associated with morbidity. An ideal treatment would stabilize clots, minimize embolization and PE burden, without worsening bleeding. Using a mouse model of venous thromboembolism, we showed that thrombin-mediated factor XIII (FXIII) activation stabilizes DVT and limits PE.

Aims: Compare the effects of epsilon-aminocaproic acid (EACA) and FXIII supplementation on DVT stability and PE burden in this mouse model.

Methods: Platelets were labelled using Alexa Fluor 488 conjugated α-CD41 Fab fragments. DVT was induced in the femoral veins of C57BL/6 female mice by application of ferric chloride. Mice received intravenous saline, dalteparin (0.2 U/g), dabigatran (33 mg/g), or EACA (1 mg/g) alone, or FXIII (1 mg/kg) in combination with anticoagulants starting 12 minutes after thrombus formation. Using intravital videomicroscopy, the thrombus sizes, and the size and number of emboli dislodging from the thrombus were quantified for 2 hours. Lungs were then harvested, sectioned and stained to detect PE.

Results: FXIII has little effect on thrombus size, whereas EACA increased thrombus size by 3-fold. Both EACA and FXIII, given with saline, dalteparin, or dabigatran, reduced the total number of embolic events. As well, the number of large emboli were reduced following treatment with FXIII and EACA, and this correlated with reduced PE burden.

Conclusions: Both FXIII and EACA increase DVT stability and decrease PE burden in this model. However, EACA increases DVT size, whereas FXIII has little effect. Therefore, supplemental FXIII may be useful to stabilize DVT and reduce the risk of PE in patients who cannot be anticoagulated.

PB 1743 | Fibrinogen May Possess a Second Factor XIII Cross-linking Site for α2-AP in Fibrin

C. Duval[1], H. McPherson[1], K. Bridge[1], M. Domingues[2], R. Ajjan[1], V. Ridger[3], S. Connell[4], H. Philippou[1], R. Ariens[1]

[1]University of Leeds, Leeds Inst. of Cardiovascular & Metabolic Medicine, Leeds, United Kingdom, [2]University of Lisbon, Institute of Molecular Medicine, Lisbon, Portugal, [3]University of Sheffield, Dpt of Infection, Immunity & Cardiovascular Science, Sheffield, United Kingdom, [4]University of Leeds, Molecular and Nanoscale Physics Group, Leeds, United Kingdom

Background: The fibrin clot is subject to challenges such as shear stress from blood flow, and fibrinolysis. A key regulator of fibrinolysis is α_2-antiplasmin (α_2-AP), which is cross-linked to the fibrin α-chain by activated FXIII, at residue Lys303.

Aims: The aim of this study was to generate a fibrinogen (FGN) mutant lacking the cross-linking site for α_2-AP, and investigate the contribution of α_2-AP cross-linking to the inhibition of fibrinolysis.

Methods: FGN wild-type (WT) and mutant (αK303R) were produced in CHO cells and purified by IF-1 affinity chromatography. The effect

of αK303R and WT on clot formation and lysis in the absence and presence of α_2-AP was analysed by turbidity. A permeation set-up was also used to study clot lysis for both variants. Cross-linking of α_2-AP to αK303R and WT was investigated in a plate-based α_2-AP incorporation assay.

Results: In the absence of α_2-AP, the turbidity and lysis profiles were similar for both αK303R and WT, in both the absence and presence of FXIII, indicating that this mutation intrinsically does not affect fibrin polymerisation and lysis. When α_2-AP was added, the difference in time to half-lysis between presence and absence of FXIII was significantly reduced (-38.8%) for αK303R (33.5±4.5 min) compared to WT (54.7±3.3min). However, mutation of the α_2-AP cross-linking site did not completely abolish the effects of α_2-AP on clot lysis. Furthermore, in agreement with the effects on clot lysis, analysis of α_2-AP incorporation into fibrin showed decreased (but not completely abolished) cross-linking by 42.7±4.8% for αK303R compared to WT.

Conclusions: The lack of full inhibition of α_2-AP reduction in lysis and of α_2-AP incorporation onto fibrin indicate that FGN likely possesses a second FXIII cross-linking site for α_2-AP. Further studies are required to identify this potential second site and investigate its physiological relevance.

PB 1744 | Fibrin-derived Bß$_{15\text{-}42}$ Peptide Is a Gatekeeper of Thrombus Resolution

S. Chausheva[1], S. Sharma[1], A. Alimohammadi[1], P. Petzelbauer[2], I. Lang[1]

[1]Medical University of Vienna, Department of Cardiology, Vienna, Austria, [2]Medical University of Vienna, Department of Dermatology, Vienna, Austria

Background: Thrombus resolution is driven by leukocyte recruitment and thrombus angiogenesis. An effective inhibition of leukocyte transmigration *in vitro* is mediated by naturally occurring peptide Bß$_{15\text{-}42}$, which is a competitive inhibitor of the interaction between N-terminus of the fibrin beta chain and vascular endothelial cell cadherin (VE-cadherin). Bß$_{15\text{-}42}$ consists of 28 amino acids corresponding to the N-terminal sequence of the ß-chain of fibrin.

Aims: Fibrin clots from patients with chronic thromboembolic pulmonary hypertension (CTEPH) are resistant to fibrinolysis. Therefore, we explored the role of peptide Bß$_{15\text{-}42}$, a plasmin-generated cleavage product of fibrin in thrombus resolution.

Methods: Study groups of 8-12 weeks old C57BL/6 mice were injected i.p. over various time periods with Bß$_{15\text{-}42}$ or random peptide after thrombus had been induced by subtotal inferior vena cava (IVC) ligation. Thrombi from each animal were collected for further Immunohistochemistry (IHC) and RT-PCR analysis. Pulmonary endarterectomy (PEA) specimens were collected during surgery from randomly selected patients with CTEPH. Anti- Bß$_{15\text{-}42}$ immunoblots of human red (erythrocyte-rich) CTEPH thrombi and white (collagenous) CTEPH thrombi were compared.

Results: Bß$_{15\text{-}42}$ delayed thrombus resolution after IVC ligation. Thrombi of all treated groups were larger than controls. We observed a significant decrease of thrombus macrophages and microvessel density. Measurements of Bß$_{15\text{-}42}$ in red clot of human cases of chronic thrombosis indicated higher concentrations compared with controls.

Conclusions: Our data suggest that excess of the fibrin fragment Bß$_{15\text{-}42}$ misguides thrombus resolution, presumably by inhibiting VE-cadherin mediated leukocyte migration.

PB 1745 | Theoretical Model for Thrombin-FXIII-A2 Complex and the Effect of Ca^{2+} Ions on the Dynamic Behavior of FXIII-A$^{2'}$

I. Komáromi, G. Balogh, A. Fekete, L. Muszbek

University of Deberecen, Faculty of Medicine, Department of Laboratory Medicine, Division of Clinical Laboratory Science, Debrecen, Hungary

Background: The normal physiological activation of FXIII-A_2 requires the concerted action of thrombin and Ca^{2+} ions. Unfortunately, neither the structure of the FXIII-A_2:thrombin Michaelis complex nor the driving force of its formation are known and the effect of Ca^{2+} on the structure and on the dynamics of FXIII-A_2' (the proteolitically cleaved but still inactive FXIII-A_2) is only partially understood.

Aims: Our aim was to get deeper insight into the process of FXIII-A_2:thrombin complex formation and the effect of Ca^{2+} ions on the structure and stability of FXIII-A_2'.

Methods: In order to derive a theoretical model for the FXIII-A_2:thrombin complex, protein-protein docking experiments were performed. On the complex derived this way 1 ms molecular dynamics simulation was carried out with explicit solvent model. Simulations have also been carried out both on FXIII-A_2' and FXIII-A_2 in the presence and absence of Ca^{2+} ions, respectively.

Results: From the analysis of the molecular dynamics trajectory one can conclude that the electrostatic forces between the thrombin and the first β-barrel domain of FXIII-A play fundamental roles in the FXIII-A_2:thrombin Michaelis complex formation. Although the structure we obtained have similarity to the corresponding one derived from the X-ray experiments, remarkable differences can also be observed between them. Simulations predict that the thrombin can also accommodate the activation peptide (AP) fragment conformation, which exists in the non-cleaved FXIII-A_2. The simulations on FXIII-A_2' and FXIII-A_2 systems revealed that the presence of Ca^{2+} ions results in increased flexibility and weaker interaction between the A subunits of FXIII-A_2'. Sampling snapshots from the molecular dynamics trajectory allow the localization of Ca^{2+} binding sites on the surface of FXIII-A_2'.

Conclusions: In conclusion, the atomic details of the first events of FXIII-A_2 activation outlined above agree well with the few experimental data revealed so far, and provide valuable complementary information.

PB 1747 | Platelet and Plasma Factor XIII Levels after Replacement Therapy in Severe Congenital Factor XIII Deficiency: Is there a Role for Factor XIII Uptake by Megakaryocytes?

C. Radu[1], C. Bulato[1], E. Campello[1], F. Sartorello[1], E. Zanon[2], M. Milan[2], S. Gavasso[1], L. Spiezia[1], P. Simioni[1]

[1]*University of Padua, Department of Medicine, Padua, Italy,* [2]*University of Padua, Department of Cardiac, Thoracic and Vascular Sciences, Padua, Italy*

Background: Factor XIII (FXIII), the fibrin stabilizing factor, is present both in plasma and platelets. Megakaryocytes can synthesize FXIII but it is still unclear whether platelet FXIII may derive from endocytosis of exogenous FXIII by megakaryocytes.

Aims: To evaluate plasma and platelets FXIII levels in a patient with severe FXIII deficiency under replacement therapy with recombinant (r)FXIII. To investigate the possible *in vitro* uptake of FXIII by patient megakaryocytes.

Methods: Plasma and intraplatelets levels of FXIII were measured before and after therapy. Clot formation was evaluated by whole blood rotational thromboelastometry (ROTEM®). Synthesis and uptake of FXIII by megakaryocytes in culture were studied by immunofluorescence technique.

Results: Plasma FXIII activity and antigen levels were < 5% and < 1%, respectively. These values increased about 100% after administration of rFXIII. Subsequently, a progressive reduction of both levels up to 32% and 24%, respectively, were seen at day 13 after infusion. Platelet FXIII antigen levels were < 1% before therapy and reached 6% within 13 days after infusion.

INTEM and EXTEM assays before therapy, showed a prolonged clot formation time, reduced clot stability and early clot lysis. Normalization of ROTEM® parameters was seen after administration of rFXIII. Patient megakaryocytes were negative for the immunostaining with anti-FXIII antibody and became positive after the addition of FXIII to the culture medium.

Conclusions: Administration of rFXIII in severe FXIII deficient patients results in restoration of FXIII plasma levels and increased intraplatelet FXIII content. Coagulation profile can be monitored by ROTEM®. *In vitro* experiments on cultured patient megakaryocytes revealed that these cells, which were unable to synthesize FXIII, can endocytose exogenous FXIII and possibly produce FXIII-containing platelets, as shown with the *in vivo* data. The role of intraplatelet FXIII still remains to be fully elucidated.

PB 1748 | Investigating the Role that a Factor XIII Binding Site on Fibrinogen αC (233-425) Plays in Controlling Glutamine Substrate Specificity

M. Maurer[1], K. Mouapi[1], L. Wagner[2], C. Stephens[1]

[1]*University of Louisville, Chemistry Department, Louisville, United States,* [2]*ENSCM, Montpellier, France*

Background: Fibrinogen αC (233-425) contains three reactive glutamines (Q) that can be crosslinked by Factor XIIIa to reactive lysines (K) located on another fibrin αC molecule. Crosslinking of the αC region modifies fibrin clot structure by enhancing lateral aggregation and increasing fibrinolytic resistance. Fbg αC (233-425) also has a putative FXIII binding site (389-403) with E396 proposed to serve as the key interaction residue. Greater knowledge on the functional role of E396 within αC (389-403) will aid in better understanding what initiates and controls fibrin clot architecture.

Aims: This study was aimed at characterizing the ability of both FXIII A_2 and FXIII A_2B_2 to cross-link reactive glutamines (Q237, Q328 and Q366) in Fbg αC (233-425) to a lysine mimic. Studies were carried out with wild-type (WT) Fbg αC versus αC E396A. Results obtained would help assess if E396 influences FXIIIa substrate specificity and/or provides an anchoring site via FXIII B_2

Methods: A mass spectrometry assay was used to monitor crosslinking of reactive glutamines to a lysine mimic in αC (233-425) versus E396A variant. Assays were performed with FXIII A_2 or A_2B_2. The lysine mimic was glycine ethyl ester and its ^{15}N-labeled version was used in 2D ^{15}N-HSQC NMR studies. Assays were done in triplicate (+/- SD).

Results: The Q reactivity rankings for WT Fbg αC (233-425) and E396A were both Q237 >> Q366 ≥ Q328. Increasing FXIII concentration by 4-fold suggested Q366 could be more reactive than Q328. Reactivity of Q237 was slightly slower with FXIII A_2B_2 than with FXIIII A_2, but the overall Q rankings were still preserved for WT and E396A.

Conclusions: Glutamine reactivity rankings are the same for both WT and E396A Fbg αC (233-425). Fbg αC E396 is therefore not critical for supporting FXIIIa activity. Results also suggest FXIII A_2 and A_2B_2 do not need E396 as an anchoring site. Other residues of αC (389-403) or a nearby region may serve as a replacement for E396.

PB 1749 | Genetic and Clinical Epidemiology of Congenital Fibrinogen Disorders

A. Casini[1], M. Blondon[1], P. de Moerloose[1], M. Neerman-Arbez[2]

[1]*University Hospital Geneva, Division of Angiology and Haemostasis, Geneva, Switzerland,* [2]*University of Geneva Faculty of Medicine, Dep. of Genetic Medicine and Development, Geneva, Switzerland*

Background: Congenital fibrinogen disorders (CFDs) are rare conditions. While the molecular basis of these disorders is relatively well studied, for some world regions reports on the distribution of fibrinogen mutations and description of clinical phenotypes are scarce.

Aims: To report the distribution of fibrinogen mutations and clinical features according to the place of residence in a large cohort of CFD patients.

Methods: We conducted a retrospective study of all consecutive CFDs cases genotyped in our laboratory from 1996 to 2016. Demographic and clinical data at diagnosis were assessed by a standardised case report form.

Results: Among 303 mostly Caucasian (97%) CFDs patients, there were 81 afibrinogenemia (Afib), 59 hypofibrinogenemia (Hypo), 163 dysfibrinogenemia (Dysf) and 16 hypodysfibrinogenemia (HDysf). Mean age at diagnosis differed: 3.4, 22.1, 30.1 and 23.7 years for Afib, Hypo, Dysf and HDysf, respectively. At the time of genotyping, patients lived in Europe (83%), Asia (9.2%) or Africa (8%). FGA null mutations were highly prevalent in Afib patients (81.5%) and FGA or FGG missense mutations in Dysf (93%). Hotspot mutations were identified in patients from all continents. Almost all Afib patients had bled (98.8%) with umbilical (66.7%), muscle (40.7%), joint (29.6%) and cerebral (23.5%) bleeds described. Nearly half of Hypo, Dysf and HDysf also reported bleeding, including menorrhagia (32%) and post-surgery bleeding (32.3%). Thromboses were more frequent in qualitative diseases (19.6% Dysf and 31.3% HDysf) than in quantitative ones (8.6% Afib and 8.5% Hypo). In Afib the bleeding phenotype was similar between continents but thromboses appeared more frequent in Asia and Africa than in Europe.

Conclusions: Hotspot mutations leading to CFDs are frequent around the world. While bleeding phenotypes appear similar between different continents, thromboses in qualitative CFDs may be more frequent in Asia and Africa than in Europe. Different modalities of fibrinogen replacement may partially explain this finding.

PB 1750 | Calcium Binding Sites in Coagulation Factor XIII and Other Transglutaminases: Their Evolution, Diversity, Conservation and Functional Relevance

S. Singh[1], S.L.S. Swaminathan[1], C. Reinhart[2], C. Krettler[2], V. Ivaskevicius[1], J. Dodt[3], H. Philippou[4], J. Oldenburg[1], A. Biswas[1]

[1]*Institute of Experimental Haematology and Transfusion Medicine, University Clinic Bonn, Bonn, Germany,* [2]*Max Planck Institute for Biophysics, Frankfurt, Germany,* [3]*Paul Ehlrich Institute, Langen, Germany,* [4]*Leeds Institute of Cardiovascular and Metabolic Medicine LIGHT Laboratories, University of Leeds, Leeds, United Kingdom*

Background: Calcium binding proteins have typically been characterized as EF hand family of proteins because of shared conserved structural and sequence characteristics. The enzyme family of Transglutaminase which includes the coagulation Factor XIII (FXIII) also binds to calcium and this has important consequences on their activation process. However, they do not share any similarity with the EF hand proteins.

Aims: To characterize the evolution, conservation, functional diversity and relevance of FXIIIA calcium binding sites by using phylogenetic strategies, protein modeling, docking and molecular dynamic (MD) simulation, *in vitro* mutagenesis and ITC (Isothermal titration calorimetry).

Methods: Structure and sequence based structural phylogeny analysis was performed for the calcium binding sites on the TreeFam, Consurf server and with structural alignment tools embedded in VMD and YASARA. Docking of sodium and calcium were performed alongwith MD simulation at high salt concentrations on FXIII core domain structures to explain their supportive functions. Recombinant FXIIIA subunit was mutated for gain of/ loss of function mutations and expressed in Pichia based system as well as in *HEK293t* cells and expression products analyzed. We also performed ITC based titrations of FXIIIA subunit and heterotetramer under different salt concentrations.

Results: Calcium binding site residues are in general highly conserved. Mutation of these sites usually results in unstable protein indicating that these sites are critical to the native fold of the protein. These sites first evolved in Transglutaminase like cysteine proteases family of proteins as crucial to their functional activity. The calcium binding sites in Factor XIII might also bind with very low affinity to sodium which explains their combined effect during non-proteolytic activation.

Conclusions: Our studies demonstrate the functional importance of the calcium binding sites in not only Factor XIII but also other Transglutaminases.

PB 1751 | On-demand Treatment with Fibrinogen Concentrate in Acute Bleeding and for Surgery in Patients with Congenital Fibrinogen Deficiency

C. Ross[1], B. Madan[2], M. Karimi[3], T. Lissitchkov[4], B.A. Schwartz[5], S. Knaub[6], F. Peyvandi[7]

[1]*St. John's Medical College & Hospital, Bangalore, India,* [2]*Centre for Haemostasis & Thrombosis, Guy's & St Thomas' NHS Foundation Trust, London, United Kingdom,* [3]*Nemazee Hospital, Shiraz, Iran, Islamic Republic of,* [4]*SHAT Joan Pavel, Sofia, Bulgaria,* [5]*Octapharma US, Hoboken, United States,* [6]*Octapharma AG, Lachen, Switzerland,* [7]*Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Milan, Italy*

Background: Patients with congenital a- and hypofibrinogenemia experience severe bleeding episodes. Human fibrinogen concentrate (HFC) can correct the hemostatic defect and arrest bleeding in these patients. Octafibrin is a highly purified, plasma-derived, lyophilized, double virus-inactivated (using 2 dedicated virus inactivation/removal steps) HFC.

Aims: To investigate the efficacy of Octafibrin in this setting.

Methods: This was a prospective, open-label, multinational study in adult and adolescent a- or hypofibrinogenemic patients. Efficacy in treating bleeding events (BEs) was assessed using a 4-point objective scale completed by the investigator and adjudicated by an independent endpoint adjudication committee. The HFC effect was also assessed using thromboelastometry.

Results: This planned interim analysis comprises data of 13 patients (11 adult and 2 adolescent), of which 11 experienced a total of 23 minor BEs. The median (range) dose of HFC administered for BEs treatment was 58.8 mg/kg (33.9-101.7 mg/kg) per BE. The success rate (efficacy rating of excellent or good) for all BEs was 100% (90% CI: 0.88, 1.00) as adjudicated by the IDMEAC (all excellent). Maximum clot firmness (MCF) measured in plasma was also determined for the first infusions administered for BEs treatment. The mean (±SD) change in MCF from baseline (0 mm) to 1 hour after the first HFC infusion was 6.5 mm (±2.0) (95% CI: 5.65, 7.40; p< 0.0001). Four patients

underwent 4 surgeries (3 major, 1 minor). The post-operative success rate was 100% (90% CI: 0.5, 1.0). There were no related serious adverse events, no thromboembolic events, no allergic or severe hypersensitivity reactions, and no anti-fibrinogen antibodies that developed during the study.

Conclusions: This interim data showed 100% hemostatic efficacy in the treatment of bleeds and during perioperative prophylaxis and no drug related SAEs of this newly developed human fibrinogen concentrate in patients with congenital fibrinogen deficiency.

PB 1752 | Congenital FXIII Deficiency in Pakistan: An Update

M. Borhany[1], N. Fatima[1], M. Abid[1], T. Shamsi[1], V. Schroeder[2], H.P. Kohler[2,3]

[1]National Institute of Blood Disease and Bone Marrow Transplantation, Karachi, Pakistan, [2]University of Bern, Department of Clinical Research, Bern, Switzerland, [3]Tiefenau Hospital, Insel Gruppe, Department of Internal Medicine, Bern, Switzerland

Background: Factor XIII (FXIII) deficiency is a rare bleeding disorder (RBD) with an incidence of about one in 1-2.5 million and its incidence is higher in populations with consanguineous marriages.

Aims: The aim of this study was to characterize patients and relatives from fourteen families with suspected FXIII deficiency from Pakistan and to identify the clinical characteristics and underlying mutations

Methods: FXIII deficient patients were enrolled in this study. The patients' medical histories were recorded in a questionnaire. As a first indicator of FXIII deficiency, a 5M urea clot solubility test was used. Plasma FXIII A- and B-subunit antigen levels were determined by ELISA. FXIII activity was measured with an incorporation assay. Sequencing of all exons and intron/exon boundaries of F13A was performed.

Results: We analyzed 14 families in which 23 were severe FXIII deficient with FXIII level < 1%. 19 first-degree relatives with mean FXIII level 71.19 ±21.1 are asymptomatic. Each family had a history of consanguineous marriages except one. 50% had significant family history of bleeding. Age at first presentation was ranged from birth to 18 years. In these patients, we identified 8 missense mutations, 5 Splicing mutations and 2-nonsense mutations. Bleeding after injury (78%), delayed wound healing (70%), umbilical cord bleeding (57%), hematoma, bruises (39%), abortions and menorrhagia (38%), circumcision (35%) were the main clinical manifestations followed by gum bleeding (30%), joint bleeding (26%), melena (9%) and ear bleeding (5%) and epistaxis in (4%) of patients.

Conclusions: We have analyzed a cohort of 42 individuals from 14 families in which 23 were severe FXIII deficient (homozygous or compound heterozygous) and remaining were FXIII deficient carriers (heterozygous). We identified 12 mutations in these families leading to congenital FXIII deficiency. Moreover, early and appropriate diagnosis of FXIII deficiency should be made so that prophylaxis can be initiated immediately.

PB 1753 | Pharmacokinetics of Fibrinogen Concentrate and Efficacy in Treating Acute Bleeding in Children and Adolescent Patients with Congenital Fibrinogen Deficiency

M. Karimi[1], C. Ross[2], G.R. De Angulo[3], B.A. Schwartz[4], C. Solomon[5], F. Peyvandi[6]

[1]Nemazee Hospital, Shiraz, Iran, Islamic Republic of, [2]St. John's Medical College & Hospital, Bangalore, India, [3]Miami Children's Hospital Research Institute, Miami, United States, [4]Octapharma US, Hoboken, United States, [5]Octapharma AG, Lachen, Switzerland, [6]Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Milan, Italy

Background: Human fibrinogen concentrate (HFC) can correct the hemostatic defect and arrest bleeding in patients with congenital fibrinogen deficiency. Octafibrin is a highly purified, plasma-derived, lyophilized, double virus-inactivated (using 2 dedicated virus inactivation/removal steps) HFC.

Aims: To describe the pharmacokinetics (PK) and efficacy of Octafibrin in pediatric patients.

Methods: Data in patients aged < 18 years from two multinational, prospective, open-label studies in afibrinogenemia patients was summarized. The studies investigated PK, surrogate efficacy and safety (study FORMA-01) after infusion of 70 mg/kg HFC, and efficacy and safety in the on-demand treatment of bleeding episodes (BE) and surgical prophylaxis (study FORMA-02). The surrogate efficacy endpoint in FORMA-01 was thromboelastometric maximum clot firmness (MCF) in plasma. Efficacy in treating bleeding in FORMA-02 was assessed by a 4-point objective scale.

Results: Seven patients aged 12-17 years were included in the completed PK study and an interim analysis of the treatment study (5 and 2 patients, respectively). The PK data showed AUC_{norm} of 1.53±0.6 h·kg·g/L/mg, clearance of 0.68±0.18 mL/h/kg, $T_{½}$ of 72.8±14.5 h, and incremental in-vivo recovery (IVR) of 1.95±0.41 mg/dl/(mg/kg). The 1-hour MCF values were 9.5±1.7 mm, from 0 mm at baseline.

Two patients in FORMA-02 received treatment with HFC for BEs. In both patients, treatment efficacy was adjudicated as excellent.

There were no related serious adverse events (SAEs), thromboembolic events, allergic or severe hypersensitivity reactions, and no anti-fibrinogen antibodies developing during the studies.

Conclusions: This analysis presents data in patients aged < 18 years from two studies with fibrinogen concentrate in afibrinogenemia patients. The safety data showed no related SAEs. A favorable PK profile was observed in the 5 patients from the FORMA-01 study and excellent treatment efficacy in the 2 patients from the FORMA-02 study.

PB 1754 | Factor XIII in Tears and its Possible Role in Corneal Wound Healing

Z.Z. Orosz[1,2], Á. Szöőr[3], Z. Veréb[2], Z. Hassan[4], É. Katona[1], G. Vereb[3], A. Facskó[2], L. Muszbek[1]

[1]*University of Debrecen, Division of Clinical Laboratory Science, Department of Laboratory Medicine, Debrecen, Hungary,* [2]*University of Szeged, Department of Ophthalmology, Szeged, Hungary,* [3]*University of Debrecen, Department of Biophysics and Cell Biology, Debrecen, Hungary,* [4]*Orbident Health and Lasercenter, Debrecen, Hungary*

Background: We have reported the presence of factor XIII (FXIII) subunits in tears, but its function has not been explored.

Aims: The effect of FXIII was investigated on wound healing, in vitro on corneal epithelial cells and in vivo in tears of patients following corneal surgeries with different types of wound: phacoemulsification, penetrating keratoplasty (PKP) and photo-refractive keratectomy (PRK).

Methods: Scratch-wound assay, proliferation and migration assays were performed on immortalized corneal epithelial cells. Using a hypersensitive chemiluminescent ELISA method, developed in our laboratory, FXIII complex and subunits were detected in tears of patients before and after different surgical interventions on the cornea; post surgical angiogenesis and re-epithelization were observed.

Results: The addition of recombinant cellular FXIII (cFXIII, rFXIII-A_2) resulted in a concentration dependent faster healing of the scratch wound. rFXIII-A_2 promoted the proliferation of corneal epithelial cells, but no effect on migration was observed. After corneal surgeries FXIII complex and subunits concentrations increased in tears, then decreased reaching the normal interval at different times after the surgical intervention. After cataract surgery, FXIII concentrations correlated with the inflammation of the eye and the corneal edema. Lower FXIII concentrations associated with slower re-epithelisation of the corneal surface after PRK. Extremely high FXIII concentrations measured in a few cases after PKP was associated with neovascularization of normally avascular cornea.

Conclusions: FXIII accelerates corneal cell proliferation. Its presence in tear proteome has a beneficial effect on corneal re-epithelisation. which results in decreased period of complaints caused by the corneal erosion. FXIII might be considered as an additional therapy in the treatment of corneal erosions, but long exposition to high FXIII concentrations in tears might induce undesired angiogenesis of the cornea.

PB 1755 | A Role for Factor XIII in Clot Formation and Clot Contraction of Whole Blood

T. Plug[1], H.M. van Beusekom[2], R. van Bruggen[3], J.C.M. Meijers[1]

[1]*Sanquin Research, Plasma Proteins, Amsterdam, The Netherlands,* [2]*Erasmus MC, Cardiology, Rotterdam, The Netherlands,* [3]*Sanquin Research, Blood Cell Research, Amsterdam, The Netherlands*

Background: Coagulation factor XIIIa (FXIIIa) is a transglutaminase that stabilizes a clot via the formation of covalent bonds between fibrin strands and by crosslinking anti-fibrinolytic enzymes to the clot. FXIIIa does not induce visible changes in a fibrin clot as observed with scanning electron-microscopy (SEM). However, recently it was shown that clots formed from FXIII-deficient blood retained fewer red blood cells (RBCs) during contraction compared to control clots.

Aims: The aim of this study was to investigate the role of FXIIIa on clot formation and contraction in whole blood.

Methods: Citrated whole blood from healthy volunteers was clotted in the absence or presence of a transglutaminase inhibitor (T101). After contraction, the number of RBCs that were expelled from the clots and the clot mass was determined for each clot. Additionally, the contracted clots, formed in the absence or presence of T101, were visualized with SEM.

Results: Blood clots formed in the presence of T101 retained fewer RBCs during clot contraction and were significantly smaller than control clots. Electron-microscopy revealed that the contracted clots formed in the presence of T101 were encapsulated with a dense layer of fibrin. No RBCs were observable through this layer of fibrin, in contrast to control clots where RBCs were clearly visible. Additionally, only in control clots we observed fibrin branches on RBCs suggesting a direct interaction.

Conclusions: In the absence of FXIIIa, fewer RBCs were retained in a contracting clot. We hypothesize that with fewer RBCs to physically block further contraction, the clot contracts to a smaller size. The reduction of the clot volume and surface area may then lead to a concentration of fibrin fibers on the surface of the clot. This process then continues until the layer of fibrin reaches a density and pore size where RBCs cannot escape the clot anymore.

PB 1756 | Structural and Phylogenetic Analysis of Coagulation Factor XIII Explains its Uniqueness in the Transglutaminase Family

A. Biswas[1], D. Davray[2], S. Singh[1], V. Ivaskevicius[1], H. Philippou[3], J. Oldenburg[1]

[1]*Institute of Experimental Haematology and Transfusion Medicine, University Clinic Bonn, Bonn, Germany,* [2]*National Center for Cell Sciences, Pune, India,* [3]*Leeds Institute of Cardiovascular and Metabolic Medicine LIGHT Laboratories, University of Leeds, Leeds, United Kingdom*

Background: The coagulation factor XIII (FXIII) belongs to the Transglutaminase class of enzymes. While it shares a number of biochemical and biophysical properties with the other orthologues and paralogues of this family, it also possesses certain characteristics which make it a structurally and functionally unique enzyme in this family.

Aims: To use structural/sequence derived phylogenetic tools to trace the structural and functional evolution of FXIII.

Methods: Structural phylogeny was traced using reported PDB structures under the search term “Transglutaminase” (FXIIIA subunit) and “Sushi domain” (FXIIIB Subunit) in the SCOP database. For proteins/domains where no structure was available, they were modeled on the ITASSER server. Structural conservation measures were generated on

the Multiseq. Phylogeny based analysis was done based on maximum-likelihood on the MEGA6 platform and MrBayes 3.1 for nucleotide sequences. Phylogenetic trees for amino acid sequences were directly downloaded from TreeFam database. Phylogenetic measures like molecular clock, substitution rates etc. were evaluated on the MEGA6 platform for all trees and alignments.

Results: Approximately 526 sequences from 91 species relevant for A subunit and 230 sequences from 87 species for the B subunit with a taxonomic distribution limited to Metazoans were analyzed for sequence conservation. Around 60 PDB files relevant for the A subunit and 84 PDB files for the B subunit were analyzed for structural conservation.

Conclusions: The A and B subunits co-evolved simultaneously approximately 500 million years back in Coelacanths from TGM1 and CFH respectively. Characteristic structural features like activation peptide, dimeric/tetrameric interfaces, catalytic triad, calcium binding sites, surface recognition residues of A and B subunit are associated with residues that show inter/intra-clade variability (responsible for protein-protein interaction) and also highly conserved residues(functionally relevant).

PB 1757 | *In silico* Analysis of Extended Promoter Regions of *F13A1* and *F13B* Genes Indicates Putative Sites Might Underlie Regulatory Variation in Factor XIII Levels

M.A. Jamil[1], S. Singh[1], V. Ivaskevicius[1], J. Dodt[2], H. Philippou[3], J. Oldenburg[1], A. Biswas[1]

[1]*Institute of Experimental Haematology and Transfusion Medicine, University Clinic Bonn, Bonn, Germany,* [2]*Paul Ehlrich Institute, Langen, Germany,* [3]*Leeds Institute of Cardiovascular and Metabolic Medicine LIGHT Laboratories, University of Leeds, Leeds, United Kingdom*

Background: Coagulation Factor XIII (FXIII) plasma levels show almost 3 fold variability (50-150%) in the general population. The variability can be attributed to genetic or non-genetic (age/sex) reasons. The 5´ untranslated region (UTR) of *F13A1* and *F13B* genes have not been elaborately investigated so far to detect its contribution to plasma FXIII level variability.

Aims: To *in silico* screen the 5´ UTR of *F13A1* and *F13B* genes in order to define putative regulatory genetic parameters governing FXIII levels.

Methods: The 5´ UTR of *F13A1* and *F13B* gene upstream of the transcription start site (till 5000 bp) was downloaded from ensemble database. The downloaded sequences were screened on the TRANSFAC platform to generate a list of putative regulatory transcription factor matrices corresponding to these regions. Similarly a list of polymorphisms and CpG sequences occurring in these regions were extracted by indicating the specific genomic locus on the dbSNP database. The data was combined and analyzed for relevant overlap.

Results: A total of 246 and 291 SNPs were located in the regions corresponding to *F13A1* and *F13B* genes respectively. Fifty and 44 CpG´s were found distributed across *F13A1* and *F13B* regions respectively. Fifty nine (130 binding sites) and 47 (143 binding sites) transcription factor (TF) matrices were predicted to bind in different parts of *F13A1* and *F13B* regions respectively. Amongst these TF matrices, 31 TF matrices were common to both genes. Fifty eight of the 130 *F13A1* and 32 of 143 *F13B* binding sites were located on reported variants many of them deletions and insertions. Twenty seven of *F13A1* and 24 of *F13B* CpG´s were also located on reported variants.

Conclusions: A high density of variability in this region is an indicator that it might be associated with the high level of variability in FXIII levels that is observed and reported from the general population. Common transcription factors between the two genes indicate regulatory crosstalk.

PB 1758 | Fibrinogen Caracas IX a Novel Fibrinogen Mutation: *FGA* g. 3057 C>T (p. 104 Arg>Cys) Impair Fibrinogen Secretion

R. Marchi[1], M. Linares[1], H. Rojas[2], A. Ruiz-Sáez[3], M. Meyer[4], S. Brennan[5]

[1]*Instituto Venezolano de Investigaciones Científicas, Medicina Experimental, Caracas, Venezuela,* [2]*Universidad Central de Venezuela, Instituto de Inmunología, Caracas, Venezuela,* [3]*Banco Municipal de Sangre del Distrito Capital, Caracas, Venezuela,* [4]*University of Applied Sciences, Medical Engineering and Biotechnology, Jena, Germany,* [5]*University of Otago, Molecular Pathology Laboratory, Christchurch, New Zealand*

Background: Abnormal fibrinogens can be caused by clinically silent hereditary mutations. A new case was detected accidentally in an 11 year-old girl when routine pre-operative coagulation tests were performed for nasal turbinate surgery.

Aims: To characterize a new abnormal fibrinogen.

Methods: The fibrinogen genes FGA, FGG and FGB were sequenced using standard protocols. The kinetic of fibrin formation was followed by turbidity at 350 nm. Purified fibrinogen was degraded with plasmin and the degradation products analyzed by SDS/PAGE. The formation of fibrinogen-albumin complexes was analyzed by immunoblotting. Fibrin structure was observed in a Nikon Eclipse TE 2000-U laser microscope. The secretion of the variant protein was analyzed directly by reverse phase-electrospray time of flight-mass spectrometry (TOF-MS).

Results: DNA sequencing revealed a novel heterozygous g. 3057 C>T mutation in the *FGA* that causes a p. 104 Arg>Cys substitution, in the proband and her father. Interestingly, the father also had the Aα Thr312Ala fibrinogen polymorphism. Both patients were asymptomatic with a mild prolonged thrombin time in the proband (+2.5 s), and normal functional fibrinogen concentration. The proband´s plasma fibrinogen polymerization was almost normal, with a 12% decrease in the final turbidity. However, the father´s fibrin formation had a remarkable diminished slope and final turbidity (2.5x and 40%, respectively). Aα 104 Arg is located in the coiled-coil region of the molecule and is cleaved by plasmin. However, the father´s fibrinogen

plasmin degradation was normal. Although the exchanged Cys introduces an unpaired -SH, immunoblotting showed no fibrinogen-albumin complexes. Furthermore, the plasma clot structure observed by confocal microscopy appeared normal. TOF-MS revealed that only 4% of the circulating fibrinogen molecules contained the Aα 104Cys chain.

Conclusions: The mutation Aα 104 Arg>Cys is barely expressed in circulation and this could account for the patients´ clinical picture.

PB 1759 | Effect of Mutations in the Fibrinogen $\alpha R_{95}G_{96}D_{97}$ Sequence on Clot Structure and on the Interaction of Fibrinogen with Red Blood Cells

A. Sabban[1], C. Duval[1], A.F. Guedes[2], H. McPherson[1], F. Macrae[1], S. Saha[1], R. Ajjan[1], N.C. Santos[2], R.A.S. Ariens[1]

[1]*University of Leeds, Thrombosis and Tissue Repair Group, Division of Cardiovascular and Diabetes Research, Leeds Institute of Cardiovascular and Metabolic Medicine, Leeds, United Kingdom,* [2]*Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal*

Background: Recent data suggest a role for red blood cells (RBCs) in haemostasis and thrombosis, driven through interactions of RBCs with the clot. RBCs are shaped into polyhedrocytes in the clot, RBC retention in the clot is dependent on FXIII, and fibrinogen has been reported to bind to RBCs via $\alpha_V\beta_3$. However, the binding site for RBCs on fibrinogen is unknown.

Aims: The aim of this study is to investigate the role of the fibrinogen α-chain $R_{95}G_{96}D_{97}$ sequence, which is located in the coiled coil region, in clot structure and binding of fibrinogen to RBCs.

Methods: Three mutations in and near the RGD sequence were produced: R95Q, D97N and F98I, the latter was previously reported in a patient with recurrent miscarriage. These mutations were stably transfected into βγ-CHO cells, expressed in roller bottles and purified. The proteins were analysed by SDS-PAGE and CD-spectra for their basic structure/function compared to wild type. A plate binding assay was developed to study the binding between RBCs and fibrinogen. Turbidity and confocal microscopy was used to study the effect of the mutations on clot structure.

Results: SDS-PAGE analysis showed high integrity and purity of the proteins, but the mobility of the α-chains appeared affected, indicating differences in polypeptide folding for all mutations. CD spectra confirmed minor differences in α-helical content for each mutation. Turbidity analysis showed reduced maximum absorbency for each mutation compared to the wild type, indicative of thinner fibres. Confocal microscopy images showed thinner, shorter and denser fibres in all mutations to a different extent. RBC binding was not affected by any of the mutations.

Conclusions: Mutations in the fibrinogen $\alpha R_{95}G_{96}D_{97}$ sequence influence fibrin formation and clot structure but do not change RBC binding. Further studies are required to locate the RBC binding site on fibrinogen.

PB 1760 | Evidence for the Presence of Cross-beta Structures in Fibrin Clots

S. Talens, F.W.G. Leebeek, D.C. Rijken

Erasmus University Medical Center Rotterdam, Hematology, Rotterdam, The Netherlands

Background: Amyloids are insoluble fibrillary assemblies that contain beta-sheets organized in a characteristic cross-beta structure. Preliminary data in literature suggests that fibrin contains similar cross-beta structures. However, these studies have not been experimentally described.

Aims: The aim of this study was to detect cross-beta structures in fibrin clots by using thioflavin T (ThT), a specific dye for amyloid-like structures.

Methods: Fibrin clots were prepared by incubating fibrinogen (3 mg/ml), ThT (25 μM) and bovine serum albumin (BSA, 0-60 mg/ml) with thrombin (1 NIH U/ml) and calcium (7.5 mM) to induce coagulation. The fluorescence of the cross-beta structure-bound ThT was measured with excitation at 425 nm and emission at 485 nm using a plate reader. Turbidity of the clots was measured at 405 nm.

Results: The purified fibrinogen and BSA preparations that were used in these experiments showed binding of ThT, suggesting that they contained some denatured protein. However, upon coagulation of fibrinogen ThT binding increased in time, in parallel with the turbidity of the clots. This indicated that clot formation was associated with the formation of cross-beta structures. In the absence of BSA the increase of ThT binding was small, but in the presence of 30 - 60 mg/ml BSA the increase was significant, indicating that BSA promoted the cross-beta structures.

Conclusions: Thioflavin T binding indicates that fibrin clot formation is associated with an increase in cross-beta structures. The promoting effect of albumin suggests that cross-beta structures are involved in the lateral aggregation of fibrin protofibrils.

PB 1761 | Prevalence of Mild Factor XIII Deficiency Phenotype: Preliminary Results of a WFH Sponsored CRGP Study

A. Biswas[1], S. Singh[1], N. Mir-Montazeri[1], I.P. Claus[1], V. Ivaskevicius[1], E. Heathershaw[2], H. Philippou[2], P. Volkers[3], J. Dodt[3], J. Oldenburg[1]

[1]*Institute of Experimental Haematology and Transfusion Medicine, University Clinic Bonn, Bonn, Germany,* [2]*Leeds Institute of Cardiovascular and Metabolic Medicine LIGHT Laboratories, University of Leeds, Leeds, United Kingdom,* [3]*Paul Ehlrich Institute, Langen, Germany*

Background: Individuals carrying the mild form of Factor XIII deficiency (FXIII) (FXIII levels in the range of 20-60%) are asymptomatic unless exposed to some kind of a trauma. This is the reason the accurate prevalence of this disorder is not known.

Aims: Under the WFH sponsored CRGP grant, we aim to screen a minimum of 1000 apparently healthy controls for their FXIII levels and their *F13A1* / *F13B* genotypes.

Methods: Peripheral blood samples are being collected from apparently healthy controls and separated into plasma and cellular component by centrifuging. Plasma samples will be evaluated for FXIII activity using photochemical and incorporation assays. The plasma samples are also being tested for FXIIIA and B subunit antigen levels as well as the $FXIIIA_2B_2$ hetero-teramer antigenic levels. Plasma samples are also being evaluated for alpha 2-antiplasmin incorporation assay and FXIIIa generation assay. In individuals detected for mild FXIII deficiency, the DNA is being extracted and sequenced to detect potential variants associated with this deficiency.

Results: At the time of submission of this abstract 360 apparently healthy controls had been collected. Amongst them 200 have been analyzed by FXIII photometric assay so far. They showed activity levels between 59.5-156%. One sample corresponded to mild FXIII deficiency level i.e. 59.5%. A total of 132 samples had also been analyzed by FXIIIa generation assay so far. The FXIII activation rates in These samples range between 26.3-87.0 (ΔRFU/Δt). The sample with mild FXIII deficiency showed an activation curve significantly different than the samples from the rest of the cohort.

Conclusions: Mild FXIII deficiency appears to have a prevalence of 1 in 200 from the currently tested cohort. FXIIIa generation assay could be useful in detecting mild FXIII deficiency. However, final conclusions can be made only after gene sequencing is done and collection as well screening is completed for all 1000 samples.

PB 1762 | Development of Fibrinogen Formulation with High Resistance to Thermal Stress

J. Son[1], M. Yoo[1], J. Kim[2], J. Seol[2], J. Choi[1]

[1]Greencross, Research Center, Formulation Team, Yongin-si, Korea, Republic of, [2]Greencross, Research Center, Downstream Process 1 Team, Yongin-si, Korea, Republic of

Background: Fibrinogen concentrates are used for patients with fibrinogen deficiency to prevent bleeding episodes. Traditional formulation products are stored at 5 to 25℃, where albumin is used as a stabilizer. For distribution and patient's usability with guaranteed product quality, improved storage conditions have been required.

Aims: To ensure high-quality lyophilized fibrinogen concentrate, we developed stable formulation under harsh thermal stress.

Methods: A full factorial design was employed to evaluate effects of albumin and L-arginine on the thermal stability of fibrinogen formulation. Contents of albumin and L-arginine were tested from 0 to 500 mg/vial and 120 to 470 mg/vial, respectively. With the selected formulation, stability studies were conducted for 6 months at 40℃ and 7 days at 60℃, respectively and size exclusion chromatography was used to detect fibrinogen monomers. Pharmacokinetic (PK) studies were conducted in Sprague-Dawley rats (60 mg/kg, IV bolus injection) using Human Fibrinogen ELISA kit (AssayPro). JMP software (ver. 10.0; SAS Institute Inc., USA) was used for statistical analyses.

Results: L-arginine showed a significant effect on the thermal stability of fibrinogen formulation after 6 months at 40℃ (P=0.0406), but albumin did not (P=0.2233). Furthermore, the monomer contents were higher in the albumin-free formulation than the traditional albumin-containing formulation under the harsh thermal stress condition (60℃): for albumin-free formulation, 99.1% and 98.4% after 3 days and 7 days, respectively; for albumin-containing formulation, 93.5% after 3 days (7 day's sample did not dissolved). No significant differences were found in PK results between the albumin-free and containing formulations.

Conclusions: In conclusion, fibrinogen formulation with high resistance to thermal stress was obtained through stability studies (40 and 60℃) with varying contents of albumin and L-arginine. We will conduct new stability studies for long-term storage above 25℃.

PB 1763 | Cellular Factor XIII in Human Cornea

L. Muszbek[1], Z.Z. Orosz[1,2], H. Bárdos[3], A.H. Shemirani[4], B. Nagy[5], J. Kappelmayer[5], R. Ádány[3], A. Berta[6], A. Facskó[2]

[1]University of Deberecen, Division of Clinical Laboratory Science, Department of Laboratory Medicine, Debrecen, Hungary, [2]University of Szeged, Department of Ophthalmology, Szeged, Hungary, [3]University of Debrecen, Department of Preventive Medicine, Debrecen, Hungary, [4]University of Debrecen, Vascular Medicine, Thrombosis and Hemostasis Research Group of the Hungarian Academy of Sciences, Debrecen, Hungary, [5]University of Deberecen, Department of Laboratory Medicine, Debrecen, Hungary, [6]University of Deberecen, Department of Ophthalmology, Debrecen, Hungary

Background: The presence of cellular FXIII (cFXIII), the dimer of the catalytic FXIII A subunit ($FXIII\text{-}A_2$) has been described earlier in platelets, monocytes and monocyte derived macrophages. More recently it has also been demonstrated in a few other cell types, like chondrocytes, osteoblasts, osteocytes, adipocytes. We detected FXIII subunits in tears, which raised the question if cFXIII is present in corneal cells.

Aims: The aim of the study was investigate the occurrence of cFXIII in cells of human cornea, and if such cells exist, to reveal their distribution in the cornea and to test if they actively synthesize the protein.

Methods: Human cornea specimens were obtained from cadavers or from surgical material obtained by enucleation. Tissue sections of cornea were investigated for the presence of FXIII-A and FXIII-B by immunofluorescence technique. Staining for FXIII-A was combined with immunostaining for CD34 antigen. The same double immunofluorescent stainings were also performed on isolated corneal keratocytes and evaluated by immunohistochemisty and by flow cytometry. Quantitation of FXIII-A in the corneal tissue was performed by Western blotting technique. FXIII-A mRNA was detected by RT-qPCR.

Results: In the cornea FXIII-A, but not FXIII-B was detected in stromal CD34+ keratocytes by immunfluorescence staining. Flow cytometry revealed that 84% of of isolated corneal cells were CD34+ keratocytes and two third of them were also stained for FXIII-A. The distribution of these cells in the corneal stroma was unequal; they were

particularly abundant in the subepithelial region. As opposed to the membrane localization of CD34, cFXIII was of cytoplasmic localization, occasionally it also appeared in the nucleus. 2.87 ng cFXIII/mg corneal protein was measured by quantitative Western blotting. The synthesis of cFXIII by these cells was confirmed by RT-qPCR.

Conclusions: cFXIII is present in keratocytes of human cornea and might be involved in the corneal wound healing process.

PB 1764 | Fibrin-associated ROTEM Variables and Thrombin Generation in Patients with Congenital Fibrinogen Defects

T. Szanto[1], A. Jouppila[2], E. Armstrong[3], A. Casini[4], R. Lassila[1,3]

[1]*Helsinki University Hospital, Coagulation Disorders, Departments of Hematology and Clinical Chemistry (HUSLAB), Helsinki, Finland,* [2]*Helsinki University Hospital, Research Institute, Helsinki, Finland,* [3]*Helsinki University Hospital Comprehensive Cancer Center, Coagulation Disorders, Department of Hematology, Helsinki, Finland,* [4]*University Hospitals of Geneva, Haemostasis Unit, Geneva, Switzerland*

Background: The clinical course of congenital hypo-/dysfibrinogenemia is unpredictable and cannot be evaluated by standard coagulation assays.

Aims: To better characterize a Finnish cohort of congenital hypo-/dysfibrinogenemia by genotyping and assessing thrombin generation (TG) and ROTEM.

Methods: Ten patients from 8 unrelated families (7 with homogeneous and 1 with mixed phenotypes) were studied, 3 with bleeding phenotype (BP), 3 with thrombotic phenotype (TP) and 4 asymptomatic with a familiar BP (ABP) in 1 and TP (ATP) in 3. Fibrinogen (Fg) activity (Clauss) and antigen, platelet functions by PFA-200 and Multiplate, and ROTEM in all, and TG by Calibrated Automated Thrombogram (CAT, 1 pM tissue factor, TF) in plasma of 7 patients were measured. Genotype was available in 6 patients from 6 families.

Results: According to Fg activity and antigen levels, 5 unrelated patients had hypo- (3 BP and 2 TP), and 2 unrelated (1 ABP, 1 ATP) and 3 related (1 TP, 2 ATP) patients had dysfibrinogenemia**.** 6 different causative mutations were identified, 4 (2 new variants) in the Fg gamma (2 BP, 2 ATP) and 2 in Fg alpha chain (1 BP, 1 TP). Overall platelet functions were not deficient. Fibrin polymerization capacity measured as clot firmness in FIBTEM was drastically reduced (maximum clot formation, MCF < 5 mm) in all patients with hypo-, but normal in patients with dysfibrinogenemia. MCF by FIBTEM correlated with Fg antigen, but not activity. Markedly prolonged CTs in FIBTEM were measured in 2/3 patients with BP. Baseline peak thrombin varied up to 7-fold between the patients (one hypofibrinogenemic patient with undetectable TG excluded) compared to 3-fold variation in 11 normal controls. No other TG differences were identified between the patients and controls.

Conclusions: MCF in FIBTEM detected hypo-, but not dysfibrinogenemia. TG varied widely, illustrating that TG could be affected by the abnormal fibrin structures. These findings should be confirmed in a larger patient cohort.

PB 1765 | Studies to Determine Novel Interacting Partners and Functional Roles for Factor XIII B Subunit

S. Singh[1], M.S. Akhter[1], V. Ivaskevicius[1], A. Reuter[2], J. Dodt[2], H. Philippou[3], J. Oldenburg[1], A. Biswas[1]

[1]*Institute of Experimental Haematology and Transfusion Medicine, University Clinic Bonn, Bonn, Germany,* [2]*Paul Ehrlich Institute, Langen, Germany,* [3]*Leeds Institute of Cardiovascular and Metabolic Medicine LIGHT Laboratories, University of Leeds, Leeds, United Kingdom*

Background: Coagulation Factor XIII B (FXIIIB) protein is present in plasma as a regulatory and/or protective subunit of FXIIIA. Unlike the A subunit for whom multiple interaction partners and several pleiotropic roles are known, B subunit so far is known to participate only in the hemostatic system. However, B subunit possesses sushi domains which are also frequent in complement proteins. This combined with the fact that the B subunit exists also in free form apart from being bound in a complex with the A subunit suggests that it might have other interacting partners and as yet unknown functions.

Aims: Investigating novel roles and partners of the free form of FXIIIB protein.

Methods: FXIIIB subunit was analyzed in 1) Content characterization of Fibrogammin was done to check putative interacting partners of FXIII 2) Using immobilized FXIIIB monoclonal antibodies, putative FXIIIB interacting partners were pulled down from FXIII deficient plasma and analyzed by Mass spectroscopy 3) Reconstitution experiments were performed to check the direct link of FXIIIB with complement activation by checking the rate of complement activation in the presence/absence of FXIIIB subunit.

Results: Fibrogammin P was found to be comprised of Complement factor H (CFH) and Alpha-2-macroglobulin apart from the coagulation $FXIIIA_2B_2$ heterotetramer. Mixing studies performed on CFH and FXIII deficient plasma and analyzed by FXIII generation assay suggests that both CFH/FXIIIB might additively control FXIIIA access to thrombin. However, no physiological role of CFH was observed in mixing studies analyzed for complement activation. Alpha-2-macroglobulin and C1q subunit were observed to co-immunoprecipitate with FXIIIB subunit.

Conclusions: C1q subunit/CFH from the complement system and Alpha-2-macroglobulin appear to have affinity for FXIIIB subunit/FXIIIB subunit epitopes. However, neither interaction seems to have strong physiological relevance although its relevance in disease like conditions cannot be ruled out.

PB 1766 | The Effect of Factor XIII Levels and Factor XIII B Subunit Polymorphisms on the Risk of Venous Thromboembolism

Z.A. Mezei[1], É. Katona[2], J. Kállai[2], Z. Bereczky[2], L. Somodi[2], B. Kovács[2,3], T. Miklós[4], É. Ajzner[4], L. Muszbek[2]

[1]*University of Debrecen, Department of Laboratory Medicine, Debrecen, Hungary,* [2]*University of Debrecen, Division of Clinical Laboratory Science, Department of Laboratory Medicine, Debrecen, Hungary,* [3]*Borsod-Abaúj-Zemplén County Hospital and University Teaching Hospital, Department of Laboratory Medicine, Miskolc, Hungary,* [4]*András Jósa Szabolcs-Szatmár-Bereg County Hospital and University Teaching Hospital, Department of Laboratory Medicine, Nyiregyháza, Hungary*

Background: As FXIII plays an essential role in the protection of newly formed fibrin, its association with the risk of thrombotic diseases has been a subject of intensive research. However, the association of plasma FXIII level with the risk of venous thromboembolism (VTE) is still controversial and the effect of the recently discovered polymorphism in FXIII-B Intron K (F13B:c.1952+144 C>G) leading to a novel splice acceptor site and 25 new amino acids at the C-terminal end has not been investigated in this respect.

Aims: The association of FXIII levels and FXIII-B polymorphisms with the risk of VTE was explored in the study.

Methods: 227 VTE patients and 227 age and gender matched controls were enrolled in the study. There was at least three months between the acute thrombotic event and the investigation. FXIII activity, FXIII-A_2B_2 antigen, FXIII-B antigen levels and fibrinogen were measured and FXIII-B p.His95Arg and FXIII-B Intron K polymorphisms were determined.

Results: Adjusted FXIII activity and FXIII-A_2B_2 antigen levels were significantly higher in the VTE group than in controls. In contrast, FXIII-B levels were significantly lower in the control group. FXIII activity and FXIII-A_2B_2 antigen levels in the upper tertile as compared to the lowest tertile increased the risk of VTE (adjusted OR:1.61 CI:0.96-2.71 and OR: 2.19 CI:1.30-3.68, respectively). Elevated FXIII-B antigen level had a protective effect (adjusted OR:0.39 CI:0.22-0.70). The Arg95 allele was associated with moderately elevated FXIII activity, FXIII-A_2B_2 and FXIII-B antigen levels in the control but not in the VTE group. FXIII-B Intron K G allele significantly lowered the FXIII activity, FXIII-A_2B_2 and FXIII-B antigen levels in both groups. FXIII-B polymorphisms did not influence the risk of VTE.

Conclusions: Elevated FXIII levels could be considered as risk factor of VTE. The FXIII-B polymorphisms are not associated with VTE risk.

PB 1767 | Novel Immunoassay Reagent for Fibrinogen without Cross-reactivity to FgDP and XDP in Plasma

Y. Magari

Q-may Laboratory Corpolation, Oita, Japan

Background: A new mouse monoclonal antibody (clone G3D4) specific to the αC domain of fibrinogen was prepared.

Aims: A novel immunolatex reagent prepared by loading this antibody onto latex particles was used to develop an immunoassay reagent for fibrinogen without interference with crosslink fibrin (XDP) and fibrinogen degradation products (FgDP) in plasma.

Methods: After mixing 140 µL of R1 reagent containing Tris buffer as a main component with 4 µL of human citric acid plasma, diluted 40-fold with a fibrinogen standard substance or physiological saline, using an automatic clinical chemistry analyzer BIOLIS 50i (TOKYO BOEKI MEDYSIS INC.), the mixture was heated at 37°C for 4 minutes. To this mixture, 50 µL of R2 reagent prepared by physically loading a mouse monoclonal IgG 1 antibody specific to the αC domain of fibrinogen onto polystyrene latex particles was added to measure absorbance (546 nm) at 30-120 seconds. Using the calibration curve of a standard substance, plasma fibrinogen levels were calculated.

Results: The immunoassay reagent for plasma fibrinogen showed excellent simultaneous reproducibility (n = 10) within the measurement range of 20-900 mg/mL: CV = 1.85% at 50 mg/dL, CV = 0.76% at 200 mg/dL, and CV = 0.95% at 800 mg/dL. In addition, a linearity was demonstrated up to about 900 mg/dL. Furthermore, no effect of coexisting substances was observed.

Regarding the reactivity of the reagent to FgDP and XDP prepared with plasmin over time, high reactivity was observed for intact fibrinogen (340-280 KD) and DesAABB fibri, while no reactivity was noted for other FgDP (X, Y, D, and E) or XDP.

Conclusions: The kit provides sensitive immunoassay for plasma fibrinogen in a wide measurement range without being affected by FgDP, XDP, and antithrombin preparations in plasma.

PB 1768 | Galactosemia Presenting with Afibrinogenemia

F. Gümrük[1], İ. Yaman Bajin[1], S. Aytaç[1], T. Çelik[2], Ş. Yiğit[2], A. Tokatlı[3], M. Çetin[1]

[1]*Hacettepe University, Department of Pediatrics, Division of Pediatric Hematology, Ankara, Turkey,* [2]*Hacettepe University, Department of Pediatrics, Division of Neonatology, Ankara, Turkey,* [3]*Hacettepe University, Department of Pediatrics, Division of Pediatric Metabolism, Ankara, Turkey*

Background: Fibrin is associated with cloth formation, thrombocyte aggregation and transport of factor VIII. Fibrinogen levels< 50 mg/dL may be associated with disseminated intravascular coagulation but levels < 10 mg/dL are usually associated with congenital deficiencies. Congenital fibrinogen deficiency is a rare genetic disorder usually presenting at neonatal period with umbilical bleeding. Cephal hematoma, melena, hematuria, hemarthrose, intracranial bleeding, spontaneous spleeen ruture may also be the presenting sign.

Aims: Here we report a boy presented with afibrinogenemia and diagnosed with galactosemia.

Methods: Our patients was born as the second child of a healthy mother and father who are first degree cousins. He was referred to our hospital when he was 10 days old because of cholestasis. Physical examination revealed hepatomegaly and leukocoria. Eye examination reported that he has cataract. Laboratory findings showed

ALT: 46U/L, AST: 69U/L ,total bilirubin: 16.9 mg/dl, direct bilirubin: 5.3 mg/dl, hemostatic parameters showed aPTT: 106 sec, INR: 4.5, D-Dimer>40 mcgr/ml, thrombin time: 15 sec. Antithrombin III activity 37% and fibrinogen level was found to be < 10 mg/dl so it was first thought that he had afibrinogenemia. He did not have bleeding, disseminated intravascular coagulation, thrombocytopenia or microangiopathic hemolitic finding in his blood smear. When he was evaluated for the etiology of cholestasis a homozygous mutation (Q118R) in the galactose 1 fosfate uridil transferase (GALT) gene was detected so he was diagnosis as galactosemia.

Results: Lactose free diet started and after that his fibrinogen levels increased and observed in normal limits during the follow-ups.

Conclusions: Coagulopathy may be associated with 4-9% of the patients with galactosemia. When GALT is defective afibrinogenemia may be caused by the liver damage. Our patient seems to had pseudoafibrinogenemia associated with galactosemia.

PB 1769 | Plasma Tromboelastometry (ROTEM) Could be a Complement in Study Fibrinogen Disorders

A.B. Vilaseca[1], R. Barbera[2], G. Vidmar[1], G. Begue[1], H. Beccari[1]

[1]*Clinica San Camilo, Hematologia y Hemostasia, Ciudad Autónoma de Buenos Aires, Argentina,* [2]*Clinica San Camilo, Clinica Medica, Ciudad Autónoma de Buenos Aires, Argentina*

Background: While the first dysfibrinogenemia mutation was identified as early as 1968 , still today , it may be difficult to diagnosis even in specialized laboratories.

Dysfibrinogenemia could be a bleeding or thrombotic disorder, or both.

Aims: Prove the possibility of whether functional Fibrinogen assay by Rotem (FIBTEM) in plasma can be a method for establishing the presence of dysfunctional fibrinogen.

Methods: Fibrinogen in plasma of 20 healthy volunteers, was measured, as Control Group using Clauss and Rotem Fibtem .Correlation between Clauss values and Maximum Clot Firmness (MCF) Fibtem was established.

Subsequently, the same correlation was performed in 17 individuals with confirmed or suspected dysfibrinogenemia. In both groups, correlation with Pearson Coefficient was made. Also ratio Fibrinogen(Clauss)/MCF were calculated in both group and comparisons with a T Test for independent samples were made. In all cases a significant p-value < 0.05 was considered.

Results: The control group showed a good correlation between Clauss and MCF values ($r = 0.693$; $p < 0.001$).

The analysis of the Fibrinogen / MCF ratio showed significant differences: Control: 11.75 (95% CI: 10.75-12.75) vs Pathological: 16.42 (95% CI: 12.70-20.14) ($p < 0.03$).

Conclusions: Perhaps combination of two functional assays like Clauss an Fibtem could be a complementary method to suspect dysfibrinogenemia. Allowing also to visualize the possible prothrombotic or hemorrhagic behavior of the patient.

PB 1770 | A Fibrinogen Activity Method on Photo-optical Coagulation Analyzers without Interference from Hydroxyethyl Starch

Z. Cao, A. Belanger, J. Mathew, C. Kung, R. Bottenus

Instrumentation Laboratory, Research & Development, Orangeburg, United States

Background: It has been reported that the use of photo-optical fibrinogen activity methods on plasmas diluted with hydroxyethyl starch (HES) can lead to clinically relevant overestimation of fibrinogen concentrations.

Aims: The aim of this study was to investigate the effect of HES on Clauss fibrinogen measurements with samples diluted with HES on a photo-optical instrument.

Methods: Two citrated plasma pools (Pool 1: a pool of 48 donors; Pool 2: cryoprecipitated to achieve a low fibrinogen level) were diluted in a 1:1 ratio with 0.9% NaCl and HESPAN (6% hetastarch in 0.9% NaCl injection, B. Braun, Bethlehem, PA, USA), respectively, generating two levels of HESPAN (0% and 50%) for each specimen. The two dilutions were used to prepare different HESPAN levels (0, 12.5, 25, 37.5 and 50%). Fibrinogen activity was tested on an Instrumentation Laboratory (IL) photo-optical based ACL TOP 700 analyzer using IL´s Q.F.A. Thrombin kit, and the average results were compared to the respective baseline mean.

Results: The two citrated plasma pools diluted with 50% NaCl had corresponding baseline fibrinogen levels at 166 mg/dL and 79 mg/dL, respectively.

Pool 1 had fibrinogen activity within the Q.F.A. test range. The Q.F.A. test reported no more than a 2% increase (within 3SD of the baseline) in the fibrinogen level when the sample was diluted with HESPAN.

HESPAN, %	0.0	12.5	25.0	37.5	50.0
Fibrinogen, mg/dL	166	169	160	170	170
SD	2.2	7.2	2.8	4.1	3.9
%CV	1.3	4.2	1.8	2.4	2.3
%Baseline	100	101	96	102	102

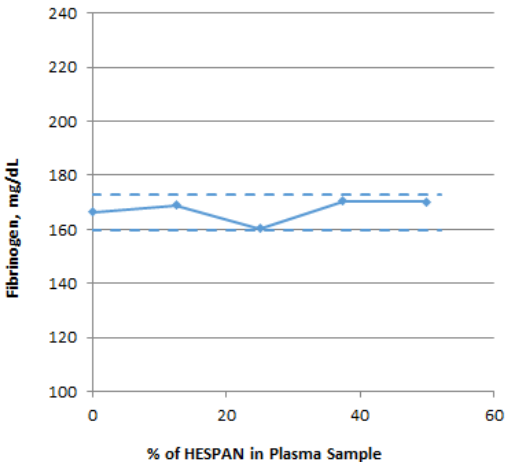

FIGURE 1 Fibrinogen measurement of HES diluted samples on ACL TOP 700: results from the Q.F.A. test with dashed lines representing the 3SD limits

HESPAN, %	0.0	12.5	25.0	37.5	50.0
Fibrinogen, mg/dL	79	78	82	82	86
SD	6.1	2.4	1.6	4.3	1.8
%CV	7.8	3.1	1.9	5.3	2.1
%Baseline	100	98	103	104	109

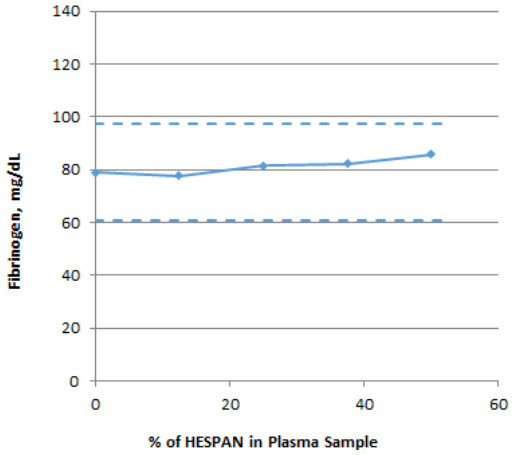

FIGURE 2 Fibrinogen measurement of HES diluted samples on ACL TOP 700: results from the Q.F.A. Low test with dashed lines representing the 3SD limits

Pool 2 had fibrinogen activity within the Q.F.A. Low test range. The Q.F.A. Low test reported no more than a 9% increase (within 3SD of the baseline) in the fibrinogen level when diluted with HESPAN.

Conclusions: The studies demonstrate that when fibrinogen measurements are performed on IL´s photo-optical ACL TOP Family analyzer using the Q.F.A. Thrombin kit, no statistically or clinically significant differences are observed in fibrinogen activity on plasma diluted with HES.

Hemorrhagic Disorders, Hemophilia

HEMORRHAGIC DISORDERS, HEMOPHILIA

PB 199 | Evaluation of the Ankle Brachial Index in Persons with Hemophilia: Unexpected Findings

H. Hop[1], P.W. Kamphuisen[1], A.M. van Roon[1], J.D. Lefrandt[1], K. Meijer[2]

[1]*University Medical Center Groningen, Internal Medicine - Division of Vascular Medicine, Groningen, The Netherlands,* [2]*University Medical Center Groningen, Hematology - Division of Hemostasis and Thrombosis, Groningen, The Netherlands*

Background: The prevalence of cardiovascular disease (CVD) is rising in persons with hemophilia (PWH). Previous studies of atherosclerosis in PWH have been limited to carotid and coronary arteries.

Aims: We analyzed the prevalence of subclinical peripheral artery occlusive disease (PAOD) in PWH by measuring the ankle brachial index (ABI), an established method to diagnose PAOD.

Methods: In consecutive PWH visiting our hemophilia treatment center, systolic blood pressure (SBP) was measured at the brachial and ankle arteries (dorsalis pedis and tibialis posterior) in supine position after a few minutes rest, using Doppler ultrasound. The ABI was calculated as the ratio of the highest SBP at the ankle to the highest SBP at the arm. We evaluated three groups: low (< 0.9), normal (0.9-1.3) and high ABI (≥1.3). Creatinine and HbA1c were measured; medical history was reviewed.

Results: 65 PWH (median age 52 years [IQR 42-64], 39% severe hemophilia, A:B 48:17) were enrolled. Nine (14%) patients had a history of CVD, 7 (11%) diabetes and 15 (23%) hypertension. Three (5%) patients had an estimated glomerular filtration rate < 60 ml/min. The median ABI was 1.26 (IQR 1.19-1.33). Only one patient had an ABI< 0.9, indicating PAOD. Notably, 32 (49%) patients had an high ABI in at least one leg. No significant differences were found between patients with an ABI ≥1.3 and patients with an ABI< 1.3 in age, HbA1c, renal function, hypertension or severity of hemophilia.

Conclusions: We found a very low prevalence of subclinical PAOD in PWH. However, we found a high prevalence of a high ABI, suggesting calcification of the medial layer of the peripheral arteries rather than thickening of the intimal layer. Medial arterial calcification (MAC) can lead to arterial stiffness and thereby cause hypertension. Indeed, literature reports an increased prevalence of hypertension in PWH. The hypothesis that persons with hemophilia have increased MAC needs further investigation.

PB 200 | A Single Center Cross-sectional Study of the Age Related Effects of Intensive Prophylactic Therapy on Annual Bleed Rate and Joint Arthropathy in 338 Patients with Severe Haemophilia A

J. Oldenburg, C. Causemann, H.-H. Brackmann, N. Marquardt, G. Goldmann

University Bonn, Institute of Experimental Haematology and Transfusion Medicine, Bonn, Germany

Background: In severe Haemophilia A current prophylactic regimens, although very effective, do not completely prevent joint disease in a long-term perspective. Absence or presence and degree of joint arthropathy can be regarded as a cumulative measure of the qualitiy of prophylactic treatment during life-time.

Aims: The aim of this study is to present age dependent data on FVIII concentrate consumption, total and joint annual bleed rate (ABR) and degree of joint arthropathy.

Methods: A cross-sectional study was performed comprising 330 patients with severe Haemophilia A that were treated in 2010. Patients were analysed in 6 groups according to age in -6 (G1, n=35), 7-12 (G2, n=34),13-18 (G3, n=35), 19-40 (G4, n=108), 41-60 (G5, n=108) and > 60 (G6, n=18) years of age. Data were obtained on concentrate consumption (U/kg/year), total and joint ABR, and joint status (Gilbert and Ptterson scores). Joint bleeds were verified by a phone interview of the physician.

Results: Median annual concentrate consumption was 4898 iIU/kg BW/year and within the age groups G1-G6 10909, 8260, 4228, 3818, 4978 and 4978 IU/kg B/year, respectively.Total ABRs was 2.8 and within the age groups G1-G6 5.4, 2.9, 2.8, 2.0, 2.7, 3.5 and 2.8. Joint ABR increased continuously from 0.2 in the youngest age group to 0.5 in the oldest age group. A Non-pathologic Petterson scores in G1-G6 were found in 100%, 91%, 65%, 15%, 2% and 0% and

non-pathological Gilbert scores in 82%, 90%,72%, 32%, 1% and 0% of the patients, respectively.

Conclusions: Most patients up to an age of 40 years (G1-G4) have received a life-long intensive prophylactic regimen. This treatment results in 1 joint bleed every 2-5 years depending on the patient´s age. Despite this intensive treatment the majority of the patients developed joint artropathy when reaching an age of 19-40 years. Thus even intensive prophylactic regimens do not prevent joint disease in a life time perspective.

PB 201 | Patient, Regional and Center-level Variation in Utilization of Arthroplasty and Arthrodesis Interventions in Persons with Hemophilia: An Analysis of the American Thrombosis and Hemostasis Network (ATHN) Dataset

T. Buckner[1], D. Cheng[2], A. Ginde[1], M. Manco-Johnson[1]

[1]*University of Colorado School of Medicine, Aurora, United States,* [2]*American Thrombosis and Hemostasis Network, Health Services Research / Biostatistics, Riverwoods, United States*

Background: Loss of joint function and pain due to arthropathy are the most prevalent long-term morbidities associated with hemophilia A and B (HA and HB). Severe, end-stage arthropathy can be treated with interventions such as total joint arthroplasty and arthrodesis. Data describing utilization of these procedures in US hemophilia treatment centers (HTCs) are lacking.

Aims: To determine the impact of patient-level factors, HTC size and geographic region on utilization of arthroplasty and arthrodesis in individuals with hemophilia A or B.

Methods: We included male enrollees with HA or HB in the ATHN Dataset as of 6/30/2016. We developed a negative binomial multivariable regression model to estimate the relative contributions of independent variables to the lifetime prevalence of arthroplasty or arthrodesis.

Results: Data from 12,324 persons with hemophilia (PWH) were included, of whom 532 (4.3%) had a history of arthroplasty and/or arthrodesis. Older age, increasing hemophilia severity, HIV, and HCV increased the odds of having had either procedure (Table 1). Surgery was more common in persons with HA compared to HB, as well as in those currently using clotting factor prophylaxis. Race/ethnicity and history of inhibitor did not impact the outcome. The likelihood of having arthroplasty or arthrodesis varied significantly among the HTC regions, and being at a large (>150 patients) or medium (51-150 patients) HTC increased the odds of surgery compared to small (≤50 patients) HTCs (Table 2).

TABLE 1 Impact of patient-level variables on the likelihood of subjects having a history of at least one arthroplasty or arthrodesis procedure

Variable	Odds Ratio	95% Confidence Interval	P-Value
Age (each additional 10-year increment)	2.16	2.00-2.33	<0.001
Hemophilia A vs. B	1.46	1.12-1.90	0.005
Hemophilia Severity			
Severe vs. Mild	7.10	4.97-10.13	<0.001
Moderate vs. Mild	2.23	1.55-3.20	<0.001
HIV	1.44	1.11-1.88	0.007
HCV	1.82	1.46-2.27	<0.001
Prophylaxis- current use	1.77	1.34-2.33	<0.001

TABLE 2 Impact of geographic region and HTC size on the likelihood of subjects having at least one arthroplasty or arthrodesis procedure

Variable	Odds Ratio	95% Confidence Interval	P-Value
Region (compared to Western Region)			
New England	2.58	1.56-4.26	<0.001
Southeast	3.22	1.98-5.25	<0.001
Great Lakes	3.42	2.12-5.52	<0.001
Northern	2.98	1.77-4.99	<0.001
Mountain	3.98	2.36-6.71	<0.001
HTC Size			
Large vs. Small	1.77	1.09-2.87	0.020
Medium vs. Small	1.86	1.16-2.98	0.009

Conclusions: Use of orthopedic interventions for end-stage arthropathy is driven in part by patient and disease characteristics, but also by HTC size and geographic region. These findings suggest that factors beyond patients' joint status affect the decision of whether to pursue these orthopedic surgical procedures to treat hemophilic arthropathy. Further investigation of the availability of orthopedic surgeons, access to hospitals capable of surgical management of PWH, and differences in HTC regional practice patterns is warranted.

PB 202 | New Tools for the Optimization of the Primary and Secondary Prophylaxis in Pediatric Patients with Severe Hemophilia: Ultrasound Thromboelastography (UT) and Joint Echotomography

F. Lionti[1], V. Dicembre[1], F. Gagliano[1], E. Parisi[2], G. Corsello[1]

[1]ARNAS CIVICO Palermo, Clinica Pediatrica, Palermo, Italy, [2]Università degli studi Palermo, clinica pediatrica, Palermo, Italy

Background: Hemophilia A and hemophilia B are hereditary hemorrhagic diseases, characterized by a partial or total deficiency of factor VIII or IX. Patients with severe haemophilia are at risk of spontaneous bleeding. Joint damage is the major complication of hemophilia, needing replacement therapy to prevent morbidity and mortality.

Aims: Addressing critical hemorrhages implies a correct interpretation of the bleeding and its consequent therapeutic approach. Therefore carrying out a dynamic coagulation monitoring aiming at an overall assessment within a short running time is crucial to assess, the risk of bleeding and provide information on clot stability. The purpose of our study is to provide a complementary tool to the laboratory tests, meanwhile demonstrating the usefulness of prophylaxis optimized by means of ultrasound thromboelastography (UT), muscle-joint ultrasonography and thrombin generation assessment.

Methods: 10 patients with severe and moderate haemophilia A receiving FVIII concentrates in the secondary prophylaxis regimen were evaluated. Factor VIII PK, UT, joint ultrasound, and monitoring of clinical response as a function of the number of monthly bleeding were analysed. Factor VIII kinetic was performed before infusion, at time 0, after 2 h and 24h. UT was performed in three stages, in line with the kinetics. Joint ultrasound was performed in supine and prone position, transverse and longitudinal sections.

Results: 40% of patients receiving prophylaxis with 1000/1500 IU of rFVIII showed sonographic signs of joint damage and more than half of patients had alterations of the parameters analysed. Table 1 shows the results.

TABLE 1

	T0	T2h	T24h
FVIII	2.71 +/- 1.86	44.26 +/- 15.6	8.61 +/- 15.6
R	40.03 +/- 29.7	18.04 +/- 18.25	33.66 +/- 10.6
K	10.16 +/- 4.7	4.62 +/- 3.1	7.24 +/- 3.5
MA	51.97 +/- 6.3	57.62 +/- 9.3	52.23 +/- 7.9
Alpha-angle	36.27 +/- 16	56.8 +/- 31.9	48.8 +/- 6

Conclusions: Customization of therapy and its management based on UT represents an innovative way to deal with patients with severe and moderate hemophilia A. This tool has to be considered complementary to routine laboratory tests and allows a good representation of in vivo clotting mechanisms.

PB 203 | Responsiveness and Construct Validity of Goal Attainment Scaling for Hemophilia (GAS-Hēm): A Novel, Personalised, Patient-reported Outcome for Haemophilia

M. Recht[1], J. Roberts[2], S. Jackson[3], V. Price[4], S. Robinson[5], S. Lattimore[1], D. Gue[6], S. Squire[6], S. Richardson[7], M. Denne[7], K. Rockwood[8]

[1]Oregon Health and Science University, Portland, United States, [2]Bleeding and Clotting Disorders Institute, Peoria, United States, [3]University of British Columbia, Department of Hematology, Vancouver, Canada, [4]Dalhousie University, Pediatric Hematology/Oncology, Halifax, Canada, [5]Dalhousie University, Halifax, Canada, [6]St. Paul's Hospital, Vancouver, Canada, [7]Shire plc, Chicago, United States, [8]DGI Clinical Inc., Halifax, Canada

Background: People with haemophilia have complex medical issues that require a multidimensional assessment, including the development of patient-centred treatment goals. GAS-Hēm is a novel, personalised outcome measure developed to establish and measure progress towards individualised goals.

Aims: To establish the construct validity and responsiveness (sensitivity to change) of the GAS-Hēm in adult and paediatric patients with moderate or severe haemophilia in a real-world clinical setting.

Methods: In a 12-week study of patients aged 5-65 years with haemophilia A or B on prophylaxis recruited from four North American centres, we evaluated the construct validity of GAS-Hēm by assessing the correlation at baseline and study end (12 weeks) of GAS-Hēm scores (range 0-100) with widely used measures: the SF-36 Physical Health Component Score (SF-36 PCS), SF-36 Mental Health Component Score (SF-36 MCS), PedsQL and annualised bleed rate (ABR). Responsiveness of GAS-Hēm was calculated using the standardised response mean (SRM; >0.2 corresponds to small, >0.5 to moderate, and >0.8 to large effect).

Results: The 42 patients (5-12 years, n=9; 13-18 years, n=9; and 19-65 years, n=24) set 63 goals. Mean subject- and clinician-scored GAS-Hēm scores at baseline (n=42), 6 weeks (n=40), and 12 weeks (n=41) are shown (Table). Correlations of total subject-scored GAS-Hēm scores with ABR, SF-36 PCS, SF-36 MCS, and PedsQL, respectively, were: 0.07, 0.19, 0.07 and -0.06 at baseline; and -0.06, 0.22, 0.00 and -0.16 at 12 weeks. The SRMs at 12 weeks for adults were: GAS-Hēm 1.25, SF-36 PCS 0.16, SF-36 MCS 0.18; and for paediatric and adolescents combined were: GAS-Hēm 1.21 and PedsQL 0.58.

TABLE 1 Mean GAS-Hēm Scores Stratified by Age Group

GAS-Hēm Version	Age Stratum	Baseline	Interim Follow-up (6 weeks)	End Point (12 weeks)
Subject-scored	Paediatric	39.2	43.9	52.0
	Adolescent	39.5	44.4	53.6
	Adult	38.4	49.1	53.0
	TOTAL	38.8	47.2	52.9
Clinician-scored	Paediatric	39.2	46.3	53.4
	Adolescent	39.5	46.7	55.8
	Adult	38.4	50.3	54.8
	TOTAL	38.8	48.8	54.8

Conclusions: GAS-Hēm was highly responsive in adult and paediatric populations. However, correlations between GAS-Hēm and standard outcome measures were small. Taken together, these results suggest that GAS-Hēm is tapping constructs not captured by ABR or QoL tools. The individualised goal setting facilitated by GAS-Hēm may account for these findings.

PB 204 | Compartmental High Resolution 3D Imaging by XtremeCT Reveals Low Bone Mineral Density in Hemophilia Patients is Attributed to Loss of Trabecular Bone

A. Lee[1], D. Raymond[2], S. Jackson[3], G. Kline[1], S. Boyd[2], M.-C. Poon[1]

[1]*University of Calgary, Medicine, Calgary, Canada,* [2]*University of Calgary, Radiology, Calgary, Canada,* [3]*University of British Columbia, Medicine, Vancouver, Canada*

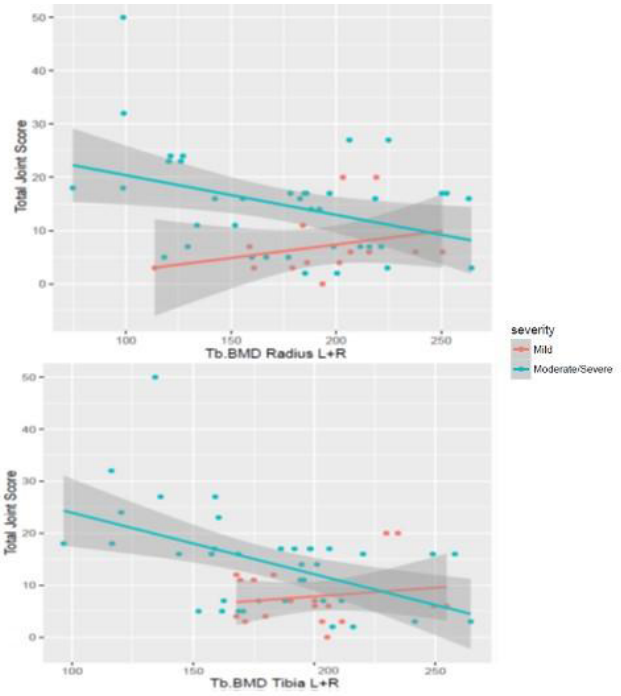
Background: Low bone mineral density (BMD) in persons with hemophilia (PWH) is a recognized concern. The contribution of arthropathy and hemophilia severity to localized and systemic BMD loss is not known.

Aims: To determine the compartmental (cortical and trabecular bone) contribution to low BMD in severe/moderate (S/M) vs. mild (Mi) PWH.

Methods: Cortical and trabecular BMD at bilateral radius (rad) and tibia (tib), was measured in S/M and Mi PWH by XtremeCT (high resolution 3D bone imaging) and compared to normative population data. BMD by DXA, bone turnover markers (BTMs) and hemophilia joint scores were measured in the PWH cohorts.

Results: Comparison of baseline characteristics and BMD results are in table 1. Total joint score was significantly higher in S/M group. XtremeCT data was available on 25 S/M and 18 Mi PWH. Trabecular BMD (Tb.BMD) at both rad and tib were significantly lower in S/M vs. Mi PWH. 64.4% of S/M (vs. 50% Mi) had total BMD (Tt.BMD) < 50th percentile of normative controls with 82.6% of S/M (vs. 60.8% Mi) having Tb.BMD < 50th percentile. Lower Tb.BMD at both rad and tib significantly correlated with worse (higher) total joint scores (Figure 1) in S/M, but there was no correlation of limb-specific joint scores with respective limb-specific BMD measures. More S/M PWH had high BTMs (CTX or NTX) compared to Mi (35 vs 20%) and NTX was significantly higher in S/M PWH (94.5 vs. 70.8, p-value=0.03).

Conclusions: S/M vs. Mi PWH have significantly lower Tb.BMD and correlates with higher total joint scores. Proximity/severity of arthropathy of a particular limb, does not seem to contribute to limb-specific BMD loss. A large proportion of S/M PWH have abnormally low Tt.BMD and Tb.BMD percentiles compared to normative, but low Tb.BMD percentiles in Mi PWH suggests adverse BMD changes are still present. Along with greater proportion of S/M PWH with abnormal BTMs, this suggests that BMD loss is due to a systemic rather than localized process with majority of loss occurring in the trabecular compartment.



Tb.BMD = trabecular BMD, measured in mgHA/cm3. L+R = left and right. Total joint score using measured by World Federation of Hemophilia joint score. Pearson correlation total joint score to Tb.BMD tibia (r= -0.487, p = 0.02). Pearson correlation total joint score to Tb.BMD radius (r= -0.377, p=0.04).

FIGURE 1 Total joint score vs. trabecular BMD, tibia and radius

TABLE 1 Baseline characteristics and BMD results of severe/moderate vs. mild patients

Clinical characteristic	Severe/moderate (n=57)	Mild (n=48)	p-value
Age (years), mean (range)	41.3 (19-76)	48.6 (19-83)	0.03
Hemophilia A/B, n (%)	43(75.5)/14(24.5)	39(81.3)/9(18.7)	n/a
Total joint score, mean (range)	16.7 (2-50)	5.0 (0-20)	<0.001
DXA BMD L-spine T/Z-score, median (IQR)	-1.1 (-1.8, -0.4)	-0.6 (-0.6, 0.2)	0.14
DXA BMD Femoral neck T/Z-score, median (IQR)	-0.8 (-1.6, -0.2)	-0.3 (-1.1, 2.6)	0.05
XtremeCT BMD results (mgHA/cm3)	Severe/moderate (n=25)	Mild (n=18)	p-value
Radius Tb.BMD, median (IQR)	184.9 (139.2, 214.7)	203.2 (184.7, 219.4	0.016
Tibia Tb.BMD, median (IQR)	177.0 (159.2, 202.1)	200.9 (178.6, 206.0)	0.020

PB 205 | No Association between HFE and HMOX1 Polymorphisms, Important in Iron and Heme Handling, and the Severity of Haemophilic Arthropathy

L. van Vulpen[1], W. Foppen[2], K. Fischer[3], S. Mastbergen[4], F. Lafeber[4], R. Schutgens[3]

[1]University Medical Center Utrecht, Van Creveldkliniek & Dept of Rheumatology & Clin Immunology, Utrecht, The Netherlands, [2]University Medical Center Utrecht, Radiology, Utrecht, The Netherlands, [3]University Medical Center Utrecht, Van Creveldkliniek, Utrecht, The Netherlands, [4]University Medical Center Utrecht, Rheumatology & Clin Immunology, Utrecht, The Netherlands

Background: Marked heterogeneity in joint damage exists among haemophilia patients, and potentially genetic differences affecting iron handling impact blood-induced joint damage. Iron levels are regulated by the HFE gene and heme degradation is influenced by polymorphisms in the $(GT)_n$-repeat length in the HMOX1 gene.

Aims: Our objective is to evaluate whether the severity of haemophilic arthropathy is associated with genetic differences in iron handling.

Methods: Patients with severe (n=211) or moderate (n=41) haemophilia A or B were included. The presence of an HFE gene mutation (C282Y and H63D) and the $(GT)_n$-repeat length in the HMOX1 promoter region were analysed via PCR. In serum samples the iron status was assessed. Joint damage was quantified on X-rays using the Pettersson score. By linear regression analysis the association of the HFE mutation (present/absent) and HMOX1 polymorphism (long (≥25) repeat/short repeat) with the Pettersson score was assessed. Analyses were adjusted for haemophilia severity, presence of inhibitors, annual joint bleeding rate (AJBR), age at evaluation, age at entrance of the Van Creveldkliniek, and birth cohort.

Results: 252 patients were evaluated at a median age of 44y (range 18-79y). In severe haemophilia the median AJBR and Pettersson score were higher than in moderate haemophilia (AJBR 2.3 (IQR 1.0-4.6) vs 0.5 (IQR 0.1-2.2); Pettersson 22 (IQR 5-44) vs 4 (IQR 1-13)). In 95 patients an HFE mutation was detected and their levels of iron and the transferrin saturation were significantly increased (both $p < 0.05$). Patients with heterozygosity for a long/short $(GT)_n$-repeat length more frequently suffered form haemophilia A compared to homozygous patients. Neither presence of an HFE mutation, nor a long $(GT)_n$-repeat length was associated with an increase in the Pettersson score.

Conclusions: This study rejects the hypothesis that carriership of an HFE mutation or a long $(GT)_n$-repeat is associated with an increase in haemophilic arthropathy.

TABLE 1 Linear regression analysis for determinants of Pettersson score

Predictor	Beta	95% CI	P-value
Age at evaluation	0.43	0.20 - 0.65	0.000
Clotting factor activity	-18.2	-23.3 - -13.0	0.000
Presence of inhibitors	7.8	2.9 - 12.7	0.002
Annualized joint bleeding rate	1.3	0.8 - 1.8	0.000
Birth cohort	-8.4	-12.1 - -4.5	0.000
Age at entrance of the Van Creveldkliniek	7.6	3.5 - 11.8	0.000
HFE mutation	1.4	-2.3 - 5.2	0.446
HMOX1 polymorphism	-0.9	-3.8 - 2.0	0.536

PB 206 | Factors Associated with Perception of Functional Abilities in US Adults with Hemophilia Beyond Joint Status: Analysis of the Pain, Functional Impairment, and Quality of Life (P-FiQ) Study

C. Kempton[1], T. Buckner[2], M. Fridman[3], N. Iyer[4], D. Cooper[4]

[1]Emory University, Hematology and Medical Oncology, Atlanta, United States, [2]University of Colorado Denver, Aurora, United States, [3]AMF Consulting Inc, Los Angeles, United States, [4]Novo Nordisk Inc, Plainsboro, United States

Background: P-FiQ enrolled US adults with hemophilia and a history of joint bleeding or pain. Participants completed patient-reported outcome instruments to assess quality of life. Functional impairment, as measured by Hemophilia Activities List (HAL), was associated with lack of college education, unemployment, older age, history of joint procedures, viral disease, comorbidities, and severe hemophilia.

Aims: This post hoc analysis assessed association between demographic and clinical characteristics independent of joint status (Hemophilia Joint Health Score [HJHS]) and HAL.

Methods: The association of HAL with HJHS and other covariates was examined using simple regression models and by a multiple regression model where HJHS overall score, age, hemophilia severity, and treatment were included with other covariates having bivariate correlations with HAL scores ($\alpha < 0.05$) using forward selection.

Results: Of 381 adults, physiotherapist-completed HJHS was available for 240 respondents (median age 32 years). Poor HJHS overall score was found to have strong association with poor HAL overall score, in both simple and multiple regression models. The overall R-squared value of 0.70 for the model with multiple predictors was indicative of high combined predictive power of HJHS and several covariates including older age, more severe hemophilia (with inhibitor patients as most severe), non-employed status, higher BPI pain severity, and higher EQ-5D-5L pain/discomfort score **(Table 1)**. EQ-5D-5L anxiety/depression and use of anxiolytics, antidepressants, and opiates were significant in bivariate but not multiple regression.

TABLE 1 Multiple Regression Models - HAL Overall Score

	Hemophilia Activities List (n=177; R2=0.700)			
Characteristic	ß Estimate*	Lower 95% CI	Upper 95% CI	P Value
HJHS overall score (10-point change)	-2.64	-3.82	-1.46	<0.0001
Age (5-year change)	-1.31	-2.12	-0.51	0.0016
Hemophilia severity				<0.0001
Mild (reference)				
Moderate	-8.35	-15.40	-1.29	0.0207
Severe	-8.28	-14.59	-1.98	0.0104
Inhibitor	-22.39	-31.00	-13.79	<0.0001

TABLE 1 Multiple Regression Models—HAL Overall Score (continued)

Characteristic	ß Estimate*	Lower 95% CI	Upper 95% CI	P Value
Employed	7.18	2.22	12.13	0.0048
BPI pain severity	-2.75	-4.14	-1.36	0.0001
EQ-5D-5L pain/ discomfort				0.0102
No problem (reference)				
Slight problem	-5.30	-10.15	-0.46	0.0322
Moderate problem	-9.06	-15.89	-2.24	0.0096
Severe problem	-16.80	-26.59	-7.00	0.0009
Extreme problem	-24.97	-46.80	-3.14	0.0252

BPI, Brief Pain Inventory v2 Short Form; HAL, Hemophilia Activities List; HJHS, Hemophilia Joint Health Score. * ß estimate measures change in outcome per change in covariate.

Conclusions: Beyond joint status, demographic factors such as older age and non-employment and clinical factors including inhibitor status and pain severity were associated with functional abilities. Variation in functional capacity was explained well (70%) using a combination of observed measures (HJHS joint status) along with patient-reported pain.

PB 207 | Long-term Treatment with Human-cl rhFVIII in Previously Treated Children with Severe Haemophilia A

R. Liesner[1], A. Klukowska[2], V. Vdovin[3], T. Szczepański[4], J. Bichler[5], I. Dzhunova[6]

[1]*Great Ormond Street Hospital for Children NHS Trust, Paediatric Haemostasis and Thrombosis, London, United Kingdom,* [2]*Medical University of Warsaw, Pediatrics, Hematology and Oncology, Warsaw, Poland,* [3]*Moscow State Healthcare Institution Morozov Children`s Clinical Hospital of Moscow, Healthcare Department, Hematology Consultative Department, Moscow, Russian Federation,* [4]*Zabrze, Medical University of Silesia, Department of Paediatric Haematology and Oncology, Katowice, Poland,* [5]*Octapharma AGAG, Clinical Research & Development, Lachen, Switzerland,* [6]*Octapharma AG, Clinical Research & Development, Lachen, Switzerland*

Background: Human-cl rhFVIII is a 4th generation recombinant FVIII produced in a human cell line without chemical modification or protein fusion. It is approved in Europe, USA and elsewhere for treatment and prophylaxis of bleeding in patients with haemophilia A.

Aims: The aim of the study was to investigate the safety and efficacy of long-term prophylactic treatment with Human-cl rhFVIII in previously treated children with severe haemophilia A.

Methods: This study (GENA-13) enrolled children who had completed the 6-month predecessor study GENA-03. Patients continued prophylaxis with injections every other day or 3 times per week. Inhibitor tests (Bethesda assay, Nijmegen modification) were performed at study start, then every 3 months and at study completion. Adverse events were recorded throughout the study. The study was approved by the local ethics committees and all patients/legal guardian(s) gave written informed consent.

Results: The study enrolled 49 patients from 10 centers across 6 European countries. Their median (range) age at study start was 6.0 (3.0-13.0) years. They received a total of 27.5 million International Units (IU) and 20,518 injections of Human-cl rhFVIII over a median (range) period of 30.1 (9.6-53.2) months. The mean (± SD) dose per prophylactic injection was 38.6 ± 6.7 IU/kg. The spontaneous annualized bleeding rate (ABR) was lower than in the same patients in GENA-03 (Table 1).

TABLE 1 ABRs* estimated by negative binomial regression (95% CIs) in GENA-13 and GENA-03 (n=49)

ABR	GENA-03	GENA-13
Total ABR	3.54 (2.42-5.17)	2.88 (1.86-4.46)
Traumatic ABR	1.88 (1.16-3.06)	1.76 (1.16-2.67)
Spontaneous ABR	1.6 (0.74-2.50)	0.67 (0.44-1.02)
Joint ABR	1.00 (0.54-1.83)	0.84 (0.53-1.2)

Conclusions: The data suggest that long-term prophylaxis with Human-cl rhFVIII has a favorable safety profile and reduces even further the already low spontaneous bleeding rates observed in the predecessor prophylaxis study.

PB 208 | Realworld Health Care Utilization and Costs of Extended and Standard Half-life Recombinant Factor IX Products in Hemophilia B Patients

A. Chhabra[1], J. Alvir[1], B. Tortella[2], D. Spurden[3], P. Fogarty[2], M. McDonald[1], A. Pleil[4]

[1]*Pfizer Inc, New York, United States,* [2]*Pfizer Inc, Collegeville, United States,* [3]*Pfizer Limited, Surrey, United Kingdom,* [4]*Pfizer, Inc, San Diego, United States*

Background: Hemophilia B management requires intravenous factor IX (FIX) infusions to replenish the missing coagulation factor. Extended half-life (EHL) FIX products were recently introduced that require fewer infusions compared to standard half-life (SHL) FIX products.

Aims: We analyzed USA real-world data to determine usage and costs associated with EHLs vs SHLs. We examined how switching from SHL to EHL impacts healthcare costs.

Methods: The Truven MarketScan claims database was queried for factor replacement costs over one year in EHL patients were compared with the patients in the SHL cohort (overall analysis), starting June 2014 (first EHL claim). Separately, we analysed FIX utilization and costs in patients who switched from SHL to EHL

TABLE 1 Hemophilia B related utilizations and costs of FIX replacement - All patients on SHL or EHL

	1-3		4-6		7-9		10-12		Overall for all available quarters
Characteristic	EHL	SHL	EHL	SHL	EHL	SHL	EHL	SHL	EHL/SHL
N	21	71	17	43	13	28	12	23	21/71
FIX Utilization - Metric Ius									
Mean/Std	95,116	66,043	58,081	66,637	61,240	71,351	69,977	64,128	75,881/61,606
Median	68,870	40,530	56,142	41,800	55,278	73,005	56,796	62,300	70,059/44,978
FIX Utiliztion Costs									
Mean/Std	$223,375	$89,194	$166,712	$82,819	$180,267	$100,339	$207,414	$91,000	$207,206/$81,664
Median	$178,650	$60,753	$152,990	$67,632	$149,436	$102,850	$162,929	$82,530	$167,909/$58,616

product during 2 years pre and post switch (switch analysis). Medians for cost and IUs were used to accommodate for date distribution skewness.

Results: In the overall analysis, quarterly costs and IUs dispensed were analyzed for 92 patients over 12 months (71 SHL; 21 EHL). The median quarterly study period factor cost was $109,292 higher (2.8 times) in the EHL cohort ($167,909) compared with the SHL cohort ($58,616). Median quarterly study period IU usage was also higher in the EHL cohort (70,059 IU) vs SHL users (44,978 IU).

In the switch analysis, 14 patients with hemophilia B switched to EHL product and had at least 3 months data pre and post switch. Median quarterly factor costs analyzed over 2 years pre/post-switch was $73,795 in the period prior to switch, and $189,083 after switch. Median quarterly metric IUs utilization in the period prior to switch was 58,535 and 65,700 IUs in the post-switch period.

TABLE 2 Costs and Utilization of FIX pre- and post-switch (SHL to EHL)

	Overall for all available quarters (24 months pre- and post-switch)	
Characteristics	Pre-Switch	Post-Switch
N	14	14
FIX Utilization - Metric IUs		
Mean/Std	77,557	79,264
Median	58,535	65,701
FIX Utilization Costs		
Mean/Std	$94,520	$235,322
Median	$73,795	$189,083

Conclusions: These analyses using real-world data suggest that total FIX costs and IU utilization are higher with EHL vs SHL use in the US. Additional real world data analyses with a larger sample size should be pursued to confirm these findings.

PB 209 | Three-year Bleeding Frequency in >1000 Haemophilia A Patients on Prophylaxis: A Reliable Effectiveness Benchmark

K. Khair[1], J. Oldenburg[2], C. Santoro[3], K. Kurnik[4], R. Parra[5], A. Huth-Kühne[6], R. Klamroth[7], K. Steinitz-Trost[8], H. Brondke[9], A. Gringeri[8], on behalf of the AHEAD Study Groups

[1]Great Ormond Hospital for Children NHS Trust Haemophilia Centre, London, United Kingdom, [2]Institute for Experimental Haematology and Transfusion Medicine, Bonn University Clinic, Bonn, Germany, [3]Sapienza University of Rome, Hematology, Department of Cellular Biotechnology and Hematology, Rome, Italy, [4]Dr. von Haunersches Kinderspital Klinikum der Universität München, München, Germany, [5]Unidad de Hemofilia, Hospital Universitari General Vall d'Hebron, Barcelona, Spain, [6]SRH Kurpfalzkrankenhaus and Haemophilia Centre Heidelberg GmbH, Heidelberg, Germany, [7]Vivantes Klinikum, Department for Internal Medicine, Vascular Medicine and Haemostaseology, Berlin Friedrichshain, Germany, [8]Shire plc, Global Medical Affairs Hematology, Vienna, Austria, [9]Shire plc, German Medical Affairs Hematology, Munich, Germany

Background: New products are becoming available leading to an increased need to compare their effectiveness in prophylaxis to standard products.

Aims: Establish an effectiveness benchmark.

Methods: To establish an effectiveness benchmark, bleeding frequency was assessed in the AHEAD studies (an International [INT] and a German [GER] arm). These non-interventional, prospective long-term cohort studies include severe and moderate (FVIII < 1-5%) haemophilia A (HA) patients treated with octocog alfa (ADVATE).

Results: Overall 1,117 patients (715 INT and 402 GER) were enrolled so far. Preliminary data of 869 patients from 22 countries were analyzed. Of these, 687 patients completed year 1, 536 year 2 and 385 year 3. Mean age at screening was 23.4 years, 67% had severe HA and 79% were on prophylaxis.

Over the first 3 years of observation, patients on prophylaxis had a median annual bleeding rate (ABR) of about 2 bleeds: median ABR 1.7 and 2.5 in year 1; 1.6 and 2.2 in year 2; 2.2 and 1.9 in year 3 in the INT and GER arm, respectively. Median annual joint bleeding rates (AJBRs) were ≤1 in the 3 years: a median of 0.9 in both arms in year 1, 1.0 INT and 0 GER in year 2, and 1.0 INT and 0.8 GER in year 3.

In the first 3 years a median of 36.3% of patients on prophylaxis (min-max: 35.1%-36.9%) had an ABR < 1. An additional 13.1% (min-max: 12.5%-15.6%) had an ABR of 1 to < 2 and further 8.8% (min-max:7.6%-9.8%) had an ABR of 2 to < 3. A median of 54.6% (min-max: 53.3%-56.4%) of patients on prophylaxis had an AJBR < 1 during the first 3 years. An additional 14.1% (min-max: 12.7-14.4) had an AJBR of 1 to < 2, and further 6.7% (min-max: 6.5-10.0) an AJBR < 3%.

Conclusions: These data show that ~30% patients on prophylaxis had an ABR < 1 and about 50% had an AJBR < 1 in routine clinical practice. About 50% of patients had an ABR < 2 and about 70% an AJBR < 2. The AHEAD studies jointly represent one of the largest long-term prospective HA cohort, providing a reliable benchmark for new products or therapeutic approaches.

PB 210 | Bleeding Phenotype In Non-severe Hemophilia A Has a Better Association with the One-stage Than the Chromogenic Assay

L.M. Schütte[1], I. Van Moort[2], S.C.M. Stoof[1], J.S. Biedermann[1], M.H. Cnossen[2], F.W.G. Leebeek[1], M.P.M. De Maat[1], M.J.H.A. Kruip[1]

[1]Erasmus University Medical Center, Hematology, Rotterdam, The Netherlands, [2]Erasmus University Medical Center - Sophia Children's Hospital, Pediatric Hematology, Rotterdam, The Netherlands

Background: Measuring factor VIII activity (FVIII) is of importance to diagnose and monitor hemophilia A (HA) patients. Two types of assays are generally used: the one-stage (OSA) and chromogenic assay (CSA). FVIII assay discrepancies have been reported in non-severe HA patients. However, it is still uncertain which assay corresponds best with bleeding phenotype.

Aims: To analyze the association between FVIII measured with the OSA and CSA and bleeding phenotype.

Methods: Non-severe HA patients (according to OSA at diagnosis) seen in the outpatient clinic of the Erasmus University Medical Center were included. FVIII was measured using the OSA and CSA during a routine visit. Severity of hemophilia was determined with the results of both assays and classified according to the SSC/ISTH criteria. Clinical agreement between assays was calculated. All documented bleedings between 2011 and 2015 were collected from patient files. Annual bleeding rate (ABR) was calculated by dividing the total number of bleeds by years of follow-up. The relationship between ABR and severity of HA was determined with Mann-Whitney U tests.

Results: In total, 140 non-severe HA patients were included (median age: 47 years [range 9-91]). Median FVIII with the OSA was 0.10 IU/mL [IQR: 0.05-0.19]. Median FVIII with the CSA was 0.09 IU/mL [IQR 0.06-0.18]. According to the OSA, 2 patients (1%) were diagnosed with severe HA, 36 (26%) with moderate and 102 (73%) with mild HA. According to the CSA, these numbers were 8 (6%), 23 (16%) and 109 (78%), respectively. The clinical agreement between assays regarding the severity of HA was 77%. Overall, median ABR was 0.40 [range 0-7.60]. Moderate HA patients had a significantly higher ABR (0.80) than mild HA patients (0.33) when analyzed with the OSA ($p< 0.01$), but not when analyzed with the CSA ($p=0.54$): median ABR was 0.40 in both moderate and mild HA patients.

Conclusions: In non-severe HA, bleeding phenotype, defined as ABR, is best associated with FVIII measured with the OSA in comparison with the CSA.

PB 211 | Inhibitor Development and Efficacy in Previously Untreated Patients with Severe Haemophilia A Treated with Human-cl rhFVIII, a 4th Generation Recombinant FVIII of Human Origin

R. Liesner[1], M. Jansen[2], L. Belyanskaya[3], E.J. Neufeld[4]

[1]Great Ormond Hospital for Children NHS Trust Haemophilia Centre, London, United Kingdom, [2]Octapharma, Clinical R&D Haematology, Vienna, Austria, [3]Octapharma AG, 3IBU Haematology, Lachen, Switzerland, [4]Dana-Farber/Boston Children's, Harvard Medical School, and Boston Hemophilia Center, Boston, MA, United States

Background: Human-cl rhFVIII (simoctocog alfa) is a 4th generation recombinant FVIII produced in human cells without chemical modification or protein fusion. The immunogenicity, efficacy and safety of Human-cl rhFVIII in previously untreated patients (PUPs) with severe haemophilia A are being assessed in the ongoing multinational NuProtect study. One hundred evaluable (110 enrolled) male PUPs of all ages and ethnicities will be studied for up to 100 exposure days (EDs) or a maximum of 5 years.

Aims: To assess the immunogenicity, efficacy and safety of Human-cl rhFVIII in PUPs with severe haemophilia A.

Methods: Inhibitor activity was defined as ≥0.6 BU as measured by the Nijmegen modified Bethesda assay at a central laboratory (low-titre inhibitors ≥0.6 to < 5 BU; high-titre inhibitors ≥5 BU). Efficacy outcomes were assessed during inhibitor-free periods.

Results: Data for 66 PUPs with ≥20 EDs (by when most inhibitors arise) from a pre-planned interim analysis were analysed. The median age at first treatment was 13 months (range 3-135). The cumulative incidence was 12.8% for high-titre (95% CI 4.49-21.15), 8.4% for low-titre (95% CI: 1.28-15.59) and 20.8% for all inhibitors (95% CI 10.68-30.95). Twelve of the 13 inhibitor patients had identifiable *F8* gene mutations, all were null, and all except one were high-risk. The annualised bleeding rate for spontaneous breakthrough bleeds (Poisson model) was 0.96 (95% CI: 0.65-1.36). Efficacy in treatment of bleeds was excellent or good for 324/353 (91.8%) of rated bleeds. The overall efficacy of surgical prophylaxis for 9 procedures with available ratings was excellent or good for 8 (89%; 7 [78%] excellent, 1 [11%] good) procedures and moderate for 1 (11%) procedure.

Conclusions: These interim data support the low rate of inhibitor development in true PUPs with severe haemophilia A treated with Human-cl rhFVIII and demonstrate haemostatic efficacy during inhibitor-free periods. Final data are expected in 2019.

PB 212 | Long-term Impact of rFVIIIFc Prophylaxis in Paediatric, Adolescent, and Adult Subjects with Target Joints and Severe Haemophilia A

K.J. Pasi[1], I. Pabinger[2], M. Wang[3], B. Kerlin[4], R. Kulkarni[5], B. Nolan[6], R. Liesner[7], S. Brown[8], E. Tsao[9], B. Winding[10], S. Lethagen[10], N. Jain[9]

[1]*Barts and the London Comprehensive Care Center, London, United Kingdom,* [2]*Medizinsche Universitat Wien, Vienna, Austria,* [3]*University of Colorado, Aurora, CO, United States,* [4]*Ohio State University College of Medicine, Columbus, OH, United States,* [5]*Michigan State University, Dept. of Pediatrics and Human Development, East Lansing, MI, United States,* [6]*Our Lady's Children's Hospital, Dublin, Ireland,* [7]*Great Ormond Street Hospital, London, United Kingdom,* [8]*Lady Cilento Children's Hospital, Brisbane, Australia,* [9]*Bioverativ, Waltham, MA, United States,* [10]*Sobi, Stockholm, Sweden*

Background: Long-term safety and efficacy of rFVIIIFc are being evaluated in the ongoing ASPIRE extension study of subjects with severe haemophilia A who completed A-LONG or Kids A-LONG.

Aims: To present data on re-bleeds and target joint resolution from subjects with target joints at entry into the parent study through the third ASPIRE interim data cut.

Methods: Subjects with ≥1 target joint (major joint with ≥3 bleeding episodes in a 6-mo period) at parent study entry with available pre-parent study data and on-study data were evaluated. ASPIRE treatment groups (≥12 y) were: individualised prophylaxis (IP), weekly prophylaxis (WP), modified prophylaxis (MP) or episodic treatment (ET); or (< 12 y) IP or MP. Outcomes were analysed over the duration of the parent study through the third ASPIRE interim data cut (11 Jan 2016).

Results: 113 A-LONG subjects had target joints at baseline; 111 with evaluable data had 287 target joints at baseline and a cumulative median (IQR) 4.0 (2.8, 4.1) y on rFVIIIFc. 13 Kids A-LONG subjects had 15 target joints at baseline and 3.0 (0.5, 3.1) y on rFVIIIFc. Target joint annualised bleeding rates were low for subjects on rFVIIIFc prophylaxis (**Table 1**). 43.9% of IP, 42.3% of WP and 6.3% of MP A-LONG subjects and 53.8% of Kids A-LONG subjects (all IP) had no target joint bleeding episodes. Among prophylaxis subjects with target joints at baseline and 12 mo follow-up, 100% of A-LONG and Kids A-LONG subjects had ≥1 target joint resolved (≤2 spontaneous bleeding episodes in 12 consecutive mo); 99.6% and 100% of evaluable target joints in A-LONG and Kids A-LONG subjects were resolved, respectively. **Table 2** shows prophylactic dose and dosing intervals. In adults/adolescents, 96.4% of target joint bleeding episodes were controlled with ≤2 rFVIIIFc injections; patients rated 82.0% of injections to control a bleeding episode as excellent or good.

Conclusions: Low target joint ABRs and effective target joint resolution occurred in children, adolescents, and adults on long-term rFVIIIFc prophylaxis.

TABLE 1 Summary of on-study target joint ABRs among subjects with target joints at baseline and an efficacy period

	Adults/adolescents				Paediatric subjects (<6 years)[a]	Paediatric subjects (6 to <12 years)
Median (IQR) on-study target joint ABR	IP (n = 82)	WP (n = 26)	MP (n = 16)	ET (n = 18)	IP (n = 6)	IP (n = 7)
Overall	0.4 (0.0, 1.7)	0.4 (0.0, 2.0)	1.6 (0.5, 6.4)	14.6 (6.1, 22.2)	0.7 (0.0, 2.0)	0.0 (0.0, 2.0)
Spontaneous	0.0 (0.0, 0.8)	0.1 (0.0, 0.8)	0.7 (0.3, 3.3)	8.6 (1.4, 16.3)	0.7 (0.0, 2.0)	0.0 (0.0, 2.0)
Traumatic	0.0 (0.0, 0.5)	0.0 (0.0, 0.5)	0.3 (0.0, 2.0)	0.5 (0.0, 6.9)	0.0 (0.0, 0.0)	0.0 (0.0, 0.3)

ABR, annualised bleeding rate; IQR, interquartile range; IP, individualised prophylaxis; WP, weekly prophylaxis; MP, modified prophylaxis; ET, episodic therapy.

[a]For 1 subject <6 years of age on MP on-study, overall target joint ABR was 1.0, spontaneous target joint ABR was 1.0, and traumatic target joint ABR was 0.

TABLE 2 Summary of dosing characteristics for subjects with target joints at baseline[a]

	Adults/adolescents			Paediatric subjects (<6 years)[b]	Paediatric subjects (6 to <12 years)[c]
Median (IQR)	IP (n = 82)	WP (n = 26)	MP (n = 16)	IP (n = 6)	IP (n = 7)
Average weekly dose (IU/kg)	78.1 (73.9, 97.6)	65.4 (62.7, 66.8)	70.1 (57.3, 81.2)	89.6 (75.3, 97.5)	82.2 (79.4, 113.2)
Dosing interval (days)	3.5 (3.2, 4.5)	7.0 (6.9, 7.0)	5.6 (4.0, 7.0)	3.5 (3.5, 3.5)	3.5 (3.0, 3.6)

IQR, interquartile range; IP, individualised prophylaxis; WP, weekly prophylaxis; MP, modified prophylaxis.

[a]Subjects who changed regimens during the study were included in summary analyses of each treatment regimen for the time period they were in that regimen and, thus, may be included in >1 regimen.

[b]For 1 subject <6 years of age on MP on-study, average weekly dose was 118.7 IU/kg and dosing interval was 2.3 days.

[c]There were no subjects 6 to <12 years of age on MP on-study.

PB 213 | Administration of Recombinant Factor VIII by Continuous Infusion (CI) versus Intermittent Bolus Infusion (BI) in the Intra- and Post-operative Setting

I. Pabinger[1], G. Spotts[2], W. Engl[3], B. Pavlova[3], J. Doralt[3], L.A. Valentino[2,4]

[1]Medical University of Vienna, Internal Medicine, Vienna, Austria, [2]Shire, Chicago, United States, [3]Shire, Vienna, Austria, [4]Rush University Medical Center, Chicago, United States

Background: Factor VIII (FVIII) replacement therapy by continuous infusion (CI) in patients with hemophilia A undergoing surgery may offer a safe and efficacious alternative to bolus infusion (BI).

Aims: To compare the peri- and post-operative (post-op) hemostatic efficacy and safety of Advate [antihemophilic factor (recombinant), plasma/albumin-free method] administered via CI or BI in patients undergoing major orthopedic surgery requiring drain placement.

Methods: In this randomized multicenter phase 3/4 study, previously treated patients with severe or moderately severe hemophilia A (baseline FVIII level ≤ 2% of normal) aged 18-59 years undergoing elective unilateral orthopedic surgery were randomized to treatment by CI or BI of Advate through post-op Day 7 according to their PK profile. The primary endpoint was the cumulative packed red blood cell (PRBC) volume in the drainage fluid during the first 24 hours post-op.

Results: A total of 63 patients were included; 32were randomized to receive Advate by CI and 31 to BI during unilateral knee replacement (n=48), hip surgery (n=4) or shoulder/elbow/ankle/knee surgery (n=8). The ratio of cumulative PRBC volume in the 24-hours drainage fluid was 0.92 with a 95% confidence interval of 0.82 to 1.05. Higher Advate doses were used in BI compared to CI intraoperatively, on post-op Day 0. and from post-op Day 15 to end of study; higher doses were used for CI on post-op Days 1-14. Transfusions were required in 18/32 and 13/31 patients on CI and BI, respectively. Of 4 reported bleeding episodes, 3 occurred in subjects on BI. Related adverse events (n=14) were reported in 5 subjects treated by CI (n=8) and 5 treated by BI (n=6).

Conclusions: CI administration of Advate is a viable alternative to intermittent BI in the peri- and postoperative hemostatic management of patients with hemophilia A undergoing major orthopedic surgery by providing comparable efficacy and safety.

PB 214 | Assessment of Clot Kinetics of Recombinant Human Factor VIII (rhFVIII), Recombinant Porcine Factor VIII (rpFVIII) Recombinant Factor VIIa (rFVIIa) and Activated Prothrombin Complex Concentrate (APCC) Utilizing Thromboelastography in Patients with Severe Hemophilia A and Inhibitors

R. Carmona[1], E. Marquez[1], H.S. Lee[1], G. Young[2]

[1]Children's Hospital Los Angeles, Los Angeles, United States, [2]Children's Hospital Los Angeles, University of Southern California Keck School of Medicine, Los Angeles, United States

Background: Approximately 30% of FVIII deficient patients will develop inhibitors (antibodies which neutralize the activity of factor replacement therapy) and therefore rely on bypassing agents (BPA) to manage bleeding.

Aims: The purpose of this study was to utilize TEG to compare clot kinetics of rhFVIII (Advate) and the 3 BPA: rpFVIII (Obizur), rFVIIa (Novosven) and APCC (FEIBA) in patients with FVIII deficiency and high titer inhibitors.

Methods: Subjects who signed informed consent to participate in an IRB-approved institutionally-funded study were enrolled. After appropriate washout, blood samples were drawn into citrated tubes from all subjects for measurement of FVIII activity, hFVIII inhibitor, pFVIII inhibitor, and baseline kaolin-activated TEG. In addition, 3 sets of kaolin-activated TEG experiments were performed:

1) *in vitro* spiking of rhFVIII and BPA at clinically-relevant concentrations;

2) *in vitro* spiking of rhFVIII and BPA at clinically-relevant concentrations after incubation of the blood at 37°C for 90 minutes; and

3) *in vivo* assays before and 30 minutes after infusion of rhFVIII 100 IU/kg in patients on immune tolerance.

Results: Two major observations were noted: 1) All 3 BPA significantly improved clot kinetics with shorter R and higher MA values in a concentration-dependent manner with a more potent effect noted for rpFVIII and FEIBA (table 1), and 2) the neutralizing effect of the inhibitor was not observed in the *in vitro* spiking experiments (even after incubation) but was observed on the *in vivo* samples (table 2).

TABLE 1 Study summary of group 1 in vitro experiments with all TEG parameters expressed as means (n=8)

	Baseline	rhFVIII 50 IU/mL	rhFVIII 200 IU/mL	rpFVIII 50 IU/mL	rpFVIII 200 IU/mL	FEIBA 50 IU/mL	FEIBA 100 IU/mL	rFVIIa 1.5 mcg/mL	rFVIIa 4.5 mcg/mL
R	124.4	4.3	4.7	4.6	3.6	5.4	3.8	20.3	10.7
K	34	1.5	1.8	1.6	1.5	3.9	1.5	3.9	2.6
angle	3.2	68.8	65.2	68	68.9	45.1	66.5	48.3	57.8
MA	15.2	65.2	59.6	64	60.2	48.3	63.5	65.9	65.3
G	1	9.9	7.5	9.7	7.8	4.9	9.1	10.3	9.8

TABLE 2 Study summary response to rhFVIII in in vitro and in vivo experiments on group 2 (n=3). TEG parameter results expressed as means.

	Baseline	rhFVIII 100 IU/mL in vitro spiking	rhFVIII 100 IU/mL in vivo
R	127.3	2	29.9
K	41.9	5.9	12.6
Angle	11.6	46.8	62
MA	33	43	60.4
G	3.3	4	5.8

Conclusions: TEG can demonstrate the *in vitro* effect of BPA at relevant concentrations and thus can be used to guide individualized therapy. However, the results of the rhFVIII *in vitro* spiking experiments did not demonstrate the neutralizing effect of the inhibitor, calling into question utilizing this method to assess the impact of FVIII therapy for bleed management in patients with high titer inhibitor patients.

PB 215 | Obesity in Patients with Hemophilia: Prevalence by Age, Clinical Correlates and Impact on Joint Bleeding

C.-Y. Chang[1,2], T.-Y. Li[3,4], S.-N. Cheng[4,5], R.-Y. Pan[4,6], H.-J. Wang[7,8], S.-H. Hu[4], Y.-C. Chen[4,9]

[1]*Taipei Medical University, Graduate Institute of Clinical Medicine, School of Medicine, Taipei, Taiwan, Republic of China,* [2]*Taipei Medical University Hospital, Division of Pediatric Hematology/Oncology, Taipei, Taiwan, Republic of China,* [3]*Tri-Service General Hospital, Department of Rehabilitation, Taipei, Taiwan, Republic of China,* [4]*Tri-Service General Hospital, Hemophilia Care and Research Center, Taipei, Taiwan, Republic of China,* [5]*Tungs' Taichung MetroHarbor Hospital, Department of Pediatrics, Taipei, Taiwan, Republic of China,* [6]*Tri-Service General Hospital, Department of Orthopedics, Taipei, Taiwan, Republic of China,* [7]*Taipei Medical University Hospital, Department of Medical Imaging, Taipei, Taiwan, Republic of China,* [8]*Taipei Medical University Hospital, Division of Pediatric Hematology/Oncology, Hemophilia Center, Taipei, Taiwan, Republic of China,* [9]*Tri-Service General Hospital, Division of Hematology/Oncology, Department of Internal Medicine, Taipei, Taiwan, Republic of China*

Background: The prevalence of obesity in patients with hemophilia (PWH) quite varies among different countries. The reports on the prevalence of obesity and impact of obesity in PWH from Asian countries are very limited.

Aims: We investigated the prevalence and clinical correlates of obesity in PWH in Taiwan, and explored the impact of body mass index (BMI) on hemophilic arthropathy (HA) and annual joint bleeding rate (AJBR).

Methods: We retrospectively collected 140 severe/ 40 moderate PWH from two hemophilia centers from 2006 to 2014. The patients' median age was 31.5 years old, ranged from 6-73 years Their BMI, AJBR and other clinical information were analyzed. HA was assessed by roentgenograms of 6 index joints including elbow, knee and ankle joints, and their Pettersson scores were calculated.

Results: The prevalence of overweight and obesity by age group were 7.1% and 0% in PWH aged 6-10 years, 6.9% and 27.6% in PWH aged 11-18 years, 35.6% and 11.1% in PWH aged 18-29 years, 23.5% and 38.2% in PWH aged 30-39 years, 24.2% and 36.4% in PWH aged 40-49 years, and 36% and 12% in PWH aged >50 years, respectively. Age, HCV infection, knee, elbow joints and total 6 index joints scores were found to have positive correlation with BMI, but severity of hemophilia, ankle scores, HBV and HIV infection were not found to have correlation with BMI. Additionally, BMI, age and HCV infection were found to have positive correlation with AJBR in both adult and pediatric PWH.

Conclusions: There were remarkably higher prevalence of overweight and obesity in both adult and pediatric PWH than those in general male population in Taiwan. Age, HCV infection, higher index joints except ankle scores were associated with higher BMI. Higher BMI or obesity had a significant correlation with higher AJBR in PWH, although the direct effect of BMI on HA could not be shown by total 6 index joints score.

PB 216 | Influence of Genetic Polymorphisms of Biological Mediators on the Phenotypic Heterogeneity in Hemophilic Arthropathy

Y.-C. Chen[1,2], S.-N. Cheng[1,3], T.-Y. Li[1,4], R.-Y. Pan[1,5], S.-H. Hu[1]

[1]*Tri-Service General Hospital, National Defense Medical Center, Hemophilia Care & Research Center, Taipei, Taiwan, Republic of China,* [2]*Tri-Service General Hospital, National Defense Medical Center, Division of Hematology/Oncology, Department of Medicine, Taipei, Taiwan, Republic of China,* [3]*Tungs'Taichung MetroHarbor Hospital, Department of Pediatrics, Taipei, Taiwan, Republic of China,* [4]*Tri-Service General Hospital, National Defense Medical Center, Department of Rehabilitation, Taipei, Taiwan, Republic of China,* [5]*Tri-Service General Hospital, National Defense Medical Center, Department of Orthopaedics, Taipei, Taiwan, Republic of China*

Background: Heterogeneity in hemophilic arthropathy indicates the difference of bleeding frequency and severity of hemophilic arthropathy. Some studies have shown that some polymorphisms or mutation of hemostatic factors, cytokines and genes involved in inflammation and angiogenesis in hemophilic arthropathy.

Aims: The aim of this study was to explore whether there is a correlation of

polymorphisms of the 8 biological mediators encoding genes with the heterogeneity of hemophilic arthropathy.

Methods: There were 74 consecutive severe type hemophilia A (HA) patients (10 with inhibitor) in this study. Their median age was 42 years old, ranged from 14-71 years. Their DNA of white blood cells were extracted. Genotyping of gene polymorphism of 8 biological mediators including Thrombomodulin/Ala25Thr, TFPI/Val264Met, TNF-α/(-308G>A), IL 6/(-174 G>C), IL 10/(-1082G>A), VEGF/(936 C>T), MDM2/(309T>G) and HFE/ C28Y&H63D were sequenced. Each patient's X ray score of 6 index joints including elbow, knee and ankle joints was calculated by Pettersson score. Unpaired Student's *t* test was used to evaluate the comparison of the eight genotype of polymorphisms.

Results: There were high frequency of variants of MDM2 and VEGF genes in our cohort. The MDM2/(309T>G) was the most frequent variant with frequency of 78.8%, followed by VEGF (936C>T) with frequency of 41.9%. The total 6 index joints score in patients with

heterozygous polymorphism of VEGF (C/T) was 35.86± 3.85 which was significant lower than the 44.67 ± 2.89 in patients with wild type VEGF (C/C) (p= 0.0336).

Conclusions: Our study demonstrates that there were high frequency of MDM2 and VEGF gene polymorphisms in severe type HA patients and patients with heterozygous polymorphism of VEGF gene (C/T) had less severity of HA of 6 index joints evaluated by X ray Pettersson score than patients without polymorphism. The mechanism for this remarkable finding warrants further investigation.

PB 217 | Joint Status and Other Factors Associated with Pain Severity and Interference in US Adults with Hemophilia Beyond Joint Status: Analysis of the Pain, Functional Impairment, and Quality of Life (P-FiQ) Study

T. Buckner[1], C. Kempton[2], M. Fridman[3], N. Iyer[4], D. Cooper[4]

[1]*University of Colorado Denver, Hemostasis and Thrombosis Center, Aurora, United States,* [2]*Emory University, Hematology and Medical Oncology, Atlanta, United States,* [3]*AMF Consulting Inc, Los Angeles, United States,* [4]*Novo Nordisk Inc, Plainsboro, United States*

Background: P-FiQ enrolled US adults with hemophilia and included administration of patient-reported outcome instruments to assess pain, functional impairment, and quality of life. Brief Pain Inventory (BPI) severity was associated with lack of college education, unemployment, older age, history of joint procedures, viral disease, and severe hemophilia.

Aims: This post hoc analysis assessed association between demographic and clinical characteristics independent of joint status (Hemophilia Joint Health Score [HJHS]) and BPI pain severity and interference scores.

Methods: The association of BPI scores with HJHS and other covariates was examined using simple regression models and by a multiple regression model where HJHS overall score, age, hemophilia severity, and treatment were included with other covariates having bivariate correlations with HAL scores (α< 0.05) using forward selection.

Results: The study enrolled 381 patients in total. Physiotherapist-completed HJHS was available for 240 respondents, with a median age of 32 years; most were employed (65%), college educated (65%), had severe hemophilia (63%) or inhibitors (9%), experienced pain (84%), and had prior joint procedures (54%). Worse joint status (higher HJHS score) was associated with higher pain scores in the multiple regression models, which had R-squared values of 0.422 for pain severity and 0.386 for pain interference. In addition to HJHS score, other predictors of worse pain outcomes included non-employed status, opiate use, anxiety, and use of anxiolytics **(Table 1)**.

Conclusions: Joint health status was an independent predictor of pain severity and interference, and opiate/anxiolytic use, anxiety, and work status were also associated with pain outcomes. Only 42%/39% of pain severity/interference was explained by the model. Continued attention to psychosocial issues, including assessing and managing pain, is essential to clinical care and future research in the hemophilia population.

PB 218 | Ranges of Risk Associated with Sports/Recreational Activities in People with Hemophilia: Results of the Activity-Intensity-Risk (AIR) Consensus Survey of US Physical Therapists

G. Hernandez[1], K. Baumann[2], S. Knight[3], H. Purrington[4], M. Gilgannon[5], M. Karelus[6], J. Newman[7], P. Tobase[8], D. Basoff[9], S. Mathew[9], D. Cooper[9]

[1]*Center for Inherited Blood Disorders, Santa Ana, United States,* [2]*University of Minnesota Health, Minneapolis, United States,* [3]*Children's Hospital of Los Angeles, Los Angeles, United States,* [4]*Phoenix Children's Hospital, Phoenix, United States,* [5]*University of Virgina Health Systems, Charlottesville, United States,* [6]*Hemophilia Treatment Center of Nevada, Las Vegas, United States,* [7]*University of North Carolina, Chapel Hill, United States,* [8]*University of California San Francisco, San Francisco, United States,* [9]*Novo Nordisk Inc, Plainsboro, United States*

Background: Limited evidence supports assessment of activity-associated risk for people with hemophilia (PWH) and other bleeding disorders. Existing consumer resources provide a single risk score for each activity based on opinions of a few physical therapist (PT) authors.

TABLE 1 Multiple Regression Models—BPI Pain Severity or Interference

	BPI Pain Severity (n=177; R2=0.422)				BPI Pain Interference (n=181; R2=0.386)			
Characteristic	ß Estimate*	Lower 95% CI	Upper 95% CI	P Value	ß Estimate*	Lower 95% CI	Upper 95% CI	P Value
HJHS overall score (10-point change)	0.30	0.14	0.47	0.0003	0.32	0.13	0.52	0.0012
Employed	-0.67	-1.38	0.03	0.0617	-0.94	-1.77	-0.12	0.0244
Patient-reported use of opiates	1.27	0.71	1.83	<0.0001	1.41	0.73	2.09	0.0001
Site-reported anxiety	1.33	0.49	2.18	0.0022	2.26	1.34	3.18	<0.0001
Site-reported use of anxiolytics	1.68	0.05	3.30	0.0429				

BPI, Brief Pain Inventory v2 Short Form; HJHS, Hemophilia Joint Health Score. *ß estimate measures change in outcome per change in covariate.

TABLE 1 Physical Therapist Ratings of Risk

Ball Sports	Low/Min Risk Median (IQR)	High/Max Risk Median (IQR)	Water Sports	Low/Min Risk Median (IQR)	High/Max Risk Median (IQR)	Winter Sports	Low/Min Risk Median (IQR)	High/Max Risk Median (IQR)
Baseball - Pitcher	3 (2, 3)	4 (4, 5)	Jet Skiing	2 (1, 3)	4 (3, 4)	Ice Hockey	4 (3, 4)	5 (5, 5)
Baseball - Catcher	3 (3, 3)	4 (4, 4)	Kayaking	1 (1, 2)	3 (2, 4)	Skating - Recreation	2 (1, 2)	3 (2, 4)
Baseball - Other	2 (2, 3)	3 (3, 3.3)	Sailing	1 (1, 2)	3 (2, 3.5)	Skating - Figure	2 (2, 3)	4 (3, 5)
Basketball	2 (2, 2)	4 (4, 4)	Diving Recreational	2 (1.8, 2.3)	3 (2, 3)	Ski - Cross Country	1 (1, 2)	2 (1.8, 3)
Football- Flag	2 (2, 3)	4 (3, 4)	Paddle Boarding	1 (1, 1)	2 (1.8, 3)	Ski - Down Hill	2 (2, 3)	4 (4, 5)
Football - Tackle	5 (5, 5)	5 (5, 5)	Surfing	2 (2, 3)	4 (3, 5)	Snowboarding	3 (2, 3)	5 (4, 5)
Rugby	5 (4.5, 5)	5 (5, 5)	Swimming	1 (1, 1)	2 (2, 3)	Other Activities		
Soccer - Goalie	2 (2, 3)	4 (4, 5)	Water Polo	2 (2, 3)	4 (3.8, 4)	Horseback Riding	2 (1, 3)	4 (3, 4.3)
Soccer - Other	2 (2, 2.3)	4 (3.8, 4)	Water Skiing	2.5 (2, 4)	4 (3, 5)	Trampoline	3 (2, 4)	4 (4, 5)

Aims: To assess ranges of risk for PWH associated with different sport/recreational activities, based on consensus of US PT experts.
Methods: Peer-nominated PTs in the US hemophilia treatment center (HTC) network were invited to participate in a survey of 100 sports/recreational activities. For each activity, respondents provided a low/minimum and high/maximum risk assessment on a 5 point scale (low=1, high=5). Position-specific assessments were made for some team sports (eg, baseball pitcher, catcher, and field positions). Sports with distinctly different participation levels were evaluated separately (eg, flag vs tackle football, boys vs girls lacrosse, Frisbee vs ultimate).
Results: Of 32 invited PTs, 17 responded with median (mean) 26.5 (22.4) years as a PT and 15.5 (16.8) years at an HTC. Most treated adults (94%) and children (88%), and worked in the HTC full-time (29%) or nearly full-time (41%); 94% worked in a comprehensive care clinic. Median (Q1, Q3) PT ratings are shown for selected activities **(Table 1)** and ball sports **(Fig 1)**. Overall, few activities had low/minimum and high/maximum risk assessments at the lower (1) or upper (5) end of the response range. For example, while swimming is typically associated with low risk, maximum risk includes potential year-round competitive swimming. In contrast, rugby and American football (tackle) had consistently high scores.

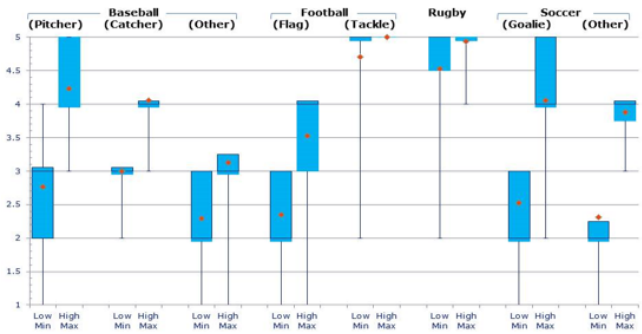


FIGURE 1 Physical Therapist Rated Range of Risk for Selected Ball Sports

Conclusions: Consensus of experienced PTs demonstrates most sports/recreational activities can be best described by a range of risk. This finding highlights the importance of individualized activity-specific risk assessment over time (eg, from recreational to competitive) as part of regular HTC discussions with patients/families.

PB 219 | The Impact of Switching Recombinant Factor VIII Product Concentrates on Inhibitor Development among Haemophilia A Patients in Australia

H. Tran[1,2], S. Parikh[3], S. McRae[4]

[1]*The Alfred Hospital, Haemostasis Thrombosis Unit, Melbourne, Australia,* [2]*Australian Centre for Blood Diseases, Monash University, Clinical Haematology, Melbourne, Australia,* [3]*Australian Haemophilia Centre Directors' Organisation, Melbourne, Australia,* [4]*Royal Adelaide Hospital, South Australia Pathology, Adelaide, Australia*

Background: The pathogenesis of the development of inhibitors in patients with haemophilia A (HA) is complex, involving the immune system, genetics and environmental factors. It is controversial if switching recombinant factor VIII (FVIII) concentrates is a risk factor for inhibitor development.
Aims: This retrospective study explores if switching between recombinant FVIII concentrates increases the risk of inhibitor development in HA in Australia.
Methods: Inhibitor and Product Usage data was obtained from the Australian Bleeding Disorder Registry on HA patients who had to switch between full-length & B-deleted FVIII products in 2012 and 2014 as part of a national tendering process. With Ethics approval, data was extracted on patient diagnosis, severity, age, date of product switch and inhibitor test results pre and post product switch including titres. Positive inhibitor is ≥0.5 BU/mL; negative < 0.5BU/mL. Post product switch inhibitor test results were recorded as transient

(1 positive followed by 1 negative) or persistent (>1 positive inhibitor result within 12 months). Multivariate regression analysis was performed to determine if product switching contributed to inhibitor development in patients with HA.

Results: 712 patients switched their FVIII product. Pre and post product switch inhibitor tests were performed on 609 patients. Post switch, 47 (7.7%) had a transient and 23 (3.8%) a persistent inhibitor. 10 of the persistent inhibitors were de novo (7/336 [2.1%] severe; 3/273 [1.1%] non-severe); and 13 occurring in patients with a prior history of inhibitor (8/336 [2.4%] severe; 5/273 [1.8%] non-severe) (table 1). Multivariate analysis showed that product switching did not impact inhibitor development, but severity of HA did (p=0.000) (figure 1).

TABLE 1 Inhibitor development post FVIII product switch by haemophilia A severity and presence or absence of past inhibitor

	Past inhibitor prior to product switch	
Haemophilia A severity	Yes	No
Non-severe	5	3
Severe	8	7

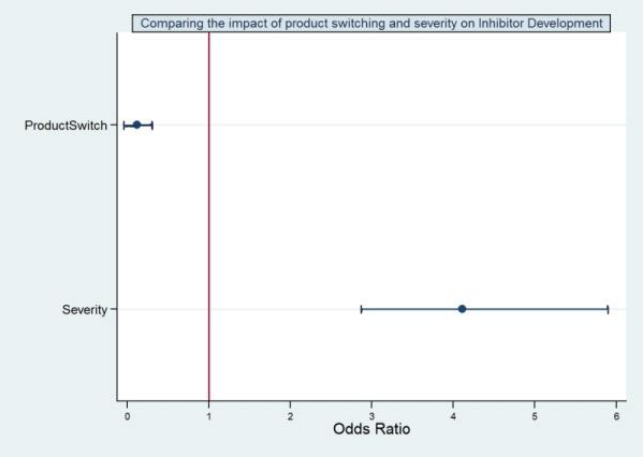

FIGURE 1 Comparing the impact of FVIII product switching and severity of HA on inhibitor development

Conclusions: Switching of FVIII concentrate in HA patients does not appear to increase the risk of inhibitor development.

PB 220 | Sociodemographic, Clinical and Psychosocial Characteristics of People with Haemophilia (PWH) in Portugal: Preliminary Results of the First National Survey

A.C. Paredes[1,2], S. Pedras[3], P. Costa[1,2,4], M. Carvalho[5], M. Lopes[5], S. Fernandes[5], M. Crato[6,7], A. Almeida[1,2], P.R. Pinto[1,2]

[1]University of Minho, School of Medicine, Life and Health Sciences Research Institute (ICVS), Braga, Portugal, [2]ICVS / 3B's - PT Government Associate Laboratory, Braga / Guimarães, Portugal, [3]University of Minho, School of Psychology, Braga, Portugal, [4]University of Porto, Faculty of Psychology and Education Sciences, Porto, Portugal, [5]Centro Hospitalar São João, Centre of Hemophilia, Department of Transfusion Medicine and Blood Bank, Porto, Portugal, [6]Portuguese Haemophilia Association, Lisbon, Portugal, [7]European Haemophilia Consortium, Brussels, Belgium

Background: Understanding PWH clinical characteristics and psychosocial needs is paramount for improvement of integrated health care. However, despite recent surveys conducted among PWH, no demographic, clinical and psychosocial data is available in Portugal.

Aims: To collect information on sociodemographic and clinical data, pain, quality of life (QoL) and functionality in Portuguese PWH, ultimately contributing for the improvement of health policies and care.

Methods: Recruitment was made through a national patient organization (Portuguese Haemophilia Association) and 477 surveys were sent by post (Table 1). Data was obtained from 71 adults [age range=18-74; M(SD)=44.18(14.02)] and 28 children/teens [age range=1-17; M(SD)=9.64(4.73)]. The survey was approved by ethical committee and informed consent was signed by all respondents or legal guardians.

TABLE 1 Survey variables and measures

Variables	Measure
Sociodemographic: age, education, employment, marital status, income and household.	Sociodemographic Questionnaire
Clinical: age of diagnosis, Haemophilia type and severity, inhibitor status, appointments with Haemophilia specialist, emergency hospital admissions, work absences, frequency and location of bleeds, Haemophilia treatments, damaged and target joints, orthopedic surgery, HIV/ Hepatitis C status, medical comorbidities and chronic medication.	Clinical Questionnaire
Pain: duration, frequency, location, triggering factors, impact, intensity, interference, relief strategies, pain specialists and satisfaction with pain treatment.	Pain Questionnaire
Pain catastrophizing	CSQ-R - Catastrophizing Subscale (Riley & Robinson, 1997)
Functional Ability (Adults / Children and Teens)	HAL (van Genderen et al., 2006) / PedHAL (Groen et al., 2010)
Quality of Life (Adults / Children and Teens)	A36HemofiliaQoL (Remor et al., 2005) / CHO-KLAT (Young et al., 2004)

Results: Haemophilia A was reported by 89.9% of participants, the presence inhibitors by 17.4%, and all disease severities were considered (mild=12.1%; moderate=31.3%; severe=56.6%). The mean of annual bleeds was 10.92 (SD=15.06) for adults and 4.00 (SD=3.66) for children/teens. In this latter group, 75% were on prophylaxis (vs.

26.8% adults). A target joint was reported by 69.0% of adults, most frequently the knees (52.1%) and by 34.6% of children/teens, most often the elbows (44.4%) and ankles (44.4%). Chronic pain was reported by 59.2% of adults and 32.1% of children/teens. Adults reported greater functional limitations on ‚Functions of the Legs' [M(SD)=55.29(29.27)] and ‚Lying/Sitting/Kneeling/Standing' [M(SD)=58.22(28.77)] and the mean normative score for QoL was 53.98(26.21). Children/teens revealed greater impairment on ‚Leisure Activities and Sports' [M(SD)=88.65(15.75)] and QoL mean score was 76.52 (SD=12.62).

Conclusions: These findings are expected to contribute to deepen the knowledge about Portuguese PWH, in order to implement multidisciplinary approaches that improve disease management, promote well-being and quality of life.

PB 221 | Understanding Burden of Illness of People with Hemophilia A with or without a Current Inhibitor

W.E. Owens[1], Y. Xu[2], A. Cyhaniuk[1,3], E. Chan[1], P. Kuebler[2], R.H. Ko[2], P.G. Solari[2], J. Chupka[1]

[1]Hemophilia Federation of America, Washington, DC, United States, [2]Genentech Inc., South San Francisco, United States, [3]AC Analytical Solutions, LLC, Barrington, United States

Background: The CHOICE Project was conducted in partnership between the CDC and Hemophilia Federation of America to survey persons with bleeding disorders (PWBD) in the US, including those who do not receive care at federally-funded hemophilia treatment centers (non-HTC PWBD).

Aims: To retrospectively characterize clinical utilization and bleeding among people with hemophilia A with or without a current inhibitor (PWH) to better understand burdens of illness and how to address them.

Methods: Demographic and clinical data were collected through CHOICE from 04/2013-07/2015 on PWBD. PWBD were recruited to take a 20-minute survey in English or Spanish, online or on paper. Non-HTC PWBD were solicited specifically but others were not excluded from participation. Participants' status as non-HTC PWBD was determined by algorithm. Descriptive statistical analysis of PWH was performed based on the chi-square test (*P* values).

Results: Of 439 PWH, 13% are non-HTC PWH and 11% have a current inhibitor (WI). In the last 12 months, due to their bleeding disorder, 18/48% (PWH without an inhibitor (WO)/WI) were admitted to a hospital (p=0.001); 31/58% visited an ER (p=0.0004); average ER visits for WO 2.8 v. WI 3.7 (p=.004); 22/13% delayed care **(Figure 1)**; 75/70% had a joint bleed, 41/58% a muscle bleed, 65/78% another type of bleed with an average of number of bleeds of 5.3/7.6 **(Figure 2)**; 26/19% always had joint problems and these problems always limited activity for 16/27%, with 35/56% taking OTC and 13/13% prescription pain medication on a few days to treat pain.

Conclusions: Burden of illness for WI is reflected in hospital admittance and emergency care along with bleed types/number, care delay, and joint problems. Additional analysis is needed to investigate the disease burden associated with different treatment regimen for PWH. This sample does not necessarily represent all PWH, as targeted outreach in some regions may have led to over-representation of some participant characteristics.

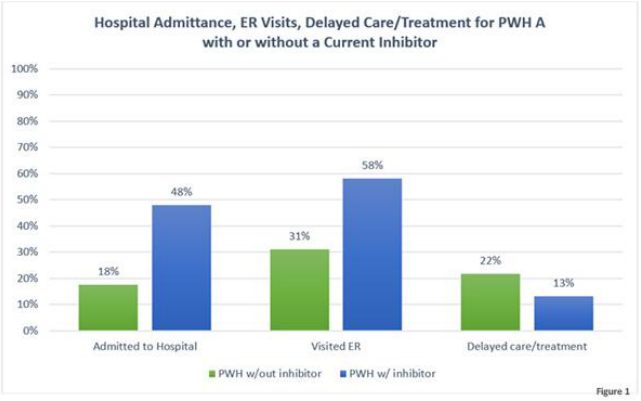

FIGURE 1 Hospital Admittance, ER Visits, Delayed Care/Treatment for PWH A with or without a Current Inhibitor

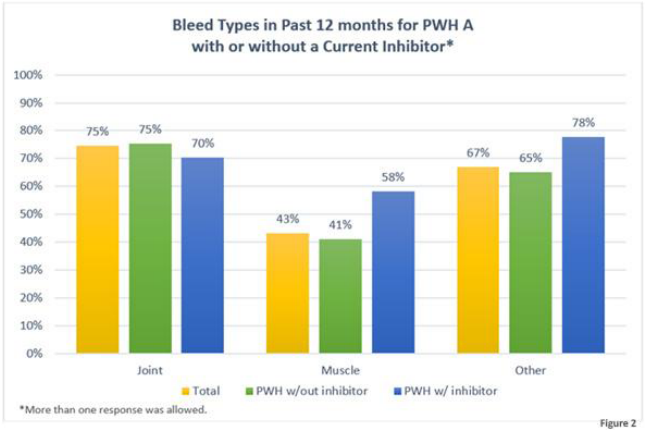

FIGURE 2 Bleed Types in Past 12 months for PWH A with or without a Current Inhibitor

PB 222 | The Continued Use of Cryoprecipitate and Plasma to Treat Bleeding Disorders

M. Brooker[1], C. Herr[1], F. Robinson[1], D. Coffin[2]

[1]World Federation of Hemophilia, Montreal, Canada, [2]World Federation of Hemophilia, Research & Public Policy, Montreal, Canada

Background: Plasma contains all the coagulation factors and can be used to treat bleeding disorders (BD). Cryoprecipitate (cryo) is preferable to plasma for the treatment of hemophilia A (HA) and von Willebrand disease. Although it is possible to apply virucidal treatment to plasma and cryo, this is not common practice. Despite the risk of transfusion-transmitted infection, these products are still used in countries unable to afford sufficient supplies of clotting factor concentrates (CFC).

Aims: To evaluate the use of cryo and plasma globally to treat BD.

Methods: The World Federation of Hemophilia Annual Global Survey (AGS) collects basic data on demographics and access to care and treatment products. The AGS asks specifically about availability and use of cryo and plasma for treatment of BD. Using data reported by 115 countries (~90% of world pop.) from 2013 to 2105, we analyzed the use of plasma and cryo around the world.

Results: 115 countries answered the AGS questions on the use of plasma and cryo. All countries reported plasma and cryo being available, but 69 (60%) reported never using them to treat BD. 40 countries (34.8%) reported using plasma (Table). Of this group, 31/40 (78%) reported receiving humanitarian aid donations of CFC and in 20/40 (50%) virtually all CFC treatments were with donated product. 83,903 patients with BD have been identified in countries reporting use of plasma. High GNI countries specified it is used for rare BD, not hemophilia. Cryo was used to treat patients in 36 countries (31.3%). Many of these countries reported some access to CFC but use of cryo when CFC were not available. Median FVIII/cap in countries using cryo was 0.07 IU. 63,848 patients with HA have been identified in countries reporting cryo use.

TABLE 1 Countries reporting use of plasma and cryo by Gross National Income (GNI)

GNI per capita US$ (World Bank data)	Countries using plasma n = 40	Countries using cryo n = 36
high income, ≥$12,475	4 (10%)	1 (3%)
upper middle income, $4,036 - $12,475	11 (28%)	11 (31%)
lower middle income, $1,026 - $4,035	19 (48%)	20 (56%)
lower income, $0-$1,025	6 (15%)	4 (11%)

Conclusions: Despite the risks, plasma and cryo are still used to treat people with BD, underscoring the need for improved safety of these lifesaving treatments and increased access to affordable and sustainable supplies of CFC.

PB 223 | Anti-CD20 and Sirolimus for Immune Tolerance in Congenital Hemophilia A with Inhibitors

B. Doshi[1], V.R. Arruda[2,3], M. Lambert[2,3], L.J. Raffini[2,3], L.A. George[2,3]

[1]*Children's Hospital of Philadelphia, Hematology/Oncology, Philadelphia, United States,* [2]*Children's Hospital of Philadelphia, Hematology, Philadelphia, United States,* [3]*University of Pennsylvania Perelman School of Medicine, Pediatrics, Philadelphia, United States*

Background: The development of factor VIII (FVIII) inhibitors in 30% of patients with severe hemophilia A (HA) results in significant morbidity. Immune tolerance induction (ITI) is only successful in 2/3 of patients and others relapse after ITI. Use of anti-CD20 (rituximab) demonstrated inconclusive benefit as a solo therapy (Thromb Haem 2014). A combined B and T cell approach aimed to increase Tregs has potential to improve refractory inhibitor patient outcomes.

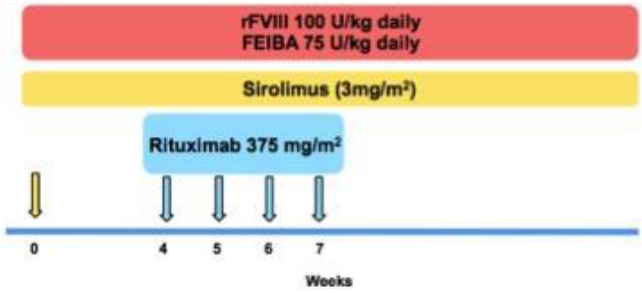

FIGURE 1 Experimental Protocol for Dual Therapy

Aims: Here we analyzed response to dual T and B cell therapy with rituximab (anti-CD20) and sirolimus in 2 severe HA patients with refractory inhibitors.

Methods: Patients consented to an IRB approved protocol. They were treated with sirolimus, rituximab and FVIII per Figure 1. Bypass agents were stopped upon high titer inhibitor resolution. Patient plasma samples were analyzed to determine Nijmegen modified Bethesda titer and FVIII-specific IgG1 and IgG4 by ELISA to evaluate for FVIII non-neutralizing and neutralizing antibodies, respectively, and compared to HA without inhibitor control.

Results: Patient 1 failed prior ITI and rituximab therapies. At enrollment his inhibitor was 23 BU. He had a rapid response to therapy with an undetectable Bethesda titer within 2 months of sirolimus initiation and 1 month after rituximab. His FVIII-IgG1 and IgG4 were undetectable at 7 and 19 months, respectively. Patient 2 failed multiple ITI attempts. His inhibitor was 384 BU with corresponding greater FVIII-IgG1 and IgG4 at enrollment (Table 1). He had a slower therapeutic response with a continued decrease in Bethesda titer, FVIII-IgG1 and IgG4, but remains on bypass therapy. Both patients had clinical improvement with marked reduction in bleeding.

TABLE 1 Bethesda Assay, FVIII-specific IgG1 and IgG4 over time

Patient	Time from rituximab (months)	Inhibitor Titer (BU)	IgG1 (mcg/ml)	IgG4 (mcg/ml)
1	-2	23	1.22	1.98
	1	0	0.17	0.11
	7	0	0	0.08
	19	0	0	0
2	-1	384	52.78	10.25
	1	166	7.99	4.86
	11	48	2.18	1.35
	17	7	2.54	0.26
HA Control	--	0	0	0

Conclusions: To our knowledge, this is the first study of sirolimus and rituximab co-administration for ITI in HA inhibitor patients. One patient tolerized rapidly to FVIII while the other has promising results at 17 months. Dual sirolimus and rituximab therapy may be a viable alternative in refractory inhibitor patients.

PB 224 | A Prospective Surveillance Study of Inhibitor Formation in Quebec Hemophilia A Patients Following a Population Switch to a Third-generation B-Domain-deleted Recombinant Factor VIII

E. Dubé[1], A. Bonnefoy[1], C. Merlen[1], J.-F. Castilloux[2], S. Cloutier[3], C. Demers[3], J. St-Louis[1], C. Vezina[4], M. Warner[4], G.-E. Rivard[1]

[1]CHU Sainte-Justine, Montreal, Canada, [2]CHUS - Hôpital Fleurimont, Sherbrooke, Canada, [3]CHA - Hôpital de l'Enfant-Jésus, Quebec, Canada, [4]Montreal Children's Hospital, Montreal, Canada

Background: For administrative reasons, most subjects with hemophilia A (HA) were switched from their current treatment to a third-generation B-domain-deleted recombinant factor VIII (FVIII). Despite a low risk of inhibitor development in previously treated subjects, we considered it important to monitor our population for this serious outcome.

Aims: To evaluate FVIII recovery and the risk of inhibitor formation in subjects switching to this product.

Methods: All subjects with severe and moderate HA were eligible unless they had less than 150 exposures days (ED) to any FVIII or detectable inhibitor at enrollment. Plasma samples were collected prior to the first infusion (ED1), at 15min post ED1, then at 6 and 12 months after switching, where feasible. All samples were analyzed for FVIII levels and inhibitors at a central laboratory. FVIII recovery (FVIIIrec) was expressed as the observed FVIII increase per unit of FVIII infused per kg ($IU.dL^{-1}/IU.kg^{-1}$). The study was approved by the REB of participating institutions and all subjects provided written informed consent.

Results: 125 male subjects were recruited (mean age 27.83±13.93). 96% had severe HA, 8% had a family history of inhibitors, and 9.6% had a personal history of inhibitors. Pre and post infusion samples were collected from 97.6 % of subjects at ED1 (mean FVIIIrec 2.45±0.61); from 68.8% of subjects at 6.58±1.60 months (mean FVIIIrec 2.43±0.73) and 84% of subjects at 12.85±2.04 months (mean FVIIIrec 2.49±0.64). No recurrence of inhibitors was observed in any of the subjects with a personal history of inhibitors. Two subjects (1.6%) developed an inhibitor: one (age 19) developed a transient inhibitor (peak titer 2.6BU) after 38ED to the new product; another (age 59) developed an inhibitor (peak titer 56.3BU) after 58ED.

Conclusions: Our results suggest that switching to this product was not associated with an increased risk of inhibitor formation as reported in similar studies.

PB 225 | Evaluation of Reagent Substitutions in the Centers for Disease Control and Prevention Modified Nijmegen-Bethesda Assay (CDC-NBA) for Factor VIII (FVIII) Inhibitors in Hemophilia A

C.H. Miller, A.B. Payne, J. Driggers, D. Ellingsen, B. Boylan, C. Bean

Centers for Disease Control and Prevention, Division of Blood Disorders/NCBDDD, Atlanta, United States

Background: The Nijmegen modification of the Bethesda assay introduced 2 changes: buffering of normal pooled plasma (NPP) in test and control mixtures with imidazole (IB-NPP) and substitution of FVIII-deficient plasma (FVIIIDP) for imidazole buffer (IB) as diluent in control mixtures and specimen dilutions for stabilization during incubation. Other reagents have been proposed to reduce cost.

Aims: To investigate the efficacy of reagent substitution in the CDC-NBA.

Methods: NPP, IB-NPP, and HEPES-buffered NPP were tested for FVIII and pH before and after 2 hours at 37°C. IB-NPP mixtures with other diluents substituted for FVIIIDP were tested for FVIII during incubation. Subsets of 1,565 specimens submitted to the Registry for Bleeding Disorders Surveillance conducted by CDC, the American Thrombosis and Hemostasis Network, and the US Hemophilia Treatment Centers Network were tested using the CDC-NBA, which includes preanalytical heat inactivation, and in parallel with reagent substitutions. IgG_4 anti-FVIII antibodies were measured by fluorescence immunoassay.

Results: IB-NPP showed greater FVIII and pH stability during incubation. As diluent, 4% bovine serum albumin (BSA), imidazole-buffered BSA (IB-BSA), and IB were not significantly different; all produced greater FVIII stability than native FVIIIDP. BSA, IB-BSA, and IB were comparable to FVIIIDP on 15 positive (≥0.5 Nijmegen-Bethesda units (NBU)) specimens with slightly higher NBU on 311 negative specimens; BSA with a cut-off of ≥0.6 NBU showed the best performance relative to FVIIIDP. Among 1206 negative and 33 positive specimens, BSA at a cut-off of ≥0.6 had sensitivity 0.97, specificity 0.99, positive predictive value 0.70, and negative predictive value >0.99 relative to the original assay. Anti-FVIII IgG_4 increased at ≥0.5 NBU with FVIIIDP and ≥0.7 NBU with BSA.

Conclusions: Substitution of BSA for FVIIIDP in the CDC-NBA produces similar results to the original assay if the cut-off for positivity is adjusted to ≥0.6 NBU. Imidazole buffering is preferred for NPP.

PB 226 | Evaluation of an Optimized Thrombin Generation Assay for Measurement of rFVIIa in Haemophilia A Patient Plasma

I. Fernandez-Bello[1], N.V. Butta[2], V. Jimenez-Yuste[3], L.F. Larsen[4], V. Lind[4], M. Ezban[4]

[1]La Paz University Hospital, Haematology, Madrid, Spain, [2]La Paz University Hospital-IdiPaz, Haematology and Haemotherapy Department, Madrid, Spain, [3]La Paz University Hospital, Haematology and Haemotherapy Department, Madrid, Spain, [4]Novo Nordisk A/S, Global Research, Måløv, Denmark

Background: NovoSeven® (rFVIIa) shows high efficacy in the treatment of bleedings in haemophilia patients with inhibitors. The standard commercial thrombin generation assay CAT (Calibrated Automated Thrombogram) is currently being evaluated for monitoring efficacy of haemostatic therapy of rFVIIa in haemophilia patients. However, CAT standard condition for haemophilia plasma samples is not sensitive to therapeutic relevant rFVIIa levels [Turecek 2003].

Aims: To evaluate an optimized CAT for *ex vivo* measurements of rFVIIa in therapeutic relevant levels in haemophilia A plasma.

Methods: Haemophilia A (HA) plasma samples (n=6 patients) were spiked with various concentrations of rFVIIa (0-75 nM, 75 nM corresponds to ≈ 270 ug/kg), Novo Nordisk A/S) and thrombin generation was measured with an optimized CAT using human soluble tissue factor (sTF, 2 nM final concentration (f.c.), Novo Nordisk A/S) + MP phospholipid reagent (4 mM phospholipids f.c., Thrombinoscope). CAT was also determined in a different set of HA plasma samples (n=11) spiked with comparable rFVIIa concentrations but using the standard CAT reagent PPP Reagent Low (Thrombinoscope) containing f.c. of 1 pM TF and 4 μM phospholipids. Thrombin generation was initiated by addition of a fluorogenic thrombin substrate containing $CaCl_2$ (Fluca, Thrombinoscope).

Results: Optimized CAT showed a clear dose-response of rFVIIa. Relevant pharmacological rFVIIa levels (1-25 nM) resulted in peak thrombin concentrations ranging from approximately 50-250 nM. The optimized assay was able to detect rFVIIa concentrations down to 0.1 nM. As expected, the standard CAT condition (PPP Reagent Low) resulted in a peak thrombin increase from 25 nM to approximately 35 nM for comparable rFVIIa plasma concentrations.

Conclusions: With the optimized CAT it is possible to detect and distinguish relevant pharmacological rFVIIa levels in Haemophilia A patient plasma. Clinical data are needed for evaluation of the optimized assay as an efficacy assay.

PB 227 | Efficacy and Safety of Human-cl rhFVIII in Patients with Severe Hemophilia A Undergoing Surgical Procedures

N. Zozulya[1], J. Bichler[2], A. Klukowska[3]

[1]*Haematological Scientific Centre, Moscow, Russian Federation,* [2]*Octapharma AG, Lachen, Switzerland,* [3]*University Medical School, Department of Pediatrics, Hematology and Oncology, Warsaw, Poland*

Background: Hemophilia A patients are at a high risk of excess bleeding during surgery. The aim of hemostatic therapy during the perioperative period is to prevent bleeding for as long as the bleeding risk persists and until wound healing is complete.

Aims: To examine the efficacy and safety of Human-cl rhFVIII (simoctocog alfa), a 4th generation recombinant FVIII produced in a human cell line without chemical modification or protein fusion, for surgical prophylaxis in patients with severe hemophilia A.

Methods: This analysis assessed the efficacy of Human-cl rhFVIII during surgical procedures and in the postoperative period in 7 clinical studies of previously treated patients (PTPs) with severe hemophilia A.

Results: Thirty-six patients (17 adults and 19 children), aged 3 to 55 years, received surgical prophylaxis with Human-cl rhFVIII for 60 surgeries. Of these, 28 were major and 32 were minor. The success rate (efficacy assessed as ‚excellent' or ‚good') of Human-cl rhFVIII treatment was 98.1% (52 of 53 evaluated surgeries); hemostatic efficacy was assessed as ‚excellent' or ‚good' in all but one major surgery (assessed as ‚moderate'). Treatment was assessed as ‚excellent' in all 24 (15 major and 7 minor) evaluated procedures in children. The number of infusions ranged from 1 to 19 for minor surgeries and from 3 to 76 for major surgeries. The median (range) daily doses were 42.0 (28.2-100.9) IU/kg for minor surgeries and 69.3 (43.3-135.6) IU/kg for major surgeries. Actual blood loss was no higher than the maximum expected blood loss for any procedure except for one minor dental extraction (actual blood loss 3 mL, maximum expected 0 mL). There were no serious treatment-related adverse events, and none of the patients developed FVIII inhibitors.

Conclusions: The results of this pooled analysis show that Human-cl rhFVIII was efficacious in maintaining hemostasis during and after major and minor surgical procedures in PTPs with severe hemophilia A.

TABLE Pooled efficacy ratings for surgical prophylaxis

Efficacy rating	Major surgeries (n = 26)	Minor surgeries (n = 27)	Total (n = 53)*
Excellent, n (%)	21 (80.8)	27 (100)	48 (90.6)
Good, n (%)	4 (15.4)	0	4 (7.5)
Moderate, n (%)	1† (3.8)	0	1 (1.9)
None, n (%)	0	0	0

*Efficacy ratings were not available for 7 of 60 surgical procedures (2 major and 5 minor) †For this patient, intraoperative efficacy had been rated as ‚good'; however, during the postoperative period the patient experienced several minor nose bleeds.

PB 228 | Comparison of Biomarkers and Immunological Parameters between Hemophilia Patients, Rheumatoid Arthritis Patients, and Control Subjects

R. Toenges, A. Wittenbrink, S. Gundermann, W. Miesbach

University Hospital Frankfurt, Frankfurt, Germany

Background: Patients with haemophilia or rheumatoid arthritis (RA) may develop severe joint damage caused by recurrent joint bleeds in haemophilia and by chronic inflammation in RA, respectively.

Aims: Biomarkers are useful diagnostic tools to assess joint damage in RA. However, to date only limited data are available for biomarkers in haemophilia arthropathy.

Methods: A panel of biomarkers was assessed in 129 men older than 30 years (40 haemophilia patients without arthropathy, 23 haemophilia patients with arthrophathy, 23 patients with RA and 43 control subjects). During follow-up examination 61 different biomarkers were analyzed including immunological, inflammation, coagulation, angiogenesis-related parameters and cytokines. Arthropathy was characterized by painfull swelling, loss of function, typical radiology images

and surgical treatment of joints. The RA patients were classified according to ACR/EULAR criteria.

Results: We identified 24 parameters of angiogenesis and cytokines with significant differences between hemophilia patients, RA patients, and healthy individuals. Most of them (20) were reduced (e.g. VEGFR1 or TNF-alpha) whereas only EGFR, osteopontin, IL6-RA and IL-7 were elevated. In a second statistical analysis, we identified cytokine MIP-1b, VEGFR- 2 and HGF significantly declined and IP-10 elevated in hemophilia patients with arthropathy and rheumatoid arthritis patient compared to healthy individuals.

Conclusions: Twenty-four out of 61 immunological parameters and biomarkers were different in hemophilia patients. In addition, significant differences could be demonstrated between hemophiliacs (with and without arthropathy) and RA patients compared to controls. Therefore, we could show a specific immunological profile for hemophilia as well as a common biomarker profile for the arthropathy in haemophilia and RA. Further research should be performed to evaluate the potential of established and new biomarkers to follow-up joint damage and chronic arthrophathy in hemophilia.

PB 229 | Frozen Autologous Platelet Gel and Fibrin Glue in Hemophilia A, B and von Willebrand Surgical Patients

A. Misiak[1], E. Lachert[1], B. Ceglarek[2], A.J. Sikorska[2], K. Bykowska[3], A. Szczepanik[1]

[1]Institute of Hematology and Transfusion Medicine, Department of General, Oncological and Metabolic Surgery, Warsaw, Poland, [2]Institute of Hematology and Transfusion Medicine, Department of Disorders of Hemostasis and Internal Medicine3, Warsaw, Poland, [3]Institute of Hematology and Transfusion Medicine, Department of Hemostasis and Metabolic Disorders, Warsaw, Poland

Background: Haemostatic, germicidal and regenerative properties of platelet-derived growth factors justify their application in in patients with congenital hemorrhagic disorders for hard-to-heal wounds or improvement of hemostasis in clean surgical wounds.

Aims: To estimate the safety and effectiveness of frozen autologous platelet gel (FAPG) and fibrin glue (FG) applied to clean postoperative or chronically infected wounds in patients with congenital hemorrhagic disorders.

Methods: 17 surgical procedures were performed in 13 patients, aged 23 - 57years (11 male, 2 female), 9 - hemophilia A, 1 - hemophilia B , 3 - von Willebrand disease. The performed surgical procedures were: strumectomy (4), fasciotomy of forearm compartment syndrome (1), necrotic skin excision after arthroplasty (3), foot and hand trauma (2), removal of hemophilic pseudotumor (3 patients, 7 procedures). FAPG was obtained by thrombopheresis using Cobe-Spectra; FG by cryoprecipitation of autologous plasma. Sealants were divided into portions, immediately frozen and thawed before application. Both were activated by thrombin solution and applied on either clean or infected wounds. Activated sealants were applied to infected wounds on Bactigras dressing or directly on clean wounds. In the perioperative period all patients were supplemented with deficient clotting factors.

Results: Clean wounds healed by primary adhesion with no bleeding or inflammatory reactions. Infected wounds presented rapid granulation tissue formation and reduction of ulcerationarea. For hemophilic pseudo tumors a gradual decrease in cavity size was observed.

Conclusions: In patients with congenital hemorrhagic disorders application of platelet gel and fibrin glue to either clean or infected wounds presented accelerated healing and shorter hospital stay.

PB 230 | Safety and Efficacy Of Moroctocog Alfa (AF-CC) in Patients with Hemophilia A: Results of a Post-authorization Study in Usual Care Settings in China

R. Yang[1], R. Wu[2], J. Sun[3], C. Jin[4], F. Sun[5], P. Rendo[6], J. Rupon[6], F. Huard[7], J.M. Korth-Bradley[6], L. Xu[5], B. Luo[5], Y. Liu[5]

[1]Blood Diseases Hospital, Chinese Academy of Medical Sciences, Tianjin, China, [2]Beijing Children's Hospital and Capital Medical University, Beijing, China, [3]Nanfang Hospital, Southern Medical University, Guangzhou, China, [4]Jiangxi Provincial People's Hospital, Jiangxi, China, [5]Pfizer (China) Research & Development Co, Ltd, Shanghai, China, [6]Pfizer Inc, Collegeville, United States, [7]Pfizer PIO, Paris, France

Background: Acquisition of real-world data is important to understand the efficacy and safety profiles of marketed medicines. Moroctocog alfa (AF-CC) is approved in China for control and prevention of bleeding events and for surgical prophylaxis in patients (pts) with hemophilia A.

Aims: Assess safety and efficacy of moroctocog alfa (AF-CC) in a real-world setting in Chinese pts with hemophilia A.

Methods: Ethics committees approved this open-label, multicenter, prospective study conducted at hemophilia treatment centers in China. Pts provided informed consent and received treatment on-demand (OD) for 6 mo or 50 exposure days, or for surgical prophylaxis, dosed according to the label. Key assessments included factor VIII (FVIII) inhibitor development; adverse events (AEs); response to treatment, no. of infusions needed to treat new bleeding events, and less-than-expected therapeutic effect (LETE) in the OD setting; and hemostatic efficacy, blood loss, and transfusion requirements in the surgical prophylaxis setting.

Results: In all, 85 pts received treatment (mean age, 9.5y; severe hemophilia, 58%). Seven pts tested positive for FVIII inhibitors (Table). Common AEs (>20%) included joint swelling, arthralgia, nasopharyngitis, and pain in extremity. In pts receiving OD treatment (n=73), 63% of bleeding events resolved with 1 infusion. Most OD infusions (87%) were rated as "excellent" or "good." One bleeding event met LETE criteria. Results were similar with subgroup analysis based on age, disease severity, and prior factor exposure. All surgical prophylaxis pts (n=14) had efficacy responses of "excellent" or "good" on day of surgery and in postoperative period. All blood loss was assessed as normal; transfusions were required in 2 pts.

TABLE FVIII inhibitor development in patients treated with moroctocog alfa (AF-CC)

Parameter	On-demand (n=73)[a]	Surgical prophylaxis (n=14)	All patients (n=85)
Patients with inhibitors, n	6	1	7
Inhibitor rate, % (95% CI)	8.2 (3.1, 17.0)	7.1 (0.2, 33.9)	8.2 (3.4, 16.2)
High-titer[b] inhibitors, n (rate [%])	1 (1.4)	0 (0)	1 (1.2)
Low-titer[c] inhibitors, n (rate [%])	5 (6.9)	1 (7.1)	6 (7.1)

[a]Two pts rolled over from the surgical prophylaxis group to the on-demand group and are counted once in the "all patients" column. [b]≥5 BU/mL. [c]<5 BU/mL.

Conclusions: The efficacy and safety profiles of moroctocog alfa (AF-CC) in the real-world setting when used for OD treatment or surgical prophylaxis in Chinese pts are similar to those previously reported in clinical interventional studies.

PB 231 | Post-authorization Study to Evaluate Pharmacokinetics of FVIII after Moroctocog Alfa (AF-CC), as Well as Safety and Efficacy in Previously Treated Pediatric Patients with Severe Hemophilia A

L. Rusen[1], J.M. Korth-Bradley[2], J. Rupon[3], F. Huard[4], A. Borodin[5], C. Alvey[6], L. Smith[3], J. Fuiman[3], M. Kuzmanovic[7], P. Rendo[3]

[1]Sanador SR, Bucharest, Romania, [2]Pfizer Inc., Collegeville, United States, [3]Pfizer Inc, Collegeville, United States, [4]Pfizer PIO, Paris, France, [5]Oblasna Klinichna Likarnia, Unknown, Ukraine, [6]Pfizer Inc, Groton, United States, [7]Mother and Child Health Care Institute Dr Vukan Cupic, Unknown, Serbia

Background: Moroctocog alfa (AF-CC), a recombinant B-domain deleted factor VIII (FVIII) protein, is indicated for the treatment and prophylaxis of bleeding events in patients (pts) with hemophilia A. There is limited pharmacokinetic (PK) information available for pts aged < 12 y.

Aims: The primary objective of this open-label, interventional study was to assess the PK of FVIII after administration of moroctocog alfa (AF-CC) in pediatric hemophilia A pts. Assessment of safety and efficacy were secondary objectives.

Methods: This study, which was approved by ethics committees and conducted in 11 EU countries, enrolled previously treated males with severe hemophilia A into 2 cohorts: 1, pts aged < 6 y (n=18); 2, pts aged 6 to < 12 y (n=19). Parents for all pts provided informed consent. Serial plasma samples to measure FVIII were collected up to 48 h after infusion of a 50-IU/kg dose in cohort 2, while cohort 1 had only recovery assessment. Recovery assessments were repeated in all pts through the final visit. After the PK or recovery assessment, pts continued treatment according to approved labels until they reached a minimum of 50 exposures days (EDs; max: 100 EDs).

Results: PK data are shown in Table 1. Recovery was consistent throughout the study. ABRs and incidence of LETE are summarized in Table 2. Among 804 first infusions, 713 (89%) were rated as having an "Excellent" response, and 761 (95%) of 804 bleeding events resolved after 1 infusion. Low-titer, transient FVIII inhibitor development was observed in 4 pts.

TABLE 1 Summary of PK Assessments

Parameter	N	Summary Statistic[a]
Recovery, IU/dL/IU/kg		
Aged <6 y	17	1.7 ± 0.4
Aged 6 to <12 y	19	2.1 ± 0.8
Cmax, IU/mL[b]	19	0.9 (45)
AUCinf, IU·h/mL[b]	14	9.9 (41)
t½, h[b]	14	9.1 ± 1.9
CL, mL/h/kg[b]	14	4.4 (30)
Vss, mL/kg[b]	14	56.4 (15)

[a]Geometric mean (geometric CV%) for all, except for arithmetic mean ±SD for incremental recovery and $t^{½}$. [b]Patients aged 6 to <12-years only. C^{max}, maximum observed plasma concentration; CV, coefficient of variation; AUC^{inf}, area under the plasma concentration-time profile from time zero extrapolated to infinite time; $t^{½}$, terminal half-life; CL, clearance; V^{ss}, steady-state volume of distribution.

TABLE 2 Summary of Selected Efficacy Assessments

Parameter	N	On-demand	N	Prophylaxis
ABR, mean (SD)	14[a]	27.5 (20.4)	22[b]	4.2 (3.8)
LETE	804[c]	0	2457[d]	2
Incidence (95% CI)		0 (0.00, 0.46) [c]		0.08% (0.01, 0.29)

ABR, annualized bleed rate; CI, confidence interval; LETE, less-than-expected therapeutic effect; SD, standard deviation. [a]Number of pts at baseline following on-demand regimen (pts not required to maintain regimen throughout study). [b]Number of pts at baseline following prophylaxis regimen (pts not required to maintain regimen throughout study). [c]Number of bleeding events. [d]Number of prophylaxis infusions.

Conclusions: The PK and recovery of FVIII activity after moroctocog alfa (AF-CC) administration in this study were consistent with the limited available PK data in this age group. Moroctocog alfa (AF-CC) is efficacious for on-demand and prophylactic treatment of hemophilia A in pediatric pts aged < 12 y. The inhibitor rate was 11%, but all were noted to be low-titer, transient, and without clinical significance. Otherwise, no new safety risks were observed.

PB 232 | Understanding Care Utilization and Perceptions of People with Hemophilia A with or without a Current Inhibitor

W.E. Owens[1], Y. Xu[2], A. Cyhaniuk[1,3], E. Chan[1], P. Kuebler[2], R.H. Ko[2], P.G. Solari[2], J. Chupka[1]

[1]Hemophilia Federation of America, Washington, DC, United States, [2]Genentech Inc., South San Francisco, United States, [3]AC Analytical Solutions, LLC, Barrington, United States

Background: The CHOICE Project was conducted in partnership between the CDC and Hemophilia Federation of America to survey persons with bleeding disorders (PWBD) in the US, including those who do not receive care at federally-funded hemophilia treatment centers (non-HTC PWBD).

Aims: To retrospectively explore and characterize demographics, disease severity, and care perceptions among people with hemophilia A (PWH) with or without a current inhibitor (WI or WO) to better understand burdens of illness and how to address those burdens.

Methods: Demographic and clinical data were collected through CHOICE from 04/2013-07/2015 on PWBD. PWBD were recruited to take a 20-minute survey in English or Spanish, online or on paper. Non-HTC PWBD were solicited specifically but others were not excluded from participation. Participants' status as non-HTC PWBD was determined by algorithm. Descriptive statistical analysis was performed based on the chi-square test.

Results: Of 439 PWH, 13% are non-HTC PWH; 17% are female; 11% have a current inhibitor; 2% of WI are mild severity v. 19% of WO (p= 0.0001) **(Figure 1)**. For their bleeding disorder, 96/89% (WI/WO) visited a HCP regularly; 96/84% saw an HCP at least once/year; 94/87% usually see* a hematologist, 14/25% a general practitioner/internist, 35/33% a social worker. Usual places of care* include: HTC 74/62% (WI/WO) and doctor's office 15/15%. In the last 12 months, WI reported a slightly higher satisfaction with care than WO, 3.02 v. 2.95 **(Figure 2)** (*More than one response allowed).

Conclusions: Despite differences in disease severity levels, care utilization, and where and who they usually see for care of their bleeding disorder, WI or WO care satisfaction was nearly equal. Additional analysis is needed to investigate care utilization by age and severity to support care improvements. This sample does not necessarily represent all PWH, as targeted outreach in some regions may have led to over-representation of some participant characteristics.

PB 233 | Utilisation of Smartphone Technology in Managing Prophylaxis for Patients with Haemophilia

M. Lavin[1,2], E. Singleton[1], R. Bird[1], F. Mc Groarty[1], K. Ryan[1], J.S. O'Donnell[1,2], B. White[1], N.M. O'Connell[1]

[1]National Coagulation Centre, St. James's Hospital, Dublin, Ireland, [2]Royal College of Surgeons in Ireland, Irish Centre for Vascular Biology, Dublin, Ireland

Background: Treatment outcomes in Haemophilia are significantly influenced by effectiveness of FVIII/FIX replacement. Adherence is critical, but often difficult to verify. We introduced HomeScan smartphone app (Crimson Tide, Ireland) to facilitate clotting factor concentrate (CFC) scanning, traceability, adherence for patients with Haemophilia taking prophylaxis in Ireland.

Aims: This study aimed to correlate factor replacement prescribed, delivered and infused over a 12 month period and to identify factors associated with use of the HomeScan app.

Methods: The records of patients with Haemophilia using HomeScan from 1 January to 31 December 2016 were reviewed. Demographic data (age, weight, severity of Haemophilia) and data on CFC infusions (dose and frequency prescribed, units of factor delivered and confirmed infusions) were collected and analysed.

Results: 128 adult patients (>16 years) with severe Haemophilia (93 FVIII, 35 FIX deficient) are registered at the National Coagulation Centre, Dublin. Of these, 52 adults use HomeScan to record prophylaxis (34 FVIII, 17 FIX deficient; median age 34, range 17-74, median HJHS 17, range 0-52).

Prophylaxis was prescribed at a median 30.8 IU/kg of FVIII/FIX per dose (range 15.5-78). HomeScan recording of prophylaxis was higher than with paper diaries, with 63.5% patients scanning >50% of prescribed doses and 52% scanning >75% doses. Age was not a

barrier to app usage with no significant difference in percentage prescribed doses scanned in patients >40yo (n=19) or < 40yo (n=33) (median 85.6% vs 51%;p=0.07). A significant relationship was seen between prescribed, dispensed and scanned doses (r^2=0.23, p< 0.005) demonstrating adherence to prophylaxis in those using HomeScan.

Conclusions: Use of the HomeScan App for Haemophilia prophylaxis assures the safety and traceability of CFC and provides real-time, reliable data on concentrate usage. Given the benefits of using this App, maximising uptake by all patients on prophylaxis is a priority.

PB 234 | Retrospective Analysis of Hemostatic Efficacy by Continuous Infusion of Recombinant Factor VIIa: A Single Institution Study

N. Suzuki[1], M. Kishimoto[2], T. Kanematsu[2], A. Suzuki[2], M. Ogawa[3], H. Kiyoi[3], T. Matsushita[1]

[1]Nagoya University Hospital, Transfusion Medicine, Nagoya, Japan, [2]Nagoya University Hospital, Clinical Laboratory, Nagoya, Japan, [3]Nagoya University Graduate School of Medicine, Hematology and Oncology, Nagoya, Japan

Background: Recombinant factor VIIa(rFVIIa) is administered to control bleeding of congenital hemophilia with inhibitors and acquired hemophilia patients by frequent every 2-3 hours injections. Some reports show continuous infusions (CI) of rFVIIa can be managed safely and may be useful.

Aims: To estimate efficacy of CI of rFVIIa by global coagulation assays.

Methods: rFVIIa was administered using CI for 19 cases including spontaneous bleeding and surgical procedures of six congenital and two acquired hemophilic patients. Hemostatic efficacy was judged in the first 24 hours after rFVIIa administration was started. Coagulation study including PT, APTT, Fibrinogen, FDP, D-dimer and FVII:C were checked during rFVIIa treatment. Global coagulation assays, ROTEM and TGA were also performed to evaluate the effectiveness of rFVIIa.

Results: There were no adverse effects including thrombosis and thrombophlebitis. According to clinical hemostatic efficacy, effective was 12/19 (63%), partially effective was 6/19 (32%), and ineffective was 1/19(5%). rFVIIa was bolus infused followed by CI in 16 out of 19 cases. The median dose of bolus infusion(BI) of rFVIIa was 110μg kg^{-1} (range: 67-273μg kg^{-1}), the mean dose of BI of rFVIIa was 143μg kg^{-1} followed by CI whose median rate was 42μg kg^{-1} h^{-1}(range: 17-50μg kg^{-1} h^{-1}), mean rate was 36μg kg^{-1} h^{-1}, the median duration of treatment was 7 days(range: 2-16 days), and the median total dose was 5273 μg kg^{-1}(range: 1000-12583μg kg^{-1}). As for global coagulation assays, not TGA with platelet poor plasma (PPP) but ROTEM assay, which showed compatible results with clinical hemostatic efficacy.

Conclusions: CIs of rFVIIa were safe and effective. ROTEM might be better to monitor comprehensive coagulation activity than TGA with PPP during FVIIa treatment.

PB 235 | An Evaluation of the Pharmacokinetics of Turoctocog Alfa in Relation to Body Mass Index (BMI) in Patients with Haemophilia A (HA)

S. Zupančić-Šalek[1], M.C. Ozelo[2], L. Korsholm[3], I. Matytsina[3]

[1]National Haemophilia Centre, University Hospital Centre Zagreb, Medical School University of Osijek and Medical School University of Zagreb, Department of Thrombosis and Haemostasis Division of Haematology, Department of Internal Medicine, Zagreb, Croatia, [2]University of Campinas, IHTC ‚Claudio L.P. Correa', INCT do Sangue Hemocentro UNICAMP, São Paulo, Brazil, [3]Novo Nordisk A/S, Søborg, Denmark

Background: Management of overweight/obese patients is a challenge in haemophilia treatment. Obese patients have a lower volume of plasma per kilogram of body weight compared with non-obese individuals, resulting in higher post-dose factor FVIII (FVIII) activity levels and higher incremental recovery of injected FVIII as FVIII products are dosed by body weight. The long-term safety and efficacy of turoctocog alfa (NovoEight®), a B-domain truncated recombinant FVIII (rFVIII) product developed by Novo Nordisk for the treatment and prophylaxis of bleeding in HA patients, has been assessed in an international open-label extension trial, guardian™2. The rationale for the pharmacokinetic (PK) subtrial of guardian™2 was to collect PK data as a basis for further investigations of FVIII dosing in HA patients with a BMI ≥30 kg/m^2.

Aims: To investigate single-dose PK following turoctocog alfa administration in patients with a BMI ≥30 kg/m^2.

Methods: Previously treated male patients with severe HA and no history of FVIII inhibitors with a BMI ≥30 kg/m^2 were selected for PK analysis. Patients received a single dose of turoctocog alfa 50 IU/kg after a washout of ≥96 hours. Blood samples taken pre-dose and at time points up to 72 hours post-dose were used for PK analysis. PK results from a patient cohort with BMI < 30 kg/m^2 with turoctocog alfa were used for comparison.

Results: The PK population comprised six patients who received a mean turoctocog alfa dose of 52.7 IU/kg. Mean PK parameters, based on a chromogenic assay, are shown in the Table.

Conclusions: The trend for higher incremental recovery and area under the plasma concentration-time curve in this high BMI group suggests that obese patients should be dosed based on individual PK and clinical response. Further investigation of turoctocog alfa in patients with a BMI ≥30 kg/m^2 is warranted.

TABLE 1

Parameter	PK trial Mean (SD) [Median] Range N=20	guardian™2 PK subtrial Mean (SD) [Median] Range N=6
BMI, kg/m^2	23.4 (3.1) [23.1] 18.1–29.2*	33.35 (2.37) [33.05] 30.5–37.2
AUC, IU*h/ml	18.70 (5.08) [17.72] 10.28–31.06	31.02 (9.78) [33.13] 12.87–41.85
CL, ml/h/kg	2.87 (0.80) [2.82] 1.61–4.87	1.94 (0.95) [1.70] 1.17–3.81
Incremental recovery, (IU/dl)/(IU/kg)	2.8 (0.6) [2.8] 1.5–4.1	3.5 (0.96) [3.4] 2.4–5.0
$t_{½}$ (h)	11.96 (9.28) [9.82] 6.06–48.50	12.40 (3.16) [13.21] 7.23–15.19

*BMI at baseline for patients in the full analysis set (n=23; three patients did not have any chromogenic assay results).

AUC, area under the plasma concentration–time curve; BMI, body mass index; CL, clearance; PK, pharmacokinetics; SD, standard deviation; $t_{½}$, half-life.

PB 236 | Pharmacokinetic Studies of FVIII in Chinese Boys with Severe Hemophilia A

Z. Chen[1], P. Li[1], G. Li[1], L. Tang[1], Y. Zhen[1], X. Wu[1], K.H. Luke[2], V.S. Blanchette[3], M.-C. Poon[4], R. Wu[1]

[1]Beijing Children's Hospital Capital Medical University, Beijing, China, [2]Children's Hospital of Eastern Ontario and University of Ottawa, Ottawa, Canada, [3]Hospital for Sick Children, University of Toronto, Toronto,, Canada, [4]University of Calgary, Foothills Hospital and Calgary Health Region, Calgary, Canada

Background: Although much attention has been paid to the pharmacokinetics (PK) of FVIII products, these have not been well characterized in Chinese boys with severe hemophilia A.

Aims: To assess the PK and the parameters influencing PK of plasma-derived FVIII (pd-FVIII) and recombinant FVIII (rFVIII) products in Chinese severe HA boys.

Methods: A total of 36 boys (pd-FVIII, n=15; rFVIII, n=21) were enrolled in this study, including 6 boys who underwent both rFVIII and pd-FVIII PK studies when they switched from rFVIII to pd-FVIII. Pharmacokinetic characteristics of two different FVIII products were studied according to a reduced 4-point design(1hour, 9hours, 24hours, and 48 hours after the end of infusion). At baseline, all patients' blood groups and levels of VWF:Ag and VWF:C were determined.

Results: The FVIII half-life time ($t_{1/2}$) varied widely from 5.5 to 20.0 hours, with a median of 10.8 hours.The PK of the two FVIII products given separately to the same 6 boys showed that $t_{1/2}$,adjusted in vivo recovery(IVR), area under the plasma concentration curve(AUC), and maximal plasma concentration(C_{max}) of pd-FVIII were slightly higher than those of rFVIII($t_{1/2}$:11.56±3.87hoursvs. 10.21±3.48hours; IVR:2.01±0.42 vs.1.76±0.48; AUC:1364±515.8 vs.1097±367.3;C_{max}(1hour):100.60±21.70vs.86.38±23.68) (*P*=0.2374, *P* = 0.0713,*P* = 0.0124, *P*=0.0018). The clearance (CL), however, was slightly longer for rFVIII(3.93±1.60 mL·Kg^{-1}·h^{-1}vs.4.74±1.72 mL·Kg^{-1}·h^{-1}; *P*=0.0018).Young patients have a shorter FVIII half-life than older patients. Patients with blood group O had a shorter FVIII half-life than patients with non-O blood group. Age and VWF antigen and activity levels were closely associated with FVIII half-life and IVR.

Conclusions: Chinese boys with HA had similar PK values to other ethnic groups and large differences in FVIII PK between individual patients. Age, blood group, and VWF levels were important determining factors for FVIII. The pd-FVIII product had a higher AUC and C_{max} and lower CL than rFVIII product.

PB 237 | Preliminary Results of a Personalized One-year Program to Individualize the Prophylactic Treatment with Recombinant Factor VIII in Severe or Moderate Hemophilia A Patients

Background: Knowledge of the individual's pharmacokinetics (PK) using Bayesian analysis with 2-3 samples could help to individualize prophylactic therapy with recombinant factor VIII (rFVIII) in severe or moderate hemophilia A patients (HA) and minimize the risk of bleeding.

Aims: Analyze if PK tailored dosing can influence in bleeding control in a single centre cohort.

Methods: Retrospective study in HA with rFVIII (Advate®) prophylaxis from January 2014 to December 2016. A previously available Bayesian model (myPKFit® 2.0) was employed to get individual PK profile using FVIII trough levels retrospective data. PK parameters analyzed were: clearance (Cl); steady state volume (Vss); plasma half-life ($t_{1/2}$); trough level at 48 or/and 72 h (TL); and time to reach rFVIII levels < 1% (T1%). Kruskal-Wallis test (R® 3.1.2) was used to compare

TABLE 1 Clinical variables and PK parameters in severe or moderate HA treated with rFVIII prophylaxis (Part 1)

Patient #	Age (years)	Dose (IU/kg/week)	Gilbert score	AJBR in 2016	Cl (mL/h/kg)	Vss (mL/kg)	t1/2 (h)	TL at 48h/72h (IU/dL)	T1% (h)
1	26	54.5	8	1	4.0	50	10.2	0.8/ND	57
2	45	69.0	22	0	2.8	50	14.4	5.5/1.7	83

TABLE 2 Clinical variables and PK parameters in severe or moderate HA treated with rFVIII prophylaxis (Part B)

Patient #	Age (years)	Dose (IU/kg/week)	Gilbert score	AJBR in 2016	Cl (mL/h/kg)	Vss (mL/kg)	t1/2 (h)	TL at 48h/72h (IU/dL)	T1% (h)
10	29	50.0	5	0	3.3	50	12.6	2.3/ND	63
11	69	50.0	28	3	2.1	50	18.6	11.5/4.7	113
12	32	60.4	14	0	3.3	40	11.0	1.5/0.9	54
13	37	57.2	23	2	2.2	50	16.5	9.4/3.4	101
14	36	51.4	5	0	3.0	50	13.2	8.4/5.9	71
15	19	79.4	8	0	3.2	50	12.8	3.6/1.3	71
16	42	63.4	19	0	3.1	50	13.2	3.1/ND	66
17	50	80.0	36	1	2.5	50	15.9	6.7/2.3	91
18	46	43.9	23	0	2.9	50	14.5	2.9/1.6	70

PK parameters and clinical variables: age, dose/kg, annualized joint bleeding rate (AJBR), Gilbert score.

Results: Eighteen patients were analyzed. Mean age was 35.8 years (SD: 13.2; range 15-69) and 115 PK monitoring (6.4 per patient) were made. Mean PK values (SD) were: Cl 2.9 (0.6) mL/h/kg; Vss 49.4 (0.04) ml/kg; $t_{1/2}$ 14.2 (2.9) h; TL at 48h 5.1 (3.5) IU/dL, TL at 72h 2.7 (1.7) IU/dL and T1% 77.9 (20.1) h. Table 1 and 2 summarizes individual clinical and PK variables.

Along 2017, 7 patients (38.9%) reported joint bleeds (JB). No association between clinical variables and PK parameters were noted, although in 3 patients (#1, #7, #9) JB were related to low $t_{1/2}$. Several JB were reported in 3 patients with high Gilbert score and severe arthropathy (#11, #13, #17), whereas their estimated TL were appropriated.

Conclusions: Bayesian estimate with myPKFit® allows to know the individual PK profile and could be a useful tool to individualize prophylaxis, along with physical activity and bleeding pattern. We are running a personalized one-year program to identify and treat the specific causes of poor bleeding control in HA on prophylactic therapy.

Study supported by Baxalta/Shire grant.

PB 238 | International Clinical Study Investigating the Incidence of Inhibitors in Previously Untreated Patients with Severe Haemophilia A Treated with a High Purity FVIII/VWF Concentrate in a 1:1 Ratio

M. Jansen[1], T. Andreeva[2], V. Vdovin[3]

[1]*Octapharma Pharmazeutika Produktionsgesellschaft m.b.H., Vienna, Austria,* [2]*St. Petersburg Haemophilia Centre, St. Petersburg, Russian Federation,* [3]*Izmailovo Children's Hospital, Hematology Department, Moscow, Russian Federation*

Background: The development of neutralising antibodies against FVIII (inhibitors) is the biggest complication of haemophilia A treatment. The SIPPET study shows that up to 37% of previously untreated patients (PUPs) develop inhibitors, mostly within the first 50 exposure days (EDs)[1]. wilate® is a high-purity FVIII/VWF complex concentrate with a physiological 1:1 ratio.

Aims: The primary objective was the assessment of the immunogenicity of this 1:1 FVIII/VWF concentrate in PUPs with severe haemophilia A.

Methods: This prospective, open-label, multi-centre study included 28 subjects with severe haemophilia A and no previous exposure to blood products. Patients were screened for FVIII inhibitors by Bethesda assay every 3 to 4 EDs until ED20 and every 10th ED or at least every 3 months thereafter. Gene analysis was performed in 28 subjects.

Results: 3 of 28 patients (10.7%) developed high titre inhibitors and 4 (14.3%) showed transient low titre inhibitors, not requiring change of treatment regimen or FVIII/VWF concentrate. One patient (3.6%) had a single positive test for a low-titre inhibitor, but died in an accident, so no follow up is available.

The most common gene mutation was an intron 22 inversion in 16/28 patients (57.1%) - higher than the overall prevalence for this mutation in severe haemophilia A patients (30%).[2,3] Despite this high-risk population only 8/28 (28.6%) patients developed inhibitors. All 3 high-titre inhibitors and 3/5 low-titre inhibitors developed in patients with intron 22 mutations.

Conclusions: The SIPPET study reported overall inhibitor rates of 23.2% (29/125) and 37.3% (47/126) for PUPs treated with pd FVIII/VWF and rFVIII from hamster cell lines, respectively.[1] The overall inhibitor incidence (28.6%; 8/28) during this study with a 1:1 pdFVIII/VWF concentrate was in line with these results. Moreover, the incidence of high titre inhibitors in this study (10.7%) compares favourably to that in the pdFVIII/VWF arm of the SIPPET study (16%, 20 of 125).

PB 239 | Magnitude of Dosing Adjustment of AFSTYLA in Clinical Trials

S. Yan[1], R. Wang[2], A. Veldman[3], M. Fries[1], G. Krishnarajah[1]

[1]*CSL Behring, King of Prussia, United States,* [2]*Advanced Clinical, LLC, Deerfield, United States,* [3]*CSL Behring, Marburg, Germany*

Background: AFSTYLA (rVIII-SingleChain) is indicated in adults, adolescents and children with hemophilia A for control and prevention of bleeding episodes, routine prophylaxis to prevent or reduce the frequency of bleeding episodes, and for perioperative management. In one adult/adolescent (12-65 years) trial and one pediatric trial (<

12 years), dosing was according to investigator's discretion in order to reflect practice in the clinical setting. Adjustment of dose or frequency was allowed at any time during the studies.

Aims: To estimate the difference in factor use of AFSTYLA between the final and the initial dosing regimens (DELTA), in two pivotal clinical trials.

Methods: Factor use per week for prophylaxis was calculated based on frequency of injection and dose per injection, for the initial and final dosing regimens. DELTA was then taken (in IU/kg per week, for prophylaxis). Patients were grouped by initial dosing frequency and DELTA was summarized for each group (in which the same patients were followed).

Results: In the adult/adolescent trial, 47 and 79 subjects initially received two and three injections per week, respectively. DELTA < =0 occurred in 78.72% of subjects receiving 2 injections per week and 77.22% of subjects receiving 3 injections per week. In the pediatric trial, 43 subjects initially received 2 injections per week with DELTA < =0 in 69.77% of the subjects; 24 subjects initially received 3 injections per week with a DELTA < =0 in 75.00% of the subjects.

Conclusions: The majority of subjects had the same or decreased factor use between the initial and final dosing regimens. Although real world factor consumption of AFSTYLA is yet to be measured, these results indicate that it is likely to be predictable and stable during the course of treatment.

PB 240 | Validity of Angiography and Therapeutic Embolization in the Treatment of Acute Bleeding in Hemophilia Patients

Y.S. Park[1], J.K. Park[2], M. Kim[1], E. Kim[3]

[1]Kyung Hee University Hospital at Gandgond, Department of Pediatrics, Seoul, Korea, Republic of, [2]Busan Paik Hospital, Department of Pediatrics, Busan, Korea, Republic of, [3]Kyung Hee University Hospital at Gangdong, Department of Pediatrics, Seoul, Korea, Republic of

Background: Clotting factor replacement is often inadequate for bleeding control in hemophilia patients, and surgery may impose a real challenge to clinicians. Arterial angiographic intervention has been utilized for the control of bleeding in the local blood vessels. Furthermore, arterial angiography is considered for hemophilia patients with various complications, especially severe bleeding at the site of a puncture.

Aims: This study inquired into the clinical courses and prognosis in hemophilia patients with bleeding, who had undergone angiography, and also evaluated the validity of diagnostic angiography and therapeutic embolization in these patients.

Methods: In this study, angiography was carried out in five hemophilia patients. These patients had uncontrolled bleeding even after clotting factor replacement.

Results: Three of all five severe hemophilia patients had antibodies to factor VIII. Two patients had postoperative hemorrhage after surgery, those were small bowel segmental resection for hemorrhagic infarction and total knee arthroplasty. Two patients had spontaneous bleeding—one with retroperitoneal hematoma and the other with hemoptysis after pneumonia. One patient had hemothorax caused by trauma. The common femoral artery puncture was performed under ultrasonography. Of these 5 patients, four were confirmed as having active bleeding and underwent angiographic embolization. Clotting factor concentrates were administered to reach the 100% factor level for hemophilia patients without inhibitors, while adequate doses of bypassing agents were administered for hemophilia patients with inhibitors. However, one patient developed uncontrolled bleeding at the puncture site, and eventually expired.

Conclusions: The consideration is that angiography and therapeutic embolization may be the preferential procedures in the treatment of hemorrhagic complications, refractory to clotting factor concentrates. Further comprehensive, skilled multidisciplinary team studies are necessary to reduce hemorrhagic complications.

PB 241 | Postraumatic Anterior and Posterior Thigh Pseudotumor in Young and Adolescent with Hemophilia

R. Silva[1], J. Marun[2], D. Perez[2]

[1]Clinica General del Norte, Orthopedics, Barranquilla, Colombia, [2]Clinica General del Norte, Hemophilia, Barranquilla, Colombia

Background: The management of the patient with a haemophilic pseudotumour is complex and carries a high rate of potential complications. There are a number of therapeutic alternatives for this dangerous condition: embolization, radiation, percutaneous management, surgical removal and exeresis, and filling of the dead cavity.

Aims: To describe 2 cases of posttraumatic pseudotumors successfully treated by well planning of elective surgery.

Methods: We describe two patients, one of 21 years of age with moderate Hemophilia A on demand treatment and recent history of mass of the posterior part of the left thigh after traumatic injury. The mass slowly progressed asymptomatically with a large mass on the posterior part of the thigh, magnetic resonance and thigh angiography were obtained showing pseudotumor of the posterior muscular compartment of the thigh. Second patient is a 13-year-old patient with a right upper quadrant mass of the thigh after traumatic injury 4 months evolution. The patient consulted due to a mass with progressive increase associated with paresthesias of the anterior thigh. Rx images, soft tissue ultrasound and magnetic resonance revealed a mass with approximately 300 mls of blood in different stages of coagulation with formation of a pseudo capsule without direct contact with the anterior cortical of the right femoral shaft.

Results: Therapeutic intervention: Due to the large size and location of the mass, it was decided to perform a surgical treatment. A large mass was found during surgery that could be completely resected and sealed with the use of fibrin sealants with a satisfactory postoperative evolution. Second patient underwent surgery for drainage and application of fibrin sealants with a remarkable postoperative outcome.

Conclusions: Untreated, proximal pseudotumours will ultimately destroy soft tissues, erode bone and may produce neurovascular complications. Surgical excision is the treatment of choice but should only be carried out in major haemophilia centres by a multidisciplinary team.

PB 242 | Vitamin D Deficiency in Patients with Haemophilia: Initial Workup and Follow-up of Supplementation

B. Krammer-Steiner[1], C. Schneider[1], R. Toenges[2], M. Steiner[3]

[1]Klinikum Südstadt Rostock, Klinik für Innere Medizin III, Rostock, Germany, [2]Universitätsklinikum Frankfurt/M., Medizinische Klinik II, Frankfurt/M., Germany, [3]Medizinisches Labor Rostock, Rostock, Germany

Background: Patients with haemophilia are at increased risk for developing bone loss. Predisposing factors include overweight, decreased physical activity, and prolonged periods of immobility. Although it is well established that vitamin D deficiency contributes to bone loss, only few studies have evaluated vitamin D status in haemophilia patients.

Aims: The aim of the present study was to evaluate the vitamin D status in haemophilia patients.

Methods: From thirty adult patients with haemophilia A (n=24, aged 19 to 73 ys) or haemophilia B (n=6, aged 15 to 74 ys) treated at the Regional Haemophilia Centre Rostock, twenty six were investigated for vitamin D deficiency. Levels of 25-hydroxyvitamin D were measured by immunoassay (DiaSorin).

Results: At baseline, vitamin D concentrations of only two patients were in the normal range (> 75 nmol/L). In contrast, 22 of 26 patients (85 %) were considered deficient in vitamin D (< 50 nmol/L) including six patients with concentrations below 20 nmol/L. A supplementation regimen consisting of 40,000 units per week was accepted by 22 patients and monitored by subsequent vitamin D analyses at six months intervals. Sixteen of twenty two patients (73 %) reached improved values within six months and did not return to vitamin D deficiency. Improved vitamin D concentrations were accompanied by normal PTH levels in all but two patients. Furthermore, follow-up analyses of TRAP5b as indicator of osteoclastic activity demonstrated decreasing bone resorption with vitamin D reaching normal levels. Compliance issues were the most likely explanation for the failure of the remaining six patients to obtain benefit.

Conclusions: The present study suggests that measuring vitamin D may form part of assessing the risk of bone loss in haemophilia patients. Vitamin D supplementation is an inexpensive and safe measure to correct vitamin D deficiency and may contribute to the prevention of bone loss as has been demonstrated by improved bone metabolism markers in the present study.

PB 243 | Severe Haemophilia A Patients Born between 2000- 2015 at a Single Haemophilia Centre: Characteristics and Inhibitor Development

M. Martorell[1], S. Alonso[1], R. Parra[1,2], M. Constans[1], C. Altisent[1]

[1]Vall d'Hebron University Hospital, Haemophilia Centre, Barcelona, Spain, [2]Banc de Sang i Teixits, Barcelona, Spain

Background: Haemophilia is a rare disease and detailed documentation and evaluation of treatment and outcomes is essential.

Aims: The aim of this review was to determine the characteristics and outcomes of the severe haemophilia A (HA) patients at our centre.

Methods: This was a single-centre retrospective observational study. All severe HA (FVIII < 1%) patients born 2000-2015 and diagnosed at or early referred to our centre were included. Date of birth, mode of delivery, family history of haemophilia, F8 mutation, neonatal head

TABLE 1 Characteristics of the 7/40 patients that developed clinically relevant inhibitor

Year of birth	F8 mutation	Family history/ Mode of delivery	Neonatal head bleed/ Treatment	Age at haemophilia diagnosis (years)	Age at first treat (years)	Age at inh diagnosis (years)	ED at inh diagnosis	Type of treatment at inh diagnosis	Max inh titre (BU)
2010	Intron 22 Inv	Sporadic/ Vaginal	No	0.8	0.9	1.0	8	Prophylaxis 1 / week	134
2009	Nonsense subst	Sporadic/ Vaginal	Cephalohematoma/ Not treated	0.8	0.8	1.2	7	On-demand	51
2006	Small insert	Sporadic/ Vaginal	No	0.8	0.8	1.2	8	On-demand	24
2005	Intron 22 Inv	Sporadic/ Vaginal	No	1.0	1.3	1.7	15	Prophylaxis 1 / week	45
2004	Nonsense subst	Sporadic/ Forceps assisted	Subgaleal haematoma/ FVIII	0.0	0.0	1.2	21	On-demand (intensive treatment)	43
2004	Small insert	Sporadic/ Forceps assited	Subgaleal haematoma+ cephalohematoma/ FVIII	0.0	0.0	2.3	50	Prophylaxis 3/ week	54
2000	Small insert	Sporadic/ Forceps assited	Subdural haematoma +cephalohematoma/ FVIII	0.0	0.0	0.6	38	Prophylaxis 3/ week	4

bleeding, age at diagnosis and age at first treatment and occurrence of clinically relevant inhibitor were collected from medical files.

Results: Forty severe HA children were evaluated (median age at evaluation 7.4 years; range 1.2-16.6 years). All patients were receiving prophylactic treatment (except 1 on-demand) via peripheral vein infusion and 39/40 received recombinant FVIII products. FVIII gene mutation was known in all cases (92% null-mutations; 53% Intron22 Inversions). Twelve (30%) patients had a family history of haemophilia and 28 (70%) were sporadic cases. Type of delivery was predominantly vaginal (80%) in spontaneous cases and caesarean (58%) in familial. Diagnosis was done at a median age of 0.5 years (range 0-1.2 years) and first FVIII infusion at 0.8 years (0-1.9 years). There were 7 delivery-related head bleeds (3 minor cephalohematomas and 4 subgaleal and/or subdural haematomas), all in spontaneous cases. Clinically relevant inhibitor developed in 7 (17.5%) patients at a median age of 14 months (range 7-28 months) and after 15 ED (7-50 ED) (Table 1). In the period 2010-15 only 1/18 children developed inhibitor, compared to 6/22 in 2000-09 (5.5 % versus 27.2%). All inhibitors were eradicated with immune tolerance treatment with FVIII.

Conclusions: A high ratio of sporadic versus familiar cases has been found in our cohort. The cumulative incidence of inhibitor in the last 15-year has been low (17.5%) and we detected a tendency of decreasing over the studied period.

PB 244 | The Effectiveness of PK-Tailored Tertiary Prophylaxis for Severe Hemophilia A Children: A Pilot Study from BCH

P. Li, Z. Chen, X. Cheng, Y. Wang, N. Zhang, Y. Zhen, X. Wu, R. Wu

Beijing Children's Hospital Capital Medical University, Beijing, China

Background: Hemophilia A (HA) is an X-linked inherited coagulation disorder, regular prophylaxis is the standard treatment method of severe HA. The pharmacokinetics (PK) driven prophylaxis is a feasible but also expensive in developing countries, like China. PK-tailored prophylaxis using more infusion frequency and allowing the 30h per week duration for FVIII level < 1% in PK driven prophylaxis might be more cost-effective method.

Aims: To explore the efficacy of PK-tailored tertiary prophylaxis in severe HA children.

Methods: Since January 2015 to May 2016, we have launched a pilot study on 15 cases from 5 to 16 year-old at Beijing Children´s Hospital (BCH). The study period was divided in two phases:

Phase I: using the original prophylaxis for 6 months (86.7% in low-dose and 13.3% in moderate prophylaxis regimens);

Phase II: separate the study cohort in two groups:

(1) PK-tailored group (modified the prophylaxis regimen according to PK data for the next 6 months),

(2) Maintain group (continued with their original regimen for the next 6 months). Comparing the bleeding rate, infusion frequency and factor consumption between two groups.

Results: In the PK-tailored group, Annual Bleeding Rate (ABR) of 8 cases was reduced from 14.2 to 4 times with annual factor consumption increased from 1619 IU· kg^{-1} to 2401.9 IU· kg^{-1} and the infusion frequency increased from 104 times y-1 in Phase I to 156 times y^{-1} in Phase II ($p< 0.05$), but without significant different in AJBR(Joint) ($P>0.05$). Between two groups, there were higher ABR in PK-tailored group in Phase I, but without difference in Phase II.

Conclusions: In conclusion, the pilot study showed that PK-tailored prophylaxis maybe the more cost-effective individual prophylaxis in China, but need further study.

PB 245 | Korea Hemophilia Foundation Registry Trends 1991-2015: Patient Registry, Demographics, Health Services Utilization

S.K. Kim[1], S.K. Park[2], K.Y. Yoo[3]

[1]Inha University Hospital, Pediatrics, Incheon, Korea, Republic of, [2]College of Medicine, Ulsan University, Pediatrics, Ulsan, Korea, Republic of, [3]Korea Hemophilia Foundation, Seoul, Korea, Republic of

Background: The Korea Hemophilia Foundation (KHF) founded in 1991 has registered Korean hemophiliacs, and updated the cohort by establishing the network of medical information between affiliated clinics.

Aims: The KHF data of over 20 years' experience was analyzed, with inhibitors change over 10 years since 2004.

Methods: Among the 2,482 patients registered in the KHF, 2,303 were alive at the end of 2015 because 179 patients had died; there were 1,654 patients (71.8%) with hemophilia A and 409 (17.8%) with hemophilia B and 116 (5.0%) with von Willebrand disease (VWD).

Results: From 1991 to 2015, while the general South Korean population grew by 15%, the KHF registration patients grew about 200% (n=2,303). Registered hemophilia patients was approximately 1:20,000 males at 1995, which gradually increased over years, and up to 0.9:10,000 males at 2015, with 80% having factor VIII deficiency. Two third of registered patients had ´severe´ disorder, 20% had moderate hemophilia and 11% was classified with mild deficiency. The registered patients with VWD grew by 116; they are now roughly one-eighteenth of the population of hemophiliacs. In patients with hemophilia A, the overall prevalence of inhibitors has a little decreased over 10 years. At least the prevalence of inhibitors in hemophilia A has not increased in spite of the increased use of recombinant factor VIII (rFVIII) agents. The prevalence of inhibitors in hemophilia B has not changed in spite of the increased use of recombinant factor IX agents.

Conclusions: Although the KHF patient base has grown much faster than the general Korea population, some patients have still been left out, especially those with VWD. Therefore, a more efficient and nationwide registry system should be fixed for the provision of comprehensive management for this disorder. Decreased or non-changed prevalence of inhibitors in hemophilia A may warrant the use of rFVIII use.

PB 246 | Safety and Efficacy of Nonacog Alfa in Patients with Hemophilia B: Results of a Post-authorization Study in Usual Care Settings in China

R. Yang[1], R. Wu[2], J. Sun[3], F. Sun[4], J. Rupon[5], F. Huard[6], J.M. Korth-Bradley[7], L. Xu[4], B. Luo[4], Y. Liu[4], P. Rendo[5]

[1]Blood Diseases Hospital, Chinese Academy of Medical Sciences, Tianjin, China, [2]Hematology Oncology Center, Beijing Children's Hospital, Capital Medical University, Beijing, China, [3]Nanfang Hospital, Southern Medical University, Guangzhou, China, [4]Pfizer (China) Research & Development Co, Ltd, Shanghai, China, [5]Pfizer Inc., Collegeville, United States, [6]Pfizer PIO, Paris, France, [7]Pfizer Inc, Collegeville, United States

Background: Acquisition of real-world data is key to understanding the efficacy and safety of marketed medicines. Nonacog alfa is a recombinant coagulation factor IX (FIX) approved in China for the control and prevention of bleeding events and for perioperative management in hemophilia B patients (pts).

Aims: Evaluate the safety and efficacy of nonacog alfa in a real-world setting in Chinese pts with hemophilia B.

Methods: A prospective, open-label, multicenter study, approved by ethics committees, was conducted in hemophilia treatment centers in China. All pts provided informed consent and received nonacog alfa (on-demand [OD] or as prophylaxis) according to approved labeling for 6 mo or 50 exposure days. Key assessments in both the OD and prophylaxis settings included incidence of FIX inhibitor development, allergic reactions, and thrombotic events, serious adverse events (SAEs), annualized bleeding rates (ABRs), and incidence of less-than-expected therapeutic effect (LETE). The number of infusions needed to treat each new bleeding event and treatment response were also assessed in the OD setting.

Results: Of 70 enrolled pts (mean ±SD age, 7.8 ±7.2y; severe hemophilia [FIX < 1%], 51%; previously untreated, 16%), 66 (94%) pts completed the study. One pt (aged < 6y) developed a transient low-titer FIX inhibitor (0.71 BU/mL) during prophylaxis, which was considered an SAE. Another pt had an SAE of oral mucosa hematoma. No pt had an allergic reaction or a thrombotic event. The table summarizes ABR and LETE results. The mean number of infusions to treat each new bleeding event was 1.5 ±1.7; 79% resolved with 1 infusion. Most OD infusions (88%) were rated "excellent" or "good." Results were similar across subgroups defined by age, disease severity, and prior factor exposure.

TABLE Efficacy Results

Parameter	Prophylaxis Patients (n=57)	On-demand Patients (n=18)
ABR, mean (SD)	6.5 (9.1)	26.3 (23.1)
LETE, n	2	0
Incidence (95% CI)	0.1% (0.0%, 0.4%)	0

ABR, annualized bleeding rate; CI, confidence interval; LETE, less-than-expected therapeutic effect; SD, standard deviation.

Conclusions: The efficacy and safety profiles of nonacog alfa in the real-world setting in Chinese pts are similar to those previously reported in clinical interventional studies.

PB 247 | Spinal & Cranial Neurosurgical Procedures in Patients with Hemophilia

C. Nakar, B. Hardesty, M. Karimi, A. Greist, R. Thukral, A. Shapiro

Indiana Hemophilia and Thrombosis Center, Indianapolis, United States

Background: Optimal hemostatic management of patients with hemophilia (PwH) undergoing surgery is challenging. Current surgical management in PwH is based on expert opinion and experience as guidelines generated from prospective trials are lacking; infrequent procedures have less supporting data to guide therapeutic decision making.

Aims: To describe the Indiana Hemophilia and Thrombosis Center (IHTC) experience with neurosurgical procedures (NP) in PwH.

Methods: The IHTC surgical database (SD) contains 1962 surgical plans with outcomes. The SD was queried for spinal/cranial NP and cases analyzed; procedure related medical records were reviewed. Both hemophilia A (HA) and B (HB) and 2 female carriers (levels of 20%) were included. IRB approval was obtained.

Results: Twenty NP were performed between 1998-2016 in 18 PwH including 16 spinal (9 fusions, 3 discectomies, 4 other) and 4 craniotomies (2 tumor resections, lobectomy, subdural hematoma). Thirteen HA underwent 14 procedures; 5 HB underwent 6 procedures. Median age was 41.5 years (range 1.5-71). Two PwH had remote history of transient or low titer inhibitors.

Target preoperative factor levels were ≥80%. Continuous infusion factor concentrate was used for severe/moderate, and 50% of mild PwH. Median therapy duration for severe/moderate was 19 days (range 8-30). Antifibrinolytics were not used in spinal procedures. Hemostatic complications occurred in 2 of 20 NP, both spinal surgery; one with intraoperative hemorrhagic shock, the 2nd with delayed surgical site hematoma after factor replacement stopped. No postoperative inhibitors or thrombotic complications occurred. Table 1 summarizes NP based on factor deficiency, age, length of therapy, and hemostatic complication.

Conclusions: Two of 20 PwH undergoing NP experienced bleeding, both in spinal surgery (2/16); no antifibrinolytics were used. Case details will be presented with recommendations; hemostatic control in specific NP may benefit from antifibrinolytics while others may require more prolonged therapy.

TABLE 1

Surgery Type	Spinal Surgery						Craniotomy	
Severity§	Mild HA	Mild HB	Moderate HA	Moderate HB	Severe HA	Severe HB	Severe HA	Severe HB

PB 248 | Pseudotumors in Hemophilia: Effective Surgery with Application of Frozen Autologous Platelet Gel

A. Misiak[1], B. Ceglarek[2], A.J. Sikorska[2], K. Bykowska[3], J. Swornóg[4], E. Lachert[5], A.J. Meissner[4], A. Szczepanik[6]

[1]Institute of Hematology and Transfusion Medicine, Department of General, Oncological and Metabolic Surgery, Warsaw, Poland, [2]Institute of Hematology and Transfusion Medicine, Department of Disorders of Hemostasis and Internal Medicine3, Warsaw, Poland, [3]Institute of Hematology and Transfusion Medicine, Department of Hemostasis and Metabolic Disorders4, Warsaw, Poland, [4]Institute of Hematology and Transfusion Medicine, Department of General, Oncological and Metabology Surgery, Warsaw, Poland, [5]Institute of Hematology and Transfusion Medicine, Laboratory of Quality Assurance / Department of Transfusion Medicine, Warsaw, Poland, [6]Institute of Hematology and Transfusion Medicine, Department of General, Oncological and Metabology Surgery1, Warsaw, Poland

Background: Hemophiliac pseudotumor (HP) is an encapsulated, chronic, slowly growing hematoma . Frozen autologous platelet gel (FAPG) contains a number of growth factors with beneficial effect on wound healing and post surgery tissue reconstruction.

Aims: Was to present our experience in management of hemophilic pseudotumors-

surgical procedures followed by application of FAPG.

Methods: Four haemophiliac patients aged 38- 57 were subjected to surgical treatment within the last 9 years.

Results:

Case 1: Hemophilia A (38yrs) patient with HP of left femur tumor (21x12x12 cm) pressed to popliteal fossa and limited knee extension. Surgery consisted in tumor evacuation with excision of its pseudocapsule and drainage. No tumor recurrence was reported.

Case 2: A 55-year old hemophilia A patient admitted to IHTM for recurrent HP in left retroperitoneal region 33x21x20 cm tumor pressing on left pelvic bone and hip joint. The front wall of the tumor was removed, the cavity drained and filled with FAPG. Replacement therapy with factor VIII and 18 portions of FAPG were applied into the HP cavity.

Case 3: A 41-year-old Hemophilia A patient (41yrs) with diagnosed factor VIII inhibitor (0.7 BU) and HP of the left iliopsoas muscle infiltrating iliac bone. HP mass was surgically removed and tumor cavity was drained. Replacement factor VIII therapy and 23 portions of FAPG were applied into the HP cavity. A significant reduction of HP cavity size was achieved and the wound healed.

Case 4: A 57-year Hemophilia B (57yrs) patient with bleeding HP (mass 2.0kg), damaging the left iliac bone, sacral bone and one lumbar vertebra. HP mass was removed. Infusion drainage, antibiotics 24 portions of FAPG and factor IX concentrate were applied.

Conclusions: One-stage surgery complete removal of HP from the abdominal cavity is often difficult. Further surgical procedures are required to remove residual parts of the tumor and these combined with simultaneous FAPG application significantly improve the quality of life of hemophilia patients.

PB 249 | Rationale and Study Design for a Prospective, Non-interventional Phase 4 Study Evaluating the Effectiveness of Recombinant Factor VIII Fc Compared with Conventional Factor VIII Concentrates in the Prophylactic Treatment of Haemophilia A: The A-SURE Study

B. Winding[1], J. Oldenburg[2], C. Hay[3], F. Peyvandi[4], F.R. Rosendaal[5], V. Jiménez-Yuste[6], J. Szamosi[1], S. Lethagen[1,7]

[1]Sobi, Stockholm, Sweden, [2]University of Bonn, Department of Experimental Hematology and Transfusion Medicine, Bonn, Germany, [3]Manchester Royal Infirmary, Department of Haematology, Manchester, United Kingdom, [4]Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Fondazione IRCCS Ca' Granda - Ospedale Maggiore Policlinico and Fondazione Luigi Villa, Milan, Italy, [5]Leiden University Medical Center –, Department of Clinical Epidemiology, Leiden, The Netherlands, [6]Autonoma University, Hospital Universitario La Paz, Servicio de Hematología, Madrid, Spain, [7]University of Copenhagen, Copenhagen, Denmark

Background: The efficacy and safety of recombinant factor VIII Fc (rFVIIIFc) have been established in phase 3 studies and extension

studies are ongoing, but there is still a need to provide routine clinical practice data to physicians, payers and patients, assessing the possibility of improved protection and reduced treatment burden.

Aims: To describe the rationale and design of the ongoing A-SURE study evaluating the effectiveness of rFVIIIFc compared with conventional FVIII in the prophylactic treatment of haemophilia A.

Methods: A-SURE is a prospective non-interventional study (NCT02976753) including males with haemophilia A from approximately 45 centres across Europe. Eligible are patients without inhibitors who currently receive and have received FVIII prophylaxis ≥12 months pre-enrolment. Personal history concerning bleeding and prescription over the pre-study period is collected. Patients in other clinical studies or those who received other extended half-life products than rFVIIIFc one year prior to enrolment will be excluded. The protocol will not dictate any treatments and all visits will be according to local practice. Each patient on rFVIIIFc will be matched for age and FVIII concentrate consumption with a patient on conventional FVIII. Safety reporting will follow European Union regulation guidelines. Statistical analyses will be adjusted for propensity scores based on baseline characteristics.

Results: The investigators plan to enrol 350 patients. The annualised bleeding rate (overall, joint and target-joint), injection frequency and concentrate consumption are measures of the primary study outcome evaluating the effectiveness of rFVIIIFc compared with conventional FVIII during 24 months. Secondary endpoints will assess patient reported outcomes and health economic parameters.

Conclusions: A-SURE, a prospective and comparative haemophilia A study, will provide evidence on the effectiveness of prophylaxis with an extended half-life FVIII compared with conventional FVIII in routine clinical practice.

PB 250 | Outcomes in Acquired Hemophilia A Based on the Choice of Hemostatic Agent: A Single Institution Retrospective Cohort Study

M. Daughety, J. Shatzel, T. Deloughery

Oregon Health & Science University, Hematology, Portland, United States

Background: Acquired Hemophilia A (AHA) is a rare disease affecting factor VIII. Only 2 products are FDA approved for bleed management in AHA - recombinant activated factor VII (rFVIIa) and recombinant porcine factor VIII (rpFVIII) - but it is not yet known how these drugs compare in terms of efficacy and overall cost.

Aims: Retrospectively review patients admitted with AHA to compare outcomes and costs based on the hemostatic agent used.

Methods: We identified patients with AHA admitted at to our facility from Dec 2014-Dec 2016, extracting relevant data including bleed severity, transfusions use, type and amount of hemostatic agent used, and survival. We calculated the estimated cost of each hemostatic therapy, using average wholesale costs.

Results: Nine patients met inclusion (mean 71.3 yo, mean inhibitor titer 63.5 BU). All presented with bleeding: 2 with Grade 4, 6 with Grade 3, and 1 with Grade 2 bleeding per WHO criteria. 8 of 9 required transfusion (mean 4.3 units/pt). 2 required surgery: internal iliac artery embolization, and spinal decompression. Of the 7 receiving hemostatic agents, 6 received rFVIIa alone and 1 received rFVIIa and rpFVIII. The average maximum rpFVIIa cost per day was $103,618 USD, with a mean total cost of $329,896/admission based on these real clinical scenarios. For the patient treated with rpFVIII, the maximum daily cost was $123,676, with a total cost of $920,923/admission. All patients achieved adequate hemostasis and all survived.

Conclusions: While our study is too small to draw strong conclusions, we found that both agents achieved adequate hemostasis in AHA patients, and all patients survived to hospital discharge. rpFVIII was more expensive per day than rFVIIa in our clinical experience. Because there are no head-to-head trials of rpFVIII vs rFVIIa, and no compelling data to suggest greater hemostasis with one versus the other, clinicians may consider reserving rpFVIII for cases of severe bleeding.

PB 251 | The Use of Multiple Drugs in a Sample of Adult Patients with Hemophilia: Considerations and Perspectives on Aging

S. Riva[1], A. Nobili[2], E. Mancuso[3], G. Pravettoni[1], L. Cortesi[2], P.M. Mannucci[3], E. Santagostino[3]

[1]University of Milan, Milan, Italy, [2]Institute of Pharmacological Research , Mario Negri', Milan, Italy, [3]A. Bianchi Bonomi Hemophilia and Thrombosis Center, Fondazione IRCCS Ca' Granda - Ospedale Maggiore Policlinico, Milan, Italy

Background: Owing to their much improved management with coagulation factor replacement therapy, patients with hemophilia (PWH) have currently reached a life expectancy similar to that of males in the general population and thus attain older ages much more often than before. However, their aging is associated with an array of hemophilia-related comorbidities (arthropathy, viral infections, liver and renal disease) that begun when treatments were inadequate but are becoming superimposed on the multimorbidities typical of aging. Thus, more and more older PWH need, beside replacement therapy, other drugs that may interfere with their bleeding disorder, increase its severity and cause additional morbidities.

Aims: To tackle these novel and so far poorly investigated issues, this study had the goal to retrospectively describe the number of comorbidities and multimorbidities and the associated polypharmacy in a sample of adult PWH.

Methods: A cross-sectional study analyzed the therapeutic agents employed by patients with severe hemophilia (A or B). The study was focused on adults aged 40 or older living in Italy.

Results: Of 135 patients included with a mean age of 47.7(SD= ±12.3) we found that older patients (50 years of age or more) took more drugs than younger patients (mean 3.4; SD ± 2.0; vs = 2.6; ± 1.8, p=0.0393). Only older hemophiliacs took anti-hypertension drugs (16.2%) and angiotensin-converting-enzyme (ACE) inhibitor drugs (40.5%) but they

did use less frequently anti-inflammatory drugs in comparison with younger PWH (18.9% vs 21.4%).

Conclusions: These findings present a favorable picture pertaining to multiple drug intake in adults and old people with hemophilia. Even if this study is an explorative description, it is specifically oriented to increase the currently scarce knowledge on the health status of older PWH, including their comorbidities, multimorbidities, disease clusters and polypharmacy features.

PB 252 | Sudden Decrease of High-titer Anti-FVIII Antibodies with Anti-inhibitor Coagulant Complex in a Patient with Severe Hemophilia A and Poor Response to Immune Tolerance Induction

I. Soto, L.F. Ávila, D. Martínez, Á. Bernardo

Hospital Universitario Central de Asturias, Hematology, Oviedo, Spain

Background: This 7-year-old patient was diagnosed with severe hemophilia A (HA) at 1 month of age. The hemophilia carrier status of the mother was previously unknown, and he was born full term in Jan-2010 by instrumental delivery with suction cup. Neurologic symptoms and cephalohematoma were observed after a few hours. Computed tomography revealed subgaleal and subdural hematoma in the right cerebral hemisphere. Anemia (Hb 5.7 g/dl) was determined and the patient received blood transfusions before and after emergency craniotomy. The subsequent clinical history and laboratory data are summarized in Table 1. The patient developed high-titer inhibitors early after exposure to replacement factor. Viral infection serology is negative. **Aims:** To describe the experience of inhibitor management in this patient.

Methods: At 3 years and 10 months, rescue immune tolerance induction (ITI) was initiated due to poor progress (Table 1). Response to treatment in Jan2016 (6 years old) was poor. Hemorrhagic episodes had increased and frequent infusion of high doses of NovoSeven were needed. NovoSeven was suspended and treatment with anti-inhibitor coagulant complex Feiba (1000 U/8 h) was initiated due to left knee hemarthrosis. After resolution, prophylaxis regimen was set at 1000 U/day.

Results: FVIII inhibitors reduced dramatically until almost undetectable (Figure 1), and clinical manifestations have greatly improved, with an important favorable impact in the QoL of the patient and his family. At present, the patient is receiving Fandhi 4000 IU and Feiba 1000 U every 48 h.

Conclusions: In this patient with poor response to ITI strategies, Feiba achieved negative inhibitor titer and elicited successful bleeding prophylaxis.

Note: *Labeled use of Feiba is 50-100 U/kg, ≤200 U/kg a day. Feiba is the only agent with an approved indication for bleeding prophylaxis in HA patients with anti-FVIII antibodies. Labeled use of NovoSeven® is 90 µg/kg initial dose in intervals adjusted according to clinical situation.*

TABLE 1 Patient's hemophilia history

Age	Clinical Event	Clinical Management
Birth	Full term delivery with hemorrhagic complications (described in text)	Blood transfusions (Hb 5.7 g/dl) and emergency craniectomy
13 days	Hematoma in right hand related to fluid infusion site and ecchymosis in other puncture sites	Hematology consultation in view of perinatal history.
15 days	Patient diagnosed with severe HA. Intron 22 inversion FVIII:C: <1; FVIII:Cr undetectable; Inhibitor: 0 BU	Replacement therapy with octocog-alpha (Advate® 200 IU/24 h) initiated. (Patient's weight approx. 3-3.5 kg)
45 days	After 23 exposures to replacement factor, patient developed low-response inhibitor (1.07 BU). FVII:C 10.6%	ITI with 500 IU/24 h of activated eptacog alfa (Novoseven®) initiated
3 years 10 months	Poor evolution of FVIII inhibitors with increasing titer in the previous year. FVIII:C 0.8%; FVIII:Cr undetectable Inhibitor: 6.8 BU	FVIII administration suspended. When inhibitor reached 6.8 BU, initiation of rescue ITI with plasma-derived FVIII concentrate rich in vWF (Fandhi®) 2000 IU/24 h (137 IU/kg) and prophylaxis with eptacog alfa 2 mg/48 h
6 years	Poor response to anti-inhibitor treatment (See methods)	Treatment with anti-inhibitor coagulant complex Feiba® (See methods)

Hb, hemoglobin; HA, hemophilia A; BU, Bethesda Units; ITI, immune tolerance induction; vWF, von Willebrand factor

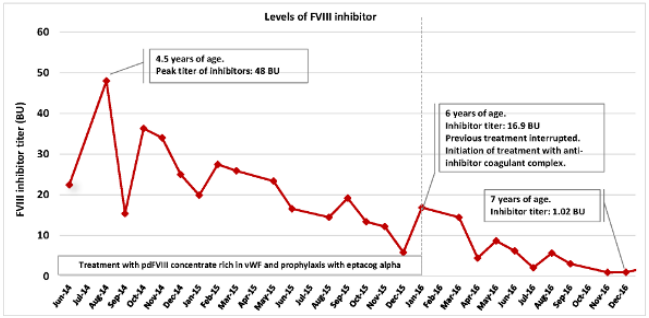

FIGURE 1 Evolution of inhibitor titer and clinical events in the last 2.5 years (since the present laboratory data monitoring system for frequent sa

PB 253 | Projecting Product Consumption of AFSTYLA vs. ADVATE in the United States

G. Krishnarajah[1], S. Yan[1], L. Stern[2], R. Hutcheson[3]

[1]CSL Behring, King of Prussia, United States, [2]LASER Analytica, New York, United States, [3]LASER Analytica, Montréal, Canada

Background: AFSTYLA (rVIII-SingleChain) is indicated in adults, adolescents and children with hemophilia A for control and prevention of bleeding episodes, routine prophylaxis to prevent or reduce the frequency of bleeding episodes, and for perioperative management.

Aims: To estimate product consumption of AFSTYLA from the perspective of a US health plan and to compare against another recombinant factor VIII product, ADVATE.

Methods: Average consumption of product per patient (IU/kg) was calculated and compared between AFSTYLA and ADVATE, based on a previously-developed budget impact model. The patient population consisted of those with hemophilia A, stratified based on age (< 6 years, 6 to < 12 years, 12 to < 18 years, and ≥18 years) and proportion on prophylaxis versus on-demand. Dosing, median annualized bleeding rates, and average number of infusions needed to treat bleeding were based on product prescribing information and other published data. Dosing frequency was 2 to 3 times weekly for AFSTYLA and 3 to 4 times weekly for ADVATE.

Results: In the total prophylaxis population, the average monthly consumption of AFSTYLA (including treatment for breakthrough bleeding) was lower than ADVATE by 6.4% among children < 6 years and 6 to < 12 years of age, and by 16.7% among adolescents 12 to < 18 and adults ≥18 years of age. When excluding treatment of breakthrough bleeds, the average monthly consumption of AFSTYLA was lower than ADVATE by 4.8% among children, and by 16.7% among adolescents and adults. In the on-demand population, consumption of AFSTYLA per bleeding episode was lower than ADVATE by 41.3% among children, and by 27.2% among adolescents and adults.

Conclusions: Without compromising the efficacy, the introduction of AFSTYLA to a US health plan may result in lower average product consumption, compared to ADVATE, in both the prophylaxis and on-demand settings.

PB 254 | Correlation between Pharmacokinetic of Factor VIII and Bleeding Frequency of Children withsevere Hemophilia A in China - A Single Center Data Analysis

X. Cheng, Z. Chen, P. Li, Y. Wang, N. Zhang, Y. Zhen, X. Wu, R. Wu

Beijing Children's Hospital Capital Medical University, Beijing, China

Background: The pharmacokinetic (PK) of factor VIII(FVIII)is individualized in hemophilia A (HA) children, the result of PK will be the indicatorof patients' bleeding phenotype and the instruction for their personalized replacement regimen.

Aims: The aim of this study was toinvestigate the relationship of PKof FVIII and time< 1 IU dL^{-1}per weekwith bleedingfrequencyof severe HA children in China.

Methods: Total24 cases enrolled in our center during Feb. 2015 to Oct. 2015, all of them were given 50IU/kg of FVIII concentrates after 72h washout period. Five points' samples FVIII:C activities were tested: baseline, 1 h, 9h, 24h, and 48h, usingWinNonlin(Pharsight Corp., Phoenix, AZ, USA) soft for PK testing, then calculated the individual half-life($t_{1/2}$) and the time (h) of FVIII concentrations < 1IU dL^{-1} within a week during prophylaxis. Date of baseline and rate of bleedings(joint bleeds and ,other bleeds') was recorded.

Results: The median age was 8.95 (range 5 to 15.98) years old, and the median annual bleeds rate / joint bleeding (ABR/AJBR) were 20 (range 5 to 30)times/12 (range 2.2 to 30)times. The mean half-life of FVIII was 10.20±2.72hand the mean hours of FVIII< 1IU dL^{-1} in one week was 50.6 h (-90.56~102.33h). Significant relationship betweenthe $t_{1/2}$ of FVIII and ABR/AJBR was found (r=0.62 and 0.75, respectively). ABR/AJBR had positive correlation with the time (h) of the hours of FVIII< 1IU dL^{-1}in one week (r=0.46 and 0.51, P< 0.05).

Conclusions: There indeed existed the significantvariation in the FVIII $t_{1/2}$ in Chinese severe HA children and had the relationship with-ABR/AJBR and time< 1 IU dLper weekduring prophylaxis.It showed that $t_{1/2}$was the important indicator to prevent bleeding for HA and shorten the time< 1 IU dL according tot$_{1/2}$ wouldreduce the bleeding of severe HA during prophylaxisin China.

PB 255 | Assessment of the Quality of Life in Korean Hemophiliacs: Impact of Disease-related Factors, Social Status and Treatment Factors on the Quality of Life of Korean Hemophiliacs

C.W. You[1], H.-J. Shin[2], S. Lee[3], M.K. Kim[4]

[1]Eulji University School of Medicine, Pediatrics, Daejeon, Korea, Republic of, [2]Pusan National University Hospital, Internal Medicine, Busan, Korea, Republic of, [3]Daegu Fatima Hospital, Internal Medicine, Daegu, Korea, Republic of, [4]Presbyterian Medical Center, Pediatrics, Jeonju, Korea, Republic of

Background: The identification of disease-related factors, treatment factors and the social status of hemophiliac patients which may have an impact on their QoL in each country, is vital in establishing potential intervention strategies for these patients.

Aims: We evaluated the impact of these factors on the QoL of Korean hemophiliac patients.

Methods: QoL was evaluated using the SF36 standardized questionnaires. Disease-related factors were obtained from the patients' medical records. Socio-demographic data, such as marital status, occupational status, education years, as well as a treatment data, self-injection ability were obtained using questionnaires.

Correlation analysis and multiple regression analysis were conducted to elucidate the impact of the observed data on the QoL of these patients.

Results: The disease-related factors were correlated with physical health of the patients. Marital status was the only social status shown to have a correlation with the QoL of the hemophiliac patients; marital status was shown to only affect patients' physical health. However, self-injection ability, the only treatment factor surveyed in this study, was significantly associated with both the physical and mental health of the patients. Mental health was revealed to be poorer in Korean hemophiliac patients when compared with that of patients residing in countries with well-organized hemophilia treatment systems.

Conclusions: One social factor (marital status) and the disease-related factors correlated with the physical health of the Korean hemophiliac patients. Self-injection ability was associated with both the physical and mental health of the patients. The differences in treatment factors across different countries may contribute to the difference in the physical and mental health of hemophiliac patients.

PB 323 | Extracellular Nucleosome Levels in the Etiopathogenesis of Sepsis-associated Coagulopathy

A. Walborn[1], P. Patel[2], D. Hoppensteadt[3], M. Mosier[4], M. Rondina[5], J. Fareed[2]

[1]Loyola University Medical Center, Pharmacology, Maywood, United States, [2]Loyola University Medical Center, Maywood, United States, [3]Loyola University Medical Center, Pathology, Maywood, United States, [4]Loyola University Medical Center, Surgery, Maywood, United States, [5]University of Utah School of Medicine, Department of Internal Medicine, Salt Lake City, United States

Background: Nucleosomes (DNA-histone complexes) can be expelled into the blood as part of the host defense process. While this contributes bacterial clearance, nucleosomes (NUCs) can play a role in disease pathology by leading to inflammation, endothelial damage, and pathological thrombosis. NUCs may contribute to the link between infection, host response, and systemic coagulation in sepsis-associated disseminated intravascular coagulation (DIC).

Aims: The purpose of this study was to demonstrate the relationship between NUCs with other mediators of inflammation in sepsis associated coagulopathy.

Methods: Plasma was collected from patients with sepsis and suspected DIC on ICU days 0, 4, and 8 under an IRB approved protocol. DIC score was evaluated using the ISTH scoring algorithm. Plasma from healthy individuals was purchased from George King Biomedical. Plasma NUCs were measured using the Cell Death Detection ELISA (Roche Diagnostics).

Results: NUCs were significantly elevated in patients with sepsis and suspected DIC compared to healthy individuals on ICU days 0 ($p = 0.028$), 4 ($p < 0.0001$), and 8 ($p = 0.013$). When patients were categorized according to ISTH DIC score, a non-significant trend towards increasing NUCs with increasing DIC score was observed. NUCs were significantly elevated in patients with overt DIC compared to normal on day 0 ($p = 0.02$). On day 4, nucleosomes were significantly elevated in patients with overt and non-overt DIC compared to controls ($p < 0.01$). NUCs correlated with D-Dimer, F1.2, PCT, IL-8, and IL-10.

Conclusions: Plasma NUCs were elevated in patients with sepsis and DIC, with a trend towards increasing NUCs with increasing DIC score, suggesting that NUCs contribute to the pathophysiology of DIC. The correlation of nucleosomes with PCT and inflammatory markers suggests that the presence of NUCs in the plasma of patients may be due to infection-related processes. The correlation of NUCs with markers of coagulation suggests that NUCs play a role in coagulation activation in DIC patients.

PB 324 | Mediators of Inflammation and Infection in Sepsis Associated Disseminated Intravascular Coagulation and Their Prognostic Role

P. Patel[1], A. Walborn[2], D. Hoppensteadt[1], M. Mosier[3], M. Rondina[4], J. Fareed[1]

[1]Loyola University Medical Center, Pathology, Maywood, United States, [2]Loyola University Medical Center, Pharmacology, Maywood, United States, [3]Loyola University Medical Center, Surgery, Maywood, United States, [4]University of Utah School of Medicine, Department of Internal Medicine, Salt Lake City, United States

Background: Sepsis is a severe systemic inflammatory response to infection that manifests with widespread inflammation as well as endothelial and hemostatic dysfunction. Both nucleosomes (NUC) and procalcitonin (PCT) are associated with the inflammatory and infectious processes that play a key role in the pathogenesis of this syndrome.

Aims: The purpose of this study is to investigate the role of various mediators of inflammation including nucleosomes and their relevance with each other in determining the severity of DIC.

Methods: De-identified citrated plasma samples from patients diagnosed with SAC (n=137) were collected from patients in the ICU upon admission and on days 4 and 8. In addition, plasma samples from healthy volunteers (n=50) were purchased from George King Biomedical (Overland, KS). Plasma samples were analyzed for procalcitonin (PCT) (Abcam) and extracellular NUC (Roche) using commercially available ELISA methods. Markers of inflammation including interleukin 6 (IL-6), interleukin 8 (IL-8), interleukin 10 (IL-10) and tumor necrosis factor α (TNF α) were measure using the Biochip Array from Randox (Antrim, UK).

Results: The levels of PCT were elevated in all three groups compared to normal ($p< 0.05$). In addition, the patients with overt DIC had a higher level of PCT on days 0 and 4, compared to patients with non-overt DIC or sepsis alone. On day 8, the overt and non-overt DIC patients had similar levels of PCT. Similarly, markers of inflammation, including IL-6, IL-8, IL-10 and TNF α were higher in the overt DIC group compared to the other groups on day 0 and day 4. The PCT levels correlated with NUC, IL-6, IL-8, IL-10 and TNF α levels ($p< 0.05$, Spearman $r>0.20$).

Conclusions: This study demonstrates the diagnostic and prognostic value of profiling several biomarkers of inflammation and infection in patients with SAC and DIC to assess the severity of illness. This study provides an initial framework in developing a multiparametric profile of biomarkers in DIC for diagnostic and prognostic purposes.

PB 325 | Crotoxin, a phospholipase A2 from Crotalus durissus terrificus rattlesnake venom, attenuates coagulation and inflammatory parameters in endotoxin-induced DIC

M.A. Sartim, G.N. Cezarette, S.V. Sampaio

University of Sao Paulo, Clinical Analysis, Toxicology and Food Sciences, Ribeirão Preto, Brazil

Background: Crotoxin (CTX) is the major component present in the venom of the rattlesnake *Crotalus durissus terrificus*, and has been widely investigated due to its immunomodulatory and anti-inflammatory properties.

Aims: Therefore, we aimed to evaluate the capacity of CTX to modulate the systemic activation of coagulation upon inflammatory stimulus, using the disseminated intravascular coagulation (DIC) model in mice.

Methods: The DIC was induced by injection of 30mg/Kg lipopolysaccharide (LPS via i.p.) in swiss mice, and blood collected by cardiac puncture after 24 hours. Mice were pretreatment with CTX (30µg/Kg via s.c.) 6 hours before LPS administration. Control mice were given saline, CTX or LPS only. Prothrombin time (PT), activated partial thromboplastin time (aPTT), platelet counting and pro-inflammatory citokine IL-6 were analyzed.

Results: CTX was capable to reduce both plasma PT and aPTT compared to animals challenged only by LPS, which presented both parameters prolonged. Moreover, mice pretreated with CTX partially recovered platelet counting (607.5±86.76x10^6platelets/mL) compared to LPS challenged animals (582.5±19.59x10^6platelets/mL). As concerning to cytokine IL-6, the pretreatment with CTX before LPS stimulation reduced in 38% the plasma concentration of the pro-inflammatory mediator.

Conclusions: The preliminary results shows that CTX is capable to reduce both inflammatory and coagulation parameters triggered by LPS. Therefore, in order to obtain more information on CTX effects we intend to continue the research on CTX. One effort consists in the measurement of an important biomarker associated with the inflammation-coagulation axis: tissue factor. Moreover, a second approach consist in using pharmacological antagonists in order to elucidate CTX anti-inflammatory mechanism possibly involved. The results obtained assign CTX as a novel approach in DIC resolution, and further steps open perspectives for different targets in DIC therapeutics.

PB 326 | Evaluation of the Diagnostic Utility of Individual Parameters in the Disseminated Intravascular Coagulation (DIC) Panel for Use in Under-resourced Settings

S. Louw[1,2], E.S. Mayne[1,2], A. Mayne[1]

[1]*University of the Witwatersrand, Molecular Medicine and Haematology, Johannesburg, South Africa,* [2]*National Health Laboratory Services (NHLS), Johannesburg, South Africa*

Background: Disseminated intravascular coagulation (DIC) is a clinicopathological condition caused by a number of pro-thrombotic inflammatory stimuli which results in dysregulation of normal coagulation homeostasis. Systemic fibrin clots are generated which result in consumption of both platelets and coagulation factors, critical organ ischaemia and ultimately in a bleeding diathesis. DIC is a strong predictor of mortality. The DIC testing panel at our centre consists of the following parameters: Prothrombin Index (PI), activated Partial Thromboplastin Time (aPTT), Platelet count, Antithrombin, Thrombin Time, Fibrinogen and D-dimers.

Aims: To assess the predictive value of the individual parameters included in the DIC screen panel at the Charlotte Maxeke Johannesburg Academic Hospital (CMJAH) in South Africa.

Methods: A retrospective review of all DIC screens performed at CMJAH over a period of 1 year was conducted. The ISTH DIC score was applied to each screen. A score of >4 was considered positive for the presence of a DIC. A logistic regression was applied to the individual parameters and a predictive Z-score was derived to assess the diagnostic utility of each parameter.

Results: The predictive value of the individual parameters of the DIC panel is depicted in Table 1. Only 18 of the 143 patients diagnosed with DIC had a fibrinogen below the normal reference range (2-4g/dl). Only 8 of these patients had a fibrinogen level below 1g/dl to qualify for ISTH DIC point allocation.

TABLE 1 Z-scores for individual parameters on the CMJAH DIC screen:

Parameter:	Z-score:	p value:
PI (s)	2.57	0.01
aPTT (s)	3.44	0.001
Platelet count (x10^9/l)	-6.88	0.000
Antithrombin (%)	-5.47	0.000
Thrombin Time (s)	1.02	0.309
Fibrinogen (g/l)	-1.60	0.110
D-dimers (mg/l)	3.29	0.001

Conclusions: To improve cost-efficiency of DIC screening, omission of fibrinogen and thrombin time analysis in the routine DIC panel could be considered in our setting. This would have a minimal impact on the sensitivity of the assay but could improve cost efficiency.

PB 327 | Circulating Nucleosomes and Neutrophil Activation Predict for Disseminated Intravascular Coagulation but Not for Mortality in Patients with Severe Sepsis or Septic Shock

M.N. Lauw[1], W.A. Wuillemin[2], G.J. Van Mierlo[3], S. Zeerleder[3,4]

[1]*Academic Medical Center, Department of Vascular Medicine, Amsterdam, The Netherlands,* [2]*Kantonsspital, Division of Hematology and Central Hematology Laboratory, Lucerne, Switzerland,* [3]*Sanquin Research, Department of Immunopathology, Amsterdam, The Netherlands,* [4]*Academic Medical Center, Department of Hematology, Amsterdam, The Netherlands*

Background: Disseminated intravascular coagulation (DIC) is a heterogeneous syndrome characterized by bleeding and thrombosis.

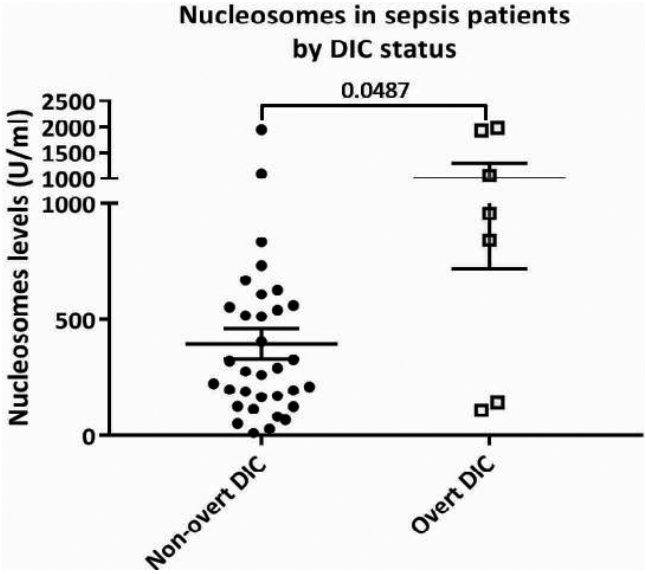

FIGURE 1A

Recently, damage-associated molecular patterns, e.g. extracellular cell-free DNA, DNA binding proteins and neutrophil activation, were shown to play a crucial role in the pathogenesis of DIC.

Aims: To explore the predictive value of extracellular DNA and neutrophil activation for DIC and mortality.

Methods: We used a well-described cohort of 40 patients admitted to the intensive care unit of University Hospital Bern, Switzerland (1998-1999) with severe sepsis or septic shock according to the American College of Chest Physicians consensus. Patients were followed for 90 days or until death. Blood samples taken at inclusion and at 24, 48, 72, and 96 hours were analyzed for extracellular DNA (nucleosomes) and neutrophil activation (elastase-a1antitrypsin (EA) complexes). DIC scores were calculated according to ISTH guidelines. D-dimer levels were categorized based on quartiles of the cohort (0 pts=1st quartile; 2 pts=2nd-3rd quartile; 3 pts=4th quartile). Predictive value for DIC (ISTH DIC score ≥5) and mortality were assessed by receiver-operating characteristic curves and Cox regression analysis.

Results: 7 of 40 patients developed DIC and 13 died. Nucleosomes and neutrophil activation at baseline were significantly higher in patients with DIC compared to those without (Fig. 1A and 1B).

Levels did not differ between survivors and non-survivors (p=0.3307; and p=0.1216, re spectively). With an area under the curve (AUC) value of 0.74 (95% CI 0.5-1.0; p=0.048) and 0.74 (95% CI 0.4-1.0; p=0.048), nucleosomes and neutrophil activation significantly predicted for DIC but not for mortality (AUC 0.598; 95% CI 0.4-0.8, and AUC 0.654; 95% CI 0.5-0.8).

Conclusions: Nucleosomes and neutrophil activation are predictive of DIC, suggesting an important role of neutrophil extracellular traps (NETs) formation. Their additive value to existing DIC or mortality prediction scores requires further investigation.

PB 328 | A Prospective Observational Study for the Evaluation of New Diagnostic Criteria for Disseminated Intravascular Coagulation by the Japanese Society on Thrombosis and Hemostasis

Y. Kondoh[1], H. Satoh[1], H. Takeda[1], S. Funakoshi[2], K. Watanabe[3], K. Sasao[4], K. Sekine[4], J. Nozaki[5], M. Kawamura[5], S. Madoiwa[6]

[1]Tokyo Saiseikai Central Hospital, Clinical Laboratory, Tokyo, Japan, [2]Tokyo Saiseikai Central Hospital, Medical Oncology, Tokyo, Japan, [3]Tokyo Saiseikai Central Hospital, Hematology, Tokyo, Japan, [4]Tokyo Saiseikai Central Hospital, Emergency and Critical Care Medicine, Tokyo, Japan, [5]LSI Medience, Tokyo, Japan, [6]Tokyo Saiseikai Central Hospital, Clinical Laboratory Medicine, Tokyo, Japan

Background: The prognosis of sepsis is affected by the presence of disseminated intravascular coagulation (DIC). Several criteria have limited application in an appropriate phase to improve the outcome of sepsis-induced DIC. The Japanese Society on Thrombosis and Hemostasis (JSTH) has proposed new DIC criteria using molecular markers and antithrombin (AT) activity to overcome problems encountered with DIC diagnosis.

Aims: The objective of this study was to evaluate the JSTH criteria for DIC in patients with sepsis.

Methods: We prospectively enrolled 28 patients with sepsis, who had platelet counts of < $120X10^3$ /μL and/or FDP levels of >10 μg/mL. Blood coagulation parameters, soluble fibrin (SF), thrombin-AT complex (TAT) and AT activity were measured on days of 1 (at the time of enrollment), 5 ,3 ,2 and 7. The JSTH criteria was validated by comparing with overt DIC criteria of ISTH and DIC criteria of Japanese Ministry of Health and Welfare (JMHW). The APACHE II score was calculated on day 1, and the outcome measures were organ dysfunction by a SOFA score and the -28day mortality.

Results: Patients who fulfilled the JSTH DIC criteria included almost all those whose DIC was diagnosed by the ISTH and JMHW scoring

systems. The SF levels on Day 1 in DIC patients by the JSTH criteria were significantly higher than those of non-DIC patients (99.1±71.9 vs 18.1±21.1 µg/mL, p=0.030). The overall mortality was 42.8%, and APACHE II score of non-survivors was significantly higher than survivors (20.3±6.8 vs 14.7±5.4, p=0.031). Higher SOFA scores on Days 2, 3, 5 and 7 were observed in the non-survivors than in survivors. Although JSTH scores did not associate with the mortality rate, the recovery of platelets counts was an important predictor of the outcome.

Conclusions: The JSTH criteria has an acceptable property for the diagnosis of DIC, as the scoring system identified most of the patients diagnosed by the ISTH and JMHW criteria.

PB 329 | A comparison of Disseminated Intravascular Coagulation (DIC) Screening Parameters with and without Human Immunodeficiency Virus Infection in an African Academic Hospital Setting

E. Mayne[1], A. Mayne[1], S. Louw[2]

[1]University of the Witwatersrand, Molecular Medicine and Haematology, Johannesburg, South Africa, [2]University of the Witwatersrand and NHLS, Molecular Medicine and Haematology, Johannesburg, South Africa

Background: HIV infection is highly prevalent in South Africa. HIV causes CD4+ T-cell lymphopaenia and predisposes to opportunistic infection and malignancies which may trigger DIC. DIC is results in dysregulation of coagulation homeostasis and systemic generation of fibrin clots with consumption of coagulation factors and platelets and the development of a bleeding diathesis. HIV positive patients show endothelial dysfunction which may cause a hypercoagulable state and affect DIC presentation in this population.

Aims: To compare the DIC presentation of HIV positive and HIV negative patients in an African Academic Hospital

Methods: All DIC screens performed over a 1 year period were assigned an ISTH DIC score. All screens with a score >4 were considered positive for a DIC. Data were accessed from the laboratory information system. All continuous variables were normalised and expressed as a mean. A 2 data-set mean comparison was performed. A level of significance of p< 0.05 was used.

Results: Of the 304 screens performed over the period, 144 were positive for a DIC. Of these, 33 had an unknown HIV status. More patients were HIV positive than negative (n=67 and n=44 respectively). HIV infected patients showed significantly higher D-dimer levels than HIV negative patients. (5.6ml/ml and 3.4 mg/ml respectively, p=0.03). The prothrombin time showed a trend to increased prolongation in HIV positive compared with HIV negative patients (28.1s vs 22.4s, p=0.06). No other parameters showed significant differences. (Table 1)

TABLE 1 Mean values for DIC screen parameters in HIV infected and uninfected patients with DIC

	HIV-infected patients (n=67) Mean Value	HIV-uninfected patients (n=44) Mean Value	Difference p-vale
D-dimer (mg/l)	5.6	3.4	0.03
Fibrinogen (g/l)	4.1	4.7	0.10
Prothrombin Time (s)	28.1	22.4	0.06
Platelets (10^9/l)	59.8	59.8	0.5
Antithrombin (%)	72.3	74.5	0.36

Conclusions: HIV positive patients with DIC showed significantly higher D-dimer levels. Higher D-dimer levels correlate with poor prognosis in patients infected with HIV and may be increased in asymptomatic HIV-infected individuals. This may act as a confounding variable and prevents accurate DIC diagnosis. he The prognostic significance of strongly raised D-dimers in patients with HIV and DIC should be evaluated.

PB 330 | International Normalized Ratio Relevance to the Observed Coagulation Abnormalities in Warfarin Treated and Those with Disseminated Intravascular Coagulation

D. Hoppensteadt[1], A. Walborn[2], S. Abro[1], J. Walenga[3], M. Mosier[4], K. Tsuruta[5], J. Fareed[1]

[1]Loyola University Medical Center, Pathology, Maywood, United States, [2]Loyola University Medical Center, Pharmacology, Maywood, United States, [3]Loyola University Medical Center, Thoracic and Cardiovascular Surgery, Maywood, United States, [4]Loyola University Medical Center, Surgery, Maywood, United States, [5]Loyola University Medical Center, Asahi Kasei Pharma America Corporation, Waltham, United States

Background: Disseminated intravascular coagulation (DIC) is characterized by an ongoing systemic activation of the coagulation and fibrinolytic systems, which can exhaust coagulation factors. Patients receiving warfarin for anticoagulation also have a prolonged PT/INR.

Aims: The purpose of this study was to compare the coagulopathy observed in patients with DIC and in patients in the initial phase of warfarin therapy.

Methods: Citrated de-identified plasma samples were collected at baseline from patients diagnosed with sepsis-associated DIC (n= 100) and from patients in the initial phase of warfarin therapy (n=100). These plasma samples were evaluated for PT/INR (IL, Bedford, MA), APTT (Stago, Parsippany, NJ), fibrinogen, (IL, Bedford, MA) and functional (Aniara, West Chester, OH) and antigenic levels (Hyphen Biomed, Paris, France) of Factors VII, IX and X.

Results: The PT/INR values were significantly higher in warfarinized patients (WP) compared to DIC patients (p< 0.001). The APTT showed no correlation with the INR in WP but increased with an increase in the INR in the DIC group (p< 0.001). Similarly, the fibrinogen levels showed no correlation with INR in WP; however, in DIC patients, the fibrinogen levels decreased with an increase in the INR. In the factor assays, both the functional and antigenic levels of factors IX and X were decreased in the WP as INR increased, but showed no variation with INR in the DIC patient group. Factor VII levels were decreased with an increased INR in WP but not the DIC patients.

Conclusions: In the DIC patients, there was no decrease in factor levels with increase in INR. In contrast warfarin patients, showed a decrease in factor levels with an increasing INR. However, in DIC greater changes in global coagulation parameters were observed. These results suggest that the coagulopathy observed in a patient with INR ≥ 1.4 is fundamentally different in a patient receiving warfarin for anticoagulation than in patients with DIC.

PB 331 | Epidemiological Evaluation of Patients Presenting with Disseminated Intravascular Coagulation (DIC) at an Academic Hospital in an African Middle-income Country

E. Mayne[1], A. Mayne[2], S. Louw[1]

[1]*University of the Witwatersrand, NHLS and Charlotte Maxeke Johannesburg Academic Hospital, Molecular Medicine and Haematology, Johannesburg, South Africa,* [2]*University of Witwatersrand, Molecular Medicine and Haematology, Johannesburg, South Africa*

Background: DIC is a serious pathophysiological condition resulting from a number of different triggers including infection and malignancy. DIC results from dysregulation of coagulation homeostasis with inappropriate generation of systemic fibrin clots and eventual consumption of platelets and coagulation factors. DIC results in significant mortality and accurate diagnosis is essential for appropriate treatment.

Aims: To evaluate the underlying causes and patient demographic characteristics in patients diagnosed with a DIC at an African academic hospital.

Methods: All DIC screens over a 1 year period were included in this analysis. An ISTH DIC score was allocated to each screen and a score of >4 was considered positive. Assignment of an underlying cause was performed using results derived from the laboratory information system. All continuous variables were described as median values.

Results: 304 DIC screens were performed at our hospital of which 144 were assigned an ISTH DIC score above 4. The median age of the patients at diagnosis was 37 year (range of 0-85 years). The male:female ratio was 0.8:1. In 111 patients, an infection was demonstrated (77%). 67 patients were HIV positive of which 43 showed

FIGURE 1 Pathogenic causes of DIC

an additional infectious agent on culture. Of the 33 patients where HIV status was unknown, 16 were culture positive. 22 HIV negative patients were diagnosed with an infection. The second commonest cause was malignancy (in 31 patients) with or without concomitant infection. In 24 patients, no cause could be demonstrated.
(See figure 1).

Conclusions: In our setting, infection continues to be the highest demonstrable trigger for development of DIC. This, in part, reflects the high HIV prevalence which predisposes to malignancy and opportunistic infection.

PB 332 | Real Word Difficulties in the Diagnosis and Management of Hyperfibrinolysis

J. Russell, W. Thomas, E. Symington, M. Besser

Addenbrooke's Hospital, Dept. of Haematology, Cambridge, United Kingdom

Background: Hyper-fibrinolysis (HF) is challenging to treat/diagnose manifesting with bleeding & thrombosis with no standard approach. Often patients may have co-existing bleeding and thrombosis creating treatment dilemmas.

Aims: We present 5 cases with management & diagnostic issues to share experience.

Methods: Case series.

Results: Patient age range was 51-84 (median 69, 4 males & 1 female). Fibrinogen at presentation ranged from < 0.17 to 0.96g/L (ref. range 1.46-3.33g/L). Causes of HF were acute myeloid leukaemia (AML) in 2 cases (t(15;17) excluded by FISH), metastatic prostate cancer, carcinoma of unknown primary (CUP) and a thoracic aneurysm. 2 patients presented with simultaneous bleeding and venous thrombosis. 3 patients presented with solely bleeding manifestations (including skin, rectal and cerebral bleeding). In all but 1 case the cause of HF was apparent at presentation. A 79 year old female presented with haematuria, fibrinogen < 0.17g/L, D-dimer 19635ng/ml (0-230ng/ml) and extensive work-up for cancer was negative. At week 6 the patient developed cerebral bleeding and the white cell count rose from 4.7x10*9/l (normal blood count/film, range 3.6-10.5x10*9/l) to 44x10&9/L with 90% blasts typed as AML. The 3 patients presenting with bleeding were managed with combinations of cryoprecipitate, fibrinogen concentrate, tranexamic acid and aprotinin. 2 patients (1 CUP & 1 AML) were treated for both thrombosis and bleeding with dalteparin along with combinations of

tranexamic acid, cryoprecipitate and fresh frozen plasma. The patient with AML had an inferior vena cava filter as therapeutic anticoagulation was not possible due to bleeding risk. Prognosis was determined by the driving disease.

Conclusions: We conclude that management of HF is treating the predominant clinical problem (bleeding v thrombosis) and the driving disease (which are predominantly malignant). Diagnosis may be obscure and HF can precede an occult malignancy so bone marrow biopsy in cases of intractable HF may reveal myeloid disease.

PB 333 | Fulminant Disseminated Intravascular Coagulation as Initial Manifestation of Pulmonary Adenocarcinoma

S. Teixeira[1], C. Monteiro[2], M. Carvalho[2], L. Gonçalves[2], C. Koch[2]

[1]*Centre of Thrombosis and Hemostasis, Transfusion Medicine and Blood Bank Department, Centro Hospitalar São João, EPE, Porto, Portugal,* [2]*Centre of Thrombosis and Hemostasis, Transfusion Medicine and Blood Bank Department, Centro Hospitalar São João,EPE, Porto, Portugal*

Background: Fulminant disseminated intravascular coagulation (DIC) is characterized by laboratory abnormalities with simultaneous widespread microvascular thrombosis and profuse bleeding from various sites.

Aims: Report a case of cardiac tamponade with fulminant DIC as an initial manifestation of primary lung cancer diagnosed post-mortem.

Methods: 57-year old patient admitted to the emergency room with signs of respiratory distress and hypoxia. Shortly after, cardiac arrest occurred. Due to unsuccessful advanced life support measures, extracorporeal membrane oxygenation (ECMO) was initiated. Echocardiogram revealed cardiac tamponade but only 70 cc of blood was withdrawn by pericardiocentesis. On admission laboratory tests results were: hemoglobin (Hb= 9,7g/dL); platelet count (plt): $40x10^9$/L; aPTT= 133,8 s; PT= 73,2 s; Fibrinogen < 10 mg/dL. Correction of coagulation parameters was attempted with fresh frozen plasma, fibrinogen, tranexamic acid and prothrombin complex concentrates. Pericardial hematic fluid was drained through open surgical approach. Abruptly shock ensued and vasopressor support was necessary. Even though repeated coagulation tests showed some improvement, profuse bleeding from various sites started. Efforts to correct hemostasis were unsuccessful.

Results: The cardiac tamponade relapsed and the patient condition deteriorated. Thoracic computed tomography (CT) angiography showed pulmonary thromboembolism in the left pulmonary artery. Head CT had evidence of tetra-ventricular hemorrhage, extensive ischemia with diffuse cerebral edema. At this point coagulation results were: aPTT= 48 s; PT= 21,3 s; Fibrinogen 142 mg/dL. There were no clinical improvements and the patient died 18h after admission. The autopsy revealed a pulmonary adenocarcinoma with pericardial and myocardial invasion.

Conclusions: This report sustains that DIC remains a syndrome of difficult approach due to its different etiologies and varied clinical presentations. Without treatment of the underlying cause it is predestined to fail.

PB 334 | Platelet-mimicking Synthetic Nanoparticles (SynthoPlateTM) Improve Hemostasis and Survival Following Uncontrolled Hemorrhage

M. Dyer[1], C. Pawlowski[2], S. Haldeman[1], A. Gutierrez[1], W. Alexander[1], U. Sekhon[2], E. Niedoba[2], D. Hickman[2], A. Sen Gupta[2], M. Neal[1]

[1]*University of Pittsburgh, Surgery, Pittsburgh, United States,* [2]*Case Western Reserve University, BioMedical Engineering, Cleveland, United States*

Background: Hemorrhage is the leading cause of preventable death after trauma. Platelet transfusions, while critical to hemostatic resuscitation following hemorrhage, are limited by availability, portability, storage requirements, contaminations risks, and a limited shelf-life. A synthetic nanoconstruct that mimics platelet-mediated mechanisms of hemostasis while resolving the above limitations can be of significant value in treating hemorrhage.

Aims: To test a novel, synthetic platelet-mimetic nanoparticle (SynthoPlate^{TM}) as a platelet substitute after uncontrolled hemorrhage.

Methods: SynthoPlate^{TM} is a biocompatible liposomal nanoparticle heteromultivalently surface-decorated with VWF-binding (VBPs), collagen-binding (CBPs) and fibrinogen-mimetic peptides (FMPs). Hemostatic capabilities were validated using ex vivo microfluidic assays and viscoelastic testing from trauma patients. SynthoPlate^{TM} vesicles (30mg/kg) were transfused in a validated murine model of uncontrolled hemorrhage (liver laceration). Mean arterial pressure and blood loss were quantified. 72-hr survival was analyzed using Kaplan-Meier method.

Results: Ex vivo clot formation was significantly enhanced with the addition of SynthoPlate^{TM} vesicles from human trauma patients. Following murine liver laceration, blood loss was significantly decreased in mice transfused with SynthoPlate^{TM} vesicles (1.6g control vs. 0.65g SynthoPlate^{TM}, $p < 0.05$). Mice transfused with SynthoPlate^{TM} vesicles took significantly longer to develop hypotension (166.7s control vs 433.3s SP, p=0.01). 72 hour survival was significantly improved in SynthoPlate^{TM}-treated mice (82% SP vs. 60% control, $p< 0.05$).

Conclusions: SynthoPlate^{TM}, a novel synthetic platelet-mimicking liposomal nanoparticle technology, demonstrates improved hemostasis, improved hemodynamics, and reduced mortality following uncontrolled hemorrhage in mice. This technology shows significant promise in hemostatic resuscitation of traumatic hemorrhagic shock.

PB 335 | Early Fibrinolytic Activation and Hypofibrinogenaemia Are Associated with Mortality in Isolated Traumatic Brain Injury

P. Vulliamy[1], S.E. Breukers[1], S. Gillespie[1], T. Walton[1], V. Carneiro Gimenez[1], C. Uff[2], K. Brohi[1], R.A. Davenport[1]

[1]*Queen Mary University of London, Centre for Trauma Sciences, London, United Kingdom,* [2]*Queen Mary University of London, Centre for Neuroscience and Trauma, London, United Kingdom*

Background: Traumatic brain injury (TBI) is among the leading causes of death and disability worldwide. Whilst the acute traumatic coagulopathy

associated with haemorrhage has been characterised in detail, the pathophysiology of TBI-induced coagulopathy remains poorly defined.

Aims: To characterise the derangements in coagulation and fibrinolysis in the hyperacute phase after TBI, and to identify patterns associated with adverse clinical outcomes.

Methods: Patients were prospectively recruited into the Activation of Coagulation and Inflammation in Trauma (ACIT) study. Blood samples were drawn in the emergency department for ROTEM, clotting factors and markers of fibrinolysis. Patients with isolated TBI were compared to minimally injured controls.

Results: Within two hours of injury, patients with isolated TBI (n=102) had markedly elevated prothrombin fragments (2,312pmol/L) which greatly exceeded the levels observed in controls (n=173; 449pmol/L, p< 0.01). Fibrinogen levels were lower in TBI patients compared to controls (2.1vs 2.6g/L, p< 0.01) and were proportional to clot amplitude on ROTEM (r^2=0.39, p< 0.01). In contrast, all other clotting factors were maintained at normal or supranormal levels, and ROTEM clotting times were similar to controls (55 vs 56 seconds, p=0.51). D-dimer levels in TBI patients were also greatly elevated (18,446 vs controls, 1,134ng/ml, p< 0.01) and were highest in non-survivors (68,250 vs survivors: 13,952ng/ml, p< 0.01). However, levels of tissue plasminogen activator (10.7ng/ml) and urokinase (3.5ng/ml) were similar to controls (tPA 9.0, p=0.39; uPA 3.3, p=0.73).

Conclusions: The principal functional impairment in coagulation early after TBI is hypofibrinogenaemia and reduced clot strength, without prolongation of clotting time. Concomitant fibrinolytic activation is associated with poor outcome and appears to be independent of the principal activators of plasminogen. Further investigation into the mechanisms of fibrinolysis and the role of fibrinogen supplementation in TBI is required.

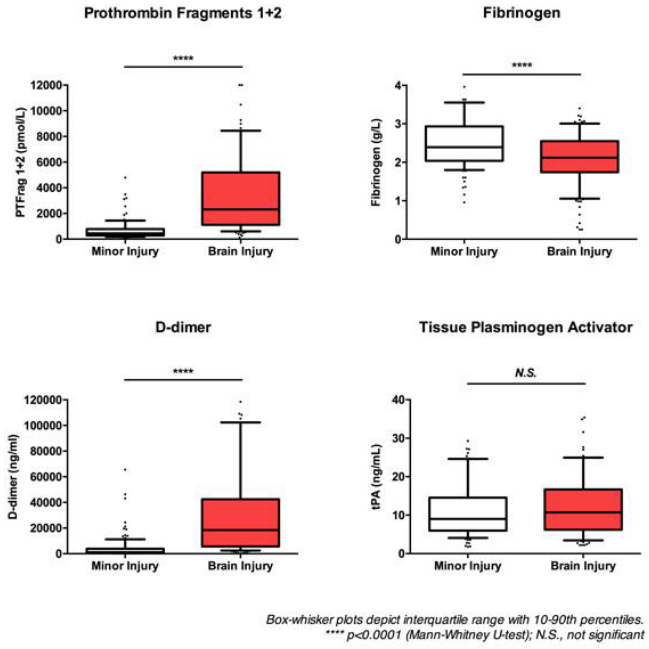

FIGURE 1 Traumatic brain injury results in increased thrombin generation, hypofibrinogenaemia and tPAindependent fibrinolysis

PB 336 | Platelets Loaded with Thrombin-encapsulated Liposomes Have Increased Coagulability

V. Chan, M. Sarkari, R. Sunderland, C. Kastrup

University of British Columbia, Vancouver, Canada

Background: Platelets are an integral part of primary hemostasis and platelet transfusions are often used to reduce bleeding during severe hemorrhage. However, transfusions of blood components are insufficient to stop the most severe cases of hemorrhage, particularly when complicated by platelet dysfunction.

Aims: Although simple nanoparticle-based systems have been developed to replace or augment platelet transfusions, they inherently lack important aspects of platelet function. In a step towards increasing the efficacy of platelet transfusions during acute severe bleeding, we asked whether the natural coagulability of transfusable platelets could be enhanced by loading them with liposomal thrombin.

Methods: Thrombin was encapsulated into nanoliposomes and delivered to platelets isolated from fresh whole blood. Platelet coagulability was determined by measuring platelet activation, clot contraction, and the time to generate endogenous thrombin from plasma (thrombin generation time).

Results: Encapsulating thrombin into nanoliposomes shielded the enzymatic activity of thrombin and caused minimal background platelet activation. Delivery of liposomal thrombin into platelets led to an increase in the sensitivity and responsiveness of platelets to agonists, enhanced clot contraction, and faster thrombin generation times in plasma. This increased procoagulant activity of the modified platelets persisted in the presence of antiplatelet drugs and in acidotic conditions, which normally inhibits platelet function.

Conclusions: Platelet coagulability can be enhanced by the delivery of liposomal thrombin, even in conditions where platelets are dysfunctional. This study is a first step towards engineering transfusable platelets that have increased efficacy for treating severe hemorrhage, and may have future applications in delivering other proteins to platelets and other cells or tissues.

PB 337 | S100B in Suspected Intracranial Hemorrhage in Patients after Minor Head Injury Older than 65 Years and on Antiplatelet Therapy

H.W. Thaler[1], J. Schmidsfeld[2]

[1]AUVA Trauma Hospital Meidling, Int. Med., Vienna, Austria, [2]Donauspital, Dep.of Traumatology, Vienna, Austria

Background: After minor head injury (MHI), in older patients and patients with platelet aggregation inhibitors (PAI) cranial computed tomography (CCT) and hospital admission are increasingly performed to rule out intracranial hemorrhage. This leads to high radiation exposure and financial burden.

Aims: Aim of this study was to determine whether the astroglial-derived protein S100B released into blood can be used as a reliable negative predictive tool for intracranial bleeding in patients after MHI older than 65 years or on PAI (low-dose aspirin, clopidogrel).

Methods: We conducted a prospective observational study in two trauma hospitals. 782 patients with MHI (Glasgow Coma Scale score 13-15) with PAI or aged over 65 years were included. Clinical examination, observation and CCT were performed in the emergency department or on the ward. Medium age was 83 years, 69% were female. Sensitivity, specificity, positive and negative predictive values of S100B with reference to CCT findings were calculated.

Results: Of the 782 patients, 50 (6.4%) had intracranial bleeding. One CCT positive patient showed an S100B level below 0.105 µg/L. Of all patients 33.1% were below the cut-off. S100B showed a sensitivity of 98.0% (CI 89.5%-99.7%), a negative predictive value of 99.6% (CI 97.9%-99.9%), a specificity of 35.3% (CI 31.9%-38.8%) and a positive predictive value of 9.4% (CI 7.2%-12.2%).

Conclusions: S100B levels below 0.105 µg/L can accurately predict normal CCT after MHI in older patients and those on PAI. Combining conventional decision rules with measurement of S100B can reduce the CCT and hospital admission rate by approximately 30%.

PB 338 | Antifibrinolytic Therapy to Prevent Oral Bleeding in People on Anticoagulants Undergoing Oral or Dental Procedures: A Cochrane Systematic Review

E.T. Engelen[1], R.E.G. Schutgens[1], E.P. Mauser-Bunschoten[1], R.J.J. Van Es[2], K.P.M. Van Galen[1]

[1]University Medical Center Utrecht, Van Creveldkliniek / Department of Haematology, Utrecht, The Netherlands, [2]University Medical Center Utrecht, Oral and Maxillofacial Surgery, Utrecht, The Netherlands

Background: Patients on continuous treatment with oral anticoagulants (OACs) such as vitamin K antagonists (VKAs) or direct oral anticoagulants (DOACs) are at increased risk of bleeding complications during and after oral and dental procedures. However, OAC discontinuation is associated with an increased thrombo-embolic risk. The use of antifibrinolytic agents could eliminate the need for dose reduction or discontinuation.

Aims: To assess the efficacy of antifibrinolytic agents to prevent bleeding complications in patients on continuous treatment with OACs undergoing oral or dental procedures.

Methods: We searched PubMed, Embase and the Cochrane Library for randomized and quasi-randomized controlled trials (RCTs and quasi-RCTs, date of last search 12 November 2016) and reference lists of relevant publications. Additional searches were performed, including ClinicalTrials.gov and abstract books of international meetings. For meta-analysis we extracted the proportion of patients with postoperative bleeding episodes requiring intervention. Estimates were pooled using the random effects model.

Results: No eligible trials in patients on continuous treatment with DOACs were identified. Three RCTs and two quasi-RCTs discussing the use of TXA in 385 patients on continuous VKA treatment were included. Two studies comparing locally administered tranexamic acid (TXA) with placebo showed a statistically significant beneficial effect of TXA on postoperative bleeding. Three studies comparing TXA with an alternative pro-hemostatic measure showed a small non-statistically significant beneficial effect of TXA [Table 1]. There were no side effects of TXA requiring treatment withdrawal.

Conclusions: The small number of identified RCTs and included participants and differences in treatment regimens do not allow to conclude definite efficacy of antifibrinolytic therapy in patients on continuous treatment with VKAs undergoing oral or dental surgery. No eligible trials in patients on continuous treatment with DOACs were identified.

TABLE 1 Results of the meta-analysis on the number of postoperative bleedings needing intervention

Postoperative bleedings	Studies	Participants	Risk difference (95%CI)	Number needed to treat (NNT)**
TXA versus placebo	2 (Ramström 1993; Sindet-Pedersen 1989)	128	-0.31 (-0.53 to -0.09)	3.2
TXA versus standard care*:	3 (Soares 2015; Bublitz 2000; Blinder 1999)	257	-0.07 (-0.22 to 0.09)	14
Total (TXA versus placebo and standard care)	5 (Ramström 1993; Sindet-Pedersen 1989; Soares 2015; Bublitz 2000; Blinder 1999)	385	-0.16 (-0.31 to -0.00)	6.3

Abbreviations: 95% CI: 95% confidence interval ; NNT: number needed to treat. *Standard care consisted of resorbable gelatin sponge and sutures, collagen fleece, mucosal flap, and dry gauze compression. **NNT to prevent 1 postoperative bleeding episode needing intervention

PB 339 | Management of Rivaroxaban or Apixaban Associated Major Bleeding with Prothrombin Concentrate: A Prospective Cohort Study

A. Majeed[1,2,3], A. Ågren[1,2], M. Bruzelius[1,2], R. Chaireti[1,2], J. Odeberg[1,2], M. Holmström[1,2], E.L. Hempel[1,2], M. Magnusson[1,4], T. Frisk[1,5], S. Schulman[2,6]

[1]Coagulation Unit, Hematology Centre, Karolinska University Hospital, Stockholm, Sweden, [2]Karolinska Institutet, Department of Medicine Solna, Stockholm, Sweden, [3]Department of Medical Epidemiology and Biostatistics, Stockholm, Sweden, [4]CLINTEC, Division of Pediatrics, Astrid Lindgren Children'sHospital and MMK, Clinical Chemistry and Blood Coagulation Research,Karolinska Institutet, Stockholm, Sweden, [5]Karolinska Institutet, Department of Women's and Children's Health, Stockholm, Sweden, [6]McMaster University and Thrombosis and Atherosclerosis Research Institute, Hamilton, Canada

Background: There is uncertainty regarding the efficacy of emergency bleeding management and risk of thromboembolic events in patients treated with prothrombin complex concentrates (PCC) for major bleeding events (MBE) related to rivaroxaban or apixaban.

Aims: We aimed to assess the effectiveness of PCC for the management of major bleeding events on rivaroxaban or apixaban.

Methods: Between 1/1/2014 and 1/10/2016, we prospectively included patients treated with PCC for emergency management of MBE on rivaroxaban or apixaban. The effectiveness of bleeding management with PCC was assessed using the International Society of Thrombosis and Hemostasis' Scientific and Standardization Subcommittee criteria for the assessment of effectiveness of major bleeding management, with the categories Good, Moderate and Poor. Safety outcomes were thromboembolic events and death during 30 days after treatment with PCC.

Results: A total of 86 patients received PCC for the urgent reversal of the anticoagulant effect of rivaroxaban or apixaban due a MBE. PCC was given at a median (IQR) dose of 2000 IU (1500-2000). There were 46 MBE on rivaroxaban and 40 MBE on apixaban. Intracranial hemorrhage (ICH) was commonest site of bleeding requiring reversal (60, 69.8%), followed by GI bleeding in 14 (16.3%). The bleeding was classified as traumatic in 27 (31.4%) of the patients. The effect of PCC was assessed as good or moderate in 60 (69.8%), and poor in 26 (30.2%). Most patients with poor effect of PCC had ICH (n=17, 65.4%). Two patients developed ischemic stroke occurring five and ten days after treatment with PCC. A total 26 patients died within 30 days after MBE.

Conclusions: The administration of PCC for the emergency reversal of MBE associated with rivaroxaban or apixaban was found to be effective and is associated with a low risk of thromboembolism. Further studies are needed to confirm these findings.

PB 340 | Favorable Thrombogenicity Profile of a Prothrombin Complex Concentrate (4F-PCC) in Animal Models of Venous and Arterial Thrombosis

F. Kaspereit, W. Krege, E. Raquet, F. Musch, M. Mischnik, E. Herzog

CSL Behring GmbH, Marburg, Germany

Background: Indications of 4-factor prothrombin complex concentrate (4F-PCC) include the prophylaxis and on-demand treatment of bleeding due to congenital or acquired deficiency of PCC factors such as the urgent reversal of anticoagulation with vitamin K antagonists. 4F-PCCs have also been shown to be of potential benefit in patients presenting with acute major bleeding related to the use of direct oral anticoagulants (DOAC). As with other procoagulant agents, PCC products carry the potential risk of exaggerated pharmacology resulting in arterial and venous thromboembolic complications.

Aims: This open-label, placebo-controlled in vivo study characterized the thrombogenic potential of a 4F-PCC, including a direct comparison to activated PCC (aPCC) and recombinant activated factor VIIa (rFVIIa), based on animal models of venous stasis and arterial thrombosis.

Methods: Anesthesized rabbits were treated with 4F-PCC (Beriplex® P/N, Kcentra®, CSL Behring) at doses of 0-500 IU/kg followed by induction of venous stasis over a period of 30 minutes at multiple time points post dosing (modified Wessler model). Anesthesized rats received 0-150 IU/kg 4F-PCC followed by $FeCl_2$ induced arterial injury. Venous thrombus formation (score and wet weight) and arterial occlusion (time and frequency) were used as primary thrombogenictiy parameters. A direct comparison was conducted to treatment with aPCC (FEIBA, Shire) and rFVIIa (NovoSeven RT, Novo Nordisk).

Results: A dose- and time- dependent increase in thrombogenic potential was observed after treatment with 4F-PCC. While there was no increase in thrombus formation seen up to the maximum clinically recommended dose level of 4F-PCC (i.e. 50 IU/kg) over placebo treatment, both aPCC (10-100 U/kg) and rFVIIa (50-300 µg/kg) elicited prothrombotic activity within their established therapeutic dose range.

Conclusions: Animal models of venous and arterial thrombosis support a favourable thrombogenicity profile of the 4F-PCC product tested.

PB 341 | fProthrombin Complex Concentrate for Major Bleeding on Factor Xa Inhibitors

S. Schulman[1], P. Gross[1], B. Ritchie[2], S. Nahirniak[3], Y. Lin[4], L. Lieberman[5], M. Carrier[6], M. Crowther[7], I. Ghosh[8], A. Lazo-Langner[9], M. Zondag[1]

[1]McMaster University, Department of Medicine, Hamilton, Canada, [2]University of Alberta, Department of Medicine, Edmonton, Canada, [3]University of Alberta, Department of Laboratory Medicine and Pathology, Edmonton, Canada, [4]University of Toronto, Sunnybrook Health Sciences Centre and Department of Laboratory Medicine and Pathobiology, Toronto, Canada, [5]University Health Network and University of Toronto, Department of Clinical Pathology, Toronto, Canada, [6]Ottawa Hospital Research Institute at University of Ottawa, Department of Medicine, Ottawa, Canada, [7]McMaster University, Department of Pathology and Molecular Medicine, Hamilton, Canada, [8]Trillium Hospital, Department of Emergency Medicine, Mississauga, Canada, [9]Western University, Department of Medicine, London, Canada

Background: Oral factor Xa inhibitors are increasingly used for anticoagulation but there is no approved reversal agent.

Aims: Prothrombin complex concentrate (PCC) for management of Xa-inhibitor-associated bleeding has been described in case reports and small case series. We evaluated PCC in a prospective cohort study.

Methods: Patients on apixaban or rivaroxaban and suffering a major bleed were treated as per existing hospital protocol with a fixed dose of PCC 2000 units. They were subsequently recruited for a 30-day follow-up. The treating physician evaluated the hemostatic effectiveness as Good, Moderate or Poor/None, using an Assessment Guide. Safety outcomes were death or thromboembolism.

Results: We recruited, as planned, 35 patients with major bleeding associated with rivaroxaban (54%) or apixaban (46%). The effectiveness was assessed as Good in 66%, Moderate in 17% and Poor/None in 17% with similar results when restricted only to patients with laboratory evidence of anticoagulant effect in plasma. For the 18 patients with intracranial hemorrhage the corresponding ratings were 72%, 11% and 17%, and for 11 patients with gastrointestinal bleeding they were 64%, 9% and 27%, respectively. There were 5 deaths (14%) by 30 days, all due to intracranial hemorrhage, one confirmed and one suspected but not confirmed ischemic stroke on day 25. Half of the patients with intracranial or intraspinal hemorrhage and effectiveness rated as Good had neurological deficit at the end of follow-up. In a post-hoc analysis of 18 evaluable cases with intracrania or intraspinall bleeding, using the adjudication rules of the ANNEXA-4 study (with andexanet alfa for reversal), 83% were rated as Excellent/Good outcome.

Conclusions: For major bleeding associated with oral Xa-inhibitors and management with PCC, treating physician assessed the effectiveness as good or moderate in 66% and 17% of cases, respectively. Thus, PCC is an option for management of critical bleeds on oral Xa-inhibitors.

PB 342 | Reversal of Dabigatran-associated Major Bleeding with Activated Prothrombin Concentrate: A Prospective Cohort Study

S. Schulman[1], B. Ritchie[2], S. Nahirniak[3], P. Gross[1], M. Carrier[4], A. Majeed[5], H.-G. Hwang[6], M. Zondag[1]

[1]McMaster University, Department of Medicine, Hamilton, Canada, [2]University of Alberta, Department of Medicine, Edmonton, Canada, [3]University of Alberta, Department of Laboratory Medicine and Pathology, Edmonton, Canada, [4]The Ottawa Hospital Research Institute at the University of Ottawa, Department of Medicine, Ottawa, Canada, [5]Karolinska Institutet, Department of Hematology, Stockholm, Sweden, [6]Soonchunhyang University Gumi's Hospital, Department of Medicine, North Kyungsang Province, Korea, Republic of

Background: The reversal of dabigatran-associated major bleeding can now be achieved with the antidote idarucizumab.

Aims: We evaluated activated prothrombin complex concentrate (aPCC) as an alternative for this purpose.

Methods: Patients treated with dabigatran and suffering a major bleed were treated as per existing hospital protocol with aPCC. They were subsequently recruited for a 30-day follow-up. Effectiveness was evaluated by the treating physician, using an Assessment Guide. Safety outcomes were arterial or venous thromboembolism or death. A comparison was also made with historic cases with dabigatran-associated major bleeds treated with supportive care, by matching 1:2 for type of bleed, age and sex.

Results: We aimed at 32 evaluable cases but the study was prematurely discontinued after 14 cases due to the availability of the approved antidote. The effectiveness of aPCC was assessed as Good in 9 (64%), moderate in 5 (36%) and poor in none. There were no thromboembolic events and one death. In the secondary adjudication of effectiveness, using the same criteria and by the same adjudicators as previously done for the historic cases, the outcome was graded for the current cases versus the historic cases as Good, Moderate, or Poor in 10 (71%) versus 16 (57%), 3 (21%) versus 4 (14%), and 1 (7%) versus 8 (29%), respectively.

Conclusions: Although supportive care is sufficient to manage many patients with dabigatran-associated bleeding, aPCC might provide an additional benefit to control life-threatening bleeding in selected cases and does not appear to cause an excess of thromboembolic events.

PB 343 | A randomized study of 4-factor prothrombin complex concentrate and tranexamic acid on bleeding, thrombin generation, and pharmacodynamics after punch biopsies in rivaroxaban treated subjects with supratherapeutic drug levels

J. Levy[1], K.T. Moore[2], M. Neal[4], D. Schneider[5], V. Marcsisin[6], J. Ariyawansa[6], J. Weitz[7]

[1]Duke University School of Medicine, Anesthesiology and Critical Care, Durham, United States, [2]Janssen Pharmaceuticals, Janssen Scientific Affairs, Titusville, United States, [3]University of Cincinatti, Cardiology, Cincinatti, United States, [4]University of Pittsburg, Surgery, Pittsburg, United States, [5]University of Vermont, Cardiology, Burlington, United States, [6]Janssen Pharmaceuticals, Scientific Affairs, Titusville, United States, [7]McMaster University/Hamilton General Hospital, Hematology, Hamilton, Canada

Background: Currently, there are no therapies approved for reversing oral factor Xa inhibitors. Although prothrombin complex concentrate (PCC) restores thrombin generation (TG) in healthy volunteers, and tranexamic acid (TXA) is often given in emergent bleeding, the effect of these therapies on bleeding reversal is still uncertain.

Aims: To assess the effects of intravenous (IV) 4 factor PCC (Kcentra/Beriplex) or TXA on prothrombin time (PT), endogenous thrombin potential (ETP), prothrombin fragment 1.2 (F1.2), and D-dimer as well as bleeding duration (BD) and bleeding volume (BV) after a 5 mm skin biopsy (Bx) in volunteers given rivaroxaban (RIVA).

Methods: After protocol approval by an independent ethics committee and obtaining informed consent, a total of 147 healthy volunteers were enrolled and baseline Bx performed. Volunteers were then given RIVA 20 mg twice-daily (off-label regimen) for 3

days to obtain a steady-state. After receiving their last 20 mg dose of RIVA on day 4, volunteers were then randomized to receive PCC (50 IU/kg), TXA (1.0 g), or saline (n=49/group) 4 hrs prior to performing a second Bx. Investigators were blinded to treatment allocation.

Results: Neither PCC nor TXA reduced BD or BV following the Bx. PCC partially reversed PT and completely reversed ETP with increases in F1.2. TXA had no effect on these parameters. Additionally, neither therapy affected D-dimer. All treatments were well tolerated, and there were no major bleeding events or thrombotic complications.

Conclusions: PCC partially reversed PT and completely reversed ETP in volunteers given a supratherapeutic dose of RIVA, whereas TXA did not. Neither intervention reduced skin Bx BD or BV. The clinical relevance of these findings are uncertain, however the pharmacodynamic changes observed with PCC administration are consistent with previous studies. Assessing PCC on bleeding associated with lower therapeutic doses of RIVA may be warranted.

PB 344 | Idarucizumab for Dabigatran Reversal in Daily Practice - First Experiences from Slovenia

N. Vene[1], A. Mavri[1], M. Bozic Mijovski[1], P. Gradisek[1], M. Gregoric[2], S. Frol[1], J. Pretnar[1]

[1]*University Medical Centre Ljubljana, Ljubljana, Slovenia,* [2]*University Medical Centre Maribor, Maribor, Slovenia*

Background: Idarucizumab is used for reversal of anticoagulant effects of dabigatran in the emergency setting.

Aims: To evaluate first experiences of idarucizumab in daily practice in Slovenia.

Methods: We analysed consecutive cases with idarucizumab use from January till October 2016. The indication for idarucizumab , assessment of clinical outcomes and the decision on blood sampling for coagulation tests (partial thromboplastin time, thrombin time and diluted thrombin time) before and after idarucizumab use were made by treating clinicians.

Results: Idarucizumab was used in 17 cases. One patient was treated with the antidote twice in the interval of two months. The median age of the patients was 83 (58-94) years, 10/16 patients were females. The median time from the last dose of dabigatran was 12 (1-72) hours. The indications for idarucizumab and clinical outcomes are presented in Table 1. In 7 cases dabigatran was reinitiated. Among cases with laboratory data available, baseline coagulation times were prolonged 12/13 cases with bleeding or emergency surgery. After idarucizumab administration normal coagulation parameters were confirmed in 10/11 cases within 16 hours, however later on re-occurrence of dabigatran effect was noted 4 patients with creatinine clearance < 30 ml/min and one patient with persistent bleeding required re-treatment with idarucizumab. In two patients with acute ischemic stroke and thrombolysis subsequently analysed baseline samples revealed dabigatran concentration < 30 ng/ml.

TABLE 1 Indications for idarucizumab and clinical outcomes

Indication for idarucizumab	No. of cases	Outcome	Death and cause of death
Emergency surgery			
- acute apendicitis	2	2 uneventful surgery	-
- stomac perforation	1		1 (septic shock)
- leg gangrene	1	1 uneventful surgery	-
Bleeding			
- intracranial	7	4 recovery and discharge 1 recovery and ischemic stroke on 6th day	2 patients (one new intracranial bleeding, the other multiorganic failure)
- gastrointestinal	2	1 recovery and discharge	1 patient (cardiac arrest)
- trauma or invasive procedure	2	1 recovery and discharge	1 patient (multiorganic failure)
Thrombolysis for ischemic stroke	2	2 recovery and discharge	-

Conclusions: Our first experiences with idarucizumab use in daily-care settings are supporting rapid and efficient decrease in anticoagulant effect of dabigatran in emergency situations. Late re-occurrence of dabigatran effect was noted in a subset of patients with severe renal failure. High mortality rate is not unexpected due to severity of the index events and associated comorbidities.

PB 345 | The Influence of Histones on the Generation of Factor XIa in Trauma Patient Blood

S. Prior[1], N. Dow[2], K. Freeman[2], C. Esmon[3], K. Mann[4], S. Butenas[1]

[1]*University of Vermont, Biochemistry, Burlington, United States,* [2]*University of Vermont, Surgery, Burlington, United States,* [3]*Oklahoma Medical Research Foundation, Oklahoma City, United States,* [4]*Haematologic Technologies, Inc., Essex Junction, United States*

Background: We previously reported that exogenous histone H4 can efficiently initiate thrombin generation (TG) in blood from healthy donors which is not affected by the addition of an inhibitory α-H4 mAb. In a current study, similar lack of an effect on TG by α-H4 was observed in trauma patient blood. It was also observed that FXIa is generated in citrated blood in the absence of corn trypsin inhibitor (CTI).

Aims: To evaluate/compare histone dependent FXIa generation in citrated blood from both trauma patients and healthy volunteers.

Methods: Three blood samples were collected in sodium citrate from 8 trauma patients and healthy donors matching in sex and similar in age. Anti-H4 mAb was added immediately to sample 1 and subsequently to sample 2 at 15 min post-draw. No additions were made to sample 3 and all samples were quenched with CTI at 15 min post-draw. FXIa concentrations in samples treated with α-H4 were quantitated based

on the response of whole blood TG and clot formation to an inhibitory α-FXIa mAb.

Results: Anti-H4 mAb added at 0 min inhibited FXI activation and consequentially delayed TG and clot formation in blood from both trauma patients and healthy donors. Based on thromboelastometry, FXIa levels in trauma patient blood treated with α-H4 at 15 min were approximately 12-fold higher (11.6 ± 6.2) than in that same blood treated with α-H4 at 0 min. In healthy donors, however, FXIa concentration increased by roughly only 3-fold (2.7 ± 1.4) in corresponding samples. Less pronounced differences in FXIa generation between healthy donors and trauma patients were observed in the TG assay, although the trend still held.

Conclusions: FXIa generation observed in citrated blood is endogenous histone-dependent and is partially inhibited by the α-H4 mAb. Furthermore, FXIa generation in trauma patient blood occurs at a more robust rate than in blood from healthy donors.

PB 346 | Markers of Platelet Activation Are Elevated Specifically on Leukocytes after Major Injury

S. Gillespie, P. Vulliamy, J. Shepherd, R. Davenport, K. Brohi

Queen Mary University of London, Centre for Trauma Sciences, London, United Kingdom

Background: Critical injury is associated with reduced platelet function, coagulopathy and immune dysfunction. The mechanisms for these remain unclear.

Aims: Our aim was investigate basal activation of whole platelets and platelet derived material bound to leukocytes in trauma patients *vs.* healthy controls, and to explore its impact on patient outcomes.

Methods: Adult trauma patients at a major trauma centre were recruited and underwent a baseline blood draw. Whole blood was incubated with a platelet marker (CD42b) and a panel of platelet activation markers; CD62P, CD63 and PAC1. Samples were fixed and processed using flow cytometry. Expression of platelet activation markers were quantified by CD42b positivity (CD42b+), either as a whole population or whether they were free or bound to leukocytes. Healthy volunteers served as controls.

Results: Expression of platelet activation markers on the total CD42b+ population was not significantly different from healthy controls. Leukocyte bound CD42b+ material had increased CD62P (MFI, 3894 patients *vs.* 1338 controls, $p = 0.08$) and CD63 expression (MFI 2149 patients *vs.* 448 controls, $p < 0.01$). Coagulopathic vs. non coagulopathic patients (MFI, 5342 vs. 3894) and patients that developed multiple organ failure (MOF) or died (MFI, no MOF 3109 *vs.* MOF 3743 *vs.* dead 4864) also trended towards greater platelet activation marker expression on leukocytes.

Conclusions: Total CD42b+ events in trauma patients did not significantly differ in their expression of activation markers from healthy controls; CD42b+ material bound to leukocytes exhibited markedly elevated expression of CD62P and CD63 in trauma patients. How this affects functional capacity of trauma patient platelets is unclear, but owing to the role platelets play in haemostasis and their potential to alter subsequent inflammatory responses, the reasons behind this phenomenon may warrant further examination.

PB 347 | Evaluation of Early Metrics of Clot Amplitude from New Generation Thromboelastogram (TEG6s) in Capturing Trauma Induced Coagulopathy

B. Mathew, C. Lopez-Espina, J. O'Mara

Haemonetics, Rosemont, United States

Background: Maximum amplitude (MA) of clot from viscoelastic hemostatic assays like Citrated Kaolin (CK), Rapid kaolin (CRT) in TEG is the result of platelet-fibrin interaction while from functional fibrinogen (CFF) assay it is primarily the contribution from fibrin. Increased MA (idicative of hypercoagulability) is associated with thromboembolic complications, while decreased MA is indicative of hypocoagulable state, and can be used in tailoring transfusion of platelets or fibrinogen concentrate in hemorrhagic patients.

Aims: This study assesses the reliability of early variables like A10 and A15 (amplitude after 10 and 15 mins respectively of defining R, where R is the time in minutes to clot initiation) in predicting MA. Our objective was to understand their correlation, and agreement in stratifying hypo and hypercoagulable states within CK, CRT, and CFF assays.

Methods: We retrospectively analyzed data from trauma patients admitted at three trauma centers (n=300). Using linear regression model

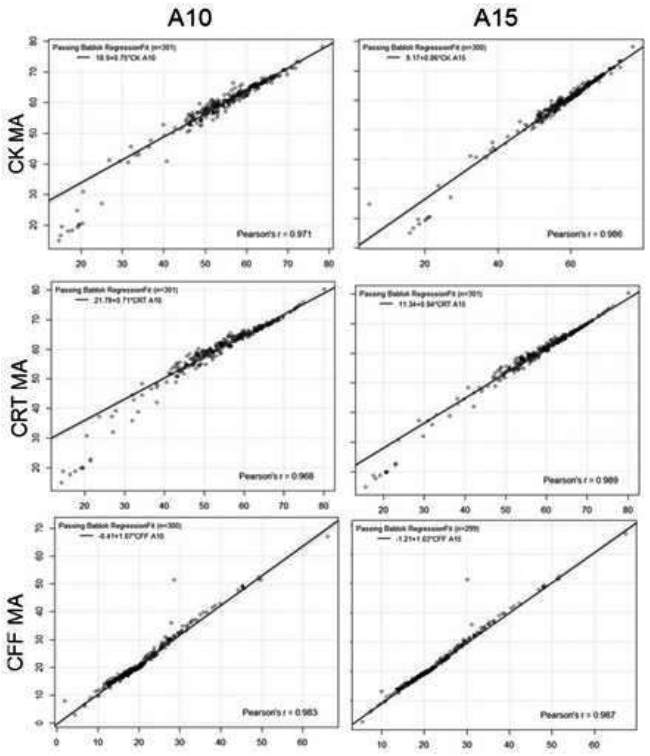

FIGURE 1 Plots showing strong correlation between MA and A10/A15 for CK, CRT, and CFF assays

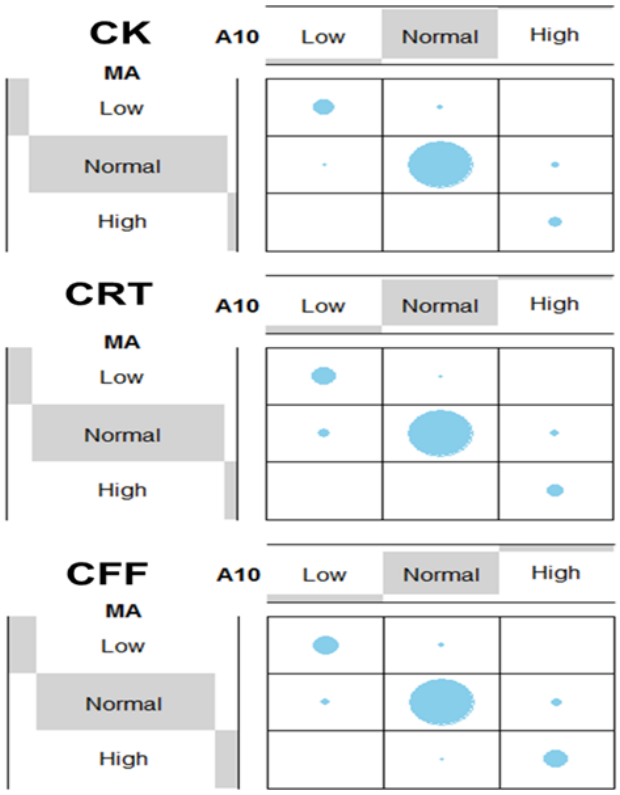

FIGURE 2 Contingency tables for A10 and MA represented using dots (size reflective of magnitude of agreement within categories)

we evaluated the correlation between MA, and the early variables. To understand the agreement between parameters A10/ A15, and MA, we categorized into Low (below range), Normal (within range), and High (above range) based on the reference ranges for each parameter within each assay and evaluated using Kappa. We compared time to reach A10 (mins) to the time to reach MA using paired Student's t.

Results: We observed excellent correlation between A10/A15 with MA (r>0.96) in each assay(Fig 1). The agreement between the early variables and MA in identifying the three levels of clot strength (Fig 2) are very strong (Kappa, A10: CK-0.92, CRT-0.85, CFF-0.89, A15: CK-0.96, CRT: 0.85, CFF-0.90). In each of the assay, the time to reach MA was significantly greater than the time to reach A10 (p< 0.001).

Conclusions: Early values of clot amplitude are fast, and reliable in predicting maximum clot strength. They may be used to get an advanced notice on coagulopathic condition like an increased risk of ischemic or bleeding events.

PB 348 | Implementation and Migration of Haemophilia-treatment-diaries from Paper Based to Electronic Documentation at Haemophilia CCC at the University of Bonn

J. Oldenburg[1], R. Langenkamp[2], G. Goldmann[1]

[1]*Institute of Experimental Haematology and Transfusion Medicine, University Clinic Bonn, Bonn, Germany,* [2]*Institute of Experimental Haematology and Transfusion Medicine, University Clinic Bonn, IT, Bonn, Germany*

Background: According to §14 of TFG (law of transfusion in Germany) all usage factor concentrates and blood-products have to be ducumented by the treating physican. In order to enable a home based tratment this obligation is usually passed to the patient. The duty of documentation mostly has been fulfilled as paper based diaries which were mostly sent by post to the treatment-center to file them for the statutory period of 30 years.The rapid progress in the electronical market now offers new abilities to fulfill the legal requirements. Two app-based protocol projects launched in the last years into the german market: a web-based application and Haemoassist 2, a native smartphone app & web-based procuct, which made it the solution of choice in Bonn.

Aims: The project should simplify the documentation obeing german legislation and proove if such a system may improve data quality and quantity provided to the physican.

Methods: The center in Bonn built a team of physicans, data entrists and IT who implemented a secure redundant server system as well as the logical registration process whithin three months. The basic preparation was followed by the implementation of an interface to the existing database containing patient-information to exchange treatment and medication information. The real test drive took about 4 months whith a selected group of patients to avoid unwanted behaviour of the App or any connected system.

Results: Since start of the daily routine in April 2016 the center was able to register about 30 patients weekly in average in Haemoassist 2. The on demand SAE-email alerts make it possible to react whithin a short period of time and reducees the risk of late complications.

Conclusions: It is already obvious that hospitalization, bleedings and fluctuation in patients amount of substituion help in decision making. Finally we can say that patients are open minded about the electronic documentation. Additionally the physicans have a mighty tool to monitor the patients tratment including automated SAE alerts.

PB 349 | Development and Validation of the Warfarin-Aspirin Bleeding Assessment Tool (WA-BAT)

C. Attard[1,2], P. Monagle[1,2], Y. d'Udekem[1,2], V. Ignjatovic[1,2]

[1]*Murdoch Childrens Research Institute, Haematology, Parkville, Australia,* [2]*University of Melbourne/The Royal Children's Hospital Melbourne, Paediatrics, Parkville, Australia*

Background: Bleeding assessment tools (BAT) are developed to screen and estimate bleeding risk in patients with bleeding disorders. A useful application of such tools would be as a standardised measure to compare rates of bleeding in patients on long-term thromboprophylaxis with either antiplatelet therapy or anticoagulation. To date, BAT have not been validated in this scenario.

Aims: To develop a self-administrable BAT to assess bleeding in patients undergoing long-term TP with aspirin or warfarin.

Methods: An online warfarin-aspirin-BAT (WA-BAT) was created based on the "Molecular & Clinical Markers for the Diagnosis & Management of Type 1 von Willebrand disease" BAT (Rodeghiero 2005). Items were refined and language adapted to be appropriate for

participants above 10 years. Items were removed (e.g. umbilical stump bleeding) and added as appropriate (e.g. bleeding post blood test).
The WA-BAT underwent validation by four experts (2 pediatric hematologists and 2 anticoagulant nurses).
Eligible participants were identified from our anticoagulation clinic database (Royal Children's Hospital, Melbourne) as patients aged above 10 years and receiving long-term aspirin or warfarin. For test-retest validation, the WA-BAT was administered twice to participants and Cohen's kappa analysis was used to determine intrarater reliability (IRR).
Results: Seven of the ten invited participants completed the WA-BAT. Of these, four completed the WA-BAT for a second time. Table 1 demonstrates the agreement between subsequent WA-BAT administrations. Substantial IRR agreement was determined.

TABLE 1 WA-BAT intrarater reliability coefficients

	Agreement (%)	Cohen´s Kappa	Days between adminstrations
Participant 1	82	0.65	91
Participant 2	100	1.00	41
Participant 3	82	0.60	135
Participant 4	94	0.85	43
Overall	90	0.77	78 (Mean)

Conclusions: The WA-BAT is the first self-administrable tool developed to assess bleeding in patients receiving aspirin or warfarin as TP. The WA-BAT showed substantial IRR, and assesses major and minor bleeding associated with long-term warfarin or aspirin use.
WA-BAT standardized questions make it suitable for longitudinal evaluation of patients. Further, this tool may be used to compare bleeding rates\types in populations on aspirin or warfarin.

PB 350 | Prothrombin Concentrate Complex for Major Bleeding in Patients Receiving Direct Oral Anti-coagulants: A Single Center Retrospective Study

M. Barzilai[1,2], D. Salzer Gotler[1,2], I. Avivi[1,2], I. Kirgner[1,2]

[1]*Ichilov Hospital, Tel Aviv Sourasky Medical Center, Hematology, Tel Aviv, Israel,* [2]*Tel Aviv University, Tel Aviv, Israel*

Background: The usage of direct oral anticoagulants (DOAC) has expanded over the last years. Major bleeding under anticoagulant treatment, including DOAC, is a life-threatening event, requiring rapid reversal of drug effect. However, in a real-world setting where direct antidotes are not yet available, administration of a prothrombin complex concentrate (PCC) is a reasonable therapeutic option.
Aims: To evaluate the efficacy of PCC administration for major bleeding in patients receiving DOAC.
Methods: A retrospective study evaluating all consecutive patients receiving PCC for major bleeding under DOAC, between 12.2014 and 12.2016. The primary outcome was 30 -day mortality. The secondary outcomes were need for blood transfusion, need for surgical intervention and thrombotic complications.
Results: 53 patients treated with PCC due to DOAC related a major bleeding were assessed. The median age at time of treatment was 81 years. 50% were male. 5 patients received dabigatran (9%), 29 received rivaroxaban (54%) and 19 received apixaban (36%). Intracranial hemorrhage (ICH) was the commonest event (29, 54%), followed by gastrointestinal bleeding (4,8%). 30-day mortality rate was 26%. Of the patients who died, 1 received dabigatran (1,7%), 10 received rivaroxaban (71%) and 3 received apixaban (4,22%). 30-day mortality in patients with ICH was 33%. Of the patients with ICH, 72% were treated with rivaroxaban and 28% with apixaban. There were no differences in primary or secondary outcomes between the groups. 2 patients (4%) only had thrombotic complications after PCC administration.
Conclusions: The rate of 30-day mortality in our cohort is slightly higher than the mortality rate demonstrated in previous studies after PCC administration for warfarin-associated bleeding. This may due to a high rate of ICH in our cohort. In current real life setting, PCC administration for ICH under DOAC therapy still seems a reasonable option.

PB 351 | Chemical Composition of Malian Medicinal Plants Used to Treat Bleeding Events

Y.L. Diallo[1,2], A. Togola[3,4], I. Sanogo[3], D. Traore[2], A.H. Babana[2], R. Sanogo[3,4], D. Diallo[3,4]

[1]*Hopital du Mali, Service de Medecine, Bamako, Mali,* [2]*Universite des Sciences, des Techniques et des Technologies, Laboratoire de Biologie et Biotechnologie Microbienne, Bamako, Mali,* [3]*Universite des Sciences, des Techniques et des Technologies, Faculté de Pharmacie, Bamako, Mali,* [4]*Institut National de Recherche en Santé Publique, Departement de Medecine Traditionnelle, Bamako, Mali*

Background: In first access to treatment for all diseases, 80 - 90 % of Malian population frequently uses medicinal plants. However bleeding diseases treatment remained a big challenge. Here, we investigate the chemical properties of 10 medicinal plants traditionally used to treat bleeding events.
Aims: Identify chemical components having hemostatic activity in the Malian flora.
Methods: Extracts from stems barks of *Annona senegalensis*, *Baissea multiflora Entada african,Carica papaya,Pteleopsis myrtifolia*, leaves of *Cassia sieberiana*, *Guiera senegalensis*, *Detarium microcarpum*, roots of *Carica papaya*, roots barks of *Erythrina senegalensis* and seeds of *Gossypium barbadense* were used. The chemical composition of dried and powdered plant material has been characterized using chemical groups' specific detection reagents and TLC. Water, dichloromethane and methanol extracts have been prepared using a 10% weight/volume proportion of powdered mater in 24 h maceration in solvents. These extracts have been tested for their hemostatic property in human blood.
Results: All plants parts were very rich in catechic tannins, sterols and terpens derivatives, flavonoids (mostly anthocyans type) and in sugars (oses and holosides). *Pteleopsis myrtifolia* contained both catechic and gallic tanins. *Pteleopsis myrtifolia* (leaves and stem bark), *Entada africana* and *Erythrina senegalensis* have shown a high content of coumarins. Water extracts from *Pteleopsis myrtifolia* (leaves and stem

bark), *Baissea multiflora* (stem bark) and *Entada africana* (stem bark) have shown potent haemostatic activity.

Conclusions: Medicinal plants traditionally used to treat bleeding event in Mali contain substances known for their pro-coagulant activity; other compounds having anticoagulant activity have also been found in smaller amount. These results when confirmed could open a new research area in the field of hemostasis in Mali.

PB 352 | First Italian Experience of Clinical Use of Obizur, Recombinant Porcine Sequence Factor VIII (RPFVIII), for Acquired Haemophilia A (AHA)

C. Lodigiani, P. Ferrazzi, L. Libre', V. Pacetti, A. Colombo, M.C. Beltrametti, I. Quaglia

Humanitas Research Institute, Thrombosis and Haemorragic Diseases Center, Rozzano, Italy

Background: A recombinant porcine factor VIII B-domain-deleted product (rpFVIII; OBIZUR, Shire plc) was recently approved for treatment of AHA in some countries, but not yet used in Italy.

Our aim is to describe the first Italian experience using rpFVIII for AHA patient.

Aims: Our aim is to describe the first Italian experience using rpFVIII for AHA patient.

Methods: A 68-year-old man with lung cancer and a recent coronary angioplasty (PTCA) accessed our emergency department with left chest intramuscular haemorrhage, right periorbital haematoma onto the chin: bleeding diagnosed as associated to dual antiplatelets therapy (DAPT) and patient was discharged. Six days later he was re-admitted for clinical worsening and AHA was diagnosed with FVIII 2%, FVIII inhibitor 55UB/mL. DAPT was stopped, blood components transfused and a prohaemostatic therapy with aPCC (80U/kg bid) and tranexamic acid (10U/kg bid) from day 1-4 was administered, with no clinical benefit. We switched to rpFVIII.

Results: rpFVIII initial dosage was 100U/kg and FVIII activity (one-stage clotting assay) 30' after infusion increased from 2 to 162%. We sustained FVIII trough level at 55±5% and at 116±16% (mean values +/- SD in %) after infusion. In 36-48 hours bleeding stopped and rpFVIII was definitely discontinued after 6 days. Anti-pFVIII antibodies were stable at 1 UB/mL. Patient was discharged on day 11. Concomitant immunosuppressive therapy with full dose of prednisone was administered.

Conclusions: RpFVIII resulted as efficient therapy with no thrombotic adverse event in AHA patient at high thrombotic risk for recent PTCA.

PB 353 | The Effect of PCC on ROTEM Parameters in Patients with Coagulopathy of Liver Disease

C. Hamid[1], J. McVey[2], A. Riddell[3], T. Fox[4], E. Brodkin[5], A. Gatt[6], R. Morris[7], P. Chowdary[8]

[1]University College London, Katharine Dormandy Haemophilia and Thrombosis Unit, London, United Kingdom, [2]University of Surrey, Guildford, United Kingdom, [3]Haemophilia Lab (HSL), Katharine Dormandy Haemophilia and Thrombosis Unit, London, United Kingdom, [4]University College London, London, United Kingdom, [5]Royal Free London NHS Foundation Trust, London, United Kingdom, [6]Mater Dei Hospital, Haematology Oncology, Msida, Malta, [7]University of Bristol, Bristol, United Kingdom, [8]Royal Free London NHS Foundation Trust, Katharine Dormandy Haemophilia and Thrombosis Unit, London, United Kingdom

Background: As an alternative to platelet transfusion for the prevention and treatment of bleeding due to thrombocytopenia, we speculated that increasing the concentration of procoagulant factors by the addition of prothrombin complex concentrate (PCC) in thrombocytopenia associated with liver disease may improve thromboelastometry (ROTEM) parameters and contribute to normalising haemostasis.

Aims: To evaluate the effect of PCCs on the parameters of ROTEM analysis in patients with coagulopathy of liver disease and thrombocytopenia.

Methods: NATEM ROTEM (TEM Innovations GmbH, Munich Germany) analysis was performed on whole blood samples from patients with liver disease and thrombocytopenia (Child Pugh Score B and C, INR >1.5, platelet count range 26-79 x 10^9/L, n=11). 10mL blood was collected into sodium citrate and corn trypsin inhibitor. A 0.12pM tissue factor/0.2M $CaCl_2$ trigger was used at baseline and after spiking with a four factor PCC at doses corresponding to 0.15, 0.30 and 0.60 IU prothrombin/mL final concentration. 0.60 IU/mL is equivalent to a therapeutic PCC dose of 25 IU/kg.

Results: Spiking with PCC significantly shortened the clot time (CT) and time to maximum velocity of clot formation (MaxV-t), with one way ANOVAs across all concentrations giving $p< 0.0001$ and 0.05 respectively. Addition of 0.15IU/mL shortened CT (M=464 to 287) and MaxV-t (M=556 to 361) compared to baseline (paired t-test $p< 0.05$ in both instances), and alpha angle was significantly increased compared to baseline (paired t-test $p< 0.001$). MCF (maximum clot firmness) showed a non-statistically significant increase (M=33 to 40, p=0.08).

Conclusions: Platelet dependent ROTEM parameters CT and MaxV-t show a significant shortening and alpha angle a significant increase in response to sub-therapeutic concentrations of PCC in samples from patients with liver disease and varying degrees of thrombocytopenia. This could infer a potential for therapeutic application for PCC in liver disease.

PB 354 | Factor VIII and von Willebrand levels at Desmopressin (DDAVP) Challenge Test: A Single Center Results

C. Casas, M.H. Solano, M.L. Parra, D. Espinosa, V. Abello, A. Palacios

Hospital San José - Fundación Universitaria de Ciencias de la Salud, Hematology, Bogotá, Colombia

Background: DDAVP is useful in the treatment of vW factor type 1 qualitative defects and, mild A haemophilia, is used to determine an increase in Factor VIII and vW, to diagnose coagulation disorders and to plan therapeutic decisions.

Aims: Describe the behavior in factor levels with the administration of desmopressin.

Methods: A retrospective cohort study in patients older than 18 years who underwent DC, known to have factor VIII, vW or ristocetin cofactor (RC) deficiency, to describe factor VIII and vWF behavior during the challenge. The test starts with a baseline sample collection to determine factor VIII, vWF and RC, followed by a subcutaneous DDAVP, and samples at hours 1, 4, 6 hours after the injection.

Results: 25 Patients with von Willebrand or factor VIII deficiency diagnosis were included. 6 men and 19 women. Median age 37 years (Range 18-65). 18 baseline samples had low FVIII levels, median activity of 37%. Median factor level were 89 (2.1 times the basal levels), 75,1 and 88,9% at 1, 4 and 6 hours respectively. 14 baseline samples had abnormal vWF values, median activity 22,5%. Median factor levels were 80 (3,5 increase from baseline levels), 84 and 63.4% at 1, 4 and 6 hours respectively. 3 baseline samples had RC abnormal levels, median 13,3%. Median factor levels were 83 (6.38 increase from baseline levels), 59 and 46% at 1, 4 and 6 hours respectively. No serious adverse event was detected during the 6-hour clinical surveillance or in the 24-hour telephone follow-up.

Conclusions: The response criteria for DC has not been clearly defined, until now 2 to 3 times increase in baseline values has been considered acceptable, however a detailed evaluation of the clinical situation of each patient should be done, as there may be an acceptable increase in levels in terms of the response criteria without achieving a safe hemostatic ranges. In this cohort of patients, the vast majority demonstrated adequate responses achieving hemostatic level for measured factors; with minimal side effects.

PB 355 | Correlation between Platelet Count and Platelet Component in Thromboelastometry

M. Milic[1,2], J. Jonjic[1], V. Seric[1,2]

[1]Osijek University Hospital, Department of Clinical Laboratory Diagnostics, Osijek, Croatia, [2]Faculty of Medicine, University of Osijek, Osijek, Croatia

Background: The difference between two ROTEM tests (EXTEM and FIBTEM) represents platelet contribution to blood clot strength i.e. platelet component. Estimation of platelet component (PC) should be done based on Clot Elasticity (CE) according to Solomon et al. It is not a routinely calculated parameter in thromboelastometry but it could be clinically useful in management of major hemorrhage. We hypothesized that platelet number correlates better with PC Maximum Clot Elasticity (MCE) then with Maximum Clot Firmness (MCF).

Aims: To establish if the platelet count correlates better with MCE PC or with MCF PC.

Methods: Routinely performed thromboelastometry results (N=45) were collected and analyzed retrospectively from laboratory database. Maximum Clot Elasticity was calculated as follows MCE= (100*MCF)/(100-MCF). PC MCE and PC MCF were calculated as follows: EXTEM MCE-FIBTEM MCE, EXTEM MCF-FIBTEM MCF. Thromboelstometric measurements EXTEM and FIBTEM were performed on ROTEM delta (TEM International GmbH, Munich, Germany). Platelet count (n=45) averaged 104±76x10^9/L was measured using Sysmex XN1000 (Sysmex Corporation, Kobe, Japan). Statistical analysis was performed using MedCalc Statistical Software demo version 14.12.0. Pearson correlation coefficients were calculated and p value < 0.05 was considered significant.

Results: Platelet count positively correlated with MCF PC (r=0.495, p=0.0005) and MCE PC (r=0.718, p< 0.0001).

Conclusions: Much higher correlation coefficient was obtained between platelet count and MCE PC then with MCF PC, as we hypothesized. However, obtained correlation coefficient is not very high since blood clot formation does not depend only on the platelet number but also on the platelet functionality. MCE Platelet Component could be a better predictor of bleeding or a better parameter in platelet transfusion management. It should be clinically validated for management of major hemorrhage.

PB 356 | Favorable Effect of Combined Use of Prothrombin Complex Concentrate and Plasma in in vitro-Induced Coagulopathy

H.J.M. Brinkman[1], M. Zuurveld[1], R. Lassila[2], J.C.M. Meijers[1]

[1]Sanquin, Plasma Proteins, Amsterdam, The Netherlands, [2]Helsinki University Central Hospital, Coagulation Disorders Unit, Clinical Chemistry, HUSLAB Laboratory Services, Helsinki, Finland

Background: Uncontrollable bleeding is a major cause of death in emergency rooms. Transfusion to secure intravascular volume with crystalloid liquids may induce dilutional coagulopathy that requires additional treatment with clotting factor concentrates, such as fibrinogen (Fbg) and prothrombin complex concentrate (PCC). For plasma resuscitation, single donor fresh frozen (FFP) or solvent/detergent (S/D)-treated plasma can be used. The use of oral anticoagulants worsens trauma- or surgery-induced coagulopathy.

Aims: To investigate the effect of resuscitation fluids, clotting factor concentrates and combinations thereof on the hemostatic profile of rivaroxaban-anticoagulated whole blood.

Methods: We used rivaroxaban spiked whole blood and tissue factor triggered thromboelastography in the presence of tissue-type plasminogen activator to induce fibrinolysis. We mimicked a resuscitation approach that resulted in a drop in hematocrit from on average 39 to 24% and a 50% reduction in rivaroxaban concentration.

Results: Spiking whole blood with 50-300 µg/ml rivaroxaban resulted in a hypocoagulabe state that remained upon subsequent dilution with plasma or saline. Combined use of FFP and PCC, however, did not only strongly improve clot formation but also clot stability. S/D-treated plasma was less efficient than FFP that is most likely due to a low alpha-2-antiplasmin level, and required tranexamic acid (TXA) in addition to PCC to compensate for induced hyperfibrinolysis. Saline also induced a profibrinolytic state as a component of dilutional coagulopathy, as such worsening the hemostatic potential of rivaroxaban-anticoagulated blood. Subsequent joint PCC and Fbg supplementation

required additional factor V and TXA for correcting clot formation and stability.

Conclusions: In the setting of rivaroxaban anticoagulation, a combination of plasma and PCC may provide the most effective resuscitation approach with the notion that S/D-treated plasma requires antifibrinolytic drug support.

PB 357 | Towards a Clinically Relevant Hybrid Adenovirus-Sleeping Beauty Transposon Vector for Gene Therapy for von Willebrand Disease

I. Portier[1], M. Solanki[2], H. Deckmyn[1], K. Vanhoorelbeke[1], A. Ehrhardt[2], S.F. De Meyer[1]

[1]*KU Leuven Campus Kulak Kortrijk, Laboratory for Thrombosis Research, Kortrijk, Belgium,* [2]*Witten/Herdecke University, Institute for Virology and Microbiology, Witten, Germany*

Background: Gene therapy offers potential for a long-term treatment of severe von Willebrand disease (VWD). Using non-viral *Sleeping Beauty* transposons (SBT), we previously achieved sustained expression of von Willebrand factor (VWF) in VWF-deficient (*Vwf*$^{-/-}$) mice. To circumvent clinical limitations associated with hydrodynamic delivery, high-capacity adenoviral vectors (HC-AdV) were combined with the SBT technology.

Aims: To develop a clinically applicable gene therapy platform for VWD based on HC-AdV that deliver the SBT system to hepatocytes.

Methods: Two HC-AdV were constructed, comprising the two-component SBT system. A first HC-AdV contained the VWF transgene under control of a liver-specific promoter, flanked by FRT sites and SBT inverted repeats. A second HC-AdV carried the Flp recombinase and SB100X transposase. After intravenous co-injection of the vectors in *Vwf*$^{-/-}$ mice, VWF antigen levels and VWF multimer pattern were regularly determined in plasma for up to 1 year. Correction of the bleeding phenotype was evaluated using tail-clip and saphenous vein bleeding models.

Results: Functionality of this hybrid adenovirus-SBT vector was assessed in *Vwf*$^{-/-}$ mice and resulted in very high and stable VWF levels, still 2072±383% of wild type levels 1 year after gene transfer. Moreover, FVIII activity was restored to physiological levels (102±33%, 1 year after gene transfer). Both tail-clip bleeding at 12 weeks and saphenous vein bleeding at 1 year resulted in small, but not significant reductions of bleeding time. The reduced fraction of high molecular weight multimers observed in hepatocyte-produced VWF might account for the partial corrected bleeding phenotype.

Conclusions: The hybrid adenovirus-SBT vectors efficiently delivered VWF transposons into hepatocytes, resulting in very high and sustained VWF transgene expression. Despite no full correction of the bleeding diathesis, this powerful vector system shows great promise towards a clinically applicable gene therapy for VWD e.g. for targeting endothelial cells.

PB 358 | Comprehensive Functional and Structural Studies to Characterize von Willebrand Factor Propeptide Novel Missense Variants with Unknown Pathological Significance

H. Yadegari[1], A. Biswas[1], S. Ahmed[2], A. Naz[2], J. Oldenburg[1]

[1]*Institute of Experimental Haematology and Transfusion Medicine, Bonn, Germany,* [2]*National Institute of Blood Disease & Bone Marrow Transplantation, Karachi, Pakistan*

Background: Six novel missense variants were identified in von Willebrand factor (VWF) propeptide either as homozygous (p.V86Q and p.C608W) in patients with type 3 von Willebrand disease (VWD) or as compound heterozygous in VWD patients with ambiguous phenotype (p.G55E, p.W191R, p.N211D and p.G344Q).

Aims: This study aimed to determine the pathological consequence of these novel variants on the structure, biosynthesis and function of VWF.

Methods: The wilde-type (wt) or mutant VWF cDNA was expressed in HEK293 cells. The levels both VWF and propeptide secreted into medium were determined and qualitative assessments including VWF binding functions and multimer analysis were performed. The subcellular localization and storage of VWF was evaluated by immunofluorescence confocal microscopy and transmission electron microscopy imaging. Protein models of the discrete propeptide (D1-D2) and D´-D3 domains were generated. The joined models were docked multimerically to generate putative tubular structures. The variants were then mapped on these models and MD simulation was performed.

Results: Transfection of the four out of six mutants (p.G55E, p.V86Q, p.W191R and p.C608W) demonstrated severely impaired VWF secretion and defect in intracellular storage. Their co-transfections with the VWF-wt resulted in correction of the expression phenotype but still showed reduction of secreted VWF, loss of big multimers and diminished binding functions of the VWF. The generated models illustrated that these mutated residues either directly disturb the core fold of the individual domains (for e.g. p.C608W), or indirectly influence the surface properties of the domains by disturbing the designated allosteric disulfide bonds (for e.g. G55E).

Conclusions: Using a combination of in vitro gene expression, modeling and MD simulation studies we have been able to expand insights into the significance of VWF propeptide missense mutations in VWF intracellular processing and pathophysiology of VWD.

PB 359 | Triggering Receptor Expressed on Myeloid Cells Like Transcript-1 (TLT-1) is a Novel Ligand for von Willebrand Factor

A. Doerr[1], C. Gardiner[2], M. Laffan[1], T. McKinnon[1]

[1]*Imperial College London - Hammersmith Hospital Campus, London, United Kingdom,* [2]*University College London, London, United Kingdom*

Background: Von Willebrand Factor (VWF) binds to platelets via interaction of its A1 domain with platelet Glycoprotein Ib and then

subsequent interaction between the RGD sequence in the VWF C4 domain and platelet glycoprotein IIbIIIa. However it has recently been shown that Vimentin present on platelets also binds to VWF and therefore other platelet receptors may act as ligands for VWF. To this end we performed a binding screen of known platelet membrane proteins and identified TLT-1 as novel VWF binding partner. TLT-1 is exclusively expressed in platelets where it is stored in alpha-granules and is presented on the platelet surface following platelet activation. A soluble form of TLT-1 is also released into the circulation.

Aims: To characterise the interaction of VWF with TLT-1 and define its functional significance.

Methods: Soluble TLT-1 (sTLT-1) and recombinant VWF fragments were expressed in HEK293T cells and purified by Nickel affinity chromatograph. Binding assays were performed using plates coated with sTLT-1 and incubation with VWF and its fragments. Flow assays were carried out perfusing whole or plasma free blood over VWF or collagen surfaces in the absence or presence of an anti-TLT-1 antibody.

Results: Using plate binding and immunoprecipitation assays we showed that VWF binds to sTLT-1 with high affinity (5.7 nM) and the binding is dependent on calcium ions and involves the VWF A3 and D4 domains. Furthermore beads coated with the extracellular portion of TLT-1 were able to interact with VWF under shear stress. Using an antibody directed against TLT-1 we were able to block the interaction with VWF and in flow assays observed a marginal reduction in platelet capture under shear stress, but a significant reduction in thrombus size and volume, suggesting that targeting TLT-1 may be a novel, safe anti-thrombotic strategy.

Conclusions: TLT-1 is a novel ligand for VWF and targeting TLT-1 maybe a potentially safe route to preventing excessive thrombus formation.

PB 360 | A2 Domain Unfloding Might Significantly Increase Shear and Elongation-meadiated vWF Unfolding in the Bloodstream

D. Nechipurenko[1], I. Krauz[1], K. Vladislav[2], I. Gudich[3], V. Alferov[4], C. Cardona[4], V. Isidorova[4], T. Kurakina[4], E. Morales[4], D. Yarotskiy[4]

[1]*Lomonosov Moscow State University, Physics Faculty, Moscow, Russian Federation,* [2]*Lomonosov Moscow State University, Faculty of Computational Mathematics and Cybernatics, Moscow, Russian Federation,* [3]*Keldysh Institute of Applied Mathematics, Moscow, Russian Federation,* [4]*School of Molecular and Theoretical Biology, Biophysics, Barcelona, Spain*

Background: Multimeric vWF molecules circulating in blood plasma are unique mechanosensitive glycoproteins experiencing significant conformational changes in response to high shear and elongation rates within the blood flow. VWF A2 domain unfolding is known to be crucial for ADAMTS13-dependet regulation of vWF multimers size distribution, however, the role of A2 domain flexibility in overall conformational dynamics of vWF multimers is not clear.

Aims: The basic goal of this work was to study the impact of A2 domain unfolding on conformational dynamics of vWF molecule using the coarse-grained computational model of vWF.

Methods: In order to account for A2 domain unfolding the classical coarse-grained model of vWF was modified to have variable inter-dimer distance. The kinetic characteristics of A2 domain unfolding in response to external force were taken from single-molecule measurements reported earlier. Conformational dynamics of vWF was analyzed for a wide range of hydrodynamics conditions, including stationary shear and elongation rates, their combinations and non-stationary conditions corresponding to local flow disturbances by vessel stenosis or platelet thrombus.

Results: The results of our simulations show that A2 unfolding might influence the conformational dynamics of larger vWF multimers, increasing their unfolding probability under both shear and elongational flows. For shear rates exceeding 3000 s-1 unfolding probabilities obtained with the modified model are significantly higher comparing to the old model, which does not take into account of A2 domain unfolding. Simulations of vWF dynamics under non-stationary conditions show significant dependencies of vWF unfolding probability on the obstacle passage time, predicting high unfolding rates for longer stenosis regions (bigger thrombus).

Conclusions: Our results show that vWF A2 domain unfolding can influence the conformational dynamics of vWF multimers under a wide range of hydrodynamic conditions, especially those expected in stenosed arteries.

PB 361 | Acquired von Willebrand Disease (aVWD) in Plasma Cell Dyscrasias (PCD): Variable Underlying Pathophysiology as Evidenced by the Analysis of Proteolytic von Willebrand Factor (VWF) Cleavage Fragments

J. Irle[1], F. Langer[2], C.C. Dicke[2], J. Fuchs[1], C. von Auer[3], S. Schneppenheim[4], H. Rossmann[5], Z. Ruggeri[6], B. Lämmle[1,7], K. Jurk[1]

[1]*University Medical Center of the Johannes Gutenberg University Mainz, Center for Thrombosis and Hemostasis (CTH), Mainz, Germany,* [2]*II. Medizinische Klinik und Poliklinik, Onkologisches Zentrum, Hubertus Wald Tumorzentrum - Universitäres Cancer Center Hamburg, Universitätsklinikum Eppendorf, Hamburg, Germany,* [3]*University Medical Center of the Johannes Gutenberg University, Department of Hematology, Oncology and Pneumology, Mainz, Germany,* [4]*Gerinnungslabor, MEDILYS Laborgesellschaft mbH, Asklepios Klinik Altona, Hamburg, Germany,* [5]*Institute of Clinical Chemistry and Laboratory Medicine, University Medical Center Mainz, Mainz, Germany,* [6]*The Scripps Research Institute, Department of Immunology and Microbial Sciences, La Jolla, United States,* [7]*University Clinic of Hematology & Central Hematology Laboratory, University Hospital and the University of Bern, Inselspital, Bern, Switzerland*

Background: PCD may be associated with hemorrhagic diathesis and aVWD, found in some PCD patients, is one of several possibly predisposing factors. The mechanism leading to aVWD may be variable and is partly speculative.

Aims: We investigated proteolytic VWF fragments from 3 published patients with PCD-associated aVWD (Dicke et al. Ann Hematol 2016; cases 1,5,6) to test whether enhanced proteolytic degradation may be a causal mechanism.

Methods: VWF from citrated plasma was immunoadsorbed in the presence of a universal protease inhibitor to rabbit anti-VWF IgG coupled

to CNBr-activated Sepharose 2B beads. Reduced and alkylated beads were applied to SDS-PAGE and immunoblotting using polyclonal anti-VWF IgG, monoclonal antibodies against N- or C-terminal VWF subunit domain (M7 and M31, respectively, Berkowitz et al. JCI 1987) or against a neoepitope on the N-terminal fragment generated by ADAMTS13 cleavage of the Y1605-M1606 bond (Kato et al. Transfusion 2006).

Results: 1 patient with decreased VWF activity (< 10%) and -antigen (12%) and another with elevated VWF levels but a paraprotein inhibiting VWF-glycoprotein Ib interaction showed, besides the intact 250 kD subunit small amounts of ADAMTS13 induced N-terminal 140 kD and C-terminal 176 kD fragments as seen in normal plasma. One patient with AL amyloidosis, VWF activity (20%) and antigen (126%) and loss of large VWF multimers showed an increased proportion of cleavage fragments. In addition to the physiologic ADAMTS13 induced fragments there was an N-terminal 176 kD and C-terminal 145 kD band, detected by M7 and M31, respectively, compatible with a plasmin induced VWF cleavage, strongly supported by elevated plasmin-antiplasmin complexes in this patient.

Conclusions: Analysis of in vivo VWF fragments revealed an aberrant cleavage pattern, presumably caused by plasmin, as cause for a PCD (AL amyloidosis)-associated aVWD. Whether fibrinolysis inhibition may correct the acquired VWD remains to be studied.

PB 362 | Axial Structure and Collagen Binding of the von Willebrand Factor Multimer

M.C. Csanyi, T. Feller, T. Bozo, M.S.Z. Kellermayer, J. Harsfalvi

Semmelweis University, Department of Biophysics and Radiation Biology, Budapest, Hungary

Background: The von Willebrand factor (VWF) is a multimeric plasma glycoprotein with size ranging between 0.5 and >20MDa. VWF binding to collagen (VWF:CB) decreases with the pathological loss of HMW multimers. Whether the accumulation of high molecular weight (HMW) multimers leads to increasing VWF:CB and changes in the VWF axial structure (e.g, length), is currently unknown.

Aims: Here we investigated the correlation between VWF:CB ratio and VWF length measured with atomic force microscopy (AFM), and the correlation between AFM-based VWF length and the SDS-agarose ELFO-based MW. Furthermore, we explored whether VWF length is affected by sample storage.

Methods: VWF from plasma-derived therapeutic specimens or platelet cryoprecipitate was fractionated according to MW and heparin affinity (Sepharose CL2B, HiTrap Heparin HP). VWF concentration (VWF:Ag) and collagen-binding capacity (VWF:CB) were measured with ELISA. HMW multimer proportion (measured with SDS-agarose ELFO followed by immunoblot and densitometry) was expressed with M_{MW25} that corresponds to the MW that demarcates the upper 25% of the densitogram integral. VWF length was measured in AFM images by tracing the contour of mica-adsorbed individual multimers.

Results: VWF multimers appeared as 100 to 2410-nm-long strings of 15-30 nm globules. In HMW fractions, long contour length chains (800-2410 nm) dominated. In this HMW fraction the VWF:CB/VWF:Ag was between 1.5 - 0.5, and the M_{MW25} was 8.6 - 3.1 MDa. We found a correlation between both VWF:CB/VWF:Ag and VWF length (r=0.9, p=0.001), and VWF:CB/VWF:Ag and M_{MW25} (r=0.9, p< 0.0001). We also found that large multimers gradually vanished after several days of storage at -20°C. After one hundred days of storage the maximum length became shorter by 50%, and the entire length distribution shifted to smaller lengths.

Conclusions: In summary, our results indicate that the elevation of the VWF:CB/VWF:Ag ratio can be a good indicator for the appearance of HMW VWF multimers in the human blood plasma.

PB 363 | Safety and Efficacy of Recombinant von Willebrand Factor (rVWF) in Patients with Severe von Willebrand Disease (VWD) Undergoing Major and Minor Elective Surgical Procedures: A Prospective Clinical Trial

F. Peyvandi[1,2], A. Mamaev[3], J.-D. Wang[4], C.A.M. von Auer[5], O. Stasyshyn[6], M. Timofeeva[7], N. Curry[8], A.R. Cid[9], T.T. Yee[10], K. Kavakli[11], M. Chapman[12], A. Grigorian[13], B. Ploder[14], A. Sytkowski[15]

Klinik der Johannes Gutenberg-Universität, Universitätsmedizin Mainz, Mainz, Germany, [6]SI Institute of Blood Pathology and Transfusion Medicine of NAMS of Ukraine, Department of Surgery and Clinical Transfusiology, Lviv, Ukraine, [7]Federal State Budgetary Research Institution ‚Kirov Scientific-Research Institute of Hematology and Blood Transfusion of FMBA', Kirov, Russian Federation, [8]Oxford Haemophilia and Thrombosis Centre, Churchill Hospital, Oxford, United Kingdom, [9]Hospital Universitario y Politécnico La Fe Hemostasia y Trombosis, Valencia, Spain, [10]Royal Free London NHS Foundation Trust, Katharine Dormandy Haemophilia and Thrombosis Centre, London, United Kingdom, [11]Ege Universitesi Tip Fakultesi Hematoloji Bilim Dali, Bornova, Izmir, Turkey, [12]Shire Inc., Cambridge, United States, [13]Shire, Inc., Westlake Village, United States, [14]Shire, Inc., Vienna, Austria, [15]Shire, Inc., Cambridge, United States

Background: Surgical hemostatic management in VWD is critical for patient safety. rVWF (VONVENDI) is safe and effective for bleed treatment, allows independent control of VWF and FVIII, and is not restricted to co-administration of FVIII, thus minimizing the risk of thrombotic events.

Aims: Evaluate hemostatic efficacy and safety of rVWF with or without rFVIII in patients with severe VWD undergoing major and minor elective surgical procedures.

Methods: Intraoperative and overall hemostatic efficacy rating using a 4-point nominal scale; overall efficacy was assessed 24 hrs after the last rVWF infusion or at day 14, whichever occurred earlier. A priming dose of rVWF, was given 12-24 hrs pre-surgery to raise endogenous FVIII:C; if target FVIII:C was not reached, a preoperative loading dose of rVWF and rFVIII was given to raise FVIII:C to recommended levels. Peri- and postoperative rVWF and rFVIII were infused to maintain target trough levels.

Results: All 15 subjects (Table 1) treated with rVWF with or without rFVIII for major (10), minor (4), and oral (1) surgical procedures had overall hemostatic efficacy ratings of excellent (73.3%) or good (26.7%). Intraoperative hemostatic efficacy ratings were also excellent (86.7%) or good (13.3%) for all subjects. Subjects received 121 infusions of rVWF with or without rFVIII, with the majority of subjects receiving rVWF alone: 100% (15/15) for the priming dose, 80% (12/15) for the loading dose, 80% (12/15) postoperatively, and 2 subjects received no additional postoperative rVWF or rFVIII. The median overall surgical dose of rVWF was 220.4 IU/kg (63.8 - 648.4 IU/kg). No treatment-related AEs occurred, and none were due to a severe allergic reaction. No subjects developed neutralizing antibodies to rFVIII or rVWF.

Conclusions: These data support the safe and effective use of rVWF with or without rFVIII in achieving peri- and postoperative hemostasis in subjects with VWD undergoing major, minor, and oral elective surgery.

PB 364 | Recombinant Activated Factor VII-Induced Correction of Bleeding Tendency in Genetically-engineered von Willebrand Disease Type 2B Mice Evaluated Using New Tail Transection Bleeding Models

V. Proulle[1,2,3], C. Auditeau[1], H. Petit[1], F. Adam[3], A. Kauskot[3], F. Moreau[3], O.D. Christophe[3], P.J. Lenting[3], C.V. Denis[3]

[1]*Service Hématologie Biologique, Hôpitaux Universitaires Paris Sud, CHU Bicêtre, AP-HP, Le Kremlin Bicêtre, France,* [2]*Université Paris-Sud, Université Paris-Saclay, Le Kremlin Bicêtre, France,* [3]*Inserm UMR-S 1176, Le Kremlin Bicêtre, France*

Background: Von Willebrand disease subtype 2B (VWD2B) is characterized by von Willebrand factor (VWF) and platelet abnormalities related to enhanced VWF/platelet interactions. Treatment of patients with VWD2B can be challenging.

Aims: Our goal was to evaluate the haemostatic efficacy of recombinant human activated factor VII (rhFVIIa) using two novel tail transection bleeding models in a VWD2B murine model (genetically-engineered mice carrying the p.V1316M mutation in the *VWF* gene (V1316M mice)).

Methods: Tail artery transection (TAT) or tail vein transection (TVT) were performed in a standardized manner (depth and diameter: 0.7 and 0.3 mm respectively). Bleeding time (BT) and blood loss (BL) were measured in wild-type (WT) and V1316M mice with or without rhFVIIa infusion (3 mg/kg).

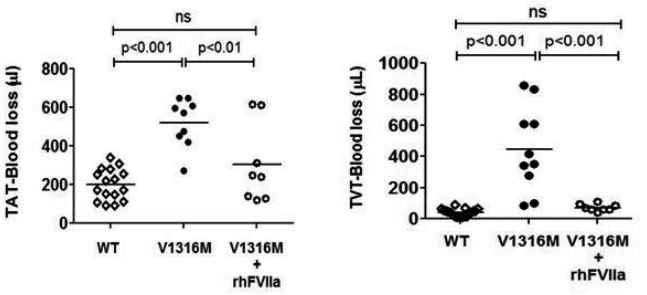

FIGURE 1 Effect of rhFVIIa on blood loss obtained in TAT and TVT bleeding models in von Willebrand disease type 2B mice (V1316M)

Results: In WT mice, BT was similar in both models (2.9±0.2 min *vs* 2.2±0.1 min for TAT and TVT respectively) whereas BL was significantly more important in the TAT model than in the TVT (201±20 µl *vs* 40±5 µl, p< 0.001). In V1316M mice, both parameters were significantly increased compared to WT mice: for TAT: 18.1±2.6 min (BT) and 522±42 µl (BL) and for TVT: 24.6±2.5 min (BT) and 448±86 µl (BL) (p< 0.001 for all parameters measured). After rhFVIIa infusion, BL was reduced in V1316M mice both in the TAT and TVT, to levels comparable to those obtained in WT mice: TAT: 303.2±72 µl (p=0.19 *vs* WT); TVT: 72±8 µl (p=0.86 *vs* WT) (Fig 1). For the BT parameter, a similar correction was observed in the TVT: 5.1±1.0 min (p=0.31 *vs* WT) but not in the TAT model: 14.1±2.8 min (p=0.004 *vs* WT).

Conclusions: In conclusion, we show that TAT and TVT are promising tools to evaluate bleeding tendency in murine models. It allowed us to show that a single infusion of rhFVIIa induces an immediate and complete correction of the bleeding tendency in V1316M mice. These results suggest that rhFVIIa should be considered as a treatment option in the clinical management of severe hemorrhagic episodes in patients with VWD2B.

PB 365 | VWF D'D3 Mutations Associated with Type 1 von Willebrand Disease Demonstrate Impaired Gp1Bα-VWF Binding under High Shear Stress

C. Ng[1,2], K. Ashworth[1], T. White-Adams[1], J. Di Paola[1,2]

[1]*University of Colorado, Department of Pediatrics, Hematology/Oncology/BMT, Aurora, United States,* [2]*University of Colorado Denver, Hemophilia and Thrombosis Center, Aurora, United States*

Background: Traditionally, type 1 von Willebrand disease (VWD) mutations are thought to decrease von Willebrand factor (VWF) quantity but not to affect VWF function. However, the incomplete penetrance and variable expressivity of type 1 VWD suggests that other mechanisms, such as qualitative defects in VWF, may explain the discrepancy between VWF levels and clinical bleeding.

Aims: The hypothesis of this proposal is that some Type 1 VWD mutations may demonstrate qualitative defects in VWF function and it is evaluated by assaying the in vitro platelet dependent - VWF function of various mutants.

Methods: Transfection: Conditioned supernatant from HEK293T cells transfected with varying DNA ratios of VWF expression vectors with and without Type 1 VWD mutations are evaluated in a platelet rolling assay. Mutations are noted in Table 1.

TABLE 1 List of Type 1 VWD Mutations

Mutation	Domain	VWD Association	Multimer Pattern
R782Q	D´D3	Type 1	Normal
V1229G	D´D3	Type 1	Normal
R1374C (Positive Control)	A1	Type 2M	Normal

Rolling Assay: 20 µg/mL of an anti-VWF antibody is affixed in a microfluidic chamber. After blocking, 10 IU/dL VWF is incubated for 1 hour and fixed platelets are then perfused ($1x10^5$ cells/µL) at shear rates $100s^{-1}$ to $4500s^{-1}$ ($1500\text{-}4500s^{-1}$ shown). High speed movies are captured and total/average pause time (the aggregate/average time of non-movement/binding time of platelets) is calculated via ImageJ/FIJI.

Results: At high shear rates, there was a significant impairment of pause time for the V1229G and R782Q mutations in terms of total pause time (seen at $3500s^{-1}$ and $4500s^{-1}$) (Figure 1A) and for average pause time (seen only at $4500s^{-1}$) (Figure 1B) suggesting impaired VWF-A1-Gp1Bα binding at high shear rates. The finding of decreased total and average pause time suggest that the impaired VWF-A1-Gp1Bα binding is an aggregate finding across multiple platelets (total pause time) but also occurs at the level of the individual platelet (average pause time).

Conclusions: Both V1229G and R782Q demonstrate qualitative deficiencies of VWF-A1-Gp1Bα binding at high shear rates. This finding may suggest an additional mechanism that may influence bleeding in patients with type 1 VWD.

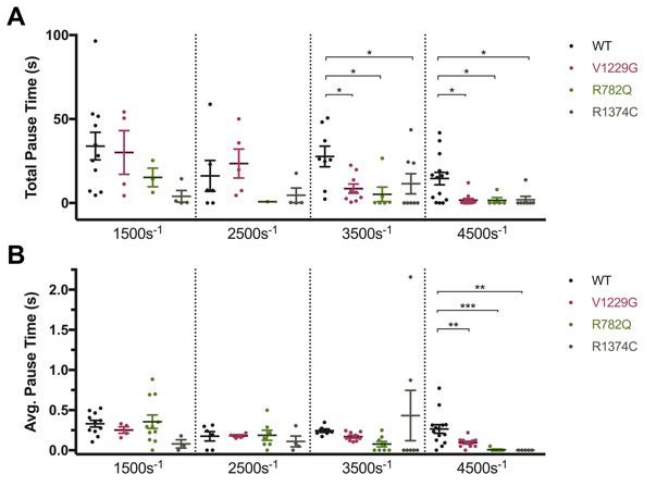

FIGURE 1 At high shear rates there is significant impairment of platelet pause times for V1229G and R782Q. * = P<0.05, **P<0.01, *** P<0.001

PB 366 | Diagnostic Challenges of Acquired von Willebrand Syndrome

S. Schneppenheim, R. Dittmer, U. Budde

Asklepios Klinik Altona, Medilys Laboratory Coagulation, Hamburg, Germany

Background: Acquired von Willebrand syndrome (aVWS) is associated with several different clinical conditions, thereby involving a variety of medical disciplines like cardiology and hematology. The most important factor causing aVWS is enhanced shear stress on VWF, which propagates VWF proteolysis, resulting in the loss of the largest VWF multimers. One problem in diagnosing aVWS accompanying these disorders, is due to the highly variable levels of von Willebrand factor (VWF:Ag) and a frequently inconsistent correlation to VWF functional activities like collagen binding (VWF:CB). Therefore, aVWS may remain undiagnosed even when combining VWF quantitative and functional assays.

Aims: To assess the diagnostic value of VWF multimer analysis in aVWS.

Methods: From 2002 until 12-2017, a cohort of 4,737 patients was diagnosed with aVWS type 2A by assessing the ratio of VWF:CB/VWF:Ag and in addition by VWF multimer analysis for comparison. Clinical data were available for 2097 patients. All patients with a reduction of VWF high molecular weight multimers were considered as having aVWS, irrespective of their VWF:Ag or VWF:CB.

Results: By multimer analysis, patients were diagnosed with aVWS. Many patients had normal or even elevated VWF:Ag and/or VWF:CB and 39% had even a normal VWF:CB/VWF:Ag ratio. The percentages of undiagnosing aVWS by using only the VWF:CB/VWFAg ratio at a cut off >0,79, is 19-52% overall in the different groups (s. Table 1).

TABLE 1 Number of patients and rate of diagnostic failure by the VWF:CB/VWFAg ratio

Conditions	n	Ratio >0.8
Cardio-vascular	918	52 %
Myelo-proliferative	677	29 %
Lympho-proliferative	294	19 %
others	208	43 %
All	2097	39 %

Conclusions: The results of our study show that multimer analysis is superior in detecting even minor deficits of the largest and most active VWF multimers. Depending on the underlying disorder, a significant number of patients with aVWS would remain undiagnosed by conventional quantitative and functional assays without multimer analysis, which is further on an indispensable tool for a valid diagnosis or exclusion of aVWS.

PB 367 | Multimer Size Distribution and Multimerization Defects of von Willebrand Factor Investigated at the Single-molecule Level by AFM Imaging

A. Löf[1], G. König[2], S. Schneppenheim[3], T. Obser[2], R. Schneppenheim[2], M. Benoit[1], U. Budde[3], J.P. Müller[1], M.A. Brehm[2]

[1]LMU Munich, Department of Physics and Center for Nanoscience, Munich, Germany, [2]University Medical Center Hamburg-Eppendorf, Department of Pediatric Hematology and Oncology, Hamburg, Germany, [3]Asklepios Klinik Altona, MEDILYS Laborgesellschaft mbH, Hemostaseology, Hamburg, Germany

Background: The multimeric plasma glycoprotein von Willebrand Factor (VWF) is crucial for hemostasis. As large multimers are hemostatically more active than shorter ones, mutations in VWF that impair multimerization cause von Willebrand disease (VWD) type 2A. Multimerization occurs in two steps: First, monomers dimerize at their C termini via the three disulfides Cys2771-Cys2773', Cys2773-Cys2771', and Cys2811-Cys2811'. Subsequently, dimers are linearly linked at their N termini via disulfides Cys1099-Cys1099' and Cys1142-Cys1142', yielding an exponential multimer size distribution, with short multimers being more abundant than larger ones.

Aims: We aimed to investigate the multimer size distribution of wildtype VWF and specific mutants, in particular to gain further insights into the distinct roles of the cysteine residues involved in dimerization.

Methods: We employed atomic force microscopy (AFM) to directly visualize recombinant VWF samples at the single-molecule level. For proof-of-principle we compared our results with electrophoretic multimer analysis.

Results: For wildtype VWF and the N-terminal mutant p.Cys1099Tyr (VWD type 2A/IIC Miami), we confirm complete dimerization and exponential size distributions, with a markedly reduced extent of multimerization for p.Cys1099Tyr. For the C-terminal mutants p.Cys2771Arg and p.Cys2773Arg (VWD type 2A/IID), we find a severe loss of large multimers and observe a large fraction of ‚non-native' multimers that exhibit N-terminally attached monomers (see Fig. 1). We quantify the degree of dimerization abolishment to be 87% and 73%, respectively. Mutant p.Cys2811Ala also exhibits a significant fraction of non-native multimers, but only a mild loss of large multimers.

Conclusions: We show that AFM is a powerful approach to assess the size distribution of VWF that can help to gain a quantitative understanding of the processes involved in VWF's multimerization and in multimerization defects. Thus, AFM is a powerful complementarily method to multimer analysis.

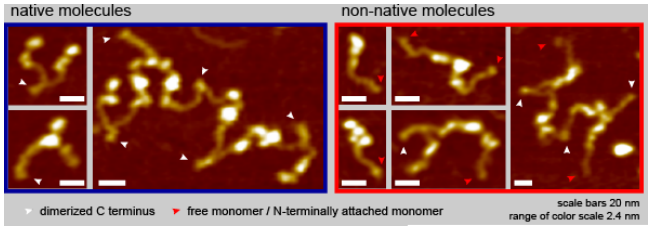

FIGURE 1 Single-molecule AFM imaging on wildtype and mutant VWF multimers

PB 368 | Exploration of Interim Bleeding Scores in VWD Subjects from Irish LoVIC, Canada and the US Zimmerman Program

P. Christopherson[1], M. Lavin[2], J. Grabell[3], T. Abshire[1], V. Flood[1], J. Gill[1], S. Haberichter[1], J. O'Donnell[2], R. Montgomery[1], P. James[3], Zimmerman Program Investigators

[1]BloodCenter of Wisconsin, Blood Research Institute, Milwaukee, United States, [2]St. James Hospital, National Coagulation Centre, Dublin, Ireland, [3]Queen's University, Department of Medicine, Kingston, Canada

Background: The ISTH bleeding assessment tool (ISTH-BAT) bleeding score (BS) includes all bleeding episodes in a patient's history.

Aims: We sought to explore an interim BS collected in 489 subjects from the US Zimmerman Program, Canada and Irish LoVIC cohort to determine its potential utility in patient management by evaluating bleeding symptoms over time in relation to VWD type, levels, age and gender.

Methods: Original ISTH-BAT scores (BS) included entire history at time of enrollment and interim bleeding scores (1BS) represented bleeding that had occurred since the BS was obtained. The original BS/year (BS/yr) and interim BS/year (1BS/yr) were calculated as a means to standardize the scores over time.

Results: Index case (IC) BS correlated with VWF levels in subjects with VWF:RCo< 30 IU/dl (8) followed by 30-50 (7) and >50 (5) ($p< 0.05$). There was a significant difference in 1BS and 1BS/yr in VWD subjects with levels < 30 (5, 1.2) and 30-50 (4, 0.8) ($p< 0.05$), but no difference between levels 30-50 and >50 (4, 0.8). 1BS in type 3 IC (13) was greater than type 2 (7) and type 1 (4) ($p< 0.01$). Type 1 IC females had higher BS (7) than males (5) ($p< 0.01$), however the 1BS and 1BS/yr were similar between males (4, 0.8) and females (4, 0.9). Original BS were lower in pediatric patients (5) than adults (8) ($p< 0.0001$), however there was no significant difference in 1BS or 1BS/yr. When type 1 IC (VWF< 50) were separated by abnormal or normal BS, there was a difference in 1BS (4, 3.5) ($p< 0.05$), but not 1BS/yr (1, 0.7) nor differences in VWF levels.

Conclusions: Higher interim 1BS in subjects with VWF:RCo < 30 show correlation between low VWF levels and increased bleeding. There was no difference in 1BS between males and females nor pediatric vs. adults. Having a positive or negative original BS did not predict a difference in interim 1BS/yr in type 1 patients. The interim 1BS may be a valuable tool to help monitor the success of treatment and bleeding symptoms over time in VWD patients.

PB 369 | Does Ageing Modify Hemostatic Parameters in Type 1 von Willebrand Disease (VWD-1)?

G. Guglielmini, M. Borghi, A.M. Mezzasoma, E. Falcinelli, P. Gresele

University of Perugia, Dept of Medicine, Perugia, Italy

Background: Plasma levels of clotting factors increase with ageing in healthy subjects but the influence of ageing on haemostatic parameters in VWD-1 is uncertain.

Aims: To assess changes in VWF:Ag, VWF:RCo, FVIII:C and RIPA in patients with VWD-1 repeatedly evaluated at our Center over a 25 yrs period.
Methods: Between Jan 1990 and Dec 2015 195 subjects (55.4% women, median age 28,7 yrs, range 0.4-74.5 yrs) with VWD-1 (Sadler JE, JTH 2006), were repeatedly evaluated at our Center for VWF:Ag, VWF:RCo, FVIII and RIPA. Plasma levels of VWF:Ag, VWF:RCo, FVIII:C and RIPA were measured by standard methods.
Results: Median follow-up was 6.6yrs (0.4-24.7); each patient was studied on average 3 times (range 2 to 14). Median VWF:Ag, VWF:RCo, FVIII:C and RIPA baseline levels were 0.45IU/ml, 0.35IU/ml, 0.57IU/ml and 1.4mg/ml, respectively. Between first and last measurement median VWF:Ag increased by 0.14±0.03IU/ml, VWF:RCo by 0.096±0.02IU/ml, FVIII by 0.094±0.035IU/ml and RIPA decreased by 0.3±0.1mg/ml (all p< 0.05).
The variations of VWF:RCo, VWF:Ag and FVIII:C were positively correlated with the length of the time interval between first and last measurement (increase rate: VWF:RCo=0.047IU/ml/10yrs, VWF:Ag=0.062IU/ml/10yrs, FVIII:C=0.102 UI/10yrs and RIPA=-0.1mg/ml/10yrs). Neither gender- nor blood group-related differences were observed. However, when patients were subdivided in mild (baseline VWF:Ag and VWF:RCo>0.3< 0.5IU/ml, n=143) and moderate (baseline VWF:Ag and VWF:RCo≤0.3IU/ml, n=52), a significant increase of VWF antigen (+0.2IU/ml, p< 0.05) and activity (+0.17IU/ml, p< 0.05) was confirmed only in mild VWD-1 with no changes in moderate (-0.001IU/ml and -0.01IU/ml, p=ns).
Conclusions: An age-related increase of VWF levels is evident only in patients with mild type 1 VWD, while in the more clear-cut cases this increase is not apparent. Our data suggest that the milder patients initially labelled as VWD-1 may be false diagnoses and changes of VWF-related laboratory parameters may be restricted to healthy individuals.

PB 370 | Common Single Nucleotide Variants in the von Willebrand Factor Gene Associate with "Mutation Negative" Type 1 VWD

C. Notley[1], M. Bowman[2], C. Brown[3], K. Tyryshkin[3], L. Swystun[3], P. James[2], D. Lillicrap[3]

[1]*Queen's University, Department of Pathology and Molecular Medicine, Kingston, Canada,* [2]*Queens University, Department of Medicine, Kingston, Canada,* [3]*Queens University, Department of Pathology and Molecular Medicine, Kingston, Canada*

Background: The von Willebrand factor (*VWF*) gene is highly polymorphic. Previous analysis of the 1000 Genomes data identified 91 non-synonymous exonic single nucleotide variants (SNVs) within the *VWF* gene. There is also evidence that sequence variations within the *VWF* locus correlate with VWF antigen levels, activity, FVIII binding and half-life in the general population. Studies investigating the mutational landscape in >500 index cases of Type 1 VWD have consistently revealed that no clear pathogenic *VWF* variant is documented in ~35% of cases.
Aims: To investigate the association between Type 1 von Willebrand disease (VWD) and common non-synonymous SNVs at the *VWF* locus in a cohort of 42 "mutation negative" patients from the Canadian Type 1 VWD Study.
Methods: The proximal promoter (1300 bps), exons 1 to 52, and approximately 70 base pairs of the donor and acceptor sites of the *VWF* gene were sequenced. Copy number variation (CNV) was previously evaluated in cases with a VWF: Ag < 0.35 IU/ML. For the remaining 42 "mutation negative" patients, allele frequencies of the 91 non-synonymous SNVs were compared to American frequencies within the 1000 Genomes. Analysis was performed using Chi-square. Alamut software analyzed changes for variant pathogenicity, Grantham distance and degree of conservation.
Results: Variation was documented in 8 of 91 non-synonymous codons. We identified 3 significant differences between the 1000 Genomes cohort and this Type 1 VWD cohort: p.Asn318Lys (c.954T>A, rs1800387, p=0.001); p.His484Arg (rs1800378, c.1451A>G, p< 0.0001), and p.Gln852Arg (rs216321, c.2555A>G, p< 0.0001).
In silico analysis (SIFT, Polyphen2) indicated the variants are tolerated, with p.Asn318Lys being possibly damaging. All variants had a small to moderate physiochemical difference (Grantham distance) and moderate amino acid conservation.
Conclusions: Common non-synonymous *VWF* variants are over-represented in "mutation negative" Type 1 VWD and may contribute to the phenotype.

PB 371 | Functional Polymorphisms of the von Willebrand Factor Gene in Patients with Mild to Moderate Bleeding Tendency and Low von Willebrand Factor Antigen or von Willebrand Factor Ristocetin Cofactor

S. Hofer[1], J. Gebhart[1], J. Rejtö[1], G. Hörmann[2], I. Pabinger[1], R. Sunder-Plassmann[2]

[1]*Department of Internal Medicine I, Clinical Division of Hematology and Hemostaseology, Medical University of Vienna, Vienna, Austria,* [2]*Department of Laboratory Medicine, Division of Medical-chemical Laboratory Diagnostics, Medical University of Vienna, Vienna, Austria*

Background: The diagnosis of von Willebrand disease (VWD) is backed by molecular analysis. Functional single nucleotide polymorphisms (SNPs) of the coding and promoter sequences in the von Willebrand factor (VWF) gene are correlated with VWF antigen and ristocetin cofactor levels.
Aims: Evaluation of the frequency of functional polymorphisms in the VWF gene in a Vienna Bleeding Biobank (VIBB) subgroup.
Methods: From November 2009 to January 2016, 431 patients (female=354, 82.1%) were included in the VIBB. Of these, 40 (female=34, 85%) were diagnosed with low (30-50%) or very low (0-30%) VWF:Ag or VWF:RiCo levels respectively. Sequencing analysis of the VWF gene revealed mutations associated with VWD in 8 patients, who were excluded from the subsequent evaluation of functional polymorphisms in exons 18, 20, and 28 of the VWF gene. The frequency in our cohort was compared to that of the European population of the 1000 genome project provided by dbSNP.

TABLE 1 Patient characteristics (n=32)

Female, n (%)	28 (87.5)		
Blood group 0, n (%) *	23 (71.9)		
	median	25th - 75th percentile	Range
Bleeding Score (Vincenza)	5	3.25-7.75	2-15
Age [years]	32	22-40.75	16-73
BMI [kg/m2]	22.7	20.3-26.1	18.6-32.5
vWF:Ag [%]	50	45.75-57	12-91
vWF:Rico [%]	44	40.25-48	13-56
FVIII [%]	72	59.25-82	8-138

* Blood group was not determined in 3 patients

TABLE 2 Frequency of functional polymorphisms in the VWF gene

SNPs	Allele Frequency (VIBB)	Allele Frequency (EUR)
E18: c.2365A>G,p.Thr789Ala	0.156	0.367
E20: c.2555G>A,p.Arg852Gln	0.125	0.0865
E28: c.4141G>A,p.Ala1381Thr	0.203	0.399
E28: c.4693G>T,p.Val1565Leu	0.125	0.076

VIBB=Vienna Bleeding Biobank. EUR= European population of the 1000 genome project provided by dbSNP.

Results: Patient characteristics are given in Table 1. Twenty-four patients (66%) had the following functional polymorphisms in Exon 18, 20 or 28: p.Ala1381Thr, p.Arg852Gln, p.Val1565Leu, and/or p.Thr789Ala. Associations between p.Arg852Gln, p.Val1565Leu and reduced VWF levels and increased proteolysis by ADAMTS13, respectively, and between p.Thr789Ala and higher VWF levels have been described.

The frequency of the polymorphisms is listed in Table 2. We detected a higher frequency of the p.Arg852Gln (13% vs. 9%) and the p.Val1565Leu SNP (13% vs. 8%) when compared to the European population of the 1000 genome project. In contrast, the p.Thr789Ala and the p.Ala1381Thr polymorphisms appear with a lower frequency (16% vs. 37% and 20% vs. 40%) in our patient subgroup.

Conclusions: In the group of patients from the VIBB study characterized by low VWF levels, we detected a shift of polymorphisms, which might partially explain the decreased VWF levels in this very specific group of patients without disease defining mutation in the VWF gene.

PB 372 | Expression of the von Willebrand Factor C-domains in E.coli

H. O'Brien[1], F. Hansen[2], T. Tuddenham[2], M. Laffan[1], T. McKinnon[1]

[1]Imperial College London - Hammersmith Hospital Campus, London, United Kingdom, [2]University College London, London, United Kingdom

Background: Von Willebrand Factor (VWF) is a large multidomain protein that performs essential roles in normal haemostasis. While crystal structures of the A1, A2 and A3 domains and the cysteine knot domain have been resolved, limited structural data exists on the rest of the molecule that is comprised of D and C domains. Such studies are hampered in part due to the large number of cysteine residues located in the D and C-domains. Recently the FVIII binding region in the VWF D' domain was expressed in e.coli and used to derive structural NMR data suggesting that other cysteine rich domains of VWF could be produced in this way.

Aims: To express and purify the individual VWF C-domains

Methods: The cDNA for the C1, C2, C3, C4, C5 & C6 domains was cloned into the bacterial expression vector pET32-TRX creating fusions proteins with an N-terminal thioredoxin tag and a C-terminal His-tag. Proteins were expressed in *E.coli* Origami cells following induction with IPTG and proteins were purified by Nickel affinity and ion-exchange chromatography.

Results: With the exception of the C5 domain, all the VWF C-domains could be expressed at high levels in *E.coli* after 6 hours of expression and were found in both soluble and insoluble fractions. In vectors lacking the thioredoxin tag no protein was found in the soluble fraction and only minimal protein was observed in inclusion bodies. Proteins were purified by two passages over a nickel affinity column and following cleavage of the TRX tag, were purified to homogeneity using ion-exchange. All proteins demonstrated good expression levels ~1mg/100ml of culture. Finally the C4 domain which contains the RGD sequence was able to bind to immobilised GPIIbIIIa confirming that the proteins were properly folded.

Conclusions: The isolated VWF C-domains can be expressed at high levels in e.coli cells and purified to homogeneity. Using this system we can now obtain structural information about this region of the VWF molecule.

PB 373 | Quantitative ELISA Assay for in vivo Proteolysis of von Willebrand Factor andBbleeding: A Pilot Study in Type 2A (IIA) von Willebrand Disease

Paris-Sud, Univ. Paris-Saclay, Kremlin-Bicètre, France

Background: Mutations within the A2 domain of VWF inducing type 2A(IIA)VWD, are classified according to their mechanism: abnormal

assembly and secretion (group 1), excessive proteolysis (group 2) or unspecified (group 3). The characterization of the mechanism for type 2A(IIA) VWD could help evaluating the bleeding tendency.

Aims: To investigate the relation between the bleeding tendency and VWF-proteolysis in patients with 2A(IIA) VWD.

Methods: We have developed an ELISA assay to measure VWF-proteolysis. Results are expressed as the proportion of proteolysed-VWF (%). VWF-proteolysis in normal plasma was 6±2% (mean±SD). This quantification was performed in 87 patients of the French cohort of VWD identified with a molecular defect in the VWF-A2 domain resulting in type 2A(IIA) VWD (group 1, n=14; group 2, n=39; group 3, n=34). The bleeding score (BS), a history of epistaxis or gastro-intestinal (GI) bleeding was available for 38 of them. Results are expressed as median [min-max].

Results: There was a significant difference in VWF-proteolysis between groups (106% [0-243] group 1, *vs* 80% [21-143] group 2 *vs* 48%[0-153] group 3, ANOVA-p < 0.01). A high degree of proteolysis was associated with a high bleeding score (Mann-Whitney p=0.05). No difference in BS was observed between groups. GI-bleeds (Item > 3 of the BS) were reported in 13/38 patients (34%) with no difference between groups. A history of epistaxis was found in 22/38 patients (58%) and appears to be more frequent in group 1 patients (4/4-100%) compared to groups 2 (8/14-57%) and 3 (11/20- 55%), respectively.

Conclusions: This study underlines the phenotypic heterogeneity of the proteolysis associated with the mutations of VWF-A2 domain in type 2A(IIA)VWD. These results confirm the data previously obtained with mutant recombinant VWF pointing the combination of several mechanisms. Further studies involving more patients, especially patients of group 1 in whom the bleeding tendency appears the most severe, are needed to confirm these preliminary results.

PB 374 | Bleeding Symptoms in Patients Previously Diagnosed as Type 3 von Willebrand Disease: Results from a Multicenter, Multinational Cross-sectional Study

Sacco University Hospital & School of Medicine, Milan, Italy

Background: Patients with type 3 von Willebrand Disease (VWD) usually have markedly reduced FVIII/VWF levels and very severe bleeding manifestations. Because of the rarity of type 3 VWD, the clinical phenotype of these patients has been however poorly evaluated in relation to demographical factors.

Aims: We aimed at evaluating age and sex distribution of bleeding symptoms in patients with type 3 VWD and comparing them with previously available data from a cohort of type 1 patients.

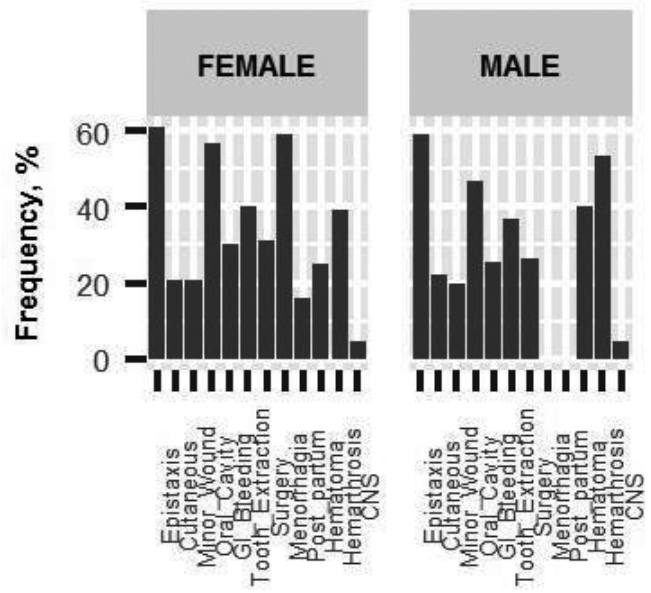

FIGURE 1

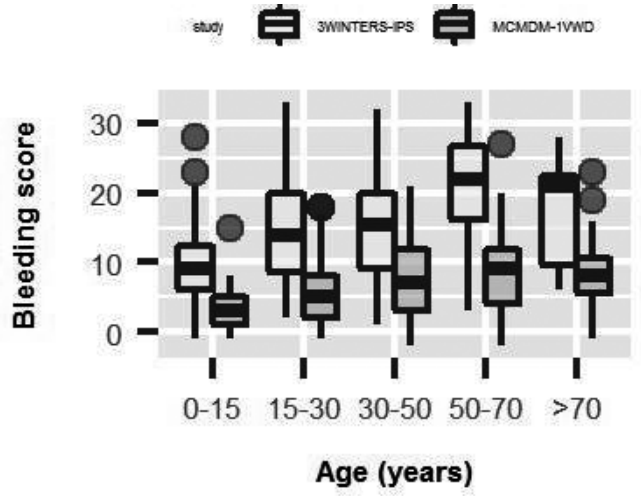

FIGURE 2

Methods: We analyzed patients enrolled in the 3WINTERS-IPS study, a multicenter, multinational cross-sectional study that analyzed clinical and phenotypical data on patients historically diagnosed as type 3 VWD. Retrospective information on bleeding symptoms at presentation was collected using the MCMDM-1 VWD bleeding questionnaire, and bleeding severity summarized as bleeding score. Individual bleeding symptoms were considered as relevant when having a score >1 (hence requiring medical attention). Data was compared with that retrieved from the MCMDM-1 VWD study database on patients affected by type 1 VWD (index cases and affected family members).
Results: We analyzed a total of 215 patients for whom bleeding symptoms history was available up to recruitment. The median age at study inclusion was 27 (interquartile range, 28); 125 were females. There were 105 of Iranian descent, while the remaining of patients were from Europe. Figure 1 shows that epistaxis was the most frequent relevant symptom, followed by menorrhagia in females.
Males had a higher frequency of hemarthroses and hematomas than females (53% vs. 39% and 40% vs. 25%, respectively). When comparing the clinical presentation of type 3 vs. type 1 VWD, increased bleeding scores were evident for all age-classes and even in pediatric cases (Figure 2).
Conclusions: This study shows that the bleeding phenotype in type 3 VWD patients is remarkably different from that of type 1 patients; hemarthrosis in males and menorrhagia in females are prevalent causes of morbidity.

PB 375 | Fluorescence Intensity-based Analysis of the Shear-dependent Internalization of Von Willebrand Factor Mutants by Macrophages

U. Klemm, G. Ahmari, T. Obser, G. König, R. Schneppenheim, M. Brehm

University Medical Center Hamburg-Eppendorf, Pediatric Hematology and Oncology, Hamburg, Germany

Background: After secretion from endothelial cells and platelets elongated VWF multimers are cleaved proteolytically by ADAMTS13 producing smaller circulating VWF multimer fragments. It has been suggested that macrophages contribute to removal of these VWF fragments from the circulation. Clearance of VWF critically contributes to the clinical phenotypes of von Willebrand disease type 1 and 2A/IIC Miami.
Aims: Aim of this study is to investigate the mechanism by which mutations alter the shear-dependent clearance of VWF by macrophages. This is also of interest with respect to half-life of coagulation factor VIII, because it is internalized together with VWF.
Methods: Human macrophages were seeded in channel slides and perfused with 75 µg/ml wtVWF or VWF mutants for 30 min at 10 dyne/cm^2. Subsequently the cells were fixed, permeabilized and intracellular VWF was detected by indirect immunofluorescence. To assess the clearance rate, the fluorescence intensities were quantified by a modified protocol using the ImageJ software.
Results: We investigated the VWD 2A/IIC Miami mutants p.Ser58Arg, p.Met1051Thr, p.Cys1099Tyr and p.Glu333_385dup and showed that the clearance by macrophages of all analyzed mutants is significantly reduced compared to wtVWF. We can now further use this method to investigate the receptor proteins which are involved in binding and internalization of VWF.
Conclusions: We successfully established and validated a quantitative fluorescence intensity-based method to quantify cellular uptake of VWF into macrophages. This method can now be used to gain deeper insights into the clearance mechanisms contributing to VWD.

PB 376 | Von Willebrand Factor Multimer Analysis in 255 Patients Previously Diagnosed as VWD Type 3 from the Iranian Republic and Nine European Countries (3WINTERS-IPS Study)

Sacco University Hospital & School of Medicine, Milano, Italy

Background: The phenotypic variation in type 3 Von Willebrand disease (VWD) is still poorly understood due to the rarity of the disease.
Aims: The 3WINTERS-IPS study evaluates for the first time the phenotypes and von Willebrand Factor (VWF) parameters in a large cohort of Iranian and European VWD patients. The VWF multimers were evaluated.
Methods: The patients stem from seven treatment centers located in the Iranian Republic (111 out of a population of ~ 84,000,000), and 14 treatment centers located in nine European countries (144 out of a population of ~ 360,000,000). All patients were previously diagnosed as type 3 VWD. Accordingly the multimers should be lacking. Last treatment with VWF concentrates was preferentially commenced more than one week before blood sampling.
Results: After exclusion of ten patients with normal (3), mildly reduced VWF (4) and so far ill defined subtypes (3), the following types of multimer patterns were revealed: 1= type 3 with visible protomer and 2 sharp single bands; 2= treated patient with residual VWF with smeary material and no banding pattern; 3= severe type 1 in whom multimers were present with additional ultralarge multimers plus a faint triplet structure; 4= severe type 2 with missing largest multimers, while the remaining multimers showed a relative decrease. Sharp central bands were visible with triplets or amorphous material.
In the patients from the Iranian Republic, 92 (83%) fell into category 1, 9 (8%) into category 2, and 10 (8%) into category 3.
In the patients from Europe, 67 (47%) fell into category 1, 38 (27%) into category 2, 17 (12%) into category 3, and 11 (8%) into category 4.
Conclusions: Thus the patients from the Iranian Republic are seemingly more homogenous compared to the patients from Europe. One reason for this diversity is the number of patients treated with VWF concentrate. But also different diagnostic procedures in the more centralized Iranian Republic compared to the heterogeneous European countries may play a role.

PB 377 | Interaction between the A3 and A2 Domains of von Willebrand Factor Reduces the Binding of the A1 Domain to Glycoprotein Ibα

S. Cirlos[1], M. Auton[1], M. Cruz[1,2]

[1]Baylor College of Medicine, Medicine, Houston, United States, [2]Michael E. DeBakey VA Medical Center, Center for Translational Research on Inflammatory Diseases (CTRID), Houston, United States

Background: The A3 domain in the A1A2A3 domains complex in the glycoprotein von Willebrand factor (VWF) is the major collagen-binding domain. Interestingly, few antibodies for the A3 domain, and, thus far, two mutations in A3 domain that cause von Willebrand disease (VWD) significantly reduce the binding of VWF to platelet glycoprotein (GP)Ib. The mechanism by which the A3 domain impacts the function of the A1 domain remains unknown.
Aims: Since we and others have demonstrated that the A1-A2 binding inhibits the interaction of A1 domain to GPIb, we examined whether a direct contact between A2 and A3 domains influences on the A1-GPIb binding.
Methods: We employed purified plasma VWF and recombinant A1, A3, A1A2, A2A3, wild type A1A2A3, and gain-of-function A1(R1450E) A2A3 mutant proteins. We also used antibodies against A2 domain of human VWF. The binding analyses were performed utilizing ELISA, surface plasmon resonance (SPR), and fixed platelets were used in other binding assays. We also used urea denaturation and differential scanning calorimetry (DSC).
Results: The A3 domain bound to isolated A2 domain or A2 in full length VWF with a comparable half-maximal binding obtained at 250 nM. This interaction was inhibited by monoclonal antibodies against the A2 domain, and isolated A3 protein. Using urea denaturation and DSC, we have demonstrated that the A3 domain associates with the A2 domain and stabilizes not only the structure of A2 domain but the overall A1A2A3 complex. Moreover, using A1A2A3 protein, the impairment of A1-A2 interaction concurrently dissociates A2 from A3 domain. Lastly, isolated A3 domain protein was capable of inhibiting the binding of purified A1A2 domains protein to platelet GPIb in solution.
Conclusions: The interactions between the A1-A2-A3 domains are essential in stabilizing the structure of the A1A2A3 complex, and in inhibiting the binding to GPIb in solution. Natural mutations in A3 domain may affect the classification of VWD.

PB 378 | Incidence and Economic Burden of Thromboembolic Events (TEEs) among US Patients with von Willebrand Disease (VWD) - A Large Claims Database Analysis

M. Lu[1], A. Oladapo[1], E. Fadli[1], A. Khachatryan[1], E. Brouwer[1], M. Bron[2], T. Kauf[1]

[1]Shire, Global Health Economics and Outcomes Research and Epidemiology, Cambridge, United States, [2]Shire, Global Health Economics and Outcomes Research and Epidemiology, Chicago, United States

Background: VWD patients face the risk of developing TEEs, especially those with risk factors for thrombosis or excessively high FVIII levels.
Aims: To estimate incidence, healthcare utilization and economic burden of TEEs in VWD patients.
Methods: VWD patients were identified from Truven databases (01/2008-09/2015). Patients were continuously enrolled for ≥12 months with no TEEs since eligibility start date, and followed from index date (12 months post-eligibility start date) to a TEE event or end of plan eligibility. Patients with TEE post-index date were matched based on age and gender with non-TEE patients. Healthcare cost/resource use in the 12-month post-TEE period for TEE patients and over a similar 12-month period for matched non-TEE patients were compared using regression analyses for matched pairs, adjusting for baseline covariates.
Results: A total of 17,549 VWD patients were identified, 74.7% were female and mean age was 33.8±19.9 yrs. During a median follow-up of 2.6 yrs, 1,076 (6.1%) patients developed ≥1 TEE type. The top 3 most prevalent TEEs were deep vein thrombosis (2.8%), ischemic stroke (1.8%) and acute cerebrovascular event (1.2%). Incidence rate for all TEEs was 2.2/100 person-year. Identified matched pairs (n=534) had mean age of 52.1±18.4 yrs. Patients with TEEs were significantly (p< .001) more likely to have an inpatient admission (OR=8.1; 95%CI=5.9-10.0), ER visit (OR=1.7; 95%CI=1.3-2.3), longer inpatient stay (IRR=6.8; 95%CI=5.0-9.1), more frequent inpatient admissions (IRR=4.2; 95%CI=3.3-5.4), ER (IRR=1.6; 95%CI=1.3-2.1) and outpatient (IRR=1.6; 95%CI=1.5-1.8) visits compared to those without TEE. Patients with TEEs also incurred significantly (p< .001) higher total healthcare cost (adjusted mean diff.=$54,095; 95%CI=$37,037-$71,152) than those without TEE.
Conclusions: Although the incidence is low, the economic burden of TEE in VWD patients is high. Clinicians need to monitor VWD patients for early signs of thrombosis, especially those receiving VWF concentrates that also contain FVIII.

PB 379 | oPerioperative Management of Replacement Therapy in von Willebrand Patients: Steps towards Individualization of Treatment?

H.C.A.M. Hazendonk[1], H.C. Veerman[1], J.M. Heijdra[1], J. Boender[2], I. van Moort[1], R.A.A. Mathôt[3], K. Meijer[4], B.A.P. Laros-van Gorkom[5], J. Eikenboom[6], K. Fijnvandraat[3], F.W.G. Leebeek[2], M.H. Cnossen[1], WIN and OPTI-CLOT Study Group

[1]Erasmus Medical Center - Sophia Children's Hospital, Rotterdam, The Netherlands, [2]Erasmus University Medical Center, Rotterdam, The Netherlands, [3]Academic Medical Center Amsterdam, Amsterdam, The Netherlands, [4]University Medical Center Groningen, Groningen, The Netherlands, [5]Radboud University Medical Center, Nijmegen, The Netherlands, [6]Leiden University Medical Center, Leiden, The Netherlands

Background: Von Willebrand disease (VWD) patients are regularly treated with replacement therapy in cases of acute bleeding, trauma or surgical procedures.
Aims: To evaluate current perioperative management with von Willebrand factor (VWF)/Factor VIII (FVIII) (Haemate P®) concentrate in VWD patients.
Methods: VWD patients undergoing minor or major surgery between 2000-2015 and treated with VWF/FVIII concentrate (Haemate P®) were included. Achieved VWF:Act/FVIII:C during FVIII:C-based treatment regimens were compared to predefined target levels in National guidelines. A waiver for informed consent was granted on behalf of the Medical Ethics Committee based on the observational nature of the study.
Results: In total, 103 VWD patients (148 surgeries) were included: 54 type 1 (73 surgeries), 43 type 2 (67 surgeries) and 6 type 3 (8 surgeries). Overall, treatment resulted in high VWF:Act/FVIII:C levels, defined as ≥0.20 $IUmL^{-1}$ above predefined levels. In type 1 VWD patients, respectively 65% and 91% of trough VWF:Act and FVIII:C levels were higher than target levels. In type 2 VWD and type 3 respectively, 53% and 57% of trough VWF:Act and 72% and 73% of trough FVIII:C levels were higher than target level. Prevalence of low FVIII and VWF:Act was rare. Furthermore, FVIII accumulation over time was observed, with significantly higher levels than VWF:Act. Occurrence of bleeding complications (3.4%) was not associated with a low trough VWF:Act and/or low FVIII (p=0.95 and 0.25). Blood group O was associated with high VWF:Act levels, explained by lower endogenous baseline levels resulting in administration of higher dosages of VWF/FVIII concentrates.
Conclusions: High VWF:Act and accumulation of FVIII:C levels was observed after perioperative FVIII:C-based replacement therapy in VWD patients, without additional hemostatic effect. Alternative more individualized dosing regimens not only based on body weight may be able to optimize treatment in VWD in the near future.

PB 380 | Deficiency of von Willebrand Factor (VWF) High Molecular Weight Multimers (HMWM) in the Presence of Normal/Increased Activity of both VWF Cofactor Activity (VWF:RCo) and VWF Antigen (VWF:Ag) in Patients with Severe Aortic Stenosis

K. Bykowska[1], D. Zakrzewski[2], B. Baran[1], P. Kunicki[2], T. Hryniewiecki[2], B. Ceglarek[3], J. Windyga[1,4]

[1]Institute of Hematology and Transfusion Medicine, Department of Hemostasis and Metabolic Disorders, Warsaw, Poland, [2]Institute of Cardiology, Warsaw, Poland, [3]Institute of Hematology and Blood Trasnsfusion, Department of Disorders of Haemostasis and Internal Medicine, Warsaw, Poland, [4]Institute of Hematology and Transfusion Medicine, Department of Disorders of Hemostasis and Internal Medicine1, Warsaw, Poland

Background: Recurrent bleeds in patients with aortic valve stenosis may be caused by acquired von Willebrand syndrome (AVWS) characterized by deficiency of high molecular weight multimers of VWF resembling type 2A VWD.
Aims: The study was designed to analyse correlation between functional results of VWF (VWF:RCo and VWF:CB) and VWF multimer structure in patients with severe aortic valve stenosis.
Methods: Our study was performed in a group of 17 patients (71-87 years old) with severe aortic-valve stenosis (mean transvalvular gradient >40 mmHg and aortic valve area < 1,0cm2. The following tests were performed: factor VIII coagulation activity (VIII:C), VWF

ristocetin cofactor activity (VWF:RCo) and antigen (VWF:Ag) by Siemens, VWF collagen binding acivity (VWF:CB) by Technoclone, VWF propeptide (VWFpp) by Sanquin; multimers studies were carried out according to Krizek et al 2000.

Results: In 7/17 patients (41%) with aortic stenosis deficiency of HMWM of VWF (similarly to VWD 2A) was determined; VIII:C, VWF:RCo, VWF:Ag were in normal range or elevated; VWD:CB was decreased in 3/7 patients. The pathological ratios (< 0,6) of VWF:RCo, VWF:CB to VWF:Ag were observed respectively in 3/7, 1/7 patients; VWFpp and VWFpp/VWF:Ag ratio were in normal range in 7/7. In all patients 7/7 with deficiency of HMWM VWF fraction non specific bleeding episodes were observed.

Conclusions: Results of our study showed that in patients with severe aortic stenosis the use of VWF functional methods and ratios of VWF:RCo/VWF:Ag; VWF:CB/VWF:Ag are insufficient to discriminate cases with deficiency of VWF HMWM fraction. Lack of bleeds in patients with HMWM VWF deficiency suggest that the multimers with lower molecular weight can support hemostasis.

PB 381 | Usefulness of VWF Propeptide in the Differential Diagnosis between Patients with VWD and AVWS

F. Stufano[1], M. Boscarino[1], L. Baronciani[1], P. Bucciarelli[1], G. Cozzi[1], F. Peyvandi[1,2]

[1]Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico and Luigi Villa Foundation, Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Milan, Italy, [2]Università degli Studi di Milano, Department of Pathophysiology and Transplantation, Milan, Italy

Background: An increased von Willebrand factor propeptide (VWFpp) to von Willebrand factor antigen ratio (VWFpp/VWF:Ag) indicates an enhanced clearance of VWF. This finding has been described in von Willebrand disease (VWD) and acquired von Willebrand syndrome (AVWS). If family history is not available, it is difficult to distinguish between VWD and AVWS because the laboratory tests rarely can discriminate. Therefore, there is a need for diagnostic biomarkers that may facilitate the differential diagnosis.

TABLE Baseline characteristics of the study population

Variables	VWD (type 1 Vicenza excluded) (n=111)	type 1 Vicenza (n=14)	AVWS (n=28)
Sex (male/female)	42/69	5/9	15/13
Age at visit (yrs) *	26 (13-42)	45 (22-62)	56 (43-71)
Bleeding score*	10 (4-16)	17 (9-19)	10 (3-14)
VWF:Ag (IU/dL)*	35 (22-46)	10 (9-13)	34 (15-65)
VWFpp (IU/dL)*	63 (46-92)	99 (89-121)	116 (89-143)
VWFpp/VWF:Ag ratio*,†	2 (1.5-2.7)	10 (8-14)	4 (1.5-8.7)

* median values (IQR), † Normal range VWFpp/VWF:Ag 0.6-1.6

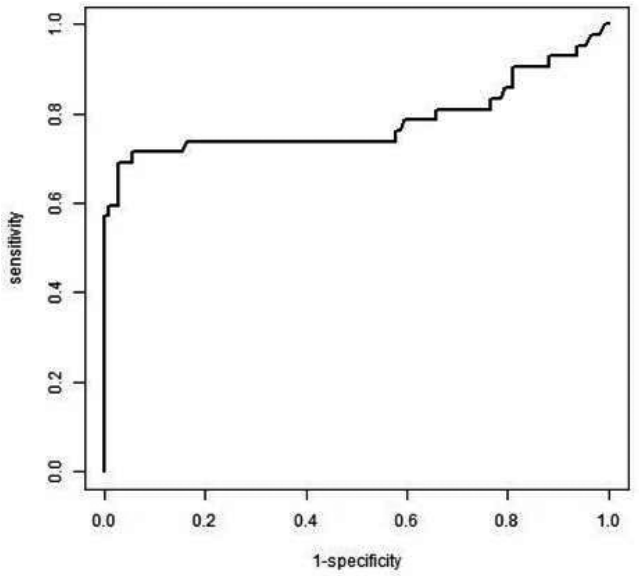

FIGURE 1 Receiver operating characteristic curve for discrimination between patients with lower VWF versus patients with higher VWF clearance

In this cross-sectional study we assessed the VWFpp/VWF:Ag in a group of 153 patients,
125 with VWD and 28 with AVWS.

Aims: To evaluate the ability of VWFpp/VWF:Ag in the differential diagnosis between VWD and AVWS.

Methods: VWF:Ag and VWFpp levels were determined by ELISA methods. In the frame of a logistic regression, a receiver operating characteristic curve was used to assess the optimal cut-off of VWFpp/VWF:Ag for discrimination between VWD and AVWS. This cut-off was identified as the value with the best compromise between sensitivity and specificity. An internal validation of the predictive model containing VWFpp/VWF:Ag, age and sex was performed with 1.000 bootstrap replicates to correct for optimism.

Results: Higher VWFpp/VWF:Ag were mainly associated with AVWS and type 1 Vicenza VWD diagnosis (Table).

The best cut-off value of VWFpp/VWF:Ag for the discrimination of patients with lower VWF clearance (most VWD) versus patients with higher VWF clearance (AVWS and type 1 Vicenza) was 3.9 (VWFpp/VWF:Ag normal range:0.6-1.6) (Figure), corresponding to a sensitivity of 70% and a specificity of 97%. The AUC of the full predictive model was 0.88 (95% CI, 0.80 to 0.95) and became 0.87 after correction for optimism.

A further evaluation of mutation p.R1205H will be necessary to discriminate between type 1 Vicenza and AVWS patients.

Conclusions: VWFpp/VWF:Ag is helpful to discriminate patients with a higher VWF clearance (AVWS or type 1 Vicenza) from those with lower VWF clearance (most VWD).

PB 382 | Lack of Discontinuous von Willebrand Factor Multimer Organization Associated with the c.2269_2270del Mutation in the von Willebrand Factor Gene

V. Daidone, E. Galletta, A. Casonato

University of Padova, Padova, Italy

Background: Reduced levels or abnormalities of von Willebrand factor (VWF), a multimeric glycoprotein involved early in hemostasis, are associated with von Willebrand disease (VWD). We describe a case of VWD lacking in discontinuous VWF multimer organization, except for two oligomers: an ultralarge band and the normal VWF protomer.

Aims: To clarify the disease's etiopathogenesis and genotype/phenotype relationship. sociated with von Willebrand disease (VWD).

Methods: We investigated the patient's hemostatic and genetic profile using DNA and RNA analyses.

Results: The proband, with a history of severe bleeding (bleeding score 30 vs normal 0-3), showed a marked reduction in VWF antigen, function and platelet content (Table 1), and no anti-VWF antibodies. Multimer analysis revealed the absence of most VWF oligomers, with only two bands detectable, the lower one (VWF dimer) and an unusually ultralarge band. DDAVP infusion induced an approximately 4-fold increase in VWF antigen and function, a stronger representation of the two VWF oligomers identified beforehand, but no other multimers became apparent. VWF gene sequencing revealed the homozygous c.2269_2270del mutation in exon 17. Three different RNA species were found associated with this mutation: the r.2269_2270del RNA, giving rise to a truncated VWF protein (p.Leu757Valfs*22); the r.[2269_2270del;2281_2282insAG] RNA, in which the acceptor splicing site of exon 18 is retained; and the r.[2269_2270del;2282_2288del] RNA, resulting in altered residues 757-763 of the VWF propeptide, a condition inducing persistence of the VWF propeptide, accounting for the factor VIII binding defect of the patient's VWF. The proband's parents were heterozygous for the c.2269_2270del mutation and consanguineous (Table 1).

Conclusions: Since the multimers are normally assembled (the ultralarge band was identified), the c.2269_2270del mutation seems to affect the discontinuous, ADAMTS13-dependent, multimer organization.

PB 383 | Surgeries in adults and Children with von Willebrand's Disease - Results from the Ongoing Study Wilate-STATE

S. Halimeh[1], M. Daoud[1], M. Rieke[2], T. Lang[2], J. Kadar[3], S. Alesci[4], J. Koscielny[5], J. Feddern[6], S. Seeger[6]

Background: wilate® is a double virus inactivated VWF/FVIII concentrate with a physiological 1:1 proportion of FVIII:VWF. With the introduction of filling sizes 500/1000 IU in 2012, a non-interventional study (NIS) was started.

Aims: In this study we are aiming to confirm consistency of efficacy and safety data of wilate® used in routine clinical practice with previous study data. The predominant reason for administration of wilate® in this study was to prevent bleeding during and after surgery. For this reason, the subgroup of patients that had surgical procedures was evaluated.

Methods: After obtaining informed consent, patients with hereditary or acquired VWD of any age requiring replacement therapy are eligible to be included in the study. A thorough documentation of anamnestic data is done before study entry. Details on surgical procedures including an efficacy assessment are documented. Surgeries are categorized as "minor" or "major" according to pre-defined criteria considering the haemostatic challenge.

Results: 55 surgeries were performed in 54 patients. The patients' age ranges from 8 months to 74 years, including 37 paediatric patients (≤14 years). All types of VWD were present: 42 (77%) patients have type 1, 10 (19%) type 2, 1 (2%) type 3 and 1 (2%) acquired VWD. Adenotomy and tonsillectomy are the most frequently documented surgeries (58%), which are classified as major operations due to their high bleeding risk. In total, 339,000 IU were administered on 161 exposure days (ED) for surgeries. Per ED, a median of 35.1 and 31.8 IU/kg, for minor and major surgeries were administered respectively. The efficacy was rated excellent/good in 96% of cases based on all surgeries. None of the patients experienced an ADR.

Conclusions: The results of this interim analysis confirm the efficacy and safety of the investigated VWF/FVIII concentrate wilate® in managing bleeding prophylaxis during and after surgical procedure.

PB 384 | Laboratory Diagnosis of von Willebrand Disease Type 2A versus LVAD-Induced Acquired von Willebrand Syndrome

S. Deconinck[1], C. Tersteeg[1], E. Bailleul[2], L. Delrue[2], N. Vandeputte[1], I. Pareyn[1], H. Deckmyn[1], S.F. De Meyer[1], N. Itzhar-Baikian[3], M. Vanderheyden[2], K. Vanhoorelbeke[1]

[1]KU Leuven Campus Kulak Kortrijk, Laboratory for Thrombosis Research, Kortrijk, Belgium, [2]OLV Hospital, Cardiovascular Center Aalst, Aalst, Belgium, [3]Hôpital Lariboisière and EA 3518-Institut Universitaire d'Hématologie, Groupe Hospitalier Saint Louis-Lariboisière, Assistance Publique-Hôpitaux de Paris, Université Paris Diderot, Service d'Hématologie Biologique, Paris, France

Background: Patients suffering from the bleeding disorder von Willebrand disease (VWD) type 2A are diagnosed by severely reduced ratios of VWF:CB/VWF:Ag (< 0.7) and VWF:RCo/VWF:Ag (< 0.7) and severely decreased high molecular weight (HMW) VWF multimers (0-15%). Patients with implanted left ventricular assist devices (LVAD) have a bleeding diathesis diagnosed as acquired von Willebrand syndrome (aVWS). Laboratory diagnosis of a defect in VWF in these patients is less obvious as their VWF:CB/VWF:Ag, VWF:RCo/VWF:Ag ratios and HMW VWF multimers do not always meet the criteria for clear VWD diagnosis.
Aims: Side by side comparison of VWF:CB/VWF:Ag, VWF:RCo/VWF:Ag and HMW VWF multimers of patients with VWD type 2A and LVAD-induced aVWS.
Methods: Plasma samples from 9 VWD type 2A and 14 LVAD patients were analysed for VWF:Ag, VWF:CB and VWF:RCo using ELISA and for VWF multimers using SDS agarose gel electrophoresis and compared to plasma of healthy subjects (NHP). Ratios and percentages are represented as median (with interquartile ranges).
Results: All VWD type 2A patients had a clear laboratory diagnosis of VWD. VWF:CB/VWF:Ag (0.0 (0.0-0.31)) and VWF:RCo/VWF:Ag (0.15 (0.12-0.64)) ratios were clearly below 0.7 and HMW VWF multimers were severely reduced (0.0% (0.0-12.29%) versus 31.00% (29.88-35.73%) in NHP, p< 0.001). In contrast, VWF defects were less pronounced in LVAD patients. These patients had slightly reduced VWF:CB/VWF:Ag (0.76 (0.71-1.03) versus 1.00 (0.98-1.02) in NHP) and normal VWF:RCo/VWF:Ag (1.00 (0.87-1.21) versus 1.01 (0.99-1.04) in NHP) ratios. HMW VWF multimers were moderately decreased (19.66% (16.05-20.43%) compared to 31.00% (29.88-35.73%) in NHP, p< 0.05).
Conclusions: Identifying bleeding linked to defects in VWF is less obvious in LVAD patients as laboratory analysis did not reveal VWF:CB/VWF:Ag and VWF:RCo/VWF:Ag ratios below 0.7. Only HMW VWF multimers are significantly reduced. Hence careful analysis of VWF parameters in LVAD patients is important to recognize aVWS in these patients.

PB 385 | Elevated Levels of vWF Antigen and Activities, Factor VIII and Fibrinogen Inversely Correlated with the Estimated Glomerular Filtration Rate in Patients with Non-dialysis Chronic Kidney Disease

B. Suwanawiboon, R. Chainarongsiriporn, Y. Nakkinkun, R. Chawanasuntorapoj

Faculty of Medicine Siriraj Hosptial, Mahidol University, Bangkok, Thailand

Background: Elevation of von Willebrand factor (vWF) antigen and activity has been shown in end-stage kidney disease and is linked to increase thrombotic risk. However, the data regarding hemostatic derangement in non-dialysis chronic kidney disease (CKD) is limited. Moreover, the relationship between vWF as well as other hemostatic markers and the estimated glomerular filtration rate (eGFR) is unknown.
Aims: To investigate the association between the hemostatic markers and the change of eGFR in non-dialysis CKD patients.
Methods: Patients with stable CKD stage 1 to 5 and healthy controls were prospectively enrolled. Blood was collected to determine the hemostatic parameters and blood groups. Patients with the conditions known to interfere with the test results were excluded. Informed consents were obtained. The study was approved by the ethic committee.
Results: The total of 252 subjects were recruited and categorized into 6 groups (CKD stage 1-5 and the controls). The mean age of CKD patients and the controls were 57±16 and 35±9 years, respectively. Of 210 CKD patients, 109 (51.9%) were female. Diabetic nephropathy was the most common cause of CKD. The mean eGFR by CKD-EPI formula in CKD stage 1-5 and the controls were 105.9±10.5, 74.2±8.2, 45.6±8.5, 23.5±4.2, 9.5±3.3 and 111.2±9.5 ml/min, respectively. Twenty-three (10.9%) and 14 patients (6.7%) with CKD stage

TABLE 1 Hemostatic parameters in patients with chronic kidney disease and healthy controls

Hemostatic Parameters	Healthy Control	CKD stage 1	CKD stage 2	CKD stage 3	CKD stage 4	CKD stage 5	P value
vWF:Ag (IU/dL), mean (SD)	104.9 (35.2)	133.7 (59.6)	141.8 (61)	149.5 (47.1)	144.9 (41.9)	170.2 (62.4)	<.001
vWF:RCo (IU/dL), mean (SD)	84.1 (21.5)	85.0 (29.6)	95.4 (23.8)	92.4 (20.2)	98.1 (18.6)	99.9 (29.8)	.009
vWF:CBA (IU/dL), mean (SD)	83.9 (25.5)	90.2 (35.7)	97.9 (42.6)	107.3 (34.6)	112.0 (40.2)	117.5 (45.4)	<.001
FVIII (IU/dL), mean (SD)	121.2(32.9)	210.7 (107.7)	214 (124.9)	218.7 (51.9)	246.9 (74.5)	290.1 (129.1)	<.001
Fibrinogen activity (mg/dL), mean (SD)	345.4 (102.5)	396.3 (132.7)	393.8 (121.2)	397.2 (145.6)	471.9 (155.5)	490.7 (167.8)	<.001
P-selectin (%), median (range)	30.4 (0.3-70.8)	19.8 (0.52-82.2)	25.6 (1.6-75.3)	7.29 (0.1-72.5)	13.44 (0.3-49.9)	27.94 (0.2-68.0)	<.001
Bleeding time (min), median (range)	4.0 (3.0-9.0)	5.0 (3.0-8.0)	5.0 (3.0-10.0)	4.5 (1.0-16.0)	5.0 (2.0-15.0)	7.0 (1.0-20.0)	<.001

2-5 had prolonged bleeding time (BT) and decreased platelet (plt) P-selectin expression by flow cytometry compared with the controls ($p< .001$ and $p=.021$, respectively). Elevated levels of vWF antigen (vWF:Ag) was found in 84 patients (40%). In addition, the mean levels of vWF:Ag, vWF activities, factor VIII (FVIII) and fibrinogen (FBG) were significantly increased in patients with CKD compared with the controls (p< .001) and inversely correlated with the decreased eGFR.
Conclusions: Elevated levels of vWF antigen and activities, FVIII and FBG were associated with decreased eGFR and suggested the prothrombotic tendency in non-dialysis CKD patients.

PB 386 | Measurement of Platelet von Willebrand Factor (VWF) Antigen Concentration and Activity Using Automated Latex-immunoturbidometric (LIA) Assays

H. Rühl, K.M. Orschulik, J. Müller, J. Oldenburg, B. Pötzsch

University Hospital Bonn, Experimental Hematology and Transfusion Medicine, Bonn, Germany

Background: Easy to perform LIA assays represent the state-of-the-art in measuring VWF antigen levels (VWF:Ag) and activity (VWF:Ac) in plasma. However, they have not yet been applied to analyze VWF in platelets (PLT) on a routine basis.
Aims: To establish a protocol allowing measurement of platelet (PLT) VWF:Ag and VWF:Ac based on commercially available assays (VWF Ag and Innovance VWF Ac, Siemens Healthcare Diagnostics, Marburg, DE) and to establish reference ranges.
Methods: PRP was obtained by centrifugation of ACD-anticoagulated blood at 1,550g x 2 min, followed by sedimentation of the cell pellet at 1,000g x 5 min. Platelets were resuspended in modified Tyrode's solution containing 0.35% BSA and washed twice in the presence of 30 µg/L bivalirudin. For platelet lysis 10% Triton X-100 was added to achieve 0.25% final concentration. After incubation for 1 h at 37°C the lysate was centrifuged at 12,000g x 30 min and the supernatant stored at -80°C before measuring VWF:Ag and VWF:Ac.
Results: The assay was feasible with $>10^8$ PLT obtained from 20 mL whole blood. In 3 measurements of 6 samples an intraassay coefficient of variation (CV) of 6.6% for platelet VWF:Ag (4.6% for VWF:Ac) and an interassay CV of 6.2% for VWF:Ag (4.4% for VWF:Ac) were demonstrated. Storage of ACD-anticoagulated whole blood samples < 4 h before processing did not affect measurement results. After the first washing cycle the supernatant did not contain measurable amounts of VWF. A preserved platelet function before lysis was confirmed using Born aggregometry. In samples from a healthy population (n=29) a platelet VWF:Ag of 0.768±0.144 U/10^9 PLT and VWF:Ac of 0.975±0.228 U/10^9 PLT were determined (mean ± SD). Platelet VWF:Ag and VWF:Ac ranged between 0.529-1.122, and 0.587-1.638 U/10^9 PLT, respectively. Obtained results lay within previously reported ranges.
Conclusions: The here presented method represents a clinically applicable approach to measure platelet VWF which might help to improve understanding and diagnosis of von Willebrand Disease.

PB 387 | Impact of Changes in Laboratory Diagnostic Criteria in the Classification of von Willebrand Disease

P. Batty, J.N. Hodgetts, C. Brown, J. Uprichard

Centre for Haemostasis and Thrombosis, St George's Healthcare NHS Trust, London, United Kingdom

Background: von Willebrand Disease (VWD) is the commonest inherited bleeding disorder. United Kingdom Haemophilia Centre Doctors´ Organisation (UKHCDO) has updated laboratory criteria for VWD diagnosis. Changes include classification of patients with "low von Willebrand Factor (VWF)" (activity 0.3-0.5IU/mL) and changes to VWF antigen:activity ratio in the classification of type 2 VWD. Desmopressin (DDAVP) provides an option for management in type 1 and 2 VWD and knowledge of response helps personalize care.
Aims: To audit compliance of laboratory testing and DDAVP response testing against UKHCDO guidelines.
Methods: Retrospective single center (St George's Hospital) review of all registered VWD patients. Classification, DDAVP testing and laboratory results (VWF activity, antigen, multimers and FVIII:C) were obtained from the electronic records.
Results: 234 patients were registered with VWD; 211(90%) had laboratory testing. Multimer analysis was performed in 75% (n=159), with testing to guide type 2 sub-classification in 88% (49/56). Multimer analyses in 110 non-type 2 VWD patients demonstrated loss of high molecular weight multimers in one patient. Review of results against current guidance changed classification in 41% (n=86); the most common reasons were change to "low VWF" (n=53, 62%) and change from type 1 to 2 VWD (n=9, 10%). Change from type 2 to 1 VWD due to antigen:activity ratios of 0.6-0.7 occurred in two patients. DDAVP response testing was performed and tolerated in 64% (n=136), with full results (pre, 60min and 4-6hours) available for 25% (n=34). Lack of compliance was mainly (83%, n=85) due to only one sample sent post DDAVP.
Conclusions: Changes in diagnostic criteria may affect classification of VWD patients. The impact of reclassifying patients as having "low VWF" is not clear and requires further study. Unselected multimer analysis is associated with appreciable cost, but minimal impact on classification. Closer adherence to sample testing post-DDAVP will identify those with rapid VWF clearance.

PB 388 | Combined Lenalinomide and Dexamethasone Treatment of Multiple Myeloma Cures Acquired von Willebrand Syndrome: A Case Report

C. Paris[1], A. Rauch[1], C. Herbaux[2], C. Caron[1], E. Jeanpierre[1], C. Zawadzki[1], V. Tintillier[1], N. Trillot[1], B. Wibaut[1], J. Goudemand[1], S. Susen[1]

[1]Institut Hématologie Transfusion, Pôle de Biologie Pathologie, CHU Lille, Lille, France, [2]CHU de Lille, Lille, France

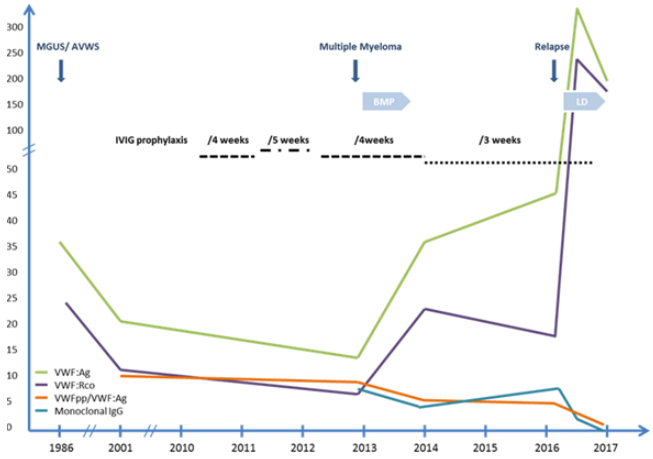

FIGURE 1 Clinical and biological follow up of our patient from 1986 to 2017

Background: Acquired von Willebrand Syndrome (AVWS) is an uncommon bleeding disorder due to acquired von Willebrand Factor (VWF) deficiency. It can be associated with monoclonal gammopathies, through an immunologic mechanism. Treatment of the underlying disorder is essential, and intravenous immunoglobulin (IVIG) proved efficient in IgG MGUS associated AVWS.

Aims: To report the effect of combined Lenalinomide and dexamethasone (LD) in a patient treated for a first relapse of IgG Multiple Myeloma (MM) who developed an AVWS thirty years earlier.

Methods: We report thirty years of clinical and biological follow up of our patient, from AVWS diagnosis to recovery.

Results: Upon diagnosis (in 1986), the patient had no personal or family history of bleeding disorder. His VWF propeptide (VWFpp) /VWF antigen (VWF:Ag) ratio showed an accelerated clearance. VWF concentrates were unable to control bleeding, whereas IVIG proved efficient for several surgeries. He developed 24 years after diagnosis several gastrointestinal bleeding episodes requiring a monthly IVIG prophylaxis. Two years later, he was diagnosed with MM. He received seven Bortezomib cycles combined with Melphalan and Prednisone (BMP) inducing a stable disease and persisting AVWS. IVIG prophylaxis was continued. MM relapsed 4 years later, and he received combined LD chemotherapy. After the first cycle, VWF levels were completely corrected, and a partial response was obtained. Lenalidomide and Dexamethasone therapy was stopped after a total of 8 cycles, achieving a very good partial response. As VWF levels correction was sustained, IVIG prophylaxis could be stopped. The VWFpp/VWF:Ag ratio was normalized.

Conclusions: In our patient, a spectacular plasma VWF level increase followed the first Lenalidomide and dexamethasone cycle, allowing us to stop IVIG prophylaxis. It was reported before in one case of MM and one MGUS. This could be an argument in favour of Lenalinomide as first line treatment of MM associated with AVWS, or even in MGUS with refractory AVWS.

PB 389 | Profile of Mutations Identified in the 3WINTERS-IPS Project on Iranian Patients with Previously Diagnosed Type 3 von Willebrand Disease

L. Baronciani[1], F. Peyvandi[1,2], F. Stufano[1], P. Eshghi[3], Z. Badiee[4], M.-R. Baghaipour[5], U. Budde[6], J. Eikenboom[7], A. Goodeve[8], J. Goudemand[9], H. Hoorfar[10], M. Karimi[11], B. Keikhaei[12], P.M. Mannucci[1,2], I.R. Peake[13], R. Schneppenheim[14], G. Toogeh[15], A. Tosetto[16], S.O.R. Zekavat[17], A.B. Federici[18]

Sacco University Hospital & School of Medicine, Milan, Italy

Background: Patients with type 3 von Willebrand Disease (VWD3) have markedly reduced levels of von Willebrand factor (VWF) and very severe bleeding phenotype. Due to the recessive inheritance pattern, VWD3 is by definition a rare bleeding disorder (1:Million) but its prevalence may increase in countries like Iran with consanguineous marriages.

Aims: To identify the VWF genetic defects in a cohort of Iranian patients with previously diagnosed VWD3 enrolled into the *3WINTERS-IPS project*.

Methods: Patients classified locally as VWD3 were enrolled in the 3WINTERS-IPS study from 7 Iranian sites. Plasma/buffy-coat samples were sent to expert labs to confirm patients laboratory phenotype and to perform molecular analysis. DNA samples were extracted and next generation sequencing was used to search for VWF mutations. All defects identified were confirmed using Sanger sequencing.

Results: DNA samples from 66 patients (F/M=37/29) with a median age of 17 years (range 1-27) were analyzed. Median (range) Bleeding Score was 11.5 (1-33). In 65 cases VWF antigen levels were < 5 IU/

dL. All VWD3 showed 2 mutations, 61 homozygous and 5 compound heterozygous. Among the 132 mutated alleles the following types of variants were identified: 41 nonsense, 35 small deletions, 18 small insertion, 15 missense, 11 splice, 6 indel and 6 large (> 2 exons) deletions. 42 different variants were found. Seven mutations were recurrent and found in 25 patients (21 unrelated individuals). 26 mutations were found only once, each one in single cases in either homozygous and heterozygous state. Seven VWD3 were homozygous and one heterozygous for 5 different missense mutations. One of these mutations was previously reported in VWD3. 2 missense mutations result in loss of cysteine residues and 2 are located in the propeptide region of VWF.

Conclusions: The majority (92%) of the patients were found to be homozygous reflecting a high rate of consanguinity. Seven mutations were recurrent suggesting a common genetic background for a part (38%) of the cohort.

PB 390 | Self-reported Experiences with Menorrhagia in Women with von Willebrand Disease: A Patient-oriented Survey Study

A. Marshall[1], H. Dasari[1], N. Warner[2], D. Grill[2], A. Ashrani[1,2], W. Nichols[1,2], R. Pruthi[1,2]

[1]Mayo Clinic, Division of Hematology, Rochester, United States, [2]Mayo Clinic, Department of Laboratory Medicine and Pathology, Rochester, United States

Background: Women with von Willebrand disease (VWD) often experience bleeding complications in the setting of menstruation. Patient-reported experiences in this setting have not been well characterized.

Aims: To elicit patient-reported menstrual health experiences in women with VWD.

Methods: We conducted a provider-administered survey of women seen at Mayo Clinic for workup and/or management of VWD. Patients were asked to discuss their diagnosis of VWD and questioned about menstrual health and how their VWD had impacted their experience.

Results: Of 103 women diagnosed with VWD, 68 (66%) agreed to participate. For those women, VWD data are shown in the Table. 61 (90%) of women self-reported a history of menorrhagia; for 17 (25%) menorrhagia was their first bleeding event. However, menorrhagia and other bleeding often occurred prior to a diagnosis of VWD (median age of first bleed = 8; overall median age at diagnosis = 24). 35 women (51%) used estrogen-containing oral contraceptives (OCPs) for treatment of menorrhagia. 26 (38%) ultimately underwent hysterectomy for menorrhagia. Other treatments included IUD (5 women, 7%), non-hysterectomy procedure (4, 6%), antifibrinolytic (3, 4%), and DDAVP (1, 1%). 29 (45%) of women reported that their menstrual health was impacted by VWD. 25 of the 29 (86%) discussed their diagnosis (once made) with their physicians, but many reported being “embarrassed” and “ashamed” about discussing menorrhagia and some were “told it was normal” before a diagnosis was made.

Conclusions: Menorrhagia is frequent in women with VWD, yet many women are not diagnosed until well after onset of menorrhagia. Women reported sensations of shame and perceived dismissal regarding menorrhagia. Physicians should be trained to recognize menorrhagia as a possible early symptom of VWD, and ideally, women with VWD should be diagnosed at an early age and managed by a multidisciplinary team to optimize reproductive health experiences and outcomes.

PB 391 | Primary Hemostasis in Severe von Willebrand Disease Patient’s Blood Is Reconstituted in vitro by Ultralarge von Willebrand Factor Multimers

T. Kragh, I. Pekrul, M. Spannagl

Klinikum der Universität München, Transfusion Medicine, Cell Therapeutics and Hemostasis, Munich, Germany

Background: High molecular weight (HMW) von Willebrand factor (VWF) multimers play a crucial role in primary hemostasis. It was shown that ultralarge MW (UL) are even more potent in VWF-platelet interaction. Severe von Willebrand disease (VWD) patients have to be treated with factor supplements.

Aims: We developed an in vitro blood circulation and simulated shear dependent processes of primary hemostasis and showed the influence of recombinant VWF (rVWF) containing UL on VWD patient’s blood in comparison to plasma derived products (pdVWF).

Methods: Blood from healthy donors and severe VWD patients was tested. Then rVWF/+UL or pdVWF products were added (1 IU/ml). First we determined the influence on the blood closure time in the PFA-200. Furthermore we observed the effects of high shear (30k s^{-1}) on VWF spiked citrate anticoagulated whole blood over collagen surface. Both techniques mimic a vascular leasion and measure, respectively visualize functional primary hemostasis and flow dynamic effects of platelet-VWF interaction.

Results: The healthy control group showed normal PFA results (ADP 81-112s; EPI 93-162s). The proportion of aggregate formation in the flow chamber was 5-25% of the surface. Patients lacking large VWF multimers had no closure in the PFA and no observable aggregation in the flow chamber. Adding rVWF/+UL to patient’s blood supra-normalized the blood closure time (ADP 50-70s; EPI 60-90s) and promoted up to 30% aggregate formation on the surfaces. On the contrary pdVWF products hardly changed results when added in the physiological concentration range to the blood samples lacking VWF.

Conclusions: We demonstrated and visualized that UL are important for primary hemostasis and promote VWF-platelet interaction in VWD patient blood leading to normal aggregate formation. UL decreases blood closure time to supra-normal levels irrespectively of the sample’s VWF:Ag value. Equimolar doses of pdVWF do not show these effects. Nonetheless all VWF products show good results in patient application.

PB 392 | Ristocetin Cofactor Latex Immunoassay, High Sensibility to Acquired von Willebrand Disease with Subtle Loss of High Molecular Weight Multimers

B. Montaruli[1], P. Sivera[2], D. Cosseddu[1], C. Fornelli[1], I. Canta[1], N. Renzi[1], O. Ruggia[1], M. Migliardi[1]

[1]AO Ordine Mauriziano, Laboratory Analysis, Turin, Italy, [2]AO Ordine Mauriziano, Hematology, Turin, Italy

Background: The diagnostic tests recommended for Acquired von Willebrand syndrome (AVWS) are the same as those used to diagnose VWD: VWF antigen assays (VWF:Ag), ristocetin cofactor assay (VWF:RCo), collagen binding capacity (VWF:CB), and multimer analysis. In AVWD, a reduced VWF:RCo/Ag ratio of <0.6 indicates inhibitory antibodies or a selective loss or decrease in HMW multimers (HMWM).

Aims: We discuss here 11 suspected AVWD associated with the following different clinical disorders:

2 hypothyroidism, 12 essential thrombocythemia (ET) and 2 autoimmune diseasaes (APS).

Methods: In order to investigate AVWD we performed the following laboratory assays: PFA-100 (Siemens), factor VIII (clotting assay, Werfen), VWF:Ag (latex immunoassay, Werfen), VWF:Activity (latex immunoassay, Werfen) and VWF:RCo [platelets agglutination assay, Bio-Data, Chemiluminescent assay (CliA) Werfen].

Results: After laboratory investigation we confirmed AVWD in both patients with hypothyroidism. On the contrary all ET and APS patients showed normal factor VIII, VWF:Ag and VWF:Act and discordant VWF:RCo depending on the laboratory method utilized for the analysis. In these subjects, VWFRCo latex/VWF:Ag ratio range was 0.2-0.5 while VWF Activity/VWF-Ag, CliA VWF Activity/VWF:Ag and VWF agglutination RCo/VWF:Ag had higher ratio ranges (0.4-0.9). The significant reduction of VWF:RCo/VWF:Ag ratios observed with the latex immunoassay in TE and APL positive patients suggested reduction of HMWM in these patients while the VWF:Activity/Ag ratios obtained with all the other VWF Activity assays utilised were only in some subjects consistent with a reduction.

Conclusions: As described in literature VWF:RCo is often inadequate for detecting AVW abnormality because most of AWD patients present abnormal VWF multimers profile with losses of HMWM and normal VWF:Ag, VWF:RCo and VWF:RCo/VWF:Ag ratios. On the contrary VWFRCo latex immunoassay in our hands showed high sensibility in detecting subtle loss of HMWM.

PB 393 | Von Willebrand Factor Antigen Levels in 255 Patients Previously Diagnosed as VWD Type 3 from the Iranian Republic and Nine European Countries (3WINTERS-IPS Study)

Sacco University Hospital & School of Medicine, Milano, Italy

Background: The phenotypic variation in type 3 von Willebrand disease (VWD) is still poorly understood due to the rarity of the disease.

Aims: The 3WINTERS-IPS study evaluates for the first time the phenotypes and Von Willebrand Factor (VWF) parameters in a large cohort of Iranian and European VWD patients. The variability in VWF:Ag was evaluated.

Methods: The patients stem from seven treatment centers located in the Iranian Republic (111 out of a population of ~ 84,000,000), and 14 treatment centers located in nine European countries (144 out of a population of ~ 360,000,000). All patients were previously diagnosed as type 3 VWD. Accordingly all should have ≤0.05 IU/ml VWF:Ag. Last treatment with VWF concentrates was preferentially commenced more than one week before blood sampling.

Results: In the Iranian patients the VWF:Ag ranged between < 0.01 IU/ml and 0.16 IU/ml. 96% showed values ≤0.05 IU/ml, and 99% ≤0.10 IU/ml. All real type 3 patients were below the lower limit of quantification (LLOQ) of our ELISA (0.008 IU/ml). Those with higher concentrations were either treated (n= 8) or were seemingly compound heterozygous (null-allele together with another VWD type; n= 9).

The European patients showed greater variability. 73% had VWF:Ag ≤0.05 IU/ml, 80% ≤0.1 IU/ml, while 20% were above 0.1 IU/ml. Again, the real type 3 patients (n= 67) with 3 exceptions were below the LLOQ of our ELISA (0.008 IU/ml). Those with higher concentrations were either treated beforehand

(n= 38) or were seemingly compound heterozygous (null-allele together with another VWD type; n= 28). In 3 patients VWF was normal, in 4 patients mildly reduced, and in 3 patients high VWF was unexplained.

Conclusions: The patients from the Iranian Republic are more homogeneous compared to the patients from Europe. The European variability is partly due to the number of patients receiving VWF concentrates. But also different diagnostic procedures in the more centralized Iranian Republic compared to the heterogenous European countries may play a role.

PB 394 | Clinical Characterization of 76 Families with von Willebrand Disease

M.S.S. Namen-Lopes[1], D.G. Chaves[2], S. Brener[2], D.D. Ribeiro[3], C. Velloso-Rodrigues[4], S.M. Rezende[5]

[1]Hospital das Clínicas da Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, [2]Fundação Hemominas, Belo Horizonte, Brazil, [3]Hospital das Clínicas da Universidade Federal de Minas Gerais, Hematologia, Belo Horizonte, Brazil, [4]Universidade Federal de Juiz de Fora - Campus Governador Valadares, Governador Valadares, Brazil, [5]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil

Background: von Willebrand disease (VWD) is the most common inherited bleeding disorder and is classified into types 1, 2 and 3.

Aims: To characterize clinical and laboratory profile of families with VWD registered in a hemophilia treatment center.

Methods: This is a retrospective study. Patients were included at Hemocentro de Belo Horizonte, Minas Gerais, Brazil after signing an informed consent. Variables were obtained from medical records and interview of patients who were diagnosed from 1994-2012. Eligible patients had at least one family member who was also diagnosed with VWD. Laboratory tests included: platelet count, VWF ristocetin cofactor assay (VWF:RCo), VWF antigen level (VWF:Ag), VWF:RCo/VWF:Ag Ratio, FVIII:C and ristocetin-induced platelet aggregation (RIPA). Data was compiled in the Epidata 3.1 and statistical analyses were performed using SSPS 17.0. The study was approved by ethical committees.

Results: Among the 388 patients analyzed, 214 (55.1%) belonging to 76 families, had an average of three affected members per family. Median age was 33 (interquartil range, 19.5-48.0) and most (53.3%) were male. A total of 45 (59.2%), 18 (23.7%), 4 (5.3%) and in 9 (11.8%) families were classified as type 1, 2, 3 and undetermined VWD, respectively. A total of 189 (88.3%) individuals (96 male and 93 female) had personal history of bleeding. Defined as a bleeding score ≥3 for men and ≥5 for women, men accounted for 51.0%(n=49) and 20.4%(n=19) for women. A total of 61/82 (74.4%) women reported data from the first pregnancy, of whom 21/61 (34.4%) informed postpartum bleeding.

Conclusions: We classified 88% of the families with VWD using personal and familial history and routine blood tests for VWD. The remaining 12% will require specialized tests to confirm subtype. Postpartum bleeding was reported by about a third of included women.

PB 395 | Clinical Evaluation of the Sebia Hydragel von Willebrand Factor Assay in Comparison to Electophoresis and Blotting Based Multimer Analysis

H. Seidel[1], P. Westhofen[1], H. Bautista[2], G. Beaulieu[2], G. Nouadje[2], J.P. Kruppenbacher[1]

[1]Centrum für Blutgerinnungsstörungen und Transfusionsmedizin, Bonn, Germany, [2]Sebia, Research and Development department, Lisses, France

Background: Conventional multimer analysis is an extensive personal and time consuming process. However, for diagnosis and (sub)classification of von Willebrand disease (vWD) multimer analysis is required. Recently, a new rapid test (Hydragel 5, Sebia, France) has been developed and is now commercially available.

Aims: We investigated the impact of the Hydragel semi-automated system (Sebia, Lisses France) in comparison to conventional method.

Methods: The Hydragel 5 von Willebrand Multimer (H5vM) kit was used with the Hydrasys 2 Scan instrumentation to perform agarose gel electrophoresis, direct immunofixation, visualisation with peroxidase-labelled antibody and densitometry. Conventional multimer analysis involves preparation low- and intermediate-resolution gels combined with an optimized visualization system. We analyzed 101 patients with suspected or confirmed vWD. Clinical and laboratory phenotype was determined by standardized questionnaire and vWF parameter, respectively.

Results: Kits of H5vM were ready to use and reagents were provided. Results were received within one working day. In total, we found 61% of samples without vWD, 22% with vWD type 1 and 16% with type 2. Discrepant findings between both assays were found in 8%. In two cases H5vM probably failed diagnosing hereditary vWD type 2M and cardial acquired vWD type 2, respectively. In two other cases with discrepant findings, clinically and laboratory based diagnosing of vWD was not sufficient. False-positive results using the conventional assay were suspected likely due to transport artefact in four cases.

Conclusions: The new assay was easy and rapid to perform. The risk of false-positive results, e.g. due to transport, could be excluded. This study confirms the reliability of H5vM in lab's routine. It detects diminution or loss of multimers in the majority of samples, for more complex samples it helps the lab in orientating the decision towards more specialized laboratory tests (i.e. visualization of triplets, genotyping).

PB 396 | Can a One-time von Willebrand Testing Rule out Type 1 von Willebrand Disease in Young Women with Menorrhagia?

E. Morita[1], E. Soundar[1], K. Bruzdoski[1], V. Kostousov[1], J. Teruya[1,2,3], S.-K. Hui[1,2]

[1]*Baylor College of Medicine/Texas Childrens Hospital, Pathology & Immunology, Houston, United States,* [2]*Baylor College of Medicine/Texas Childrens Hospital, Pediatrics, Houston, United States,* [3]*Baylor College of Medicine/Texas Childrens Hospital, Medicine, Houston, United States*

Background: While there are guidelines as to what laboratory values are diagnostic for Type 1 VWD, there is little information regarding how many repeat tests are necessary to rule out the diagnosis.

Aims: The purpose is to determine: 1. the prevalence of Type 1 VWD among young women presented with menorrhagia; 2. the likelihood that Type 1 VWD can be predicted by history and clinical symptoms; 3. if a one-time VWF testing can rule out Type 1 VWD.

Methods: This retrospective observational cohort study from a single center hospital included consecutive post menarcheal females with menorrhagia (< 22 year-old) who had at least 2 VWF studies done between 2010 and 2016. VWF study included Factor VIII, VWF Antigen (VWF:Ag), VWF ristocetin cofactor activity (VWF:RCo), and vWF:RCo/vWF:Ag ratio. Data including age, ABO blood group, family history, along with other bleeding symptoms were collected from medical records and analyzed for information regarding VWD status. Type 1 VWD was defined as having vWF:Ag and/or vWF:Rco < 30% with a ratio of >0.7 and/or normal multimer analysis.

Results: A total of 65 patients were included in this study. Only 6 patients (9%) eventually met laboratory criteria for Type 1 VWD. Family history, blood group, epistaxis, and other bleeding symptoms besides menorrhagia were not statistically associated with Type 1 VWD in the first or subsequent studies. There was no difference in number of repeat study between the two groups (p=0.73). Of note, among the 6 patients who met the laboratory criteria for Type 1 VWD, had the median value of 42% for VWF:Ag and 33% for VWF:RCo on all testing combined.

Conclusions: Our study suggested that there was a high prevalence (9%) of Type 1 VWD among young women with menorrhagia. However, history and clinical symptoms and even the number of repeat testing cannot predict the likelihood of Type 1 VWD. VWF:Ag >54% and VWF:RCo >42% makes Type 1 VWD unlikely and subsequent studies likely unproductive.

TABLE 1 VWF:Ag and VWF:RCo value for Type 1 VWD patients vs. non-VWD patients

	VWF Antigen, % Median(IQR)	VWF Activity, % Median(IQR)
Patients with Type 1 VWD diagnosis	42(35-54)	33(30-42)
Patients without Type 1 VWD diagnosis	72(57-110)	68(48-289)

PB 397 | Screening of von Willebrand´s Disease in a Region of High Consanguinity

Y. Ouarhlent, H. Laiadhi, M.R. Makhloufi, R. Chafai, S. Chichoune

CHU Batna, Hematology, Batna, Algeria

Background: Von Willebrand disease (VWD) is the most common constitutional abnormality of hemostasis. It is related to a quantitative abnormality (types 1 and 3) or qualitative Willebrand factor
(type 2) Autosomal dominant or recessive transmission • Extremely heterogeneous phenotypically and genotypically.
VWD may be more complicated to diagnose in women because abundant and prolonged menstruation is often wrongly attributed to a gynecological disorder and also the epistaxis attributed to a local cause, so this disease must absolutely be diagnosed.

Aims: Identification of people with Von Willebrand disease who have not yet been diagnosed or treated appropriately.

Methods: It is a transversal study in the maternity and consultations of ORL from 1 September to 30 January 2017. A standard haemostasis assessment with a study of the Willebrand complex (FVIII: C, VWF: Ag and VWF: RCo), blood grouping and hemogram are performed Diagnosis of type 2B is suspected in association with a combination of VWF: RCo / VWF: Ag < 0.7 with thrombocytopenia.

Results: Screening :26 cases of VWD are diagnosed including 17 women and 9 men The average age at diagnosis is 17 years [5-49 years]. The sex ratio M / F is 0.5, five patients are classified as type 3 (19.2%) 7 type 2 (26.9%) and 14 type 1(53.8%).

Conclusions: Von Willebrand disease screening is vital Knowing the prevalence, while knowing that Willebrand disease is the most common hereditary haemorrhagic disease, the complexity of the diagnosis partly explains why this disease remains less well known than hemophilia.

A second transvesal study is scheduled from1 May to 30 November, screening will be carried out as follows, patients will be identified through awareness or education activities or through active research by contacting patients already known to try whether the family members are suffering from disorders of hemostasis and have not been diagnosed yet.

PB 398 | Management of a Spontaneous Ileo-psoas Haematoma in a Girl with Type 3 von Willebrand Disease and Alloantibodies to von Willebrand Factor

C. Ambaglio[1], G. Giorgiani[2], N. Decembrino[2], F. Zane[1], M. Russo[1], C. Sacco[1], E. Genini[3], P.S. Preti[1], M. Zecca[2], G. Gamba[1]

[1]Fondazione IRCCS Policlinico San Matteo, Department of Internal Medicine, Haemophilia Centre, Pavia, Italy, [2]Fondazione IRCCS Policlinico San Matteo, Department of Pediatric Hematology - Oncology, Pavia, Italy, [3]Fondazione IRCCS Policlinico San Matteo, Laboratory Analysis Service, Pavia, Italy

Background: Type 3 von Willebrand disease is caracterized by undetectable levels of von Willebrand factor (VWF) and very low levels of FVIII; affected patients experience severe spontaneous bleeding tendency since childhood. In 5-10% of patients alloantibodies can develop against VWF causing loss of haemostatic response to infused concentrates but also sometimes leading to anaphylactic reactions. In such cases a limited but favourable experience has been reported on the use of recombinant FVIII concentrates (rFVIII).

Aims: We describe the case of a 12 years old girl with type 3 von Willebrand disease and inhibitors.

Methods: At the age of 6 years old she presented an anaphylactic reaction after the infusion of FVIII concentrates rich in VWF, with arousal of inhibitors against VWF. She was then treated on demand with recombinant FVIII concentrates. On December 2016 she attended Emergency Room because of arousal of intense left inguinal pain, she denied any thrauma. Her PTTr was 1.7, VWF:Ag < 3 IU/dL VWF:RCo < 4 IU/dL and FVIII:C 3.9 IU/dL, FVIII inhibitors were 0.23 BU/ml and VWF inhibitors were 1.96 BU/ml.

The CT showed a large haematoma in her left ileo-psoas muscle.

Results: The patient was admitted in hospital, she was anaemic; rFVIII concentrate at 60 IU/Kg was started every six hours but in 24 hours anaemia worsened with the need of transfusion, so we started continuous infusion of octocog alfa: a bolus of 60 IU/Kg was followed by continuous infusion 30 IU/Kg/h. Haemoglobin promptly was stabilized, levels of FVIII were maintained around 40 IU/dL. Pain and leg function improved in few days. Infusion speed was reduced after three days to 20 IU/Kg/h, till the stop after two more days.

Conclusions: Alloantibodies against vWF in type 3 von Willebrand disease are a rare complication after the treatment with vWF rich concentrates. With this case report we can confirm that, as previously described in few cases, the continuous infusion of recombinant FVIII concentrates may be useful, as an alternative to bypassing agents.

PB 943 | Genetic Risk Stratification to Minimize Inhibitor Risk with the Use of Recombinant Factor VIII Concentrates: A SIPPET Analysis

F.R. Rosendaal[1], R. Palla[2], I. Garagiola[2], P.M. Mannucci[2,3], F. Peyvandi[2,3], SIPPET Study group

[1]Leiden University Medical Center, Department of Clinical Epidemiology, Leiden, The Netherlands, [2]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Angelo Bianchi Bonomi Haemophilia and Thrombosis Center, Milan, Italy, [3]Università degli Studi di Milano, Department of Pathophysiology and Transplantation, Milan, Italy

Background: The development of neutralizing antibodies against factor VIII is a serious complication of hemophilia A treatment. A recent randomized trial showed a higher risk of inhibitors with recombinant factor VIII (rFVIII) than plasma-derived (pdFVIII) concentrates (44.5% vs 26.8%, hazard ratio 1.87 (95% confidence interval (CI95) 1.17-2.96). Given the high risk with rFVIII, it has been suggested to restrict the use of rFVIII to low risk patients.

Aims: Utility of treatment with rFVIII or pdFVIII based on genetic risk factors.

Methods: SIPPET is a randomized trial in which 251 previously untreated or minimally treated patients were treated exclusively with a concentrate from the class of rFVIII or pdFVIII. Patients were tested for inhibitors before entry and at regular intervals during follow-up. Patients were classified at high risk when they carried a null mutation (inversion, large deletion, frameshift, nonsense mutation) in the F8 gene and as low risk when they carried another causative variant (missense, splice site, polymorphisms). We estimated cumulative incidences, hazard ratios and numbers needed to harm (NNH).

Results: Among 251 patients, 76 developed an inhibitor (all > 0.7 Bethesda Units (BU)) of which 50 were high-titer (> 5 BU). High and low risk patients were equally distributed over the two arms of the trial, i.e., 96 out of 126 treated with rFVIII were high risk, and 101 out of 125 treated with pdFVIII. Among high risk patients, CI was 30.7% with pdFVIII, and 46.5% with rFVIII (risk difference 15.8%). Among low risk patients, no inhibitors developed with pdFVIII, whereas the cumulative incidence was 43.2% with rFVIII (risk difference 43.2%). This implies that the Number Needed to Harm for rFVIII was 5.6 overall, 6.3 for high-risk patients, and 2.3 in low risk patients.

Conclusions: Risk stratification by the type of F8 mutation does not identify patients with hemophilia A who have a low inhibitor risk when exposed to rFVIII.

PB 944 | Pharmacokinetics of Recombinant Fusion Protein Linking Activated Factor VIIa to Human Albumin (rVIIa-FP), Eptacog Alfa and Plasma-derived Factor VII in Patients with Congenital FVII Deficiency
