DIEF Seminar, October 2019

The problem (again)

We consider the unconstrained nonlinear programming problem:

minimize
$$f(x)$$

for $x \in \mathbb{R}^n$ and $f : \mathbb{R}^n \to \mathbb{R}$ smooth.

For now, focus on the

unconstrained case

but we are also interested in the case featuring

inexpensive constraints

An overestimating model

Note the following: if

 f has gradient g and globally Lipschitz continuous Hessian H with constant 2L

Taylor, Cauchy-Schwarz and Lipschitz imply

$$f(x+s) = f(x) + \langle s, g(x) \rangle + \frac{1}{2} \langle s, H(x)s \rangle + \int_0^1 (1-\alpha) \langle s, [H(x+\alpha s) - H(x)]s \rangle d\alpha \leq \underbrace{f(x) + \langle s, g(x) \rangle + \frac{1}{2} \langle s, H(x)s \rangle + \frac{1}{3}L ||s||_2^3}_{m(s)}$$

 \implies reducing m from s = 0 improves f since m(0) = f(x).

Griewank, 1981

Approximate model minimization

Lipschitz constant L unknown \Rightarrow replace by adaptive parameter σ_k in the model :

$$m(s) \stackrel{\text{def}}{=} f(x) + s^T g(x) + \frac{1}{2} s^T H(x) s + \frac{1}{3} \sigma_k ||s||_2^3 = T_{f,2}(x,s) + \frac{1}{3} \sigma_k ||s||_2^3$$

Computation of the step:

• minimize m(s) until an approximate first-order minimizer is obtained:

$$\|\nabla_s m(s)\| \le \kappa_{\text{stop}} \|s\|^2$$

Note: no global optimization involved.

4□ > 4□ > 4□ > 4□ > 4□ > 900

Second-order Adaptive Regularization (AR2)

Algorithm 1.1: The AR2 Algorithm

Step 0: Initialization: x_0 and $\sigma_0 > 0$ given. Set k = 0

Step 1: Termination: If $||g_k|| \le \epsilon$, terminate.

Step 2: Step computation:

Compute s_k such that $m_k(s_k) \leq m_k(0)$ and $\|\nabla_s m(s_k)\| \leq \kappa_{\text{stoo}} \|s_k\|^2$.

Step 3: Step acceptance:

Compute
$$\rho_k = \frac{f(x_k) - f(x_k + s_k)}{f(x_k) - T_{f,2}(x_k, s_k)}$$

and set
$$x_{k+1} = \begin{cases} x_k + s_k & \text{if } \rho_k > 0.1 \\ x_k & \text{otherwise} \end{cases}$$

Step 4: Update the regularization parameter:

$$\sigma_{k+1} \in \begin{cases} \left[\sigma_{\min}, \sigma_k\right] &= \frac{1}{2}\sigma_k & \text{if } \rho_k > 0.9 \\ \left[\sigma_k, \gamma_1 \sigma_k\right] &= \sigma_k & \text{if } 0.1 \leq \rho_k \leq 0.9 \\ \left[\gamma_1 \sigma_k, \gamma_2 \sigma_k\right] &= 2\sigma_k & \text{otherwise} \end{cases} \quad \begin{array}{l} \textit{very successful} \\ \textit{unsuccessful} \\ \textit{unsuccessful} \\ \end{array}$$

Evaluation complexity: an important result

How many function evaluations (iterations) are needed to ensure that

$$\|g_k\| \leq \epsilon$$
?

If H is globally Lipschitz and the s-rule is applied, the AR2 algorithm requires at most

$$\left\lceil \frac{\kappa_{\mathrm{S}}}{\epsilon^{3/2}} \right
ceil$$
 evaluations

for some κ_S independent of ϵ .

"Nesterov & Polyak".

Cartis, Gould, T., 2011, Birgin, Gardenghi, Martinez, Santos, T., 2017

Note: an $O(\epsilon^{-3})$ bound holds for convergence to second-order critical points.

Evaluation complexity: proof (1)

$$f(x_k + s_k) \le T_{f,2}(x_k, s_k) + \frac{L_f}{p} ||s_k||^3$$
$$||g(x_k + s_k) - \nabla_s T_{f,2}(x_k, s_k)|| \le L_f ||s_k||^2$$

Lipschitz continuity of $H(x) = \nabla_x^2 f(x)$

$$\forall k \geq 0 \qquad f(x_k) - T_{f,2}(x_k, s_k) \geq \frac{1}{6} \sigma_{\min} ||s_k||^3$$

$$f(x_k) = m_k(0) \ge m_k(s_k) = T_{f,2}(x_k, s_k) + \frac{1}{6}\sigma_k ||s_k||^3$$

Evaluation complexity: proof (2)

$$\exists \sigma_{\mathsf{max}} \quad \forall k \geq 0 \qquad \sigma_k \leq \sigma_{\mathsf{max}}$$

Assume that
$$\sigma_k \geq \frac{L_f(p+1)}{p(1-\eta_2)}$$
. Then

$$|
ho_k - 1| \le \frac{|f(x_k + s_k) - T_{f,2}(x_k, s_k)|}{|T_{f,2}(x_k, 0) - T_{f,2}(x_k, s_k)|} \le \frac{L_f(p+1)}{p \, \sigma_k} \le 1 - \eta_2$$

and thus $\rho_k \geq \eta_2$ and $\sigma_{k+1} \leq \sigma_k$.

Evaluation complexity: proof (3)

$$\forall k \; ext{successful} \quad \|s_k\| \geq \left(\frac{\|g(x_{k+1})\|}{L_f + \kappa_{ ext{stop}} + \sigma_{ ext{max}}}
ight)^{rac{1}{2}}$$

$$||g(x_{k} + s_{k})|| \leq ||g(x_{k} + s_{k}) - \nabla_{s} T_{f,2}(x_{k}, s_{k})|| + ||\nabla_{s} T_{f,2}(x_{k}, s_{k}) + \sigma_{k}||s_{k}||s_{k}|| + \sigma_{k}||s_{k}||^{2} \leq L_{f}||s_{k}||^{2} + ||\nabla_{s} m(s_{k})|| + \sigma_{k}||s_{k}||^{2} \leq [L_{f} + \kappa_{\text{stop}} + \sigma_{k}] ||s_{k}||^{2}$$

Evaluation complexity: proof (4)

$$\|g(x_{k+1})\| \le \epsilon$$
 after at most $\frac{f(x_0) - f_{low}}{\kappa} \epsilon^{-3/2}$ successful iterations

Let $S_k = \{j \le k \ge 0 \mid \text{iteration } j \text{ is successful} \}.$

$$f(x_{0}) - f_{low} \geq f(x_{0}) - f(x_{k+1}) \geq \sum_{i \in \mathcal{S}_{k}} \left[f(x_{i}) - f(x_{i} + s_{i}) \right]$$

$$\geq \frac{1}{10} \sum_{i \in \mathcal{S}_{k}} \left[f(x_{i}) - T_{f,2}(x_{i}, s_{i}) \right] \geq |\mathcal{S}_{k}| \frac{\sigma_{\min}}{60} \min_{i} ||s_{i}||^{3}$$

$$\geq |\mathcal{S}_{k}| \frac{\sigma_{\min}}{60 \left(L_{f} + \kappa_{\text{stop}} + \sigma_{\max} \right)^{3/2}} \min_{i} ||g(x_{i+1})||^{3/2}$$

$$\geq |\mathcal{S}_{k}| \frac{\sigma_{\min}}{60 \left(L_{f} + \kappa_{\text{stop}} + \sigma_{\max} \right)^{3/2}} e^{3/2}$$

Evaluation complexity: proof (5)

$$k \leq \kappa_u |\mathcal{S}_k|, \ \ \text{where} \ \ \kappa_u \stackrel{\text{def}}{=} \left(1 + \frac{|\log \gamma_1|}{\log \gamma_2}\right) + \frac{1}{\log \gamma_2} \log \left(\frac{\sigma_{\max}}{\sigma_0}\right),$$

 $\sigma_k \in [\sigma_{\min}, \sigma_{\max}] + \text{mechanism of the } \sigma_k \text{ update.}$

$$\|g(x_{k+1})\| \le \epsilon$$
 after at most $\frac{f(x_0) - f_{low}}{\kappa} \epsilon^{-3/2}$ successful iterations

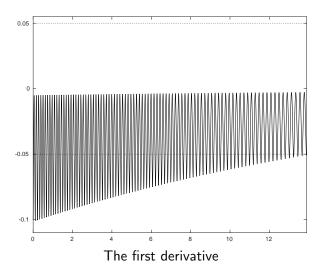

One evaluation per iteration (successful or unsuccessuful).

Evaluation complexity: sharpness

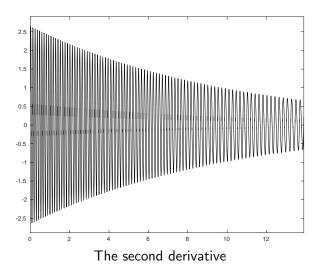

Is the bound in $O(\epsilon^{-3/2})$ sharp? YES!!!

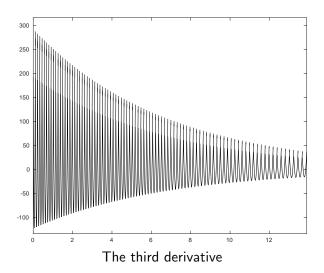

An example of slow AR2 (2)

An example of slow AR2 (3)

An example of slow AR2 (4)

Slow steepest descent (1)

The steepest descent method with requires at most

$$\left\lceil \frac{\kappa_{\mathrm{C}}}{\epsilon^2} \right\rceil$$
 evaluations

for obtaining $||g_k|| \le \epsilon$.

Nesterov

Sharp??? YES

Newton's method (when convergent) requires at most

$$O(\epsilon^{-2})$$
 evaluations

for obtaining
$$||g_k|| \le \epsilon$$
 !!!!

High-order models for first-order points (1)

What happens if one considers the model

$$m_k(s) = T_{f,p}(x_k, s) + \frac{\sigma_k}{p!} ||s||_2^{p+1}$$

where

$$T_{f,p}(x,s) = f(x) + \sum_{j=1}^{p} \frac{1}{j!} \nabla_{x}^{j} f(x)[s]^{j}$$

terminating the step computation when

$$\|\nabla_s m(s_k)\| \leq \kappa_{\text{stop}} \|s_k\|^p$$

now the first-order ARp method!

High-order models for first-order points (2)

unconstrained ϵ -approximate 1rst-order-necessary minimizer after at most

$$\frac{f(x_0) - f_{\text{low}}}{\kappa} e^{-\frac{p+1}{p}}$$

function and gradient evaluations

Birgin, Gardhenghi, Martinez, Santos, T., 2017

Technique of proof very similar to that used above.

Derivative tensors for partially separable problems

f is partially separable if

$$f(x) = \sum_{i=1}^m f_i(U_i x) = \sum_{i=1}^m f_i(x_i)$$
 where $\operatorname{rank}(U_i) \ll n$

Then

$$\nabla_x^p f(x)[s]^p = \sum_{i=1}^m \nabla_{x_i}^p f_i(x)[U_i x]^p$$

Note:

$$size(\nabla^p_{x_i}f_i(x)) \ll size(\nabla^p_xf(x))!!!$$

One then wonders...

If one uses a model of degree p ($T_{f,p}(x,s)$), why be satisfied with first- or second-order critical points???

What do we mean by critical points of order larger than 2 ???

What are necessary optimality conditions for order larger than 2 ???

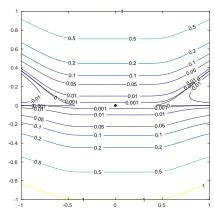

Not an obvious question!

A sobering example (1)

Consider the unconstrained minimization of

$$f(x_1, x_2) = \begin{cases} x_2 (x_2 - e^{-1/x_1^2}) & \text{if } x_1 \neq 0, \\ x_2^2 & \text{if } x_1 = 0, \end{cases}$$

Peano (1884), Hancock (1917)

A sobering example (2)

Conclusions:

- looking at optimality along straight lines is not enough
- depending on Taylor's expansion for necessary conditions is not always possible

Even worse:

$$f(x_1, x_2) = \begin{cases} x_2 \left(x_2 - \sin(1/x_1)e^{-1/x_1^2} \right) & \text{if } x_1 \neq 0, \\ x_2^2 & \text{if } x_1 = 0, \end{cases}$$

(no continuous descent path from 0, although not a local minimizer!!!)

Hopeless?

A new (approximate) optimality measure

Define, for some small $\delta > 0$, $(\mathcal{F} = \mathbb{R}^n)$

$$\phi_{f,q}^{\delta}(x) \stackrel{\text{def}}{=} f(x) - \underset{\|d\| \leq \delta}{\mathsf{globmin}} T_{f,q}(x,d),$$

and

$$\chi_q(\delta) \stackrel{\mathrm{def}}{=} \sum_{\ell=1}^q \frac{\delta^\ell}{\ell!}$$

x is a (ϵ, δ) -approximate qth-order-necessary minimizer

$$\phi_{f,q}^{\delta}(x) \le \epsilon \, \chi_q(\delta)$$

- $\phi_{f,q}^{\delta}(x)$ is continuous as a function of x for all q.
- $\phi_{f,g}^{\delta}(x) = o(\chi_g(\delta))$ is a necessary optimality condition

Approximate unconstrained optimality

Familiar results for low orders: when q=1

$$\frac{\phi_{f,1}^{\delta}(x) = \|\nabla_{x}f(x)\| \, \delta}{\chi_{1}(\delta) = \delta} \right\} \Rightarrow \|\nabla_{x}f(x)\| \le \epsilon$$

while, for q = 2,

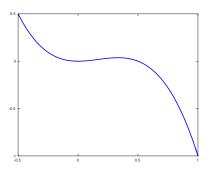

Suppose that $\nabla_x^q f$ is β -Hölder continous near x_{ϵ} and that

$$\phi_{f,q}^{\delta}(x_{\epsilon}) \leq \epsilon \chi_{q}(\delta).$$

$$f(x_{\epsilon}+d) \geq f(x_{\epsilon}) - 2\epsilon \chi_q(\delta) \quad \forall d \mid \|d\| \leq \min \left[\delta, \left(\frac{(q+1)! \, \epsilon}{L_{f,q}} \right)^{\frac{1}{q-1+\beta}} \right]$$

The need for δ

Let
$$x = 0$$
 and $T(x, s) = s^2 - 2s^3$

Then

- the origin is a local minimizer of T
- $\phi_{T,3}^1(1) = -1 \neq 0$ but $\phi_{T,3}^{\delta}(x) = 0$ for all $\delta \leq 4/7$.

ロ ト 4回 ト 4 三 ト 4 三 ・ り Q (~)

Introducing inexpensive constraints

Constraints are inexpensive

their evaluation/enforcement has negligible cost (compared with that of evaluating f)

- evaluation complexity for the constrained problem well measured in counting evaluations of f and its derivatives
- many well-known and important examples
 - bound constraints
 - convex constraints with cheap projections
 - parametric constraints
 - ...

From now on: $\mathcal{F} \stackrel{\mathrm{def}}{=}$ (inexpensive) feasible set

A very general optimization problem

Our aim:

Compute an (ϵ, δ) -approximate qth-order-necessary minimizer for the problem

$$\min_{x \in \mathcal{F}} f(x)$$

where

- $p \ge q \ge 1$,
- $\nabla^p_x f(x)$ is β -Hölder continuous $(\beta \in (0,1])$
- ullet \mathcal{F} is an inexpensive feasible set

Note:

- $oldsymbol{0}$ no convexity assumption on \mathcal{F} (not even connectivity)
- **3** reduces to Lipschitz continuous $\nabla_x^p f(x)$ when $\beta = 1$.

A (theoretical) regularization algorithm

Algorithm 3.1: The ARp algorithm for qth-order optimality

Step 0: Initialization: x_0 , δ_{-1} and $\sigma_0 > 0$ given. Set k = 0

Step 1: Termination: If $\phi_{f,q}^{\delta_{k-1}}(x_k) \leq \epsilon \chi_q(\delta)$, terminate.

Step 2: Step computation:

Compute* s_k such that $x_k + s_k \in \mathcal{F}$, $m_k(s_k) < m_k(0)$ and

$$\|s_k\| \ge \kappa_s \epsilon^{\frac{1}{p-q+\beta}} \text{ or } \phi_{m_k,q}^{\delta_k}(x_k + s_k) \le \frac{\theta \|s_k\|^{p-q+\beta}}{(p-q+\beta)!} \chi_q(\delta_k)$$

Step 3: Step acceptance:

Compute
$$\rho_k = \frac{f(x_k) - f(x_k + s_k)}{f(x_k) - T_{f,p}(x_k, s_k)}$$

and set $x_{k+1} = x_k + s_k$ if $\rho_k > 0.1$ or $x_{k+1} = x_k$ otherwise.

Step 4: Update the regularization parameter:

$$\sigma_{k+1} \in \begin{cases} \left[\sigma_{\min}, \sigma_k\right] &= \frac{1}{2}\sigma_k \text{ if } \rho_k > 0.9 \\ \left[\sigma_k, \gamma_1 \sigma_k\right] &= \sigma_k \text{ if } 0.1 \leq \rho_k \leq 0.9 \text{ successful} \\ \left[\gamma_1 \sigma_k, \gamma_2 \sigma_k\right] &= 2\sigma_k \text{ otherwise } \text{unsuccessful} \end{cases}$$

Finding a step

Compute*: does a suitable step always exists?

Either

$$globmin_{k} m_k(s) = 0$$

$$x_k + s \in \mathcal{F}$$

or there exists $\delta_k \in (0,1]$ and a neighbourhood of

$$s_k^* = \underset{x_k+s \in \mathcal{F}}{\operatorname{arg globmin}} m_k(s)$$

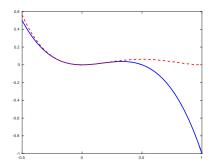

such that, for all s in that neighbourhood

$$m_k(s) < m_k(0)$$
 and $\phi_{m_k,q}^{\delta_k}(x_k+s) \le \epsilon \chi_q(\delta_k)$.

Note: (ϵ, δ) -approximate *p*th-order-necessary minimizer in the first case!

Need for the first case

Let
$$x = 0$$
, $T(x, s) = s^2 - 2s^3$ (as above) and $\sigma_k = 24$, yielding
$$m(s) = s^2 - 2s^3 + s^4 = s^2(s-1)^2 > 0$$

Further comments on the algorithm

- **1** when $||s_k|| \ge \kappa_s \, \epsilon^{\frac{1}{p-q+\beta}}$, no need for computing $\phi_{m_k,q}^{\delta_k}(x_k+s_k)!$
- ② for p = 1 and p = 2, computing it is easy
 - p = 1: analytic solution
 - p = 2: trust-region subproblem with unit radius
 - ⇒ practical algorithm
- § for p > 2: hard problem in general
 - ⇒ conceptual algorithm

The main result

The ARp algorithm finds an (ϵ, δ) -approximate qth-ordernecessary minimizer for the problem

$$\min_{x \in \mathcal{F}} f(x)$$

in at most

$$O\left(\epsilon^{-rac{p+eta}{p-q+eta}}
ight)$$

iterations and evaluations of the objective function and its p first derivatives. Moreover, this bound is sharp.

What this theorem does

 generalizes ALL known complexity results for regularization methods to

arbitrary degree $\emph{p},$ arbitrary order \emph{q} and arbitrary smoothness $\emph{p} + \beta$

- applies to very general constrained problems
- generalizes the lower complexity bound of Carmon at al., 2018, to arbitrary dimension, arbitrary order and to constrained problems
- provides a considerably better complexity order than the bound

$$O\left(\epsilon^{-(q+1)}\right)$$

known for unconstrained trust-region algorithms (Cartis, Gould, T., 2017) Note: linesearch methods all fail for q > 3!

is provably optimal within a wide class of algorithms (Cartis, Gould, T., 2018 for $p \le 2$)

A slide from the ICM in August 2018...

Where do we stand (for convexly constrained problems)?

Complexity of optimality order q as a function of model degree p

Trust-region algo

Regularization algo

[] for unconstrained problems only!

Moving on: allowing inexact evaluations

A common observation:

In many applications, it is necessary/useful to evaluate f(x) and/or $\nabla_x^j f(x)$ inexactly

- complicated computations involving truncated iterative processes
- variable accuracy schemes
- sampling techniques (machine learning)
- noise
- **⑤** ...

Focus on the case where f and all its derivatives are inexact

The dynamic accuracy framework (1)

How are the values of f(x) and $\nabla_x^j f(x)$ used in the ARp algorithm?

• $f(x_k)$ and $f(x_k + s_k)$ are used in order to accept/reject the step when computing

$$\rho_k = \frac{f(x_k) - f(x_k + s_k)}{f(x_k) - T_{f,p}(x_k, s_k)} = \frac{f(x_k) - f(x_k + s_k)}{\Delta T_{f,p}(x_k, s_k)}$$

where

$$\Delta T_{f,p}(x_k, s_k) = f(x_k) - T_{f,p}(x_k, s_k) = -\sum_{\ell=1}^{p} \nabla_x^p f(x_k)[s_k]^p$$

is the Taylor's increment

$$\Delta T_{f,p}(x_k, s_k)$$
 is independent of $f(x_k)$

Hence we need

Absolute error in
$$f(x_k)$$
 and $f(x_k + s_k)$ " \leq " $\Delta T_{f,p}(x_k, s_k)$

The dynamic accuracy framework (2)

- $\nabla_x^j f(x_k)$ used in
 - computing

$$\begin{aligned} \phi_{f,q}^{\delta_{k-1}}(x_k) &= \min \left\{ 0, \operatorname{globmin}_{\substack{x_k + d \in \mathcal{F} \\ \|d\| \leq \delta}} \left[f(x_k) - T_{f,q}(x_k, d) \right] \right\} \\ &= \max \left\{ 0, \operatorname{globmax}_{\substack{x_k + d \in \mathcal{F} \\ \|d\| \leq \delta}} \Delta T_{f,q}(x_k, d) \right\} \end{aligned}$$

• defining the model $m_k(s)$ which is minimized to compute s_k , i.e.

$$\max_{x_k+s\in\mathcal{F}}\Delta T_{f,p}(x_k,s)$$

computing

$$\phi_{f,q}^{\delta_{k-1}}(x_k) = \max\left\{0, \operatorname{globmax} \Delta T_{m_k,q}(x_k,d)
ight\} egin{array}{c} x_k + d \in \mathcal{F} \\ \|d\| < \delta \end{array}$$

Relative error in $\Delta T_{\bullet,\bullet} < 1$

The dynamic accuracy framework (3)

Denote inexact quantities with overbars.

Note: $\overline{\Delta T}_{\bullet,\bullet} \geq 0$

Accuracy conditions $(\kappa_1, \kappa_2 \in [0, 1))$:

$$\max \left[|\overline{f}(x_k) - f(x_k)|, |\overline{f}(x_k + s_k) - f(x_k)| \right] \le \kappa_1 \overline{\Delta T}_{f,p}(x_k, s_k)$$
$$|\overline{\Delta T}_{\bullet, \bullet} - \Delta T_{\bullet, \bullet}| \le \kappa_2 \overline{\Delta T}_{\bullet, \bullet}$$

The latter relative error bound can be obtained by

iteratively decreasing the absolute error until satisfied

Only impose absolute error levels ε on $\{\nabla_{x}^{j}f(x_{k})\}_{j=0}^{p}$

The ARpDA algorithm

Algorithm 4.1: The ARpDA algorithm for qth-order optimality

Step 0: Initialization: x_0 , δ_{-1} and $\sigma_0 > 0$ given. Set k = 0

Step 1: Termination: If $\overline{\phi}_{f,q}^{\delta_{k-1}}(x_k) \leq \frac{1}{2} \epsilon \chi_q(\delta)$, terminate.

Step 2: Step computation:

Compute* s_k such that $x_k + s_k \in \mathcal{F}$, $m_k(s_k) < m_k(0)$ and

$$\|s_k\| \ge \kappa_s \, \epsilon^{rac{1}{p-q+eta}} \quad ext{or} \quad \overline{\phi}_{m_k,q}^{\delta_k}(x_k+s_k) \le rac{ heta \, \|s_k\|^{p-q+eta}}{(p-q+eta)!} \chi_q(\delta_k)$$

Step 3: Step acceptance:

Compute
$$\rho_k = \frac{\overline{f}(x_k) - \overline{f}(x_k + s_k)}{\overline{\Delta T}_{f,p}(x_k, s_k)}$$

and set $x_{k+1} = x_k + s_k$ if $\rho_k > 0.1$ or $x_{k+1} = x_k$ otherwise.

Step 4: Update the regularization parameter:

(as in ARp)

Evaluation complexity for the ARpDA algorithm

And then (sweeping some dust under the carpet)...

The ARpDA algorithm finds an (ϵ, δ) -approximate qth-order-necessary minimizer for the problem

$$\min_{x \in \mathcal{F}} f(x)$$

in at most

$$O\left(\epsilon^{-rac{p+eta}{p-q+eta}}
ight)$$

iterations (inexact) evaluations of the objective function, and at most

$$O\left(|\log(\epsilon)| + \epsilon^{-rac{p+eta}{p-q+eta}}
ight)$$

(inexact) evaluations of its p first derivatives.

A probabilistic complexity bound

Suppose that absolute evaluation errors are random and independent, and that, for given ε ,

$$Pr\left[\|\overline{\nabla_{x}^{j}f}(x_{k}) - \nabla_{x}^{j}f(x_{k})\| \leq \varepsilon\right] \geq 1 - t \quad (j \in \{1, \dots, p\})$$

where

$$t = O\left(\frac{t_{\text{final}} e^{\frac{p+1}{p-q+\beta}}}{p+q+2}\right)$$

Then the ARpDA algorithm finds an (ϵ,δ) -approximate qth-order-necessary minimizer for the problem $\min_{x\in\mathcal{F}}f(x)$ in at most $O\left(\epsilon^{-\frac{p+\beta}{p-q+\beta}}\right)$ iterations and (inexact) evaluations of the objective function, and at most $O\left(|\log(\epsilon)|+\epsilon^{-\frac{p+\beta}{p-q+\beta}}\right)$ (inexact) evaluations of its p first derivatives, with probability $1-t_{\mathrm{final}}$.

□ > <回 > < 亘 > < 亘 > < 亘 < り へ ⊙ </p>

Selecting a sample size in subsampling methods (1)

Now consider p = 2, $\beta = 1$, $\mathcal{F} = \mathbb{R}^n$ and (as in machine learning)

$$f(x) = \frac{1}{N} \sum_{i=1}^{N} \psi_i(x)$$

Estimating the values of $\{\nabla_x^j f(x_k)\}_{j=0}^2$ by sampling:

$$\overline{f}(x_k) = \frac{1}{|\mathcal{D}_k|} \sum_{i \in \mathcal{D}_k} \psi_i(x_k), \quad \overline{\nabla_x^1} f(x_k) = \frac{1}{|\mathcal{G}_k|} \sum_{i \in \mathcal{G}_k} \nabla_x^1 \psi_i(x_k),$$

$$\overline{\nabla_x^2} f(x_k) = \frac{1}{|\mathcal{H}_k|} \sum_{i \in \mathcal{U}_k} \nabla_x^2 \psi_i(x_k),$$

and applying the Operator-Bernstein matrix concentration inequality...

Selecting a sample size in subsampling methods (2)

Suppose that $\beta=1\leq q\leq 2=p$, that, for all k and $j\in\{0,1,2\}$, $\max_{i\in\{1,\dots,N\}}\|\nabla_x^j\psi_i(x_k)\|\leq \kappa_j(x_k)$

and that, for given ε ,

$$|\mathcal{D}_k| \ge \vartheta_{0,k}(\varepsilon) \log (2/t), \quad |\mathcal{G}_k| \ge \vartheta_{1,k}(\varepsilon) \log ((n+1)/t),$$

 $|\mathcal{H}_k| > \vartheta_{2,k}(\varepsilon) \log (2n/t),$

where

$$\vartheta_{j,k}(arepsilon) \stackrel{\mathrm{def}}{=} rac{4\kappa_j(x_k)}{arepsilon} \left(rac{2\kappa_j(x_k)}{arepsilon} + rac{1}{3}
ight) \;\; \mathsf{and} \;\; t = O\left(rac{t_{\mathrm{final}}\,\epsilon^{rac{3}{3-q}}}{4+q}
ight).$$

Then the AR2DA algorithm finds an ϵ -approximate qth-order-necessary minimizer for the problem $\min_{x \in \mathbb{R}^n} f(x)$ in at most $O\left(\epsilon^{-\frac{3}{3-q}}\right)$ iterations and subsampled evaluations of f, and at most $O\left(|\log(\epsilon)| + \epsilon^{-\frac{3}{3-q}}\right)$ subsampled evaluations $\nabla_x^1 f$ and $\nabla_x^2 f$, with probability $1 - t_{\text{final}}$.

Turning to non-smooth problems: non-Lipschitzian singularities 1

Now consider

$$\min_{x \in \mathcal{F}} f(x) + \sum_{i \in \mathcal{H}} |x_i|^a, \quad a \in (0,1)$$

with \mathcal{F} convex and "kernel centered"

(i.e.
$$P_{\operatorname{span}\{e_i\}^{\perp}}[x] \in \mathcal{F}$$
 for all i and $x \in \mathcal{F}$)

Define

$$C(x) = \{i \in \mathcal{H} \mid x_i = 0\}$$
 and $R(x) = \bigcap_{i \in \mathcal{H} \setminus \mathcal{R}(x)} \operatorname{span} \{e_i\}$

Criticality measure

$$\phi_{f,q}^{\delta}(x) = f(x) - \underset{\|d\| \le \delta, d \in \mathcal{R}(x)}{\mathsf{globmin}} T_{f,q}(x,d)$$

◆ロト ◆個ト ◆意ト ◆意ト ・ 意 ・ からぐ

Non-Lipschitzian singularities 2

- define a Lipschitzian model of the non-Lipschitzian singularities based on inherent symmetry
- ullet prove that the related Lipschitz constant is independent of ϵ
- assemble the singular and non-singular complexity estimates

$$O(\epsilon^{-\frac{p+\beta}{p-q+\beta}})$$
 evaluations of f and its derivatives

Non-smooth Lipschitzian composite problems

Finally, consider

$$\min_{x} f(x) + h(c(x))$$

where f and c have Lipschitz gradients but are inexact, and h is convex, Lispchitz and exact.

- not a special case of smooth inexact case because $\overline{\Delta f}$ now involves h as well as $\overline{\nabla_v^1 f}$ and $\overline{\nabla_v^1 c}$
- simpler termination for step computation possible

$$Oig(|\log(\epsilon)| + \epsilon^{-2}ig)$$
 evaluations of f , h , c , $abla_x^1 f$ and $abla_x^1 c$

Also for problems with inexpensive constraints

Conclusions 1

Evaluation complexity for qth order approximate minimizers using degree p models for β -Hölder continuous $\nabla^p_x f$

$$O(\epsilon^{-\frac{p+\beta}{p-q+\beta}})$$
 (unconstrained, inexpensive constraints)

This bound is sharp!

Also valid for a class of function with non-Lipschitz singularities

Conclusions 2

Allows partially-separable structure within the objective function

Extension to inexact evaluations for smooth problems:

$$O(|\log(\epsilon)| + e^{-rac{p+eta}{p-q+eta}})$$
 (unconstrained, inexpensive constraints)

Extension to inexact evaluations for non-smooth Lispchitzian composite problems:

$$O(|\log(\epsilon)| + \epsilon^{-2})$$
 (unconstrained, inexpensive constraints)

Conclusions 3

Consequences in probabilistic complexity and subsampling strategies

Other results available for first-order optimality in problems with expensive constraints

Perspectives

Complexity for expensive constraints for q > 1?

Subsampling of derivative tensors

Optimization in variable arithmetic precision

etc., etc., etc.

Thank you for your attention!
